Name	Year	Profession
Lichfield	1956	Planner and consultant
Bather	1976	County Planning Officer
Chapman	1978	Town Planning Institute
Goodchild	1985	Chartered Surveyor
Collins	1999	Bank Professional
Schiller	2001	Property/Real Estate Professional

About Jonathan Drane

Jonathan Drane is a commercial builder, property developer and educator who started his career in 1976. In 2011 he was drawn to write about the property development mechanism and its part in the growth of cities, through a PHD candidacy at the Faculty of the Built Environment at UNSW, Sydney Australia.

His topic is named *The Seed in the Cityscape- A proliferation model of high growth cityscapes based on the property development mechanism*, and he is in his second year of candidacy.

His supervisors are Emeritus Professor Ian Burnley, Senior Lecturer, Associate Dean (Education) Nancy Marshall. His panel includes Professor Michael Neuman and Dr Jinu Kim.

Appendix

Glossary of Terms

Term. *(and dictionary definition where appropriate)*	**The concept relevant to this article.**
Academic	The author's discipline as noted on the relevant article as represented by an academic institution. Reference to prior other experience out of the academic field is not included (unless specifically noted).
Constructionism	*"Constructionism is an ontological position that asserts that social phenomena and their meanings are continually being accomplished by social actors. Also called constructivism".* (7, pp.19)
Epistemology *"the theory of knowledge, especially with regard to its methods, validity, and scope, and the distinction between justified belief and opinion."* (1)	Here it is used in context with *"Sources of Knowledge"*: how knowledge is gained through empirical or other forms of data collection. (2, pp.977).
Fallow	A 'fallow cityscape' is termed in context with the proposed model, and seen to be a dilapidated, obsolete or undeveloped area whose use is not consistent with the surrounding areas of the city, and which has not been rejuvenated for a long period. Put simply: (obsolete, dilapidated and at their lowest use).
Institutional Model	As defined under 'institutional theory' by Healey see below.
Institutional Theory	Refers broadly to a view of social systems and the relationships between structure and agency in the modern context. As noted by Healey: *"the link between structure and agency empirically through relating the construction of roles, and the strategies and interests of agencies, to the material resources, institutional rules and organizing ideas which agents acknowledge implicitly and explicitly in what they do"* (6, pp. 35).
Neoclassicism	Refers here to the return to classic economic theory in the mid to late 20th century by relevant

*"the revival of a classical style or treatment in art, literature, architecture, or music."(*1)	theorists and as noted by Healey: *"preoccupation with the processes and consequences of the formation of prices in markets".* (3, pp.232).
Neo-Marxist	*"an interest in the way markets are structured through the power relations of capital, labour and landowner".* (3 p232).
Models of the development process	Theoretical representations of key components and their relationships in either a graphical or textual format which offers insight into structures, roles, processes and behaviours of relevant actors in the development process.
Morphology	The study of cities through the charting and analysis of its 'face' and patterns.
Objectivism	*"Objectivism is an ontological position that asserts that social phenomena and their meanings have an existence* that is independent of social actors". (7, pp.19)
Ontology *"the branch of metaphysics dealing with the nature of being*". (1)	*"The nature of existence and the categorical structure of reality."* (2, pp.670). Here it is used in the context of the way we see the world through different theoretical perspectives.
Political Economy	*"The production, distribution and consumption of wealth*". (5)
Practitioner	Where the author is noted as representing a practitioner company or body on the relevant article. Reference to prior other experience out of the practitioner field is not included (unless specifically noted)
Praxis *"practice, as distinguished from theory". Accepted practice or custom".* (1)	*"Aristotle once refers to his whole "practical philosophy" as the part of philosophy concerned with the problems of man."* (4, pp. 11)

	Here it is used in context with the notion of a 'practical philosophy"- a 'model' or concept of actual practice which has theoretical significance.
Property Development	Relates to third party distribution of titled land and property, and excludes property investment for the sake of holding property and improving it without changing title structures.
Structures of Provision	*A structure of building provision refers to the contemporary network of relationships associated with the provision of particular types of building at specific points in time.* *Those relationships are embodied within the organisations associated with that type of building provision, and they may take a market or a non-market form. `Provision' encompasses the whole gamut of development, construction, ownership and use."* (Ball 1998)
Study	Studies involve an empirical study of an aspect of the development process.
Taxonomy *"the branch of science concerned with classification, especially of organisms; systematic"*. (1)	Here it is used in classifying the elements and forces involved in the mechanistic phenomena of the property development process.
Textbook	Involved a text book or similar approach. This involved purely descriptive accounts with a lesser emphasis on theoretical content.
Theory	Theoretical analysis that involved a review of the development process based on literature or theory alone.
Third party title distribution	The act of trading property title/s from one party to the other in the form of increased numbers and yields of title.

Smart cities in Japan and its application in developing countries

Noriko Kono[1], Aki Suwa[2], Sohail Ahmad[3]

Abstract

Smart cities, smartization and improved efficiency in managing utility like electricity, gas, water, waste, and transportation, are presently one of the most important keywords to city development. The concept is often thought as a panacea for the present global issues and inefficiencies, such as growing energy consumption, food wastes, rapid urbanization, industrial pollutions, endangered biodiversity, and traffic problems. Developed countries have discussed the concept profoundly these years in the context of green innovation, green economy, or green new deal.

Also, rapidly industrialized cities in developing countries are promoting smart cities. Nikkei BP (2011) estimates the smart cities makes the market potential of 52 trillion US$ by 2030, and most of the estimation came from developing industrial countries. Though the interests to smart cities are quite high, little literature has been published in the fields of urban planning and international development. This paper treats the smart cities as an important trend proceeding to the historical thresholds of urban planning such as streetcar city, dispersed city, linear city, and smart growth city.

The traits of smart cities has summarized in four representative aspects: energy management, waste management, water management, and transportation. Energy management includes: electricity smart grid with distributed power sources, and diverse energy sources including solar, wind, and hydrogen. Waste management includes: 3R and material cycle economies. Transportation includes: EVs and Hybrid cars, Non-motorized transport (NMT), and car sharing system. Finally Water includes: renewable energy sources for water facilities and looping water use. The authors compared these trends with Indian slum situation and discussed the application to these sites.

Through the analysis of a smart city in Japan, many new attempts are being pursued. However, some challenges exist due to well-established existing infrastructure and solid urban systems of Japanese cities. On the other hand, the great potential was found in developing country cities. Specifically in energy sector, through microgrids

financed by microcredit system, slum areas could leapfrog to the most advanced smart cities. Introducing smartization of cities, slums or the poorest areas could be one good example where smart cities shifts could fit into.

1. Introduction

Smart cities, or smatization of cities, would be the most important buzzword for development field. The concept is thought as a panacea for the present global issues and inefficiencies, such as growing energy consumption, food wastes, rapid urbanization, industrial pollutions, endangered biodiversity, and traffic problems. Developed countries have discussed the concepts profoundly for these years in the context of green innovation, green economy, or green new deal. Also, rapidly industrialized cities in developing countries are promoting this concept.

Japan, where most of the related technologies patents exist, has been working hard to promote the environmental technologies, such as solar batteries and electric vehicles. These shares are now closely to 70 % and it is important for Japan to keep the edge as one of the most advanced countries for the model of smart cities. However, difficulties lie in many aspects, and most of the barriers are reputational and institutional, not technological (METI 2012).

This paper first examines policies of smart cities in Japan and summarized their typical traits relevant to representative fields. The paper also examines these policies in terms of regulations, standards, plan and administrative directions, economic measures, and voluntary actions and environmental ethics. Next the paper discusses the possible application to developing countries, especially in slums in India. Then it discusses how to lay microgrids in slum areas in both technological and financial aspects. Finally it presents a model for application of SC to developing countries.

2. Definition of SC and Case of Japan

2.1 The recent definitions of SC

According to Fukuchi (2009), a member of Nomura Research Institute-NRI, which has been involved in smart city research in the early stage, the definition of Smart City has not been established necessarily. In the literature of NRI define the smart city as "*A city which possesses an integrated infrastructure that supports urban life by the power of ICT, at the same time it contributes to sustainable growth as well as decreases the demerit of urbanization.*" However, this concept has not been established on where and how much the smarter a place should be.

According to Aida and Morozumi (2011), who are forerunners of smart grid, whereas the micro-power network for the entire power grid, and smart grid power

network and is including the entire side and demand-side network power, with respect to Smart City, presented a diagram like Figure 1.

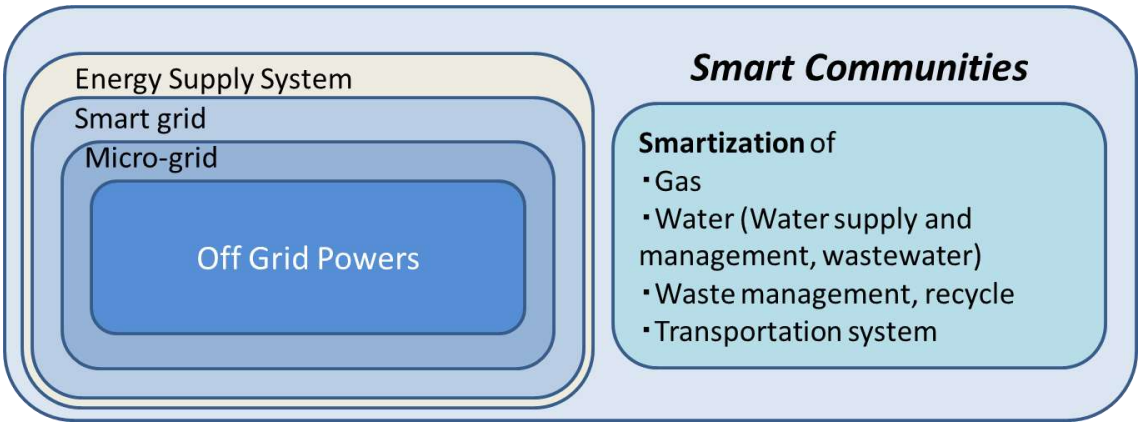

Figure 1: Smart Grid and Smart Communities
Source: Aida and Morozumi. 2010. Smart Grid Textbook. Tokyo: InPress Japan.

Although SC has advanced without standardization until now, in 2011, as for the smart city infrastructure evaluation-index international standardization domestic preparation committee and standards authorization innovation technical research association (IS-INOTEK) which are organized in the Japanese company and economic organization of 20, installation of the subcommittee within ISO was approved aiming at standardization. On the other hand, France and the World Bank agreed to put the SC criteria for selection in Global City Indicator as a standard of ISO at the period (Mochizuki, 2012).

Japan aims "measurement standard," for related products, while France and the World Bank aimed at "operating standards," which plans the state of the residents and administration in SC. In Japan, SC definition focuses on technical ones and in the West, the focus rests on soft elements, such as management and business mode.

2.2 Ecological implication of SC

The World Bank Urban group summarized a book called “Eco2 Cities: Ecological Cities as Economic Cities," meaning that a good city is both economically and environmentally (ecologically) feasible city. By this literature, in future cities, while it is important to connect linking artificial city infrastructure by using the advanced technology such as smart grids, it is also important to link new infrastructure to existing ecosystem.

Ecological implications such as looping and cascading the materials could strengthen the smart city ideas. For example, cascading of the water use: using graywater as other uses, should be appeared in modern water use. Also, looping waste

management by using the heat, wastewater, ashes, and so on could be one other option (Suzuki et al., 2010).

Chinese smart cities always refer to the ecological parts when referring the smart cities. Thus, this paper also includes these ecological concerns of the smart cities, referring to the efficiency in ecosystem.

SC definition can be a city which has efficient system in energy, waste, water and transportation by smartization and technological innovation and which become low carbon as well as ecologically feasible.

2.3 The four categories of SC

Aida and Morozumi (2010) has identified five areas; electricity, gas, water, waste management, and transportation systems. Moreover, the four pilot study areas of Japan has the projects of smartization of electricity, gas, transportation infrastructures and some cities broaden the areas to water and waste. In this paper, the definition looks at several important infrastructure sectors of SC.

Though the definition of the term smart cities, or smart communities, fluctuates presently, it is possible to gather some requisites. Through literature reviews, authors have summarized the typical traits of smart cities in four sectors.

Table 1. Traits of Smart Cities

	Energy	*Waste*	*Transportation*	*Water*
Special Traits	・Smart grid system with distributed power sources ・Ene-farm (self powerplant from hydrogen) ・Hydrogen reuse system ・Co generation	・3R (reuse reduce recycle) policies ・Co generation at the source ・Bio energy made from solid waste	・Using EVs and Hybrid cars for leveling off the peaks ・Car sharing or other volunteer car shares programs …make private property as public property	・Renewable energy sources for water facilities (solar power, wind power etc) ・Looping water use would be another solution (use of graywater)

3. Yokohama Case

3.1 Minato Mirai 21, Dawn of City-Smartization

Yokohama is one of the first Westernized cities in Japan and it had developed as a leading industrial city since the opening of Yokohama Port in 1858. During 1980s, it finished environmental enhancement in the CBD by industrial relocation to the suburbs and servicized its industry. Especially, Minato Mirai 21 is a project planned and built for the long period (approximately 50 years), as it is started as one of the "6

big declarations of Yokohama" in 1965. The establishment of the "utility tunnels" in the district can be called as the dawn of city smartization. Electric wires and telephone wires (optical fibers), waterworks, sewage, and garbage collection tubes are laid underground together, and community-central-heating-and-air-conditioning institution is managed by utility tunnel, which is energy-saving.

The electric power cable in utility tunnels is transformed by substation facilities within a power line from two plants in the CBD in Yokohama 500,000V, 154,000V, 66,000V, 6,600V, and 100-200V, and the electricity of voltage corresponding to each scale is sent to consumers. The space for substations was provided and what is called "smart power transmission" has been started since the start of the 1990s (Kishida and Uduki, 2008). Yokohama was the first runner of SC when the word did not exist yet in the world.

3.2 Global Warming Mitigation Policies in the Context of SC in Yokohama

By the "green innovation" determined by the Cabinet in 2009, "New growth industry strategy: towards bright Japan," the Ministry of Economy, Trade and Industry selected four “next-generation energy and a social system demonstration area” in 2010 and has tackled the promotion of smart-izing of the cities in Japan.

Yokohama was chosen, as one of the domestic four pilot study areas, along with Kitakyushu, Keihanna university town, and Toyota, and many ingenious industries of each city has followed. SC of Yokohama has the feature of the point which is a big city, the advantage of various industrial accumulation is employed efficiently and traffic infrastructure, and covered smart-ized item of each building comprehensively (Sasaki, 2012).

In this paper, developed countries' infrastructure maintenance as global warming policy of Yokohama was examined in the context of SC. In order to take a closer look, it was divided into four elements of energy, waste, traffic, and water and it analyzed by dividing into three policy fields: 1. Regulations, Standards, Plan and Administrative Directions Regulations, 2. Economical means, 3. Voluntary actions and Environmental ethics.
Table 2 describes the regulations, standards, plan and administrative directions. Energy sector is represented by the measure of smart grid and Yokohama Smart City Project (YSCP) Plan made in 2009 is in response to specification of the next-generation energy and the social system demonstration enterprise of the Ministry of Economy, Trade and Industry centering on three areas (Minato Mirai21 area, the Kohoku new town area, and the Kanazawa area) of the city.

There was The Great East Japan Earthquake in 2011, and the concerns of the stable supply of energy in and outside the country is very high, and the measure attracts attention from different parts of the world. The duty of the city in YSCP is to specifically distribute 6 billion yen of "the next-generation energy fund" from the

Ministry of Economy, Trade and Industry to participating companies (Toshiba, Meiden-sha, Nissan, etc.). Yokohama is performing control of a board of governors or a joint session in the YSCP promotion conference. The city plays a facilitator's role in this plan.

Waste category is characterized by citizens' cooperation at G30 plan, which is a general waste disposal master plan for 2003 - 2010. This plan is aimed at reducing the waste to be incinerated. At the "Yokohama 3RMu(dream) plan" from 2011, reducing the total amounts of waste including resources are mentioned.

Transport sector's emphasis is put on the modal shift. The goal setting was made in 1997 of 15-minute from every station plan, and station power, which is to make more amenity in the vicinity of every stations. This aim is completed 88.4% in 2006.

In the scope of YSCP, Yokohama smart mobility defines the various projects including promotion of EV, and promotion of paratransit. Although the means of transportation not using motor power [Non-motorized transport=NMT] promotion is encouraged, goal setting of the modal split for NMT is not performed. NMT promotion is on-going as the social experiment of community cycles. The Yokohama Bay Bike enterprise is undertaken by funding of NTT DOCOMO for three years during 2011 to 2014.

Water sector also has shown the policy of reserving the remote reservoir for years. The Waterworks Bureau submits the environmental accounting report every year. The guideline of environmental accounting is followed to the Ministry of Environment Plan and they include environmental preservation cost, the environmental preservation effect, and economic effects. The trial calculation is made by yen terms and t-CO2.

Table 2: Regulations, standards, plan and administrative directions

	Energy	*Waste*	*Transportation*	*Water*
Regulations, standards, plan and administrative directions	Smart grid (YSCP plan)	Yokohama G30 plan 2003-2010 3R dream plan 2011-	Promotion of Non-Motorized Transport ,smart mobility plan, 15-minute anywhere plan, and Station Power	Reservation of remote reservoir, Calculation of cost benefit environmental accounting

Table 3 explains the economic measures of Yokohama. Energy includes the Yokohama Green Power Model Project promoted by the city's own funding. YGP model project collected monitor households from the YSCP pilot study area and the

companies introduced HEMS and PV to these households. The charge systems in household waste are not introduced in Yokohama. However, the city charges the bulky wastes for a long time.

Transportation category introduces 100 yen buses on weekends and holidays. The buses run along the tourists' stops and they are all municipal buses. The discount system is hard among each line as seven private companies exist in the city, but the statistics say that 100 yen buses promote the transit usage.

Water system uses the step-up charge system based on the idea that daily use water should be used in low rate. As the system charge more to the people who use more, it is said to get demand management.

Table 3: Economic Measures

	Energy	*Waste*	*Transportation*	*Water*
Economic measures	Yokohama Green Power Model Encouraging the local industry to enter YPORT	No charge on plastic bags Bulky waste	100 yen bus, Support for community cycle project	Charge system Yokohama Water Company

Table 4 illustrates the voluntary actions and environmental ethics. Energy sector elaborates on the lectures on introduction on HEMS. Action Plan for G30 articulates on citizen partnership in recycling and separating, and the city officials are very satisfied with the results. Transportation sector has the visibility in the voluntary community cycle project Hama-chari, which was run by the NPO. There is an NPO that promotes the transit usage as well. Water sector include various citizen participated events to enlighten the importance of saving water, which was participated by many interested citizens.

Table 4: Voluntary actions and Environmental ethics

	Energy	*Waste*	*Transportation*	*Water*
Voluntary actions and environmental ethics	Lecture on introduction of HEMS	Action Plan for G30	Hama-Chari	Vaporization heat Practical use of a hydrogen hybrid truck

3.3 Summary and Challenges in Yokohama

Previously it explains that in Yokohama, there are the balanced policies in four sectors (energy, waste, transportation, and water) in three policy fields (1. regulations, standards, plan and administrative directions, 2. economic measures, and 3. voluntary actions and Environmental ethics). The city has many innovative plans

and regulations as well as well organized environmental education system and environment-conscious citizens. Given the fact that Japan is one of the most industrialized nations in the world, Yokohama is among the best smartized cities in the present world.

On the other hand, difficulties are found in this city. These are: the measures against surplus electric power at the time of photovoltaics spread, the storage battery / EV practical use by the side of demand, solar cell power generation control by AMI, demand regulation capability grasp by demand response, construction of the micro grid which held down cost, and difficulty to the large cost reduction by electric power supply increase in efficiency. These problems are raised because the present system of Yokohama or cities in Japan is too systematized or institutionalized to adapt a new system.

4. Conditions of India

4.1 Slums in India

According to 2011 census, India's urban population was 377 million, about 32 percent of total population of India (Census-of-India, 2011). About one-fourth of the urban population (≈93 million) live in 49,000 slums spread across the country (NBO 2010). Slums are the manifestation of housing poverty. The proliferation of slums and severe housing shortages (over 24 millions) give a panoramic view of the housing poverty (NBO, 2007). Various government reports show growth of slum population, housing shortages and urban poverty (head count) across the states are severe and pathetic conditions.

Table 5 presents changes in slum characteristics during 2002 and 2009 based on nationally-representative survey. In the span of six years (2002 to 2009), housing conditions have not improved radically; nevertheless, incremental changes have been noticed in almost all housing indicators, for instance, proportion of households living with more than three persons per living room decreased from 32 to 28 %. Though there is a slightly bright side in the change, but there still exist a number of challenges to overcome as international living standards.

Table 5: Changes in housing conditions of slum households, 2002 – 2009
Indicators

Indicators	2002	2008-09
Consumption expenditure (INR)	2929.97	3924.3
Living space per member (m2)	5.84	6.92
Households with more than three persons per living room (%)	52.72	42.92
Structurally bad dwelling (%)	24.28	23.54
Separate kitchen (%)	30.08	39.04
Tap as a drinking water (%)	78.72	77.23

Own toilet (%)	21.45	31.22
Motorable access road (%)	44.26	45.85
Sample size (≈)	6,130	8,273
(% of total)	14.64	14.68

Source: NSSO 2004; NSSO 2010

Note: A slum is a settlement with a collection of poorly built tenements, mostly at temporary nature, crowded with inadequate sanitary and water facilities in unhygienic conditions. Such an area was considered as a "slum" if at least 20 households lived in that area (NSSO 2010).

4.2 The four elements of infrastructure

To analyze slum household characteristics, a few indicators were selected from energy, water, waste and transport sectors. Although indicators are not comprehensive, it can give a fair idea about position of slum households in Indian context. Moreover, this is only a source at household level in urban India. The next section describes the each category in detail.

Table 6 presents three types of slums notified slum, non-notified slum and squatter. A comparison between non-slum and slum shows that slum households are relatively in poor condition. The table identifies the conditions of electricity, water service, and waste management. For example, though there are provisions of 95.5 % electricity of non-slum households, only 91.5 % slum households have electricity. Over 31 % of slum households have only temporary wiring.

74 % of non-slum households use tap/bottle water as a major source of drinking water and corresponding value for slum households is 77.3%.
Notably, 43.5% of slum households have access of drinking water within dwelling unit or premises, while 74.7% in non-slums. In same pattern, almost 29 % of slum households do not have garbage collection arrangement and while non-slum households 24.4%.

Table 6 Typologies of slums with characteristics, 2009

	notified slum (1)	non-notified slum (2)	squatter (3)	all-slum (4=1+2+3)	non-slum (5)
household (#)	3,957	3,553	763	8,273	48,085
Household have electricity (%)	94.19	89.36	87.42	91.49	95.51
If yes dwelling with conduit wiring (%)	33.3	22.17	16.94	27.19	42.41
If yes dwelling with fixed to the wall (%)	41.75	38.46	57.87	41.79	44.87
If yes dwelling with temporary wiring (%)	24.95	39.37	25.19	31.07	12.77

Electricity hours (median)*				18	21
Electricity Payment (median) (INR/month)*				150	200
Payment to SEB (%)*				84.6	75.84
Tap/bottle water as a major source of drinking water(dw)	83.04	74.19	61.21	77.27	73.93
Water within dwelling unit or premises (%)	49.47	34.64	54.07	43.52	74.74
Garbage collected by:					
Local governments (%)	62.84	47.26	42.6	54.28	56.92
Residents or others (%)	15.67	17.62	20.45	16.95	18.7
No arrangement (%)	21.49	35.13	36.96	28.77	24.37

Notes: Sources: NSSO (2010); * these figures is calculated from Desai, S. and R. Vanneman (2009); SEB: State Electricity Boards

Figure 2 shows the maximum distance to the place of work normally travelled by each household. Despite poor living conditions and low income of the slum households, most slum households travel relatively more than the non-slum households. Figure 2 also reveals that high proportion of non-slum households are in less than 1km travel, while the number of slum households that travel more than 1km are about 7 point bigger than non-slums. It can conclude that slum households are located near workplace. It also shows a great burden on mobility on slum households, given their low income and accessibility of job.

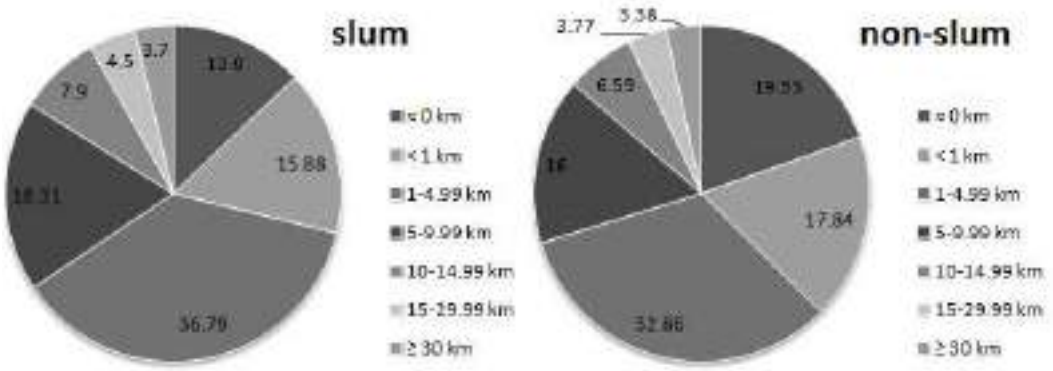

Figure 2: Maximum distance to the place of work normally travelled by any earner of the household
Source: NSSO 2010

Table 7 shows the firewood dominant as a fuel for cooking and kerosene for lighting in slum households from "Indian Human development Survey" a multipurpose household survey conducted by the University of Maryland and National Council of Applied Research. This survey is also based on nationally-representative survey. In non-slum, dominant form of fuel for cooking was LPG and Kerosene for lighting (Desai and Vanneman, 2009). According to the survey, 6.9 % of slum households

and 8 % non-slum households use their dwelling as residential cum commercial. It should be also noted that 37.2 % slum dwellings are bad ventilation while only 14.6 % of non-slum households are badly ventilated.

Table7: Fuel and energy use by slum and non-slum, 2005

Variables	Slum		non-slum	
	mainly cooking	mainly lighting	mainly cooking	mainly lighting
Number (#)	725		13,818	
Firewood (%)	45.69	0.41	21.38	0.14
Dung (%)	24.68	0	9.56	0.09
Crop residue (%)	0.55	0	1.3	0.04
Coal/charcoal (%)	4.83	0	5.66	0
Kerosene (%)	22.07	27.03	15.25	23.03
LPG (%)	33.38	0	54.11	0.53

Source: Desai, S. and R. Vanneman (2009)

Table 8 summarized the Indian slum conditions in India and summarized the four sectors in infrastructure: energy, waste transportation, and water. The slums can have the potential that they do not have proper system of anything. In other words, it could have some possibility, if guided properly.

Table 8: Slums condition in four sectors

	Energy	Waste	Transportation	Water

Special Traits of Slums	- There is a serious issue of energy security, limited hours of electricity supply - Households are connected with centralized grid system -LPG are used as cooking energy, however, significant proportion of households also use firewood and other traditional solid fuels for cooking energy.	- No proper system of waste management - Hardly any effort by local government for waste management. - Significant proportion of slum household livelihood depends upon the recycling of waste (an informal way). - Liquid waste (storm, drain and sewerage) management are in pathetic condition, needed great attention for better physical condition.	-Most of the slum dwellers are pedestrians, however, low percentage of them also use bicycle and public transportation for mobility. - They also use hawker cart for their informal economy.	- No regular water supply (w/s). - Community based w/s system available only for few hours in a day (say 2-3 hours daily). - They also use hand-pump for water, however, there is no satisfaction over the quality of water.

5. Application to India

5.1 Energy use in the poorest urban conditions

Previous section has shown that Kerosene and biomass are the main energy sources for cooking purpose in majority of households in Indian slums. This section illustrates the energy use in slums or in the poorest urban conditions. Kerosene is a standard fuel for cooking, but biomass is another source especially when poors do not have access to Kerosene. Kerosene is supplied with subsidized price, for ration card holders and often difficulty to have a ration card especially to new migrants. Biomass, on the other hand, do not need such proof, but burning of biomass often causes severe air quality problems, used both indoor and even outdoor when smoke generated in one time for cooking.

A closer look will reveal more characteristics on the fuel composition for households. Table 9 demonstrates different income level seems to influence on the choice of energy carriers. It shows biofuel is commonly used as a cooking fuel in low income level households than those with higher income. Electricity usage for cooking is highly limited both for low and high income groups. Electricity is

widespread for high income groups for lighting purpose, with less usage by lower income households (Reddy and Srinivas, 2009). Also Table 7 in page 11 shows fuel composition comparison between slum and non-slum for mainly cooking purpose. Firewood and biomass (e.g. dung) are more commonly used in slum area than non-slum area. LPG, on the other hand, is more used in non-slum area than in slum.

Table 9: Energy carrier mix for various end users (2004-2005)

End use	Energy carrier	% Of households using various energy carriers		
		Low income	Middle income	High income
Cooking	Biofuels	81.3	61.8	31.8
	Kerosene	8.0	5.2	4.5
	LPG	8.5	31.3	61.2
	Electricity/others	2.2	1.7	2.6
Lighting	Kerosene	29.1	15.2	6.1
	Electricity	69.5	83.1	93.6
	Others (including no lighting households)	1.4	1.7	0.3
Total households (million)		68.3	107.6	29.5

Source: International Institute of Population Studies 2003, adopted by Reddy and Srinivas, 2009

As also demonstrated by Table 10 on typologies of slums with characteristics, it is rather surprising that the slum households have relatively high electricity accessibility, though most of the slums in Delhi are unelectified. Even when there is a certain degree of accessibility to electricity, Transmission and Distribution (T&D) losses are generally large. For the OECD countries, the T&D losses are normally less than 10%, while the rate is more than 30% as average in India (Joseph, 2010). In India, one of the main reasons for the loss is attributed to power theft (Dhingra, et al, 2008). But some of the residents of slums acquire electricity through hooking or through paying contractors, thus the high access rate to electricity is sometimes characterized with illegal wiring.

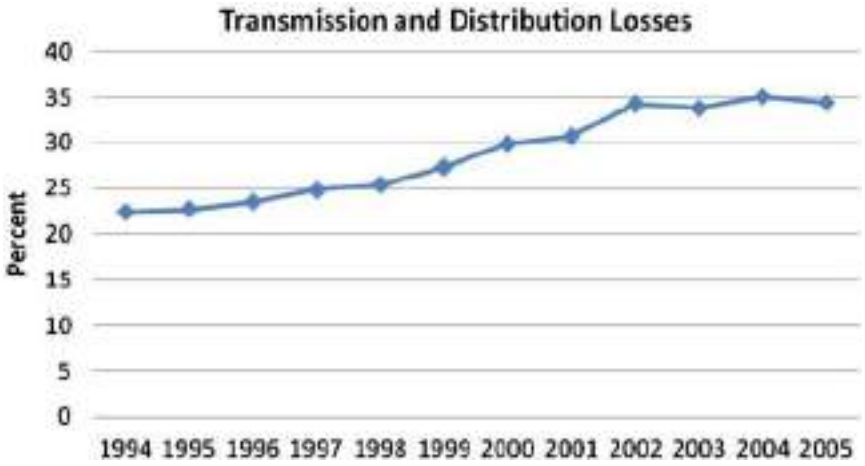

Figure 3: Average Transmission and Distribution Losses.
Source: All India Electricity Statistics, General Review. Central Electricity Authority: Delhi, 1994–2006, adopted from Joseph, 2010

5.2 Electricity in the poorest areas

As electricity, at the point of its use, do not emit harmful substance, it has potential to provide environmental and health benefits to the urban residents. Electricity, however, is not officially available in the most of the Indian slums as seen. When available, no matter if legal or illegal, electricity is generally used for lighting (Reddy and Srinivas, 2009). Using electricity for other purposes than lighting may be a too expensive option, since cooking and heating normally require higher caloric values, potentially leading to higher prices to be paid if electricity is used for those purposes. However, if electricity tariff is set as low as the slum dwellers may be able to pay, they may be encouraged to use electricity for multiple ends.

Currently, necessary political commitment, business interest and technological infrastructure are all absent to legally provide electricity to slum. These setbacks mean that there is a need to formulate a strategy to make the utilities and others to invest into the areas where normally neglected from commercial operation. It is also important to create a framework where these investments can be collected back in a sufficiently short period.

One way of doing this may be to focus on microgrid. Microgrid is generally referred as an aggregation of electrical generation, storage and loads. The generators in the microgrid may be micro turbines, fuel cells, reciprocating engines, or any of a number of alternate power sources. A microgrid can be a completely self-sufficient network. A device such as static switch can disconnects the grid from the main grid, so that it can operate in isolation. Microgrid demonstrates its primal features as enabling stable operation in the time of faults and other network disturbances. When the microgrid is separated from the main grid, microgenerators are supposed to sustain sufficient power quality within the grid. It comprises low voltage distribution

systems with integration of diverse energy sources, such as photovoltaic, wind, biomass, biofuel and fuel cell together with distributed storage such as flywheels, advanced power electronic conversion and control capabilities (Agrawal and Mittal, 2011). Thus renewables, such as solar and biomass, can be the energy sources for microgrids electricity, and environmental benefits are larger if the microgrid electricity is sourced from renewables.

Also, microgrid can be operated with smart grid gadgets. Once connected to smart meters to a central control system, households can be provided with a real-time view of the amount of energy consumption. More importantly, it creates more advantage to the grid owners to have improved energy management and control over the energy production/consumption. The smart meters are particularly associated with better charging mechanisms as they are supposed to identify non-technical losses on T&D on the grids, thus it has a potential to work against power theft (Depuru, et al, 2011).

While the concept of microgrid has been developed in case of emergency and power interruption in the main grid, there is a growing interest in applying the system as an effective solution of providing electricity to the areas that have been long unelectrified. Currently focuses are much more on its application in rural areas, where the distance from urban areas prohibits connection to main grids. One of the social entrepreneurs, Mera Gao Power (MGP), for example, started to provide extremely low cost lighting and mobile phone charging services to the households in Uttar Pradesh, through building and operating village-wide photovoltaic microgrids. Households will be given two LED lights and a mobile-charging point with a cost of 25 rupees (US$0,46) per week, and MGP is expecting that their investment in each microgrid collected back in around 18 months (de osta, 2012).

Funding agencies, such as US AID is also strongly focusing on microgrid provision in rural areas of developing countries. (US AID and microgrid in India).

5.3 Financing the microgrids

The microgrid has also a large potential in slums to connect the residents to electricity. As stated, the microgrid is an islanding electric infrastructure requiring relatively inexpensive investment than the main grid. Possibly combined with smart grid devices, the microgrid has a better chance to deliver electricity in specific areas in the urban areas of developing countries, as well as giving the utilities and investors the chances to control over technical and non-technical losses on T&D.

There is surely a problem of financing the microgrid in slum areas. Investing into these difficult areas may require, at least high social motivation, but also a skillful strategy to ensure return on investment. Collecting funds back from slum dwellers is a particularly difficult task for microgrid investors, as slum dwellers' willingness to pay could be a critical barrier. In rural areas, dwellers usually have higher sense of residentialship in their area, no matter how poor or not. In slums, on the other hand,

residents see their dwelling as temporally, particularly in non-notified slums and squatter settments thus it is highly difficult to expect them to invest into upfront cost for the lasting facilities. The legal status of the slum dwellers has been recognized as one of the major problems, and allowing them secure tenure status, regardless of permanent or temporally, is recommended to secure their accessibility to cleaner energy. In addition to giving them tenure status, it is possible to reduce the initial costs burden through installment payment. The suppliers have to reach out to the poor customers, breeding trust and integrate them as part of business portfolio and encourage them to be willing for legal connections (Dhingra, et al, 2008).

It is quite difficult to expect the existing utilities to take up the microgrid business. It has been well documented that Indian government adopted the Electricity Act 2003, which introduced significant changes to the electricity industrial structure. The background to the enactment of the act is a number of challenges that the Indian electricity industry were facing. In India, the electricity industry had been dominated by the State Electricity Boards (SEBs), vertically integrated monopolies, for decades. The SEBs are in a severe financial difficulty, to the extent they are lack of funds to even invest into maintenance of the currently available infrastructure (Bhattacharyya, 2005, Dubash and Rao, 2008; Joseph, 2010). Pouring money into the new microgrid in high risk areas would be out of their financial capability. New energy and electricity entities with viable financial capacity are required for investment into microgrid for the poors.

Microgrid shall find a better partner through social entrepreneurship. Social entrepreneurship is process whereby the creation of new business enterprise leads to social wealth enhancement so that both society and the entrepreneur benefit (NYU Stern, 2005). Social entrepreneurs usually apply practical, innovative and sustainable approaches to benefits society in general, with an emphasis on those who are marginalized and poor (Schwab Foundation, 2005). In general, majority of existing definitions suggest that opportunities for social change and benefits are explored through social entrepreneurship (Zahra, et al, 2009).

Social entrepreneurs are in a good position to provide social benefits through creating business models on the microgrids in slums. One of the social entrepreneurs' successes has been demonstrated as a case of Grameen Shakti, which provided solar powered facilities in Bangladesh with soft loans through installment. With the affordable price set, the installed number of Grameen Schakti's Solar Home System has risen from around 230 in 1997 towards more than 520,000 in 2010 (Asif and Barua, 2011). Its innovative business model and operational framework can be seen as a benchmark to be applied to other countries.

Foreign aids, majority of which are focusing on rural electrification, may also have to pay more attention to slum electrification. Urban air quality can be improved significantly, once microgrid is available to slums. There is an increasingly wider recognition that there is a strong linkage between global climate change (GCC) and local air pollution (LAP). Options to mitigate GCC may show strong co-benefits in

terms of less LAP and vice versa. Policies neglecting these co-benefits may be sub-optimal, as the co-benefit approach is to cope with the global and local emission control at the same time, where strategic design of policies is indispensable. Also, the international attention is moving more to integrate wider areas and measures to optimise the policy effects. Thus mitigating the slum air quality also needs to be placed in the context of urban co-benefits policy formulation (UNU-IAS, 2012). In addition, the microgrid will enhance accessibility and availability of electricity that would definitely ensure environmental sustainability in slums that is one of the key Millennium Development Goals (MDG).

An analysis demonstrated that mere top-down and technology focused approaches have limitations in making people willing to pay for electricity. Social elements, such as local norms, trust and sometimes sanctions, seem to work better for ensuring compliance (Winther, 2012). Nevertheless, the combination of technological solution, together with enhanced social contexts, would create an environment where cleaner energy may be accessed by the slum dwellers. The microgrid funded by social investors has a very large implication for slum/urban environmental benefits, through air quality improvement, and social benefits via energy and electricity provision to the poors. The role of the national government to play is ever more important, for the development of policy on the slum dwellers' accessibility to cleaner energy. The local government shall be equally imperative to encourage and cooperate with social groups and entrepreneurs to establish new business models for providing clean electricity, as also seen in Japan where the Yokohama city government' smart community initiative and its liaison with new business enterprises demonstrate.

6. Conclusions

6.1 Traits of Urban Development in Different Level of Nations

In this paper, the policy measures against global warming by Yokohama were considered from a viewpoint of SC, and each measure was analyzed in four categories and three fields. Here in conclusion, how to transfer SC to developing country cities is taken into consideration based on the experience of Yokohama in international development. Table 10 shows this image summarized by literature and interviews on each country-level situation: the poorest country cities, fairly-developed country cities, and advanced nation cities.

In this Table, it notes that there is a tendency for the cities of fairly-developed country to experience the peak of the Environmental Kuznets Curve (EKC) in their process of economic development. EKC was described on x-y coordinate, where x-axis is represented by the GDP per capita and the y-axis is shown as the environmental pollution level. It is said that it is shown with inversed U-curve, where the pollution increases as the GDP increase, peaks at the mid-income level, and decreases as the GDP approach to the highest point.

It can be said that technical innovations by efficiency are needed in the increase in efficiency using new technology, such as explosive increase in energy demand, excessive wastes and insufficient processing, increase in traffic and its involved externalities, and increase in water demand. Also the demanders' side needs environmental ethics to change their behaviors. It is important for developing countries to reach the SC situation like developed countries soon enough.

Table 10: Different Type of City Development in Different Economic Conditions

	Energy	*Waste*	*Transportation*	*Water*
Slums or the Poorest Economies	-There is a serious issue of energy security, limited hours of electricity supply - Households are connected with centralized grid system -LPG are used as cooking energy, however, most households also use firewood and other traditional solid fuels for cooking energy	- Hardly any effort by local government for waste management. - Significant proportion of slum households livelihood depend upon the recycling of waste (an informal way). -Poor liquid waste (storm, drain and sewerage) management	-Most of the slum dwellers are pedestrians, however, low percentage of them also use bicycle and public transportation for mobility. - they also use hawker cart for their informal economy.	- No regular water supply (w/s). - community based w/s system available only for few hours in a day (say 2-3 hours daily). - They also use handpump for water, however, there is great level of unsatisfaction over quality of water.
Mid-level courtiers	- In urban areas, it is begun to ensure a stable supply of electric power. -Improvement in the concern about pluralization of energy source. - Gap with farm villages.	- In urban areas, it is begun to carry out fixed recovery. - There is also a place where intravenous business is realized. - Gap with farm villages.	- Correspondence of the increase in the means of transportation with much GHG discharge by private cars. - Aggravation of traffic congestion or air pollution.	- In urban areas, stable supply of water. - uncertainty in sanitation. - Gap with farm villages.
Developed	・Smart grid system with distributed power sources ・Ene-farm (self powerplant from hydrogen) ・Hydrogen reuse system ・Co generation	・3R (reuse reduce recycle) policies ・Landfills are less GHG emitting than combustion	・Using EVs and Hybrid cars for leveling off the peaks ・Car sharing system or other volunteering car shares programs …make private property as public property	・Renewable energy sources for water facilities (solar power, wind power etc) ・Looping water use would be another solution (use of graywater)

6.2 Laying Smart Grid in International Settings

The power network of the present developed countries is at the zone A: concentrated type supply where the supplier (major electric power companies) has mainly participated in electric supply. The present U.S. policies are represented by the zone B: large-sized demanders (manufacturing industry) and restrictive suppliers' participation. Although there are small suppliers participation by solar and wind powers in Europe or Asia, zone C is still only advantageous to large-sized suppliers in terms of regulations and technologies.

Both zone B and the zone C are insufficient as new generation smart grid and to be distinctive as new deployment in Japan, not only the large suppliers, but the small suppliers, to be able to take full advantage of ICT technology and legal system (you can freely buy and sell electricity). The zone D should be aimed in order to be ahead of any other country (Kato, 2010).

Figure 4: The four type of Smart Grid Conditions
Source: Kato 2010

6.3 Planning Smart Cities in International Settings

In this paper, in relation to SC at large, a development model as shown in Table 6 is proposed using the model of the above smart grid model. In this model, x-axis: concentration vs distribution, and y-axis: demand person, and a supplier scrutinize the plane model (x-y coordinates) of separation vs one (one-way vs both directions). Concentration vs distribution, a service supplier, and a city resident are separation vs one. The model which applies and takes into consideration the quantity of each activity (z axis) on x-y coordinates was considered.

In the poorest country, an active mass is zero or that our country performs international cooperation on the occasion of the city development which goes to a fairly-developed country although it is very small, and thought that development in SC could be performed by what is called leapfrogging.

SEEK RESILIENCE IN RECONSTRUCTION:

Towards a Resilient Post-disaster Urban Development in Sichuan, China

Yan Guo*

Abstract
This article discusses the post-disaster urban resilience design framework in the case of post-disaster urban reconstruction in Sichuan after the Great Sichuan Earthquake (also known as the Wenchuan Earthquake) in May 2008 in China. The focus is on three main aspects of post-disaster urban reconstruction: socio-spatial coherence, temporal continuity, and multi-stakeholder integration and communication. Critical interpretation of the government-guided reconstruction reveals that reconstruction was limited to the generic production and implementation of top-down planning. From the perspective of urban resilience, and through an alternative design scenario developed in this research, this article highlights an urban resilience design framework based on post-disaster development in the Sichuan city of Dujiangyan. By identifying the deficiencies of the governmental reconstruction where in many aspects resilience has not been considered, and by proposing the alternative where resilience has been considered to develop a better living, this research seeks to integrate urban resilience as a key aspect in the Sichuan reconstruction and as essential for developing the post-disaster city towards a more coherent, sustainable, and integral urban future.

Keywords Dujiangyan, Great Sichuan Earthquake, post-disaster reconstruction, design for urban resilience

1 Introduction

"Cities always sought resilience to the hazards they have faced. In this sense, resilience has been core to urbanism" (Coaffee, Wood, and Rogers 2009, pp. 3). This article aims at examining the case of the Great Sichuan Earthquake reconstruction

* School of Doctorate Studies, University IUAV of Venice (Istituto Università di Architettura di Venezia), 30125 Venice, Italy. E-mail: charles.yan.gore@gmail.com

guided by the government from the perspective of urban resilience. It presents a contextual interpretation of the government-led reconstruction, in which urban resilience was not applied as an initial concept. The reconstruction has been used as an opportunity for territorial development, mostly focused on the extremely rapid economic recovery. In the city of Dujiangyan the generic top-down planning has caused socio-spatial incoherence; the prompt massive urbanization has created discontinuity in the city's development taking little account of its urban history. Cooperation among multiple stakeholders could have been much more extensively promoted, but its absence from government-led reconstruction efforts have created urban fragmentation and are thus problematic. This raises questions on how urban resilience should be developed in the reconstruction, and "*who* should recover *which* aspect of the city, for *whom*, in *what* intention and by *what* mechanism" (Vale and Campanella 2005, pp. 337).

Through a specific understanding of the concept of urban resilience in this relatively underdeveloped but rapidly urbanizing area in western China, the following discussion demonstrates that it is important to maintain the socio-spatial coherence of "urbanity"[i] in the existing urban area. It is also necessary to consider the history of the city over time. In addition, smooth communication among and integration of different stakeholders are fundamental to resilience building. By proposing a design framework based on the concept of urban resilience, this research presents an alternative integral design scenario for the post-disaster city of Dujiangyan, to integrate local resilience building into the government reconstruction process. With a perspective from urbanism, the scenario focuses on design proposals that contribute to the overall socio-spatial coherence and temporal continuity in the post-disaster urban development of the case study area. The design scenario also explores the potential of multi-stakeholder integration, which contributes to a resilient reconstruction.

2 Sichuan: Strategic Post-Disaster Reconstruction Guided By the Chinese Government

On 12 May 2008, the catastrophic Great Sichuan Earthquake struck some of the most inhabited regions in western China, mostly in Sichuan Province. With a magnitude of 8.0 on the Richter scale, this earthquake caused 69,226 deaths, 17,923 people were listed as missing, 374,643 were injured, around 7.79 million houses collapsed and 24.59 million were damaged, resulting in direct economic losses of RMB 845.1 million yuan (approximately USD 134.2 million)[ii] (UNCRD 2009, pp. 3). Due to the grievous losses and the severe impacts of the disaster, the region attracted a tremendous amount of national and international attention, resulting in a three-day national mourning period and unprecedented post-earthquake relief and reconstruction efforts[iii] led by the Chinese government. Different from any other urban

redevelopments in contemporary China, the post-disaster redevelopment of Sichuan has not only been a massive urban intervention to recover from the catastrophic impact of the earthquake on the Sichuan region and its local communities, but is also seen as a strategic opportunity for the territorial development of the area.

2.1 The Government Plan for Reconstruction

Within one month after the earthquake, a detailed ordinance of eighty bylaws in nine chapters, the *Post-Wenchuan Earthquake Restoration and Reconstruction Ordinance*, was approved for the Sichuan post-disaster reconstruction at the 11th executive meeting of the State Council of the People's Republic of China and was announced (State Council of the People's Republic of China 2008). With this Ordinance, the massive and rapid urban reconstruction process of Sichuan was officially initiated in a top-down fashion. The Ordinance stated the policies and schedules for the reconstruction in Sichuan. Policies for the reconstruction covers areas including spatial layout, urban housing, urban construction, rural construction, public services, infrastructure, industrial recovery, disaster prevention and reduction, ecological environments, mental care, policy measures, reconstruction funds, and plan implementation.

Each single bylaw in Chapter Four of the State Council Ordinance intends to guide a careful and strict planning scheme. Bylaw No. 31, for example, states that the establishment of post-earthquake recovery and reconstruction planning should integrate the relevant organizations and experts, and should sufficiently consult the post-disaster victims; significant decisions should be evaluated by corresponding experts in special discussions (State Council of the People's Republic of China 2008). Although the policy statements remained on an abstract level, they still clarified issues such as how the reconstruction planning should proceed, who should get involved at which stage of the process, and so on. In addition, this document proposed some innovative approaches to reconstruction planning, such as democratic decision making and a participatory process as suggested in Bylaw No. 31, as well as paying special attention to disaster risk areas, and suggestions to avoid future disaster risks as suggested in Bylaw No. 32. However, some of these suggestions remained as policy guidelines and was never reflected in detailed reconstruction planning and implementation.

This detailed official document was released by the central government within a short time after the disaster, which was incredibly efficient and fundamentally important for launching the reconstruction in a prompt manner. It also determined that the post-disaster reconstruction in Sichuan is an extremely organized and centralized planning action, principally led by the government.

2.2 Potential Mediators between Top-Down and Bottom-Up Initiatives

Although the post-disaster recovery of the Great Sichuan Earthquake is a government-led process, there have been various nongovernment organization (NGO) and nonprofit organization (NPO) involvements. In response to the practical demands, their assistance ranged from medical aid and finance management to technical expertise and knowledge provision, covering almost every area of disaster relief and recovery. The NGOs and NPOs have been constantly looking for possibilities and operating efficiently for constructive interventions. However, they have been excluded from the official reconstruction scheme, regardless of their areas of expertise. Our experience with some local NGOs during a planning workshop (Sichuan Workshop: Dujiangyan Dreams)[iv] suggested that this is a pervasive phenomenon in post-disaster Sichuan.

It is clear that NGO development in China was still at an early stage. But they could play an active role in integrating the top-down governance and bottom-up initiatives (Ge, Gu, and Deng 2010). Given the NGOs' power and efficiency in the relief phase and their huge and rapidly increasing number after the Great Sichuan Earthquake,[v] it is not difficult to see that NGOs could have been a powerful and efficient mediator among multiple stakeholders, to improve the communication between the government and the public. However, this potentially very important resource was only tapped into during the relief phase and largely ignored in post-disaster reconstruction.

2.3 Strategic Post-Disaster Territorial Development Programs

Post-disaster reconstruction should not stop at rebuilding a city to the state before it was destroyed by the disaster, but use the opportunity to improve the city and its infrastructure and urban environment for a better living in the future. Especially in the Sichuan Earthquake case, with massive financial and material support from governmental authorities, various institutions, and individuals across the country and from around the world, the reconstruction became a rare opportunity of territorial development for many places in Sichuan. Several strategic territorial development programs have been promoted by the governments of various levels to achieve the development goals.

2.3.1 Regional Development Plans

Since the Small Town Construction Program assigned by the State Council of the People's Republic of China in the early 1980s, by 2000 Sichuan had transformed 18,139 rural villages to small towns, pioneered a shift from rural to urban in the west of China, and developed a large number of small and medium enterprises in rural towns and villages. Sichuan was designated as a key region in China's West

Development Program under the National 10th Five-Year Plan in 1999. In the National 11th Five-Year Plan from 2005, Sichuan established its role as a primary region in the program of Building a New Socialist Countryside, which has placed a central focus on rural communities and harmonious societal development. These programs (Kuang and Jiang 2010) set the social, economic, and spatial development context of pre-disaster Sichuan.

Sichuan has been a very strategic region in the territorial development of China, even before the earthquake in 2008. Because of its strategic geographic location between the more urbanized regions in the east and the less urbanized regions in the west, Sichuan's development pushes the frontier of urban development from eastern China towards western China. Therefore, it has been significant to China's overall territorial tactics in the context of recent rapid urbanization. The opportunity of urbanizing through post-disaster reconstruction has great regional and local importance for areas severely affected by the earthquake. Other than achieving redevelopment in the damaged region, the reconstruction has also developed a visionary scenario for the region's long-term development. But the central planning approach continues to prevail—similar characteristics existed in urban development prior to the earthquake since the 1980s and the post-disaster reconstruction, particularly that the reconstruction applied the same top-down approach to its planning and plan implementation.

2.3.2 Post-Disaster Tourism

The Sichuan Earthquake, in spite of its immense damages and losses, has been recognized as a rare opportunity of development by the Chinese government. It represents a form of Chinese optimism in which Crisis equals Hazards plus Opportunity. The strategy of developing post-disaster tourism is an example of this view. It aims to integrate the rich ecological and cultural resources to boost regional tourism development for a prompt economic recovery.

In line with the principle of turning the post-disaster area into a land of opportunity, the national government announced a territorial strategy of post-disaster tourism, soon after the post-disaster relief had started. The first intention of this policy has been to quickly recover the economy and basic infrastructure in designated areas. The key of this strategy has been to attract mainly domestic tourists who are emotionally motivated to contribute to the post-earthquake recovery to visit the disaster area, and to understand the local situation through personal experiences. It also intends to bring large numbers of potential tourists to the region to help the local economy through tourism consumption. The strategy has both educational and economic values.

In order to implement this strategy, the national and municipal governments have

engaged many commercial developers for investment. The constructions started with recovering and upgrading the transport system and other urban infrastructure, then followed with tourism facilities, and finally opened up for commercial developments of related urban activities.

During the post-disaster recovery phase, which started approximately 3–18 months after the disaster, post-disaster tourism worked efficiently and successfully for the economic recovery. Through the implementation of this strategy, a major portion of the reconstructions on basic urban infrastructure and tourism facilities have been completed in a short time. The tourist center of Dujiangyan City, for example, was recovered in one year and was ready for post-disaster tourism activities in 2009. This approach aided the recovery process for post-disaster tourist cities.

2.3.3 One-on-One Assistance Reconstruction Programs

Another important strategy in Sichuan Earthquake post-disaster reconstruction is the one-on-one assistance program, which has played a critical role in the post-earthquake recovery. Different from previous post-disaster reconstructions, the central government of China appointed many municipalities of well-developed provinces and Direct-Controlled Municipalities (DCMs)[vi] from other parts of the country to assist the local municipalities in the disaster areas. Each of those external municipalities formed a one-on-one assistance partnership with one of the local disaster-affected cities and counties (Table 1) for the reconstruction. This has been the first, and so far the only, urban development strategy that cooperates on a territorial level on post-disaster urban reconstruction in China.

Table 1. One-on-one assistance partnerships for the Sichuan Earthquake post-disaster reconstruction

Disaster-Affected Cities and Counties	Supporting External Municipalities from
Sichuan Province	
An County	Liaoning
Beichuan County	Shandong
Chongzhou City	Chongqing†
Dujiangyan City	Shanghai†
Hanyuan City	Hubei
Heishui County	Jilin
Jiange County	Heilongjiang

Wenchuan County	Guangdong
Xiaojin County	Jiangxi
Gansu Province	
Seriously affected areas in Gansu	Shenzhen
Shaanxi Province	
Seriously affected areas in Shaanxi	Tianjin†

†: DCM.

Source: UNCRD 2009.

Under the one-on-one assistance program, competitions among the reconstruction teams composed of local and external partners were encouraged. The progress of all reconstruction teams has been presented on many public occasions. These teams were under great pressure to carry out a “best” paradigmatic reconstruction for the political achievement and social image of both the assisted and the assisting parties. For instance, the reconstruction team of disaster-affected Dujiangyan City and its one-on-one assisting partner Shanghai Municipality competed with that of Wenchuan County and municipalities from Guangdong Province. Competitions were through comparison of the reconstruction plans’ productivity, implementation efficiency, construction quality, and so on. Such competition forces the participating teams to come up with broad innovative ideas and to use the resources more efficiently. As a result, it has accelerated the reconstruction progress and led to an incredibly rapid recovery.

2.3.4 The Shanghai-Dujiangyan Urban Reconstruction Project

To evaluate the efficacy of such a top-down approach of territorial development in an area prone to frequent earthquakes, a review of this process from a risk management point of view is necessary. Also important is the efficiency of economic recovery and the consideration or lack of consideration for sustainable local livelihoods and cultural sustainability. The one-on-one assistance partnership has also introduced some external architectural characteristics to the local built environment through the reconstruction. Some of these issues can be examined through the Dujiangyan and Shanghai assistance partnership case.

Dujiangyan, a county-level city of Chengdu Municipality, is a very significant small

Chinese city of approximately 680,000 inhabitants (including 420,000 urban inhabitants), with a historic center based on the Dujiangyan Irrigation System that dates back to around 2250 years ago. The irrigation system, as the first man-made hydraulic irrigation system in human history, has been diverting water from the Min River to irrigate the West Sichuan Plain for thousands of years. The region has been one of the most irrigated and fertile territories in China throughout history. Therefore, the city of Dujiangyan is fundamentally important to the ecological landscape of the region and is tied to the region's agricultural profile because of its social and demographic characteristics, economic dynamics, and ecological settings. For its natural beauty and significance of hydraulic achievement, the Dujiangyan Irrigation System was designated a UNESCO World Heritage Site in 2000. It is a nationally renowned tourist site and has contributed increasingly to the tourism economy of the city as tourist activities have become more and more popular in China in recent decades. During the Sichuan Earthquake, many places in the historic center and within the first ring road of the city were seriously damaged; some districts within the second ring road suffered medium damages.

Appointed by the central government, Shanghai Municipality was responsible for assisting with the reconstruction of Dujiangyan during the first three years of the reconstruction period. The government authority that is responsible for executing the reconstruction launched an international competition on 12 July 2008, inviting ideas for Dujiangyan's reconstruction. Some of the proposals came up with an over-scaled waterfront development scenario (see example in Figure 1) to promote a new Dujiangyan as a regional center for international tourism and leisure. This kind of post-disaster reconstruction plan does not adequately take into account Dujiangyan's special and significant agricultural and ecological profile. Mega-structures of relief housing agglomerations (Figure 2) for tens of thousands of households now appear in some places in the relatively small city of Dujiangyan. Many housing projects were constructed neither at a moderate scale nor in the style of traditional Sichuan houses, but in the cosmopolitan and modern taste that is commonly seen and may well be appreciated in Shanghai (Figure 3).

Figure 2. Relief housing agglomerations beside transitional disaster shelters in Dujiangyan, Sichuan Province in 2009
Photograph by the author, 3 July 2009.

Figure 3. Post-disaster reconstruction housing project in Dujiangyan, Sichuan Province in 2010
Photograph by the author, 23 July 2010.

This kind of approach to reconstruction often leads to urban development at a scale and with a design that is out of context and lacks essential respect for the specific characteristics of a region. Such generic urban planning and design is context

ignorance and low sustainability based solely on a common understanding of urbanism. It would also increase the risk of disasters and vulnerability for those who inhabit in this urban space, as well as create massive chaos in the resettlement of disaster victims. Fundamental socio-spatial coherence is missing. In addition, the dominant top-down planning has always executed the reconstruction with a rapid schedule decided by higher-level government authority, in order to fulfill the emergent demand of recovery. This is associated to the competition for a “better” reconstruction that requires quick measurable results with an extreme emphasis on economic efficiency and construction productivity. With such a strong focus on efficiency and productivity in redevelopment urban reconstruction is often accelerated in ways that make it difficult to implement a holistic development approach that takes into account urban history and cultural traditions. Therefore, post-disaster planning has been inevitably limited to providing quantity of urban interventions, but has not provided quality of urban life. Furthermore, the lack of cooperation among stakeholders increases misunderstandings and conflicts. It does not help resilience building but makes communication between various stakeholders of post-disaster recovery problematic.

3 A Critical Concept: Urban Resilience

Resilience is a critical concept to guide urban reconstruction of a post-disaster territory and to reflect on the post-disaster urban condition of vulnerability. Examining the post-disaster urban reconstruction organized by the Chinese government in Sichuan from the perspective of resilience construction raises critical questions about the complex and paradoxical relationship between rapid urban reconstruction and urban resilience.

3.1 From Disaster to Resilience

Like disaster, resilience as a set of multidimensional concepts, tools, and characteristics, is site- and context-specific to various types of disasters in different places. To define resilience for urban projects, desirable characteristics for cities, and useful tools in a post-disaster practice, it is crucial to identify which type of resilience is key to the process of post-disaster redevelopment. It is important to specify urban resilience in a post-disaster territory.

Resilience was first defined by Holling as the time required for an ecosystem to return to an equilibrium or steady-state following a perturbation (Holling 1973; Gunderson 2000). This definition did not only view resilience in a systematic perspective, but it introduced resilience also with a temporal attribute. The push for resilience has been a response to existential or material vulnerability, insecurity, and change. Resilience can also be defined as a sociotechnical or even techno-centric

concept in many of its versions, from Timmerman's "capacity to adapt to stress from hazards and the ability to recover quickly from their impacts" (Timmerman 1981, pp. 5) to Pelling's "capacity to adjust to threats and mitigate or avoid harm" (Pelling 2003, pp. 5). Dovers and Handmer (1992), by reasoning on the resilience of social systems, distinguish the processes of adaptation of a society between proactive and reactive. A further distinction in conceptualizing socio-ecological system resilience is made between "specified" and "general" resilience. Specified resilience is the resilience "of what, to what" (Carpenter et al. 2001, pp. 765). General resilience is "the resilience of all aspects of a system to unspecified, including novel and unforeseen, disturbances" (Resilience Alliance 2009).

3.2 From General to Specific: Urban Resilience

While natural disasters and environmental hazards are far from being exclusively urban experiences, the recent surge in events affecting large-scale conurbations has led to a significant shift towards analyzing the adaptive capacity of governance institutions and communities and how this might be utilized in developing a new "urban resilience" (Bull-Kamanga et al. 2003; Pelling and High 2005). Social or community resilience is seen as the participation of citizens in the process of making the state of the society or community more resilient and in helping to manage threats and conditions of uncertainty, because shared and coordinated action can reduce collective vulnerability. At the urban level, the idea of critical infrastructure protection (CIP) or the protection of lifelines has become common. Godschalk argues that "resilient cities are constructed to be strong and flexible, rather than brittle and fragile. Their lifeline systems of roads, utilities and other support facilities are designed to continue functioning in the face of rising water, high winds, shaking ground, and terrorist attacks" (Godschalk 2003, pp. 137). Goldstein (2011) argues that the communication between different stakeholders is also fundamental to the social aspect of urban resilience towards disasters, conflicts, or urban security risks.

The contribution of these emergent interdisciplinary studies on resilience emphasizes emergency planning and disaster management as an integrative and holistic exercise, which is seen as a collective responsibility, and refines the concept of urban resilience as both reactive and proactive to disasters.

3.3 Urban Resilience in Sichuan Reconstruction

In developing their historic perspective on urban resilience, Coaffee, Wood, and Rogers argue that "resilience is most effective when it involves a mutual and accountable network of civic institutions, agencies and individual citizens working in partnership towards common goals within a common strategy" (Coaffee, Wood, and Rogers 2009, pp. 3). Vale and Campanella point out that "[…] the resilient city is a

constructed phenomenon, not just in the literal sense that cities get reconstructed brick by brick, but in a broader cultural sense. Urban resilience is an interpretive framework proposed by local and national leaders and shaped and accepted by citizens in the wake of disaster. However equitable or unjust, efficient or untenable, that framework serves as the foundation upon which the society builds anew" (Vale and Campanella 2005, pp. 353).

The debate on resilience and resilient city is helpful for finding clues on how cities could and should be recovered from disasters. Using the above frameworks to verify if the government-guided reconstruction in Sichuan has made the region more resilient, the following observations can be made:

Despite systematic organization and efficient implementation, several aspects of urban reconstruction can be better integrated in the process:

(1) From the perspective of urbanism, there should be more considerations of social and spatial coherence for the recovery or redevelopment of the urbanity of the post-quake cities, that is, comprehensive recovery of urban fabric (built structures), urban system (system that operates and organizes the urban dynamics), and urban livelihoods. While mentioned in the government's visions of the recovery plans these concepts have hardly been implemented in the government-guided reconstruction.

(2) A resilient reconstruction should also consider the specific urban profile and configuration of the place, to redevelop a site- and context-specific urbanity, instead of reconstructing everything with the generic vision of a top-down plan.

(3) Different processes of reconstruction and recovery should be more integrated with progressive collaboration; resilient reconstruction cannot be achieved by focusing on individual aims (in the case of Sichuan, the economic recovery) and implementing plans in a great rush or even at the same time as they are made.

(4) Improved integration and collaboration in terms of public-private partnerships would be very beneficial. The expansion of NGO involvement in the process of mediating, reflecting, and engaging top-down approaches and bottom-up initiatives would be beneficial. As concluded in a report on identifying resilience after the Sichuan Earthquake: "engineering management needs to include social metrics further if it is to achieve the outcomes that China now seeks" (Potangaroa, Wang, and Chang 2008, 6).

4 Seeking Urban Resilience: An Alternative Scenario for Development in Dujiangyan

From the perspective of an architect, in the following section this author focuses on how an alternative design scenario for the reconstruction can contribute to the urban resilience of the post-disaster city of Dujiangyan in Sichuan Province. The scenario development is guided by a post-disaster resilience design framework, which in the

aspects of urbanism focuses on socio-spatial coherence in the urban design, temporal continuity in the urban development strategy..

4.1 The Urban System before and after the Earthquake Impact

To find clues to urban resilience in the original setting of Dujiangyan, analyses in the alternative proposal started with exploring the urban system of the city, before and after the earthquake. Due to its unique UNESCO World Heritage Site status, its particular cultural landscape of hydraulics, and its demographic and ecological settings of agriculture, although relatively small in population and area, Dujiangyan as a city plays a significant role in the region. There are five types of urban subsystems to be noted: production, commerce, dining, leisure, and tourism. They represent the major urban activities of Dujiangyan. By mapping the facilities and related transportation networks in these five types of urban activities in the city (Figure 4), this work identifies the allocation of different functions in the original urban fabric. By overlaying the layers of the five urban subsystems, Figure 5a illustrates the original pattern of the urban system before the earthquake. From these maps, we can see that the city has a systematic and well-developed transportation network connecting to its surrounding rural areas, which represents a strong connection for agricultural trading activities. Yet, seeing from this figure, the two concentrations of the city's daily activities are around the historic center, where the irrigation system and the tourism center are close to, and around the intercity bus station that locates at the cross of the main axis formed by the highway (connecting the provincial capital Chengdu and the inner mountain region to Tibet) and the first ring road, where the city's main bus station is located. Both of these elements of the city, namely the places of daily activities and the route network that provides access to these places, are fundamentally important to the urbanity of Dujiangyan.

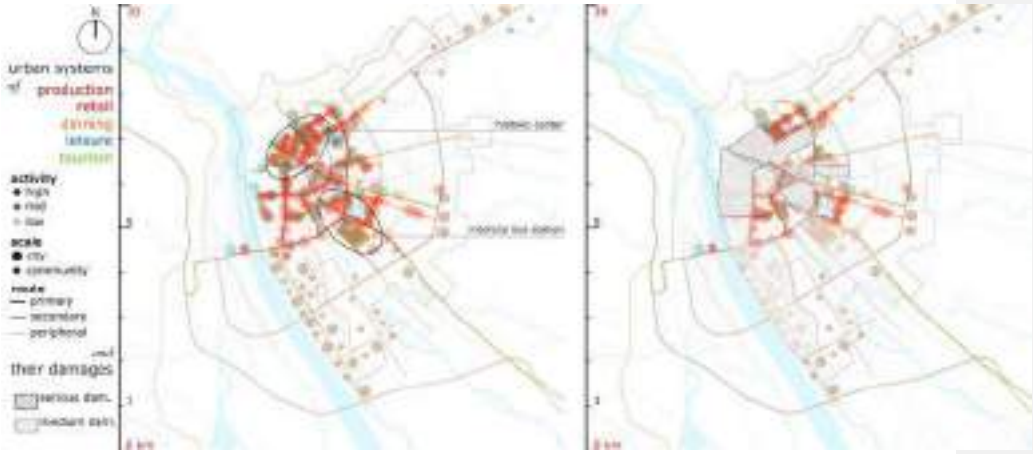

Figure 5. The original pattern of Dujiangyan's urban systems (a) and their damages after the May 2008 Great Sichuan Earthquake (b)
Source: Guo 2010.

Instead of just considering the damage of the urban fabric itself, this study pays particular attention to the damages of the urban system. Figure 5b indicates the extent of damages of the urban system after the earthquake. This set of mapping analyses together reveals a fact that although the serious damage did not necessarily affect all of the built urban fabric of the city and the rural areas, the majority of the most active urban area, the city center, has been mostly eliminated. This explains why the damage has not only largely ruined the urban fabric, but it has also severely destroyed the urbanity of the city. The argument is that, only repairing or reconstructing the built structures is not sufficient for rebuilding the resilience of the city from the physical damage of the disaster. It is also necessary to pay careful attention to the damage of the urban system and the urban livelihood and to redevelop the socio-spatial coherence of the place.

4.2 An Integral Scenario of Urban Resilience

"Disasters did neither inevitably destroy cities or societies, nor indeed produce decline. Cities are obdurate and resilience is there for perhaps as long as cities themselves exist" (Coaffee, Wood, and Rogers 2009, pp. 17). Yet, with the changes to urban form and civic governance structures in response to natural hazards, disasters can act as a stimulus to encourage post-disaster rebuilding and innovation. Urban administrations

often emphasize “that their city has come back stronger than ever” (Vale and Campanella 2005, pp. 17).

The alternative proposal (Guo 2010) investigates how to construct a resilient city from the disaster with an independent yet critical point of view as an urban professional. In this task, the goal is to seek integral development interests based on the resources that the government would provide, yet to fulfill the needs of the city and its social groups, by initiating new urban programs and designing urban projects to promote urban resilience. Figure 6 is a result of this design exercise, showing an alternative scenario to the vision of the government, to lead the city into a more resilient future through its transformation in the reconstruction. It tries to integrate the intention of the government on tourism development in the region based on the local resources, and to improve the urbanity by recognizing the original social and spatial quality, which has been considered as the pattern of the urban resilience that has existed for thousands of years in Dujiangyan. This interpretation of urban resilience pays extra attention to the city’s rural demography and economy and productive agricultural landscape, and tries to integrate it into the post-disaster urban transformation. The integration, between tourism development and the existing urban quality, between agriculture, ecological landscape, and the urban expansion, improves the social and spatial coherence, and defines the development for the specific urban profile. Yet the systematic and holistic approach opens up the possibility to continue the significant history of Dujiangyan in its future; that approach is the key of the design proposal.

Figure 6. An alternative scenario—Dujiangyan, Sichuan Province: an tourbanistic agropolis for 2012, which integrates sustainable agriculture economy and landscape development and the government’s touristic and urbanistic ambition into the urban future
Source: Guo 2010.

Given the fact that the future development of Dujiangyan inevitably involves urban expansion, the alternative design proposal argues that in order to use the resources for reconstruction strategically, urban projects should be located either in the extension parts of the city or along related routes to enhance the interrelation with similar facilities in the city; these projects should be located in the new settlements with direct connections to the existing urban route system, so that they create new urbanity by serving the inhabitants in the newly developed neighborhoods and extend the urban system by connecting the existing and new parts together. Urban projects at various spatial scales should create diverse densities of housing and commercial developments along the outer ring road: some with high density of social housing that accommodates the victims who have to move to the periphery of the city; others with larger-scale commercial and leisure facilities along the ring road and its major exits; and commercial and leisure developments on secondary streets or on the streets of neighborhoods that are relatively small in scale, to match the local urban and rural fabric of Dujiangyan, as well as to reduce the risk of disasters by dispersing settlement (Figure 7).

In order to make the city more resilient, a further phase after the reconstruction is also proposed, in a continuous line of urban development, to extend the road networks into the surrounding villages, following some corresponding small-scale developments of facilities and landscapes along the way. By reinforcing the connection between the urban and the rural, it integrates the urban inhabitants' and farmers' networks of daily exchange, trade, social contact, and participation in each other's lives—the city of Dujiangyan becomes a coherent and integral whole.

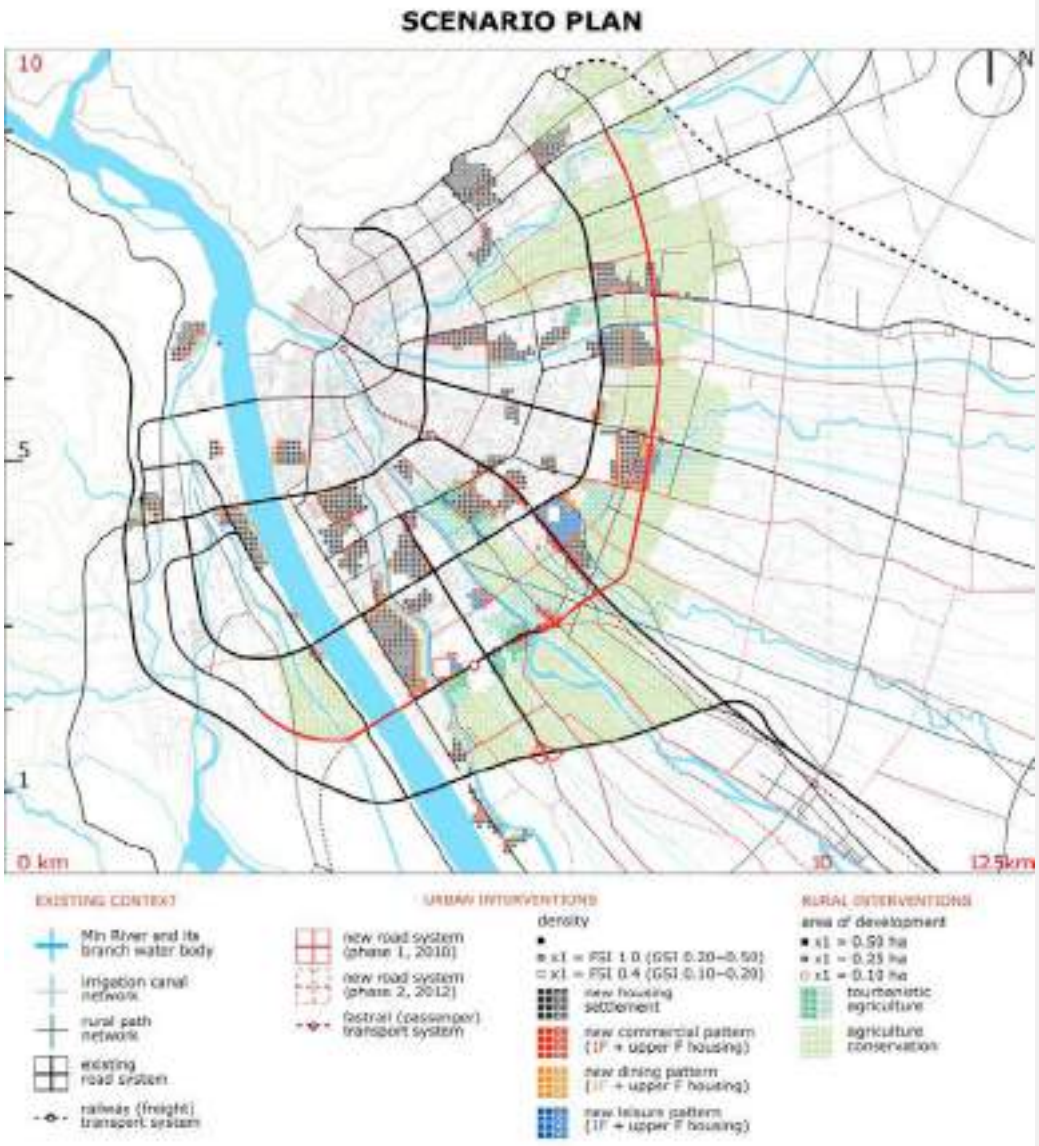

Figure 7. Alternative development scenario for Dujiangyan, Sichuan Province. FSI, Floor Space Index (also know as FAR, Floor Area Ratio) = Total covered area on all floors of all buildings on a certain plot / Area of the plot; GSI (Ground Space Index) = Constructed area / Surface area
Source: Guo 2010.

5 Conclusion

The post-disaster reconstruction in Sichuan guided by the government has been a notable success in many aspects, such as emergency response and relief, economic revival and construction efficiency, political achievement and social image promotion, as well as the fact that there was an innovative emergence and remarkable involvement of NGOs during the post-disaster relief period. For many remote rural places, it has been the opportunity of a lifetime to be part of the blueprint, which promises to upgrade the local built environment in ways none of its residents ever expected.

But none of the official documents or urban plans of reconstruction and redevelopment seems to indicate that urban resilience is treated as an intentional, integral part of the government vision. One of the keys to maintaining and improving the resilience of a city is the integration between top-down planning and bottom-up demands from relief to reconstruction phases, and it is missing in the Sichuan Earthquake case. Instead, the dominant top-down planning did not integrate, or not as much as expected, the bottom-up initiatives to reflect the cities' actual demand for development, but promoted a generic development at many individual post-disaster sites. Such ignorance of the local cultural context and site-specific resilience cannot be considered sustainable.

Developing urban resilience of a post-disaster city calls for socio-spatial coherence in the urban plans and projects, temporal continuity of the urban interventions, and inter-disciplinary and multi-stakeholder integration and communication. To achieve this, it is necessary not only to repair or reconstruct what has literally collapsed in the disaster. It is critical to interpret an urban resilience in the specific post-disaster urban context of the many urban components, elements, networks, dynamics, and capacities. It requires attentive and inclusive consideration in planning and design of the scales, tools, approaches, and intensity of the intervention, instead of rapid and generic urbanization or interruption to the urban system with radical social and spatial changes that decreases these systems' capacity to cope with future disasters.

Even though the achievements in Sichuan post-disaster reconstruction have been significant and the government interventions are technologically advanced and organizationally efficient, disaster recovery in China still lacks sufficient support for the integration of various stakeholders, as well as socio-spatially coherent and holistic redevelopment scenarios. Seeking urban resilience can be an arduous task, but the exploration of alternative scenarios indicates that it is possible.

Notes

[I] Urbanity is considered as a core concept in the field of urbanism. In general, it can be described as the characteristic of a city or the quality of an urban space. It has to

do with the "hard" entities, such as built form and spatial condition of the urban fabric; it also has to do with the "soft" aspects, such as demographic settings, social activities, political regime, and economic dynamics that are associated with the daily urban livelihood, which are held in the urban fabric.

[ii] Based on the March 2012 exchange rate of USD 1 = RMB 6.29.

[iii] Right after the Great Sichuan Earthquake, the government executed the post-disaster rescues and relief with impressive efficiency by coordinating military forces and an enormous number of volunteers. Approximately 4.9 million volunteers joined the relief effort (512 Help 2008). Soon after, 19 other provincial governments were ordered to assist the local municipalities with post-disaster reconstruction. This has been the most efficient post-disaster relief action in China, integrating governmental and military forces, NGO initiatives, technical experts, and business contributions in a very short time.

[iv] The Sichuan Workshop: Dujiangyan Dreams was an interuniversity and interdisciplinary summer workshop (19 July–6 August 2010) carried out in Sichuan, with a group of teachers and Masters of Science students in Urbanism, Architecture, Building Technology, and Real Estate & Housing from the Faculty of Architecture at Delft University of Technology and postgraduate students in the European Masters in Urbanism (EMU) from four leading European universities (Universitat Politecnica de Catalunya, Spain; Delft University of Technology, The Netherlands; Katholieke Universiteit Leuven, Belgium; and Università IUAV di Venezia, Italy), as well as teachers and undergraduate/graduate students in the School of Architecture at Southwest Jiaotong University, China. The workshop was initiated by the author.

[v] To optimize the efficiency of relief, the government introduced a strategic policy to involve NGO initiatives after the Great Sichuan Earthquake. With this support, the number of NGOs has risen to approximately three hundreds, involving three million volunteers. (Lin and Zhan, 2010).

[vi] Direct-Controlled Municipality (DCM) is the highest level classification for cities in China with a status that equals that of provinces.

ABSTRACT:

The rapid development of China's urbanization has led to rural industries decline, rural exodus and the growing gap between urban and rural. So China needs to find the new spatial strategies of development to achieve the goal of urban-rural integration. Then it is necessary to explore the rural areas' spatial structure and the affecting factors of its development. With its large rural population, Chongqing was chosen as the pilot zones for Urban-rural Integration Reform. So this paper chosen Xiushan county of Chongqing as an example to analyze the rural spatial structure and its affecting factors. Firstly, we develop a database which stores the information such as population, land-use and industry in a format supported by GIS (Geographic Information System) based on the questionnaire for the 260 villages of Xiushan. Secondly, with the aid of GIS visualization function，it is convenient to study the spatial distribution characteristics of administration maps of Xiushan rural areas from aspects of location, topography, population, industry, public services and so on. After a preliminary study on the inequality distribution of each villages based on the maps, the results showed that the terrain and the traffic play a notable role in the economic development of rural area in Xiushan. And there are some close relationships between the spatial distribution of population, land-use and Industrial structure.

KEYWORDS:

Rural transformation, Spatial inequality，Urban-rural integration, GIS , Urbanization of China,

1. Introduction

1.1 The Urban-rural Integration Reform in Chongqing

The rapid development of China's urbanization has led to rural industries decline, rural exodus and the growing gap between urban and rural. So China needs to find the new spatial strategies of development to achieve the goal of urban-rural integration. Then it is necessary to explore the rural areas' spatial structure and the affecting factors of its development. With its large rural population, Chongqing was chosen as the pilot zones for Urban-rural Integration Reform. So this paper chosen Xiushan county of Chongqing as an example to analyze the rural spatial structure and its affecting factors.

1.2 rural planning and rural survey

Rural planning is the comprehensive strategies about the village's social, economic, technological development, and also the basic guidelines for the rural development and construction. The plan includes the analysis and evaluation of economic and natural resources; the strategic objectives and the distribution of the rural social and economic development and last the implementation of the rural planning. Therefore, the rural planning should be based on its resources, the existing production conditions, the nation's economic development objectives and policies and then choose the optimal solution.

Through filed research，it is reasonable to identify existing problems in rural areas, and establish the main content of the Rural Planning , the framework of rural living environment improvement and municipal management model. With the establishment of Chongqing rural management system including the content of rural planning，the index system such as rural land use classification (as distinct from urban land use classification), land scale per person and the public facilities and infrastructure to explore the new paradigm of rural planning and new models of Chongqing rural construction, for example, the public participation, community planning. Chongqing, as the urban and rural reform experimental zone, its rural planning requires special consideration to the relationship of the villages with its surrounding cities in transport planning, industry, and functions of the floating population of migrant workers. The optimal hierarchy structure of the villages and the spatial pattern should be researched to achieve the urban and rural public service facilities equalization. The villages at different location advantages should take diverse planning strategies.

1.3 GIS analysis function

Geographic information systems (GIS) is a set of tools that captures, stores, analyzes, manages, and presents data that are linked to location(s). In the simplest terms, GIS is the merging of cartography, statistical analysis, and database technology. GIS systems are used in geography and urban planning. With the aid of GIS, it is convenient to study the urban space structure combined with the social and economic attributes. As in a thematic map, GIS requires both spatial data and attribute data: information attached to each object in a layer. Within the program the attributes most often are in spreadsheet format. The initial data consist of the map of the administrative regions and the attribute data such as GDP (GDP measures the value of all goods and services produced in the county during the year)，the total population and the proportion of Xiushan. Several datasets were used to generate variables that measure the geophysical and socio-economic attributes of each county. One of the distinguished properties of themiatic map is that it can provide an effective visualization of population density from statistical density functions of spatial distributions.

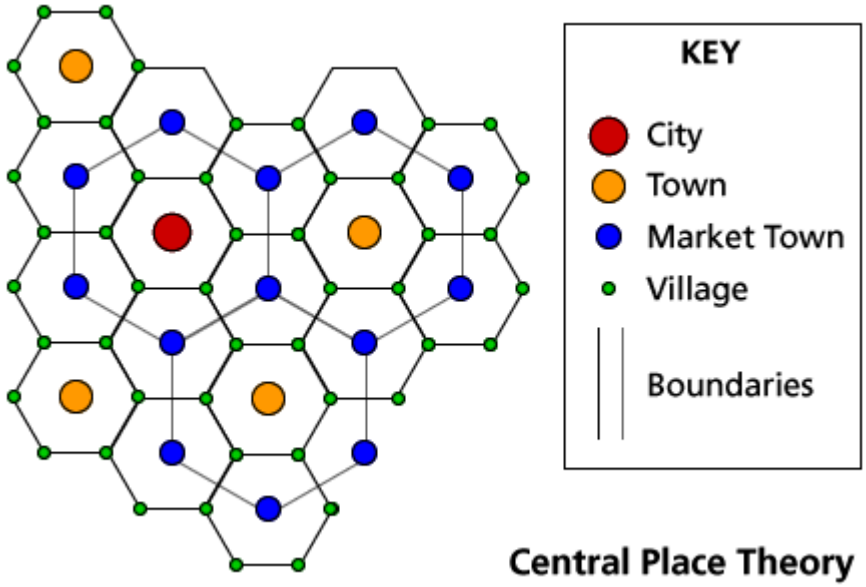
2. Theory

2.1 Central place theory

Central place theory is a geographical theory that seeks to explain the number, size and location of human settlements in an urban system. The theory was created by the German geographer Walter Christaller, who asserted that settlements simply functioned as 'central places' providing services to surrounding areas. The result is that a system of centers of various sizes will emerge. Each center will supply particular types of goods forming levels of hierarchy. In the functional hierarchies, generalizations can be made regarding the spacing, size and function of settlements.

The larger the settlements are in size, the fewer in number they will be, i.e. there are many small villages, but few large cities. The larger the settlements grow in size, the greater the distance between them, i.e. villages are usually found close together, while cities are spaced much further apart. The higher the order of the goods and services (more durable, valuable and variable), the larger the range of the goods and services, the longer the distance people are willing to travel to acquire them.

At the base of the hierarchy pyramid are shopping centres, newsagents etc. which sell low order goods. These centres are small. At the top of the pyramid are centres selling high order goods. These centres are large. Examples for low order goods and services are: newspaper stalls, groceries, bakeries and post offices. Examples for high order goods and services are: jewellery, large shopping arcades and malls. They are supported by a much larger threshold population and demand.



http://watd.wuthering-heights.co.uk/mainpages/sustainability.html

2.2 G. William Skinner's Chinese rural hierarchy theory

G. William Skinner's groundbreaking research into rural Chinese economic systems displayed the value of spatially explicit theories such as central place theory in applied situations that served to explain or even fundamentally reshape our understanding of social and economic systems in a way that other approaches could not.At the root of rural economic activity in China was the village. The average peasant lived here with his family and engaged in a largely subsistence existence, producing goods for immediate consumption. It would be wrong, however, to view such a family or a village as being a closed system, entirely self-reliant. Excess food, clothing or other goods were produced. Such items flowed upward to the next step in the hierarchy: what Skinner dubbed the standard market town. "What [the village] household produced but did not consume was normally sold there," Skinner observed of the standard market town. In addition, "what [the village household] consumed but did not produce was normally bought there." The standard market town itself only had a limited range of goods available. Itinerant merchants would travel to and from intermediate market towns which represented the next level. At the top of the rural

hierarchy were the central market towns, which were the most rarified and had the most exclusive items available. Beyond the central market town, we move into local cities and regional cities, which were beyond the scope of Skinner's rural model.

3. Framework

3.1 Rural information questionnaire

This paper chosen Xiushan county of Chongqing as an example to analyze the rural spatial structure and its affecting factors. Firstly, we develop a database based on the questionnaire for the 260 villages of Xiushan and the formulation of rural basic information questionnaire will based on the direction and significance of the study. The content of the questionnaire was based on the social and economic structure of rural area including the indicators such as settlements in land area per capita, the public services and facilities per capita area， arable land change rate, rural population change rate, a production share of employment, agricultural real estate rate, agricultural labor productivity , etc.

4. Analysis (case study)

4.1 Location and introduction of Xiushan County

Xiushan Tujia and Miao Autonomous County, or Xiushan County for short(Pinyin: XiùShān) is located in southeastern Chongqing Municipality, China. Xiushan has a special location position among 38 districts and counties for it is at the junction of Hunan, Hubei, Guizhou Province and the No.326 and No.319 National Highway runs through the county. However, Xiushan county's terrain is mostly low mountains, valleys and the hillside area. The county accounted for 28% plains, hills for 29%, mountain for 43%. Hills account three quarters of the area. In particular, more than 10 surrounding townships are in a bad situation for the steep and inaccessible mountains. Paddy fields are mainly located in the flatland and hilly region.

5. Conclusions

5.1 The Driving Forces of economic elements' distribution

(1) The traffic has a huge role in promoting the economics:

(2) The restrictive effect of the terrain:

(3) The unique role of the mineral resources, for example, the village near the mines often has a higher industrial output or GDP compared to other villages.

5.2 The characteristics of economic elements distribution

5.2.1 Population distribution:

(1) the resident population and the migrant population tend to located along the main roads;

(2) the transport and land terrain conditions have a great impact on the population density distribution, which was the core radial distribution pattern;

(3) the northern mountainous area has a high population mobility and the rate of moving out accounts for 35%;

5.2.2 Industry distribution:

(1) The output value of the western is higher than that of the east；

(2) Agricultural output in the south villages is higher than those in the north, the eastern mountains of agricultural output value accounted up to 80%, the main industry of Xiushan County is agriculture;

(3) The services is distributed along the roads.

5.2.3 Land use distribution:

(1) The distribution of the state-owned land for construction was associated with the industrial land layout, which was concentrated mainly in the western mountainous edge regions with rich mineral resources;

(2) The collective construction land of the villages distributes along the roads and has a close relationship with the transport, indicating that the farmers spontaneously gathered to the road;

Trust – a 'new' institution to improve urban governance

Peter Edwards[1]

Abstract

With a participatory turn in planning having happened over a decade ago it is time to reflect on whether participation has delivered something new or whether it is simply more of the same with new labels. When we look at many of these participatory planning institutions against Arnstein's (1969) ladder of citizen participation, many of these new planning approaches were/are hardly new. There are very few planning authorities that are willing to redistribute their resources and the power that can be exercised from mobilizing these resources to enable citizen power. However, where some effort has been made to go beyond the 'informing' and 'consultation' rungs on the ladder, there is some evidence that these moves that incorporate community engagement can help develop trust. There may be anecdotal evidence that the farther one climbs up the ladder towards citizen power, the stronger the trust that can be developed.

The central theme of this paper is that through the development of mutual trust between communities and planning authorities, appropriate, quality and legitimate planning decisions can be made and implemented.

This work delves deeper into the institutional and governance aspects of the work by Edwards (2009) looking at how power and trust work in participatory planning exercises. Data has been collected through documentary analyses and follow up narrative interviews with selected actors involved in planning and community on the Gold Coast, Australia.

The author expects that by looking at participation through the lens of trust, will provide another perspective on collaborative planning other than power (c.f. Flyvbjerg 2003). While Stein & Harper (2003) claim that a focus on power can reduce trust, I believe that it detracts from the attention that trust deserves, particularly the role that trust plays in improving democratic legitimacy.

Keywords: trust, participation, power, democratic legitimacy, planning decisions

Introduction

Participation in urban planning has variously been called participatory planning, collaborative planning, and community engagement, among others. It has gained prominence over the past few decades from theoretical and practical perspectives – new tools for practitioners to developments on its fundamental basis in Habermas' communicative action theory, such as the work of Iris Marion Young. As Head

[1] Department of Forest Products, Swedish University of Agricultural Sciences, Box 7008, 75007 Uppsala, Sweden. Peter.Edwards@slu.se

(2007) notes, this is partially due to the insufficiency of formal institutionalized democracy as we know it. Participatory planning has been used at local, regional and national scales with varying levels of success, no matter what the scale. While there have been many participatory successes at varying spatial scales, there are many more participatory processes that have failed and further contributed to the divide between citizens, stakeholders and government (c.f. Innes & Booher, 2004).

While participation, and in particular meaningful participation, may have failed innumerable communities, there may still be hope that through conceptualizing the research undertaken in participation, there is hope that communities can once again feel that their governments have their best interests at heart. Through looking at trust and how the power relations in participatory planning processes relate to it (trust), it would appear to provide a productive way forward in planning governance. By developing trust between citizens, stakeholders and government agencies, even the limited way in which participatory processes are carried out may be able to improve planning processes and legitimacy.

The paper will set out what participation is, what ideal participation hoped to achieve and predominantly discuss how participation has failed. The failure of participation will be linked with the concept of legitimacy and how participatory planning has been unable to deliver legitimate planning outcomes. Legitimacy is also linked to the idea of trust. Trust will be explored, first introducing it, how it can be considered an institution and finally how trust as an institution can be used as a governance framework to develop legitimate planning decisions.

Participation and its failures

Wade Davis (2001) noted that "Every view of the world that fades away, every culture that disappears, diminishes a possibility of life and reduces the human repertoire of adaptive responses to the problems that face us all". While this speaks to a specific way that participation can provide a benefit to society, it has also been held up to provide a range of broader benefits. These benefits include good governance, modernizing government, and addressing a democratic deficit found in representational democracy and improving legitimacy of decisions and providing a better picture of what is happening in communities and neighbourhoods (Curtain, 2004; Nicholson, 2005; Edwards et al., 2008; Nienhuis et al., 2011). Innes and Booher (2004) further note that there are five purposes of participation, including allowing decision-makers to find out what the public wants, incorporating local knowledge, fairness and justice, legitimacy and legal requirements.

While some authors (ASR Research & Red Road Consulting, 2002; Giessen, 2008; Edwards, 2009) among many note that participation has delivered numerous benefits to citizens and communities, including additional or improved information, a dialogue between government and citizens/stakeholders (Head, 2007), deliberation between stakeholders, improving understandings between groups with differing interests ( ).

While Head (2007) notes that participatory democratic theory assumes that positive outcomes come from participation, there are numerous critiques of how participation has failed communities and neighbourhoods. Innes & Booher (2004) and Cheng & Mattor (2006) note that one of the root causes of failure is through having rigid, legally mandated participation. These rigid, legal requirements often result in the coordinating government agency 'going through the motions' to satisfy the requirement, while not concerned at all about the input from citizens and stakeholders. Additionally, the amount of time that these processes can take (approximately two years in several local government and almost eight years in a state government cases in Australia) (Edwards, 2009) make them unattractive to both governments and citizens and stakeholders, in addition to possibly ending in poor decisions (Innes & Booher, 2004).

Participation, therefore has overall not delivered on the grand promises made, simply 'greenwashing' over traditional styles of government policy and planning. Maginn (2007) notes that information sharing and data collection did not provide any meaningful participation from citizens and stakeholders in Perth nor did just going through the legal motions in Colorado (Cheng & Mattor, 2006).

Nienhuis et al. (2011) indirectly note that participation can fail in two distinct ways when they claim that process design and lifestyle choices affect participation. The first is through failure of the process, where the process employed has failed to work 'properly' (i.e. incorporating bias, exclusion, lack of independence, agenda control by policy-makers, etc.) (Head, 2007; Maginn, 2007; Bond & Thompson-Fawcett, 2007). The second way in which participation fails is through simply 'bad' participation. This is where citizens and stakeholders simply do not participate – through lack of time or connection to the community (Nienhuis et al., 2011), being out of touch with political and economic realities (Innes & Booher, 2004) or where the organising agency does not identify or reach 'hard to reach' groups (Bond & Thompson-Fawcett, 2007).

These failures of participation have led, in part, to a decrease in legitimacy of participatory processes. Beetham (1991) notes that legitimacy is derived both through process and norms – focusing on the process, it therefore must be inclusive and have outcomes that are binding on decision-makers. In many cases, neither of these criteria are met, making plans illegitimate in the eyes of citizens and stakeholders.

The failures of participation have led to unhappy experiences on the part of the citizens and stakeholders (Head, 2007) and letting the public believe that government at all levels is unresponsive to their concerns (Innes & Booher, 2004). They also note that citizens may not be in touch with the long-term outlook, political and economic realities of the area, however, it can be noted that politicians (who, in some cases, 'control' the planners, c.f. Edwards & Bond, 2011) do not look to the long term either, but simply the next election. Through these failures of participation,

citizens and stakeholders have found that their expectations of being heard and involved are not being met. The message here is that citizens and stakeholders are not able to share power with the planning authorities in planning processes.

Both of the threads above (legitimacy and un-met expectations) have several things in common – trust and power. Dunn et al. (2008) note that trust is a component of process legitimacy while Möllering (2005) and Bijlsma-Frankema & Costa (2005) note that as a generalisation, trust involves the meeting of expectations (with mistrust the non-meeting of expectations). Parsons (1986) and Misztal (1996) both note in general that legitimacy is closely linked to trust. Trust is a powerful phenomenon that can have far-reaching consequences for citizens, stakeholders and government involved in planning. Bijlsma-Frankema & Woolthuis (2005) note that trust is a superior form of governance than control, however, in terms of planning practice, this form of governance has not been adopted or trialed.

Trust as an institution

Approaching this idea from a normative direction, trust in (participatory) planning could become an institution. For this paper, I use a very broad understanding of norms and the normative approach. Norms can be simply the implicit or explicit laws that govern the behaviours of society or the community. These don't have to be legislated laws, they can be actions or values that are promoted in society and after repeated 'use', become universally socially accepted. The normative approach simply suggests that the values and actions that society considers ideal are encouraged and acted upon over time. As these values and actions are enacted over time, they become institutionalised in society, where Berger & Luckman (1967: 54) describe institutions as "stable patterns of social interaction" that come out of recurring encounters between individuals.

The social relations (actions) that result in trust (a value) could be quite easily institutionalised through repeated enactment. The actions or relations that work towards building trust include 'getting to know each other', knowledge sharing, dialogue, time and meeting expectations (Edwards, 2009). Citizens and stakeholders who are generally active in a community may know of each other, if not actually knowing each other through their active involvement. Those citizens and stakeholders who are not active or have most of their social interactions outside the community in question therefore may not be known. However, this is not the only building block of trust, although having something in common and knowing each other makes the development of trust much more likely (Uslaner, 2002).

Sharing of information and understanding where each citizen, stakeholder or government agency is coming from is another building block in the development of trust. Currently, parties may share information (informing or consulting on Arnstein's ladder), but there is only limited use of the information, and often no deeper understanding of why different actors have these views or how the knowledge that they have has come about. Sharing and understanding of knowledge comes

about through both dialogue and the amount of time that individuals spend together. Through dialogue and self reflection, citizens, stakeholders and government agencies have the capacity to gain a deeper understanding of others, as well as their positions and understandings as related to the others (Foucault, 1990; Edwards, 2009). While the amount of time that individuals spend in each other's company is important (Uslaner, 2002; Uslaner and Richardson, 2003), Edwards (2009) found that while the amount of time is important, how that time together is spent is also important. Getting to know people in a more social setting rather than simply a 'work' or 'official' setting is of great importance.

One of the most important actions that can be undertaken with respect to developing trust is the meeting of expectations. It can be seen allegorically through the following description. As someone who is willing to trust another, I make my expectations of what I want done clear to them. At that point, I have taken a 'leap of faith' – jumping out over the chasm-line unknown. If the other person does what I have asked them to do, they have positively met my expectations – I land on solid ground on the other side of the chasm. The next and subsequent times I take this leap of faith and find that my expectations are met by this person, the leap becomes smaller and smaller. I am building up a trust relationship with this person. However, should I take the leap of faith and find that they have not met my expectations, I don't land happily on the other side of the chasm, I fall into it, severely injuring myself. In this instance, I have been 'hurt' – my expectations have not been met. Because there is no meeting of positive expectations, I may give them one or several more chances, and start to build up distrust as they are unable to meet my expectations.

If we focus on this key aspect of positively meeting expectations, if citizens and stakeholders clearly let planners and politicians know what they want to see in the community and the planners and politicians get back in touch with the community through building up an understanding and rapport with the community (which they lack), (c.f. Innes & Booher, 2004; Edwards & Bond, 2011), community-wide trust may be developed. However, there is still another 'force' at play that can cause problems – power.

Trust and power – a brief note

Starting with participation, communication is at the centre of the 'cutting edge' of deliberative participation (Edwards et al., 2008). Communication, which is also one of the building blocks of trust, is infused with the exercise of power. The exercise of power, in the form of communication adjuncts, such as eloquence, rationalization and charisma can also lend the appearance of legitimacy to the speaker and their information (Flyvbjerg, 1998). While this paper does not focus on the exercise of power per se, Stein & Harper (2003) claim that by focusing on power in participatory planning processes, there is a 'muddying of the waters' surrounding trust, however, participation and trust are intimately linked to the exercise of power (Edwards,

2009). In an overall sense, power must be incorporated into any broad analysis of participation and trust (c.f. Edwards, 2009).

Trust as a 'new' form of governance

Bijlsma-Frankema & Woolthuis (2005) re-propose trust as a global form of governance, although they note there are some serious difficulties as globalisation and neo-liberalism make their inexorable march and organisations move towards networks and alliances, they are less and less embedded in communities where social mechanisms to ensure trust is maintained. While the global is not embedded in communities, planning at the local community or neighbourhood level can still be considered embedded in their localities.

Trust, however, can and should be used to govern and develop appropriate and legitimate planning decisions and outcomes at the local level. Local officials and politicians are supposed to represent the interests of their department or their constituents, however, Edwards & Kleinschmit (in press) note that bureaucrats and politicians may, in the end, be more inclined to represent their own interests, party interests or other special interests rather than the interests of their departments or constituents. As Innes & Booher (2004) note, bureaucrats and politicians have become distant from the people they are 'working for', leading to citizens and stakeholders not having their expectations met, and ergo a decline in trust. The introduction of trust as a mode of governance would therefore require behavioural change on the part of the politicians and at the very least getting back to the fundamentals of representational democracy. This would require bureaucrats and politicians to listen to constituents and take into consideration their input.

Best practice would be 'scale up' to at least the placation rung on Arnstein's (1969) ladder of participation. While placation is still within the tokenism range, citizens and stakeholders are able to provide detailed input into a plan or policy, however the final decisions still rest with the bureaucrats and politicians, who ostensibly have a wider spatial and temporal view than the community. This can help prevent fragmentation within and between urban areas.

A case in point is the Gold Coast Waterfuture process and other community engagement processes hosted by the Gold Coast City Council. While the decision-makers still retain the final authority to approve a plan or policy, citizens and stakeholders have been able to provide input and influence the final plan, generally shaped to the wants and needs of the community (Edwards, 2009). Edwards (2009) found that on the whole, the community trusted the City Council and its organisations to listen and incorporate citizen and stakeholder input to city planning decisions.

Conclusion

The focus on participatory governance in planning in order to get more legitimate planning decisions has not been the panacea that many authors have held it up to be. This paper and others detail many failures of both the processes used in participation and in participation itself. These failures of participation have led to unmet expectations and distrust of planners and politicians on the part of citizens and stakeholders. Power relationships between citizens, stakeholders and government officials play an important role in participation, trust and governance in local planning.

Trust has previously been proposed as an institution for governance by a number of authors, although not specifically in planning at the local level. Trust as a form of governance has been 'forgotten' in favour of more control-based mechanisms due to the increasingly globalised and networked society we have. However, at the local government or community level, there is still space for trust to become the governance institution of choice. There is great opportunity for citizens, stakeholders and government officials to interact, share knowledge and understandings and engage in dialogue to eventually to positively meet each others' expectations, leading to the development of trust.

One way forward is through getting back to the basics of representational democracy, where decision-makers represent the views, values, wants and needs of the community, rather than representing their own views, those of special interests or party interests. This may be possible through the elimination of party politics at the local level. This is one possible reason why the (previous) Gold Coast City Councils have such a deeply intstitutionalised participatory planning regime, that while only at the placation rung, still engenders trust – the Gold Coast City Council has been run by independent councilors, not representing any particular political party.

With some hard work on the part of citizens, stakeholders, bureaucrats and politicians, trust can become a governance institution for community planning.

ABSTRACT
Public open spaces have taken on an increasingly complex role in the city. In addition to their social role as the site of urban public life, they are now considered part of the city's "green infrastructure," expected to provide a broad array of ecosystem services such as microclimate regulation, air pollution and noise reduction and water management (Bolund and Hunhammar, 1999). Additional goals include adaptation to climate change and linking natural areas to counter fragmentation and preserve biodiversity (Sylwester 2009). This approach to the planning and design of public open space (POS) has been adopted as urban policy by many cities, often within a suite of related policies. Some of the most prominent examples of green infrastructure guidance include New York City Department of Parks and Recreation's "High Performance Landscape Guidelines 21st Century Parks," (2010) and London's "All London Green Grid" (2011), a follow-up to the "East London Green Grid" (2008).

Green infrastructure is based on the goals of "protecting, restoring and interconnecting the city's ecological structure" (Girling 2005). The GI approach has three defining characteristics. First, the systems approach implicit in the concept of infrastructure stresses the interconnectedness of open spaces to achieve ecological functionality (Benedict and McMahon, 2006). Second, the emphasis on performance suggests that POS must be multifunctional rather than single-purpose, and third, they must be planned to function as a network at multiple, nested scales-- from the region to the neighborhood.

How do these characteristics of spatial distribution, multifunctionality and scale change the conception of POS and suggest new typologies of open space—introducing new forms, configurations and uses? This paper will focus on the relationship of sustainable urban water management (stormwater management, flood control, water supply and waste) to POS in the city.

Keywords: green infrastructure, sustainable water management, water sensitive design, public open space

Introduction: Infrastructure and Public Open Space

In 1904 the Olmsted Brothers produced a new park plan for Baltimore. Their sweeping proposal was to create a new valley park and parkway system along the stream valleys of Jones and Gwynns Fall, connected by parkways to be laid out in the lateral channels. The 1904 report is full of detailed photographs of Baltimore's rolling piedmont landscape, documenting each natural stream valley and noting their subtle differences -- their varied topographies and unique vegetation. (Olmsted Bros. 1904)

Bottomlands are typically the forgotten spaces of the city- wet, unbuilt, neglected, often inaccessible. The Olmsted Brothers' far-reaching recognition of the topographic and hydrological systems as an urban armature recognized the significance of urban stream valleys as a resource at a time when other cities were filling their ravines and culverting their streams in order to build new housing and transportation systems. Their approach represented a prescient floodplain protection strategy, but it also effected a fundamental change in the perception and experience of the city (Olson 1995). The park plan proposal transformed the stream valleys from inaccessible, neglected urban leftovers to unique and valued landscapes, inverting the topographic reading of the city, which, until then, had privileged the hilltops where its landmark buildings were located, and rendered the stream valleys invisible.

The Olmsted Brothers' park plan provides an early example of a hydrologically based urbanism. The management of water has always played a key role in the development and form of cities, whether for the supply of fresh water, the provision of drainage or protection against flooding. This basic relationship between water systems and urban form was eroded in the modern city. Modern water technologies are no longer legible; the visible elements that were once centers of social life—wells and cisterns, street fountains, and aqueducts—have been replaced by invisible systems, either remote or underground. The relationship between urban functions and the natural environment has become opaque. This is a result of a profound cultural change. If once engineering and urban design were intimately connected, became increasingly autonomous with the rise of professional specialization in the 20th century. Functionalism and efficiency were seen as ends in themselves, divorced from civic meaning. The planning and production of infrastructure has become increasingly technocratic and standardized, losing its connection to the environment (Shannon 2010).

With the increased scale and complexity of urban infrastructure projects, landscape architects have turned their attention to the reintegration of infrastructure with the city and its landscape in order to address ecological, functional, aesthetic and social concerns (Strang, 1992, Rosenberg 1996, Allen 1999, Raxworthy 2004, Belanger 2009, Shannon 2010, Hung 2011). The interest in infrastructure landscapes has emerged to reintegrate engineering and urbanism and "instill purpose, legibility and cohesiveness" (Hung 2011, 15) through site-specific solutions that are integrated into the landscape. This focus

parallels the development of ecological design, as influenced by the new conceptual frameworks introduced by the subdiscipline of landscape ecology in the 1980s.[1] The relationship of ecology and infrastructure landscapes reframes landscape architecture by foregrounding two key ideas: landscape *performance*, and the conceptualization of the landscape as a *network.* Performance characterizes the landscape as working landscape that can be empirically evaluated for achieving specific goals: "As a nonisolated system, landscape infrastructure has the ability to adhere to a set of requirements and achieve measurable results" (Hung, 2011, 17). The network concept stresses that landscapes operates as systems, not as discrete "objects" or "scenes." **"**Infrastructure is a connective tissue that brings together disparate elements, instilling cohesion and purpose. The sheer scale and vast resources spent on network infrastructure present tremendous opportunities to leverage unrealized potential in the urban environments. ." (Hung, 2011, 18)

A parallel discourse has developed among planners around the concept of "green infrastructure." Green infrastructure is 'an interconnected network of green space that conserves natural ecosystem values and functions and provides associated benefits to human populations' (Benedict and McMahon, 2002,12). The GI approach is based on

[1] Ecologist Y. Haila writes: "Landscape ecology originated as a new research program in the 1980s, in a way as an amalgamation of all these theoretical developments (Wiens 1995b): a uniform Cartesian space was replaced with environmental heterogeneity; equilibrium assumptions were replaced with spatial and temporal variability driven by nonequilibrium processes in various scales; and an unquestioned search for universal regularities was replaced with the acknowledgment of spatial and temporal specificity of ecological processes. New hypotheses were suggested about non-equilibrium processes determining landscape dynamics." (Haila 2002, 349)

the goals of "protecting, restoring and interconnecting the city's ecological structure" (Girling 2005). Although the term has a wide range of definitions (Sylwester 2009) it can be said to have three main defining characteristics. First, it is based on identifying and working with the city's existing ecological structure. The systems approach implicit in the concept of infrastructure stresses the goal of interconnecting open spaces to achieve ecological functionality (Benedict and McMahon, 2006). Open space must be planned to function as a network at multiple, nested scales, from the region to the neighborhood. Second, the emphasis on performance suggests that POS must be multifunctional rather than single-purpose.

Public open spaces have taken on an increasingly complex role in the city. In addition to their social role as the site of urban public life, they are now considered part of the city's green infrastructure, expected to provide a broad array of ecosystem services such as microclimate regulation, air pollution and noise reduction and water management (Bolund and Hunhammar, 1999). Additional goals include adaptation to climate change and linking natural areas to counter fragmentation and preserve biodiversity (Sylwester 2009). This approach to the planning and design of public open space (POS) has been adopted as urban policy by many cities, often within a suite of related policies[2]. This paper will discuss the emerging field of sustainable urban water management

[2] Some of the most prominent examples of green infrastructure guidance include New York City Department of Parks and Recreation's "High Performance Landscape Guidelines 21st Century Parks," (2010) and London's "All London Green Grid" (2011), a follow-up to the "East London Green Grid" (2008).

(stormwater management, flood control, water supply and waste) in relation to the planning and design of urban POS. As distinct from conventional approaches, the integrative perspective of sustainable urban water management, which brings together engineering, hydrological, ecological and urbanistic perspectives, demands new holistic frames of analysis (Hill 2009). I will look at how sustainable urban water management suggests new planning and design approaches to POS using the central tenets of green infrastructure, with a focus on hydrological functionality. These tenets are based on the following concepts: 1) landscape structure and the principle of decentralized spatial distribution; and 2) multifunctionality. I will show how these sets of ideas suggest the ways in which hydrology can become an armature for urban form and POS, and how, in turn, POS may take new forms and suggest new configurations and uses.

Sustainable Urban Water Management: WSUD/LID approaches

The growth of cities has had a dramatic impact on aquatic ecosystems. The substantial increase of impervious surfaces has had a direct effect on increasing urban runoff volumes, rates of discharge as well as overall affecting water quality. These three processes have in turn, decreased infiltration, caused erosion, sedimentation, and loss of aquatic habitats. Sustainable urban water management approaches have reoriented conventional engineering approaches to stormwater management from an almost exclusive emphasis on drainage and conveyance, aimed at flood prevention and protection of property, to broader set of goals based on ecological functionality of

terrestrial and aquatic ecosystems. (Prince George's County, MD, 1999). Several approaches developed in parallel. Here I will refer to the techniques of Water Sensitive Urban Design (WSUD) which developed in Australia (Wong 2000, 2006) and Low Impact Development (LID) which developed in Prince George's County, MD, USA (Prince George's County, MD, 1999.) The goal of LID is not only to reduce the negative impacts of stormwater runoff, but to create an ecologically functional landscape that mimics natural hydrological functions (discharge, frequency, recharge and volume) and seeks to replicate predevelopment hydrology by designing hydrological functions into the site design. LID is based on small-scale, "source controls" of runoff dispersed in the landscape that minimize the need for storm drain piping and pond solutions. Additionally, it encourages multifunctional site design that maintains and restores terrestrial ecological processes necessary to protect the ecological integrity of the receiving waters—stream stability, habitat structure, base flows and water quality (Prince George's County, 1999, 5). WSUD emphasizes the integrative framework of stormwater management with the broader planning and design of the contributing urban area. (Wong, 2000): it "provides a common and unified method for integrating the interactions between the urban built form (including urban landscapes) and the urban water cycle." WSUD considers the water network as a whole, including potable water supply, stormwater and wastewater. In addition to treating stormwater, WSUD aims to reduce potable water demand and encourage treatment of wastewater to a standard suitable for re-use. (Wong, 2006).

Landscape structure and hydrological function -decentralized spatial distribution

Similar approaches to water management have developed contemporaneously in the US, UK, Australia, Japan and Israel (Carmon and Shamir, 2009). However, the planners, designers, and scientists involved in its application frequently do not share the same analytical frameworks (Hill, 2009). Each tend to use a distinct frame to guide practice: the "regulatory frame," in which social and legal structures are mapped and assessed; the "site frame," which is focused on the design of site-scaled best management practices, and the "geography-based frame" which stresses the water system as a network within a dynamic mosaic (Hill 2009). Hill notes that although these frames are not necessarily mutually exclusive, they are often applied as if they were. She proposes a landscape-based integrative framework that creates overlap across all three, based on hydrological function. The model identifies three kinds of sites: *upland* (where stormwater is first generated); *network* (linear concentrations of flows, such as streets) and *shoreline* (receiving waters). This model references the flow of water and adds directionality to the system. It also expands the sites of intervention and identifies sites according to their strategic locations in the watershed. For example, while most interventions now take place at the source (upland sites), network and shoreline sites may offer greater benefit due to their larger catchment areas and thus reduce downstream impact.

This model identifies the strategic relationships between the site scale and the overall watershed, recognizing the essential interconnectedness of interventions at multiple scales

from the individual lot to the precinct, with regard to their corresponding scales of catchment: from micro-catchment to the watershed. This analytic frame also suggests that there may different kinds of design approaches to POS that correspond to the scale and location of each of the three types, with some being site-specific, one-off designs while others, such as the network type, may be more prototypic and system-wide. Examples of prototypic network applications in city streets are the Green Streets in Portland, and Street Edge Alternative (SEA) streets in Seattle, which began as a pilot project and has since been replicated and adapted throughout the city.

The decentralized spatial distribution that defines sustainable water systems lends itself to retrofits in existing urban voids, creating new interstitial neighborhood POS that can provide social or productive functions such as play spaces or community agriculture.

Multifunctionality

The principle of multifunctionality calls for enrichment of urban space with multiple programs and purposes. In his discussion of urban parks, Michael Hough highlighted the need for "multifunctional, productive working landscapes": "Urban land as a whole will be required to assume environmental, productive and social roles in the design of cities, far out-weighing traditional park functions and civic values." (Hough 1995, 31). This hybrid conception of urban space allows for new combinatory programs and imagines a new kind of mixing in which open space serves multiple roles. Thus, in

addition to providing storm water management, open space may also serve social, cultural, environmental and economic roles, by creating habitat and increasing biodiversity, controlling microclimate and contributing to community revitalization. (Wiggering 2003, Hung 2011).

Village Homes in Davis, CA, designed by Michael and Judy Corbett in the early 1970s, is an interesting early example of a sustainable community that was designed to promote energy conservation and use of solar energy, walking and bicycling, neighborhood agriculture and natural drainage. The community consists of 242 single- and multifamily residences on sixty acres. (Francis, 2002). There are several types of open space, including including private gardens, common areas, agricultural lands, and sports turf that incorporate the use of native or edible plants. All stormwater is managed in an open system as surface flows that allow for infiltration. The surface stormwater system structures the overall plan of the housing and open space network, providing pedestrian circulation and a continuous network of public open space. In the dry months this area doubles as children's play spaces (Francis, 2002). Other playgrounds use permeable surfaces (sand), and are intended to double as stormwater storage areas. Close to $200,000 in development costs were saved by eliminating conventional storm sewers, which covered most of the landscape costs (Francis, 2002). In addition, the planners fought hard to narrow the streets from the accepted standard widths of 44 ft. (13.4 m) down to 23 ft. (7 m.) in order to minimize impervious paved surfaces. Road surfaces amount to a total of 15% of the overall area, as compared to 22% average in the

surrounding area. The multifunctional approach to stormwater management allowed the system to provide an armature of POS to the community.

Conclusions

By approaching the design of water as an integral element of urban design , it can be reintegrated into the visual and spatial experience of the city. In this way, water infrastructure can once again become a source of civic meaning instead of being relegated to a separated functional realm: expressive, sensate, present. The return to the design of the utilitarian landscape celebrates the interrelationship between natural systems and everyday urban life.

Place-Based Crime Prevention Planning: Cultural Constraints and Applicability in the City of Abu Dhabi, UAE

A. Qamhaieh[1]

Abstract

Place-based crime prevention planning approaches have been widely employed for combating crime and fear of crime in large metropolitan areas within the US and UK (Schneider and Kitchen, 2008). Despite their fair share of criticism, these approaches have demonstrated success in making communities safer, and have been utilized repeatedly by law enforcement agencies in tandem with urban planners to combat crime. During the last decade, middle-eastern countries and particularly Gulf Cooperation Countries (GCC) have witnessed an increase in crime rates as a result of tremendous growth in metropolitan areas. This growth has been accompanied by large increases in populations and changes in societal and cultural norms due to the large influxes of migrant workers. As a result, law enforcement and regulatory government agencies are paying more attention to crime prevention planning approaches such as CPTED. This paper examines the applicability of place-based crime prevention planning approaches within the cultural context of the middle-east. It explores if these concepts work, are effective, and to which extent could succeed in reducing crime rates. The focus area for the study is the City of Abu Dhabi - the capital of the United Arab Emirates. The city is growing at a rapid pace, and the population is expected to double within the next 15 years reaching a figure of 3 million people. The paper concludes that that place-based crime prevention planning approaches do have a potential to work within such contexts, yet do run into certain cultural barriers that prevent a direct application in favor of a more-customized application of these concepts.

Keywords: Crime Prevention, Abu Dhabi, Middle East, CPTED, Defensible Space

Introduction:

The United Arab Emirates – similar to other Gulf Cooperative Countries (GCC) - has historically had very low crime rates as result of its small population count, and high per-capita incomes due to its oil based economy (OSAC, 2011). During the last decade, the UAE gained importance as a as the result of the huge investments in infrastructure initiated by the government in an attempt to position the country to be an economic and

[1] Urban planning Department, ALHOSN University, Abu Dhabi, UAE - a.qamhaieh@alhosnu.ae

cultural hub. As the growth continued, the country witnessed an influx of expatriates seeking employment opportunities, with the vast majority of these expatriates working in the construction, services, and banking industries.

The city of Abu Dhabi, the capital of the UAE has witnessed significant growth as a result of the aforementioned dynamics. The capital is home to around 1.2 million people as of 2011 (SCAD, 2011), and is projected to reach a population of 3 million by 2030 (UPC, 2008). With these current and projected increases in population, the city is growing in size at a rather fast rate, and the country's society is changing at an even faster one. With the large influx of people, the once traditional Emirati town has become a sprawling, diverse and multi-cultural city, along with a whole new range of urban challenges and problems- including crime.

In attempt to direct the city's growth, a number of government planning initiatives and agencies were established. More recently, more attention is being given by the authorities to the issue of crime prevention planning especially since long-range planning is currently underway. As a response, this paper attempts to shed some light on placed-based crime prevention planning approaches. The paper will explain some of the theoretical concepts behind crime as it relates to the built environment. It will also discuss relevant issues within Abu Dhabi's urban planning scene and society.

Theoretical Considerations: Crime and Community

High levels of crime continue to affect the quality of life for large numbers of people within large metropolitan areas, especially those living in neighborhoods exhibiting trends of decline. Traditionally, and especially in the US, higher levels of crime have been associated with neighborhoods of lower socio-economic status, (Bursik, 1988; Samposn et al, 1997). Still, research over the past few decades has shown that low socio-economic status is only one part of the bigger picture. Other important elements have to be present for the rapid decline, and the higher levels of crime to emerge. Furthermore, not all such neighborhoods are equal in the levels of crime; some have average crime rates when compared to other neighborhoods with more affluent inhabitants, even lower in some cases (Sampson and Groves, 1989; Bursik and Grasmick, 1993; Sampson et al, 1997).

Probably one of the most important elements affecting neighborhood decline and crime levels could be the strength of social ties within the community as outlined by the social disorganization theory and its supporters (Shaw and McKay, 1942, 1969; Bursik, 1988; Sampson & Groves 1989; Bellair, 1997; Sampson et al, 1997; Sampson and

Raudenbash, 2004). According to this theory, social disorganization takes place when social relations within a neighborhood weaken significantly; this leads in most cases to a failure of the informal social control process that would otherwise inhibit crime and disorder within the neighborhood community (Skogan, 1986; Sampson & Groves 1989). In other words, when social ties weaken within a neighborhood, residents no longer can act collectively to control what goes-on in the streets and public areas. The most crucial point here is the failure to supervise or discipline groups of young teenagers engaged in disorderly conduct within the public realm, or even identifying and challenging suspicious strangers within the area. Once this social control aspect is weakened or no longer exists, the area becomes even more welcoming for criminal behavior. Problems such as public intoxication and drug dealing usually become more evident making the area even more attractive for other offenders. This process usually forces residents to withdraw from communal life, and increases the levels of fear while further accelerating the neighborhood decline process. Physical signs of neighborhood decline such as graffiti and abandoned structures contribute greatly to this process also, as will be discussed later in this review (Shaw & McKay, 1942, 1969) Skogan, 1986; Sampson and Raudenbash, 2004).

As for the causes of the social disorganization process, Shay and McKay (1942, 1969) identified socio-economic deprivation coinciding with a concentration of immigrants (community heterogeneity), and residential mobility as the main ingredients for social disorganization. This notion has been supported by the literature over the years despite its fair share of critics, and it still seems to be gaining importance today (Kornhauser, 1978; Skogan, 1986; Bursik, 1988; Sampson & Groves 1989; Bellair, 1997; Sampson et al, 1997; Sampson and Raudebash, 2004; Martinez et al, 2008). Looking at these components closely, socio-economically deprived areas in western societies usually have a high concentration of lower income residents, especially immigrants, migrant workers, and minorities, in addition to female-headed families. Such residents lack money and resources, and are usually socially and economically isolated, therefore cannot easily come together for collective action within their neighborhoods (Sampson et. al 1997). They are also hard to mobilize and lack the ability to secure public goods and services from outside city agencies such as the police department or the city (Bursik and Grasmick, 1993).

On the other hand, it is very common to find a high number of new migrants, in socio-economically deprived or declining neighborhoods. The rental prices are usually cheap compared to other areas, and there is usually little documentation required to rent, with minimal intervention from the authorities. This heterogeneity of the community could

impede the residents' capacity to realize mutual values; it also makes communication between the different residents harder due to language and cultural differences. Furthermore, racial and ethnic tensions between the different neighborhoods groups could exist. This contributes to the weakening of the social-ties, and the increase in crime levels (Shaw and McKay, 1949, 1967; Sampson et. al 1997). It is important to note here that new immigrants in general tend to report crime less to authorities, as they are usually fearful of both the authority and retaliation. Also cultural considerations could make reporting certain crimes -such as rape- shameful, only to increase levels of crime and fear even more (Davis & Erez, 1998)

Finally, residential mobility is the third ingredient in the social disorganization theory. Residents of such disadvantaged neighborhoods usually consider them to be "zones of transition" until they can afford financially to move to a different area. This notion is especially true for migrants, whom usually have very limited economical standings initially. Neighborhood ties are very hard to emerge within such conditions since the residents are mostly un-interested in the neighborhood, and do not consider it home. Also, the continuous changing of residents within the area greatly weakens the chance of any significant ties to emerge, since such ties require a long time to emerge (Shaw & McKay, 1942, 1969; Korhauser, 1978; Sampson & Groves 1989)

Crime and the built environment: place-based crime prevention planning

"One broken window leads to many!" (Wilson and Kelling, 1982, p5)

The built-environment is an important element that could potentially influence crime levels, or fear of crime within city neighborhoods. Although not a cause of crime by itself, it could play an important role in encouraging it, or determining where it takes place, especially when the conditions for social-disorganization are ripe within an area. Over the years, a number of theories emerged that linked the built-environment to crime. Known as place-based crime prevention theories (Schneider and Kitchen, 2002; 2007), they hold a common premise which is the importance of community strength, involvement, and self-policing in the reduction of crime and fear of crime, in additional to the physical features and condition of the built environment.

One of the main theories linking the built environment to crime was Defensible Space theory, as first introduced by Oscar Neman (1973). Influenced by the writings of Jane Jacobs (1961), and Elizabeth Wood (1961), Oscar Newman developed Defensible Space after his studies of a number of public housing projects within the US. He noticed that certain design layouts and features seemed to contribute the higher levels of crime

within the areas of study. Newman suggested that designs which encourage territorial behavior and natural surveillance, while also having clearly defined areas of responsibility and good maintenance, could deter disorderly behavior and crime within the public space, especially since residents of such environments will have better control over them (Newman, 1973). The theory has had its share of critics (Mayhew, 1979; Booth, 1981; Merry, 1981), yet it has gained importance and acceptance over the years, with a number of real life applications especially in the public-housing sector (Cisneros, 1995).

A second major theory in place-based crime prevention is Crime Prevention Through Environmental Design, better known as CPTED. Developed by C. Ray Jeffery in 1977, and later expanded by Timothy Crowe (2000). Although distinct from Defensible Space, it shares similar concepts of natural surveillance, boundary definition and image enhancement, but is not specific to public housing or housing in general. The theory has had wide support and adoption from law enforcement agencies in the US and the UK, while also providing some significant real life results (Schneider and Kitchen, 2002). Originally, CPTED was considered to be more comprehensive than Defensible Space since it expanded beyond the environment-only focus to include issues of public-space management, activity generation, and communication between the different neighborhood parties (Crowe, 2000; Schneider and Kitchen 2002; 2007). Today, the CPTED theory and practice have been moving away even more from the limited built-environment only focus, to include themes such as sustainable design, urban meeting places, community and youth participation, and human scale neighborhoods. This expansion of the theory has been known as 2nd Generation CPTED (Cleveland & Saville, 2003, Schneider and Kitchen, 2007)

A third theory, and probably one of the most famous theories relating to crime and the built environment is the "Broken Windows Theory", by Wilson and Kelling (1982). According to its authors, the first signs of decay within the neighborhood environment, will soon lead to disorderly conduct and crime if remained unchecked and uncorrected. An unattended, crumbling built-environment or a building with broken windows will soon indicate that no one cares about the area; the same applies to the unchecked panhandlers on the street, or disorderly youth – all could be considered broken windows. Once these problems are not corrected, they could signal to potential offenders that the risks of being stopped, or held accountable within the area are low; in other words, no one cares within the neighborhood. This could increase crime and fear of crime rapidly within the area (1982).

The theories discussed here briefly are some of the most famous place-based crime prevention theories within the US context. A number of other theories/guidelines of equal importance have emerged in the US and Europe over the years. Examples of these are Situational Crime Prevention by Clarke (1997), Routine Activity Theory by Cohen and Felson (1979), and 'Secured by Design' program in the UK, in addition to others (Schneider and Kitchen, 2002; 2007). Despite their differences, they share some of the basic premises of the three theories discussed here, mainly that a poorly designed and poorly maintained built-environment could encourage delinquency and criminal behavior, increasing by that crime, fear of crime, disorder, and neighborhood decline.

Land-use and crime

When examining residential neighborhoods, the literature indicates that certain non-residential land-uses, could contribute to the neighborhood decline and higher levels of crime in some cases (Taylor and Gottfredson, 1986; Taylor et al, 1995; McCord, 1997). The impact level of such land-uses varies depending on the types and distribution of these land-uses. It also depends heavily on the context, neighborhood layout and design, socio-economic conditions, and existing crime levels. (Sampson & Raudenbush, 2004; Wilcox et al 2004).

The non-residential land-uses could contribute to the decline in a number of ways: First, and relating to informal social control networks, non-residential land-uses breakup or weaken these networks since they represent a break in the residential fabric. Generally speaking, a resident of the neighborhood will keep an eye on the area continuously vs. a business owner who only observes the vicinity of his business during business hours. Secondly, these businesses attract large numbers of strangers to the neighborhood, which usually undermines residents' abilities to identify who-is-who, especially identifying those with criminal or suspicious behavior (Brantigham & Brantigham, 1993; Taylor et al, 1995).

The type of land-uses complicates this issue even further; for example bars and shops selling alcoholic beverages contribute to the disorder within area as a result of alcohol consumption by their clientele, as could Motels. Vacant lots, parking garages, and abandoned buildings could become hangout spots for youths and a base for disorderly behavior; they also affect the area's image negatively. High Schools also are generators of groups of youths and have similar impacts. Finally, discount stores, pawn shops, and convenience stores are traditionally places for suspicious transactions, therefore could attract even more criminal activities (Brantigham & Brantigham, 1993; Wilcox et al., 2004).

Meanwhile, planning decisions, especially those relating to positioning transportation networks add to neighborhood problems in some cases. Crime rates are usually elevated near major streets and highways, or with grid-style roadway networks within residential neighborhoods. These transportation routes increase neighborhood permeability, and allow easy access and escape routes for strangers and offenders therefore contributing to disorder, and making it easier for crime to occur (Brantigham & Brantigham, 1993; Newman, 1996; Schneider & Kitchen, 2007). Furthermore, transportation hubs such as bus stations, metro, and train stations could increase the levels of crime and fear of crime within an area. These points represent what is known as crime 'hot spots', as they attract large numbers of offenders. For example metro stops potentially weaken residents' ability to recognize strangers and control their environment, due to the high traffic they create. They also attract criminal activity due to this high traffic which translates into more disorderly conduct and opportunities for crime. Examples of this would be an increase in pan-handling, public intoxication, drug dealing, pocket-picking, and violent crimes in the vicinity of transportation hubs (Sideres, 1999; Mcord et al, 2007).

Crime rates and law enforcement in Abu Dhabi

Detailed crime statistics are not available to the public in the UAE. Instead official crime rates figures are only released through official government statistics which do provide for a brief description of crime categories. Internationally, the UAE is consistently ranked in the lower percentile of countries throughout the different crime categories. For example, when comparing the UAE (Population 8.5million) to Sweden (Population 9 million) the robbery rate per 100,000 was (11.9) for the UAE vs. (94.4) for Sweden. This trend continues throughout most crime categories (European Institute for Crime Prevention, 2010)

In Abu Dhabi emirate, latest government statistics indicate that there were around 63,005 reported crimes, out of these 59, 673 were considered misdemeanors, and 1,791 were considered felonies. When looking at the city of Abu Dhabi only, the city was responsible for 63% of all reported crimes, which totals to around 39,693 reported incidents (SCAD, 2011). No break-down of crimes by type is available, but in general serious crimes (both violent and nonviolent) such as murder and robberies remain very rare and far apart.

Community characteristics with implications for crime

The community composition in Abu Dhabi is a complex one due to the large influx of expatriate workers seeking employment. Out of the total 1.2 million residents of the city

and its suburbs, only 20% are nationals - a figure which translates into roughly 200,000 UAE nationals and around 1 million expatriates (SCAD, 2011). Furthermore, the majority of expatriates in the UAE originate from South-Asian countries, including India (1.75 millions), Pakistan (1.25 millions), and Bangladesh (500,000). The remainders of the expatriate population are mostly of Arab, European, and North American origins (Gulf News, 2009).

In addition to this very diverse community, the income levels are also very different depending on profession and nationality in some cases. The UAE in general (and Abu Dhabi in particular) has one of the highest average per capita GDPs in the world (88,000$ as of 2009) (SCAD, 2009). The income levels for the nationals are significantly higher than the average national GDP due to major business activity and investments, in addition to government assistance and job placement programs. On the other hand, the majority of the expatriate workforce consists of blue collar workers - either skilled or unskilled- with most of the unskilled working in construction industries. These 'unskilled' workers receive very low monthly salaries in comparison to the national GDP, and mostly originate from the countries mentioned earlier. The professional expatriates though do receive competitive salaries which are on par with the country's nationals in some cases.

The substantial cultural differences between the country's nationals and this colossal group of foreign workers create significant tensions in the city's communities – weakening by that the sense of community. The presence of large numbers of mostly male, bachelor workers living next door to Emirati and other expatriate households has proven to be a point of discontent for the (Gulf News, 2012). In a country with traditionally conservative Muslim and Bedouin-derived traditions, gender sensitivities are expected to be adhered to within the public realm and issues like the harassment of women (even if minor and even if perceived) are not taken lightly. This tension has forced the authorities to intervene, and adopt extreme measures such as moving the workers out of the city and into worker only housing projects in the suburbs. Workers for the most part are treated with mistrust in the city, and are accused of being responsible for robberies, violent crimes, noise, littering, begging and even diseases in some cases, although as evident from the crime rates, such perceived threats are hugely exaggerated. One more important point to be added here is that most work contracts in the country are renewed on a three year basis –if not shorter, and there are no paths towards citizenship and permanent stay in the country. This is further complicated by housing market and rental value fluctuations. These conditions create a very mobile society, and make it very hard for strong communal ties to emerge. These elements

collectively create a classic scenario of social disorganization as described by Shaw and Mckay.

Built-environment conditions with implications for crime

Abu Dhabi is an island city, surrounded by water from three directions and has a very limited usable land-mass. Historically, city planning was not a top priority for the local officials, and zoning codes were very relaxed – only to start changing recently (UPC, 2007). As the population exploded during the last decade, the city became very congested. Buildings began expanding vertically especially with the limited available land. As a result, two main housing typologies appear to be the norm: residential towers which include a retail component on the ground floor, in addition to office space in some of the towers. Residential villas are the second main housing typology in the city. Villas are usually inhabited by the local population due to the higher cost and high rental values. In some cases, these villas are also converted in office space providing for no separation between residential, commercial, or retail land uses. This mix of land uses threatens the residential character of the different neighborhoods, weakens the sense of community, and makes it harder for communal ties to emerge. Residential neighborhoods are filled with shops, workshops, car repair facilities, and offices –even some government offices are located in some converted residential villas (Figure 1). Despite the convenience of these arrangements, this makes it extremely hard to recognize who is a resident vs. a passer-by or in the area for business reasons. This could lead to an increase of crime rates, especially as the population continues to increase, and if economic conditions take a turn to the worse.

Figure 1: Mixed land uses create a chaotic environment in the city. Source (author)

The transportation networks within the city are another challenging factor: the city as a whole is completely dependent on the automobile due to higher income levels, cheap gasoline, weather severity, and the absence of meaningful public transport networks. The street networks follow a grid system even within residential areas. Parking is a huge problem within the city due to the abundance of cars, and no requirements for parking garages in the residential towers until recently. This resulted in streets that are packed with cars parked on both sides and on the sidewalks or in the middle of the streets in some cases (Figure 2). These elements only add to the sense of chaos in residential neighborhoods, and lead to declining neighborhood images and signs of 'disorder'.

Figure 2: Car parking in the residential areas. The residential towers have no parking arrangements. Source (author)

The design of residential villas is also an issue with implications for crime. Firstly, adjacent residential plots are divided by a narrow right-of-way strip of land as dictated by the municipality requirements. This right of way requirement designed for utilities resembles an alley, and soon becomes an area of neglect and an access point for people filtering through the neighborhood (Figure3). In some cases, some residential villas use at a storage area which affects neighborhood images even more. Secondly, due to privacy and cultural constraints, residential villas are surrounded usually by high walls to maintain privacy. These walls act as a double edged sword since they block residents from observing their neighborhoods as encouraged by the concept of ‘eyes on the street’.

Causes for reduced crime rates and is crime prevention planning needed?

Despite all the problematic aspects mentioned above, crime rates appear to be very low as discussed at the beginning of the paper. This is rather contradictory considering that the social and environmental conditions appear to be conducive of criminal activity. Crime occurrences remain rather rare, and fear of crime is not an issue often mentioned (further research will explore this in the future papers). The reasons for this could be multiple: Firstly, unemployment levels within the emirate of Abu Dhabi are relatively low, especially within the expatriate population (around 6% as of 2008) (SCAD 2011). This could be mainly the result of a solid economy and immigration policies where residency in the country is tied directly to employment. Secondly, most those living in Abu Dhabi and the UAE in general are residents of the country for economic reasons. Any criminal activity could lead to job loss and deportation (Ministry of Labor, 2001). Most of expatriates, even those on the lower end of the economic spectrum will most likely not risk losing their jobs since a good majority of expatriates support family and

investments in their home countries through remittances. Thirdly, Abu Dhabi has a modern, well equipped police force, with a strict law enforcement regime. Otherwise minor issues such as public intoxication could lead to jail time (The National, 2010). Finally, as a majority Muslim society with a strict religious outlook, certain cultural constraints such as the ban on alcohol consumption (for Muslims) and the ban on public drunkenness for could have an impact on crime. Dress code regulations, conduct in public places, and strict punishment are all elements that could help keep crime rates at bay.

Considering these previous points, crime prevention planning might not be an immediate necessity, but as the population grows and social norms change, and if the population of Abu Dhabi doubles by 2030 as expected, applying these principles in new developments could prevent future problems within the city. More importantly of some concepts in existing neighborhoods could help reduce signs of disorder which are rampant especially within the older residential areas.

Conclusions: limitations on current place-based crime prevention in Abu Dhabi

In order for place-based crime prevention planning to work as outlined by its principles and theories, the built-environment factors within the residential areas should be conducive to the strengthening of community ties. In the current conditions within Abu Dhabi, and if the principles were introduced into the existing built environment, they might have a very minimal impact – if any, and for a number of reasons. First of all, a separation of land uses within the residential neighborhoods is crucial. Though most modern urban planning theories encourage smart growth and the mix of land uses (Congress of New Urbanism, 2001), the current status in Abu Dhabi is rather odd as it has too many retail and commercial facilities within residential area (too many eyes on the street!). Secondly, overall improvements in the built environment should be introduced - these include parking solutions and open space improvements otherwise the signs of disorder will remain rampant. Finally, the traditional building practices and some current zoning and building practices should be revised. Residential plots should be adjacent and the neglected right-of-way parcels between residential villas should not be the norm. Also, regulations pertaining to the exterior of residential villas, especially the heights of outside walls and fences should be introduced.

As the built-environment issues are addressed, two main obstacles remain. First, the transient nature of the society and its large number of workers are serious impediments to community development. These will remain mostly unchanged unless serious changes to employment conditions and immigration policies take-place. This change is a highly

unlikely to happen within the near future. Secondly, crime prevention planning principles rely heavily on the activeness of the residents of an area, their sense of vigilance, and their willingness to come together with others living nearby. This might be the hardest element to materialize due to gender-related cultural constraints, language barriers due to the heterogeneity of society, extreme weather conditions which limit the usage of communal space and an added layer of maids, butlers, and drivers whom act as a buffer between different neighborhood residents. These cultural aspects are unlikely to change any time soon, and remain one of the biggest obstacles to successful implementations of crime prevention planning principles.

Nevertheless, planning for the road forward, and considering these principles in current and future developments within the city is the way to go. The principles are simple to apply, and have benefits beyond crime prevention. They are logical, and do improve the quality of residential areas. Most importantly, they help combat disorder in the built-environment, which is the biggest issue Abu Dhabi is currently facing.

Centralization and Peripherization by Urban Renaissance Policies in the Polycentric Kansai Region, Japan

Jan Polivka, Uta Hohn, Satomi Kiuchi, Frank Roost

TU Dortmund University, Ruhr University Bochum

Introduction

The structural dynamics of the Japanese urban and metropolitan development, similarly to many other highly developed countries in a post-industrial structural change of the national economies, is currently strongly influenced by a spatial and functional resetting, led by the urban renaissance (UR) strategies. In many cases, the UR analysis concentrates on the physical city core developments, without taking in account the larger metropolitan and governmental context. This paper is examining the emergence of new spatio functional disparities arising on behalf of centralisation and peripherisation within Kansai metropolitan area, occasioned by the implementation of Japanese national UR policy on the polycentric metropolitan Region of the cities of Ôsaka, Kyôto and Kôbe. The focus is initially directed on how the national government led UR policy influences the regional and local level. We further ask whether the UR policy on different governance levels of the polycentric structured Kansai-Region leads into new forms of regional and local peripherization and centralization of urban functions.

General conditions of the UR in current Japan

The UR policy is usually seen as a local, but state supported conceptual reaction on the effects of post- industrial structural shifts on central urban areas, where low dynamics of the urban economy at the beginning of the post-industrial era within highly developed economies, accompanied by changes in the traditional employment patterns based on the long-term-stability of industrial production and related services, and the peripherization of residential functions lead to a stronger social and economical disparity effects within central urban areas (cf. Allin et al. 2004; cf. OECD 2003). Parallel to this, a strong international competition among cities in the context of globalization creates a pressure on positioning on a global scale (BMVBS

2011). As redistributional means of capital are reduced due to economical stagnation, shifts in the urban and metropolitan governance arise, aiming towards a selective distributional pattern of large projects in order to create positive "hot spots" effects within the central city areas instead of aiming on an spatially even welfare redistribution and spatio-neutral urban development policy, using measures of deregulation and location-specific investment. It is defined as a property-led regeneration and often seen as "privatization of urban policy". (DiGaetano/Strom 2003). On the other hand, regional players often tend to ballance uneven development or ist negative effects by securing services for the public etc. However, usually central government plays a direct role in decisions regarding public and private stakeholders and enterprise zones participating in the UR process (cf. Hall / Tewdwr-Jones 2011; cf. Imrie / Thomas 1999).

In the Japanese case, the UR term is used widely as a tool of the state urban development policy, including the national housing policy estates, safety measures in catastrophe protection and many others. However differing the implementation is, the Japanese Urban renaissance law of 2002 defines two kinds of UR "policy": the machizukuri-type, aiming on a close cooperation with citizens in order to improve local quality of urban communities' life in cities of all sizes and locations, and the toshi-keikaku type, aiming on international competitiveness of large cities by fundamental urban restructuring in a close coalition with the private sector. In terms of investment volumes, centrality of location and the spatial as well as functional effects, the pro-growth toshi-keikaku type prevails, using, among others, special urban use zoning bonus and rules in order to steer private investments into centrally designated areas of a strong growth potential by offering closed-shop negotiations about FAR bonus between investors, the city authorities and the national government (cf. MLIT 2012).

Roots of the UR policy in Japan

As urban policy in Japan is traditionally closely connected to the economic policy, the role of the Japanese state in the planning always remains strong (Hohn 2000, Feldhoff 2002). During the post-war period, the policy of so called „Japanese developmental state" (JDS) followed by the Liberal Democratic Party (LDP), which was leading Japan nearly continuously between 1955 and 2009, was marked by a stable political-bureaucratic elite, strong enough to deter interest groups from undermining economic growth, a planning agency that guided relations between public and private sectors, substantial investment in mass education, equitable income distribution, economic intervention through market incentives and strong concerns with a

national security in the world order (cf. Johnson 1987 Fujita/Hill 2003, Fujita 2011). To a certain level, this policy was preventing from the peripherization of weak, mostly rural areas and the concentration of development and capital in the strong, mostly metropolitan areas, especially Tôkyô (cf. Seta 2002 & Sorensen 2011). On the other hand, the JDS was based on a strong japanese "iron triangle" (Feldhoff 2002) consisting of selected members of the parliament, high subgovernmental and private companies management officers, who coordinated the national and regional development by steering distributive state investment incentives. (Tsukamoto 2012). Such system also continuously strengthened the agglomerations and industrial areas especially within the Japanese urbanization belt between Kantô (Tôkyô) and the North-Kyûshû, including also the metropolitan Areas of Aichi (Nagoya) and Kansai. On the other hand, it depended on redistribution to prevent peripherization and therefore to ensure stable and enduring political preferences in the rural areas which, within the Japanese voting system, were privileged in vote counts against the city population.

Even before the introduction of the UR policy, the Japanese planning policies and laws showed a long deregulation tradition led by the developmental state, especially when it came to urban redevelopment. In 1961, the Special Block System[1] enabled to redevelop city blocks into large super-block projects, reacting on the most development difficulty caused by scattered use and ownership, mainly contributing to the reshaping of central areas of cities by larger mono- and polyfunctional modern structures. Three years later, a first Incentive System was introduced, aiming on the claim for open space and infrastructure by providing bonus FAR in exchange for building setbacks. The bonus system was the initial direct step towards an incentive planning deregulation policy in Japan, which until today remained one of the most fundamental steering tools of the Japanese urban planning system. Together with the Urban renewal Law of 1969[2], which regulated the replacement of previous structures by new using measures of ownership transfer, it allowed to reshape the urban area's city structure by concentration of urban functions such as residence, commerce and services into large multifunctional buildings especially in the central urban areas. A Comprehensive design system[3] added the negotiate agreement on FAR bonus (Hohn 2000).

Neoliberal Turn of the developmental state and Rise of the 2nd phase of the UR Policy

The effective state spatial development policy system of the developmental state was affected by a number of economical influences since the 1970's such as post-industrial structural changes and the oil crisis, which led into a slowing down of the GDP growth on one hand and to the rise of the state debts due to continuing intensive redistribution policy on the other. This period marks the beginning of a gradual reorientation of the Japanese policy towards neoliberal economic measures (Tsukamoto 2012/2012a). The initial concept of the neoliberal policy shift in Japan was inspired by Raeganism and Thatcherism, introducing a neoliberal position of a weak and small state, allowing the market to act freely with only the less possible interventions. Such neoliberal thoughts as "travelling concepts" became increasingly influential among high-developed economies since the 1970's due to the late phase of industrialization and global competition, which put pressure on the national protective state policies. The very beginning of institutional infiltration of neoliberalism into the developmental state in Japan can be seen as the growing influence of the non-governmental level with the JAPIC (Japan Project Industry Council) in 1979, directly connected to the liberalization efforts backed up by shared beliefs of industrial stakeholders and the high policy individuals under prime minister Nakasone (1982-1987). It can also be recognized as one of the fundaments of the bubble growth in the 1980's in Japan (cf. Sorensen 2012) and the first period of UR in Japan. Nakasone implemented an aggressive policy of planning deregulation and private sector mobilization in order to get the economy growth raised and the public debt of the still distributive developmental state lowered. The state a.o. sold publicly owned land in central areas in order to encourage private developers to invest. In 1988, the Urban renewal district plan was implemented in order to ease and force the redevelopment of such brownfields. The shift of the national plan strategies towards a „conception of cooperative network" in 1987 marks the shift in roles of the central government, the private sector and the public during the first phase of the UR policy. However, this phase of development effectively came to the end as the bubble economy collapsed in 1990 and many projects ended up in debts (Seta 2002).

Rescaling of the developmental state by devolution of the governmental decision power and responsibility towards local level

A further infiltration of neoliberal thoughts into the JDS organizational structures was led by the political turn towards neoliberal beliefs, which begun to reform the Japanese governance system by normative guidelines. To achieve the goals of fiscal discipline, the Japanese governance[4] system was set to undergo a graduate shift from an egalitarian distribution pattern towards a strategic spatial and selective concentration of state support, and therefore to a large extend also of private investments into specific areas and fields. The rescaling (Brenner 2004) of the Japanese state was a gradual process, as there were strong resistances along the financial distribution on the subgovernmental level. Attempts to slim the government were already made by Prime Minister Nakasone in the 1980's, when he "applied ‚small government' to control the LDP-bureaucracy subgovernments, mainly responsible for the clientelistic redistributive policy, in order to restore government efficiency. However, the subgovernments prevailed and continued clientelistic practices through the 1990's, which grew until 1995. Since the early 2000s, Prime Minister Koizumi (2001-2006) made frontal attacks on the subgovernments for a breakthrough" (Tsukamoto, 2012a), among others by cutting off financial sources by privatizing large national companies. A significant step in the urban policy was the devolution of state finances towards municipalities, a rescaling policy which replaced the central redistributional system, and the deregulation of urban land use in order to evoke local entrepreneurship. In the meantime, the emphasis was laid onto local self-sufficiency, based on public-private and non-profit sector, in order to strengthen the decentral welfare functions (cf. Tsukamoto 2012). Since 2003, Koizumi initiated laws which directly aimed on strengthening the self efficiency of local governments by significantly reducing tax payments to the national state by even stronger reduction of transfers from the state towards local governments. This led to lower incomes on the local level, which, in Koizumi's plan, was to be substituted by higher local taxes and better efficiency of the local government under the neoliberal premise of a „slim state". As smaller and mainly rural municipalities faced extreme financial difficulties, a five year municipality merge program was introduced in 2004 (Kitayama & Ryu 2005). In the sum, weakening of the national subgovernmental structures and devolution of responsibility towards local government institutions can be seen as the main structural effect of the „Japanese neoliberal turn", restructuring the JDS.

The second generation of the UR policy implemented since 2002 is fully conform to such measures. The local level of city administrations became

[4] The governance terminus in this paper is used in the definition by Gualini (2001) as stated in Salet (2004, 9).

main actors and partners of the national government by decisions in negotiating and implementing of urban development projects for the price of a self-standing responsibility and competition. Aiming mostly on stopping the fall of land prices by stimulating growth in the construction sector, it first partly re-emerged in 1997 when new rules for construction of high rise buildings in city areas were promoted. But by that time, still struggling with the consequences of the bubble economy blast, the policy of activating the private sector, as a system origining in the 1980's, showed no significant effects (Izumi 2011). Also, the financial crisis did not allow to steer the growth policy by sufficient public financial supports any more. In this situation, the national government took initiatives to concentrate public investment into selected metropolitan regions based on the paradigm shift from a balanced land development policy towards a policy in favour of potent key areas within large cities, and to steer more by deregulating thang pubic finance incentives. The decisive step towards an institutionalized UR policy was taken by Prime Minister Koizumi, based on an emergency economic plan. Deregulations in urban planning in GB, US and Germany and the designation of special economic zones in Ireland or China were taken into account when designing the UR policy (ibid.). Under conditions of fundamental differences between Japan and Asian states in levels of development on one hand and growth dynamics on the other, it was not possible to reach competitive advantages simply by raising national competitiveness of production. The challenge for Japan was not the national productivity and effectivity issue as such, but mainly the international and global competitiveness in the role of a high developed state, which it was loosing especially within East Asia as new young competitive economies raised. Under such conditions it was necessarily targeted on strengthening the forerunner role in highly specialized innovative fields, concentrated in specific areas of both innovation and space, where the potential to succeed is strong and the state directed incentives clearly addressed. In 2002, Koizumi enacted the UR Special Law, initially limited to 10 years, which focused on incentives by negotiable deregulations instead of public investments, including five main points:

1) Private investment in urban development was steered by the central government's UR Headquarter, founded 2001 and headed by the Prime Minister himself, towards 63 centrally designated Priority UR Development Zones in strategic locations of the leading Japanese cities and metropolitan regions. The concept strengthened the steering position of the central government against the gradual decentralization policy heralded already by the Urban Planning law of 1968 as well as the "watering-can principle" of redistribution by replacement with national policy which conformed and

targeted development steering towards the creation of internationally high competitive clusters of knowledge, culture, exchange and new industry.

2) Incorporation of previously informal procedures into the formal process of the negotiation and widening the palette of negotiating partners by incorporating the city governments into the process. This concept virtually legalized negotiations between the private and public sector within the process by giving them clear rules within the process, by the same time remaining "closed-shopped" and without a broader public participation. Negotiating became one of the fundamental tools in implementation of UR projects.

3) Within the Priority UR Development Zones, cities and private Developers were enabled to agree with the central government on the designation of particular projects or UR Special Districts, in which Exemptions of the planning laws, including especially the very significant extent of the FAR bonus (in Ôsaka up to 160 %), could be implemented on behalf of flexible negotiations between the city and the private sector. This further strengthened the city governments and the private sector in the UR process

4) By simplifying the urban designation rules, the final maximal reachable FAR bonus was set in advance of the negotiations in order to provide the private investors with planning reliability during the planning phase. Additionally, the administrative procedure was speeded up by a 6 months deadline for an urban planning decision in order to minimize planning risks, costs and negative effects of falling land prices for the private developers.

5) The abolition of the 1959 Location Control Law for Industry and Universities within the built up areas of the large metropolis of Tôkyô, Ôsaka and Nagoya in 2002 after more than 40 years opened the possibility for a re-centralization of know-how oriented institutions and new industries within the central urban areas.

These measures mainly aimed on fostering the international competitiveness of big cities by strengthening metropolitan gateway functions, building up international clusters of knowledge intensive and advanced industries, creating knowledge capes based on cooperation of private companies, universities and research institutes and improving the living quality of cities by reducing deficits of open and green spaces, providing high quality inner city housing and all kinds of urban amenities in multifunctional projects (Takahashi 2011, Izumi 2011, Kubo 2011). It was a policy of creating global hotspots which would be able to play a crucial role in bearing Japan's

competence by keeping the global pace in selected fields and areas of the hi-end industry and economy, functioning as an acupuncture revival strategy by "strenghtening the strenghts". Due to high public debts, the role of the public sector shifted at the same time from a direct steering by an active participation in investments towards indirect steering by zoning, linkage policies, bonus systems, tax incentives and financial guarantees in connection with deregulations. The financing and implementation of UR projects was put in the hands of the private sector. It can be summarized that the UR policy in Japan remained to be „government-controlled" and „corporate-made" or „government-steered" and „corporate-implemented". At the same time, the power of local governments was further raised by the UR law, being strongly included into the interest triangle of state and private stakeholders. This shows a fundamental difference to the previous centralistic managed deregulation policies and therefore the first phase of the first UR of the 1980's, and shifts the attention to the UR policy effects further towards the local and regional level.

As the driving decisional force remained on the national level, this policy did not affect the governmental power of the JDS as such, nor did it make subgovernmental structures disappear; it rather dissolved the subgovernmental political connections related to the redistributional functions by new selective local government partnerships, which were run under the self responsibility of the local governments and at the risk of the private sector (Okada/Yoneda 2011) without significant financial interests of the central government, especially when compared to the first UR phase, strongly based on the 3rd sector and PPP models. It led to a decentralization of the national subgovernmental redistribution power and responsibility for balanced development towards a decentral system of local responsibility, which was no more protected by redistributional financial measures of the central government, but dependent on local success within an international competition. The government steering and developer participation potential remained, but a new strong local governance base emerged, with an impact on the distribution of power between the former two and the strenghtening regional prefectural as wenn as municipal level.

Urban renaissance under peripherization and centralization – the central Kansai region case

During the first UR phase, led by the bubble economy of the 1980ies, the development of the central Kansai metropolitan region (Kinnai) was marked by decentralization of urban functions, mainly residence and additional

centrality functions such as office, entertainment and shopping, into the existing regional centres or new planned regional edge cities, flanked by enduring residential suburbanization. Accordingly, UR projects were dispersed in many areas of the metropolitan regions, respecting the still remaining structural and functional centrality hierarchy of the existing polycentric structure (cf. Todokoro 2000) on one hand and enlarging it by adding new locations such as of postindustrial waterfront and brownfield re- and development projects.

The focus of the second phase UR however brought a significant spatial and functional diversification within the metropolitan areas. First, together with strengthening the local governments since 2000, the communal law change of 2003 led towards a stronger competition in competence between the local and prefectural (regional) governments, as the prefectures had to give up a part of competences in common communal functions (Kitayama & Ryu 2005). Second, as cities in Japan savour a specific degree of independency from the national and prefectural government related to the number of inhabitants[5], larger cities directly join the urban renaissance decisive triangle together with the investors and the national government. Only cities under 500.000 inhabitants are subordinated to the regional prefectural government. As will be shown under, the most important projects of the urban renaissance are situated in central metropolitan areas of large(st) independent cities. This makes it generally difficult for smaller cities and the prefectural governments to take a significant part in the metropolitan renaissance policy. Such situation is well visible in the polycentric Kansai metropolitan region, where 21 UR priority zones with a total of 1710 ha have been designated by the national government in three out of the six calls undertaken between 2002 and 2012 by the national government. Out of these, totally 1.341 ha lay in 9 zones within the three largest cities of Ôsaka (796 ha), Kyôto (225 ha) and Kôbe (320ha).

To understand not only the spatial, but also the functional distribution of the urban renaissance designated zones for the state steered investment politics, Hall's definition of a global city region (2001) based on networked archipelagos of global development helps to understand the globalizing centralization and peripherization of the polycentric Kansai city region in order to monitor, typologize and hierarchize the project sites. Hall comes up with definitions for geographic structures of globally acting polycentric metropolitan regions, formed in order to compete and be connected globally:

[5] Seirei toshi; Designated City System (政令指定都市制度)

In the first urban renaissance call in 2002, four central locations in Ôsaka City with a total area of 490 ha were designated, including the very central Ôsaka Umeda station vicinity as (*defined by Hall*) the main *business center* of the city, including a 27 ha of enlargement brownfield area of a previous cargo rail yard. The area also included Nakanoshima island and the Midosuji Boulevard, both the most central and traditional *downtown center*. Four further locations in the Ôsaka Prefecture (total 188 ha) were designated, however, none of these bearing any global functions according to Hall's definition. The prefectural projects are located in the centres of regional cities of the metropolitan areas, bearing some regionally important functions, such as of transport node and new university location and apartment projects. The development of these sites were often planned long before, many of them, such as Sakai Station project, Sakai Bay project or Senri New Town centre project, as self standing edge cities in the context of the Kansai metropolitan region. The growth decrease after 1990 partly resulted into a centrality descaling of planned peripheral regional centres, which were also weakened due to the centralization strategies of the core cities due to the implementation of the UR strategy. This reaction, steered by the rising power of local governments of large independent cities under the centralization strategy of the Urban Renaissance law, enabled many central areas to functionally overtake their regional centres. As example, the Rinkû Town Airport City, situated next to the region's international Kansai Airport and planned as a new edge city during the 1990's, was on behalf of its strategic location and the role as a regional subcentre being considered to become Urban renaissance priority development zone, but then finally dropped according to its low potential for investment and far distance from the metropolitan core (Izumi 2011, Kubo 2011). Currently the role of Rinku Town degrades to a „background service area of the airport" (Kubo 2011). The core of the Sakai Bay man made island industrial brownfield area, situated on the south border to Ôsaka on the way to the Airport and planned as a new regional edge city centre with a new town for more than 5000 inhabitants during the 1980ies and 1990ies, was designated Urban renaissance priority development zone (90 ha), but finally only developed as a regional suburban shopping and entertainment area neighbouring a new Sharp company hi-tech production site, which probably could be seen as in by Soja (1995/ 2000) – mainly because only production and not innovation oriented – as a geography of metropolitan restructuring of a technopolis, but not as an edge city. Also together with Sakai Ôtori Urban renaissance priority development zone, designated in the first UR call just after the plan to locate the Kansai Universal Studios regional entertainment area there was changed in favour of Ôsaka City (Toshikouzoukaikakukenkyukai 2003).

2003), it shows a strong centralization process towards Ôsaka city: the Kansai Universal Studios were finally opened in the Bay of Ôsaka City in 2001, and Sakai Ôtori area was turned into a residental project, similar to many other large urban renaissance designation zones outside the Ôsaka city

UR Call	**LA (Local Authority)**	**UR stakeholder status of LA**	**Zone/Project Area**	**ha**	**1st room global (Hall)**	**2nd room regional**
1st 2001	Ôsaka City	Ôsaka City	Umeda, Umeda North, Nakanoshima, Midosuji	490	***Downtown Downtown*** *Business centre*	
1st	Ôsaka City	Ôsaka City	Namba, Abeno	57	*Specialized subcentre*	
1st	Ôsaka City	Ôsaka City	Cosmosquare Bay	154	***Internal edge city***	
1st	Moriguchi City Sakai City	Ôsaka Prefecture	Moriguchi Dainichi Sakai Ôtori	80 25		Housing and shopping
1st	Sakai City	Ôsaka Prefecture	Sakai Station	70		Regional centre housing, shopping
1st	Sakai City	Ôsaka Prefecture	Sakai Bay	95		Shopping and entertainment
1st	Neyagawa City	Ôsaka Prefecture	Neyagawa Station East	11		Regional centre university venue
2nd	Kôbe City	Kôbe City	Sannomiya Station			Regional busines centre
2nd	Kôbe City	Kôbe City	Port Island		*External edge city*	
2nd	Amagasaki centre	Hyogo Prefecture	Amagasaki Station North			Regional centre housing, shopping
2nd	Amagasaki Bay	Hyogo prefecture	Amagasaki Bay			Brownfield revaluation
2nd	Kyôto city	Kyôto City	Aburanokoji		*Internal Edge City*	
2nd	Kyôto City	Kyôto City	Kyôto Station South			Regional centre hotel and shopping
2nd	Kuze city	Kyôto Prefecture	Brownfield redevelopment area			Shopping and entertainment
2nd	Nagaokakyo City	Kyôto Prefecture	Nagaokakyo Station	8		Suburban development
4th	Takatsuki City	Ôsaka Prefecture	Takatsuki Station North			Regional centre

Table 1: The table shows that the designation of the urban renaissance priority development zones was mostly determined by following measures: local path dependency of the project, and - in case of the 1st room projects - a national strategy of global competition. There is no evidence of a regional balance policy and, with just very few exceptions, any redistribution welfare philosophy.

borders, such as the Moriguchi Dainichi brownfield redevelopment area (80 ha). As Rinku Airport Town did not prove enough vital force, the Abeno and Namba areas, one of Ôsaka subcentres located in the southern part of Ôsaka's downtown on the main train terminals to the airport, both designated UR zones in the first call, could strenghten their role of the city and region *specialized subcentres*, functioning as an airport entrance gate into the city and region instead of Rinku Airport town, and accommodating, among others, hi-end hotels, shopping and entertainment projects. On the other hand, within Ôsaka City municipal borders, the Cosmosquare Bay development area was designated an Urban renaissance priority development zone, strongly pushed by the Ôsaka metropolitan government and the Ôsaka Port and Harbour Bureau, even though it beared only low potential to become an *edge city (Hall)* due to its peripheral location and high land prices.

In the second call, only four projects in two zones in Kyôto City (225 ha) and two zones in Kôbe City (320 ha), the two second largest cities in the Kansai metropolitan region were designated, which marks the functional subordinace position of these two poles against Ôsaka City (796 ha and five projects) within the polycentric metropolitan region. According to Hall's definition, only one of the project zones of the second call takes the position of an archipelago within the region, which is the Kôbe Port Island project, functioning as an *external edge city*, a man made island re- and development by hit-tech and medicine cluster specialization, closely connected between the Kôbe Airport and the city centre. Just there it was able to effectively develop a global region archipelago outside Ôsaka city borders. An innovation hub became also the urban renaissance restructuring project Amagasaki Bay, located in the industrial by zone between Ôsaka and Kôbe, accommodating, among others, hi-tech productions of Panasonic, but similarly to the Sakai Bay, it is only limited on production without research and development functions (Kubo 2011, Yasuba 2011).
All other designations, including Kyôto city, and especially those of the third and last designation wave, including important further regional centres (Takatsuki, Senri Chuo and others, total 98 ha) within the imaginary triangle of Kansai regional metropolitan core area between Ôsaka, Kyôto and Kôbe centres, did not reach global but only a regional relevance, mainly as

additional suburban downtown housing clusters. Table 1 summarizes the classification of the Kansai Urban renaissance zones in two main groups: the specializing global regional city archipelagos ("First room UR zones") according to Hall, and the regional archipelagos ("Second room UR zones"), which do not fit into the international target of the urban renaissance policy. There are effectively no fully-fledged global locations outside the Ôsaka city existing except of the Kôbe Port island, which is functioning as an external edge city (cf. Izumi 2011).

The "first room UR zones" areas are located in areas with a high distinctive development competence within the national and international competition, and therefore mostly in Ôsaka City as the largest cities of the polycentric Kansai metropolitan region. Raeganism Further, they are located in Ôsaka's city core areas selectively chosen as those with the best development potentials. During the first phase of the UR, under the basic conditions of the bubble economy, the location of large project was coherent to the premise of expansion, with a concept of subcentres within the metropolitan area. Within the cities, the waterfront redevelopment as a reaction on the structural change of the industrialized bay played a crucial role for both Ôsaka (Cosmosquare Bay project) and Kôbe (New Waterfront). After the bubble era since 1990, in the period of economic deprivation, Ôsaka city government adjusted its polycentric development plan towards a more centralistic system of one main central urban development axis of downtown and business area by skipping 5 out of 11 specialized centres between 1991 (OMG 1991) and 2002 (OMG

2012), and started, as many other cities did, to promote inner city living, mainly on behalf the new construstion norms allowing high rise appartment buildings. With the exception of the Cosmosquare Waterfront area, Ôsaka City readjusted for only five most central areas during the first UR priority development zones call, skipping centres in peripheral locations. The city was about to centralize possibly most of development potentials into the centre in order to concentrate power to rebuild it under special urban renaissance conditions (Takahashi 2011). This induced massive investment of the private development sector in the city centre. However, as the economy power of Ôsaka is not growing, new developments started to compete with other existing locations, so critics see a threath of a real estate bubble (Koura 2011, Tôkyû 2011). Ôsaka started to welcome new redevelopment housing project in the city centre also in order to fill the evolving real estate market gaps (Takahashi 2011). Since 2005, after some decades of population decrease, Ôsaka's inner city population begun to grow (cf. Ôsaka 2011). These investments can be seen as a reurbanization and centralization shift within the city and the region, as the main functions of the

metropolitan area are concentrated into the Ôsaka City borders, and within Ôsaka City, into the central „hotspots“ of the downtown, the traditional business centre and selected specialized subcentres. On the other hand, the peripherization of the outer zones occurs. The policy of centralization still continues: in the first call after the 2002 Urban Renaissance law validity extension from 2012 to 2017, a new *internal edge city* was included among the Urban Renaissance Zones at the beginning of 2012: the Ôsaka Business Park, a business cluster development from 1980's and 1990's first urban renaissnace phase, located just next to the historical site of Ôsaka Castle.

As mentioned above, UR zones located outside large cities within the prefectures did mostly not aspire on a function of a global regional archipelago network of a national or international relevance during the second urban renaissance phase. Within the globalizing structure of Kansai metropolitan area, the „universal edge city“ concept related to the polycentric concept of the first half of the 1980's, where polyfunctional nodes were hierarchically sorted by their size and marked by a mutual interdependency and nourished by the suburban growth, was redeemed due to centralization into selected and specializing geographic structures which globally act within the polycentric metropolitan region (Hall 2001) by a new hierarchy. This hierarchy is based on relation to selected global nodes instead to the hierarchy of the polycentric network. This shift resulted into a peripheral role for the metropolitan region centralities: On one hand, they were not able to reach global hot-spot status, as it was reserved for the few most potential central areas within the premium centralities. On the other, the development shows a specialization on secondary functions such as housing and local supply functions, instead of functional diversification, which can be found within *downtown centre* and *business centre* urban renaissance projects in Ôsaka (cf. Hasegawa 2011, Kubo 2011, Yasuba 2011). Only two of 11 regional UR project zones actually became a place of innovative functions such where university or research venues have been realized. As many "second room" projects show a strong path dependency covering a large scope of individual characteristics, their participation in urban renaissance was most likely used as a „free rider effect“ and remained therefore strongly embedded in the local context than to reach national or international effects (Hasegawa 2011, Konishi 2011, Yasuba 2011). Their implementation stands for a path dependency of „regional spots“, based on the traditional regional hierarchy. Partly, the urban renaissance area status was an incentive compensation for projects already planned under the first UR phase of the 1980ies, still led by a comprehensive polycentric network strategy, which did not come out due to the decreasing growth power of the region since the 1990's (cf. Kubo 2011). This relation also explains how the centralization of

the global regional functions into a few strong areas, mostly located in the Ôsaka City centre, led into a graduate peripherization of the regional centralities since the the 1990's. A significant example of the peripherization and "free-rider effect" shows the refurbishment of the Senri Chuo New Town city centre located within the northern part of Ôsaka city urbanized area in the administration area of Ôsaka Prefectural government, which during the 1980's and 1990's was planned to become one of the regional edge cities, inhabiting also office building and research clusters. Since the 1990's, as back offices of many companies were abandoned due to rationalization and economy measures, it became loosing its role as an administration location. The development of new office space capacities in Ôsaka city centre further accelerated the diminishing of the office function from peripheral areas of the polycentric metropolitan area (Toyonaka 2011). The prefectural government as the owner of still vacant building lots in the central area made the local city authority to join the fourth Urban Renaissance priority development zones call in order to rise the own profit by selling the prefectural ground. The city joined the call, but finally did not make use of the possible high UR related FAR bonus in the planning permission, arguing that the local community and functional mixture would be affected by the potential mass of high-rise housing projects (Hasegawa 2011, Kubo 2011).

From the regional point of view, the shift towards a new regional geography of centralization an peripherization from 1960ies until the first two UR phases can be reinterpreted by Todokoro's explanation of regional nodal structure development phases in the Kansai Region (2000). It marks the development of metropolitan network structures from the city hierarchy towards a city network in four phases, where the fourth phase (1985-2000), covering the late first UR phase, is characterized by strong and equal interactions between all levels of centralities. By the centralization policy of the third phase based on the Urban Renaissance Law since 2002, there is a shift in the region's nodes hierarchy. If further developed on behalff of Todokoro's thesis, the new selective connections between the networked archipelagos of global development according to Hall (2001) and Soja (1995, 2001) became to overlay the existing spatio-hierarchic connections after 2000 (ibid.). This structure not only copes with the urban renaissance zone hierarchy, it also shows the strengthening role of global arenas within the polycentric geographic structure of Kinnai, located mostly in the central areas of the largest cities, mainly Ôsaka as the main economic hub, and some selected specialized centralities within the Kinnai central regional area. Most of the areas of the previous hierarchy based on traditional measures of size and distance are after 2000 experiencing peripherization if related to the

previous traditional regional functional distribution patterns of the Todokoro's large-middle-small city hierarchy.

Regional concepts of a new governance structure

The centralization and peripherization within the Kansai region have been influential to the regional governance policy. Regional organizations in the larger Kansai area (Kinki) were since 1965 when they started to issue Basic Development Plans for the Kinki Region, introducing own planning concepts tied up in accord to the periodically issued five national Development plans between 1962 and 1998. They were defining and providing detailed standards for the Suburban Development Areas, the Urban Development Areas and the Conservation Areas in order to reach a balanced development of the whole region (MLIT 2012, 2012a). Though focal points have been changing during the decades according to actual situation in economy, demography and land use trends, the issue of regional disparities and especially the widening gap between Ôsaka/Kyôto/Kôbe city cores and other areas on one hand and an equipoise to the trend of the relative weakining position of Kinki in a unipolar concentration of the national economy and central functions on the national and international main activity arena of the Tôkyô metropolitan area. Since 1978, proposals on improvement of vital force and catch up with internationalization and informatization on the other can be traced in Kansai. The influential "Subaru Plan", issued 1987 as an alternative plan against concentration in the Tôkyô metropolitan area, envisioned the "creation of an international economic cultural zone" within *the whole* area, proposing a multipolar distributed polycentric structure, conform with the expansion planning of the first UR phase during the bubble economy era of the 1980ies. For its realisation, three strategic project families were designated: 1. international exchange urban zone with the Kansai International Airport as a core, 2. Pioneering economy zone for cooperation with Asia and the Pacific areas, 3. Creative cultural zone of Kansai Cultural and Academic Research City (Keihanna gakkentoshi). The core projects of Kansai decentrally located projects of International Airport and Kansai Cultural and Academic Research City were opened in 1994. The heritage of the Subaru plan lies underneath the designation of the core area of Techno Port Ôsaka, founded in 1987, the Cosmosquare, as an UR priority development zone. The plan also directly pointed out the decline of industries in large cities in the south and north extremities of the Kinki region, which was already hit by the peripherization phenomena (City of Ôsaka 2000/2012).

The comprehensive regional planning for the Kinki region, targeted on developing the area as one polycentric global city, was evidently not directly conform with the spatially selective second UR phase policy of 2002. On the regional level, this policy opened a gap along the centralizing and globalizing Ôsaka City area and the spatially widely defined and peripherizing Kansai region. This gap became visible on the level of institutional governance mainly by the growing endeavour to establish an Ôsaka metropolitan prefecture during the first decade of the 21st century, as well as the foundation of the Union of Kansai Governments in 2010. For the former, Ôsaka City and the Ôsaka Prefectural Administrations proposed a plan for a larger than City government structure, which would more likely include the whole area of Ôsaka prefecture and so create a centralized metropolitan area, which until now was applied exclusively for Tôkyô. The idea of Ôsaka as a metropolitan government entity reaches back to the beginnings of Japanese modern state in the 19th century, guiding the city's enduring endeavour to replace the national monopolar centrality of Tôkyô by a bipolar system of Tôkyô and Ôsaka. After WWII, the graduate system of city independency on the national prefectural government relating to the number of inhabitants was established and conflicts decreased for some time. However, since the Ôsaka metropolitan area grew together on both city and prefecture territory during the 1960's and 1970's, challenges of overlapping administration came up again. Since then, Ôsaka city was proposing a merge into a metropolitan prefecture. The reason why this issue became highly actual again during the last decade, was nothing less but the stronger decentralization endeavour of the 1990ies and of the Koizumi national government since 2001, which started a significant devolution of planning competences to the regional and municipal levels. By changes in the City Planning Law in 2000, the decision-making powers of the designated cities were strenghtened especially in fields of urban redevelopment and infrastructure or zoning. A majority of urban decision-making powers shifted from prefecture to the Ôsaka city. Together with the UR policy it provided significant moves within the regional governance structure and enabled Ôsaka city to draw functional centralization on regional level as a strategy against its peripherization on the national and global level, also in order to accumulate growth power and to stop the economic outflux, which made it permanently weaker against Tôkyô's unbroken prosperity and global connectivity.

On the other hand, the Union of Kansai Governments became an official regional government in 2010 (by now the biggest regional administrative unit in Japan) by the National local government law, functioning as a special regional administrative unit. Its Kansai development strategy issued in the

same year replaced the official regional development plan. It was the first approach for an extended association bringing different prefectures together in Japan. Its foundation was strongly supported by the Kansai Economic Federation, representing the heads of the most important private companies in the Kansai region, also strongly lobbying for the implementation of a new federal system in Japan. This alliance shows a respectable political strength not only because of the long industrial tradition of the Kansai region, but also on behalf of the relatively weak regional political voice of Kansai, typical for polycentric regions if compared to the metropolitan policy of the monocentric Tôkyô capital region. In the process of current national decentralization, the Union overtook competences devoluted from the national level. On the regional level, it acts towards a decentralization strategy through a thematically focussed administrative cooperation within the region in order to prevent peripherization (The Union of Kansai Governments 2011 & 2012, MLIT 2012).

A third phase of urban renaissance

Paralelly, a third period of urban renaissance policy has started by the revision of the urban renaissance law in 2011 and its extension till 2017. The 11 so called "*Specified* UR Priority Development Zones" were designated, covering an area of 3,396 ha in 7 cities. Highly visible is the reconcentration of urban renaissance policy towards Tôkyô, where 75% of the designated specified area is located. In contrast to that, in the whole Kansai region only two zones were designated, situated in Ôsaka city and including the previous UR Priority Development Zones in Ôsaka Umeda (*downtown centre*) and the Ôsaka Port Town Cosmosquare area (*internal edge city*). By that means, the centralization of Ôsaka becomes even more evident. Those zones shall be successfully positioned in the competition with Asian cities like Shanghai, Hongkong, Singapore or Seoul. Beyond that, the revision of the UR law has led to an even more speeding up the urban planning decision process and to a continuation of the development path of deregulation (MLIT 2012).

However, besides the updated UR policy, a new economic promotion policy based on the new growth strategy of 2010 and linked to the designation of seven so called „comprehensive special (economic) zones"[6] in 2011 becomes important: In 2009, the Japan democratic party, ruling Japan since the post-growth period, was released by the Democratic party of Japan, which established a New Growth Strategy in the following year. Among 21 national

[6] Sôgô tokku (総合特区)

projects, it includes a “Comprehensive special zone system”, which even closely connected the existing urban renaissance sites with the national strategic economic promotion policy, based on a “selection and concentration of resources on areas with potential international or local competitiveness”. The system is not based on FAR bonus and exact geographical hot-spot determination, it rather works on tax reliefs and comprehensive fiscal and financial support for innovation clusters (PM 2012 & 2012a).

This current developments can be characterized as a Third phase of the UR in Japan, which shifts from physical to a more thematic-oriented regional intermodal connectivity among a selected mixture and interaction between strategic functional and physical urban renaissance zones and projects; next to the Hall’s global city region polycentric geographic structures, based on networked archipelagos of global development hot-spots, a non physical, thematically highly specialized network areas emerge, connecting the fragmented archipelagos of the existing UR priority development zones of all three UR generations with knowledge hubs such as the Kansai Cultural and Academic Research City. Doing so, it may contribute to a further diversification of the Kinnai regional landscape, creating centralizing node hubs of global prosperity and peripherizing areas situated not only on outskirts, but also in between and in a direct proximity of future prime centrality nodes.

Conclusions

The paper shows a change between the three phases of the UR in the Kansai region in connection to the relevant changes in national politics as well as the development and regional planning policies by marking implications on the strategies to steer distribution of urban development investment on the example of the polycentric Kansai area. Regarding centralisation and decentralisation, three phenomenons can be stated:

1. The UR Policy in Kansai is instrumentalized in order to profit from decentralization on the national level and to prevent peripherization of Kansai on the national and international level on both spatio functional and governance level.
2. There is an evidency of changes within the regional polycentric hierarchy of the region’s centrality, including the (re-)centralisation of Ôsaka City and Prefecture on behalf of large UR projects, in order to gain international competitive power in East Asia, a national competitive power against Tôkyô, and a regional competitive advantage against other centres of the polycentric area.

3. On the regional level, further peripherization is being prevented by regional cooperation within the large polycentric structure on the Kansai regional level.

During the first UR phase, an equal polycentric understanding of the region based on a redistributional policy of the JDS national government, regional development plans an the necessity to redistribute investive tensions by decentralization of urban functions, mainly centrality and housing. This led on one hand to a continuous urbanized area expansion, an equal strenghtening of existing regional centres and establishing new subcentres in transforming areas, such as waterfront, airport hubs or new science, research and development parks. Areas of functional peripherization were mainly recognized in larger peripheric locations.
During the second UR phase, the national redistributive policy slowly turned towards the policy of "strenghtening the strenghts", aiming on less support for redistributive spatila and economic equality and more on national and international competition in qualified, selective, high specialized fields by designation of UR priority development zones. In the Kansai regional area, the competitive situation between centralities and region led into a concentration of crucial economic functions in selected super-central urban or technology "hot-spots", which took over the polycentric hierarchy system of the industrial era, and became a multipolar system with specialized centralities.

In a third phase of the UR since 2002, a further centrality layer is being added, based on even stronger centralization by an updated UR national policy, further focussing on the main central areas, especially in Ôsaka city as the largest metropolis of the region. In order to institutionalize its centralization efforts, Osaka City and Prefecture endeavours to to merge into a larger and even stronger entity ("unique we are strong"). Similar tendencies, in order to protect from peripherization, can be recognized by other large, regional and smaller cities due to growing competiotion atmosphere. Regional stakeholders however react on preipherization by institutionalizing decentralization efforts through the establishment of new regional governance entitiy ("together we are strong") in order to strenghten the regional horizontaly interdependence and so to meet profits from further decentralizatrion efforts by the national government.

Since 2012, the new national government program marks a further spatio fuctional focus, based on the creation of thematically specialized economy condition zones or clusters. Geographically, they include broadly designated areas less spatially focussed than the UR policy, as the functional thematic

cluster connections are in focus. According to this, the hierarchy of the centralities and peripheries may may even more differentiate in the future by creating more thematically and less spatially defined centrality networks.

WORKER RESIDENTIAL VILLAGES: THE IMPACT OF CULTURAL DIVERSITY

Abdelatif Qamheieh[1] and Saif alZahir[2]

Abstract

During the last two decades and due to its huge oil reserves and industry, United Arab Emirates has been renovated to an international hub for business and tourism. Such dynamics created a colossal influx of foreign workers to meet the huge demand for skilled and unskilled workers in the various economic sectors.

The State statistics show that the ratio of expatriates to UAE national is 80% to 20% respectively. This huge foreign workforce has created an unprecedented change in the UAE society, and challenged its traditional and relatively undisturbed values, even its day-to-day lifestyle in some cases. The large numbers of foreign workers, especially unskilled workers have historically lived in poor, unhealthy, and mostly overcrowded conditions within urban centers. In attempt to improve their living conditions, and to address internal societal challenges, the authorities opted to establish worker-only dedicated villages outside the major urban areas. In this paper, we scrutinize the concept of Worker Residential Villages (WRCs) within the Context of Abu-Dhabi, and investigate the applicability of Defensible Space (DS) theory to such model. Our results show that DS theory failed to provide a successful model to worker residential villages in UAE due to social and economic impairments.

Keywords: Worker Residential Villages, Defensible Space, Multicultural Societies.

1.0 Introduction

The abundance of oil and natural gas in the Arabian Gulf area has caused remarkable growth in infrastructure projects over the last few decades in most Gulf Cooperative Countries (GCC) in general and in the United Arab Emirates (UAE) in particular. More recently, the cities of Dubai and Abu-Dhabi have been the Mecca for construction companies and design firms alike. This has been in response to a construction boom resulting from the country's drive to become a commercial as well as a financial hub in the Middle East.

[2] University of N. British Columbia, BC, Canada, zahirs@unbc.ca

The UAE has a population of approximately 8.9 million residents according to the latest government statistics. Out of this number, only 20% are UAE nationals (Emiratis) whereas the rest are expatriate workforce (UAE Government, 2009). Indian, Pakistani and Bangladeshi represent the largest expatriate communities in the UAE with nearly 1.75 millions from India, 1.25 millions from Pakistan, and 500,000 from Bangladesh. The rest of the foreign workforce originates mostly from European, Arabian, and North-American countries (Gulf News, 2009). This colossal foreign workforce has created an unprecedented change in the UAE demographic structure and its societal values and customs.

Although the expatriate workforce enters the country with legal and mutually agreed upon company or government contracts, and despite the government's attempts to regulate and safe guard the rights of temporary workers, the labor conditions leave much to be desired. The UAE has been criticized repeatedly by the international community for its treatment of the expatriates especially the blue-collar labor force, in particular for the treatment of the temporary workers employed by the construction industry (Human Rights Watch, 2006; 2007; 2009). Unskilled and semi-skilled foreign workers are usually subject to harsh working conditions, and infringements on some of their basic rights, mainly by their employers — the construction companies (Keane D. & McGeehan N. 2008). Some of these workers have their passports withheld by their employers to guarantee that they don't attempt to change jobs or leave the country without notice. Also, some of them experience extended periods of employment without pay and without any consequences for the employer (2008); others suffer from long work hours even in the extreme desert heat where the average summer temperature during July and august could range between 42-52 degrees Celsius (115-130 Fahrenheit).

One area that has received major criticism is the living and accommodation conditions of these workers (Gulf News, 2009). Historically, worker accommodations in Abu Dhabi have taken one of two distinct forms: first, employer sponsored on-site accommodations, especially for construction workers using temporary / prefabricated structures; secondly, private market accommodations arranged by the workers themselves, or by their employers in some cases. In the later scenario, the workers live within existing buildings or villas in the city or its suburbs. Both of these approaches have had their merits and demerits, but in both cases, the living conditions are usually extremely poor. Space shortages, overcrowding, and unsanitary living arrangements are very commonplace.

The problems associated with temporary-worker accommodations are neither new nor exclusive to the UAE or the GCC countries. A significant number of industrial nations have had their share of experiences dealing with such conditions. Examples from South Africa (Hartwig and Marais, 2005), Singapore (Phang, 1999), china (Ngai, 2007), and the US (Goodno, 2003) are testaments to the complexity of such situations. Most temporary-worker housing arrangements are plagued by poor accommodation

arrangements for the workers and abuses by employers and the authorities in some cases. Still, the heart of the matter is not necessarily housing availability, but the low wages and minimal rights such temporary workers receive. These problems are even more prevalent in the cases of unaccompanied (bachelor) workers whom are usually the least paid, and are the ones who are most likely to be treated with suspicion by nearby communities.

In an attempt to improve the living conditions for the foreign workers within the city of Abu Dhabi, and to curb employer abuses, the authorities set-out to establish new worker-only residential cities, with a goal of making this arrangement the sole form of worker accommodation. In this paper, we focus on these Worker Residential Cities, with a special focus on the cities within the metropolitan area of Abu Dhabi as an example.

The remainder of this paper is organized as follows: in section 2 we will present various international responses to worker housing projects in different parts of the world including some industrial countries. In section 3, background information about worker conditions and housing policies within Abu Dhabi will be provided. Section 4 will include discussion and analysis of the worker cities phenomenon in Abu Dhabi, and finally in section 5 we provide our conclusions.

2.0 International Responses to Worker Housing

Worker villages or cities are not a new phenomenon. The 20th century has seen numerous examples of worker encampments in different names such as worker camps and factory dormitories. In the US for example, housing of the seasonal farm workers has been a significant challenge for the authorities. Mostly workers are bachelor's migrants, and in some cases illegal immigrants, the living conditions of these workers have been extremely poor (Housing Assistance Council, 2001). These workers usually do not have stable incomes, and move from one area to another depending on the agricultural season. Locating accommodation is usually a great challenge, and most of them live in extremely poor conditions, with 10 – 15 individuals often sharing a room. Farm-owners sometimes provide them with on-farm housing in the form of barracks or mobile homes. In other cases, the workers have to fend for themselves, living in private residences, parks or in the open (2001).

The state of Florida has some of the largest seasonal farm-worker force with a population of around 200,000 each year. These workers work only during certain periods of the year depending on crop harvest cycles, and are mostly from South American origins. Due to their limited income they do not only struggle to find accommodation, but they have limited access to basic services such as health care and education (Flocks et al., 2002). The biggest expense they have to pay is money for accommodation, and the majority of them pay significant portions of their income to live

in low-quality, even run down housing, while usually sharing such accommodations with other - unrelated individuals. Although some of them receive on-farm accommodations from their employers as we mentioned earlier, but those who do not receive such arrangements are usually the ones who live the worst conditions (2002).

In an attempt to improve the conditions of workers, the US Department of Agriculture (USDA) through its Rural Housing Service (RHS) program has attempted to regulate the situation in order to protect the rights of such a crucial workforce. A number of federal programs target the issue of farm worker housing specifically, and the general direction of these programs revolves around two main concepts: grants for developers to build low cost-good quality for workers, and direct rental assistance subsidies for some of the workers. In some cases, the USDA also has developed some farm-workers only residential communities or villages. A good example of such development would be the Everglades village in Florida. Although most of these initiatives target workers with families, and they provide housing for single workers who represent the bulk of the population, they are still extremely complex, and workers remain living in sub-par conditions (Goodno, 2003). Despite the success of some of these programs, they continue hampered by insufficient funding to match the high demand, NIMBY issues originating from the communities where worker housing is needed, and resistance from some developers and landlords who risk losing some of their clients as a result of these government assistance programs.

South Africa has its share of farm-worker housing issues as well. Similar to the US, the large number of seasonal farm workers struggle to find decent accommodations for themselves and their families. The country is home to around 60,000 commercial farms, which in turn create work opportunities for around 900,000 farm workers (as of 2005). Historically, most of these workers receive little, if any, labor protection, and were subject to discrimination and unfavorable work and living conditions. More recently, legislation to protect labor rights has been introduced in the country. These new regulations focus mostly on wage and working hours, but not necessarily on accommodation, despite the fact that nearly 80% of these workers live on the farms according to employer arrangements. In some areas of the country, farmer - initiated off - farm housing projects have taken place. These projects are usually heavily subsidized by the local authorities, and provide very basic shelter units and amenities. Such examples are showing signs of success within the South-African context especially since they provide the workers with certain ownership rights. Yet, the cost issues keep amenities at absolute minimum, and the workers are relatively isolated from the surrounding areas and worksites, and have to rely a great deal on the availability of public transportation (Hartwig and Marais, 2005).

In China, the boom in the export-industry has created a tremendous need for labor force especially in the south of the country. In the 1970s, the Chinese government created a number of Special Economic Zones (SEZ) that acted as commercial or industrial

incubators for foreign companies. These special zones depended on manual laborers who were mostly migrant - female workers from the countryside and continue to be so. These migrant laborers live and work in these economic zones, and are given accommodations within these areas in a system known as the labor dormitory system. In this system, employers provide their workers with buildings or dorms in close proximity to the factories with an aim of increasing production and efficiency, while controlling the mostly rural migrant workforce. The workers are prohibited from living in urban centers, and are confined to these dormitories. Most of the dormitories are within walking distance from factories, which limits the need for transportation and thus effectively reducing cost for the employers. The dormitories also act as a pool for employers, and help them in securing fast, readily available workers to keep-up with the manufacturing process' rapid demands (Ngai, 2007).

3.0 The Labor Force in the UAE

Like all other countries, UAE labor force comprise of two types: (i) the professional white-collar workforce who earn decent income and on par with the national GDP; and (ii) the unskilled or semi-skilled labor workforce who earn very low income in comparison. In UAE, an unskilled construction worker could earn anywhere between AED 400 – 650 a month, whereas a worker with more experience could earn between AED 750 – 1,500 a month. These numbers are very low in comparison to the national GDP, yet due to the poor economic conditions and differences in the standard of living in the workers' own countries, the influx of workers continues, and most of the money they make finds its way to the countries of origin of these workers in the form of remittances (Gulf News, 2009).

Majority of the workers in the UAE are young single males. Married workers are forced to leave families behind due to the high cost of living in the UAE. Due to their limited income, workers usually seek shared accommodation in some of the older apartments and villas within the cities. It is not uncommon to find between 10 – 15 people sharing one room due to the very high rent prices in Abu-Dhabi. In some cases, employers do provide accommodation for the workers. Sometimes a flat could be provided and shared by a number of people. In other cases, the mezzanine level of a shop could be transformed into an accommodation of some sorts. Some large construction companies usually construct workers' accommodation on site using barracks or temporary structures, but the living conditions in such arrangements are extremely harsh, and such arrangements were mostly unregulated until fairly recently (Abu Dhabi Municipality, 2010).

The situation with workers' accommodations has created a number of problems for the city of Abu Dhabi. First, the presence of large numbers of mostly male, bachelor workers living next door has proven to be a point of discontent for the local population.

Traditionally conservative Muslims and with mostly Bedouin-derived cultural traditions, gender sensitivities are expected to be adhered to within the public realm and issues like the harassment of women (even if minor) are not taken lightly. Generally speaking, workers are treated with mistrust, and are accused of being responsible for robberies, violent crimes, traffic congestion, noise, littering, and even diseases in some cases — similar to some of their counterparts in other countries. Despite the fact the workers rarely cross any of the society's red lines due to fear of harsh punishments and employment termination, and despite the relatively low crime rates within the country (UNODC, 2008), the local families (or Emiratis) and some expat communities – have made their voices heard, and demanded that the authorities find a solution for what they viewed as a serious problem and threat to their communities.

Secondly, most employers are required to provide housing accommodations for their employees. Due to negligence and abuses by some, the living provisions are usually in very bad shape, if not dangerous in some cases. Overcrowded, dark, and unhealthy living arrangements are very common; workers are even forced to live in the business itself in some situations, with nothing more than a mattress provided (Abu Dhabi Municipality, 2010). These abuses harm the workers and complicate their lives, and have forced the authorities to crackdown on employers who do not provide adequate accommodations for their employees. Finally, the large concentration of workers in some buildings and areas has led to neglect by landlords, and caused the image and physical conditions of these buildings and areas to decline rapidly.

3.1 The non-existence of low-income class in Abu-Dhabi

Abu Dhabi is a growing city with nearly one million people. This population is projected to grow to three millions by 2030. The city has a severe shortage in rental apartments due to limited supply of new buildings to match the demand. What exacerbates the situation even further is that Abu Dhabi is located on an island, and is bounded by the see from three directions making horizontal expansion very limited. Due to the global economic downturn in last few years and the crash of the housing market in Dubai in 2009, the demand for housing in Abu Dhabi has increased drastically especially due to businesses and individuals relocation to the city from neighboring Dubai. Unfortunately, this increase in demand was accompanied by a slowdown in construction due to investor and financial institution fears. The new environment made Abu-Dhabi rental market a very expensive one - peaking in 2009. As of Q1 2011, the average annual rent for a single bedroom apartment in the city ranges anywhere between 30,000 AED to 120,000 AED ($8,000 – to – $32,000) depending on location and quality (Astecoreports.com, 2011). On the other hand, Abu Dhabi has the highest average per capita GDP in the world - estimated at around 325,000 AED per capita ($88,000) as of 2009 until present. These numbers could be a bit deceiving though as the wealth distribution is skewed in favor of the country nationals, which represent a minority at nearly %20 of the total

population in the Emirate as mentioned earlier. It could also be fair to say, that within the city's and emirate's nationals, a low-income population does not exist. In comparison, the average per capita GDP for some unskilled labors is around 13,500 AED, which translates into roughly 1,200 AED per month (Statistics Center – Abu Dhabi, 2009). Against these odds, the accommodation options for workers are extremely limited and most of them end-up sharing rooms in older run-down villas and flats and in very unsanitary conditions sometimes.

3.2 Abu Dhabi Middle Income and Housing Policies

Historically, and until this moment, most government housing policies focus on housing for the local population only (Abu Dhabi Government, 2011). These policies are also geared towards homeownership with no assistance for the rental market. The Emirati nationals receive land grants from the government, and are provided with generous and long-term interest free loans to build homes. Some are also granted a readily built house(s) assuming they meet certain age, income, and marital status criteria. On the other hand, expats are not allowed to own property within the emirate and are forced to rent properties from local landlords. More recently, some special development zones have been created where expats are allowed to own residential units, but with certain restrictions and for certain durations (2011).

In the year 2007, the government established Abu-Dhabi's Urban Planning Council (UPC) with a mandate to regulate and monitor the growth within the city of Abu Dhabi and the entire emirate. The UPC developed Abu-Dhabi's 2030 master plan and projected a population of 3,000,000 in the city by 2030 (UPC, 2007). The 2030 plan is a rather ambitious one and proposes significant growth to the capital in the coming years. One of the most recent regulations introduced by UPC as part of the plan has been the "Middle Income Rental Housing Policy" (UPC, 2010). This policy requires large-scale developers to dedicate 20% of the proposed total Gross Floor Area (GFA) in the form of middle-income housing. From the perspective of the middle-income residents of Abu-Dhabi, the policy could be a step in the right direction, and it is the first time that rental subsidies are provided in the state of Abu-Dhabi.

Unfortunately, the UPC and the 2030 plan are only requiring rental subsidies for middle-income households, but no provisions for low-income housing are included or even proposed. The irony of the situation is that UPC's policy appears to be derived from some of the American lower-income housing rental assistance programs, namely from the Low Income Housing Tax Credits (LIHTC) system (Orlebeke, 2000). In such systems, the developer provides a certain percentage of subsidized rental housing units and receives tax credits or other forms of easements in response. The LIHTC system aims at reducing expenses for the government, and at dispersing lower-income households throughout the society, as opposed to concentrating them and isolating them

in one location. It seems rather counter-intuitive for the UPC to exclude the lower-income segments of society from this new policy (2000).

On the other hand, most of the unskilled workers' income level is extremely low, and will not qualify them for any of these subsidies as they exist right now. In fact, within the context of the UAE, it could be fair to say that the unskilled/semi-skilled workers are exclusively the low-income segment of the society. Even in the unlikely case of qualifying for such assistance programs, the restrictions imposed on them by their employers, and the resistance from the community for having workers live amidst them could prevent them from benefiting from these programs.

This point raises a further important question about how these workers are viewed by the regulating authorities and policy makers. Similar to all expats in the UAE, most of the workers come to the country on contracts of three years duration, and usually end-up staying for more than one contract period. Some expatriates, especially those originally from neighboring Arabic countries, could live for decades in the UAE. Alternatively, most government policies are catered to the local population only in the first degree – and understandably so. Yet, what makes the situation rather unique and challenging is the sheer number of this foreign workforce, as they represent the vast majority of the population. It appears that this lower income class is viewed by the policy makers as a temporary class, and not as part of the overall housing policy.

3.3 Worker Residential Cities – Al Raha City Example

The mounting internal pressures for a housing solution to the expat workers, international criticism, and due to the absence of any lower-income housing policy, the government of Abu Dhabi set out to build new worker residential cities, WRCs, for the labor workforce. These WRCs are purposefully built residential areas located in the outskirts of Abu Dhabi, complete with housing, amenities and services. The government of Abu Dhabi entrusted Zones Corporation with the task of building and administrating these cities. The Higher Corporation for Specialized Economic Zones (Zones Corporation / Corp) is a government run agency established in 2004 to administer and establish economic investment zones within the emirate, and was later entrusted with the task of establishing these residential cities (Zonescorp, 2011). According to the corporation's publications, the WRCs are supposed to be built to the highest urban design standards, and are supposed to provide the workers with improved accommodations and ample amenities and services. The goal is to prevent overcrowding and sub-par living conditions for workers throughout Abu-Dhabi and reduce employer abuse while also limiting friction between the local and the worker populations (Khaleej Times, 2010).

Up to date, eighteen 18 WRCs have been completed within the city of Abu-Dhabi metropolitan area limits and its surroundings, with a capacity of 300,000 beds, and with a current population of around 149,000 workers. Out of these 18 cities, 3 are intended to be long-term villages, whereas the rest are of a more temporary nature surrounding major construction projects (Al-Etihad Newspaper, 2011). The numbers of cities are to be increased to house 800,000 workers by 2012 (Gulf News, 2008). To ensure quality control, the government authorities make regular inspections of the cities to make sure that the facilities are well managed and controlled. It is also a requirement now in Abu Dhabi for all construction companies to relocate their workers to these cities, with other industries soon to follow.

As part of this research, we were able to visit one of the WRCs named Al-Raha Residential Village (workercities.com, 2011). The city is a newly established worker community in the outskirts of Abu-Dhabi, located in Al-Wathba area approximately 40 kms away from Abu-Dhabi. The city is near completion with a full capacity of 34,000 workers. The current population of Al-Raha is around 22,000 workers and the total area of the city is around 5 km squared. Figure 1 shows the main approach way to the city. It is clear that the city is outside the city and in an isolated area. Company busing is the only available mean of transportation of its inhabitants.

Figure 1: Al-Raha Worker City main approach road

Al-Raha (translation: rest area) consists of a number of residential dormitory style buildings, some are open spaces, and some are common facilities. The common facilities

include a number of dining facilities, a shopping center, a small medical center, a mosque, a main security center and a banking facility among others. In house laundry facilities are also provided for the city's inhabitants. Figure 2 depicts the outside dormitory building of the Al-Raha city.

In our site visit, we found that most of these facilities and equipments are already visible and operational.

Figure 2: Overall view of some dormitory buildings

As part of the contract with the employers, the village management provides the workers with room cleaning services, 3 daily meals, and laundry services for an additional cost. The average cost for each worker is approximately AED 390 per-month per-bed, which is paid by the employers. The price includes coverage of electricity and water fees. The employers could also subscribe to a meal plan ranging between 400 - 450 AED per-month for each worker, although the subscription to this plan is optional. Finally, for an additional 50 AED per-month, laundry services could be provided for the workers, as the villages do have in-house laundry service facilities (Al-Etihad Newspaper, 2011).

In the villages, unskilled workers (the vast majority) have the least space allocation at 3 meter squared per person, and accommodation is usually in the form of one large room with 10 bunk beds as shown in Figure 3. Skilled workers receive a little bit more space at 9 meter squared per person, with 4 sharing a room. Finally, supervisors receive the most space at 12 meter squared per person, with 2 sharing a room and with a private small bathroom. Each floor in these residential dormitories has 12 rooms for unskilled

workers, 6 for skilled workers and 2 rooms for supervisors. With the exception of supervisors, all floor residents share a common bathroom facility.

4.0 Discussion and analysis

The Al Raha residential city and other similar worker cities in Abu-Dhabi represent a rather dramatic approach to solving a multifaceted and complicated problem. The design, facilities and amenities themselves are to be commended, and the cities could be considered an upgrade when compared to some of the run-down accommodations for workers within the city. The cities do provide the workforce with low cost accommodations, and help improve their living conditions. They also provide the workers with much-needed amenities and services, which are usually lacking in their current living arrangements. WRCs achieve another extremely important goal which is regulating the housing arrangements for such labor forces, since without this drive to regulate by the government, workers are under the mercy of their employers, and historically wide-spread abuses have been documented and represented in the poor living arrangements they are forced to cope with. By creating these cities, employers are forced to either allocate space for their employees in these cities, or provide accommodations which are at least of equal quality.

Looking at the extremely inflated rent prices in Abu Dhabi and the region in general, such cities make even more sense as workers cannot afford decent accommodation

arrangements based on their low wages and limited economic means. WRCs also limit the friction between workers and the local population, and address the cultural concerns of this population as indicated earlier. It is worth noting here that the general drive to improve labor work and accommodation conditions has been commended by international observers, even by the Human Rights Watch themselves (7days.ae, 2009).

On the other hand, and despite the positives of the WRCs approach and some improvements in the living conditions, a number of issues are important to consider. First, these cities isolate the workers from the surrounding communities. The access to the cities is controlled, and the workers are not free to leave at any time. They are expected to leave the cities only to work, and through employer arranged transportation. This is an issue with potentially serious ramifications for the workers as it does greatly limit their freedom. It also prevents them from mingling with the local communities, and socially isolates them from their surrounding and even other workers in other villages.

Secondly, the villages are located in the outskirts of the city, and mostly in desert areas with a harsher than usual climate. Aside from the climate, the geographic distances they have to travel every day to reach their employment sites takes a significant time out of their days, and only adds to their everyday harsh work conditions. It is also worth noting here that most buses that transport workers to and from construction sites are of poor quality, and appear to be lacking air-conditioning which is extremely important in such climate.

Thirdly, these villages are for males-bachelor workers only, and provide no arrangements for workers with families or even female workers. Zonescorp indicated their intention to establish family-oriented worker villages (Gulf News, 2008), yet none of these have materialized until this moment. Although most of the work force are male and bachelors accommodation arrangement for workers with families should be considered, and the dynamics of a family oriented community are much different than those of a male only community. Even more, these male only mandatory living arrangements prevent workers from hosting their families if their economic means allow for such arrangements.

Fourthly, looking at lower-income housing policies worldwide, and especially the American system, the model of isolated and concentrated living arrangements for lower-income segments of the society has proven to be a failure worldwide. It could create tremendous resentment within the worker population, and will most likely lead to complex social ills including crime and violence. Finally, these worker residential cities put the worker communities in an out of sight-out of mind status. It makes their needs and problems less apparent to the society, and only masks the greater problem which is their fragile existence within the UAE. It also makes them easily subject to infringements on their rights by the regulating authorities.

Conclusions

In this paper, we have presented Abu Dhabi's experience with workers residential cities. The residential cities approach is a commendable approach, though not without some areas of concern. It does assure a certain amount of protection for the workforce, and provides them with necessary basic needs which they could be otherwise lacking. Similar approaches have been used in other international examples, including some western democratic states. Probably the most positive aspect of this approach is that it brings the issue of workers' rights into the mainstream debate, and that it emerges from a general drive by the authorities to improve worker conditions in general.

Still, in the case of Abu Dhabi, we found that this approach points to a larger problem within the overall society, which is the attitude towards this workforce. It also highlights the low-income levels of such work force in comparison to the national levels – hence raising valid and just questions about fair compensation. The dynamics that create this situation are definitely unique: The small local population in the UAE, the relaxed immigration policies relating to workers and the dire economic needs of these workers in their home countries creates a huge influx of workers, and will continue to do so for the foreseeable future. This influx has changed the country's society, and has made this subject an extremely complicated and sensitive one. By creating these cities, some of the workers' rights might have been upheld, and the friction with local community might have been reduced to a certain extent. Still, this solution infringes on some of the workers' basic rights such as their freedom to choose where and how they live, their right to move freely, and the right to be active members in the overall society. These cities in the current format only complicate their lives even further despite their provision of basic and much needed services.

We believe that this worker residential cities approach is merely a band aid, and truly avoids the core question which is if this 'majority' population is a population of temporary residents with rights and obligations or is a population of temporary workers only. What is needed is to rethink immigration and labor policies in the country and in a way which better protects the workers' rights and addresses the labor needs within the UAE, while also protecting the country's interest and wellbeing. We also believe that general improvements in worker conditions and income levels are still needed, and recommend better enforcement of labor laws, with harsher punitive measures targeting abusive employers. Also needed are comprehensive and just lower-income housing programs - which are currently lacking in the UAE - and for the worker population to be included in policy formulation, especially considering their large numbers. Such housing programs if adopted could help reduce the need for such WRCs, and could even help address the residential needs of the middle-income expatriate work force and the countries nationals alike.

Problematic Issues of Citizens Participation on Urban Heritage Conservation and Planning to Achieve Sustainable Conservation in the Historic Cities of Iran

S. Koorosh Sarvarzadeh [1], Syed Zainol Abidin IDID [2]

Abstract

The views with regard to citizens' participation in cultural heritage issues have become a worldwide issue as the bottom-up approach. It is penetrated across the field of urban heritage conservation and city planning. This paper aims to examine the problematic issues in citizens' participation in urban heritage conservation (UHC), of historic cities in Iran. The paper begins to highlight global and local concern on citizen's participation (CP) in built-heritage conservation and prepares a concept on the role of CP in decision making and planning, in Iran, and the other countries; then, it examines the experiences of UHC in the face of urban development trends in Iran and provides an understanding for the roles and effects of modernization trends on extensive damages of tangible and intangible heritages. In the next part, it investigates a historical study on CP, management system of urban planning, and approaches of urban planning system regarding to UHC in Iran. In fact, it provides a concept to appreciate conservation and planning process in Iran during contemporary period. This study found that development and conservation approaches have always been in serious challenge practically; the role of citizens' participation has been faintly in the making decision and planning process, rapid urban sprawl has had many impacts on valuable textures of historic cities in Iran, Therefore, integrated practices and interactive approaches between development and conservation together with public participation are successful approaches to meet sustainable conservation in the historic cities of Iran.

Keywords:
Citizens Participation- Urban Heritage Conservation- Urban development- Sustainable Conservation- historic cities of Iran,

1. Introduction:

This paper implies that the old and historic areas of cities are a significant part of historic cities, and it should be conserved for future generations. The historic urban area of Iran has been identified to be reviewed, because the world's oldest,

[1] Universiti Teknologi Malaysia (UTM), Johor Bahru, Malaysia – E-mail:ssarvarzadeh@yahoo.com
[2] Professor, Urban Design and Conservation Research Unit (UDCRU), Faculty of Built Environment, Universiti Teknologi Malaysia, E-mail: ididsza@yahoo.com

continuous, major civilization has been appeared in Iran, and its historical and urban settlements date back to 4000 BC (Zarrinkoob, 2007). Literature in urban heritage conservation and urban planning suggest that historic urban fabrics in the most of historic cities like Iran in developing countries is currently faced with similar issues, which on one hand, they are experiencing a rapid population growth, high development pressure, rising area of historic districts and destruction of cultural heritage, and, on the other hand, they don't pay attention to the importance of citizen's participation as the most significant factor to solve their issues in the decision-making process. (Yung et al, 2011). Moreover, because of the long date of Iran, it can be an appropriate case in between developing countries to investigating the role of the public in the process of urban heritage conservation. By the study, of literature review can be find several evidences that they imply to increasing the role of public in the policy making process(Taylor, 2007). Therefore, an evaluative research on historic urban fabrics would lead to an empirical finding that show the role and position of people and some issues related it in the decision- making and policymaking process in the cultural and historic city of in Iran.

2. Issues and Problem Statement

1.1. Global concern on citizen participation in built-heritage conservation

According to UNESCO's definition, cultural heritage includes monuments, groups of buildings, and sites, which have historical values, in the other ways all tangible heritages which include natural and cultural sites and even all intangible heritages which are consisted of living dimensions of heritage and all aspects of the physical and spiritual relationship between human community and their local environment (UNESCO, 1972; Tweed et al, 2007). It is important to know that urban heritage also is an embodiment for values of traditional urban cultures which take place as the memory of mankind (ICOMOS, 1987). Nowadays, a lot of such cultural assets are being threatened, physically degraded, damaged at an alarming rate around the world as a consequence of a little or lack of consideration to their conservation by beneficiary people and practitioners and of course government (Tweed et al, 2007). These significant issues are not more complex nowhere as quickly as in developing countries and regions with limits of financial resources available (Yung et al, 2011). Although researchers and practitioners points are that there are many challenges on the issue of urban heritage conservation such as depopulation of inner city, development pressures, insufficient Legislations and poor enforcement, poor design new township, changing lifestyle and consumption patterns, tourist expectations, public awareness, and, etc, but since the last twenty years, lack of citizen participation has increasingly become a significant challenge throughout the world (Cohen, 1999; ICOMOS, 1999; ICOMOS, 2002; Engelhardt, 2002; Lane, 2005; Imon, 2006; Tweed et al, 2007; Sirisrisak, 2009; Yung et al, 2011). It is of the same opinion that one of the key elements in the successful at the sustainable development process is citizen participation, which has been neglected, or it was slightly considered in the planning process of urban heritage conservation (Tweed et al, 2007; Sirisrisak, 2009; Yung et al, 2011).

1.2. Loss of unique historical and cultural heritage in old cities of Iran

Challenge between urban development and conservation and lack or a little citizen participation in the process of preparation, approval and implementation of urban heritage conservation is controversial issues in Iran and other developing countries (Hanachi et al, 2007). In fact, strong development process and the relevant constructional operations have led to demolition of intangible and tangible heritage in the Iranian cities (Seyedian, 2003). According to some studies, UHC has been seen as an obstacle to progress and development, especially in developing countries (Idid, 2005). It is pertinent to mention that heritage conservation is always defeated in competition with the development and it will be seen that heritage conservation will get out of the pit (GCI report, 2009). Moreover, it will make another negative consequence when we see that authorities and practitioners don't believe to people contributions and their roles in the heritage conservation process.

Heritage conservation is an issue which needs to be protected by a power except governmental protection. According to the cultural heritage studies, if governments allocated so many budgets for heritage conservation without any accompaniment and determination of native people, these financial resources are certainly wasted. Despite the passing of almost five decades and earning many experiences for performers and providers, urban plans could not balance between urban development and urban heritage conservation in Iran (Poorahmad et al, 2006). Hence, a lot of evidences have shown by the studies that cultural heritage is being threatening and damaged by master plans without citizen participation (Habibi et al, 2002).

3. Analysis of the experiences of UHC facing with urban development trends in Iran

At the turning point towards UHC, we review some experiences related to it since the beginning of measures to now. With this review, it aims to examine conflict between development and conservation. Researchers believe that there are certain periods seven in interaction and conflict between development and conservation approaches.

First period, 1785-1906, from the beginning of Qajar dynasty rule until the Constitutional Revolution: What is considered in this period is the beginning of archaeological excavations; also Iranian people, especially western countries, would become familiar with Iranian culture and civilization. In 1895, the first formal agreement is signed for archaeological excavations between Iran and France (Hanachi, 2007). In this period, most of the monuments are used for daily living. Some of buildings which had not required performance were conveniently damaged. It was not mooted to conserving monuments and precious fabrics in this period. The pattern of demolition and renovation was crucial system during this period. Concept of conservation was only used for keeping antiques and expensive goods (Hanachi, 2007). It could be seen that the pulse of excavation and cultural preservation was in charge of the foreign experts in this period.

Although some serious measures are carried out for slow-growing development by famous people like AmirKabir such as construction of Dar-ol-Fonoon, reconstructing shops in the Naseriyeh Street, construction of Chehel-Sotoon

building beside Kolah Farangi building and so on, but likewise, the demolition was on the agenda of development planning (Habibi et al, 2002).

Second period, 1906-1922, from the Constitutional Revolution until Establishment of National Assembly of Monuments:

The popular movement, the Constitutional Revolution, with the slogan of democracy and parliament establishment was won by leadership of religious clergymen and political intellectuals in 1906 (Bahar, 1971). The king and his entourage had to take it, and the king issued the constitutional decree. It was the first time that people were allowed to participate in their own destiny. It had some advantages in the municipal heritage conservation such as (Hanachi, 2007):

- Increasing importance of UHC among the educated classes,
- Increasing public awareness led to establishing Antique Administration by The Ministry of Culture in 1910.
- Increasing involvement of Iranian experts in conservation era, which was only limited to preserve the antiques.
- Cultural heritage took on some importance in the minds of the general public and journalists.
- Legalizing urban development planning by permission of Baladieh Act in 1907.

Third period, 1922-1944, from the establishment of National Assembly for Monuments until the amendment for Act of National Monuments Preservation:

The beginning of this period coincided with two important events;

Firstly, in 1923, 'National Assembly for Monuments' was established by which precious historical relics were considered as a part of country's cultural heritage (Habibi et al, 2002). Unfortunately, as opposing to the previous rule, Qajar era's clues did not take place as cultural heritage, which provided simple conditions for their destruction. For example, a large part of Golestan Palace was destroyed in order to construction of the Ministries of Finance and Justice in historical fabrics of Tehran. It should be mentioned that a new Act was approved for that Qajar era's clues be placed as cultural heritage in 1944. It was a serious measure to promoting heritage preservation (Hanachi, 2007).

Secondly, first codified Act on heritage conservation was approved under the name of "The Antiques Regulation" in 1930 (Habibi et al, 2002). Up to this time, archaeological excavations were in the monopoly of French and then Germans. The fact is that a new Act of urban development under title of 'street modification and extension' was approved in 1933 which opened a way for widespread demolitions in the urban fabrics and monuments. In fact, The Act priority was for streets and cars and process of development was hurried which felt adverse effects across the old areas particularly on Bazar. For example, construction of 15 Khordad Street in Tehran, Emamkhomeini Street in Semnan, Zand Street in Shiraz, and even demolition of historic Ecbatana (Hegmatane) Hills in Hamadan by geometric patterns are as samples in this considerable damage to the cultural heritage throughout living textures (Habibi et al, 2002).

During this period, the demolition and renovation pattern was significantly increasing due to the following factors:

- Increasing technological developments and presence of new materials like Iron and cement,

- Increasing urban rapid development in the new part of cities by removing walls around the cities,
- Tending to modernism the west as a symbol of development.

Fourth period, 1944-1965, from Amendment to Act of National Monuments preservation until Establishment of National Center for Protection of Iranian Antiquities:

The landmark of the demolition and renovation patterns was created by the establishment of the Plan and Budget organization, which was the responsibility for providing the country's Development Plan in 1948 (Karimi, 1998). The first plan, 1955-1962, as before was focused on widening existing streets and roads while was not seen the necessary for heritage conservation in a certain plan. However, extensive damage in the historical and cultural textures caused to make out a regulation on heritage conservation in 1956 (Habibi et al, 2002). It should be mentioned that it could not be an obstacle for the damage because approval of 'Possession Act' provided a context for increasing the demolitions and declining the living quality in the old areas, in 1960 (Hanachi, 2007).

The country's Second Development Plan was formulated for a Seven-year period (1955-1962). Its main effect was preparation of the master plan by foreign consulting while development approach of dominated conservation and conservation concept was simply included buying monuments and maintenance of them (Habibi et al, 2002). At the end of this period, injuries resulting from development revealed a need for specialized devices for steering its process. As a result, the National Council Parliament approved to establishing 'The Ministry of Development and Housing' in 1965 and 'the High Council for Urban Planning and Architecture' in 1966 (Azizi, 2000). It is pertinent to mention that development process was targeted by these devices and through the master plans. It was interesting that the Ministry of Art and Culture' was established in 1966, which became the responsibility of heritage conservation.

Fifth period, 1965-1978, from the establishment of National Center for Protection of Iranian Antiquities until victory of Islamic Revolution:

Because of the tremendous loss of cultural heritage in the last periods, it was considered slightly more during this time. As, the parliament approved 'Act of Buying Lands, Buildings, and Utilities for Preservation of Monuments' in 1968 and 'Act of National Works Registration' in 1973 (Habibi et al, 2002). Subsequently, department of preservation was formally established to preserve monuments. In fact, preservation programmes found out a greater share in the programmes of macro policies in the society. Such attitudes led a certain consideration to precious monuments like Tekye-Amir-chakhmagh in Yazd, Green Dome in Mashhad, Sheikh Safi Tomb in Ardabil, and Imam Reza (A) Shrine. In some cases, the selected monuments turned into a museum such as Ghavam el-Saltaneh house which was become Abgineh museum by Hans Hollien (Hanachi, 2007).

However, it cannot be denied that urban development processes would still threaten heritage conservation during this period. Urban renovation was the main axis in the country's Third, Fourth, and Fifth Development Programmes from 1963 to 1977 (Habibi et al, 2002). Heritage was constantly under threat of destruction in the

historical textures in these years. These issues had brought up an understanding that there was a necessary for going toward a combined programme in Fifth programme.

Sixth period, 1978-1985, from victory of Islamic Revolution Until the establishment of Cultural Heritage, Handicrafts and Tourism Organization in Iran:

After the victory of Islamic Revolution, Iran was brought to an imposed war by Iraq, which contributed to intensify the demolition process of monuments and historic textures in the cities (Poorahmad et al, 2006). In addition to the war, some other factors like going out of foreign experts and lack of financial resources faced with a recession in the urban development and conservation programmes. From 1982 on, The Fluency Plans were provided and notified by the Ministry of Interior for confronting uncontrolled expansion of cities and preserving cultural heritage. These plans were merely succeeded as provisional and preventive measures for improving arterial roads (Ali Abadi, 2008). It is important to know that they damaged urban landscape and physical fabrics in the old areas. What was considered in the war forgot preservation issues of monuments and historic values in urban textures. In fact, they were unnecessary issues and outside the priority system. Furthermore, lack of legal requirements and weakness in the regulatory agencies caused to damage so many of historic works simply (Hanachi, 2007).

Seventh period, 1985-2011, from the establishment of Iran's Cultural Heritage, Handicrafts and Tourism Organization until now:

In 1985, the statute of Iran's Cultural Heritage, Handicrafts and Tourism Organization was approved which found a mission in order to the preservation, protection, and revitalization of monuments and historical textures (Falamaki, 2005). Seventh period was a turning point for urban heritage conservation in Iran. In this period, bureau of urban rehabilitation was established in the Ministry of Housing and Urban Development in 1985. In this respect, various plans had been implemented for urban heritage conservation such as rehabilitation plans (1987-1990), Plans of Historical-Cultural Axes (1990-1992), Revitalization and Reconstruction Plans or Aggregation Plans (1992-1994), Plans for Problematic Textures (1994-1997) (Karimi, 1998). Some these plans like Plans of Historical-Cultural Axes emphasized on museum preservation based on urban structure, which was not successful practically. Some another one like Plans for Problematic Textures focused on the destruction and renovation policy which led to tremendous demolitions in the precious textures (Hanachi et al, 2001).

However, the establishment of Urban Development and Revitalization Organization was the most important and effective program in U.H.C, in the old areas. It was toward implementing Clause 33 of country's Second Development Plan. This plan was particularly considered to old areas in two parts of housing and urban development. Some its objectives were (Hanachi et al, 2007):

- Constructing organizational homes in the old areas by funds of private sectors,
- Purging around monuments in the old textures based on heritage criteria,
- Constructing buildings in the extra lands in order to providing revitalization fees in these textures and encouraging residents to living there.

Third Development Plan of Iran was also pushed toward controlled and balanced development in urban regions in order to renovation and reconstruction in the old textures.

Table1. A comparison between concepts of development and conservation from 1785 to now

Period	Year (A.D)	Important Events	Concept of Development	Concept of Conservation
1st Period	1785-1906	**From,** the beginning of Qajar dynasty rule **To:** the Constitutional Revolution	1-Demolition of single monuments 2-Slow-growing development in the physical boundaries of cities.	1-Limited protection on antiquities. 2-Demolition and reconstruction in monuments
2nd Period	1906-1922	**From:** the Constitutional Revolution **To:** Establishment of National Assembly of Monuments	1-Continuing in the process of demolition and reconstruction. 2- Development of the physical range of cities.	1-Developing in the protection of antiquities. 2-Continue in the demolition and reconstruction in monuments
3rd Period	1922-1944	**From:** Establishment of National Assembly of Monuments. **To:** Amendment to Act of National Monuments preservation.	1-Extensive demolition of precious buildings, monuments and historic fabrics, and 2-construction of a wide street in the fabrics.	1-Very limited protection from single buildings, and 2-Lack of consideration to historic fabrics.
4th Period	1944-1965	**From:** Amendment to Act of National Monuments preservation. **To:** Establishment of National Center for Protection of Iranian Antiquities.	1-Decreasing in the monuments demolition and increasing in the demolition of fabrics. 2- Continuing in the hurried development of cities	1-Limited protection from single buildings, and 2-Lack of consideration to historic fabrics.
5th Period	1965-1978	**From:** Establishment of National Center for Protection of Iranian Antiquities. **To:** The victory of Islamic Revolution	1-Continuing in fabrics demolition. 2-Construction of historic buildings. 3- Continuing in the hurried development of cities.	1-Increasing in the scope of preservation from monuments. 2-The beginning of considering to urban fabrics.

6th Period	1978-1985	**From,** The victory of Islamic Revolution **To:** Establishment of *Iran's Cultural Heritage*, Handicrafts and Tourism *Organization*	1- The hurried development of cities. 2-Development of settlement and land	interrupting urban conservation of monuments and valuable urban fabrics
7h Period	1985-2011	**From** Establishment of *Iran's Cultural Heritage*, Handicrafts and Tourism *Organization.* **To:** Now	1- Increasing urban collections 2- Raising issue of sustainable development.	A variety of programs for conserving historic areas

4. Historical study of citizen participation regarding urban heritage conservation in Iran

It cannot be denied in scientific assemblies that consideration to the local communities has been the most important ways for accessing to participation, realizing participatory planning, and urban sustainable development (ICOMOS, 2002). Todays, urban planning approaches have faced with various changes. It seems that planning in the local scale can be an appropriate choice for implementing participatory planning. Local community in urban planning is a device that can realize the real meaning for planning with people instead of planning for people (Taylor, 2007).

In Iran, patterns of citizen participation can be divided into two parts; traditional and modern. Traditional participation, which is based on religion, traditions, habits, and customs appear without any planned program. It so has a long history in the past centuries in Iran. In fact, government has not any control for conducting programs in this type of participation. The public is responsible for all affaires (Mohammadi, 2010). There are several examples for it such as celebrating religious rite for birth and death of religious Imams and prophets in special months and days, building mosques or schools forgivingly, and even forming a small group of individuals for traditional agriculture and animal husbandry (Alavitabar, 2000).

Historically, the modern participation patterns date back to Constitutional Revolution in 1906 (Alavitabar, 2000). In fact, establishment of the first parliament and approval of Constitution were the first participatory experience for Iranian people. This Constitution, which provided based on the European version, gave an extensive power to the State and Provincial Assemblies. However, the modern participation patterns can be studied at three different parts:

- Before the Constitutional Revolution(1906)

- Between two revolutions(the Constitutional Revolution in 1906 and the Islamic Revolution in 1979)
- After the Islamic Revolution from 1979 to now.

4.1. Before the Constitutional Revolution (1906)

There is no trace of citizen participation in the urban affairs before 1906. Indeed, a prince or a military man appointed by him as the governor was the only decisionmakers in the planning process. He did not allow people or a group of people participate in decision- making process. Therefore, the political system did not allow that the people participate in urban administration of the country, and dictatorship was being governed throughout the country (Madanipour, 1998).

4.2. Between two revolutions (the Constitutional Revolution in 1906 and the Islamic Revolution in 1979)

There are several landmarks for the beginning of citizen participation in the planning process during this period. Some of the important event are such as the establishment of parliament and approval of the Constitution which were granted a part of king power to the public following the democratic trends against dictatorships throughout the world (Alavitabar, 2000). In fact, the first participatory experience of Iranian people was established in a new pattern of citizen participation after the establishment of parliament and approval of 'Baladiyeh Act' in 1906 (Madanipour, 1998). Some characteristics of this period are:

- With the approval of this Act, the right of citizen participation was admitted for electing parliament's member to all people.
- The modern municipalities were established under the control of elected representatives as a town and city council.
- Urban administrative system was included some significant features such as full independence and elective basis of urban management, and also the mayor was under control of councils\, not central government.

In 1911, government was permitted to dissolve the councils by the parliament. There were some issues that led to this decision such as intervention of some of the local influential persons in the elections, lack of experience for actualizing this Act in the cities by the government (Alavitabar, 2001). In 1930, the second municipal Act (the second Baladiyeh Act) was approved instead of the first one. This Act turned into municipalities more dependent than the local agencies of central government. Some other characteristics of this Act are (Mohammadi, 2010):

- The influence of the Ministry of Interior increased by establishing municipalities, appointing their management personal, and also controlling their measures,
- The first effort was partly carried out for creating an autonomous urban government.
- The people could just elect five times representatives from whom the government would choose and appoint the member of the council.

After the Second World War and following a set of democratic activities, the third municipal Act (the third Baladiyeh Act) was implemented in 1949 which reverted to

the municipalities a degree of legal autonomy (Madanipour, 1998). Table number 2 compare some differences between the municipal Acts of 1930 and 1949 in Iran.

Table2. Differences between the municipal Acts of 1930 and 1949 in Iran

Acts / Characteristics	**1930**	**1940**
Conditions of Electors	The right for voting was only for landlords, businessmen, and merchants	Anyone who was living at least 6 months in the place of election or having a job there.
Conditions of Candidates	From particular classes	Anyone was known as a dweller or who was living at least 5 years in the place of election or having a job there.
Election/Appointment of the Mayor	Appointed by the Ministry of the Interior	The mayor was appointed by the Ministry of the Interior from three candidates who had been nominated by the city council

Source: Mohammadi H, 2010

Some amendments were carried out in the context of third municipal Act in 1952, 1955, 1966, and 1976. With these amendments, the municipalities would provide for more autonomy. Some of its characteristics are (Mohammadi, 2010):

- The members of the city council were elected by citizens for a period of four years. They had a wide power for appointment or dismissed of the mayor, the right to legislate and devise local taxes, controlling over financial and administrative affairs of municipalities, and so on.
- Citizens could protest to the council's decisions. It is predicted a way for corresponding citizens' protestation and considering their ideas.
- The number of council members depended on the population of each city which was from 6 to 25 people \, and it was just 30 people in Tehran.
- The representatives were elected from different districts of a city. In fact, it was due to having more direct relationship with their district's people.
- According to this law, the municipalities were formally established in a city with the population of 5000 people and more.

4.3. After the Islamic Revolution in 1979 to now

After the Islamic Revolution, there were fundamental changes within social and political structure. The most important these changes were in the area of establishment of local organizations and entrusted affairs to the people in the different levels (Madanipour, 2001). In fact, the Islamic city councils were One of the most important of Revolutionaries' aims was the presence of people for administrating urban affairs while the establishment of city councils was practically

remained on paper up to 1999 (Alavitabar, 2000). There were many factors that they led to postponement of establishing councils, but the imposed war was the main reason. In 1996, a law under the name of 'Organization, Responsibilities, and Authorities of Islamic Council Act' was approved by Islamic parliament. This law provided a context for establishing the 1999 Islamic councils' elections. Since 1999 up to now, councils' elections were held three periods in 1998, 2002, and 2006. Some of significant features of Islamic city councils are (Mohammadi, 2010):

- After over 20 years, Revolution, establishing councils provided a context for realizing slogan of democracy and decentralized the power of central government.
- With establishing city councils, urban management system has administrated as Mayor-Council system.
- The recent Islamic Councils Act, Article 75, have emphasized that the financial requirements of councils must be provided by the municipality's budget. So, it would be possible to make the councils more dependent to the municipalities.
- According to the organizational chart of Islamic Councils Act, High Council of the provinces supervises over the councils. In the other word, the councils are not subordinate to the central government. Nevertheless, the central government can dissolve the councils, if there is a serious diversion in their legal duties.
- Some of the main points of the Councils' 1996 Act were their legal authority concerning policymaking and decision-making for all urban institutes and agencies, while it is now seemed that it has reduced and limited only to the municipalities.
- It is now considered that the supervisory duties of city councils have divided in two different parts. The main part consists of mandatory supervision, which is restricted to the municipality's affairs such as supervision over their revenues, expenditures, and so on. The subsidiary part is included to consultative role, which is regarded government sectoral or inter-sectoral agencies involved in urban affairs.
- There are various committees such as public affairs, urban development, plan and budget, legal affairs, and so on in councils by which complex and divers responsibilities of councils are divisible in them.
- Although, it appears that city councils and neighborhood councils have been able to provide a level of participation in the Iranian society \, but the researchers have shown that they could not prepare a type of direct participation and involvement of all individual citizens.

Table3. Extent and mode of Citizens Participation in the experiences of urban planning management from 1906 to now

Row	Period	Extent of Citizen Participation
	Before the	No citizen participation on urban

1	Constitutional Revolution (1906)	administration, and just the executive head of the town (appointed by princes) was the actual regent of the town
		Establishment of Town and City Assemblies in 1907, formation of Parliament, and approval of the Constitution (the first Baladieh Act) are new pattern for the beginning of citizen participation in the decision-making process for town and city administration.
2	Between two revolutions (the Constitutional Revolution in 1906 and the Islamic Revolution in 1979)	1-The beginning of the throne of Reza Shah and a wide change with severe political centralization. 2-Approval of the second Baladieh Act. 3-The first effort to establishing an autonomous urban management. 4-Decreasing citizen participation with decreasing independence of Assemblies.
		1-Approval of the third Baladieh Act in 1949 which returned to the municipalities a degree of legal autonomy. 2-Increasing citizen participation with taking power by Town and City Assemblies. 3-Assemblies members had much social responsibility because they were voluntary and without any salary.
		1-Decreasing citizen participation due to the failure of Assemblies. 2- Factors of their failure were: -Lack of people awareness to elect competent members for Assemblies. -Intervention of local government officials in the elections.
3	After the Islamic Revolution in 1979 to now	1-Lack of citizen participation on urban affairs 2-Increasing citizen participation in religious activities and 3-attending in military applications against enemies.
		1-Establishing Islamic rural & city councils 2-increasing local power for monitoring urban affairs.

5. Management system of urban development planning in Iran

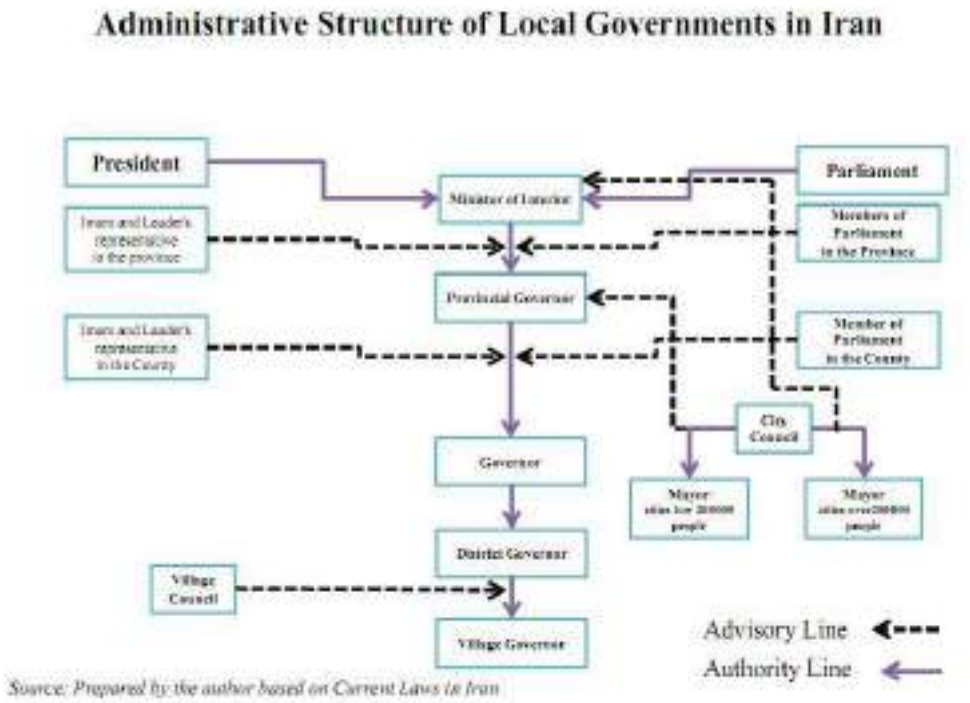
The responsibility of management of urban development planning is undertaken local government and organizations which consist of the municipality, Islamic City Council, and the other organizations. On the one hand, an up-down administration system has caused that the municipalities are under the control of central government (the Ministry of the Interior) and, on the other hand, they are under the supervision and control of the city councils (Mohammadi, 2010). It is difficult to believe that city council is independent of government administrative tools such as the executive, the judiciary, and legislative systems.

Main base of local government in urban governance are the municipality and city council while they are not only player this function. There are four different groups which are binding on the decision-making process of urban management such as:

- *Local government* consists of the municipality and city council.
- *Government intersectoral organizations* include Ministry of the Interior, Ministry of Housing and Urban Development, Governor Generals, and the High Council for Urban Planning and Architecture, Organization for Employment and Administrative Affairs.
- *Government sectoral organizations* consist of branches from ministries like Education, Energy, Industries, Commerce, and so on.
- *Non-governmental organizations* include Society of Urban Planners, Consultancy Engineers, and Iranian Construction Engineers Organization and so on.

The presence of multiple actors with different roles cause that the purpose of united urban management cannot comprehend, and function of the above organizations affected on the process of the making-decision, making-policy, management, monitoring, and implementation on the total of system(Madanipour, 2001).

Although it takes about five decades from preparation of master plans in the Iranian cities which aim to prevent unplanned development, also cultural heritage conservation but these plans could not comprehend the objectives, and we are observing inappropriate development and neglecting cultural heritage in the process of preparation, implementation, and monitoring on these plans.



6. The approaches of urban planning system in the face of cultural heritage in Iran

The tremendous loss of cultural heritage materials led to change concept of "a future for the past" in 1970s to the concept of "a past for future" in 1980s and nowadays, it means "to make the past part of our future" (Habibi et al, 2002). In Iran, some activities have been done by some governmental institutes like the Iranian national organization of conservation of historic works, which carried out after 1965, and some academic attempts which contributed to highlight the significance of historical and cultural values in the historic urban areas (Falamaki, 2005). According to Prof. Falamaki, due to lack of attention to "Heritage" as "cultural wealth", historic cities of Iran have faced with great damages, particularly, by the hands of modernization tendencies. It is obvious that the modernization trends have led to urban instability, especially, it has caused to create an imbalance between old and new areas. In recent years, these areas have been considered through compiling strategic planning in order to rehabilitation and conservation by municipalities and heritage organizations (Ali Abadi et al, 2008). These plans include a regular process of recognition, analysis and planning, decision making, and suggestions. They are seeking to control the physical development based on physical, historical, and cultural values and also assessing appropriate opportunities according to participation, management, and legal issues. Although these plans have brought up promising perspectives, but planning and heritage conservation approaches have still been summarized in zoning.

The following figure shows the structure of city management in which extent of citizen participation is less.

7. Conclusion

An overview of the results obtained in the previous section shows that historical cities of Iran have facing with unprecedented changes, which impacted the urban environment. These changes have derived from the modernizing tendency which was accompanied with the other impacts such as rapid, uncontrolled development, demographic changes, and economic pressures. In fact, these large changes have been the main factor for creating changes in the urban environment which directly impact the preservation of historic urban environments. In Iran like the other developing countries, on the one hand, historic cities have faced with great immigration, population growth, and a large increase in density in the old areas of historic cities, and, on the other hand, there have been a large migration, population decrease, emptying smaller rural centers. These opposing conditions that have led to urban sprawl and reinforce urban development trends, they caused to threat and damage many tangible and intangible heritage relics in Iran. Historical study of urban planning and conservation has shown that approaches based on development and conservation could not access to a constructive interaction. Therefore, there is still serious challenge between them. Some of selected achievements of this study are as follows:

- Despite, development and conservation approaches have been effective side by side in the experiences of urban planning and conservation in Iran, but both approaches have always been in serious challenge practically.
- The role of citizens' participation has been faintly in the making decision and planning process. There is no trace of the public and their ideas on the most of urban programs, which was done during last decades. Experiences of last decades illustrate that even the best planning programs will not succeed in the long-term without the participation, support, and initiative of stakeholders.
- Historical study shows that heritage conservation programs had succeeded when there was peace and stability in the area of the management system cities. In fact, mutual trust between people and authorities has assisted to conserve cultural heritage of countries, even though it was limited.
- The investigation has shown that rapid urban sprawl has had many impacts on valuable textures of historic cities in Iran. Hence, it seems that urban programs should not only rely on development approaches without conservational heritage ideas.
- However, it cannot be denied that museum conservation approaches have had numerous damages on valuable textures in these cities. Therefore, integrated practices and interactive approaches between development and conservation together with public participation are successful approaches to meet sustainable conservation in the historic cities of Iran.

LEARNING BY DESIGN IN AN INTERNATIONAL URBAN PLANNING AND POLICY DESIGN MASTER PROGRAM

Antonio Longo[1], Marco Mareggi[2]

Abstract

The paper illustrates an experience in the teaching of urban design and planning carried out at the Politecnico of Milano where the School of Architecture offer a two-year Master of Science program in Urban Planning and Policy Design open to international students. The master, organized by semesters, offers both introductory courses and topics of advanced research activities. In the first workshop, *Urban Design and Planning Studio*, the students are encouraged to challenge with experimental themes and innovative forms of urban design. In coherence with the recent experience developed at the Politecnico of Milano (Bologna and Milan, sharing the keyword "città di città"), the urban planning and design require a range of activities that generates knowledge, a survey conducted through design and imagination, through the ability to orient the information, systematise the data collected. This way of looking at the project activities means that the correlation between survey, urban analysis and project will not be linear and consequential. Therefore the teaching approach of the Design Studio simulate a highly complex professional design work and research situation, guided by a sequence of concrete, hands-on experiences: the objective is to introduce the student to a critical reading of the context, the identification of intervention priorities, the production of strategies and guidelines and territorial re-composition schemes.
The contribution is organised in three parts: an initial part deals with the School's specific approach to the teaching of urban planning and design (§ 2) and how this correlates with the recent internationalisation of the School (§ 1). The second part describes the didactic principles and practices underlying the activities of the Design Studio, a hands-on experience that brings together project and research (§§ 3 and 4). The third part is about the results of Design Studio activities, which are analysed from a critical perspective (§§ 5 and 6).

1. Introduction: teaching to international students at a polytechnic school

Since 2005, the School of Architecture of the Politecnico of Milano has offered a two-year Master of Science program in Urban Planning and Policy Design open to international students. This program is a challenge and lends itself to experimentation, on account of at least three of the conditions that characterise it: the

[1] Department of Architecture and Planning, Politecnico di Milano, Milan – antonio.longo@polimi.it
[2] Department of Architecture and Planning, Politecnico di Milano, Milan – marco.mareggi@polimi.it

integration of different disciplines, its international dimension, integration between teaching and research activities.
It is in line with the Politecnico's long-standing tradition in bringing together urban design, planning, regional studies and the social sciences, and its goal is to provide a broad education in planning and policy making. It lasts four semesters and is meant for students in possession of a bachelor's degree in a variety of disciplines: urban planning, architecture, landscape design, geography, economy and territorial engineering.
Five years on since the inauguration of the Master program, the student body is highly heterogeneous, in terms of country of origin and previous studies: more than 25 different nationalities and at least a dozen different educational backgrounds are represented among the approx. 80 students that enrol every year[3]. The courses attract many Erasmus students from architectural degree programs, whose presence contributes even further to the diversification of the student body.
For this reason, first semester courses are designed to set a common frame of reference and provide a common basis in terms of cultural and operative tools, whereas from the second semester on the students may opt for urban design oriented or planning & policy design oriented courses.
The *Urban Design and Planning Studio* is one of the entry courses of the Master program[4]. Its objective is to get across the basic knowledge and skills for the creation of structural and spatial design schemes in a contemporary urban context, and it constitutes the first, essential design experience offered to the students. The relationship between the polytechnic tradition of Italian schools and the diversification of the classes by skills and by origin is a challenge we have decided to take up by giving the course an experimental and research-oriented character.
For many students who come from different educational backgrounds and especially those who may have accumulated extensive professional and research experience, possibly according to more narrowly defined criteria, even getting an understanding of the goals and the scale of the project and the instruments available might prove difficult. In the minds of many students, in fact, and especially those coming from the Asian countries, urban design has a strictly morphological acceptation, to do with the conformation and the arrangement of the buildings and the infrastructures. For students who have studied in Europe, the dialectic relationship between planning and urban design, between architecture and the organisation of the functions and the economy of a territory is more elaborate. And there are also quite a few students coming from geography, economics and sociology studies who have no prior

[3] For instance, in academic year 2011-2012, the program is attended by students coming from the following educational backgrounds: planning, urbanism, philosophy & urbanism, architecture & urban planning, architecture, landscape architecture, restoration, management, sociology, environment engineering, architectural engineering, geography.
[4] The course was set up by Patrizia Gabellini together with Matteo Bolocan Goldstein, and Andrea Di Giovanni, and with Bertrando Bonfantini, Antonio Longo, Marco Mareggi who during the last two years have been responsible for the management of the course. Its structure is documented in (Di Giovanni, 2008). Nowadays the Urban Planning and Design Studio encompasses the subjects of Urbanism (Bertrando Bonfantini), Urban Design (Marco Mareggi), and Vision and Rendering Tools (Antonio Longo).

familiarity with territorial planning. In some of them this makes for an open, inquisitive mind, and therefore it is not necessarily a problem.

2. Urban Design and Planning at the Milan School of Architecture

Before we proceed with a presentation of the didactic activities of the program, we should take a look at the type of design and planning activities that are proposed to the students. Since a description of the multi-faceted characteristics of the "progetto urbanistico" in its Italian acceptation goes beyond the scope of this report[5], we can only provide a summary of the main points. Three keywords may help gain an understanding of some of the basic concepts that will be developed in the following paragraphs in connection with their educational implications: contemporary city, context, composition.

The first keyword, *contemporary city*, defines the urban field to which the project is applied. The reference space is the contemporaneity of the existing city, the real city in its historical evolution. The urban project for the existing city in Italy, albeit with different acceptations, has always devoted great attention to historic conditions, and has taken into due account both the heritage from the past and the current evolution of a city. Thus, the project develops in the manner of a work in progress, in close correlation with the physical, social and economic aspects of the existing city.

The second keyword, *context*, indicates that the project is not applied to a situation defined *a priori*, through a consequential relationship between analysis and project. On the contrary, the context is an artificial device, arising from the interpretation of the multiplicity of factors that characterise a city. It is made from a set of features that force themselves to the attention of the urban planner, which either emerge or are deliberately sought and picked out, and thus selected. Project activities, in their initial stage, mostly consist of working out the answers to a series of elementary questions: what problems come to the fore, what are the resources of the territory? What transformations are currently underway and, conversely, what elements are static, unchanging? What is the geographic scope of the problems observed? Are the client's requests clear, or do they imply other issues, other undeclared requests? To give an answer to these questions calls for a critical activity, a selective work through which the context is constructed, thereby delineating the urban field to which the project applies. The project is an activity that generates knowledge, a survey conducted through design and imagination, through the ability to orient the information, systematise the data collected. This *modus operandi* means that the correlation between survey, urban analysis and project will not be linear and consequential, but rather will consist of progressive adjustments and will be perfected through clues, trials, errors and iterations, reflecting the cyclic nature that is typical of the craftsman's work, as aptly described by Richard Sennet (2008).

The last keyword, *composition*, originating from the previous two, describes a process that is inextricably associated with the making of a plan for the contemporary city. Physical fragmentation, the acceleration/ slowdown of transformation processes, the multiplication of the subjects and the demands that animate the urban scene are

[5] For a general account of the Italian urban design and planning tradition, see (Palermo, 2006).

recurrent characteristics, together with a scarcity of territorial and financial resources, and the prevalence of existing elements to be reused and improved over new interventions. The urban project addresses these issues by making a combined use of techniques and approaches that pertain both to urban design and to planning, by working on different scales, and through the use of different techniques, that is to say, through an integrated vision of the social, economic and spatial aspects at stake, both in interpreting the phenomena observed and in defining the actions to be undertaken. In urban planning and design, composition is a work of selection and coordination, a form of design which is based on the ability to establish correlations and cause and effects relationships, and to give a new meaning to existing elements, as opposed to bringing in new elements, a form of design which interprets and uses the relationships between the individual parts, instead of introducing new structures (Gabellini, 2008; Bruzzese & Longo 2011).

3. The common area and shared theme of intervention of the Design Studio

Within the framework of the international dimension of the School, it was felt that to underscore the Italian approach to urban planning and design was the best way to satisfy the multifaceted demand for a broad educational program expressed by the students enrolling in the Milan Politecnico in recent years.
As mentioned before, the profiles of the international students are extremely heterogeneous and mature. The students are highly motivated in their choice of a multidisciplinary program, oftentimes they have gained extensive experience doing research and professional work, and have a strong propensity for mobility. These conditions require a taxing preparatory work to bring into alignment and share the language and tools of the urban project. Needless to say, to involve such a rich and diversified student body in a practical and experimental activity, which for many students amounts to exploring a hitherto unknown territorial field, calls for a clear identification of issues and objectives, mated, on the part of the teachers, to a good knowledge of the territory chosen as the planning and design experimentation field.
Accordingly, it was decided on the one hand to focus on a nearby territorial field that was alive and would provide opportunities to come to grips with dynamic phenomena underway, i.e., the Milan Urban Region, that was interpreted as a "city of cities". On the other hand, it was decided to thematise design research on habitability as a quality of the places that the urban project could affect and enhance.
Thus, the attention was focused on sections of the *Milan Urban Region*, the vast urbanised area that surrounds the city of Milan. It is a territory displaying many of the typical characteristics that are observed in Europe's major cities: administrative fragmentation (the Province of Milan includes 134 municipalities with 3 million inhabitants), unbalanced demographic dynamics (Milan, the regional capital, with 1,320,000 residents has been losing inhabitants and the demographic balance is compensated for only the by inflow of immigrants, while the population is on the rise in the other municipalities of the province), impoverishment of the farmlands and the landscape, in a territory that is one of the most fertile in Europe, loss of production activities as major manufacturers move out of the area and the size of companies in general declines, a drastic drop in the number of people employed, atomised decision

making and fragmentation of territorial resources, a geography packed with traditional ancient centres increasingly hemmed in by new residential and commercial centres.

Within this framework there is room for the most diverse types of settlement, which cut across the administrative boundaries and that hinge on a combination of factors to do with the economy, the settlement pattern and the history of the area. We are dealing with the so-called "city of cities", the expression coined for the Strategic Plan for the Province of Milan developed between 2005 and 2007 with the support of the Department of Architecture and Planning (DiAP) of the Politecnico of Milan, a strategic project that has into focus the settlement, economic and social geography of the contemporary metropolis of Milan (Balducci, Fedeli & Pasqui, 2011).

Equally important is the identification of a clear-cut thematic focus. The expression "city of cities" recognises a set of factors to do with mobility, access to healthcare, employment, culture, welfare, the environment, factors that, in their rich interrelations, define the concept of *habitability*; this concept refers to the quality of the habitat and establishes a close correlation between the way people live, their needs and the quality and forms of the urban space. The concept of *habitability* makes it possible to correlate the quality of life as experienced by the inhabitants and urban quality in the broadest understanding of the term. To use this concept as a basis for developing a strategic vision makes it possible to steer and guide projects, policies and initiatives. This approach was put into focus within the educational and research framework, during the same time period, by the group headed by Patrizia Gabellini (2006) who defined the purpose and the setup of the Design Studio and produced the thematic reference submitted to the students from the very start of the activity. Using habitability as the term of reference has many interesting ramifications. The theme was conceptualised in research works in relation to different but mutually correlated aspects (moving and breathing, innovating and operating a business, generating culture and enjoying it, producing urban welfare, residing, sharing spaces) that focus the attention on different places and infrastructures, derived and correlated issues, different types of inhabitants and living practices in the city. The habitability of places, seen as a multidimensional condition, enables the actions of a project to be defined as a function of the quality of life of the people.

From a didactic standpoint, choosing a nearby, accessible territory means giving the students a chance to visit, walk through and stop in the area, that is to say, to learn from a first-hand experience of the places. To work from the perspective of habitability has meant providing a clear mission to orient the students' planning and design activities, by focusing their attention precisely on the quality of living in a place on the part of the population, with their human bodies and different needs, and the way those inhabitants relate to the places and the urban policies.

Thus, the heterogeneous student body is provided with a common territory and a shared perspective, so that they may learn to formulate working hypotheses for the physical transformation of the land. On this common basis, the student may exercise their different outlooks, as determined by the different cultural and educational backgrounds. Possibly, it is thanks to the variety of skills and origins characterising the student body that this approach enables the individual students to assess their

skills and verify their background. Thanks to a common territory and a common theme, the difficulties that are encountered at the start appear as a viable alignment and setting modality to get the class started on doing design and planning group work.

4. Didactic organization of the Design Studio

The objective of the Design Studio is to introduce the students to a critical reading of the context, the ability to prioritise the initiatives, the capacity to produce guidelines and schemes for the territorial re-composition of an area.
Design Studio activities simulate a highly complex professional design work and research situation, to be addressed in a didactic setting. Clearly, it is associated with a form of practical knowledge and it is precisely through a guided sequence of concrete, hands-on experiences that the students are introduced to the task.
Work is carried out in the style of an atelier, in a dedicated classroom where it is possible to draw, both on paper and on a computer, with Wi-Fi connections, books and project documents available for consultation, where a large screen may be used to give theoretical and case lectures and show examples. The students are divided into groups responsible for different project areas within the Milan Urban Region, chosen from among five areas suggested by the tutors (Fig. 1). The five areas are

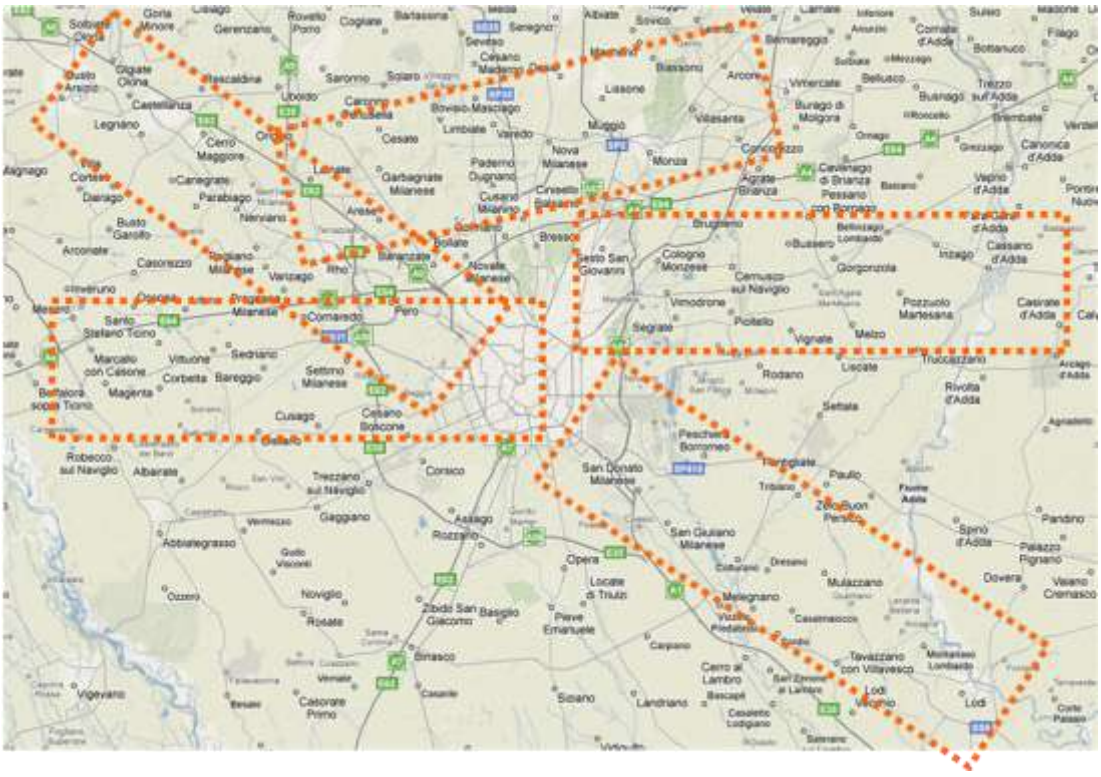

Figure 1. The Desing Studio program starts from the choice of five different parts of the Milan Urban Region where it is possible to find interesting conditions for the project exercise: from Legnano to Milan; from Treviglio to Milan; from Lodi to Milan; from Magenta to Milan; from Rho to Agrate.

urban sectors situated around the central core of Milan, measuring about 10 km x 30 km, characterised by widely differing geographic features and identified with the expression "in-between" (Milan and Lodi, Milan and the Adda river, …). A deliberately vague identification of the "urban field" assigned to the groups helps to prevent the attention from focusing on preconceived viewpoints.
Teachers and tutors are present in the classroom and discuss with the students sitting at a drawing board or in front of a computer. Meetings between the teachers, the tutors and the students are held on a weekly basis, accounting for a sizeable portion, a day and half, of the five-day week that characterises the students' schedule between October and January. Accordingly, it may be rated as the most demanding activity that students have to engage in during their first year of attendance. Evaluation seminars conclude the two steps of the didactic organization.
The workshop is organized in two steps: a first part, dedicated to describing the territorial field and a habitability profile, is followed by a second part during which the students produce schemes and guidelines for a re-composition of the territory assigned to them.
The hypothesis driving the work is that the project can be addressed only through the description of the urban and territorial field. The description of the context is a process of research and analysis that is not clearly separable from the project of transformation. The project itself represents a form of knowledge of the context and, similarly, the construction of the physical, social, economic conditions of the territorial field is essential to be able to identify the resources and the materials necessary to the composition of the project.

4.1. Describing the territorial field and a habitability profile

The goals of the first step of the learning process of the Design Studio are: the identification of the "territorial field" as the area of intervention, and the description of its profile, as necessary in order to define the transformative interventions to be undertaken. The definition of the territory and its description/interpretation is addressed from the standpoint of habitability.
A *territorial field* is a chain of spaces in which social practices establish urban-like relations in the use of open and built-up spaces, and which is perceived by its inhabitants (whether permanent or transitory) as a significant set. This portion of territory is not given beforehand and it has no clear-cut boundaries. It is defined through its description and interpretation. The territorial field shows a number of shared physical characteristics, some of the transformation phenomena underway, the mobility patterns affecting the daily life of the population. That is to say, it displays chains of spaces that may be viewed as "cities in the making" (Calafati 2009), to which the project is applied, and which the project can enhance, through replacement, addition, and rehabilitation interventions (Gabellini 2008).
The activity starts with a virtual exploration of the territory (using aerial photos and satellite photos from Google Earth and similar tools) with the aim to identify different urban patterns at an intermediate scale. In the «contemporary territory like milestones … we can observe settlements with distinguishable features and settlements: … historical centres, planned districts, … citadels, … clusters

(homogeneous nuclei) of what is referred to in Europe as "Diffused City" or "Dispersed City"» (Gabellini 2008). The survey is applied to the physical form and composition of the settlements and territorial infrastructures. Because of having to explore vast areas in a short time, teachers «suggest to use a … "by samples" survey … to explore an unknown territorial situation, catching and focusing its basic elements (materials), and also verifying and improving some starting hypotheses about its composition. The sampling operation is generative, and it is open to original running and interpretations by the different groups… The creation of a catalogue of patterns, is the first required "move" to draft an image of the considered territorial field» (Bonfantini 2011).

Starting from the catalogue of patterns recognized, through four operations the students are invited to consolidate the boundaries of their territorial field and to identify its salient features, by focusing on the characteristic relationships between space and society in order to recognize problems and opportunities. The surveys are conducted according to four different themes deemed useful in interpreting the habitability profile of a territory, and namely:

- urban material *facilities* (i.e., the physical equipment, features of buildings and open spaces) and their *performances* (the way in which territorial materials work, their usability, efficiency and effectiveness, their qualities);
- ways *of use*, the social practices in the space of different populations with different rhythms;
- *perceptions and memories*, how an urban settlement is perceived at present and how its past history persists in the memory;
- *construction sites and projects*, and disused and rundown areas, as opportunities for territorial transformation and their implications.

In the study of the four operations each group may decide which and how many surveys to do and to this end must define suitable boundaries and choose appropriate scales. In any case, institutional and technical standards are references for evaluating performances; data, inspections and chronographic research are ordinary tools for practices of use; interviews and historical documents can help understand perceptions and memories; journals, magazines, books, websites are references for construction sites and projects… The teachers give lessons on the specific tools and show examples.

The tight schedule suggests a selective strategy, to be defined by each individual group. The product of the first step is a report. The effectiveness of the report, i.e., the development of an impressive outline, is the core of the first step. With this operation the various portions of the Milan Urban Region are redefined and specified too, in preparation for the project to be developed during the second step of the Studio.

These operations may concern specific patterns/landscapes or territories, and may also suggest the presence of spaces where social and economic relationships are vibrant and able to compose urban settlements as new "cities in the making".

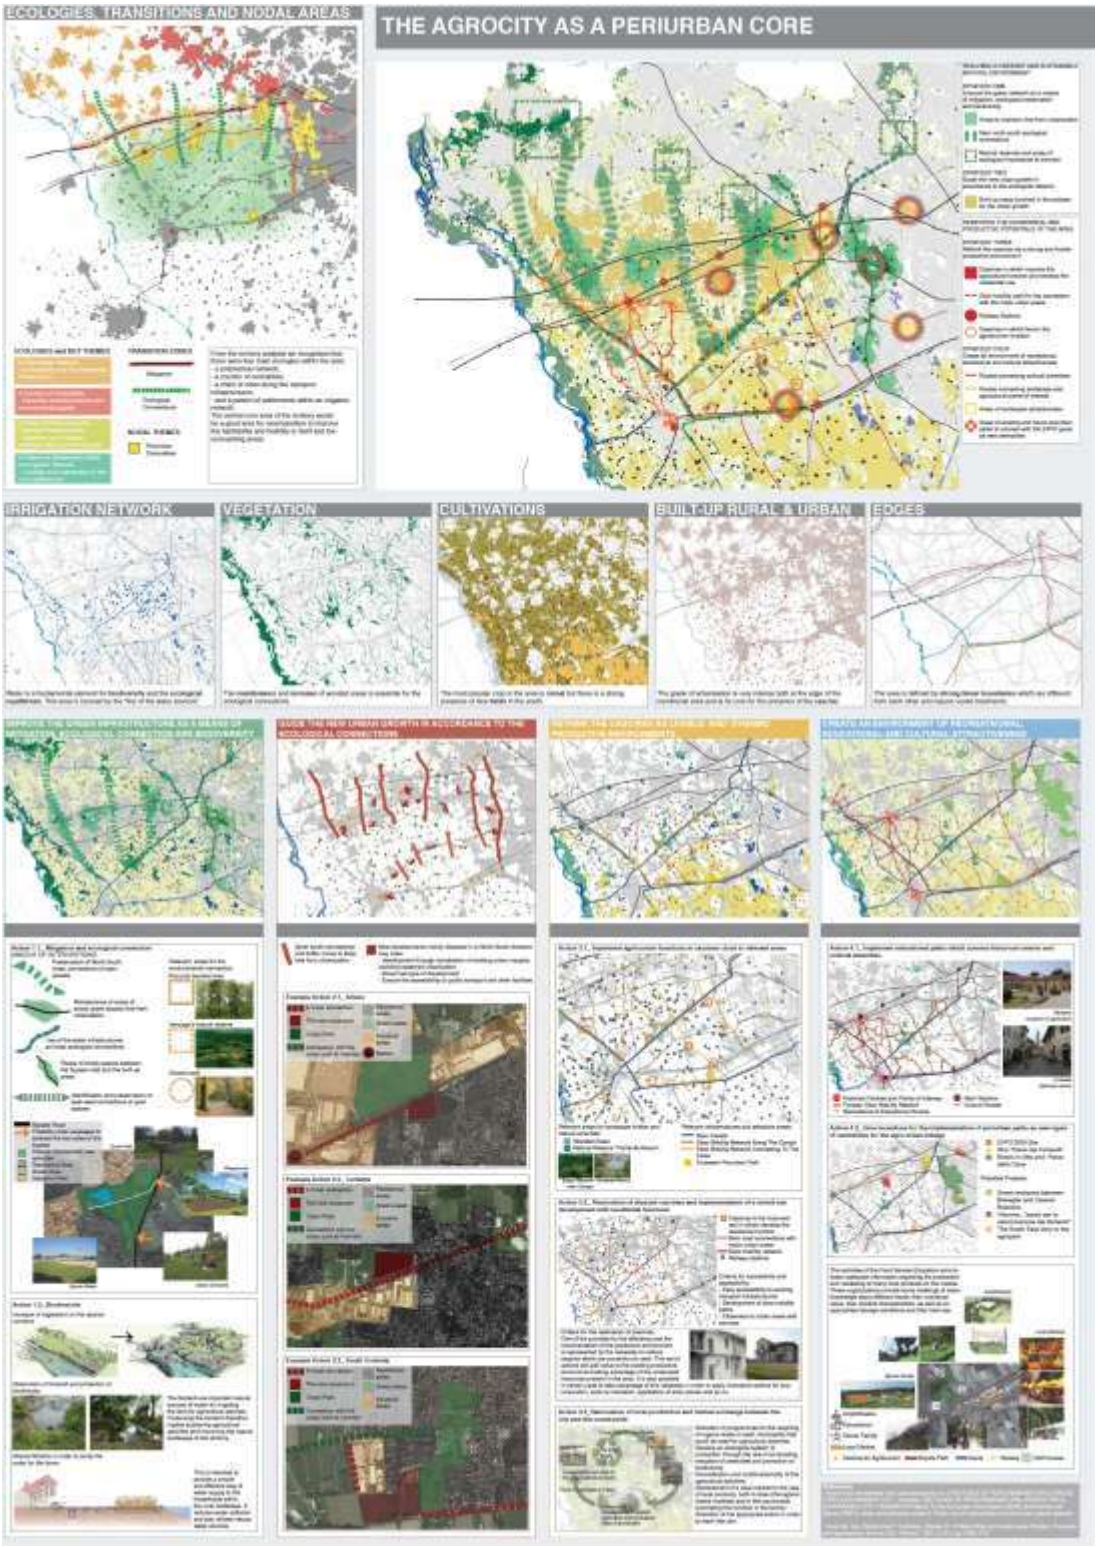

Figure 2. The Desing Studio program finish with the poster on re-composition schemes: proposal for Magenta to Milan.

4.2. A territorial re-composition scheme to outline the project

The aim of the second step of the Design Studio is the development of a re-composition project for the territorial field in question, based on the outcome of the first one. The re-composition project consists of the definition of schemes and guidelines for the same area, developing the profile outlined, geared towards formulating the project of a new city.
Each group needs to work to define an overall vision for the territorial field and, at the same time, to identify ad hoc strategies to modify individual and different parts and situations.
Some suggestions for a work of re-composition can be: proposing a *concept*, a vision for a perceivable aim, which means suggesting some *figures* able to support the urban practices of specific populations; specific *rules* and, sometimes, *models* for improving synergies and avoiding conflicts between different uses of the space; selecting suitable *infrastructures* to support efficient and effective relationships between different materials, and creating connections and opportunities for use. Open spaces, as a chain of different materials for leisure time activities as well as work (parks of various kinds, agricultural fields, natural reserves and oases, environmental corridors, urban green spaces, forests…), may become an uninterrupted sequence of built-up areas, acting as an infrastructure[6].
In the project, the infrastructural space, considered in a broader sense as the reframing element of the territorial composition, will be an essential element to redefine the relationships between the different parts identified in the first step and recognized in their qualifying themes: to connect them, re-link, integrate, separate them as the case may be. The spaces in-between the different settlement patterns are the "infrastructure" to be designed, for example: mobility spaces, formation and texture of the open spaces, water system, ecological network, minor routes network (secondary roads, footpaths, rural tracks), collective spaces and centralities, service systems (public, private and semi-public spaces).
To develop the project, the students must combine two different learning activities. The first is to look for, and learn about, past and present experiences and international good practices in the area of composition/re-composition projects. Professors and tutors, and also each group of students, give public lectures on this topic to create a large shared *repertory of cases*. The second learning activity is the nature itself of the traditional Architectural Studio as described by Donald A. Schön (1983; 1987), in which a project is constructed through an ongoing process of

[6] «The term infrastructure should not be construed in a reductive sense, should not be limited to technical artifacts, whether a canal, a road or a railway line, but rather should be conceived in a broad acceptation, as a support to the fast evolving processes of social reproduction currently underway» (Secchi, 2010, p. 13). «Equipment, roads, collective spaces and centralities, ecological networks, water system and sewage networks: for the term "infrastructure" we must go back to the original meaning, it is what allows and facilitates the continuance of social reproduction, i.e. the pursuit and development of production activities and social practices. So in this sense the concept of infrastructures is much wider than what is normally understood by the term. The infrastructure of a territory is made up of environment elements as well as roads, communal or provincial technical offices, professional organizations, the hospitals, schools, universities, railway and roads systems» (Viganò & Secchi, 2001, p. 119).

reflection-in-action with the people involved (in the school, students as architects and teachers as personal trainers) *and with the situation*. The design discussion process is a sequence of moves involving the students and the teachers, as well as the project drawings. No situation is like any other and it is not just the individual moves and the sequence or the scale of the moves that differ. The whole approach is open. During the group discussions in the classroom, teachers, students and tutors practice the design research to formulate intervention proposals.
The outcome of the second step is an A0 poster with a short report summarising the purpose and the features of the proposal. A proposal usually contains: main goals, general strategies of intervention (and sometimes the policies of intervention), territorial schemes on different scales, sketches of local and spatial solutions, basic rules or ways of intervention (Figure 3, 4 and 5). The outcome of the second step looks like a policy design output with a spatial dimension; it encompasses both action guidelines and a territorial scheme.

5. Results

What are the educational results obtained in three years of experimentation with the Design Studio having the characteristics described so far?
It should be kept in mind that the objective of *Urban Planning and Design Studio* is to introduce the student to a critical reading of the context, the identification of intervention priorities, the production of guidelines and territorial re-composition schemes.
In the course of the semester, the students have learned to:
- Identify, name and classify urban materials according to a physical-

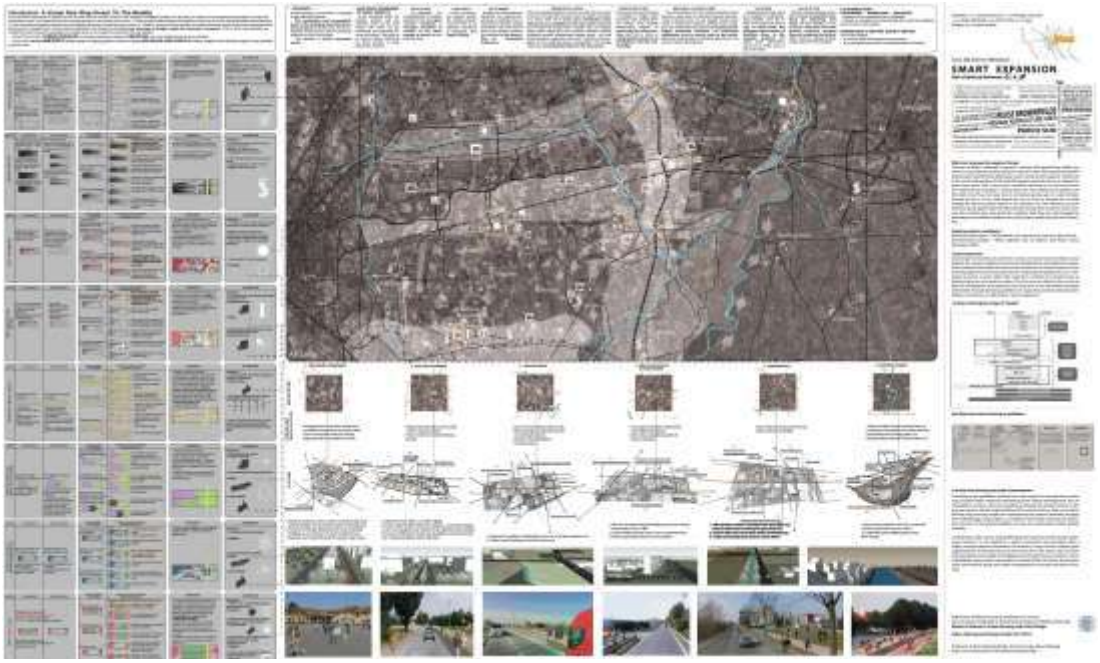

Figure 3. The Desing Studio program finish with the poster on re-composition schemes: proposal for from Treviglio to Milan.

morphological approach. Being the entry activity of the Design Studio, this becomes a way to accustom the students to observe the physical aspects of the territory, an activity that is able to promote the definition of viable large-scale initiatives and policies during the proposal stage;

- Conduct structured surveys. Walking, passing through and stopping in the area, and talking with the inhabitants, i.e., learning from the naked eye observation of the places and from listening with one's own ears (Secchi 1995; Scalvi 2000), enables the designer to acquire a sensitivity for and a knowledge of the real-world;
- Produce good descriptions of the allotted territory. The descriptions formulated by the students identify viable modalities to illustrate the transformations taking place in the territories, by taking into account a multiplicity of physical and social factors, some of them also tied with the economy and the history of the areas. In particular, great value is ascribed to the capacity to acquire skills and innovative modalities for the identification and representation of the population, and, in some cases, the capacity to analyse the rhythms that characterise specific places (Mareggi 2012). It is a description that can return a good selection of data and interpretations in relation to the short time available for its formulation;
- Collaborate with peers coming from different cultures and backgrounds. This result stems from the composition of the class on the one hand and from the explicit intention of the faculty to form groups composed of students of diversified geographic and professional origins;
- Identify the project not on the basis of a predetermined form and style (e.g., a planovolumetric masterplan, a spatial concept, an open space landscape project, an environmental network, an infrastructural scheme, a hierarchy of places and centralities), but rather by indentifying, case-by-case, what form is best suited to address a set of themes and problems. During the course of its five years of activity, the Design Studio has proposed the same territorial fields to the students and has obtained extremely different results, sometimes fairly elementary, sometimes highly advanced, but invariably original in generating project forms and action scales carefully calibrated as a function of the problems identified;
- Present the project through a complex logical organisation, communicated with the aid of posters that include maps, short descriptive texts, charts, and all sorts of graphic representation modalities as may be necessary. The poster format eliminates the possibility of using a close, linear narrative form, and encourages the students to produce open texts, veritable theme maps, that may serve as a support to the discussion, when talking with the teachers and in the final presentations;
- Acquire a capacity for dialogue through the project, and dialogue as tool to enable a project to evolve: within the groups, in their dealings with the teachers and discussants, and, in future, in their relations with organisations, offices and citizens.

It should be noted that in the first step the studies may be heterogeneous and differ to a considerable extent in terms of depth; while, at the proposal and intervention stage (second step), the design solutions leave unanswered questions to do with the

definition of the interventions and, only in rare instances, formulate detailed proposals of standards for the implementation of urban plans.

6. Conclusions

In concluding this report on a didactic experience, we deem it useful to set forth a few considerations that bear out the notion that the Design Studio is a place and a moment of learning by design.

1. The scientific rationality of the survey "by sample" is typical of design and planning disciplines and perfectly suited to architecture and city planning, two fields that find it hard to achieve a "neat" accumulation of knowledge and know-how. In 1989, architect and urban planner Giancarlo De Carlo acknowledged the difficulties encountered in «reading a large city in depth. But even this may be accomplished by considering that a large city is always made up of many different layers: it is not a monolithic city, but rather a blend of situations that are homogenous in themselves and more or less inhomogeneous with respect to one another. … Having identified the parts that, within an overall framework of non homogeneity, display a measure of homogeneity, it becomes possible to consider them in isolation, but only for the time it takes to study them and get to know them, and after that they must be returned to the whole as quickly as possible. I claim that this process is scientific... in as much as this is the way scientists proceed when they isolate a part to examine it more thoroughly, knowing full well that what they are looking at is not reality, but merely

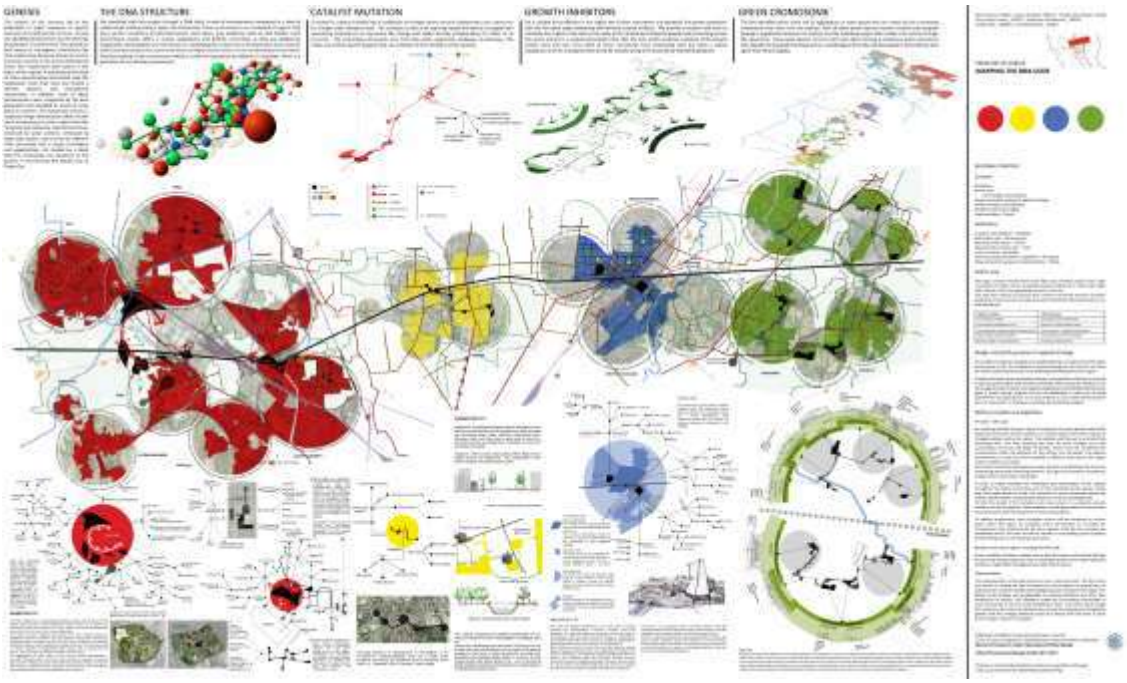

Figure 4. The Desing Studio program finish with the poster on re-composition schemes: proposal for from Rho to Agrate.

a provisional schematisation, which, nevertheless, is meaningful, in that it supplies information that is helpful in gaining an understanding of the whole of which the individual element is part » (De Carlo, 1989, p. 17).

2. The Design Studio is at once an equipped space for design review activities and the design review itself. It is at once the venue and the time both for a discussion of the territorial interpretations suggested and for the graphic formalisation of the proposed interventions; moreover, it is the place that, through gradual moves, identifies persuasive words to advocate the solutions that emerge during the course of the design process. The Design Studio is organised around groups composed of students acting professionals and teachers acting as personal trainers. In some instances, the skills of the international students with longstanding professional experience will reverse the roles of the participants, whereby, temporarily, the students will take on the role of trainers. It is a didactic approach that enables the students to learn from guided experiences, where the teacher behaves like a trainer, an approach that Donald A. Schön referred to as «educating the reflective practitioner» (Schön 1983). Thus the Design Studio is at once a teaching and a learning context.

3. Although the exercise performed by the students identifies two development steps, there is no clear-cut separation between the analytical-descriptive part and the part that puts forth the transformation proposal. In fact «describing means selecting according to some specific criteria which correspond to the reason of the description … [and] the description does not follow the change, but it helps to produce it» (Dematteis 1999, pp. 117-118) and to orient it towards specific direction. This approach does away with any conflict between urban design and planning and the need to reformulate the paradigms of the project for the city. Moreover, with this working method the unnecessary distinction between “planning to achieve” and “planning to avoid” is circumvented.

From spatial planning to socio-spatial activation

Emerging new planning approaches in post war housing estates in Flanders – the case Luchtbal

Luuk Boelens* & Tom Coppens**

Abstract

In this paper we reflect upon emerging planning practices based upon an actor-relational approach of planning in the case of Luchtbal Antwerp, in Belgium. This approach draws on recent insights in planning theory, grounded in a relational understanding of space, Latours actor-network theory and urban regime theory. It breaks with traditional government-centred forms of planning and stimulates the formation of associative governance networks around spatial issues; hence the label socio-spatial activation.

The case concerns a deprived high-rise social housing estate in the northern fringe of Antwerp. Since 2005 the city of Antwerp and the social housing company have been taken initiatives to restructure the area, with the goal to increase the social mix of the area and to attract new inhabitants. Although a considerable effort had been made to develop a physical masterplan for the area, the implementation of the plan was very weak.

The failure of traditional physical masterplanning in this area led to the development of new and innovative approaches. Instead of relying on traditional resource-intensive physical approaches, following a technical and government-centred approach, the city opted to develop an approach focused on identifying and activating socio-spatial networks in and around the area.

In this paper we will discuss the context of the case, experiences with this actor-relational approach and its preliminary outcomes. This paper is written from an insiders' perspective of two practitioners. Whereas Coppens has been involved as the project manager within the administration of the city of Antwerp, Boelens has been involved as a planning consultant for the city of Antwerp.

Keywords: Actor-relational planning, social housing restructuring, socio-spatial activation

Introduction

The revitalization of post war social housing estates has been a major concern for Belgian cities over the last 20 years, as in many other European cities. During the heydays of the European welfare state, many social housing estates have been built in reaction to the steep increase in housing demand, caused by a combination of a booming demography, economy and the need to sanitize the existing older inner city housing stock. Once attractive places to live in, many of these areas have changed for the worse. General impoverishment, ethnic tensions, high levels of unemployment, crime, social exclusion and physical decay have turned these areas into the most problematic neighborhoods in the European cities (Van Beckhoven and van Kempen, 2006). Already 15 years ago Peter Hall (Hall 1997) identified four typical interrelated problems regarding post war housing estates, including physical, social, amenity and economic problems. The physical problems not only relate to building technology failures, but also to the planning policies of the post war era. Planned as dormitory areas, post war housing estates often lack qualitative amenities and - due to the prevailing CIAM zoning models at the time - a local economic base providing job opportunities and local private services. Furthermore social problems have accumulated because of the attraction of the most marginalized social groups to these areas over time. The global migration processes forced many newcomers in European countries to settle in the least wanted parts of the cities, such as the post war housing estates, resulting in significant concentrations of ethnic minorities. That is what Doug Saunders (2010) recently called ‘Arrival Cities’, clusters of urban newcomers, struggling to survive and hoping to establish a new social and economic live; and if they do so moving out, creating room for the next wave of migrants and leaving the most disadvantaged behind. This concentration of the poor and hopeless people is further related with high levels of crime, and low career prospects for the younger. It has triggered social tensions and unrest over the years in Europe’s major cities, as demonstrated for instance by the 2005 riots in the Paris suburbs, and the 2011 riots in London.

Unlike neighboring countries such as the Netherlands, France or the UK, post war housing policies in Belgium however, and especially in the Flemish speaking part, prevented large concentrations of post war social housing estates. The number of social rental dwellings per 1000 inhabitants is for instance 32 units, which is low compared to the UK (80 units), France (86.5 units) and the Netherlands (138 units) (Pittini and Laino 2012). Housing policies over the last century in Flanders have been primarily oriented to the acquisition of private property on individual parcels, and have inherently supported a process of suburbanization (De Decker and others 2005), avoiding strong concentrations and high densities of social houses.

Nevertheless, some of the larger cities such as Ghent and Antwerp, and some regional cities such as Leuven or Genk do have significant concentrations of social housing estates, facing the same challenges as in many European cities. One of these neighborhoods is Luchtbal Antwerp.

Introducing Luchtbal - From model city to problem area

Luchtbal is an post war social housing area with about 2500 families in the northern fringe of the city of Antwerp, bordered by large infrastructures such as the High speed train railroad and the ring road in the East, the Albert Canal in the south, the Noorderlaan and the port area in the west, and the A12 highway in the North (Figure 1). The social housing company "Woonhaven" (which is a fusion of MGH and Huisvesting, see below) owns about 90% of the housing stock, whereas 10% stock has been sold in the past to private owners, mainly the renters of these houses. Situated on a water-sick soil of a former polder landscape, the area was uncultivated until the 19th century. However, when in the early 20th century the port of Antwerp extended to the north, the water-sick northern polder area was reclaimed and sold to the Catholic housing company *Maatschappij voor Goedkope Huisvesting* (MGH) to house the dockers working in the port. Following the principles of the garden city, about 350 single family houses had been constructed in the 1920's, together with public facilities such as a school, a church and outdoor sport facilities. After the second World War, another socialistic housing company - *NV Huisvesting* - developed new houses, mostly apartments, to meet the fast growing demand resulting from the postwar economic and demographic growth, and the need for new laborers in the harbor-area. *Hugo van Kuyck*, who had studied at Yale during the war and was very much inspired by CIAM and post-war America car-based urban principles, delivered the extension plan. The plan consisted out of largely standardized, high-rise housing ensembles in an open plan layout with large green collective spaces, and amenities such as schools, sport infrastructure and shopping facilities along the Noorderlaan. At the time the apartments of the high rise buildings were considered very modern and convenient, certainly when compared with the 19th century dens and low quality housing stock in the inner city of Antwerp. Therefore, Luchtbal with its spacious and modern apartments was considered as a premium residential location in the 60ties, attracting not only workers from the port area, but also middle class families from Antwerp.

However, over the years, the reputation of Luchtbal dramatically changed from model city to an unpopular area. The relation between the workforce of Luchtbal and the port area gradually faded away, as the workers retired and the harbor area extended towards the Sea and on the leftbank of the Scheldt. As the first generation inhabitants aged, died or moved away, immigrants replaced the inhabitants. Although Luchtbal can't be regarded an 'Arrival

City' while it's tenants need to live in Belgium for several years to be eligible for social housing, the one-side supply of social dwellings and the social housing allocation policy resulted in a constant import of relatively poor families in the area, and a fast and dramatic change in the social-economic and ethnic composition of the area over the last 20 years. The once almost mono-ethnic neighborhood changed rapidly into a diverse cultural neighborhood with about 47% of the population having its roots in various parts of the world, mainly North Africa and central Africa, and to a lesser extend from Asia and east Europe (Stad Antwerpen 2012). As a result social tensions in the neighborhood have increased, as well as the physical examples of decay and unemployment towards 18% at the time (Stad Antwerpen 2012). Given the demographic boom of immigrant families in the area, there is fear for a further spiral of negative decline (Sociale Planning 2009).

The failure of the masterplan Luchtbal

Although international scholars have stressed time and again the need for a long term, local embedded and integrated physical, economic, social and cultural approach in these areas, and have stressed that physical improvements alone are unsustainable helping to solve the problem (Christianse et al, 1993, Parkinson 1998, Hall 1997, Musterd et al. 1999, Andersen 2001), until now basically two main strategies have been applied by the Flemish government, the municipal governments and the social housing companies. The first strategy has been the physical regeneration of these housing areas. Many of the houses from the interbellum and the post war era no longer meet modern comfort, technical and safety standards. The necessary renovation of the housing stock mostly not only aims to increase housing comfort, but is also used as an opportunity to change the mix and typology of dwellings and to invest in the public domain and additional amenities.

The second strategy has been "social mixing" (Loopmans and others 2010; Decker and Pannecoucke 2004). "Social mixing" refers to the idea that a change in the social composition of such a neighborhood could reduce the concentration and accumulation of social and economic problems and contribute to the liveability of social housing estates. The previous Flemish decree on social rental dwellings (or "huurbesluit" of 20 Oktober 2000), made an explicit link between livability and social composition, stating that *the care for liveability might require to aim for a social mix*. A social mix strategy thus tries to prevent concentrations of lower incomes, elderly people or ethnic groups, meaning in practice for many social housing estates the import of middle class, 'white families' into downrun areas. And although it must be noted that Flemish housing policy from 2007 gradually started to abandon the social mix matra in the preparation of the new Flemish decree on social housing

(Heylen and others 2007), until now municipal governments still stick severely to the “social mix” strategy.

As such, the Masterplan Luchtbal, which De Nijl Architecten put up during 2005-2007 in assignment of the social housing company, the city of Antwerp and the Flemish agency for social housing, still consisted of both strategies mentioned before (Figure 2). On the one hand the masterplan opted for the regeneration of the existing housing stock, including the improvement of the existing public realm, the restoration of the spatial coherence of unfinished Van Kuyck masterplan, and the concentration the amenities in new so-called ‘centralities’ according to the present needs. On the other hand the masterplan opted also for an improved social mix by densifying existing open areas, especially along the Noorderlaan, with housing for new middle and high-income groups (De Nijl Architecten 2007). However due to the lack of a sound complementary social strategy, initially the masterplan was not fully supported by the city and the housing company. Therefore the social department of the city of Antwerp decided to make up their own strategy based on some interviews with several inhabitants and stakeholders. It resulted in an action plan of twenty ‘actionpoints’ in the social-cultural and spatial realm, and on the short and middle long term (Sociale Planning. 2009). But again, it didn’t consisted of an integrated physical, economic, social and cultural approach, while at the same time all the actions where very much dependent on the investment willingness of the Antwerp municipality.

Therefore, and after the masterplan together with the social action plan was approved, additional surveys in 2010 with regard to the expected traffic noise and market conditions made clear that the proposed densifications would hardly attract the intended target groups. The bad reputation of the area, its spatial isolation, its exposition to severe noise loads from large infrastructure and the improper potentials of the densification areas for new attractive housing typologies, made the area hardly competitive in reference to housing projects elsewhere in Antwerp. Even scarce new cheap housing projects and apartments, developed by the city, and put on sale below construction costs, are currently hardly sold. Moreover the rigid zoning scheme – which characterizes not only the current layout, but also the New Masterplan - makes the area hardly attractive for organic, self-organized, co-evolving urban regeneration processes. For this reason it became doubtful whether the strategy of ‘social mixing by densification’ would actually result in the desired social uplift of the neighborhood and its residents. Perhaps it would result into a subsequent internal social and ethnic segregation and a potential further economic impoverishment of the area, as Dutch research had shown in similar restructuring projects of post war estates (Kleinhans 2005; Ouwehand and Davis 2004). Moreover, big infrastructure projects in the direct surroundings of the neighborhood result in a growing social unrest, encouraging new resistance- and

actiongroups with new interests and ambitions. With this new information, the Masterplan Luchtbal got into a deadlock. Despite the fact that some parts of the masterplan were indeed implemented, the general strategy of "mixing by densifying" was obviously failing.

It was felt that the area needed a new, integrating, but open and communal investment strategy, not so much based on a municipal plan or municipal subsidies, but on a co-evolutionary strategy between the various public, civic and business stakeholders in and around the area from the bottom-up. And although Doug Sanders (Saunders, 2012) claimed that such an embedded, organic strategy would only be feasible when one could get rid of the rigid high rise post war housing areas all together, the challenge would be to implement such a bottom-up, organic approach within the existing layout. Otherwise physical, municipal, one-sided improvements would still precondition such a strategy and would need massive financial means. Therefore the main question was: would it be possible to develop embedded, organic, co-evolutionary planning strategies in post-war housing areas to improve resilient living conditions in as well a social, economic, cultural and physical sense? How would such a planning look like and in which way would it be different to existing strategies?

Actor-relational approaches

That kind of planning strategy is very much inspired by the poststructuralists ideas on geography (Thrift 1999, Graham and Marvin 2001, Belsey 2002, De Landa 2006, Murdoch 2006), in which space is not so much seen as a ‘container’, a prefabricated décor or platform upon which social, economic and/or cultural activities appear, but as an actor itself capable of influencing and stirring other actors, as that it is stirred and influenced by those actors and others spaces itself. Space is therefore not closed or contained in a pre-given three dimensionality, but it is made of relations; or in other words it is relational. The possible spatial developments of Luchtbal and its social-cultural practices are in this respect very much intertwined, as that they are related to general economic developments and institutional changes within and around the neighborhood. Moreover, especially over here it is connected to the increasing transnational settings of the people and communities living in the neighborhood (Appadurai 1996, Anderson 1998). Luchtbal, as space in general, could therefore be regarded a multiplicity, that is made of differing, spatial practices, (degrees of) identification and forms of belonging. Especially in cases like Luchtbal there could be acute struggles over who’s reading on space should take priority, leading to new controversies and/or riots. But, if intertwined, it could possibly also lead to new ‘openings’, innovations and forms of spatial practices. In David Harvey’s terms (Harvey, 1996) these new practices could

possibly evolve into ‘temporarily permanences’, meaning that they only stabilize provisionally, and need to be made and remade by various actors continually. Moreover in our differentiated and volatile society several of such continually changing ‘temporarily permanences’ exist next to each other - autonomously or interrelated - developing dynamically towards new, surprising and often unexpected (temporarily, but if possible resilient) urban assemblages (Farias & Bender 2010).

That kind of spatial planning goes beyond the plan, and takes the ongoing complexities and non-linearities of present day networked societies serious (Hillier 2007, Boelens 2009, De Roo 2010, De Roo/Boelens 2012). It is always focused on ‘becoming’, not on ‘how to get to a prefixed ideal situation’ (that is in essence ‘ the plan’). Its main drive is focused on facilitating a translation towards (temporarily) innovative, more resilient assemblages in space, embedded in specific local settings, but with an open eye to changing, reciprocal adaptive circumstances. That kind of planning goes beyond a simple engagement with new objects of analysis or with a broader orientation on various social, economic, morphological or political landscapes of concern, as that it goes beyond simple action research (Coppens 2011) or participatory, collaborative planning (Healey 1997). Instead it refocuses on, as that it takes part in the actual actor-networking between the various interests and space itself.

In this respect, that kind of actor-relational planning comes very near to the Actor-Network-Theory (ANT) of Callon (1986), Law (2004) and Latour (2005). Like ANT it is no longer focused on the sociology of the social, or the ‘planology’ of planning, but it goes back to very core of engaged spatial planning itself; that is the best reciprocal adaption of space and society, such for the sake of society (Van Veen 1973). However there is no such thing as ***a*** society (anymore), nor ***one*** prefixed idea of space. There are several societies and various interconnections to space, and therefore various spaces, evolving autonomously, next to or at its best intertwined to each other. Moreover, we have got business societies with a principal focus on money making in last instance, public societies with their representational democratic principles, institutional means, laws and regulations and focus on periodic (re)election, as that we have got civic societies with their struggles for survival, daily experiences, growing (multi-media) self-organizations around specific, common interests and/or civil disobediences. Each of these societies identifies itself to space differently, showing various forms or ambitions of belonging.

Therefore this kind of planning goes also beyond the restrictive confines of governments (Boelens 2009, Boonstra/Boelens 2011). It is not so much focused on collaboration or coproduction around specific issues, objectives or ambitions of representative governments, from the inside-out, such for the sake of the public interest in general. Instead it is focused on

co-evolution of the various forms of spatial belonging mentioned above, from the outside-in. While it is convinced that this kind of coevolution between leading actors of the business, public and civic society, in reference to the specific institutional setting and local situatedness, promises the most sustainable, innovative and resilient cross-overs. These kinds of co-evolutions evolve along the four phases of translation of ANT: problematization-interessement-enrolment-mobilization (Callon 1986), or the four collectives wonderment-consultation-hierarchization-institution (Latour 2004). However, while ANT particularly proves its strength in retrospect, and planning is mainly a prospective operation, several adjustments of ANT to an Actor-Relational-Approach (ARA) are introduced to deliver a suitable strategy for spatial planning (Boelens 2012).

One of the first is the interpretation of ANT's notion of 'all (heterogeneous) actors are equal'. Although ARA takes non-human actors very seriously, while it is convinced that collective actions are not only dependent on the interests and ambitions of humans, but also on the specific conditions of the soil, the morphology or the characteristics of the build environment, existing plans and the like; it is also convinced that in prospect these non-humans are always meditated by humans in some way or another. In our case it would mean that the specific morphological, social, economic characteristics of post-war housing areas, including the specific layout of the garden city and high-rise Luchtbal, condition the specific possibilities and even changes of co-evolutionary planning over here. However these characteristics (their flexibility to adapt, stay foot or change) are highly mediated by the respective home-owners, spokespersons of the housing corporations, municipality, architectural organizations, inhabitants etc. To coevolve with these non-human actors, would therefore mean coevolving with those intermediaries.

About the normative grid of ANT: although Latour (2004) has highly disputed the normative characteristics of ANT, Callon (2009) and Venturini (2010) recently produced the idea of hybrid forums, bringing opposing forms of delegative democracy and dialogical democracy together in order to constitute collective decisions, without excluding the continuous exploration of possible worlds and new identities beyond those decisions. But while Venturini and Callon remain very vague what this would mean exactly and seem to be convinced it would be possible within the existing realms of representative democracy, it remains unclear how these ideas should be implemented. How could representative delegates, locked-in by the path dependencies of their delegative powers, still explore all the identities en possible innovations beyond those restrictive confines? In this sense representation, or more specific representative democracy – on which planning relies heavily – is already strongly and widely

disputed (Harvey 1989, Cohen & Rogers 1992, Gans 2003, Hirst 2001, Swyngedouw 2004, Purcell 2008). Representative democracy would widen an already enormous gap between the representative democratic bastion and the daily lives of citizens and businesses, mediated through a growing bureaucracy. The middle of the road, 'one-size-fits all' policies of representative democracies wouldn't be no longer adequate for a growing pluralism in present day society. Furthermore representative democracies would always relate to a nice, but precisely bounded, organizational hierarchical stratified piece of land, while in present day societies many (spatial) questions cut right across different levels or just fall in-between. In the last decades many alternatives have been sketched to deal with those issues in a better way. But here we take the stance that a more associative democracy would fit in with the non-linear and co-evolutionary approaches described before, while associationalists plea for a more direct self-organized (in)formal governance, promoting an organic representation of currently underrepresented interests, and thus encouraging the formation of pluralists, independent associations around specific interests.

Although associative democracies could occur (not instead, but) next to representative democracies, for planners it would mean to move more and more beyond representative governments, and to serve emerging self-organizing (if necessary multi-level) actor-networks around specific issues from the outside-in. It would be consistent with the pleas of Elinor Ostrom (1990) with regard to common pool resources management and the collective self-governance, in which she identified eight design principles. But that would also mean that planners would become less spatial driven, but more and more issue and involved actor-network driven. Nevertheless, their 'spatial instruments' – their design researches, spatial explorations, plans, graphs and the like – would become important tools (instead of means or objects) helping to discover new possibilities, innovations an crossovers in those co-evolving assemblages. Following Deleuze & Guattari (1980) and Jean Hillier's (2011) 'strategic navigation towards a speculative future', at least four alternative kinds of decisive planning documents are distinguished in its proceedings, intended to stimulate so-called 'tipping points' in the formation of new alliances (Sanders 2009, pp. 166-179):

- tracing documents, exploring the potentials of the site or of the planning challenge involved;
- mapping documents, tempting an educated matchmaking between the potentials traced and possible actor-networks;
- diagram documents, following the transformations of actor-networks and their fields of influence during the proceedings and

- agency documents, the potentially more binding and passive elements for actor-networks, such as laws, regulations, contracts, arrangements, etc.

Each of these documents plays an important role in each of the aforementioned translation phases of possible co-evolving networks.

Applying ARA to Luchtbal.

Bearing these ideas in mind, let's go back to the planning practice of Luchtbal. Faced by the deadlock of the master plan, we engaged the municipality and housing company to explore new approaches, by which the inhabitants themselves would be activated to (self)organize their living environment, if necessary or possible with help of other stakeholders, like the government, (new) entrepreneurs in and around the area etc. Urban Unlimited executed this program in cooperation with the Flemish consultancy firm Omgeving, in assignment of AG Stadsplanning Antwerp, the Flemish Government and the housing cooperation Woonhaven, with help of the Universities of Leuven and Antwerp. Since November 2011 they applied the aforementioned new relational co-evolutionary ideas to an experimental planning strategy for Luchtbal Antwerp. Until now it has consisted of four phases, navigating through the complexity and multiplicity of Luchtbal

- tracing the unique selling points of Luchtbal by design research
- exploring the needs and ambitions of the civic, business and public society within and round Luchtbal;
- roundtables with regard to first ideas on communal, coevolving opportunities based on those (mono-, bi- or trilateral talks)
- ideas for a communal investment strategy in reference to that.

Tracing Unique selling points

First we executed a short inquiry into the Unique Selling Points (USP's) of Luchtbal. On first sight, Luchtbal is a generic social housing estate, following the rigid CIAM-principles. However, going beyond the clichés of post war housing estates, we searched for elements that differentiated Luchtbal from its look-alikes. To do this, we used various interpretative methods of analysis, such as mapping and ethnographic methods, each of them revealing specific assets and opportunities of the area, trying to understand Luchtbal from an insider's perspective. In our analysis, we have involved Master students of the Master Urban and strategic planning (MAUSP) of the KU Leuven in the analysis, as part of their curriculum.

Because of the international orientation of the Masterprogram, some students came from the East and North Africa. This helped in overcoming cultural and language barriers. And from these embedded analysis we eventually found four unique selling points that provide opportunities for the near and long future, including a) the relation with the port, b) public space, c) the mix of public facilities and d) finally the relation with large infrastructures.

Relation with the Port

Pivotal in the history of Luchtbal has been its relation to the port and the port-related industries. In fact, Luchtbal owns its existence to the port. The sand dug out for the enlargement of the port and the construction of the new docks in the early 20th century was used to reclaim the water-sick land of the area. Moreover, the large scale and labor-intensive Fordistic port production activities of the post war area provided jobs for the new residents in the early history of Luchtbal. One of the main employers has been for instance the plant of General Motors, sited along the Noorderlaan, and one of the largest car constructors and employers in post war Belgium. However, over time, the link between the social housing estate and the production activities gradually weakened. When the global crisis of the Fordistic mode of production hit the port area, more and more industries closed their doors. As the Noorderlaan is a main traffic road within the Antwerp agglomeration for car commuters, new large scaled commercial activities, large facilities such as the fire station, sports retail, car retail and the biggest multiplex cinema of Western Europe replaced the production halls. Next to that new, temporally and informal uses are gradually taking up the new voids. But these facilities attracted not so much employment for the old Luchtbal dockers, but attracted large crowds, providing the area with potential visitors from all over the region, even from across the Flemish borders. Opportunities exist for the retail and construction companies at the former port plots to cooperate with the planned technical campus in the area, and to provide a link between education, innovation and practice. The lost link between Luchtbal and the port could therefore be reconnected in different ways, in finding both new employment and education and new relations with visitors and customers. Renewed alliances at the local level between inhabitants of Luchtbal and investors in the port might result in a new dynamic for the larger area. Also, the vast amount of unused space along the Noorderlaan might accommodate new informal economic activities and entrepreneurial opportunities for the residents of Luchtbal.

Public Space

A second important selling point is the vast amount of green spaces in Luchtbal. Designed as a modernist city, Luchtbal still has many open - though formal - green spaces. It is further connected to a larger green corridor along the ring Road relating the inner city with its

hinterland. Despite the abundance of open areas, the formal public space seems however to be underused and hardly appropriated. Although some 5500 inhabitants live in Luchtbal, there is hardly any public outdoor life. In the history of the Luchtbal, open spaces within the northern garden city played an important role in the social and spatial fabric of the neighborhood. Semi-public inner yards were used for recreational uses, and the semi-private gardens created a collective good for its inhabitants. The larger open area of the Schijn was used for agriculture for some time. Different sport, social and cultural clubs rooted in the area, organizing festivals and markets up until the seventies. But over time, the uses diminished as clubs disappeared and as the population shifted and ethnic diversity increased. Our analysis showed a very specific use for different ethnic and age groups, mostly outside the formal public spaces of Luchtbal. (see Figure 3). A renewed use or a new collective appropriation of public space in the area again could initiate a new dynamic in Luchtbal. The immigrants in Luchtbal don't tend to apply and pay for traditional Flemish club memberships, but they are interested in informal or free activities concerning urban gardening, exotic food markets and sport activities specifically for women. These kind of activities fit well within the original spatial structure of Luchtbal as a kind of 'garden city'.

Mix of public facilities

Third, unlike many other social housing estates in Western Europe, there is a large supply of public facilities in the area. There are many schools in the neighborhood, including a sport school and a swimming school, a community center, a cultural center, a child daycare center, a home for the elderly, a sports hall, and sport fields. The city is also investing in additional public facilities such as a large playground, a small sports hall and a youth center. From the analysis, we noticed that many of the existing public facilities have users outside Luchtbal, and that users from Luchtbal do not always make intensive use of the facilities, such as the cultural centre. On the other hand, contrary to the abundance of public facilities, there is a lack of commercial private facilities, certainly for daily needs. There is a large discrepancy between the large retail facilities at car commuters, and the lack of shopping facilities in the area, oriented at the residents themselves. Nevertheless, the abundance of public facilities can be seen as a specific asset for Luchtbal. Luchtbal provides a high level of cultural and sports programs and physical space for a large city audience, thereby escaping the isolation or possible ghettoization of the area. At the moment it provides a destination for visitors outside Luchtbal, but the actual audience doesn't mix with the Luchtbal people. It is a challenge to match the programs to the local demand without losing the city audience, vice

versa. Some of the public facilities could provide supra-local services, entangled with the outside attraction and the inside embeddedness of the area.

Good connections

Last, as already mentioned, Luchtbal is surrounded by large infrastructures: the Noorderlaan in the west, the A12 in the North, the ring road and main railroads in the east, and the Albert Canal in the South. Although these large infrastructures decrease in many ways the environmental qualities of Luchtbal, they also provide many opportunities. The main infrastructures make Luchtbal highly accessible by various modes of transport: it has two railway stations, it is a main entrance point of the city and in the future, a new tram connection with the city and the northern village of Eekeren will improve these conditions even further. However, in relation with the Noorderlaan the car has always been the main mode of transport. Worth mentioning is the fact that the plan of architect *van Kuyck* contained one of the first car-oriented shopping centers of Belgium along the Noorderlaan. But within Luchtbal, an over-abundance of asphalt is apparent; while at present an increasing number of inhabitants do not even own a car. Next to that, Luchtbal is also situated near the nature reserve of *Oude Landen*, providing a unique ecological background to the intense accessibility.

These USP's of Luchtbal provided us with additional information about the factors of importance (the so-called non-human actors), which could play a decisive role in our exploration towards possible new embedded innovative urban assemblages, e.g. actor-networks. But are these USP's also recognized by the inhabitants and other (mediated) human actors themselves? Therefore we proceeded to the interests, needs and ambitions of those human actors in our quest through complexity.

Exploring the needs of various societies

As mentioned before, here we distinguish the needs, interests and ambitions of the civic, business and public communities, while – differentiated in their primordial drives - we are convinced they could be complementary and co-evolve beyond more or less one-sided operations towards more resilient alliances.

Civic Society

Firstly the interests of the residents of Luchtbal themselves; that is those of the civic societies within the area. They are multiple and highly divers. And since the introduction of participatory, communicative and collaborative planning approaches, these interests, needs

and ambitions have been put foremost on the agenda, trying to stimulate inclusionary plans. As such, these ideas have also guided the masterplan Luchtbal mentioned before, including other plans in the wake, like housing renovation programs, plans for new playgrounds, the neighborhood traffic circulation plan etc. Nevertheless – and although they have climbed Sherry Arnsteins (Arnstein, 1969) 'Ladder of Participation' profoundly - these participatory, communicative and collaborative approaches still receive persistent critiques. They would be time consuming and only result in another *Diktatur des Sitzfleiches* (Weinrich 1987, Schaap & Van Twist 1992, Frissen 2007). They would be foremost focused on process and hardly on content (Wigmans 1982, V.d. Cammen 1995, Bakker et al. 2006), and would not genuinely improve the quality of planning decisions that matter (Innes & Booher 2000). They would only meet a specific kind of citizens with time and know how (Flyberg 1996, De Graaf 2007, Van der Arend 2008) and therefore evolve in a kind of 'public support machine' (Pløger 2000, Hendriks & Tops 2001, Woltjer 2002). Therefore they would be indeed procedural, thematic and spatial inclusive, framing spatial developments in the public path dependencies of governments, and excluding novel, innovative and self-organizing activities in potentia (Boonstra and Boelens 2011). And precisely some of those features also occurred with regard to the spatial planning in Luchtbal. Experiencing and attending some of the participation meetings with regard to upcoming venues, revitalization programs, the neighborhood circulation plans etc., it became very much clear they attracted only the native, Dutch speaking, somewhat elderly residents, because they would have the time and preparedness for long lasting participatory processes and familiar with the options, rules and institutional (im)possibilities of the planning conditions in question.

Therefore we had to invent alternative ways to get a more genuine picture of the residential needs, interest and ambitions, of the growing immigrant population too, including their possible already strong self-organizing networks. For that purpose, in cooperation with the social faculty of the University of Antwerp (UA), we organized a half-our long door-to-door inquiry among some 800 random households (of the 2500 in total), with regard to a) their housing history and possible relocation ambitions, b) their appreciation of the neighborhood on several aspects, c) their functional, social and economic networks within and around the area and d) ideas about a possible future investment program (financial, in time, experience, physical, organizational) and their willingness to contribute themselves. It was executed by 17 bachelor-students (second year) of the Faculty of Social & Political Sciences of the UA. In addition, and in cooperation with the Catholic University Leuven (KU-Leuven), Faculty of Architecture, Urbanism and Spatial Planning, we organized with some 15 (research)master students 5-10 minutes long, so-called location-inquiries to by-passers at the small shopping

center in Luchtbal, the central pub, library, cultural center, elderly center, kindergarten, schools, mosque, church and the like. Eventually they got a response of some 250 inquiries.

Although the response with some 125 door-to-door inquiries was a little bit low (even compared to other surveys in immigrant neighborhoods), together with the location-inquiries and the periodic city-wide digital inquiries of the municipality we got a more or less accurate idea of the opinions, needs and ambitions of the residents themselves. It confirmed the notion that Luchtbal isn't an arrival neighborhood (see Figure 4). Moreover, overall, residents liked to live in Luchtbal, and responded that it was a nice, green and quiet neighborhood, although it is surrounded by main and massively used infrastructures. There are hardly any relocation ambitions on short and mid long terms because of the neighborhood itself; if there are any, reference is mainly made to the existing small apartments and the ambitions to live in bigger houses due to the number of family members. However one wouldn't recommend family, friends or other acquaintances to come and live in Luchtbal also (see Figure 5). One is worried about a possible negative spiral of the neighborhood. Here we can distinguish three populations camps: natives (mainly living in the garden city part) who are more or less intolerant to immigrants, immigrants (mainly living in the high rise part of Luchtbal) who have the perception that they are discriminated, and another group - natives and immigrants – (luckily still the vast majority throughout the neighborhood) who experience a lack of good communication among each other and look for opportunities for a better dialogue to live together. Surprisingly (in reference to the large number of transnational communities), the residents are also highly focused on the neighborhood itself; only with regard to work, shopping and other non-daily activities they orient themselves to (the greater region of) Antwerp as a whole (see Figure 6). Accordingly, concerning a possible future investment program, the respondents are mainly focused on improving the public, communal space; firstly (18 to 21%) with regard to better and more appropriate shops in reference tot the changing population and needs, and furthermore in better sport facilities (7%), economic activities and small business opportunities (6%), activities for the elderly, young people (5%) and investments in the maintenance and security of the public domain (4%) (see Figure 7). Approximately one third of the respondents would be willing to contribute (their spare time, experience and knowledge) to this program.

Business Community

Parallel to these inquiries, we explored the ambitions of leading actors in the business communities as well. It was executed by Urban Unlimited, firstly through an extensive actor-analysis on internet (investigating year reports, investment strategies, news items etc. on possible involved actors within and around Luchtbal in reference to the unique selling points

of the area) and secondly in primordial bilateral interviews with some twenty of those leading actors. From these explorations we concluded that there were hardly any leading business actors within the neighborhood itself; leading defined as those business actors who are willing and also able to (financially) invest in their physical, business, socio-cultural etc. environment in order to benefit from it by itself. Nevertheless we also concluded that in the (direct) surroundings of the neighborhood, several leading actors in the business society could be identified, which could possibly be involved in the investment strategy for Luchtbal at the right time and/or under precise conditions. Although the project was restricted by the municipality by the main infrastructures mentioned before, we decided to open up and extend the assignment beyond those borders (see Figure 8). Here we interviewed the directors of the St. Jozef schools and DAG/WAG organizations; two main actors in the broader Antwerp-region to organize education and after-school work and internal housing for physical en mental disabled people. They opted for an appropriate extension of their infrastructure, together with new amenities for their promising candidates for the Paralympics. Next we talked to the director of the International Seamen Hotel who had to move his hotel to the outskirts of Luchtbal en was looking for new promising arrangements with surrounding actors. Moreover we spoke with representatives of Kinepolis (the biggest multiplex cinema in Western Europe) who wanted to extend its program towards a 24-hours activity confronted with a downfall of traditional cinema visitors; or with those of Decathlon (a major European retailer of sportarticles), tempting to extend its interest in outdoor sport activities, also as a try-out zone for their products. We talked with the CEO of BRICO-Plan It (a major retailer in construction materials and garden supplies) to discuss if they were interested to invest in the greeneries of Luchtbal; with two main car retailers in Antwerp (Beerens-Audi and Jorssen-BMW) who wanted to revitalize the old, empty GM factory building at the Noorderlaan into a main leisure, car-selling center – Autostad – also as a new training and internship possibility for young, unemployed people from Luchtbal. We have discussed with the four directors of the secondary technical profession schools in Antwerp – who wanted to concentrate their activities in a Polytechnical campus in the north of Luchtbal – the possibility to erect new incubators, as well as the co-use of necessary amenities. We have talked with the regional director of the NMBS (the Belgian Railways) about the possibilities to extend and rearrange their two stations and station-areas nearby, according to a possible new investment program for Luchtbal. Etc.

Nevertheless, already during these open, primordial investigating talks it became clear that traditional bureaucratic, political ideas about predefined, restrictive planning blocked some of these discussions; partly because they were surpassed and partly of non-transparent internal

deliberations. These internal public path dependencies, or better still ‘lock-ins’, need to be overcome in order to stimulate a real open and innovative actor-relational progress.

Public Society

Therefore and in the third place, we organized several brainstorms with the main servants and officials of the involved departments of the public society; that is with Housing, the Economic and Shopping department, Mobility & Infrastructure, Youth & Education and the Public Domain. The main objective of these brainstorms was to inform and to be informed. Secondly we opted for an open mind, discussing possible new and/or innovative solutions. As such these brainstorms seemed to work. Especially with regard to the public domain and the youth & education workshop new ideas evolved with regard to a so-called ‘green Luchtbal carpet’, including a varied involved management of the different open areas depending on the social ‘situatedness’ of these areas within the neighborhood, block-wise urban farming experiments, community schools, additional sporting facilities and a more efficient reciprocal co-use of the available amenity spaces, during the day and week. The same occurred within the economic and shopping workshop, with regard to for instance the realization of a containerpark for start-ups and incubators, new financial models for self-producing neighborhood retail, Mediterranean markets, repair stores in combination with a new and already existing recycling shop, additional services around the planned bicycle highway etc. Next to that extra emphasis was put on an integrated event programming, in combination with a geared new image branding of the neighborhood. Nevertheless, especially with regard to the Mobility & Infrastructure Department main blockades became apparent; particularly with regard to main infrastructure projects, induced by the Flemish Government and De Lijn (The Flemish Public Transport Organization), like the Oosterweel connection and Brabo2 (reconstruction of the Noorderlaan). But also with regard to the domestic neighborhood circulation plan, which is in fact the responsibility of the northern district of Antwerp. Apparently it is hard for stratified governments and straightforward functionalistic and technical departments to deal with a more open, volatile and therefore non-linear process. However, while these infrastructures are conditional for the changes discussed, we needed to find a new balance between more objective and more intersubjective planning approaches.

Opportunity Maps and Roundtables around promising features

Nonetheless, at that moment we managed to get a sufficient insight in the actor-network possibilities, constraints, challenges and threatening deadlocks for ‘temporarily and/or resilient Luchtbal assemblages’. There is a real threat for a further isolation of the neighborhood as a result of the so-called ‘urban spine’, of the Structureplan of Antwerp,

including its adjoining revitalization of the Noorderlaan (Brabo 2- project), Oosterweel connection, restrictive planning measures in Luchtbal its direct surroundings and the like. There could occur an ongoing negative spiral of the neighborhood, due to its bad image, the increasing concentration of the disadvantaged, low opportunities for work, non-adaptive public spaces, growing immigrant youth, acute struggles for belonging and riots in space. But it became also apparent, that there were several changes for new cross-overs, new innovations and embedded openings for resilient spatial alliances between several heterogeneous actors; improving the spatial conditions of Luchtbal not only for the inhabitants themselves, but also for visitors and new investors. We listed some 50 of those appealing practices, differentiated by the short, medium and long term. Provisionally we clustered some of those most relational and promising practices within three opportunity maps with regard to sport/leisure, relational green spaces and new adaptive challenges for work, retail and centrum facilities.

The sport/leisure opportunity map (Figure 9) concentrated around the existing, but down run athletic course in the South of Luchtbal, with relational connections to the Sports retailer Decathlon, the Multiplex Theater Kinepolis, the primary School Sportomundo, the Luchtbal Theater and the International Seaman House. Intention was to:

Short term (2012-2015)

- Revitalize and upgrade the athletic course for multipurpose sportactivities for the (young) inhabitants themselves, but also as a try-out course for the customers of Decathlon, the school and semi-pro soccer teams of visiting footballers from elsewhere;
- Extend the existing sporthal with a new entrance, and an adjoining Decathlon sportarticle lend center, annex cloth change and shower rooms
- Develop an outdoor cinema/playground/café, including climbing tower with Kinepolis/Luchtbal Theatre at the residual spaces next to the athletic course and Sporthal;
- Organization of a yearly Streetolympics in three age-categories (6-12, 12-18, >18) sponsored by the stakeholders mentioned above.

Medium term (2015-2020)

- Improve/realize a safe pedestrian crossing between Kinepolis/Decathlon over the Noorderlaan with the athletic course Luchtbal, including new biking routes with the International Seaman House;
- Rearrange the neighborhood traffic circulation adapted to the new developments above and the rearrangements of the Noorderlaan;
- Redesign of the public space between the Luchtbal Theatre/Sportomundo and the athletic course, partly also as the starting point of a neighborhood runcourse to the nature reserve ‘Oude Landen’ and back;

Long term (>2020)

- Development of a waterramp and climbing course towards abandoned and residual places in the Harbour area
- Revitalize the old Sporthal
- Intensifying the leisure/sporting program with additional facilities/sporthousing.

The Green Carpet Luchtbal opportunity map (Figure 10) concentrated on a renewed use and a collective appropriation of the public space in the area, to initiate a new dynamic outdoor daily live in the neighborhood again. It focused on:

Short term (2012-2015)

- The development of a flower carpet around the Towerblocks of Luchtbal, designed, planted and maintained by the residents themselves;
- A change of ownership of the courtyards in the Gardencity of Luchtbal – from the Housing Company to the residents themselves – to stimulate urban farming, including improved pedestrian routing through the neighborhood;
- Redesign of the agora to an adventure park, next to the cultural center, by the growing immigrant youth according to their own ideas, needs and interests;

Medium term (2015-2020)

- Reorganization and refurbishment of the green areas between the Longblocks in the South of Luchtbal by the residents according to the principle of participatory budgeting
- Development of a green (car free) bike/pedestrian route along the neighborhood runcourse ‘Oude Landen’ (see above)
- Improvement of a green corridor between Luchtbal and Oude Landen, including green allotments and an improved entrance for the railway station Noorderdokken;

Long term (>2020)

- Revitalization of the Old Luchtbal Park in the north of the neighborhood, possibly intertwined with the new neighborhood circulation plan, a new appropriation of the adjoining Swimschool and the housing reconstruction on the south-side of the Park.

And finally the work/center opportunity map (Figure 11) concentrated on improving the possibilities for new start-ups and incubators in cooperation with the planned Polytechnical Campus in the North of Luchtbal, including the concentration of the dispersed shops, the week market and a new supermarket in the center of the neighborhood. Among others it consisted out of the following projects:

Short term (2012-2015)

- Development of a new neighborhood office for the Housing Corporation ‘Woonhaven’, including a ‘Job-’ and a ‘Recycle-shop’;

- Development of a polyvalent containervillage for new (neighborhood) start-ups and repair workshops, connected to the Reclycle-shop mentioned before, with an average container rent-rate (80 m2) of € 1200,-/year;
- Extension of the horeca-facilities of the existing Luchtbal Centrum Pub, in reference to the developments above and in relation to the new Playparc;
- Implementation of new facilities for the weekmarket, including stands for the urban farmers (activity 12) and room for a periodic recycle/flee market and other venues;

Medium term (2015-2020)

- Revitalization of the old GM-factory towards a poly-functional CarCity (with Jorssen-BMW and Beerens-Audi), including polytechnical interships for young Luchtbal inhabitants and a new pedestrian/bicycle crossing of the Noorderlaan;
- Development of new incubator facilities along the central Tampicosquare, in cooperation with the planned Polytechnical campus

Long term (>2020)

- Development of a new pedestrian/bycicle bridge between Luchtbal and its neighboring village Merskem as part of the bycicle highway Essen-Antwerp;
- Integrated redevelopment of the old shopping center of Luchtbal, including a further densification of the area.

Each of these opportunity maps have been discussed in three roundtables of some 12-15 leading actors, roughly divided into 1/3rd of the business society, 1/3rd of the civic society (that is the Luchtbal inhabitants themselves) and 1/3rd of the involved public society and/or its civil servants. Criteria for invitation was if they appeared to potentially evolve into a kind of 'leading actor' from the first investigations mentioned before. We were looking for new cross-overs between each of these possible 'leading' stakeholders, challenged by the proposals in the opportunity maps. And although these 'leading actors' hardly knew each other or had spoken each other before, each of the roundtables resulted into a lively debate about the projects and possible spatial presented. Some of these proposals could only count on little support, but others were firmly embraced, or even extended and/or elaborated according to each and communal views. Therefore and on the whole, form each of these roundtables emerged a new dynamism and buzz, crossing old (physical, functional and social) barriers, with new perspectives for communal, innovative and even surprising development proposals. At the moment we facilitate this new buzz by elaborating integrated short term investment proposals in money, time, expertise, law, institutional arrangements and the like, in which each of the aforementioned 'leading actors' could perform its own role. Additionally and for the medium term we elaborate at the moment proposals for communal preparatory studies/measures in order to prolong the buzz after 2015 and for the long term a kind of co-evolutionary route how to proceed out of the self-reinforcing negative spiral. And although

this route could hardly be planned, let alone prefixed towards of a clear or promising future, we will present all three proposals for a broader public of involved stakeholders in August this year, as a possible more resilient and innovative way to go. At that time, it will become clear if the prominent old plan stakeholders, would like to co-evolve with the broader public and investors along this route, or that they will stick to the traditional planning path-dependencies with their apparent clear roles, jurisprudence and stratified means, but including its constraints and sometimes even lock-inns.

Conclusions with regard to post-war area planning strategies

Due to this ongoing process and at the moment of the writings of this paper, the results of the new strategy are still unsure. Moreover the proof of its effectiveness will only be given over time, when resilient and robust new alliances in Luchtbal have formed and resilient new socio-spatial practices have emerged. Nevertheless, without being able to present at the moment hard evidence of ARA for post war housing estates, some concluding remarks could be given from the current insights and already evolved broad and enthusiastic buzz of the process.

The shift from physical masterplanning with an underlying social engineering strategy within the administration and the Housing Company of the municipality of Antwerp towards an embedded strategy within evolving and possibly extended actor-networks of the community itself, is a major achievement on its own. As Christiaens, Moulaert and Bosmans have argued in their analysis of recent urban policies in Antwerp, these policies reflect a “physicalist” and “new economist” approach that favors top-down, City-Hall-controlled territorial division of labor, rather than a real partnership with civil society organizations (Christiaens et al, 2007). Urban planning or urban regeneration within the government in practice is too often still a technocratic top-down enterprise, seeking to control according to a prefixed ideal world, rather than to enable an open-ended resilient and robust spatial development. Government planners work too much accordingly to their own problem definition and their own set of predefined solutions, leading to one-dimensional and one-sided planning proposals, such as the masterplan for Luchtbal, rather than being sensitive to the multifaceted socio-spatial relations that unfold before them. Also during the round tables and brainstroms in the Luchtbal it became clear that traditional bureaucratic, political ideas about predefined, restrictive planning concepts blocked some of these discussions. These internal public path dependencies, or better still ‘lock-ins’, have and still are frustrating a real open and innovative actor-relational progress.

Certainly for post war housing estates, such an inside-out approach could be detrimental to the multifaceted opportunities that are hidden behind the surface. As Doug Saunders (2010) recently stipulated again, amongst and on top of a vast and ever growing group of scholars studying transnational communities (Andersen 1983, Appadurai 1996, Blokland 2008), to conceive migration areas as just areas of problem concentration doesn't do any justice to the diverse opportunities and self-organizing dynamism these show below the apparent surface accordingly. The same goes for formalistic, high rise postwar housing estates, which seem to be very mono-functionalistic at first glance, but over time hide a tremendous diversity, (non-) human capital and range of possibilities when examined in more detail. The range of (partly self-organized) activities, ambitions and programs described above proofs all that. It is more than ever our duty as planners to look them up, trying to engage them within and through more institutional modes of planning vice versa, in order to deliver more resilient urban assemblages in our times of an ever-growing complexity, volatility and cross-bordering challenges. The ARA approach holds significant advantages on this respect. It tries to capitalize on the diversity of and within transitory communities, by activating and forging heterogenic alliances between different social groups, aimed at the collective remaking and governance of space. It seeks to bridge the cleavages between government, market and society to set up self-governing assemblages between social networks and spatial configurations. And it seeks to restore a new, relational civism, rather than a preconceived static and passive citizenship. Time will learn in the very near future, if we are able to connect the upcoming fruits of this and these kinds of embedded, organic approaches with the more traditionalistic and path dependent planning programs of the current Antwerp municipality. Not only high rise post-war housing estates in general or Luchtbal in particular, but also the new generation of evolutionary, relational and actor-oriented planning of a complex future are in need of that.

Between landscape rhetorics and 'scalar traps': the asymmetric governance of contentious urban development

BARBARA PIZZO

SAPIENZA UNIVERSITÀ DI ROMA (DEPT. OF PLANNING, DESIGN AND TECHNOLOGY)
Via Flaminia 70, I-00196 Rome, ITALY

barbara.pizzo@uniroma1.it

Keywords / governance and participation spatial and political re-scaling, urban development and the landscape

One day in February 2001, the street-walls of Rome have been filled up with posters celebrating the safety of Tor Marancia estate, a broad green area strategically positioned within the city centre of Rome, which was expected to be the site of a high-density development project.

These placards have been signed and placed by each single political party, NGO, and civil society association, exulting for having saved the estate, and claiming credit for the result.
A question obviously arises: if everyone was happy for the conservation of the estate, who wanted its exploitation? Tor Marancia was saved from whom?

At the time, I was doing a research project on the relationship between landscape and planning, and I was interested in deepening the actual role of the landscape within planning processes and tools.

Because the supposed victory against the building exploitation of Tor Marancia was said to be determined by its importance for the urban landscape, and its protection established according to its landscape and heritage values, it caught my attention.
It was really because of the landscape that the motleys of actors involved in the decision process converged toward the same understanding, and succeeded in erasing 2 millions of cubic meters of building rights? Have they been erased, or what else happened to them? Which kind of process determined that result? What happened exactly, how and why?

Unfortunately, that day of 'collective celebration' was not the end of the story.

Aim of this paper is to present the results of two research pathways which converge on, and through, the case-study of Tor Marancia.

The first one is dedicated to the forms of governance which can (or are expected to) be activated on landscape issues, and to the actual role played by the landscape in governance

processes, considering their outcomes. It is also related to the question of the implementation of the European Landscape Convention (ELC), particularly in its explicit reference to participation and governance. The relationship between landscape and planning - the meaning and role that the landscape assumes within planning theory and practices - and the actual role played by the landscape within planning processes and tools provide a background.
The landscape is intended here as:

- a field for experimenting forms of inter-institutional cooperation, participation, civil society commitments, and governance (as normatively stated in the European Landscape Convention - ELC);
- a tool for measuring and/or a field for improving institutional capacity and the effectiveness of what is (at least by words), normatively assumed.

The implicit assumption is that the landscape mirrors the space-society relationship, and that once the rhetorics which commonly shadow its actual role within planning are unveiled, it can be useful to understand and to deepen these relationships in their power and hegemonic meaning.

The second one is a still on-going multidisciplinary research dedicated to the forms which neo-liberalization is assuming at local level[1]. It focuses particularly on the changes they determine in the public discourse on land use, and on their translation into urban policies: how they affect socio-spatial configurations, which is their spatial meaning and outcomes, their impact on the formation of coalitions, and on democratic decision processes (Harvey 2005; Brenner and Theodore 2002; Peck, Theodore and Brenner 2009; Brenner, Peck and Theodore 2010). These policies, which can be referred to forms of neo-liberalization, make recourse to spatial and political re-scaling (Brenner 2000, 2001, 2004), while often hiding actual interests and values through 'main issues' – those issues which always appear as priorities in the political agendas at all level – such as that of environmental sustainability, or, as in this case, that of landscape protection.

The case-study of Tor Marancia - one of the most controversial cases in the recent planning history in Rome - allows to put together these questions and to unveil rhetorics, asymmetries of power in governance and planning processes, and the 'scalar traps' they produce.
In fact, it is precisely because of the recourse to the landscape, for the specific meaning that the concept of scale (and of scaling) it embodies, that actual interests and powers can be disclosed. The case enlightens problems of power as related to knowledge, of 'transparency' of decision processes, and the actual meaning of participation and governance in neo-liberal socio-political contexts. But it also shows how through the landscape, declamatorily used by the different coalition discourses, the contradictions between planning objectives and results, between the advantages and disadvantages at stake and those actually produced, are clearly revealed.

Although 10 years have elapsed since the planning controversy concerning Tor Marancia has been legally solved, the whole story with its territorial consequences at the urban and metropolitan scale are still largely unknown, and quite underestimated.

[1] The research group is composed by Ernesto D'Albergo and Giulio Moini (dept. of Social Sciences), Barbara Pizzo and Giacomina Di Salvo (dept. of Planning), La Sapienza Università di Roma.

A brief 'case history'

Tor Marancia estate is a broad green area (200 hectares) at the border of the 'Parco dell'Appia Antica' (whose it is considered as a 'natural' extension): since the '50ies, through the political action of an important group of intellectuals led by Antonio Cederna[2], it has been the object of a strong civic battle for landscape protection. But the land-use statute of a half of the site (114 hectares) was that of a building site, deriving from precedent land-use regulations (the prevision dated 1962 was of 4 million cubic meters of new buildings, for 40.000 inhabitants, afterwards it has been considered as over-dimensioned, as well as the whole 'old' plan). In the '90ies the estate became the field of a long-lasting conflict which opposed public institutions at all levels, land-owners and real-estate investors, NGOs, associations and the civil society, together with representatives of all political parties.

The actors involved (institutional and non institutional) were divided into two opposite coalitions, whose unbalance has been displayed later. More precisely, an historical reconstruction of the case (Pizzo and Di Salvo 2011) showed that there were two different arenas: one in which the actors played the role they publicly have assumed, the other in which positions were much more unstable and fluctuating, capable to change according to the context's changes. Furthermore, not every actor had access to both arenas demonstrating deep asymmetries of power in the governance setting, while the City Council and the Executive played an ambiguous role: seemingly that of *super partes*, while negotiating with land-owners and real-estate investors[3].

The conflict lasted more than 10 years, and was almost causing the failure of the on-going redaction of the regulatory plan for the city of Rome.

The solution which followed consisted in 'compensations': the building rights (which meanwhile had been reduced to less than 2 millions of cubic meters through 'protection variants'), have been shifted to other parts of the city - precisely to 16 rural areas, enormously re-increased thanks to forms of reward[4].

Within the years 1999-2002, the choices which mostly influenced the course of the conflict have been taken.

---

[2] Antonio Cederna (1921-1996), archaeologist, journalist and political activist, co-founder of Italia Nostra, spent his life studying, disseminating and fighting for the protection of Italian cultural and environmental heritage. The Committee against the development of Tor Marancia estate, was named 'Comitato Cederna' in his honour.

[3] A more complete and detailed history, already presented and discussed in conferences and seminars, will appear in forthcoming publications.

[4] Regarding the mechanism of compensations, it can be briefly highlighted that it was already foreseen by the preliminary 'Plan of Certainties' (Piano delle Certezze) in 1997, as part of the technical norms of implementation of the Regulatory Plan. This tool allows to 'transfer' development (building) previsions involving protected or high-value sites (from an ecological or landscape point of view), to other sites: the former land-owners would be refunded for their lost ownership and rights and also rewarded for accepting to move, not in monetary terms but through an increase of building rights. It was presented as an alternative solution to expropriation for public utility. Moreover, it was implemented through a simplified administrative procedure, and precisely through the 'Accordo di Programma' (Program Agreement) established at national level (Legislative references are: L. 142/90; D.lgs. 267/2000 art. n. 34), which permits individual, one-by-one agreements. The point here is clearly how this tool (of compensations) has been used, and what its use meant in planning and in governance perspectives.

- The Ministry of Cultural and Environmental Heritage, imposed a restriction on the land use of the area, while the Archaeological Office ('Sovrintendenza') asserted the incompatibility of any building exploitation with its landscape and heritage values. But in 1999 the City Council approved the building plan named 'Parco Numisia' ('Piano di lottizzazione').
- In 2001, the Region declared the estate as part of the 'Parco dell'Appia Antica' – changing it into a Regional Park. According to the Italian planning legislation, it means that no form of refund was required.
- In 2002, the City Council, from the part of the City of Rome, decided for the public acquisition of the estate through compensations. As explained before, this was not compulsory with the restriction imposed by super-ordinates institutions (the Region). Anyway, it was presented as unavoidable in order to convince owners and investors to 'renounce' to the building rights they claimed; according to the City Council, the decision was consistent with the Major engagement for Tor Marancia, which was finally 'saved'.

The 'mechanism' of compensation produced an increase of buildings rights which turned out to be more than the former previsions of 1962 - whose over-dimensioning had been commonly recognized. Furthermore, the land-use of 16 rural areas all around the sub-urban region have been changed into development areas, and their potential to seriously compromising the whole 'urban balance' is very high.

I want to underline here that each decision has been taken 'in the name of the landscape', and justified through a 'landscape discourse'. In fact, except for a preliminary phase in which the mobilization was addressed at defending the estate as an open space against the risk of a further increase of the building and urban density, the civil society engagement was in landscape protection. Each public institution, notwithstanding their own different understanding and behaviour, declared to aiming at that same objective, and also the owners and real estate investors, in presenting their development project under the name of 'Parco Numisia', cunningly allude to its environmental value (they wanted it to be intended as a 'park'), and to its historical and archaeological value (the name makes reference to an ancient roman family, that of Numisi).
But the same landscape, which was a main issues in the public discourse on Tor Marancia and, more generally, in the discourse which was used to sustain planning choices, now openly shows the contradiction between discourses and actions, objectives and results[5]. It reflects the policies that have been actually implemented, what kind of socio-economic interests have been taken into consideration, and which kind of socio-spatial configurations have been actually produced[6].

[5] Shifting the attention to the whole regulatory plan whose redaction was on-going while the story of Tor Marancia estate developed, the two main planning strategies of the rail-road network, known as 'iron therapy', and of the ecological network (the 'green wheel'), which had a strong meaning and value for the urban landscape and its inhabitants, tended to hide millions of cubic meters of new buildings realized through various forms of public-private negotiations in order to get private financing for public spaces and public goals – while a general look to what the plan actually produced until now shows the well-known gap between private and public advantages.

[6] As to landscape as a 'by-product' of the interaction of different policies and actions, intentionally and even un-intentionally produced, and as its capacity of mirroring socio-economic and socio-spatial relationships, see: Pizzo B.

Tor Marancia was safe and included within the 'Parco dell'Appia Antica', but the very principles which guided the mobilization against its exploitation have been negated. We may say that the ideological position of the landscape and environmental associations has been used by the counterpart in order to exacerbate the conflict and obtain the maximum result for private investors. In fact, if the goal of the mobilization was the protection of the urban landscape and the environment, we may now say that this objective has been undoubtedly not reached. The same can be said focusing on land-use and urban expansion control as main objectives: the case of Tor Marancia contributed in determining an impressive waste of land, a reckless exploitation of the soil, so that the 'Campagna Romana' has been deeply jeopardized.
Obviously, this do not necessarily mean that the local associations were wrong in promoting their action, or that the very action was wrong in expressing just local interests (a kind of NIMBY reaction), but just that it did not result into a victory.
On the contrary, the case demonstrate of the lack of a consistent policy of landscape and environmental protection – in counter-tendency with a general orientation at European level at containing land consumption and urban expansion.
Moreover, it can be said that the problem was not 'solved', it was just moved - from a highly conflictual context to a very broad context (16 areas in the suburbs) where no immediate opposition, nor conditions for contestation, were to be expected; and that won who had well-defined but non site-specific, 'un-spatial' interests, as required by the present forms of the Market. In fact, unlike the people involved in the mobilization who were fighting for a certain site, real-estate interests could have been moved almost anywhere within the metropolitan area, as the Public Administration itself helped to do, through the mechanism of compensations.
The case displays how the landscape, interpreted as a by-product of policies and actions, mirrors space-society relationships in their socio-economic and socio-spatial features, thus showing the contradiction between objectives and results in spatial planning and policies, and helping at unveiling actual power relations orienting or even driving governance processes.

About landscape and *governance*

There are some fundamental reasons for relating landscape issues to that of governance.
For my present purpose particularly, they concern first of all the related conceptual developments of landscape and of scale, which have been provided by (critical) human geography.
In my view, landscape studies gave a fundamental (even if very often implicit) impulse to the problematisation of geographic scale which has been seen, before the last two decades, as pre-given and fixed. This derives from landscape's trans-border nature, from its aversion to be constrained within pre-defined borders, and even more from its intrinsic trans-scalarity which combine a geo-spatial dimension and a social dimension. It is also related to the rather acknowledged trans-scalar definition of its values and interests, which brings about the problem of establishing to whom the landscape is (must be) referred.

2005, 2007. A fundamental reference for this approach to landscape studies is E. Sereni (1961), *Storia del paesaggio agrario italiano*. Roma−Bari: Laterza.

So the quest for trans-scalar understanding, and for its political meaning and implications, is particularly important for tackling landscape issues, thus implying multi-level decision making and governance.

Landscape governance / landscapes of governance

Iridescent concept, vague meaning, 'empty signifiers' (Offe 2008): these are just a few among the definitions used to refer to the highly disputed nature of the concept of governance, which also fit for the landscape.

Notwithstanding the definitions of both concepts seem to lean toward their intractability, they are at the core of the reflection and of the scientific production of many disciplines since decades –as literatures fully shows–, broadly and commonly used and, more recently, also in joined forms.

For my present purpose, I need to point out here just two problems, also for the relevance they assume within the selected case study:

1. Disciplines which have a normative and operational dimension require operational concepts. The question arises of how can the landscape be adequately operationalized, and which operational definitions reveal to be the more useful in a planning perspective.
2. A step toward the operationalization of too theoretically rich concepts is that of joining them with, and constraining them within, a defined operational approach. Is it the case of landscape and governance? Which are, or could be, the operational implications of threatening the landscape through forms of governance?

1. It is long that the landscape has a predominant position within different disciplines, where it assumes a broad range of meanings. What would differentiate planning in threaten it, is that it could not simply accept its ambiguity as constitutive. More precisely, accepting it does not mean necessarily and directly that the concept of landscape can be used with each one of its manifold nuances for each different purpose. As for planning in particular, it means that for each different approach and planning tool (e.g. regulative, structural, strategic), must correspond one precise definition/interpretation of the landscape. The alternative to this basic rigour is the intractability of the topic, and the related (inevitable) dissatisfaction for the results of planning policies and actions (Pizzo 2005, 2007). Experience shows rather a different trend. The fields (of both research and practice) where the concept of landscape is used are still increasing, not implying a progressively more specific
differentiation and disciplinary framing, but a further stretching of its semantics instead.

2. Given the highly contentious nature of the concept of governance, it is rather clear that its combination with that of landscape hardly can bring towards a higher accuracy.
However, their use in combined form is increasing. The question can be analysed in a double direction: how and why governance enters into the landscape discourse, and how and why landscape enters into the governance discourse, and precisely:
a) The turn toward participation *and* governance is a fundamental content of the European Landscape Convention (ELC), and also a priority for its implementation. So that it is more than

a decade that the discourse on landscape is developed in relationship with one concerning socio-political and institutional settings and behaviour. b) Landscape enters in the field of Governance contributing to its further extension, also suggesting the wide range of governance approaches and styles; in particular, c) Landscape Governance can be interpreted as a broadening of the field of action of Environmental Governance, appeared in the '90ies, with which it shares similar problems (those problems which cannot be tackled within predefined borders, nor just within the realm of public actions). Emphasizing the need for a more integrated approach of nature and culture (Whatmore 2002), or the socio-cultural construction of the very concept of nature (Castree and Brown 2001), it allows a more specific focus on socio-cultural aspects.

I will summarize here some of the more interesting case-study results, highlighting what we can learn from the story of Tor Marancia about the actual role of the landscape in planning and governance processes, proposed as conclusions.

In the name of the Landscape

Within planning processes the landscape is very often presented as a 'main issue' as well as a shared common interest and as a 'common good' to be strenuously defended – hardly ever explicitly clarifying what is really at stake under such a broad and multifaceted concept, and to whom the same landscape is referred.

The title / legitimacy which is given for justify public or collective choices, in a system where democratic representativeness is often questioned for its weakness and limits, became progressively decisive. While a recent essay titled 'In the name of whom?' (T. Vitale, 2007 - original title in Italian), there is a broad and differentiated 'Not in my name' movement (largely diffused through the web) which refuses institutional positions as non-representative of the citizens will, while reclaiming the right of individual expression.

The political and sociological critique about this question is here intertwined with the one related to planning, to space and territory which represent the object and also the field of the conflict which, 'mediated' through the landscape, concerns socio-economic and socio- spatial development models.

The case of Tor Marancia enlightens that the claim to landscape goals, and the recourse to the concept of landscape for sustaining the political discourse on spatial planning did not contribute in considering the decision as a political construction; on the contrary, it left space for 'naturalistic' explanations, technical judgments and expert solutions which hidden elitist economic interests and the political dimension of the question.

In the name of the landscape, every kind of spatial policy can be promoted. In most cases, it is not the landscape the focus of the interest: it is rather the medium through which some kind of public discourse on territorial development (urban, metropolitan, regional) is conducted.

To whom does the landscape belong?

In the European Landscape Convention (ELC) perspective, member states are asked to establish procedures for the participation of the general public, of local and regional authorities and all interested groups in decisions processes related to the landscape, implicitly assuming the competition among different interests. From an ELC point of view, which is

strongly locally-oriented, participation and governance on landscape matters are recognized as able to re-built social relationship and sense of community, local identity and exchange, to tackle conflict and to strengthen democratization, legitimacy and social justice (Jones and Stenseke 2011; Jones 2011; see also: Pedroli B. and Van Mansvelt D.J. 2006; Prieur M. and Durousseau S. 2006).

The case presented here demonstrates that all these potentialities must be seriously revised, at least when overcoming the local dimension, which is usually the case, particularly considering that globalized neo-liberal policies are trans-scalar by nature (as the landscape itself). Participation and governance should become rhetoric, which mystify power relations, tend to erase or to soften inequalities of knowledge, power positions, interests and motivations of the different participants, and can led to manipulation by the strongest among stakeholders.

To be assumed as a field for practicing forms of governance, also in the sense of ELC, a 'non-naturalistic' definition of landscape would be preferable, such as that of 'strategic construct' (Pizzo, 2005, 2007). This would highlight the nature of social construction of the landscape, and of the choices it requires as political.

Landscape and 'scalar traps'

ELC focuses particularly on the local dimension and scale, thus contributing in diffusing the interpretation of the local level as the more adequate and preferable for tackling landscape issues. This because of their nearness to the population effectively involved into decision processes and affected from the choices related to their 'living environment'.

This can led to what has been called 'the local trap': a prejudicial consideration that localized decision-making is inherently more socially just or ecologically sustainable (Brown and Purcell 2005).

The case of Tor Marancia shows that the landscape has been able to widely mobilize the civil society at local level. But because of the incomplete knowledge owned by the involved actors about the factors and variables at play in the controversy, and because of the weak understanding of its multi-scalar implications, it brought, through a 'scalar trap', to results which are definitely far from what the civil society movement, NGOs and associations ever expected.

The landscape has the power to activate mobilization but people involved do not always have the knowledge/power to understand what was going on, and particularly in a trans-scalar perspective, for which they often demonstrate insufficient cognitive, and an even more poor strategic capacity or understanding. The fall into a 'scalar trap' is often the case. Moreover, a paradox emerges: the wider is the impact of the issue, the weaker the mobilization could be. (D'Albergo, Moini eds. 2011. See Moini pp. 17-43, and Inwinkl pp. 101-123).

The need of a cognitive and a strategic trans-scalar capacity

Landscape can be dealt with governance (multi-level governance particularly) assuming its social construction and its socially constructed political scales. From this perspective, the focus of ELC on the local scale represents a critical point, since the same ECL can be interpreted as an example of the trans-scalar dimension of landscape governance. In fact, while ELC concentrates on local landscapes, recognized and defined as such from their inhabitants, in

that they are the object of a Convention at trans-national level, signed by a supra-national institution (European Commission), and from its Member States (national level), they inevitably assume a trans-scalar character.
This address the reflection toward the role of transnational organizations (also NGOs) and corporations which, together with the most powerful among the National States, play a decisive role in the governance processes at all levels.
The relationship between the rise and diffusion of the concept of Governance with that of Globalization, interpreted as a re-articulation of politics at different spatial level (Brenner 1999, 2000; Jessop 2003) is of primary importance for the argument proposed here.
The case presented here clearly shows how the more preferable solution at the local scale (envisaged also by the local community) is no more likely to lead to the preferable outcome for the landscape, in general terms, than one at any other scale: instead, it should have unexpected negative effects at a different (wider, in this case) scale. Moreover, scales are always the product of political struggle, and, as the case rather clearly shows, the same power positions which determined a certain solution define also the proper scale for that solution, so that political rescaling cannot in any case be disregarded, on the contrary it has to be the focus of critical inquiry, also (and particularly) when talking about the landscape.

Urban design, public space and the dynamics of creative milieus: a photographic approach to Bairro Alto (Lisboa), Gracia (Barcelona) and Vila Madalena (São Paulo)

Pedro Costa[1]
Ricardo Lopes[2]
ISCTE-IUL – Lisbon University Institute / DINAMIA'CET

– draft version – English language not revised –

Abstract
Drawing on some results of the research project "*Creatcity – A governance culture for the creative city: urban vitality and international networks*", the aim of this paper is to discuss the relation between urban design and the creative dynamics in cultural districts. Assuming a perspective focused on the understanding of the spatial conditions that support creative clusters and the vitality and sustainability of "creative milieus", an analysis of the appropriation and production of public spaces in the "creative quarters" is made, departing from 3 case studies of creativity-led territorial systems in Lisbon, Barcelona and São Paulo metropolitan areas. The specific conditions and ambiances which seem to be determinant to embed sustainable creative processes in these areas are studied, aiming to explain the development of "creative milieus" situations and their relation with the urban socioeconomic and morphological dimensions. The main concern is centered on the governance and the sustainability of these territorial dynamics, at the light of the research framework pursued in this project.
The general conceptual and empirical framework of this project is briefly presented and the methodological approach that was followed is described. Then, attention is focused on 3 of the 10 case studies analyzed on this project, three cultural quarters, one in each city (Bairro Alto, Lisbon; La Gracia, Barcelona; and Vila Madalena, São Paulo). The main characteristics of each of these territorial systems are briefly presented, as well as their main regulation mechanisms and the main conflicts verified.
A comprehensive photographical approach to those public spaces and those dynamics, assumed as central in the empirical work conducted in each quarter in each city, is the departing point for the specific analysis presented in this paper (which is complementary to diverse other methodologies used in the overall project). The analysis and discussion of more than one thousand images allowed characterizing each district through 15 different analytical dimensions, covering material aspects of those spaces, their human appropriation and livability and the symbolic dimensions of this appropriation.

[1] pedro.costa@iscte.pt
[2] ricardovenanciolopes@gmail.com

The main characteristics and dynamics of each of these experiences are discussed, evidencing how urban morphology, features of "physical" place and potential for public space appropriation are determinant to the vibrancy and liveliness of these areas. Departing from a discussion on the boundaries of public spaces and their relevance for the creative dynamics (through the conviviality and sociability they promote), it is argued that the characteristics of urban design, specific place morphologies and typologies are determinant for the attractiveness of creative activities and for the appropriation of these areas. They are also discussed as central at the light of the main challenges to the sustainability of each of these areas as "vital" and "creative" centers in their cities. Finally some concluding policy-making guidelines are drawn out from the analysis.

Keywords
Creative milieus; Creativity; Cultural quarters; Public spaces; Photography.

1. Introduction

This paper aims to discuss the relation between urban design and the creative dynamics verified in cultural districts. In recent years multiple territories have stood out as 'creative milieus' as they offer a specific atmosphere or certain conditions required to embed and develop sustainable creative processes in cultural activities (see Camagni et al. 2004; Cooke and Lazzeretti 2007; Costa 2007; Costa et al, 2011; or in a wider perspective, O'Connor and Wynne 1996; Scott 2000). This "creative milieus" configure very distinct situations and usually are based on specific governance mechanisms that play a key part in most of those success cases. In this paper we focus specifically on the "cultural districts" or "cultural quarters" case (cf. Costa et al, 2008).

Our analysis draws upon some of the results of the research project "*Creatcity – A governance culture for the creative city: urban vitality and international networks*", which focused on the understanding of the spatial conditions that support creative clusters and the vitality and sustainability of "creative milieus". An analysis of the appropriation and production of public spaces in the "creative quarters" is made, departing from 3 case studies of creativity-led territorial systems in Lisbon, Barcelona and São Paulo metropolitan areas. Through a photographical approach that complements other methodological approaches to these experiences, and departing from the study of the specific conditions and ambiances which seem to be determinant to embed sustainable creative processes in those areas, we aim to explain the development of these "creative milieus" and their relation with the urban socioeconomic and morphological dimensions. The perspective is centered on the governance and the sustainability of these territorial dynamics, at the light of the research framework pursued in that project.

The general conceptual and empirical framework of the project is briefly presented on section 2 and the methodological approach that was followed is generally

described on section 3. We focus on 3 of the 10 case studies analyzed, one cultural quarter in each city (Bairro Alto, Lisbon; La Gracia, Barcelona; and Vila Madalena, São Paulo). The main characteristics and dynamics of each of these territorial systems are discussed, evidencing how urban morphology, features of "physical" place and potential for public space appropriation are determinant to the vibrancy and liveliness of these areas. Departing from a discussion on the boundaries of public spaces and their relevance for the creative dynamics (through the conviviality and sociability they promote), on section 4, we discuss how the characteristics of urban design, specific place morphologies and typologies are determinant for the attractiveness of creative activities and for the appropriation of these areas. Consequently, on section 5, we debate their importance at the light of the main challenges to the sustainability of each of these areas as "vital" and "creative" centers in their cities. Finally some concluding policy-making generic guidelines are drawn out from the analysis.

2. The *Creatcity* project framework

The aim of the 'Creatcity' project ('Creatcity: A Governance Culture for the Creative City: Urban Vitality and International Networks'), funded by the Portuguese Science and Technology Foundation (FCT/MCTES), was to discuss territorially based creative dynamics and their governance mechanisms in diverse urban contexts. Drawing on the 'creative cities' debates, it sought to further knowledge and to build strategic action guidelines on governance mechanisms and dynamics that promote and embed urban vitality, creativity and competitiveness. It combined a conceptual and empirical component, focusing on the cities of Lisbon (Portugal), Barcelona (Spain) and São Paulo (Brazil), where ten empirical case studies were selected for in-depth analysis.

The project was based on a transversal analysis of creativity in the three cities with the aim of drawing strategic policy-acting guidelines for the Lisbon metropolitan area. It encompassed several thematic dimensions: (a) systematizing contemporary economic restructuring and territorial challenges in each metropolitan area; (b) mapping their creative activities and resources; (c) analyzing the relation of these creative dynamics with material space, urban morphology and social appropriation of urban areas; and (d) examining local policy actions for internationalization.[3]

In addition to specific case studies, other methodologies were applied (desk research, both empirical and conceptual, etc.). Complementary empirical analyses were made in the three cities (data series, statistical analysis, etc.) as well as extra fieldwork in some case studies (urban, functional and morphological analyses, photographic survey, image examination, etc.). In articulation to all these, the main core methodological framework combined two steps:

[3] For more information see http://creatcity.dinamia.iscte.pt.

(i) A set of exploratory interviews: twenty-two exploratory interviews (ten in Lisbon, six in Barcelona, six in São Paulo) with local/regional/central government authorities in different fields from urban, cultural and economic policy areas; with experts in consultancy and the academic world; and with some prominent creative/cultural institutions (cf. Seixas and Costa, 2010 for details).

(ii) A set of case studies: ten case studies in the three metropolises (using nearly seventy in-depth interviews and other methodologies), i.e. Bairro Alto, Almada, Alcântara and Martim Moniz areas in Lisbon; Gracia district, 22@ urban renewal operation, and Palo Alto Association in Barcelona; Vila Madalena district, the event São Paulo Fashion Week event, and the institution SESC (Commerce Social Services) in São Paulo (cf. Costa 2012, 2012a for details).

A comparative approach was taken in just three of these case studies: Bairro Alto in Lisbon, Gracia in Barcelona and Vila Madalena in São Paulo, all of which are 'conventional' creative districts or cultural quarters. Despite slight differences and nuances, and quite diverse historical and institutional backgrounds and urban characteristics, they share an analogous situation: 'creative' segments of the population (artists, bohemians, cultural activities, nightlife and other conviviality and sociability nodes) were going through a process of 'taking over' traditional residential areas in the three cases. Moreover, they are now all experiencing growing gentrification processes and a sort of shift from production to consumption, or from traditional cultural activities to more commodified market based aesthetic-driven activities (with the progressive replacement of performing and visual arts with design shops and nightlife, for instance). Like many other cultural and creative districts all over the world, there are also strong use conflicts between residents and users, night-time and daytime activities, traditional and new residents, traditional and new activities, etc. These conflicts, most of them expressed in daily life and on the public space appropriation by their diverse users, play an essential role in the governance of these districts and on their sustainability challenges (see Costa et al, 2010; Costa 2012a, 2012b for details).

A comprehensive photographical approach to those public spaces and those dynamics, assumed as central in the empirical work conducted in each of these quarters, is the departing point for the specific analysis presented in this paper. The analysis and discussion of more than one thousand images collected in the 3 case studies allowed characterizing each district through 15 different analytical dimensions, covering material aspects of those spaces, their human appropriation and livability and the symbolic dimensions of this appropriation. That is what we will go through in the subsequent sections.

3. A photographic approach to the three districts: methodological approach

There are several ways to analyse the public space, and many were used by us along this *Creaticity* project. This photographic approach is part of the analyses conducted in these 3 districts, which aimed to compare the different realities founded in each of them, following a set of pre-systematized criteria.

Through a wide range of images collected in a photographic survey, realized alongside other surveys and other kinds of approaches aimed at the systematic collection of qualitative and quantitative empirical evidence on the same locations, we sought to understand the creative dynamics and the appropriation of public space concerning 15 thematic issues, grouped around a restricted set of broader dimensions of analysis.

The photographic survey obeyed a set of rules and presupposed certain objectives for the fullest possible coverage of the dynamics verified on these neighborhoods. For each quarter, six streets or squares, with diverse uses and users, were selected. We tried to cover with that selection the different dynamics pre-identified in the area.

Throughout two specific days of the week (Thursday and Friday), and on three different moments (morning, afternoon and evening), photos were made in those six places pre-chosen in each quarter, by five elements of the research team involved in this task. As aim of this specific work it was to make a photographic survey assuming the personal interpretation that each elements of the team brought about that public space.

In any perspective, we would need to learn how the appropriation of the public spaces of the quarter is done and how this affects the social, economic and cultural practices that take place in them.

For such, bearing in mind the "documental" side about the reality that each one would want to convey, it was necessary to identify a group of outlining aspects of each one of these quarters and their everyday life, from the diversity of its users and regulars (in its various times and spaces) to the multiplicity of existing spaces (morphology, physical characteristics, materials, urban furniture, etc.); from the plurality of uses, experiences and appropriations possible to recognize in there (forms of using, coding, etc.), to the conflicts of use and the problems associated to occurring externalities; or also to the variety of signs and symbols, direct or indirect, which can be associated to existing social practices in those spaces.

On the basis of a conceptual framework that looked to these spaces in a triple perspective (crossing morphology, forms of appropriation and governance forms), we built a set of variables that were taken over as key to the analysis of the urban vitality of these areas, aiming to cover aspects as diverse as the social and functional diversity, accessibilities, identities and social capital, the “quality” of place or the local creativity.

Within this framework, we defined three broad dimensions for analyzing public spaces:

A) **The material space**: the way natural and built space conditions the activities and functions that take place on it;

B) **The living of the spaces**: the way it is experienced and appropriated by its diverse users (residents, workers, tourists, etc.) and the conflicts that this engenders;

C) **The symbolic dimension:** the way it is perceived and represented and how it conditions and multiplies its appropriations (and the symbolic and cultural accessibility into it).

These three major dimensions were decomposed into themes, from which the photographic collection was conducted and the scan was completed, using the images. We opted to add a fourth dimension of analysis to those 3, focalizing on cross-cutting themes, and embodying the very dynamics of these quarters in their diverse times and spaces, that is, their multiple (but coincident) temporalities and spatialities.

Nº	Dimension	Theme
1	A – The material space	**The materiality** (morphology, volumes, topography,...)
2		**The urban facilities** (urban equipment, public furniture)
3		**The green spaces**
4		**The "light"** / the luminosity / the "ambiances"
5	B – The living of the space	**The functional diversity in the neighborhood**
6		**The social diversity in the neighborhood**
7		**To "dwell" the neighborhood**
8		**To "circulate" in the neighborhood**
9		**To "live" the neighborhood**
10		**The use conflicts**
11	C – The symbolic dimension	**The signs and symbols**
12		**The identity characteristics of each quarter**
13		**The spaces of inclusion and exclusion (symbolic/cultural)**
14	"Transversal" dimensions	**The different times / rhythms of the quarter**
15		**The different "spaces" of the quarter**

Figure 1: Dimensions and themes for photographic recollection

4. Public space appropriation and creative dynamics in the 3 cases

Public space is an arena for several appropriations, place of exchanges, meetings and sociability, one of theaters of everyday life. It is traditionally characterized for being a collective place that doesn't belong to anyone and belongs to everyone, usually managed by a public entity that has the duty to administer it and the conflicts that take place in there. If in beginnings, from an urban-morphological perspective, they could be characterized by being only the leftovers spaces between the buildings, where one could circulate, or the market squares at the city gates, where trade took place, rapidly and encompassing evolving civilization they assume another importance in cities, becoming privileged places for power demonstrations, for worship, for trade, for traffic or for conviviality and social representation.

Thus, naturally, this basic concept which could be characterized as a space of inclusion and citizenship, where all citizens could access, quickly is diluted by the hierarchical and social construction that takes place in all societies, and that is being complexifyied by evolution and technological progress. However, "the notion that the public space should be an equal space, not exclusionary, and of free access to all individuals is a central idea of the current theoretical debate in the city" (Balula, 2010, pp. 44).

In effect, those are central issues on contemporary discussions on public spaces and public sphere in the city. Public space is not as easy concept to operationalize, particularly on present-day societies. In the framework of this research we discussed

and assumed a concept that is embodying the crossing of three different layers (i) the public/private or collective/individual property and management of those spaces; (ii) the public/private interests around their development and use (e.g., public/private goods); (iii) and the collective/individual appropriation of them (e.g., on their access). The crossing of the several possibilities in each of these layers gives us the wide diversity of situation that characterizes contemporary polemic on public spaces definition and their boundaries (e.g. public streets in private urban resorts; public spaces in private-managed shopping malls; private management of public facilities, and so on). It is not our intention to in-deep this debate here (cf. Costa, 2012a on that), but just to frame briefly how we got an operative tool to analyze these spaces in our photographic approach.

The Italian architect Giambattista Nolli was the first to introduce in a plant from one city the question of the limits and boundaries of the public space, when mapping the city of Rome, in 1748, has represented the urban spaces of public sphere of Rome in the same way that the conventional public spaces[4] (e.g. church interiors). That arose naturally the question about where begins and ends the public space, which is a debate that continues until today, as seen above. However, assuming that the public space is a diffuse place, with rather uncertain and changing boundaries, and expressed in quite undefined spaces within the core of increasingly "privatized cities", it interested to us in this work to photograph and analyze the appropriations that occur in spaces in the urban public sphere, that, regardless of belonging or being managed by "public" or "private" entities, could be freely or easily appropriated by the population. Also, it interested to us to assume the public space appropriations which have a direct influence on "conventional" public space, by their own nature, such as ground floor business, car's parkings, gardens or cultural facilities, which regardless to need an invitation, authorization or economic transaction to be used, can be appropriated essentially in a "democratic" way. If we just call "public space" to places which could be appropriate by all, without any schedule, economic or social restriction, we could call urban spaces belonging to the public sphere to those others. Thus, we felt the need to extend our research to those "urban spaces of public sphere" because increasingly we see a relative decline of the importance of "traditional public spaces" in the life of society. Furthermore, these places affect directly the vitality of public spaces adjacent to it, functioning as its extension, where boundaries and borders disappear. In the presence of this decline of importance of archaic public space, other seem to arise, as shopping centers or other, that simulating the appearance of traditional public spaces, offering a controlled environment, and easy access by car, give the possibility to find a large agglomeration of services, differently from what we have in the city. Despite this more mediatized panorama on many contemporary cities, it continues to coexist with areas that due to their characteristics and peculiarities keep particularly vital, and the case studies in our analysis area good example of that.

In effect, cities are regulated by segregation systems. Through various ways it is possible to mediate and control the modes of city appropriation, at diverse scales.

[4] Assuming "conventional public space" as places where anyone could access without any kind of restriction, as city streets or squares.

That always happened in such a way, as Balula describes in relation to social segregation of Greek Acropolis, according to the social status of the population, or in numerous other conviviality spaces throughout history: "As the Greek polis, many of the public spaces of the past – as Roman Forum, the medieval market, the monumental squares and boulevards of the Renaissance, the bohemian cafes, or the salons of Enlightenment – were in fact places relatively few inclusive, in the modern sense of the term" (Balula: 2010, 44).

Creative dynamics often take place and develop in this threshold ground, in the diffuse field of the places of conviviality, in the urban spaces of public sphere. Multifunctional places in the city, dense, and composed by several layers of segregation, which are being permanently de-codified and appropriated by different audiences, which face these areas as great showcases for visibility, away from traditional circuits. The urban creative milieus and particularly the cultural districts are good examples of this.

Characterized by being places of the city where there is more freedom for speech and for expression and creation, with fewer levels of social control and often greater tolerance to informality, consequently, they left more opportunity for space appropriation, and mostly for diversity and heterogeneity of appropriations. This makes these urban spaces of public sphere areas of major importance for a sector like cultural activities, where not only is important to think about places of production (which in most cases does not even occur in these areas, with the exception of fields such as street art or urban artistic intervention in visual and performing arts , that have ample importance and visibility in these territories), but also as fundamental arenas for developing conviviality nodes, mediation activities and to occur affirmation within artistic circles. In parallel, but also for all these, they easily assume their liminal character, being particularly attractive to transgression, experimentation and all kinds of social mobility (cf. Arantes, 1997).

In these spaces the symbolical sphere plays an important role and its importance is fundamental for understanding the existing fragmentation. The ones who come to these spaces are looking for a constructed image (of the place, of themselves, of their groups, of what they want to be), they are looking for symbolism. These are particular places for representation, for the assumption of specific lifestyles and ways of life (Cf O'Connor and Wynne, 1996) and therefore, the concept of urban theatricality is sharp in these territories, and along with the liminality processes, we can watch to a natural segregation of practices and people in the different spaces (or even in the same places, each with several codified layers of representations, differently de-codified by their different audiences and users). Often, this process is based on auto-segregation, but sometimes it naturally also involves conflict between the diverse potential users and power relations that take place and develop within that system or with external regulation.

It is therefore usual to watch, in all the three cases studies, to a constant appropriation of urban spaces belonging to the public sphere, as uses are evolving and changing through time and users and audiences also evolve, adapting to the new ways how these spaces are being appropriated. This mix and this continuous social and cultural

negotiation leads naturally to permanent (but evolving) use conflicts, that are particularly notices in each of this cultural districts. When in the same area of the city we can watch different times and rhythms throughout the day, or even co-existing parallel dynamics in the same moment at the same place, that would be perfectly natural. But these dynamics existing in these areas is an intrinsic part of its vitality, and the changes and tensions in the public users and in the uses of those areas are one key-issue for the neighborhoods to keep always its life and its liveliness.

A transversal pattern in all these districts is accentuated by the calm rhythm met by the mornings in contrast with the rush that these spaces stage by nightfall, when the local traditional commerce start to close its doors and in counterpoint come to life the locations of conviviality and bohemia such as restaurants and cafes, and the "alternative" or "fashion" shops that are increasingly replacing former areas of artistic production or commerce of proximity. This panorama is a well known part of the particular processes of gentrification occurring in those kinds of districts, all over the world, and is probably natural in the evolution of cities and their revitalization processes. These territorial systems evolve, with their changing dynamics, the evolution in the dominant uses and the replacing of their regular users, and in some cases it may put in cause these dynamics as we knew it (Costa, 2009, 2012). As we defended somewhere else (Costa, 2012a), if this situation may not be problematic when there are other areas in the city with the same dynamic as in the Barcelona and in São Paulo cases, it may be more worrying in terms of the sustainability of the "creative system" in the Lisbon case, when we do not identify another area with the same dimension, density and heterogeneity of relations and other characteristics essential to maintain this agglomeration of creative sector's activities.

In conclusion, we noticed in this section that several factors influence how urban spaces of public sphere are appropriated and shape the social relations that take place on it. The morphology and the urban design of these territories have also a particular importance in the sustainability of these dynamics and in the vitalization of these areas as cultural districts and attractive arenas for cultural production consumption and mediation processes. We will explore that in the next section, but before that, we suggest a digression through these spaces in our 3 case studies, by observing the selection of images presented in Figures 2, 3 and 4, which give us some brief insights on the reality of each of those experiences. That is with that ground that the discussion of the next section will be held.

5. Urban morphology and sustainability of each area

Urban morphology conditions the way how the spaces are lived and appropriated by the population and the way social practices take place on it. The urban design, the characteristics of the public space, and the private spaces of public use are then some of the main factors that contribute to the development and sustainability of creative dynamics.

Concerning our specific case studies, as Balula puts it, they "seem to confirm the argument of Gert-Jan Hospers (2003), when he affirms that creativity doesn´t occur in vacuum, and that some urban contexts, rich in historic sediments, are the places – the physical and social supports – by excellence where creativity finds its roots." (Balula, 2010, pp. 55). All the quarters analysed are the construction of an identity that is composed throughout its centuries of history. The continuous overlapping of these layers gives at these places of the city a great functional and social diversity that sustains the development of this kind of dynamics. The essential characteristics that are in the genesis of creative dynamics (Costa et al, 2008) are more likely to develop in such conditions (Scott, 2000). Like Richard Florida notices "the urban places more attractive for the creative clusters are those that offer a diversity of experiences, and a variety of activities, and enable different lifestyles" (Florida, 2002: pp.11). This affirms undoubtedly the importance of the multifunctional urban areas against monofunctionals, as in the later the margin for interaction of different publics, styles and uses is naturally less common.

Thus, it will be interesting to give a brief framework of the historical evolution of these districts in order to understand better their current contextualization. We start the framework by the historical period of their implementation, when each area appears, in the cities of Lisbon, Barcelona and São Paulo. All the three case studies were located in the periphery of the cities on the occasion of their implantation and then they were progressively inserted in the urban core with the development and growth of the respective cities. Despite having an area of implantation and an "image of the city" that are very diverse, deriving from the different realities and historical periods in which they developed, "the three quarters have a similar morphology, being formed entirely by irregular orthogonal grid" (Balula, 2010, pp. 49). But in addition to the morphological aspects we should note that the analysis of urban morphology cannot be dissociated "of the moving parts of a city especially people and their activities, [that] are as important as the physical and real estate" (Lynch, 1960, pp.11).

The Bairro Alto was the first urban core built outside the city walls, dating from the early 16th century, being located near to one of the Lisbon "city doors" at the date. Its drawn adapts to the topography of the terrain, being the one of the three cases analyzed in which the orthogonal grid is more organic. The quarter is characterized

by its narrow streets composed majority by buildings of *Pombalino* period[5], and despite the numerous renovations and additions, keeps essentially the historical and picturesque image of the quarter over the years. Its streets are paving by stone, the floor is irregular and away from modern mobility rules, the sidewalks are narrows our inexistent. The traffic is closed inside part of the quarter (just in recent decades), where just is possible access on the part of residents or to "charge and discharge". So the main car traffic is carried by the peripherals limits of the quarter, being just possible to cross it by Rua da Rosa that divides the quarter into two parts with different characteristics, being the Western zone mostly residential, and the Eastern zone characterized by functional diversity, and where occurs the majority of functions with social character. This is the one of the three quarters that presents a smaller area of public space[6], existing only in the streets that cross the quarter, and its peripheral limits. Thus, the streets assume the function of "living room of the quarter" to the regulars who wander and chat there during daytime and for those who flock at the quarter at night, standing or sitting along the streets. The urban furniture for permanence is practically non-existent within the quarter, as well as green areas or public spaces with great dimensions (all in the outskirts of the quarter), because this this was not a concern at the time of its construction. Considered marginal, insalubrious, and poor in habitability conditions in the mid-20th century, it led to that projects for demolition of the quarter and the construction of a new one following news urbanisms patterns were proposed. However this did not occurred, which allowed the deployment in this area of the city of a series of activities that took advantage of the fact that it was a central and relatively low-priced economic zone to develop, such as the case of the printing cluster. Is following this logic that the contemporary creative industries begin to develop in the territory, articulating the axis Chiado – Bairro Alto, and exploring the long-term inter relation and complementarity between the institutional-daily pattern of Chiado (the side "inside" the ancient walls and institutional cultural pole of the city) and the alternative-marginal-nightlife image of the Bairro Alto area (Costa, 2007, 2009). This proficuous relation, exploring also the transgressive tradition in terms of sociability and conviviality in Bairro Alto, feed the area as the main cultural area of the city. The artistic universities placed in Bairro Alto as in Chiado increased the critical masses of who lived and attended the activities in this district, and it was in this general context that this part of the city affirmed itself over the years as the cultural and creative place for most cultural activities in Lisbon, although in recent years, this centrality has shifted progressively for consumption-oriented and social and conviviality-based activities, also essential for the structuring of the creative activities cluster, but not centered on cultural creation and production.

The Gràcia was also result of a development and urban planning outside the city of Barcelona. Distanced approximately 2 km of the walled city, it developed as an autonomous "Pueblo", which structural characteristics still remain until today and

[5] It is included in the "Pombalino period" all the work done in the scope of the period after Lisbon 1755 earthquake, on the regia of King José I, where Sebastião de Carvalho e Melo, Marquis of Pombal was Secretary of State of the Kingdom, having promoted a wide reconstruction plan, with very distinctive character.

[6] Consult data in Balula, 2010, pp. 53.

that is reflected also in a strong sense of local identity in its population. It's encompassed in the city of Barcelona after the Cerdà[7] plans. The quarter has a superior population density when compared with Bairro Alto, as happen with its implantation area and the height of the buildings. The narrow streets are usual framed by builds between 4 and 5 floors, around two more floors than the buildings of the Bairro Alto. The orthogonal grid is interrupted several times by squares, where people meet, which are the main public spaces of the quarter, equipped with plenty of urban furniture and shaded from the sun by trees. These are the scenario for the public convergence of people with a high degree of heterogeneity, assuming the role that in Bairro Alto was confined to the streets. Gràcia characterizes for being an autonomous "small city" within Barcelona. It is perfectly possible to live, to work and to access to cultural events without leaving the quarter. This mix of "needed activities", as well as both of "social" and "optional" nature (cf Balula, 2010, pp. 50), confer to the quarter a vitality and a dynamic throughout the day, being the one of the three cases which presents a better balance between the three groups. The circulation in the quarter is organized and some streets are closed to traffic, while in others one can only circulate motor vehicles and bicycles. With these three kinds of circulation in correct hierarchy in the quarter, cars, motor vehicles and pedestrians, this doesn't reveals so much the circulations problems founded in the others quarters. The issue of parking also seems in this case somehow solved, as the car parks situated beneath the numerous squares respond to local needs, contrary to what happens in Bairro Alto as in Vila Madalena where the users take hours to park their vehicles. The sidewalks are regular and prepared for the movement of persons with reduced mobility, it's usual to found the sidewalk in the same plan the road to resolve the previous problem of the narrow streets; with this solution and the traffic controlled the major part of the time most of the streets are large sidewalks. Today, we can find a quarter accessible to any citizen. For this, the characteristics of the territory and city's town planning rules contributed a lot. The quarter doesn't have significant topographical variations; it presents a slight pending throughout the territory, however this does not feel the scale of person when compared with the others cases. The pavement of the streets and sidewalks is in most cases the same, polished stone, larger than the ones that we found in Bairro Alto, although the streets with more car traffic are paved in asphalt.

In Vila Madalena the aspect of street pedestrianization seems to be one of the most problematic to the quarter. In a place where there isn't an entity responsible for the organization, construction and management of the sidewalks each person is responsible for the construction and maintenance public space adjacent to its housing. Without any explicit planning rule about that or restrictions about mobility, the landowners build as they well understood. The quarter is implanted in topography of pronounced slopes which by itself would easily render its users. In addition to this factor, the hardly considered sidewalks configuration makes that it would be impossible to move around in the quarter some person with reduced mobility, although the sidewalks are large, and they are assumed as the places appropriated for

[7] Author of the expansion plan of the city of Barcelona out of the walls in the 19th century, giving to the city the distinctive urbanism that we know today

the costumers who come to the zone. Contrary to what happens in other cases, in this quarter the hierarchy of streets is less marked; cars can circulate in all of them, as after all it is really an important piece to live in the quarter, contrary to what happens in the other two cases where the access to the various services is easier moving by foot or by public transport. That is one of the biggest counterpoints to those who live and go to this quarter.

Vila Madalena starts being as a small group of houses out of the city of São Paulo (such as Gracia in Barcelona). Only in beginnings of the 20th century, with the construction of the railway line that would connect the small cluster of houses to city centre, and later in the 70's with the transfer of the Arts University of São Paulo for a near neighborhood, is that this area starts to assume the setting that we find today. Like São Paulo itself, it is characterized for being in constant mutation. It is a quarter with little more than 100 years of history. It displays an urban drawing of wide streets to automobile scale, contrary what happen with the others, which grew up before its appearance. From the beginning it was a quarter composed mostly by single-family homes. Today, it is in quite advanced state of gentrification and many of the single-family building that composed (and symbolized) the quarter has been replaced by buildings with more than ten floors. These urban changes are disfiguring, in physical terms, the "old" artist quarter (that itself is a gentrification of the precedent blue-collar workers neighborhood, although in that previous case the change did not reflected too much in the buildings characteristics). As Samuel Dias states, "in São Paulo, it was built up on top instead of building next to" (Dias, 2010, pp. 20), and we can say also at high speed, due to the economic and demographic expansion, that progressively get new areas of the city. The municipal master plan allows the replacement of the old builds by others with completely different characteristics, contrary to what happens in the Spanish and Portuguese case, where the regulations don´t allow this kind of modification in the characteristics of existing edification, with more restrictions in the Portuguese case and a more flexible paradigm in the Spanish case. These kinds of alterations in edification typologies of Vila Madalena are changing the intrinsic characteristics of the district, due to the changes in uses and in the population that these restructurings generate. The old buildings are mostly replaced by private condominiums that not only involve lesser levels of public space appropriation as also do not guarantee the same mix of activities that was present in the old structure of the quarter. That have being conducting to a certain lost of vitality, contrary to what seems to happen in both the other districts, where the strategy has been keeping mixed uses in the buildings and multifunctional areas, in spite of the use conflicts that this can also generate.

The private spaces of public use also diverge between the different cases. Different uses and spatial typologies affect the way how the public space adjacent is appropriated, depending on the characteristics of the activity and how they develop, and these diverse situations generate different appropriations of public space by breaking the boundaries between private space of public use and public space, originating in some cases (noticeable the ones related to conviviality or some artistic interventions on these spaces) considerable use conflicts between users and residents. When economic and cultural activities leave private space of public use and implant

themselves in the public space, they became the center and target of polemic and divergent opinions, typical in this kind of quarters, marked by the heterogeneity of resident population and regular or occasional users, which make themselves evident, at different rhythms, throughout the day. This kind of dynamics are one of the most visible “brand images” of these kinds of districts, where it is not unusual to find many of the public spaces regularly occupied by multiple passersby, who fill the streets and sidewalks in Bairro Alto, the squares in Gràcia and the large sidewalks of Vila Madalena, making part of the urban landscape of these places, and being the main actors on the stage where most of interpersonal contacts take place.

In addition to the physical and material appropriation, it is important to mention how private spaces of public use show themselves and make themselves evident throughout public space, assuming a great importance in those places. The images that can be perceived through the shop windows, the light that is reflected in public spaces, the sounds and the smells, among many other, are all fundamental elements that contribute to the identity of the these places. The Bairro Alto and the Gràcia with its mixed-use buildings and the commerce along the streets turn out to be an element of great attractiveness, “enriching" the experience of walking and wandering through each of these quarters. On the contrary, in Vila Madalena, being a quarter marked by more monofunctional buildings, it can become a more tedious or at least less surprising experience, as activities are a little more divided between the different territories. This can lead to lower conflicts of use in this place, when compared with the rest of the cases; however, it can represent also a certain loss of one of the great virtues of these territories, that is to enable the confrontation of different people and uses, that by their diversity enriches the city and the lives of who uses it.

This kind of districts, as already explained, has at its disposal a diverse range of qualities and cultural offers that make them most desirable in the city. Joining to this factor its centrality, this leads to that they can mobilize a strong demand, even in central functions of high level, with larger demand thresholds. However, it is not always easy to an old quarter to continue offering the best commercial typologies, residential conditions or access to public facilities, while technological evolution, city spread and people’s expectancies and ways of living constantly evolve. The three districts are all good examples of this, with difficulties in accompanying these structural changes, at least for some markets (mostly the more generalist and mass-based ones, both at residential and commercial levels). However this can be one of the main factors that contribute to the sustainability of the activities that keep in the quarter and to the dynamics of the area as creative system (Costa, 2012, 2012a, Costa et al, 2010). If the commercial typologies would be more versatile, like the ones found on a shopping mall or on other commercial centers of the same city, they would be quickly occupied by other economic activities, with more financial capacity to pay that place, as soon as they become more mainstream in people’s practices and in people’s representations. That would rapidly conduct to the decrease in the specificity of the offer of products found in this type of quarter, with the subsequent consequences in the field of the symbolic and the representations, with greater impact in the cultural related activities (cf. Costa, 2012). By the same token, if the housing stock would be all equal, this would encourage a more egalitarian city,

with more similar rhythms and life styles, and daily lives, turning these areas into a less attractive kind of city for whom looks for it today, and to a place that would not be lived at all the different times of the day, as it happens in many suburbs of the same cities.

Summing up, as can be seen for all that is said in the precedent paragraphs, w3 can assume that the characteristics of urban design, specific place morphologies and typologies are determinant for the attractiveness of creative activities and for the appropriation of these areas by sustainable dynamics on the cultural and creative sector. That is a conclusion that we could draw from the empirical analysis of the 3 quarters that were studied in this project. As seen before (Costa et al, 2010; Costa, 2009, 2012, 2012a) these are not sufficient conditions for the development of those dynamics, and moreover, for their sustainability through time. But they are important conditions for the development of these systems, for the functioning of their governance systems, and for their sustainability. The gentrification processes in all of these quarters would be far more extent now if there wasn't some of the strong morphological (and urban planned-based) conditions that regulate their development. For instance, in the case of Bairro Alto (where planning conditionings are stronger and these effects are mostly noticed) if we would not have those kinds of streets, dwelling conditions or traffic structure, for instance the selective gentrification process that took place, privileging creative and artistic oriented lifestyles, would be far gone. At the moment that houses or shops could be bigger, with different typologies, that they could have a lift, that the car could be parked near the door, that the multiple conflicts in the public space decrease, that the diversity of the people present in that public space decrease, probably other social segments would take the place of the artists and the creative people in this part of the city, as recurrently happened in other cities before. Both by the effect in land prices and the effect in the symbolic mainstreaming of the quarter, the artists give place to the ones that have the power to keep in the area. And on that moment, the sustainability of the area as creative system is clearly challenged.

6. Concluding note

This paper aimed to discuss the relation between urban design and the creative dynamics in cultural districts. Urban morphology clearly takes a relevant place in this relation. Departing from a discussion on the boundaries of public spaces and their relevance for the creative dynamics (through the conviviality and sociability they promote, which is a key feature to creative dynamics - cf Scott, 2000 - and to the reputation and gatekeeping mechanism essential to cultural activities development – cf. Costa, 2012 -), it was discussed how the characteristics of urban design, specific place morphologies and typologies are determinant for the attractiveness of creative activities and for the appropriation of these areas. The uses, practices and symbolic representations that take place in those areas, as well as the use conflicts that arise on those multiple arenas (e.g. between nightlife users and residents that want to sleep, between grafitters and property owners, between street performers and residents,

between traditional activities and newcomers,…), are essential for the balances on the evolution of these territorial systems, and often are key-factors associated to their governance systems. As consequence of this, these morphological aspects should be also discussed as central at the light of the main challenges to the sustainability of each of these areas, when we think of them as "vital" and "creative" centers in their cities.

Not being our intention to discuss here in more detail the governance of these systems (see Costa, 2012, 2012a), or even the general regulation and governance of the public spaces of these areas (cf. Costa et al, 2010, Costa, 2012), we just want to sum up some ideas about the particular issues on the governance of these systems that are specifically related to urban morphology and to the design of public spaces.

As we have seen, the situation is very different in each of the 3 cases. While in São Paulo the action of the diverse stakeholders is much free than in the other cases, and the planning procedures are much softer, in the Lisbon case we have the opposite situation, with strict regulation, about what can be done (or not) in private and public spaces (although many times not fully effective…). In the Barcelona case, with an intermediate situation in terms of policy-orientations and planning practices, other factors, such as associative tradition and social composition of the district, play a major role in the governance of the area, and the results are many times more efficient than in Lisbon.

Facing several common problems (infrastructure congestion, use conflicts related to different interest on public space utilization, and so on), local stakeholders negotiate diverse situations and policies through time: e.g., closing streets to traffic or not; investing in public facilities on public space; controlling building permits or not; limiting nightlife schedules mechanisms; managing permits and licensing for the several kinds of economic and cultural activities functioning conditions; allowing or nor more deviant behaviors towards social norms, and being more or less tolerance regarding diversity manifestations in public places; being more strict or less strict concerning the accomplishment of all legislative and security criteria for all activities; approving the construction of private managed *condominiuns* in the area; managing commercial or artistic use of public squares and streets for events; managing permittivity to wall appropriation, for artistic or communicational purposes; managing of urban hygiene problems due to the pressings over these systems; and so on. Some of these actions can be translated in common procedures in terms of urban planning in the 3 cities (concerning traffic regulation, parking, noise, schedules,…), but other represent very diverse approaches to planning, some of them due to the diversity of the degree of those problems and to the diversity of planning frameworks (urban licensing, hygiene, security).

Two main ideas result from this diversity. One is that we need to understand that these areas are naturally marked by conflicts between agents with diversified interests. Such conflicts may be minimized in order to promote well-being and quality of life in the area, to their residents, activities and users, and this is a role that public authorities must try to accomplish. But sometimes that conflict can be also important to maintain the diversity of this site, to be possible to that system to

sustain, to that place to renew and reinvent itself, and to keep always its vitality. Activities rarely maintain over long periods of time in the same place, which increases their rotation, and makes those places living organisms, with a local dynamic themselves, distinctive in their city. Regulation must go through an attempt to leave these spaces living by themselves, giving room for happen different things, differently to what happens in the rest of the city, giving space for greater freedom. By their own nature, creative activities are anti-institutionalization, and more open planning instruments, dealing with creative solicitations from society, will be certainly more efficient that too rigid ones.

The other idea in terms of the concluding policy-making guidelines that are drawn out from the analysis, is that we can never forget the diversity of this situations and non-transferability of policy instruments or policy agendas. As it is also clearly demonstrated in these 3 cases, even with many similarities in this 3 cultural districts and the challenges that all of them are going through, with their transformation and gentrification risks, the fact is that the sustainability of each of these territorial systems is dependent of the specific actors and specific processes that take place in each situation. Policy responsible authorities have to understand the specific governance mechanisms that are the driver of each system (that are very diverse in each of these 3 cases), and then act specifically considering what are the real possibilities, instruments and objectives that they can manage and negotiate with all the other involved stakeholders. It is easy to design and set up a "creative city" strategy in each of these districts or even in other part of these cities. The difficult is to do that without destroying all the mechanisms that were underneath the creative dynamics that previously existed in those places, and without putting at risk the mechanisms that enable the sustainability of that system as a creative one. And for that, amongst many other things, we need to fully understand the morphology of the area, the urban design, and the way it interacts with the social and cultural practices that took place in it, and the interaction with the symbolic system that is inherent to it.

Urban and architectural design and scientific research: how to save an arranged marriage?

Coppens, T., Associate Professor at the Master of Urban Design and Regional Planning, Department of Design Sciences, University college Artesis, Antwerp

Van Geel, H, Associate Professor at the Master of Urban Design and Regional Planning, Department of Design Sciences, University college Artesis, Antwerp

Abstract:

As a result of the Bologna treaty, many architectural and planning schools are in transition in Europe. As the educational landscape is changing, new standards are set to meet the criteria of scientific research based on higher level education. The demand to integrate scientific research in the curricula and the demand to develop a scientific research programme into planning and architectural schools is a real challenge for many planning and architectural schools, that are traditionally centered around studio work and design. Moreover, the criteria on which research output and research excellence are measured traditionally seems unfit to grasp the specificity of urban and architectural design research and education.

For some design teachers this transformation should not affect at all the primary focus on the tacit, practical nature of design study. This position postulates that practice in itself offers a sufficient condition for validation. Others advocate to revise the traditional criteria for research validation and to broaden the scope and nature of scientific research in order to reconcile science and architectural or urban design.

In this paper we argue that neither a strategy of business as usual, nor a strategy of stretching up science are a defendable approach to the demands of a transforming educational landscape. We propose that instead of altering the criteria of scientific

excellence and output, design excellence and output should be assessed by its own specific criteria and institutions. We develop a framework in which a distinction is made between different forms of knowledge, and suggest how different criteria can be applied for design excellence and output.

Introduction: The arranged marriage of science and design

As a result of the Bologna declaration of 1999, many architectural and planning schools are in transition in Europe. The declaration of 1999 aimed to develop a uniformed structure of higher education in Europe, making academic degrees comparable and promoting mobility between European institutes. The declaration set in motion a reform process of education towards a system based essentially on two cycles: a first cycle geared to the labor market and lasting at least three years resulting in the degree of Bachelor, and a second cycle conditional on the first one, resulting in the degree of Master[1].

Although Universities in Belgium have been able to transform their education structures successfully, the University Colleges (*Hogescholen*) are still undergoing a reformation process. Some of the former Colleges in Belgium, provided a two cycle education programme, and are considered *de iure* as academic courses. However, the Flemish Government which is competent for education in Flanders, had devised a process of "academization" in order to increase and strengthen the connection between academic research and academic education in the university Colleges. Together with this academization, the Flemish government decided to rationalize the educational landscape and set in motion a process of the integration of the former two cycled courses of the Colleges into the Universities. As the former architecture

[1] The European Higher education area, 1999, The Bologna Declaration of 19 June 1999

college schools (including interior design and urban design) also provide a two-cycled system, they are now in this process of "academization".

The process of academization of Architectural Schools proves to be an all but smooth process. The demand to integrate scientific research in the curricula and the demand to develop a scientific research programme into planning and architectural schools turns out to be a real challenge. Many planning and architectural schools are traditionally centered on studio work and design. Academic research was nearly absent in former *practice based* design teaching, and the staff of the former architectural schools did not have track record of traditional academic output, such as peer-reviewed articles, peer-reviewed academic books or conference proceedings. When assessed by traditional indicators of academic production, the architectural schools therefore severely underperform.

Confronted with the poor research assessment outcomes, the academization process (re)started in the Flemish architectural schools a fierce discussion on the nature and the role of science and academic research within architecture, and related disciplines as urban design and interior design. Within this discussion, broadly two basic viewpoints can be traced. One viewpoint is seeking to conform to the traditional media of scientific output, oriented to journal articles, books, conference proceedings etc. and to shift the research focus into more vested research disciplines, which have vested methods and established media for academic output. Such a strategy of academization might be successful for a part of the staff that focuses on supporting disciplines of architecture and Planning such as architectural history, construction engineering, environmental psychology, political sciences, building economics, process management, cultural theory…. However, this strategy is largely unattractive for the majority of the teaching staff in Architectural schools that lack any track record in research, is design oriented and faces a fierce competition with more established institutes in these disciplines on research funding. Moreover, such a research program is felt as an alienation from what is often considered as the core of the discipline, namely the design process.

Therefore a second viewpoint increasingly emerges, which aims to transform the vested methodologies in validating and assessing academic research output. Central to this approach is the idea of design based research. Illustrative for this viewpoint is the declaration of the European Association for Architectural Education, which confirms that "*architectural research has a particular knowledge base, tools and methods*" (EAAE, 2011). It therefore calls for a "*recognition of all appropriate areas and modes of architectural research, for better definition of context and scope and acknowledges research by design as part of the diversity of valid methods with which to research, practice and study architecture"*. A similar viewpoint comes from the UK Research Assement Excersise (RAE, 2006). Panel H, responsible for the RAE of Architecture and the Build Environment defines research output as "*any form of publicly available, assessable output embodying research as defined for the RAE may be submitted, as may confidential outputs that are not publicly available (p10)*". The Panel declares that "*In addition to printed academic work, research outputs may include, but are not limited to: new materials, devices, images, products and buildings; intellectual property, whether in patents or other forms; performances, exhibits or events; work published in non-print media"* (p10). The appendix of Panel H also specifies how research excellence should be assessed. It provides a peer review process of research output, assessing with criteria of originality, significance and rigor. Significance will be assessed *by dissemination and impact, and the work will be assessed on actual and/or potential significance, in recognition of the time-frame over which some work reaches and influences its audience*. In panel H no bibliometric data will be used to assess the impact. Rigor is defined *as including research processes which are* ***not necessarily systematic or linear****, yet demonstrate intellectual precision and material integrity, and innovations in process and/or product in relation to its context (p 24, emphasis added).*

Panel H holds an extremely relativistic approach on the nature of scientific knowledge and scientific output. The basic motto seems to be: everything goes, as long as it is confirmed by peers. It is therefore assumed that a consensus between panel members on originality, rigor and significance is sufficient to demarcate scientific work from non-scientific research. But in the first place, these criteria do

not reflect a coherent conception of scientific research or output. Its incoherence is easily demonstrated when rigor is defined as “not necessarily systematic or linear”, implying thus that rigor can be unsystematic, which is a contradiction by itself. Furthermore, correspondence with truth or experience (external validity) seems not to be a criteria of research output. Thus according to the Panel, original, significant but not necessarily systematic, ideas that are plainly wrong can be considered as valuable academic output.

But even if the demarcation criteria between science and non-science were clear, the proposed assessment method of panel H is likely to result in severe bias. Panel H is overwhelmingly silent upon the many potential failures of panel judgments such as group think (JANIS, 1972), peer pressure and power relations. Certainly if research outcomes cannot be validated or reproduced by other researchers (such as images or buildings), there is no external impetus to be self-corrective on the longer run and to separate scientific findings from non-scientific findings. Power relations between institutes, norms of reciprocity between the assessors with affiliation to the institutes all might trigger strategic behavior in these panels, rather than a sincere, neutral evaluation of research output. Sure, the traditional peer review process of journal articles follows a similar procedure and might have a similar bias. However, the anonymous peer review process of journal articles is only one step in the validation of scientific output, and the fallibility of the review process is backed up by bibliometric citation patterns, but also the tendency to self-correct over longer periods when research outcomes cannot be reproduced by other researchers or do not match new findings (KUHN, 1972).

One might argue that the demarcation between scientific output and non-scientific output is artificial or old fashioned. However such an argument would contradict the process of academisation itself, and would raise serious questions on the role public funded universities and academic institutions in society. If the academic institutes mission is to produce scientific research output, but if there is no demarcation between science and other forms of knowledge or action, than the purpose of academic institutions is obsolete and there is no legitimation for their existence. Any

assessment method which is not based upon a philosophy of science and a set of demarcation criteria is therefore doomed to fail. The real basis question for Architectural Schools is thus not how to assess research output, but how design output can relate to scientific output?

Design versus science

Obviously history repeats itself in the course of this debate. In the former century, academic discussion on design and research appeared, faded away for a while to re-appear again. The discussion develops mainly along two lines *art versus science* on the one hand and on the other hand the *Practice based research (PbR) versus academic research.*

Nigel Cross observed a 40 year cycle of alternating pro's and con's concerning the possibility to 'scientise' design. (N. CROSS 2001:49) Already in the early twenties of the former century the 'Stijl' movement questioned subjective speculations in Art and design. The movement aspired for more objective methods in the design process. A similar aspiration occurred in the 'design method movement' during the sixties of the former century. Objectivity, rationality and method were key issues at the 'Conference of the Design Method' in 1962.

In the broader 'planning community' similar movements can be traced during the fifties and sixties with – in the footsteps of Wiener - the introduction of the computer based 'cybernetic' models, elaborated by Chadwick and Mc Louglin during the heydays of synoptic planning. A setback came in the seventies with, for instance, Christopher Alexander – although a former adept of a rational, methodological approach in design - questioned the plausibility of an objective method in the design process. Alexander affirmed:

" I've disassociated myself from the field… There is so little in wat is called 'design methods" that has anything useful to say about how to design buildings that I never even read the literature anymore…I would say forget it, forget the whole thing" (quoted by N. CROSS 2001:50)

Also Christoppher Jones deplored *" the machine like language, the behaviorism, the continual attempt to fix the whole of life into a logical framework". (quoted by N. CROSS 2001:50)*

Cross justly places these statements in the social and cultural climate of the late sixties with the rise of radical political movements on campuses. Needless to remind that a then dominant positivist current in social sciences had to deal with a same kind of criticism. A new turning tide appeared in eighties en nineties with emergence of new journals of design research, theory and methodologies creating a new forum for reflection on 'scientisation' of design.

Cross suggested new categories in order to break through obstinate obscurities in the debate among 'believers' and 'non believers' concerning the place and the meaning of research in design matters. According to Cross, 'Design science' stands for a belief in a rational method, 'Science of Design' should focus on the study of the nature of the design process and the 'Design discipline' emphasizes the specific nature of a design practice. (*CROSS 2001:51-53*) In his conclusion Cross sees broad opportunities for design knowledge in the specific object of the design discipline:

"What designers especially know about is the 'artifical world' – the human-made world of artifacts. What they especially know how to do is the proposing of additions to and changes to the artificial world. Their knowledge, skills, and values in the techniques of the artificial (Not 'the sciences of the artificial'). So design knowledge is of and about the artificial world and how to contribute to the creation and maintenance of that world…." (*N. CROSS 2001:54*)

Question is whether the definition of this supplementary category of a 'Design discipline' can completely dispel the confusion. The 'artificial world' can hardly be considered as the privileged territory of a design discipline. Close encounter with sociology, cultural anthropology, literature and linguistics and so on and so forth, seems to be inevitable within this field of 'study' and the introduction of this new

category does not clarify the particularity of the ‘discipline’ like approach of the former against the ‘science’ like approach of the latter.

Cross’ reference to former discussions about art vs. a scientific practice then centers around broad dichotomized categories like art vs science, fact vs. value, truth vs. opinion, positive vs. normative, rigorous vs. intuitive etc. For the believers of ‘scientization’ of design the challenge then is to push research practice to the other side of the opposition.

More recent reflections in favor of a ‘scientisation’ of the design discipline clarify the fundamental requisites for a science image modeling of design research. De Jong and Van der Voordt for instance underline in a quite exhaustive reader on design and research the importance to adopt *methodological* standards in design research: 1) reliability or the possibility of repetition of measurement under unchanged conditions; 2) validity, dealing with adequate measurement of concepts 3) open to criticism; 4) scientific relevance, or the perspective of deepening the development of the discipline in question.

“If a (tentative) design applies for being branded as result of scientific activity, it should comply with general requirements put to the scientific approach, to wit: inter-subjectivity, reliability and verifiability in an empirical sense. ‘Inter-subjective’ was defined … as ‘interpreted by different people in the same way’… Verifiable points to the description of the design in terms of the grounds on which the decisions have been taken, including validity and tenability. Additionaly, ‘verifiable’ includes, that the design can be specified according to concrete situations and can be generalized to possible applications in different situations or contexts. (De JONG T; VAN DE VOORDT T 2002: 25).

The position of these scholars is quite radically stated in the introduction of the reader:

“If design is left to creative powers and does not need to comply with scientific criteria, each and every university education lacks it’s right to exist”. (DE JONG; VAN DER VOORDT 2002: 12)

But conclusions of De Jong and Van der Voordt remain ambiguous. The authors admit that *hard* criteria of science cannot in all situations be met in design research. The standard of reliability becomes precarious when multi-functionality leaves open more possibilities than predictable during research; design is context sensitive, hence resistant to validity claims and to the possibility of generalization. Moreover, if reflection would be broadened – which is mostly not the case – to methodological differences between the three families of science –exact sciences, social sciences and design sciences- , other questions might support the effort of comparison and demarcations. What about for instance the status and the role of theories in design research? Taking into consideration the context sensitivity of design 'discipline', are under certain conditions nomothetic statements conceivable in design research or not? Is the inevitable use of normative theories (not *what is*, but what should *be*) in design research part of the restriction to the applicability of the hard science model in design research? Reminiscence of analogue questions in the history of social and human sciences – the so called 'methodological struggle' is inevitable.

It is striking that comparisons of scientific research with design research refer either to an undifferentiated image of science or restrict to a sole comparison with the logic of research in exact sciences. Reflection on a possible common ground with the methodological ambiguities in social and human science - the so called double hermeneutic (GIDDENS,A., 1976) – is scarce, though it might deepen insight in similarities or distinctions in the logic of research within the three science families on one hand and designingly research on the other hand..

Differentiation of the practice of scientific research can be conceptualized on four dimensions – epistemology, theory, techniques and morphology (DE BRUYNE P; DE SCHOUTHEETE, HERMAN J., 1974). Similarities and differences in research practice are roughly schematized under these four dimensions.

		EPISTEMOLOGY	THEORY	TECHNIQUES	MORPHOLOGY
'Exact sciences'	Goal Means *World Orientation*	Objective 'truth' seeking as an open system Probability Hypothetical – deductive ' Mind to world'	Explanation Generalization about how the physical world behaves Empirical concepts	Quantitative Measurement Statistics Experimental Quantitative	Coherent, logical consistent statements; Predictive statements Symbolic mathematical formalization Quantification Output: peer reviewed articles; books manuals
Social/human sciences	Goal Means *World Orientation*	Objective 'truth' seeking as an open system Probability Hypothetical – deductive **or** interpretative, heuristic ' Mind to world'	Explanation (causality; correlation) or understanding (verstehen); ideal types about how the social and meaningful world behaves Hypothetical – deductive method or 'ideal types' Empirical concepts	Measurement or classification; typology statistics Experimental; quasi experimental Or heuristic Quantitative or Qualitative	Coherent logical consistent concepts and statements Discursive; narrative; metaphorical Output: peer reviewed articles; books; manuals
'Design discipline'	Goal Means *World Orientation*	Normative, action oriented Possibility Testing design solutions World - to - mind	Normative (normative) Spatial concepts Spatial vision	Scale modeling Drawings; Typôlogy	Visual Narrative Metaphorical Prescriptive statements

Inevitably, for the sake of clarity, the scheme offers only a basic comparison, further differentiation can/must be made within the 'traditional' science families. A psychological aspect, a mental state, the intentional orientation to the world, is placed in this scheme under the epistemological dimension due to epistemological implications. Unquestionable a fundamental similarity between the three science

families is what Heilighen, Cavallin and Bianchin – inspired by J. Searle - call a 'mind- to- world direction of fit'.

"…The mental activities of a scientist are characterized by a mind-to-world direction of fit. Researchers seek knowledge as an end in itself…The beliefs and insights they produce may be true or false, and it is their responsibility to match the world in order to be true and therefore successful (A. HEYLIGHEN, H. CAVALLIN, M. BIANCHIN 2009:97)

By contrast, a designer's mental activities seem to be dominated by a world-to-mind direction of fit. Designers are concerned not only with what is, but with what should be. Their attention is focused on possibility, "*the search for new or better solutions to problems encountered in everyday living*". *Thus, even if architectural design contributes to the creation of knowledge, the knowledge created is usually a side-product of an activity with another aim. Moreover, the solutions designers produce cannot be true or false*" (Ann Heylighen, Humberto Cavallin, Matteo Bianchin 2000:98). The mind – to – world direction of scientist is founded on theory based research, generating hypothetical statements about the behavior of the physical or social world[2], and structuring research activities aiming at the corroboration of those statements.

A clear distinction between the 'exact' sciences on the one hand and 'social sciences' on the other hand involves the status of theories (range of explicative power; predictive power etc.), the nature of corroborative procedures (hypothetical testing vs ideal type understanding) and the nature of discursive argumentation (use of mathematical models; role of narrative etc.). A fundamental demarcation between the three science families vs. 'design sciences' is the (mainly) world-to-mind mental activities of designers, focusing on possibilities, on the search for better (spatial) solutions. It explains the normative nature of its theoretical frameworks, the action oriented spatial concepts and the highly *prescriptive* character of design statements vs. the *descriptive or predictive* character of scientific statements. (LADRIÈRE, J., 1969). Obviously, claiming a scientific status for design research, by solely referring

[2] In his 'road to reality' the mathematician and physicist Roger Penrose states that modern scientists avoid the 'what question' (what the world is; or why the world is what it is) but prefer questions in terms of how reality behaves (Penrose: :1028)

to a necessary adoption of *methodological* criteria like validity and reliability is not a sufficient condition to legitimize this claim. Epistemology, theory, morphology and adequate techniques are inseparably linked. Whether one wants to explain (causality; correlation) or to understand (heuristic) will affect forms of exposition and chosen techniques (qualitative or quantitative). The nature of involved theories will structure the whole research strategy, being a consistent set of methodological decisions, in the blueprint of the research process.

Up to now, an important *missing link* in the discussion about design research as scientised activity is the role of theories in structuring the practice of (academic) design research. Especially the notion of validity is interwoven with theory based research in common scientific practice. Internal or external validity refers to theoretical concepts and to more or less adequate operationalization of those concepts through index construction and measurement.

Clarifying the shift from art to science on a continuum, with art on one extreme and science on the other, earlier mentioned scholars Van de Voordt and De Jong consider typological studies in architecture and urbanism and 'research by design' as examples of a scientific form of research. The concept of 'research by design' is an interesting case. It gets privileged attention in the present discussion on 'academisation' and 'scientisation' of the education program of architecture and urban design. Tough definitions of this type of research can still vary from scholar to scholar the definition of Van de Voordt and De Jong will probably be endorsed by many. They define study by design, or research by design as "t*he development of knowledge by designing, studying the effects of its context, and studying the effects of its transformation…*" (Van de Voordt; De Jong; 2002: 455). An important element is the research like character of design, operating in function of research not in function of a design program.

Subtypes can be distinguished according to the degree in which the objet and context (space, time, programme, boundary conditions), are constant or variable. Some scholars will add the importance of participation of involved users or stakeholders in the design process. In that case it is considered as a form of action research, quite

similar to this research method used in social sciences. Emphasis on the primordial role of knowledge development (design in function of research) explains the privileged attention for this kind of research. However, considering the *pure methodological* nature of this form of research it is quite unclear – taken into consideration the variety of contexts and the singularity of situations - how this *design driven* methodology might develop to a theory driven scientific practice. The morphological dimension of research (morphology in the sense of forms of expositions, of syntax etc.) is rarely subject of investigation, though an essential part of the process. Examples in social sciences are semiotic approaches by Greimas and Landowski in their discourse analysis of social science discourses (A J.,GREIMAS, E. LANDOWSKI, 1979) and McCloskey's illustration of the role of the narrative aspect in economic expertise (D N. McClOSKEY 1992) Morphology is the place of articulated objectivity. It forces the researcher to place his/her subject of research in a 'configurative space' of presentations, of discursive articulation of research concepts and research elements (DE BRUYNE, HERMAN a.o.). Forms of exposition (e.g. style), relational statements in terms of causality or correlations, information about the objectifying process such as the chosen research strategy, are important aspects of this configurative space. In the first place one thinks about the end product of research: the output, be it a research report or a scientific publication. Their 'convincing' qualities depend on the excellence of exposition which is in the end are an essential part of evaluation by peers. But the same requirements must be met at the very beginning of the process: the elaborated proposal of a research project. In design study – unlike in fundamental science - a pragmatic approach in argumentation and persuasive rhetoric is a necessary component in looking for and presenting *the best design* solution (R. Foqué 2003: 3). In consequence this leads to a shift of meaning when terms like 'testing' and 'hypothesis' are used in a designing context. In this context testing a design assumption is not a matter of being true or false but - given a particular spatial context - a matter of being the 'best' solution based on vision and believes. (R. FOQUE 2003: 3)

"Testing a design hypotheses is therefore unextricably bound up with the ethical normative framework of society and with its epistemological principles. In addition

the testing can only be done within a well determined context which is both physical and non physical. Non physical because design is embedded in a formal, legal and historical context; physical because every design is related to the constraints and characteristics of a context, being a real site or an imaginary or virtual one" (R. FOQUE 2003: 2-4)

In a scientific context testing a hypothesis means confronting statements about an assumed relationship between phenomena with empirical facts. Ignoring this fundamental distinction of meanings runs the risk to formulate pseudoscientific statements[3] by paying lip service to a scientific syntax though deprived by means of testing in the scientific sense of the word.

This might explain why, at least in our experience, quite some *design based* research proposals seem to fail for a positive judgment in order to grant research funding. Critical reviews by academic peers applying the regular standards for eligible research proposals, often mention the absence of essential ingredients for the elaboration of consistent research proposals: the lack of a theoretical framework, and the absence of empirical measurable concepts. Some might put forward that this situation is inevitably part of typical discomforts of a maturing discipline, but, taking into consideration the essential theory driven character of scientific research and the design driven character of design research it is equally justified to question the compatibility of a scientific logic of discovery with design logic of enquiry. As Heilighen and others put it:

"By consequence, very different logics of discovery may be at work in design practice, and the way they are mixed varies from one case to another. However, this variation cannot be used to question the fundamental distinction in principle between design and research. For whatever the mix, you still need a theory to account for what happened, and this is something that just continuing designing will not be able to give you. You need some theoretical model, concept, strategy, or the like to come to grips with what has or has not worked and to explain why. In more technical words, you need an

[3] Wikipedia defines pseudoscience as; "a claim, belief, or practice which is presented as scientific, but does not adhere to a valid scientific method, lacks supporting evidence or plausibility, cannot be reliably tested, or otherwise lacks scientific status.[1]

explicit interpretation of what constituted the tacit understanding just displayed by your practice". (A. HEYLIGHEN, H. CAVALLIN, M. BIANCHIN 2009:104)

Practice based vs. academic research

A second line of discussion centers around the poles practice based (design) research (PbS) vs. academic research, focusing on the issue whether knowledge-gathering *in professional experience* can be integrated in academic research (BIGGS AND BÜCHLER 2008). As design teaching in university colleges is up to now mainly practiced based teaching this question is not of minor importance. It touches interests in terms of staff recruiting policy, funding channels and allocation of recourses and consequently also in terms of the nature of research output

The path of this discussion and of conclusions will be influenced by (inter)national differences in the organization of higher education and funding policies of research, as Biggs and Büchler made clear in a comparison of the British, the Brazilian and the Swedish case. (BIGGS AND BÜCHLER 2008); When for instance in 1992, the British polytechniques were accorded university status, it could establish discipline-specific regulation to define research. According to the authors the consequence was that criteria for research practice that previously seemed to be clear and universal in most disciplines, such as: knowledge, creativity, reference, method and audience , were put into question and generated, as they call it, 'hybrid' concepts like 'tacit' and experiential knowledge, reflexive method, grounded theory and 'knowledge – in – action'. In terms of the assessment of research quality, diverse and alternative concepts of quality and understanding were used, together with a variety of Phd models, ranging from traditional bound textual documents to the possibility of submitting a work of art or an exhibition. The Swedish case is comparable with the British case when it comes to adapted standards of research output in design disciplines. On the other hand, in the Brazilian case, the structure of higher education divided disciplines dealing with fundamental and theoretical issues from those having more a technical or productive character, design included. This distinction bears consequences for the access to research funding as professional developed

research has to rely on other than academic resources for (less substantial) financial support.

Briggs and Büchler defend practice based research as 'subcategory' of academic research and suggest the adaptation of the conventional criteria of academic research to the specific nature design practice provided that three fundamental criteria of academic research are respected: 1) dissemination of knowledge; 2) originality and 3) context. They consider these criteria as necessary and sufficient conditions for any form of academic research, whether practice based or not. Disseminating research is, according to Biggs and Büchler, necessary because the produced knowledge must influence actions of other practioners, here considered as the advancing aspect of knowledge. The opposite would be a situation in which everyone is originating knowledge for themselves which might lead to something like reinventing the wheel. Originality is necessary and sufficient. Produced knowledge must be new for an audience and not just for the researcher. Contextuality places the outcome in a critical context by making clear in which way knowledge develops or departs from existing modes of understanding. One can concur with the necessity aspect of these fundamental criteria, but the sufficient condition is not thoroughly clarified in order to consider practice based design research as a *subcategory* of academic research. Whether they are sufficient or not will mostly depend on dominant institutional definitions of academic practice, which – hardly surprising - tend to model these definitions according to the image of scientific practice.

In regular science dissemination refers to a well-defined research product belonging to what Karl Popper called world 3. (K. POPPER; 1974:210). Popper's world 3 is the world of statements in themselves[4]. Statements that stand in logical relations to each other. Dissemination then must occur in some more or less permanent form, as Popper puts it: "A written form will be preferable to a spoken form and printing may be better still". (K. POPPER; 1974:213). Furthermore disseminated statements of world 3 are inseparably related to theories as a more or less consistent system of

[4] In Popper's view world 1 is the external physical world and world 2 refers to the thought *process*, psychological in nature.

statements, which brings us back to the research structuring role of theories in regular sciences and to the question what this can mean in practice based design research as an academic subcategory.

Another important aspect of dissemination in regular science is the role of specialized scientific journals. The ideas of Thomas Kuhn became a common property when thinking of the paradigm concept – whether properly interpreted or not[5] – less quoted is the crucial role Kuhn assigns to specialized journals for the formation of a discipline or subdiscipline and eventually for the acceptance of a unified paradigm. (KUHN1972: 34) In the present integration process into the university this is not a minor issue, taking into consideration that chances for research funding are related to this kind of textual based output. Given the established university regulations about the controlling audience for assessing a claim of originality, the audience, the peers, will presumably have to match the strongly institutionalized criteria for the eligible audience. In most Flemish universities acknowledgment of *practiced based excellence* without Phd references will not fit to the standard credentials.

Last, what Biggs and Bühler consider as the fundamental necessary and *sufficient* context criterion under the label of a subcategory of academic research supposes the inscription in a firm tradition of specialized research, which is hardly the case in design research, first because any form of research tradition is lacking, second because the fairly idiosyncratic nature of practice based research complicates the creation of a common ground for a research tradition.

Integrating "design" in academic curricula

Obviously, from the above discussion, a rather pessimistic view emerges on the ability of design to ever become a vested scientific method, in the sense that design research can produce valid scientific knowledge about our external world. At best design and design research are pseudosciences, mimicking the semiotics of scientific

[5] Searching for paradigms in other than exact sciences looks like a production in line work, especially when it is interpreted in an in appropriate way. Often one seems to forget that Kuhn preferred to keep a keen distinction between 'exact' sciences and human sciences. (Van Bedegem 2009: 55)

methods, but failing to address the basic criteria for reliable scientific knowledge. The gap between design and science is simply too large, and design research methods fails to produce a logical and internal consistent epistemological framework.

But one might wonder whether design should be a scientific discipline at all? It seems to us that the discussion on design and science has simply started on the wrong footage. In fact, we believe that the career opportunities of the architectural school staff and the distribution of funds for education and research among institutes are really at the heart of the discussion, rather than a sincere and genuine discussion on the relation between design and research. There is for instance remarkably hardly any internal controversy among design researchers about the nature of their research, although the topic in itself could trigger substantial discord as we argued above. A genuine discussion would allow dissonant voices to come in, certainly when arguments from the design side often lack internal consistence and rigor. Of course, one cannot ignore that most participants in the debate have a direct stake in the issue. The new academic institutional context in which the former staff of the architectural schools will have to operate is hostile to them, and their academic position is threatened in many ways. Making design count as research would be a convenient way to accommodate to this new environment without large sacrifices.

The result is that the arranged marriage between architectural design and scientific research presumably pushes and pulls the discussion about the nature of design based research into a *logic of scientific discovery*, and that the meaning of scientific knowledge is therefore stretched beyond a meaningful concept. Such a shift is not innocent, since it leads to an institutionalization of a pseudoscientific practice within the academic institutes. One might wonder for instance how master students in architecture schools, that are supposed to have skills to use and process scientific knowledge production, will develop an understanding of science if the teaching staff holds at least a confusing viewpoint on the matter, and how this will affect architectural practice? One might wonder how the precedent of institutionalizing design research might open the way to institutionalize other forms of pseudoscientific methodologies at academic institutes. Our arguments do not

however imply that architectural schools, or design schools should not have a place within the academic institutes. The profession of architect for instance requires more competences than design only, and many of them – such as building and material technology, building physics and building economics – are firmly grounded in academic research disciplines. In an academic environment it is also recommendable that courses on research methodology are incorporated in the curriculum in order to stimulate insight in the different logics of research. We agree with Heylighen that the product of design is not a truth seeking effort, but a possible solution to a specific social demand in a very specific cultural context. This should be a value on its own. Therefore it must be acknowledged that design skills are off utmost importance for Architectural schools and that design staff should have proper means of evaluation of their design expertise and teaching abilities.

In order to save both research and design, we advocate therefore a strict intellectual hygiene. Blending scientific knowledge production and design in one institutional measurement system does not really contribute to both. Nor would a *scientification* of design practice do right to the art of design. The unique *world-to-mind orientation*, the ability to integrate various demands into original and creative design proposals, and the cultural embeddedness of design would hardly gain from the methodological approaches from the scientific discovery. If we accept that architectural design values and norm deeply embedded cultural norms in practice, practice based education such as studios should have a firm position in the curricula of architectural Schools.

A possible and more productive strategy for the integration of architectural design into academic institutes would therefore include a proper acknowledgement of design competences without necessarily being based upon scientific research. This would require a multidimensional measurement system of the performance of design-oriented fields such as architecture, both in term of career development as in for the purpose of allocating funds. Such a multidimensional evaluation could make a distinction between research output on the one hand, and design excellence on the other hand. The traditional parameters for the measurement of scientific research

output are already established. What is needed is to develop and acknowledge criteria for design output and excellence. Architectural designers produce designs of interiors, buildings, landscapes and urban configurations. What could generally be regarded as design excellence is the cultural impact architectural work has on other architectural designers in the first place and society at large in the second place. This cultural impact could be measured by indicators such as the number of key-note lectures on the work and the audience, the number of publication on the work of an architect and the number of exhibitions on the work of the architect. No doubt, this will pull back a broader spectrum of design practice into to the realm of academic performance and offer the perspective of a marriage by consent.

PLANNING ON SAFER URBAN MOBILITY THROUGH SPATIAL ANALYSIS: APPLICATION TO VILA REAL, PORTUGAL

Inês Moreira [1], Alexandre Gonçalves [2], Sílvia Shrubsall [3]

Abstract

Land use and transportation interactions have been subject to different studies. Analytical studies on synergies between road safety and the road environment is also very relevant yet less common. It has long been known that urban road accidents tend to cluster in particular sites and that this often indicates an inadequacy between the urban road environment and its current functions (Levine *et al*., 1995; Elsenaar and Abouraad, 2005; Elvik, 2006). Improving the road environment where accidents road users' behaviour to prevailing circumstances. Designing self-explaining roads (Theeuwes and Godthelp, 1995) can contribute to increasing road safety for drivers and vulnerable users (e.g. pedestrian and children) whilst improving cities general environment.

An efficient approach to reduce the number and severity of urban road accidents is the identification, analysis and treatment of road sites where road accidents tend to aggregate, i.e., hazardous road locations (HRL) (CIHT, 1990). However, no commonly accepted definition for HRL has been established. Moreover, many countries – like Portugal – do not systematically apply HRL programmes and, indeed, have insufficient resources allocated to road safety.

The aim of this research project described was to compare and discuss the applicability of different existing HRL definitions as well as their respective identification methods given the current availability of road accident and exposure data and resources in Portuguese local authorities.

Within this context, three types of HRL identification methods were applied. Analyses were carried out using two spatial analysis software packages for road accident data from the Portuguese city of Vila Real. Application of the different methods and their respective parameterisation led to the identification of different numbers and locations for HRL; however, a considerable number of HRL was regularly identified using distinct methods and/or parameter values.

[1] Instituto Superior Técnico – Technical University of Lisbon, Portugal – ines.moreira@ist.utl.pt
[2] ICIST, Department of Civil Engineering, Architecture and Georesources, Instituto Superior Técnico – Technical University of Lisbon, Portugal - alexg@civil.ist.utl.pt
[3] CESUR, Department of Civil Engineering, Architecture and Georesources, Instituto Superior Técnico – Technical University of Lisbon, Portugal – silvia.shrubsall@civil.ist.utl.pt

The adequacy and effectiveness of the diverse methods is analysed. Results indicate the suitability of the applied methods and their potential as tool leading to the identification of measures to improve road safety in countries with limited availability of resources available to significant urban environmental changes. The study here described also suggests that the integration of HRL identification and treatment with the general transport and land use policies will be beneficial by promoting best use of resources.

1. Introduction

Urban road accidents are responsible for considerable human and material losses all over the world, of which a large proportion occur in urban environments (ECMT, 2006; WHO, 2011). The need to seriously address this situation led the UN to launch the Decade of Action for Road Safety in 2011.

An efficient approach to reduce the number and severity of road accidents as well as their casualties, in particular in urban areas, is the treatment of locations(s) where these tend to aggregate, the HRL (CIHT, 1990). Despite its effectiveness, this approach has not been systematically implemented in many countries, including Portugal. As there is no commonly accepted international definition for HRL (Geurts and Wets, 2003; Geurts, *et al*., 2005; Cheng and Washington, 2008; Anderson, 2009), this work intends to compare and discuss the implementation of methods and definitions that enable its identification in countries within this context. A case study has been developed in the Portuguese city of Vila Real and took into account the current road accidents and exposure data availability and quality and scarce resources allocated to road safety by Portuguese local authorities. Dealing with HRL entails their identification followed by ranking, detailed analyses (see section 2.2) and identification and implementation of corrective road safety measures. This study focuses on the first stage.

To apply such approach spatial data analysis software, such as Geographic Information Systems, are commonly applied. Those spatial tools are also used for many purposes, including helping urban planners to identify, analyse and promote corrective interventions to solve urban problems. As urban characteristics have influence on road safety, planning and road safety approaches should be combined in order to seek solutions taking into consideration a wider perspective of the complex urban problems.

2. Hazardous Road Locations

2.1 Identification

Road accidents often accumulate in particular sites, the hazardous road locations. The investigation of factors which lead to accidents' clusters is an important topic in the road safety activity (Moons *et al*., 2009), since it is a strong indicator of a road related problem (Elsenaar and Abouraad (2005).

Several different methods have been applied to identify these locations (Retting, *et al*. 2001; Hauer, *et al*. 2002; Flahaut, *et al*. 2003; Brijs, *et al*. 2007; Elvik 2008; El-Basyouny and Sayed 2009; Pirdavani, *et al*. 2010).

Elvik (2007), based on an OECD report, proposed a distinction between the different definitions of HRL into:

- *Numerical*: locations where usually the recorded accident number or rate (e.g. accidents per traffic flow), during a period, is higher than a threshold;
- *Statistical*: locations where the recorded accident number or rate is significantly higher than the usual, taking into account the type of location (e.g. an intersection). Examples of this type definition can be found in Elvik (2008) and Erdogan *et al*. (2008);
- *Model-based*: locations identified based on the recorded and expected accident number taking into account the characteristics of the place. The expected number of accidents is obtained through an accident prediction model. There are several of these models (Lord and Mannering, 2010).

Generally, the identification through *numerical definitions* can be applied with information only about the road network and accidents, including their location. These definitions identify sites where the recorded number of accidents (or their rate if an exposure measure, such as traffic flow, is also available) during a period, is higher than a threshold. Examples are presented in Table 1. The remaining types of definitions require complementing information, such as traffic data, which is often not available, especially in countries where road safety programmes have not been recurrently applied (Sørensen, 2007). For this reason, *statistical* and *model-based* definitions were out of the scope of this work.

Table 1. Some of the operational numerical HRL definitions found in literature

Definition	ANSR	Belgium	Flanders	Hungary	Germany	Norway
Period of records	1 year	Over 1 year	3 years	3 years	3 years	5 years
Location (road extension)	100 m	50 m	50 m	50 m	50 m	50 m
Severity index (SI)	SI=100F+ +10SerI+ +3SliI	-	SI=5F+ +3SerI+ +SliI	-	-	-
Criterion 1: No. of accidents	≥ 5	≥ 3 serious	≥ 3	≥ 4	≥ 5 with casualties or ≥ 3 serious	≥ 4
Criterion 2: Severity index	∑ SI > 20	-	∑ SI ≥ 15	-	-	-

Definition	ANSR	Belgium	Flanders	Hungary	Germany	Norway
Source	ANSR, 2011	Flahaut *et al.*, 2003	Elvik, 2007; Geurts *et. al.*, 2006	Elvik, 2007	Elvik, 2007; 2008	Elvik, 2007; 2008

Legend: F – fatal injury; SerI – seriously injured; SliI – Slightly injured

Besides the abovementioned definitions, other practical methods were applied in this study with the purpose of identifying HRL (Retting *et al*. 2001; Mungnimit *et al*.,2009; Xie and Yan, 2008). Examples are the *Kernel Density Estimation* and the nearest-neighbour methods (Anderson, 2009; Nicholson, 1998).

To apply these definitions and/or methods, the use of spatial analysis software has been suggested (Elsenaar and Abouraad, 2005). Specialised literature lists a range of available options (TRL, 2011; TES, 2011; Jarvis and Kamal, 2009; BioMedware, 2010, Levine, 2010), including the two (ArcGIS™ and CrimeStat®) adopted in this study (see section 4.2).

2.2 Subsequent steps of a HRL programme: HRL ranking detailed analysis

After the identification of HRL, these sites are usually ranked in order to select a few priority sites for further detailed analysis. Possible ranking criteria are accident frequency, accident rate, proportion of accident types considered susceptible for treatment and severity of casualties. The selection, often made by local authorities, includes political, economical or logistical aspects. Selected sites are particularly analysed in order to understand what may be the causes of road accidents, and which might be suitable for treatment. These analyses often include site visits or production and analysis of stick diagrams which identify common patterns among accidents that occurred in the same place, contributing to the elaboration of countermeasures. There are cases that a special focus is given to particular type of road users (e.g., children, elderly, vulnerable road users) or a specific road accident type. It is, however, important to state that accident analysis may not lead to the finding of common contributory factors to road accidents in a HRL, as they might be an outcome of random circumstances.

3. Methodology

The proposed innovative methodology aims at comparing HRL identification procedures, which can be adopted with limited resources and information, usually available in Portuguese local authorities. Each tested approach is required to be applicable to any urban area using basic generically available accident and road data and common software (GIS or other programs with analytical capabilities for spatial data). This work comprises: (1) data collection; (2) implementation of different methods to identify HRL; (3) discussion of the results, and (4) detailed analysis of the accidents that occurred in selected HRL.

3.1 Data collection

The first step of the methodology is the delimitation of the urban area under analysis. For this area indispensable datasets are identified, and after a formal request have been accepted, road accident data and road network information is collected, homogenised and (when needed) georeferenced. If complementary data is available (such as road traffic data and geographic data) it can be integrated in the analysis stage. Road network should be analysed in order to establish the city functional road hierarchy, as it might have an important role in the problem diagnosis and in the recommendation of solutions related with the enhancement of road safety. Usually, this procedure is defined based on the traffic and pedestrian information as well as experts' knowledge, and must be independent of the accident historical information.

3.2 Identification of HRL

In the proposed methodology, the identification of HRL consists in the implementation of three types of methods: (i) methods based on definitions applied in some European countries; (ii) methods based on the Euclidean distance between points; (iii) methods based on the point density.

Methods based on definitions applied in some European countries

These methods have the purpose to reproduce *numerical definitions* (see section 2.1) applied in some European countries to identify hazardous road locations. Chosen definitions were those from: Belgium, Flanders, Germany, Hungary, Norway and Portugal (ANSR), as these are not based on traffic flows (as they might not be available in some countries – see section 2.1), consider the universe of injury road accidents and provide a noteworthy differentiation between them (see Table 1). To replicate these definitions, two methods were created, here named I and II.

On Method I the number of recorded injury road accident data in each definition is previously selected; for each road accident a severity index (SI) is calculated (according to the definition); a radius is fixed, corresponding to half of the road section length present in the definition; the centre of the circle is applied to the entire urban area according to the cells of a grid, with a specific spatial resolution. Then, two calculations are executed: (i) the number of accidents in each circle and (ii) the sum of the severity index in each circle, resulting in two grids. These are then aggregated and a reclassification is made according to the criteria of the definition in practice to identify the HRL.

On Method II the number of recorded injury road accident data in each definition is previously selected; for each road accident a severity index (SI) is calculated according to the definition; along the segments of the road network, regularly distanced points are set; a fixed radius, corresponding to half of the section length of road present in the definition, is considered; a circle with this radius is centred over the regularly distanced road network points; in each circle road accidents are counted

and the values of the severity index are summarised; finally, areas within the circles which verify the correspondent criteria of minimum number of road accidents and sum of the severity index given by the definition in use are selected as being HRL.

The definitions which use the definition of *serious* road accident were applied according to the definition adopted by ANSR (2011). Relatively to the Belgian definition, two periods of records were considered: one and five years as that corresponds to the smallest period allowed by this definition and the larger period, taking into consideration the available dataset.

Methods based on the Euclidean distance between points

This type of methods encompasses those that only require the Euclidean distance between points (road accidents) to identify locations where points are spatially aggregated. Examples are:

- *Count coincident points*: when there are more than a specified number of coincident (road accident) points, such location is considered as a HRL;
- *Count points within a neighbourhood of each point***:** (road accident) points within a neighbourhood area of a road accident location (point) are counted; areas where the number exceeds a threshold are selected as HRL; the procedure is repeated for all road accident locations.
- *Identify spatially close point groups*: the Euclidean distance between points (road accidents) is compared to a threshold distance; pairs of points closer than this distance are aggregated and define a spatial cluster); point aggregations are then selected according to an established minimum number of elements. This value does not interfere with the shape or size of point aggregations which are dependent on the value of the threshold distance. The threshold distance can be either defined by the analyst or based on a random distribution of points for which the area and number of points are equal to the case study.

Methods based in density functions

These methods are based on a point density function calculated for all the cells of a grid (after setting a spatial resolution value) covering the entire area under analysis. Cells exceeding a cut-off point density value are identified as HRL. This value is chosen by the analyst and can be adopted according to the size of the identified HRL (e.g., it can be determined according with the maximum distance between the HRL boundary from a road network centreline).

To represent this type of methods, the *Kernel density estimation* (KDE) was adopted. Its application requires these steps: (i) definition of the extension (area of study) and spatial resolution of the grid; (ii) selection of a density function (e.g.: based on the Normal distribution) and a bandwidth value; (iii) application of a symmetrical surface (defined by the selected density function) centred on each injury road accident location point and dependent on the bandwidth value; (iv) calculation, for

each grid cell, of the sum of the abovementioned density surfaces' value producing a single surface (kernel density surface) covering the area under study. After this calculation the cells with density over a cut-off value are selected as being HRL.

3.3 Choice of hazardous road location for detailed analysis

After the identification of HRL, these are ranked to prioritise locations for detailed analysis and subsequent identification and implementation of corrective physical schemes. Criteria to rank the identified HRL are: (i) the coincident identification of a particular HRL by different methods; (ii) the number of road accidents that each HRL contained (accident frequency); (iii) the severity of accidents in a particular HRL; (iv) the focus on a particular type of accidents or road user involved in accidents; and (v) the opportunity to collaborate with urban maintenance, improvement or expansion programmes.

3.4 Detailed analysis of a hazardous road location

Within the framework of this study, stick diagrams analyses are carried out. These are analytical tools which present the road accident information in a diagram form supporting the identification of common characteristics between the accidents, including those which can be improved by the implementation of physical alterations of the urban environment (see section Abstract).

4. Application to Vila Real

The methodology presented in the previous section was applied to the City of Vila Real (described below) and led to the identification of several HRL in Vila Real (section 4.2). It also allowed comparison between different definitions and methods currently used in Europe as well as other that have been sporadically used (see sections 2 and 4.2 – Discussion of results).

4.1 Description and data collection

Vila Real, a medium sized city located in the interior north of Portugal, was chosen for the application of this research work. Its hilly urban area has an irregular shape covering 12,8 km^2. It has an organic urban morphology which has evolved from the historical central area in an amphitheatre shape. Technicians of Vila Real local authority identified three functional road levels in its road network. Injury road accident data in Vila Real (2004-2008) were collected from the national database and complemented with information from the local traffic police departments. 381 injury road accidents were georeferenced in the road network.

4.2 Identification of HRL

Methods based on definitions applied in some European countries

Some parameters were adopted in Method I and II, both applied using ArcGIS™ software: Method I was applied using the *Point Density* function to produce a density grid with 10 m-sided cells whereas in Method II equidistant points (distanced of 20 m) were placed along the centrelines of the entire road network.

Firstly, Method I was applied to reproduce the definition of ANSR (Portugal), leading to the identification of 1 to 3 HRL per year (from 2004 to 2008). The same definition when reproduced by Method II led to the identification of 3 HRL (a single HRL in 2004, 2005 and 2007). The comparison between these two results and taking into consideration the computation process of Methods I and II let realising that the latter allows a more accurate reproduction of the definition as explained in the "Discussion of results" section. For his reason, for five definitions only Method II was applied (Table 2). Figure 1 illustrates the results of the Norwegian definition for Method II.

Table 2. Number of identified HRL by Method II for each applied definition

Years	Definitions					
	ANSR	Belgium	Flanders	Hungary	Germany	Norway
2004	1	0	0	15	8	25
2005	0	0	0	19	8	
2006	1	0	0	7	3	
2007	1	0				
2008	0	0				

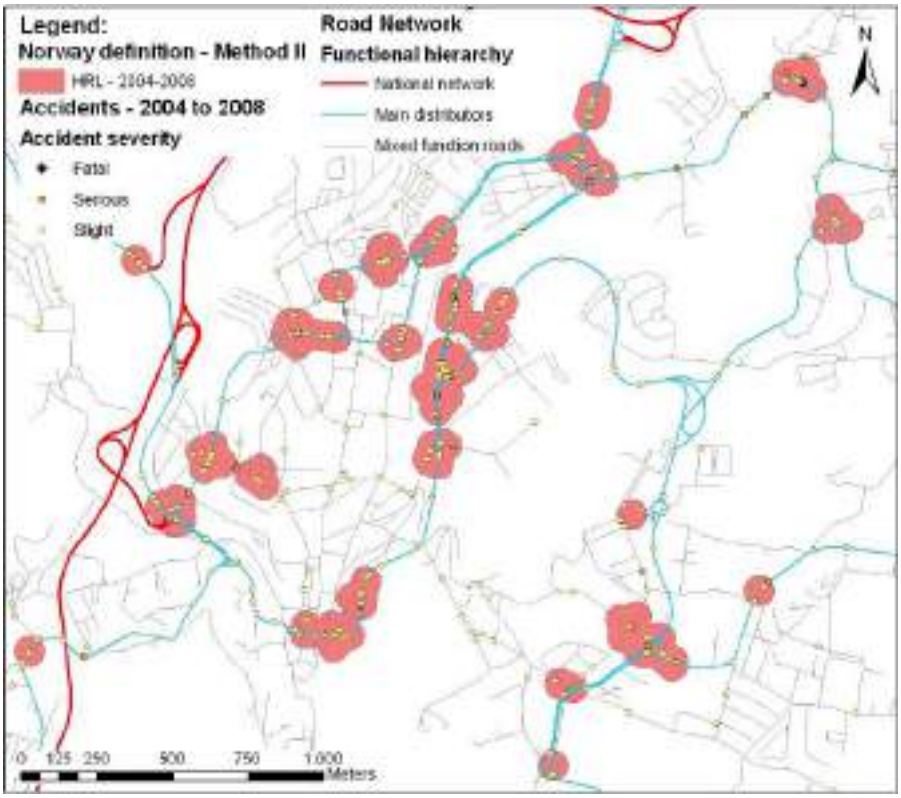

Figure 1. HRL identified with Method II applying the definition of Norway

Methods based on the Euclidean distance between points

The analysis of HRL based on the Euclidian distance between road accident location points was carried out using *CrimeStat*®, a software that includes three routines based on the Euclidean distance between points, usable to identify point agglomerations: (1) *Mode*: counts coincident points; (2) *Fuzzy Mode*: counts points within a neighbourhood of each point, and (3) *Nearest Neighbor Hierarchical Spatial Clustering* (*NNH*): identifies spatially close point groups based on a random distribution of points within the same area and the same number of points as the case study. Its calculation is described in section 3.2. All were applied to the dataset of injury road accidents that occurred between 2004 and 2008 in Vila Real.

In the *Mode* routine only locations with at least three road accidents were considered as hazardous. This criterion was adopted as the occurrence in the exactly same place of three accidents in five years might indicate road safety issues; on the other hand this value, although not isolated, is also used in other definitions (see Table 1). This routine identified one location with four coincident accidents and 4 with three accidents.

In *Fuzzy Mode* routine, a minimum of 4 accidents were adopted as the selection criterion to the HRL identification and two values of searching radius were applied:

50 m and 100 m These values were considered adequate for this purpose and it has been applied for the same purpose, as Table 1 shows. For example, for the radius of 50 m, this routine led to the identification of 19 HRL.

The *NNH* routine was computed considering several values for the minimum number of points as presented in Table 3. One of these solutions is illustrated in Figure 2.

Table 3. Number of HRL obtained with the NNH routine

Minimum number of road accidents per HRL	5	7	8	10
Number of identified HRL in Vila Real	20	12	9	3

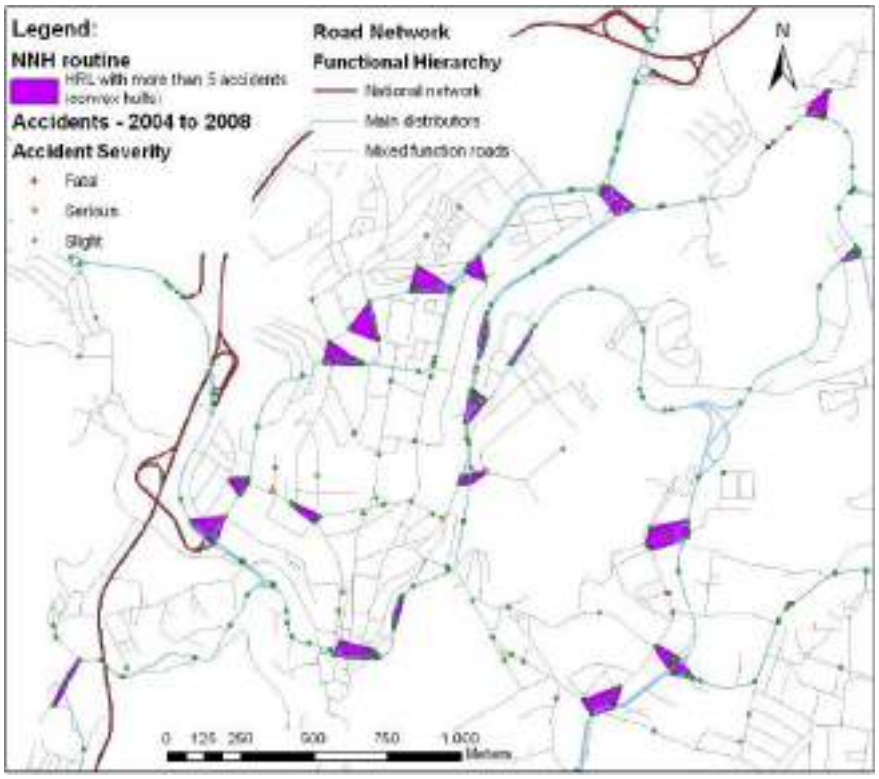

Figure 2. HRL identified with NNH routine

Methods based in density functions

Kernel Density Estimation (*KDE*) was the adopted to identify HRL. This routine requires a set of parameters, displayed on Table 4.

Table 4. Input parameters of KDE routine in CrimeStat®

Parameter	Adopted option
Interpolation function	based on Normal (or Gaussian) distribution
Bandwidth type	adaptive
Bandwidth criterion	minimum number of road accidents of 10, 5 and 3
Cutoff value (density)	0.0002 points/m^2 (corresponds to a 50 m limit away from the road network centreline)
Cell size	10 m

Table 5 presents the number of HRL according to the tested bandwidth values. One of the results is illustrated in Figure 3.

Table 5. HRL identified with *KDE* routine for different bandwidth values

Minimum no. of points to include in the bandwidth	10	5	3
Number of HRL	2	12	28

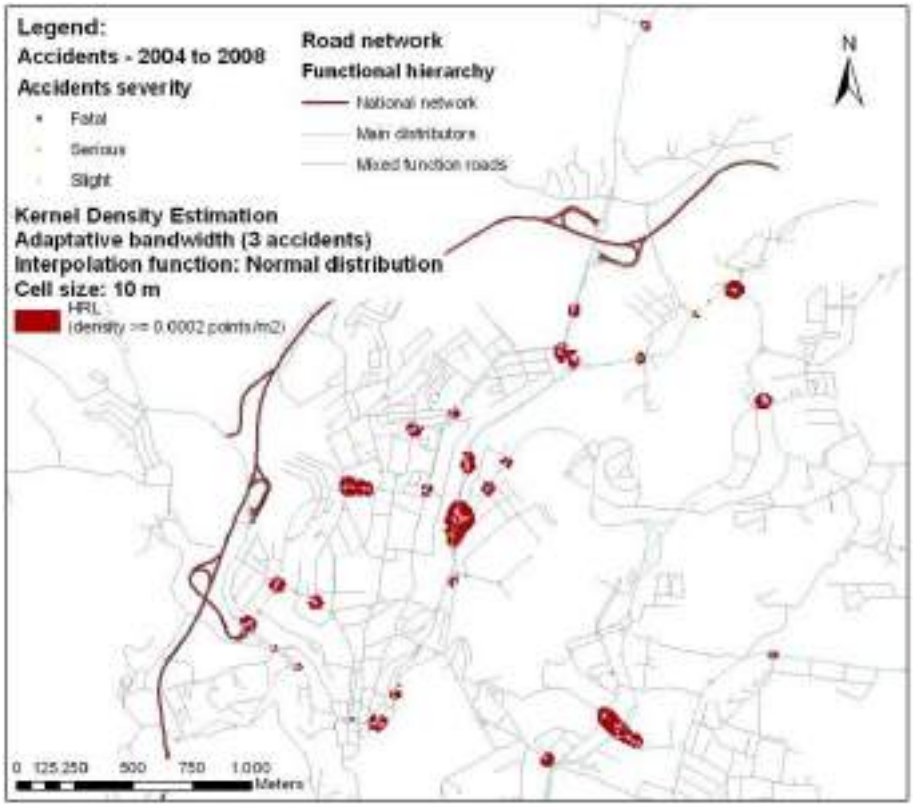

Figure 3. HRL identified with KDE routine
(with a minimum three accidents adaptive bandwidth)

Discussion of results

Results suggest that Method II allows a more accurate reproduction of the selected definitions (see section 2.1) because it considers only an area around the road network avoiding the identification of HRL outside road network, while Method I applies a grid into the entire area, regardless of the road network location. Despite Method II being superior to Method I, it still presents some limitations to the strict application of European definitions (e.g. it applies a searching area instead of a road section). The HRL identified by Method II depend on the definition applied; indeed, some definitions did not identify any HRL (such as the Flemish, Belgian) whereas the Norwegian led to the identification of 25 HRL (see Table 2). This might indicate that some definitions can be more suitable than others to particular city circumstances (from urban layout to data availability). For cities with a larger number of injury road accidents, the Belgian or Flemish definition might be more suitable to identify locations with more severe road accidents, than the remaining applied definitions.

Also, results obtained from the application of different definitions adopted in various countries might be an indication of the road safety performance in each country. For instance, Method II applied to the Norwegian definition led to the identification of more HRL in Vila Real than the remaining definitions. Analyses must keep in mind that results are also dependent on the parameters adopted in Method II, as well as the method itself, which is not an accurate reproduction of the various definitions.

The *Mode* routine reveals low suitability for HRL identification, at least in this case study, because it only identifies locations where road accidents are exactly in the same place (point). Furthermore, its results might be considerably influenced by the georeferencing options that are adopted (e.g. snap the road accident points to the centrelines of the road network and minimum spatial unit used).

Fuzzy Mode routine and Method II showed some similarities, when similar parameters are adopted. It was possible to conclude that, for the same searching area and minimum number of accidents per HRL, Method II identified more HRL than the routine, as it focus the HRL identification process over each point regularly distanced (of 20 m) over the entire road network, whereas the routine only focus over the location of road accidents.

Results show that the *NNH* routine might lead to the identification of HRL which shape corresponds to a long road sections containing a chain of road accidents without length limit. This is suitable for other road safety approaches, such as *route analysis* (CIHT, 1990), but is not adequate for HRL analysis.

Results from the *KDE* routine, show that the specification of the bandwidth has a large influence on the number of identified HRL. Smaller bandwidths might have a tendency to identify more locations.

In general, all methods are relatively simple to apply and require only few calculation minutes; however, other characteristics, capabilities and consequences might influence the choice of a method for identifying HRL and the interpretation of its results. For this reason, a brief comparison was performed between Method II and the *Fuzzy Mode*, *NNH* and *KDE* routines, summarised in Table 6. Method I and the Mode routine were not included in this comparison, as they were considered to perform worse than other essayed methods, as mentioned in this section.

Table 6. Main comparative aspects of Method II and *Fuzzy Mode*, NNH and KDE routines

	Method II	*Fuzzy Mode* routine	NNH routine	KDE routine
Parameters and analysis dependence	Searching radius; Selection criterion; Period of data records; Step of sliding window.	Searching radius; Selection criterion (no. of accidents); Period of data records.	Value of study area; Minimum number of points per agglomeration; Period of data records.	Cell size; Minimum number of bandwidth; Cut-off value; Interpolation function; Period of data records.
Consideration of accident severity	Yes, according to the definition	No	No	No (although possible, not applied in this study)
Some adopted parameters	Time period of accident records; Radius and selection criteria according the applied definition; Step of sliding window: 20 m	5 years of accident records; Radius: 50 m Selection criterion: ≥ 4 accidents with casualties	5 years of accident records; Threshold distance based on a random distribution; Minimum of 5 accidents per agglomeration	5 years of accident records; Cell size: 10 m; Adaptive bandwidth; Cut-off density: 0.0002 points/m^2; Interpolation function: Normal
Shape of HRL	Buffers along the road network centrelines	Buffers along the road network centrelines	Convex hulls	Grid cells with density above the cut-off value

	Method II	*Fuzzy Mode* routine	NNH routine	KDE routine
Main advantages	Allows the definition application; Applies a sliding window; which in the same conditions of *Fuzzy Mode* routine identifies more HRL	Identification HRL centred on road accidents	Requires calibration of few parameters; Identification based on statistical evidence; HRL size dependends on area/number of accidents;	Promotes identification on areas where more road accidents occur (adequate to *area wide analysis* where HRL have to be identified)
Main drawbacks	Results varied according to the applied definition; Implementation proceeding more susceptible to errors: Measurements through Euclidian distance	Choice of search radius and criterion for HRL identification; Measurements through Euclidian distance	Delimitation of the study urban area without considering its shape; Choice of minimum number of accidents in the HRL; Measurements through Euclidian distance	Choice of cut-off value which interferes with the number and shape of HRL; Need of bandwidth determination; Isolated aggregations of accidents have less density value than those surrounded by areas with more accidents.

Although Method II and the *Fuzzy Mode*, *NNH* and *KDE* routines all present advantages and weaknesses, for Vila Real circumstances *NNH* would be a recommendable approach for systematic application.

4.3 Detailed analysis of a hazardous road location

Several locations were identified as hazardous: some of them are consistently recognised by different methods. One of them was identified with seven essays and as it had the highest number of injury road accidents it was chosen for detailed analysis. It corresponds of a road extension of about 250 metres, includes a roundabout and contained 18 road accidents, which 9 are *running over pedestrians* (mainly located over crosswalks) as Figure 4 illustrates.

The analysis of this location was based on stick diagrams (see section 3.4) with the purpose of finding possible problems susceptible of being treated through engineering road safety measures. The analysis of road accidents which often involved one single vehicle (*running over pedestrians* and *run-offs*), indicated a possible problem related to exceeding speed. The analysis of the remaining 9 road accidents did not enable the finding of a common pattern between them which could be indicated as probable causes for their occurrence.

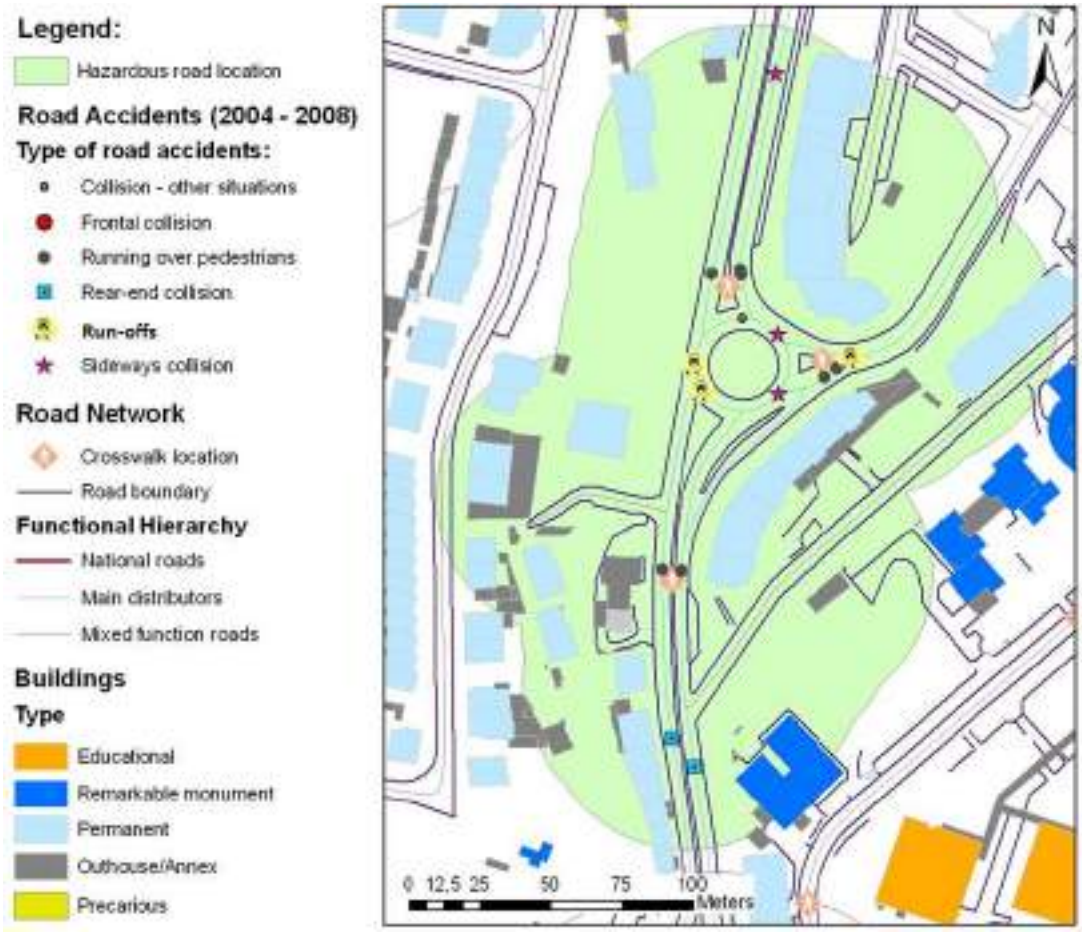

Figure 4. Location of the road accidents in the HRL selected for detailed analysis

The identification of the correct road measure to be applied should take into consideration the safety characteristics and requirements of this site as well as urban function of this area. Possible unwanted side effects of any identified measure, for instance increased noise levels or additional accessibility difficulties for vulnerable road users, must be considered. These sorts of analysis clearly illustrate the multidisciplinary of required working teams including road safety, urban planners and environmental experts.

5. Conclusions and Discussion

The central aim of this work is to compare different methods to identify HRL for which an internationally accepted definition is not available. The treatment of such locations is suitable to be integrated with other types of interventions (e.g., in urban planning) which, for instance, potentiate the optimisation of resources (e.g., in the problem analysis and intervention phases), and promote a wider comprehension of the complex urban road problems in different perspectives which in turn might contribute for integrated/globally better interventions. The work is focused in urban areas taking into consideration the limited resources (including data) that exist in countries where road safety programmes have not been systematically applied. In the scope of this research project different approaches are proposed and implemented: methods I and II and routines *Mode*, *Fuzzy More*, *Nearest Neighbor Hierarchical Spatial Clustering* (*NNH*) and *Kernel Density Estimation* (*KDE*). Spatial analysis software, ArcGIS™ and CrimeStat®, was used.

Results showed that the number and location of the identified HRL in Vila Real between 2004 and 2008 varied depending on the applied method, definition or routine. Amongst all the identified HRL, a considerable number was systematically produced by most methods and/or routines. Results indicate the identification of HRL from 0 for the definitions adopted in Belgium, including Flanders, (reproduced according with Method II) to 28 for the KDE (considering adaptive bandwidth including at least 3 road accidents, the Normal distribution as interpolation function, 10 m cells and a cut-off density value of 0.0002 points/m^2). The differentiation between results also stresses that the establishment of the parameters used in the several methods or routines might influence considerably the identification of HRL. In general, all the methods identified HRL of different sizes and shapes, mostly located on intersections of the highest road functional hierarchy levels suggesting that traffic data would be important to recognise accident rates.

The comparison between methods and their results highlights that *Mode* routine seemed to be inadequate for the HRL identification and Method I showed to perform worse when compared to Method II to reproduce the applied European definitions. The NNH routine is the least dependent from parameters established by the analyst as it has a statistical basis of spatial randomness. However, its calculation does not consider characteristics such as the shape of the area under analysis and relies on the assumption of a homogeneous space (see section 4.2 Discussion of results).

Some of the applied methods and/or routines (Method I and II, Fuzzy Mode, *NNH* and *KDE* routines) consider that space is assumed to be contiguous and homogeneous. This might lead to the identification of HRL containing road accidents that occurred in non-contiguous roads, which is undesirable, as local characteristics might be different from case to case, and the possible underlying problems of road accidents might also be different. Another aspect that should be taken into account in the analysis of the results is the possible error of location of injury road accidents, in particular in the georeferencing process.

To cement conclusion, the implementation to other contexts is recommendable (e.g. larger and smaller cities, with different road accident rates, different types of urban tissues, reflecting its diverse history and complemented with information about *only damage road accidents* as well as exposure data from vehicles and pedestrians).

The suggested methods can be implemented in urban areas in a short term (even if no traffic data is available). Previous studies have demonstrated that perception of the road surrounding influences the road user behaviours which in turn impacts road accident records. Hence, urban interventions should integrate the impact on road safety, in order to improve the entire public space in terms of use and safety. Urban changes should be supplemented with educational, encouragement and/or enforcing road safety measures.

This type of road safety methods/approach is suitable to be integrated with different policies beyond the road safety or oriented to specific targets. Also they might be an important tool to be integrated in a big restructure of a part of an urban area or in other policies, such as: health (promoting safer and pleasant road environment to walk), educational (safety near schools) or intelligent transport systems. Such interventions should include multidisciplinary working teams.

Acknowledgements

We would like to thank the contributions of the Municipality of Vila Real, particularly from Eng. Adriano Sousa and Eng. Joaquim Magalhães for their collaboration in the data collection and georeferencing process, of Autoridade Nacional de Segurança Rodoviária for the road accident data and of Doctor Ned Levine for his suggestions about some of the analyses. We appreciate the partial financial support of Fundação para a Ciência e a Tecnologia.

HOUSING AS AN APPROACH FOR THE BROWNFIELD REGENERATION KNOW-HOW TRANSFER

Zuzana Ladzianska[1]

Abstract

Regeneration of brownfields is nowadays a welcome approach mainly in the urbanised areas of the city centres. Mainly the cities of the Central-East European countries suffer from the lack of housing opportunities in the city centres as a result of the former socialist system and the strong suburbanisation in the following decades. Due to this urbanisation processes people started to leave the urbanised cores of the cities and even more new brownfields have emerged. Nowadays, not only due to the crisis but as well due to the reurbanisation tendencies in the cities, brownfields are seen as a new potential for the housing in the many times neglected areas of the cities. The process of the brownfields redevelopment contributes to better use of space and brings a new life to the upgraded areas. Improved organisation of the space linked with the new use of the space – housing – communicates better with the other parts of the city.

Improvement of the brownfield sites can be perceived not only through the physical change of the space. Gentrification as a social process is one of the possible options how to enrich the process of transformation on the brownfield areas. The regeneration process takes usually many years and the process of gentrification and the presence of alternative entrepreneurs ensures stable development of the site visible in many cities around Europe. This is a reason why in the study programme "Spatial Planning" redevelopment of brownfields should be included, based on transfer of know-how and experience from other countries. The focus of the work is therefore put on the brownfield regeneration based on the housing examples from the European cities focusing mainly on the example of Bratislava.

Transfer of Innovation is a new project under the Lifelong Learning Programme – Leonardo da Vinci No. 11310 1614 on "Brownfield Regeneration Know-How Transfer" (acronym: BROWNTRANS) that has started with the support of the CEE countries (CZ, SK) and will disseminate the gathered know-how and experience into several professions that deal with brownfields. This project runs in 2011-2013 in the frame of Leonardo da Vinci and summarizes knowledge and know-how on brownfield redevelopment in the modules that deal with economic, financial, legal, technological,

[1] Institute of Management, Department of Spatial Planning, Slovak University of Technology in Bratislava, Slovakia – zuzana.ladzianska@stuba.sk

managerial, social and cultural and environmental aspects. Outcomes in the form of a handbook will bring substantial increase in the skills and knowledge potential of human capital involved in cross-professional activities. There is a unique opportunity to communicate results from praxis within the theoretical teaching process as well as to use the theoretical approaches to improve production processes of the brownfield redevelopment from the European perspective.

1. Introduction

In this paper I would like to make a brief overview of brownfield sites regeneration approaches in the urban space. Creativity has always been a capability and privilege of a human being. It can be followed many aspects of our lives. In the past, nowadays city centres were usually on the edge of cities itself which gave them the ideal position for situating working opportunities in the form of diverse industries. After the WWII and later after the Velvet revolution followed by the political changes many of those industrial areas did not survived and brownfield site arose. In many countries especially these sites, nowadays centrally situated, were recognised as a potential for cities and shortly afterwards were converted into diverse uses. In many cases this process of regeneration was not straight but catalysed by the activists operating in those spaces using them on the temporary basis, later on converted to the housing use. In meantime we can find some successful conversions in Slovakia too.

Methods used for this work were of an analytical nature, applied in the theoretical part as well as in the part where good-practice examples from the city Bratislava are introduced. In the theoretical part the focus is mainly on the analysis of the existing literature on manifold aspects related to the gentrification and brownfield regeneration in urban space while synthesising the knowledge along with the personal experience from the research. The second analytical part is a base on the analysis of existing projects of brownfield sites conversion made in the recent time and at the same time being used by the creative class and the housing approach is visible.

2. Gentrification

The origin of the word “gentrification” derives from “gentry” (French origin “genterise” denoting “of gentle birth” and “people of gentle birth”). In England (“landed gentry”) it denoted the social class, consisting of “gentlemen” (wikipedia, 2012). As described in the book Gentrification by Loretta Lees (Loretta Lees, Tom Slater and Elvin Wyly, 2008), the term gentrification was for the first time defined in 1964 by the British sociologist Ruth Glass who is perceived as one of the pioneers of urban sociology in Europe. She used the term gentrification to describe distinct processes of urban change affecting the inner parts of London. Nowadays, the changes described, are known as the classical gentrification. She has investigated this process on disinvested inner-city neighbourhoods which are upgraded by pioneer gentrifiers where the indigenous

residents are displaced and working-class housing becomes middle-class housing in London. Throughout the history we can follow several waves of gentrification (Table 1).

Table 1: Waves of gentrification

1950s – 1973	**First-wave gentrification – Sporadic gentrification**	Prior to 1973, the process is mainly isolated in small neighbourhoods in the north eastern USA and Western Europe.
	Transition – Gentrifiers buy property	In New York and other cities, developers and investors used the downturn in property values to consume large portions of devalorised neighbourhoods, thus setting the stage for 1980s gentrification.
1970s – 1980s	**Second-wave gentrification – The anchoring of gentrification**	The process becomes implanted in hitherto disinvested central city neighbourhoods. In contrast of the pre-1973 experience of gentrification, the process becomes common in smaller, non-global cities during the 1980s. In New York City, the presence of the arts community was often a key correlate of residential gentrification, serving to smooth the flow of capital into neighbourhoods like SoHo, Tribeca, and the Lower East Side. Intense political struggles occur during this period over the displacement of the poorest residents.
	Transition – Gentrification slows	The recession constricts the flow of capital into gentrifying and gentrified neighbourhoods, prompting some to proclaim that a "degentrification" or reversal of the process was afoot.
Mid 1990s –	**Third-wave gentrification – Gentrification returns**	Prophesies of degentrification appear to have been overstated as many neighbourhoods continue to gentrify while other, further from the city centre begin to experience the process for the first time. Post-recession gentrification seems to be more linked to large-scale capital than ever, as large developers rework entire neighbourhoods, often with state support.

Stage model of Gentrification according to Hackworth and Smith (Jason Hackworth and Neil Smith, 2001)

Gentrification, even 50 years later after the first definition by Ruth Glass, is still a current topic in urbanism. It is mainly perceived as a transformation of a working-class or vacant area of the central city into middle-class residential and/or commercial use. It is a process that has attracted the attention of the media, local governments, urban planner, architects and developers, businesses, city stakeholders, and political activists. In the 1990's in several works we can follow the shift from the classical gentrification to the new-build gentrification described by Neil Smith as a much broader phenomenon. He perceives it as a highly dynamic process where the reinvestment of capital at the urban centre which is designed to produce space for a more affluent class of people than currently occupies that space (Smith, 1996).

The city of Newcastle upon Tyne can be perceived as an example for new-build gentrification. The city council introduced a citywide regeneration strategy named "going for growth" that sought to remodel low-demand housing areas in inner-city Newcastle. One of the objectives was to rebalance the population of disadvantaged and stigmatized communities by building housing that would attract the middle classes into these areas. Gentrification that took place here, was not on the former brownfield site, rather it took place on pre-existing residential land. This new-build gentrification was about social engineering aiming to attract the middle classes to parts of inner-city Newcastle with the aim to socially rebalance these areas (Loretta Lees, Tom Slater and Elvin Wyly, 2008). Example of the city Newcastle shows how the city can make an advantage from gentrification and at the same time obtaining the status of a creative city (see Chapter 2).

3. Temporary use of brownfield sites

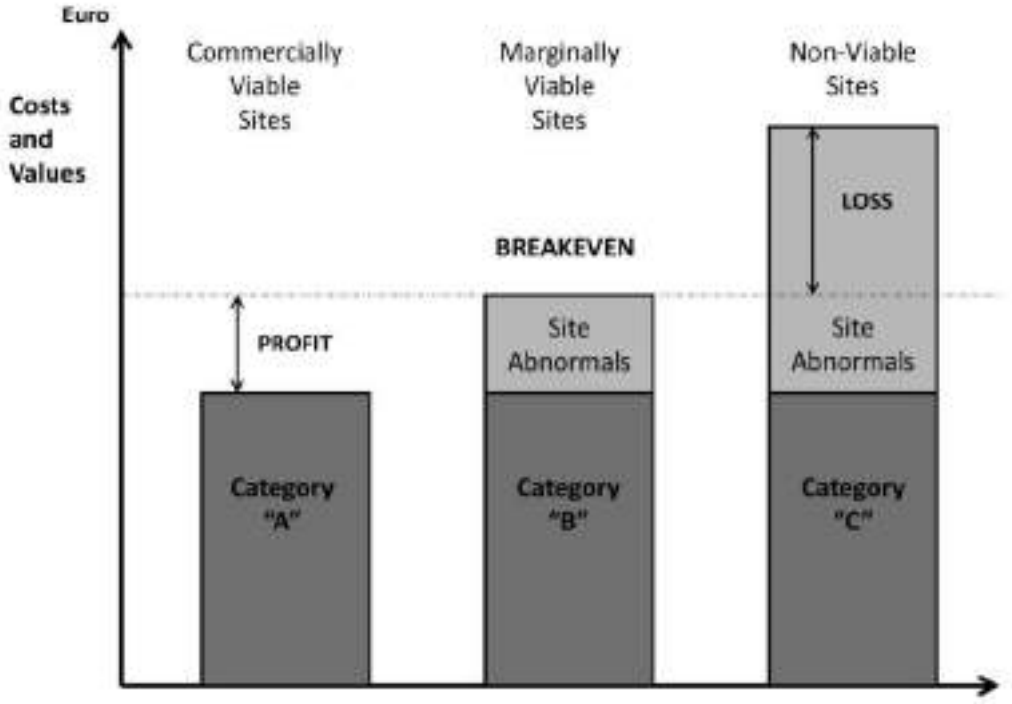
3.1. Brownfield Sites

Urban derelict sites are results of changes in functional use of the sites. The loss of main functions of the area leads to the degradation of the environment and further loss of the reputation and attraction of the sight from the point of view of users. Brownfields are predominantly perceived as a result of industrial destructuralization and wave of the recession. Brownfields regeneration is very often very complicated with respect to the strict legislation and environment protection as well as with the respect to the housing market and banking sector. Sustainable way of regeneration requires the integration of social, cultural, economic and environmental aspects(BRIBAST, 2010).

Integrative approach to regeneration lies in a sustainable way in implementation of combinations revitalization strategies based on the knowledge of mutual links among economic recession, degradation of the physical environment and social stress factors. Strategy for brownfields regeneration depends on external and internal framework conditions for the process of regeneration. One of the key factors for strategy selection is the possibility to gain the financial support for regeneration of external resources and

total costs for the regeneration of the site (Picture 1). Application tools for the brownfield sites regeneration can be divided into passive (e.g. local taxes, intervention for investors) and active (e.g. improvement of the infrastructure, social infrastructure, transport, social infrastructure, environment, economic activities) financial interventions. The legal framework of the environment, lack of trust and practical experience in majority of the sites is a limit for the private-public-partnership, but the cities should look for other forms to how to use this approach for their advantage(BRIBAST, 2010).

Picture 1: A-B-C Model for the site regeneration



A-B-C-Model for the brownfield site regeneration according to BRIBAST (BRIBAST, 2010)

3.2. Creativity, Culture and Creative Cities as an Approach for Brownfield Site Use

Creativity itself has a very long history and therefore we can find thousands different types of creativity and always from a different point of view. In general it is very difficult to define the creativity. We can understand it as a capability to create new and genuine thoughts, which were before unknown for the definer (Zlatá, 2011). As many authors as many definitions. Robert Weisberg perceives creativity as a work of the

history´s most creative personalities and innovation (Weisberg, 1993), and John Howkins links the word with the spiritual and very personal point of view (Howkins, 2005).

Culture is an important source of creativity. Creative industries foster on the rich core of the cultural heritage, gifted artists and culture professionals. This core is linked with connected innovative services bringing creativity to the market (Zlatá, 2011). Many professionals consider linkage of arts and creativity with innovation crucial for the creative potential of the place. Richard Florida, the author of "Creative Class", sees the connection of culture with economic growth by producing incentives that promote effort, thrift and hard work. Culture according to his view motivates economic growth by focusing human energy and effort on work and away from the pull of distraction(Florida, 2005). Charles Landry describes creativity as historical evolution, while understanding a place from which culture comes from. This attitude creates a potential for a city to rethink its attitude and vision for the future. Landry, as the inventor of the idea of "creative cities", sees a hidden potential in each city. This concept is a positive one; he assumes that ordinary people can make extraordinary happen if they receive a chance to do so(Landry, 2008).

Creative cities are spaces you want to live in, places to be visited (Hartley, 2005). Often they possess various characteristics as: vibrant arts and cultural sector, capability to produce employment, distribution of resources, etc. As summarized by Jinna Tay, "creative cities" is about how local urban spaces can be remained, rejuvenated and re-purposed within a competitive global framework. Traditionally the city has been studied from disciplines as architecture, sociology and urban planning, developing ideological concerns. Concern over how the new economy may impact on the local has also played a part in directing attention toward the city as a possible site for social and economic renewal. The establishment of a creative milieu is frequently identified as the means of meeting development outcomes. Cities are sites where shifts in social and economic processes, development strategies and emerging spaces can be observed. Creative cities highlight the significance of consumption-led economics, cultural production and urban space designing (Tay, 2005).

The concept of the creative city can be replicated but the success itself is depended on how it deals with long-term development questions, such as economic and social sustainability, gentrification and local displacement, exclusionary practices, and local identities. Creative expression may come up against conservative systems or ideological cultural bias, which may act to smother the natural diversity of creativity (Tay, 2005). This renewed focus on social identities also manifest in lifestyle and service consumption as cafes, restaurants, bars, tourism, the nigh-time economy. Cities that offer lifestyle and creative sector but at the same time they provide affordable loft spaces and heap drinks will always be greater attracter for creative workers and diverse communities. This social aspect of the creative industries links the cultural network to

economic and creative production and the city of Newcastle upon Tyne can be perceived (Ward, 2002) as an outstanding example able to compete world-wide known centres of culture.

3.3. Temporary Use of Brownfield Sites

Temporary use describes the interim stage when a sites original purpose has been abandoned, its future development is still uncertain, and it can be used on favourable terms. It refers to an extremely wide range of concepts and timeframes, from single events through to seasonal projects and creating the field for the permanent establishment. This term is not a new social phenomenon: temporary ventures have always been a feature of cities that were conceived and built for the long-term. Temporary uses are now becoming more diverse, leaving their foot print on the city locations, mostly on derelict sites becoming a structural component of urban development. Temporary uses today are the product of structural changes in the economy (ed., 2007). Older industries that occupied extensive sites are disappearing. The main criterion when choosing a new production location is its accessibility. Thanks to new technologies goods can be supplied whenever needed. Former industrial premises, disused railways and rail-freight yards, or wastelands created by the demolition of large housing estates are spreading mainly throughout the inner cities.

There is a growing demand for free and affordable space mainly by artists, creatives, social initiatives, youth and sport projects. Facing the problem of derelict brownfield sites, people involved in such developments reintegrate apparently redundant spaces into the urban structures. These “space pioneers” (they discover abandoned sites and reinvent them), often perceived as temporary users, are evidence of a trend to greater social commitment (ed., 2007), to more participative approach (BRIBAST, 2010). Such creativity has a chance to blossom on disused sites and in vacant buildings. The aim is to initiate a temporary use at a suitable site or premises. At the same time, the concept of many temporary use projects rests on the liberty of organizing everything oneself (ed., 2007). Space pioneers, as mentioned above, apply particular criteria to their search for the right location. Alongside the characteristics of the location itself, a personal commitment to work, available networks, mutual voluntary support, creativity and a love of experimentation, all play a role at the start of a temporary use project. They re-cycle the structures for little cost trying to compensate the deficits of a peripheral location by actively networking with other temporary users. Shared locations help to create creative clusters and support the creative environment of the site.

By helping temporary use projects settle at such locations, local authorities can regenerate the latter as a part of a lively cityscape. The potential of these sites is a chance for young creative start-ups as well as voluntary workers, to implement their ideas without making major financial investments and subsequently, to contribute to the

social and economic foundations of urban society. Particularly in a projects initial phase, conditions for rapid “cellular growth” tend to be ideal.

4. Case studies from the city Bratislava, Slovakia

The topic of brownfield sites regeneration under the Slovak conditions has been a relatively new topic. By now we have had relatively little experience with regeneration of brownfield sites in our country, however, the quantity of them, the economic situation in the country and the (lucrative) position of brownfield sites within the towns obliges us to be increasingly interested in the issues of how to transform and bring them back to life. It is not a simple task, given the fact that former industrial buildings and other underused areas are frequently perceived as underestimated and investors as well as municipalities often do not consider their importance and value of their cultural heritage. The general attitude is rather to "erase" brownfields, eliminate any traces of the past and reshape the land for “empty site” and start to build from on the greenfield site. In Slovakia, majority of the unused brownfields are considered only as a great potential for the future and they still wait for their chance, but some of them have already been successfully rebuild and some are currently undergoing important changes towards the new future. Examples introduced are from the city capital of Slovakia, Bratislava, where many brownfield sites have been already demolished, focusing on three examples of successful conversions through various approaches at different stages.

4.1. Design Factory (Bottova ulica)

Design factory is one of the few examples how old industrial places can be transformed into cultural place. The building is situated in the area of a former industrial zone in Bratislava where a Kablo factory of a 15 000m2 size was situated(Wikipedia, 2011). Originally this site was suggested for a transformation into a multifunctional complex Twin City, the plans have changed several times, by now no investment except demolition has been made. In the area were located some valuable objects possessing the potential to be listed as technical monuments and at the same time to be protected from dereliction or further demolition. Inflexibility of authorities led to the decision to demolish the former valuable industrial buildings with the excuse of a bad technical state of art and threat to the population (Mistrík, 2011).

Nowadays the former industrial building where the Design Factory is situated serves as an exhibition space, gallery, cafe and ateliers for 3 architects who were behind this conversion. After its opening in 2005 design factory won several awards for design and architecture. Atmosphere of the place aims to be the intermediary between business sector and cultural happening, an example where history meets creativity and culture. Design factory is only a small “island” of creative industries in the area possessing a significant potential to become the creative centre of Bratislava (designfactory, 2005-

2012). The site has got a good location close the city centre, neighbouring with the site where the Slovak National Theatre is located, called Eurovea.

4.2. Cvernovka

Cvernovka is an example how the former industrial site, where knits were produced, can be transformed into a centre of culture based on a temporary way. At the beginning of the 20th century the factory had already eight buildings. In 1948 the factory was a part of socialization process while in the 1960's the production has reached its maximum with up to 2,500 employees. Goods, mostly sewing and knits were exported all over the world. Due to the economic reasons in 2004 the factory was closed, industrial buildings remained (Mistrík, 2011). Nowadays these buildings are used for cultural purposes. In the entire area of Cvernovka about 300 companies, including paintball arena, bookstore, alternative workshops and Gallery of Cvernovka, have found its place here. Nevertheless, Cvernovka is very well known for the location of creative ateliers of painters, architects, interior designers, photographers, fashion designers, graphic and industrial designers, including lofts.

The second building is located on the block of the streets Trnavská, Záhradnícka, Miletičova and Jégého. The architecture of the building is very valuable and atypical for an old industrial architecture. Nowadays the area is used for cultural purposes. After PKO (Park of Culture and Leisure) was closed it became a popular space for cultural events, concerts and exhibitions.

4.3. Eurovea

Eurovea is the name of a new international trading centre in Pribinova Street on the left bank of the Danube River, between the Apollo bridge and the Old bridge in Bratislava, in the vicinity of the new Slovak National Theatre building and office building Tower 115. Thanks to its location in the city centre it connects the river embankment with the old town and extends the offered open public space. The whole area of Eurovea is a former brownfield site. An oil refinery was originally located in this place, which was founded in 1885 and produced gasoline, kerosene, paraffin, candles, mineral jelly and asphalt. In 1944, during World War II the refinery was bombed and 80% of the factory was destroyed and continuously caused contamination of soil. All refinery activities were definitively shut down at this place in 1963 when the plant moved to other location in the outskirts of the city. In July 2006, the execution of the first phase of the project began. Eurovea (phase I) was opened in spring 2010 and in an area of 230,000 square meters it offers 60,000 m2 of shopping spaces, leisure facilities and entertainment as well as other area over 60,000 m2 of office spaces, hotel facilities and apartments (wikipedia, 2011). The completion was possible thanks to foreign capital of the Irish developer who cooperated also with Slovak architects on the final design. It is

considered to be a successful urban extension of Bratislava´s (relatively small) historic city centre.

An important part of the project, in terms of the brownfield regeneration, is the Warehouse No. 7 object. The reinforced concrete structure was built in the 1920s in a functionalist style, as a reminiscent of the classical style. The industrial nature is enhanced by the railway track leading directly to the object, still preserved, which originally connected the entire embankment of the Danube from the refinery to the contemporary port. The building was completely renovated and nowadays it houses an exhibition related to the Eurovea. The role of the Warehouse No. 7 should increase its importance in the near future, when the transformation to the city auditorium, as an alternative to the former PKO (Bratislava's Culture and Relaxation Park), will be finished.

5. Conclusion

This contribution shows how the underused areas and spaces, situated mainly in the city centres, can be repeatedly used and successfully converted into housing. These conversions of former brownfields are influenced by several conditions one of which is gentrification as sociological changes in urban space. The process of gentrification is often used together with the approach of a temporary use of the site through interventions, actions, acts or events. Three on-going projects from Bratislava were described as an example of successful brownfield sites regeneration in the urban space showing the capability to transform the former brownfield sites into successful projects in the Central Europe.

„This project has been funded with support from the European Commission. This publication [communication] reflects the views only of the author, and the Commission cannot be held responsible for any use which may be made of the information contained therein.“

Party-politics and planning. Mapping political values for a better understanding of decision-making on spatial development

W.W. Buunk[1]

Abstract

Over past few years, political support for spatial planning has evaporated in Dutch politics. The ministry of housing and spatial planning is abolished and central government involvement in strategic planning is to be decentralised to the regional government tier. These sudden changes to the Dutch planning system have surprised many practitioners, as well as scholars, that appear to have little understanding of the party-political dimension of spatial planning and policies.

This paper presents the outcomes of a research of party-political values relevant to the field of planning and discusses the research methods used. The variety of Dutch political points of view on spatial planning and policies are defined in terms of political values. A mind-mapping approach was used to make a practically useful representation of the variety of political values found. A map of party-political values was designed as a tool for improving decision-making on spatial development issues.

1. Introduction

Spatial planning has become contested ground in Dutch politics. For decades, there was to a broadly shared belief in strategic spatial planning by central government, as well as a strong position for comprehensive local and regional public spatial planning approaches. Over past few years, political support for spatial planning has evaporated. Two years ago the ministry of housing and spatial planning was suddenly abolished by a new government coalition. With this change, the traditionally crucial link between the housing policy and strategic spatial planning by central government was cut. Central government involvement in strategic planning is to be decentralised altogether to the regional government tier and planning legislation is to be reformed and simplified.

These sudden changes to the Dutch planning system have surprised many practitioners, as well as scholars. An important reason for this surprise is that the party-political dimension of spatial planning and policies were never studied, the dominance of certain political values rarely explicitly recognised as a possible issue

[1] Windesheim University of Applied Sciences - ww.buunk@windesheim.nl. This paper is based on a part of a chapter for the book "Research inquiry in the spatial planning field" (Elisabete A. Silva & Patsy Healey, eds.) to be published by RTPI.

for scientific debate and that changes in political thought were not foreseen. Yet, these political changes did not come out of the blue.

Planning practice has been going through a fundamental change the past decade. Collaborative planning approaches have emerged, in which government agencies need to cooperate with private parties, social organisations, individual stakeholders and other interested citizens. In complex processes of joint fact-finding, spatial planning and design, negotiation and decision-making take place. This often means that in strategic planning processes as well as concrete projects, each time a new and basic decision on the preferred spatial development needs to be made. Such a basic decision is a deliberation of values, or in other words as a normative or political decision. Spatial development issues and planning therefore transcend the confined arena of professional planners and have (re-)entered the party-political arena.

The Dutch political arena traditionally is varied, multicolored and some say fragmented. Like many other European countries, new political movements and parties have emerged over the past decade of a left and right wing populist variety, that compete with mainstream social-democratic, liberal an Christian-democratic parties. Despite the new spatial development practices and despite these general political changes in the Netherlands, the knowledge of political thought on spatial development issues and spatial planning is limited amongst practitioners and scholars.

This paper presents the outcomes of a research of Dutch party-political values relevant to the field of spatial development approaches and planning. In section 2, the pluralist theoretical perspective is defined that underpins the value-oriented approach to spatial development and planning. Section 3 presents the research strategy that was followed to gain insight in political values and the research method that was chosen. Section 4 presents the outcomes of the research, and shows how the categorisation of the variety of political values has been used in a mind-mapping approach with practitioners on two cases. Section 5 discusses the relevance of the outcome in the form of a map of party-political values as a tool for improving the practice of decision-making on spatial development issues.

2. A pluralist approach

Spatial planning is an instrument for making well-informed decisions on our physical environment (Friedman 1987). These ‘well-informed’ decisions are the result of careful preparation and consideration of various proposals, for which a logically argued preference is reached following a functional or technical-instrumental rationality (Nozick 1993). In practice, planning nowadays is more than a technical analysis of the spatial development issue at stake and the best-designed solution. In contemporary process-oriented spatial planning approaches, methods of analysis and design are combined with participation of stakeholders, methods of negotiation and procedures for joint decision-making (Healey 1997, 2003; de Roo & Silva (eds.) 2010).

In policy arenas that emerge around urban and regional development challenges, none of the participating actors is able to deal with these challenges on

their own behalf. Being mutually interdependent, the participating actors need to make a joint effort to define what is the spatial development issue at stake and decide upon the preferred solution (Buunk 2003: 126-133). This inevitable means that existing planning policies may need to be set aside in favour of new custom-made ways of working, which in the end require a basic or political decision.

With comprehensive planning policies in place, for a long time the final political decision on a spatial development issue may have been a formality. A mere confirmation of what was decided upon in earlier stages, along the line of strategic planning guidance. This is no longer the case, as basic decisions need to be made in each collaborative process. Despite sophisticated and professional planning approaches, the final decision on a spatial development issue may often seem illogical or riddled with situational or even emotional arguments. Planning researchers and practitioners alike, need to be gain a better insight in how these basic decisions are being made.

2.1 Technical-instrumental rationality

Planning practice and planning theory has long been dominated by a technical-instrumental rationality. Robert Nozick even calls the theory of instrumental rationality the "default theory, the theory that all discussants of rationality take for granted" (Nozick 1993: 133). The idea of instrumental rationality is that actors are supposed to choose rationally between instruments or measures that to the best of their knowledge helps to achieve the aims that are set. The rational approach to planning was later refined by approaches of planning as a process of communication that follow a communicative rationality (Fisher & Forester 1993; Forester 1999). In this perspective, planning is seen as a process in which rich and multi-layered policy stories are formed that help understand spatial development issues and define the preferred way of dealing with them. But when it comes to those seemingly random or odd decisions on spatial development issues that often astound the practitioners that have been working hard to help prepare for proper rational and logical decision-making, the communicative rationality also falls short in understanding what is happening.

Whatever the planning approach followed or whatever professional techniques applied, in the end a decision needs to be taken about what is considered to be the best solution to the perceived problem. Despite the variety of techniques of urban and regional planning and collaborative processes that have been developed over the years, there seems to be little insight in the nature of these supposedly well-informed decisions. These decisions often appear – at least in part – to be an expression of somewhat random normative or political preferences, rather than of professional planning approaches and well-considered policies (Flyvbjerg 1998). Even after extensive participative process, a final decision may differ considerably from what was expected to be a rational or logical outcome of the process, and therefore was prepared by planning practitioners or expected by participants.

The problem with these seemingly random or odd decisions is not their inherent lack of logic, but the kind of logic planners and planning researchers apply in their scientific and analytical methods. The question therefore needs to be raised

whether the technical-instrumental and the communicative perspectives are sufficient to understand all aspects of the planning processes. The technical-instrumental approach to planning, as well as the communicative approach, both presume logical ways of reasoning and argumentation when it comes to decision-making. In order to gain a better understanding of seemingly random or odd decisions on the spatial development, and on the design and use of land or urban territory, a different research approach is required (Flyvbjerg, 2001; Buunk 2010). An approach in which seemingly random or odd decisions on spatial development issues, can be understood better.

2.2 Value-oriented research

Theory driven research that assumes planning processes follow a scientific logic, needs to be complemented by a value-oriented approach. Flyvbjerg (2001) even calls for a completely different social science that not focuses on theory building like the natural sciences do, but that is geared predominantly to contributing to practically applicable insights: "...we must drop the fruitless efforts to emulate natural science's success in producing cumulative and predictive theory; this approach simply does not work in social science. [...] we must take up problems that matter to the local, national, and global communities in which we live, and we must do it in ways that matter; we must focus on issues of values and power (Flyvbjerg 2001: 166). When the focus is on the value issues, it soon becomes clear what problems planning practitioners often face.

Flyvbjerg states that the purpose of social science is: "...not to develop theory, but to contribute to society's practical rationality in elucidating where we are, where we want to go, and what is desirable according to diverse sets of values and interests" (Flyvbjerg 2001: 167). He sets out what he calls a phronetic approach, following Aristotelian distinction between scientific knowledge (episteme), technical ability (techne) and prudent use of knowledge and technology (phronesis). Flyvbjerg defines this as a value-oriented approach to social science: "Phronesis thus concerns the analysis of values - "things that are good or bad for man" - as a point of departure fo action. ... It focuses on what is variable, on that which cannot be encapsulated by universal rules. Phronesis requires an interaction between the general and the concrete; it requires consideration, judgement, and choice" (Flyvbjerg 2001: 57). The role of values and judgments of actors are distingued from other factors like institutions or procedures. Flyvbjerg's call for social scientists to reflect on the practice of argumentation and the prudent use of knowledge in practice further focuses on the relation between knowledge and power, rather than elaborating on the judgemental aspect of argumentation and the role values.

In order to make an analysis of political values that play a role in decision-making on spatial development issues and in planning, a value-oriented rationality research approach is followed. Following a value-oriented rationality means that planning is seen as normative effort, in which moral or ethical aspects of choices are made on spatial development issues. Such a perspective is rare, although there are some examples in adjacent fields (e.g. van Wee 2011). Below, this normative approach is further explored with a view to the research strategies needed to gain

insight in underlying values of planning, in order to help practitioners to find ways of contributing to a proper deliberation of values.

2.3 Ethical pluralism

The assumption behind proper value-oriented research approach is that 'good' decision-making requires that all relevant values are explicitly considered – as far as possible – in decisions on spatial development, design and use of land or urban territory. This is not a judgement of decision in terms of their outcome, but in terms of the decision-making process. It is a procedural valuation with a normative point of departure that follows the principle (or value) of ethical pluralism of Isaiah Berlin (Berlin, 1969 and other years, in; Hardy 2002). Berlin, as characterised by Blokland, throughout his work argues that there are many values worth pursuing, yet that they more often than not are incompatible, which means we need to choose (Blokland 1997: 169). Berlin saw this as a tragic situation that we experience on a daily basis, yet we need to do it anyway in a search for a better life.

A pluralist approach is therefore necessary. Alternatively, a monistic approach that would favour one normative perspective over others, would drastically limit the insight in possibly relevant values. Such a perspective would not lead to better decision-making. Political scientist Hans Blokland (2001) sees this as a challenge for the political system of democracy. A pluralist approach is needed to improve our insight in and our ability for proper democratic decision-making, not only in formal political institutions but also in all sorts of participative local processes. A value-oriented research into spatial planning and decision-making on spatial development issues requires a pluralist approach, which accepts that there will always a variety of values at stake.

With a social science that, according to Flyvbjergs, needs to contribute to prudence and to practical wisdom to find ways of dealing with issues, a research strategy is required that focuses on judgmental processes in the way spatial development issues are dealt with. Flyvbjerg suggests three questions to guide such research: "1. Where are we going? 2. Is this desirable? 3. What should be done?" (Flyvbjerg 2001: 60). He later adds a fourth question, "Who gains and who loses; by which mechanisms of power?" as he is mainly interested in dominance of ideas, knowledge and judgements. Here, the focus remains with the processes and mechanisms of judgement, in which values can be seen at work. Unlike Flyvbjerg, who doesn't define values, nor appears interested in finding out what values guide these judgemental efforts in practice, the aim of research here is to find and define the variety of values that are being used.

3. Finding values

Studying values is the field of moral philosophy, which is enjoying something of a revival. Frontman Alisdair MacIntyre stresses that “every action is the bearer and expression of more or less theory-laden beliefs and concepts; every piece of theorizing and every expression of belief is a political and moral action” (MacIntyre

2007: 61). Understanding moral concepts is considered necessary, as these are used by all sorts of social actors in the choices they make as “his or her reasons, motives, intentions and actions, and in so doing generally presupposes some claim that these concept are embodied or at least can be in the real world” (MacIntyre 2007: 23). Analysing values from a perspective of morality may seem farfetched, but dilemmas of spatial development often have an unspoken moral or ethical dimension.

A question like "what is a just housing program?" will help clarify underlying dilemmas of an urban transformation project. Planners are not used to explicitly debating such questions, as long-term policy aims - such as the aim for 30% social housing - are considered to be a broadly accepted expression of a moral stand. The question is whether this is true. Or to turn it into a moral issue, the question is whether this is just. Moral philosophers and moral psychologists, such as Shalom Schwartz and Jonathan Haidt c.s. plea for a better understanding of the moral dimension in actions people take and choices people make. This plea is answered here by concentrating research on the variety of values that may play a role in spatial planning processes.

3.1 Defining values

A value can be defined here as an expression of a deep-rooted belief, motive, incentive, desire, or ideal for spatial development, and for the design and use of land or urban territory. Values have no meaning for practice or for scientists alike, when they are a mere dead letter in a book. Values only have a true meaning when they are recognisable in social interactions, as the underlying motivation of actors in their judgements for action. Similar to the political scientists' concept of power or social scientists' concept of meaning, values are only real in their application in social interaction. In interaction, values are found as words. Words like 'justice', 'pride' or 'urban density' that have a specific meaning in social interaction. Discourse analysis is the appropriate research method to unravel the meaning the specific meaning of in their social context.

With the communicative turn of spatial planning, planning research has adopted methods of linguistic analysis, following great philosophers like Lyotard and Foucault (Hajer 1995; Torfing 1999). Discourse analysis as a qualitative research method helps to insight in the frames and storylines by which actors create their view of the world, and of spatial development issues. Discursive analysis of text and talks looks for specific words that are used often or that seem to specify certain meanings. Looking for signal words or phrases helps finding dominant storylines that show what preferences actors have and how and why they will act on the issue at stake.

For a value-oriented research, the challenge is to reconstruct the underlying values and sets of values behind these storylines. These values are concepts (in abstract terms of concrete) can be found by further examining the signal words and their use in building arguments and judgements behind choices that are made. Values are defined as specific phrases or sentences that are considered to characterise the deep-rooted belief, motive, incentive, desire, or ideal behind a storyline.

However difficult it may seem to reconstruct underlying values of texts, it is not more difficult than selecting sections of text of which a researchers thinks they

are typical for the dominant discourse. In the end, it is all about gaining insight in the categorisations, judgements and preferences of actors in social and political processes: "... values, pragmatic considerations, and strategies for action are a prerequisite for, and part of, the method, and hence, do not stand in opposition to the understanding-oriented project" (Flyvbjerg 2001: 126). The most difficult part of the analytical work is to focus on discursive elements, on sections of text and on words that appear to bear a specific meaning of deep felt desire about what is good, for that is what values are.

3.2 Abstract and concrete values

The choice for a pluralist approach requires a research strategy that distinguishes between values. A first distinction can be made between abstract and concrete values. Abstract values are often related to virtues, like temperance or courage. With a view to basic decisions on the spatial development, design and use of land or urban territory, values like justice (the just division of land) and aesthetics (the perceived beauty of the countryside) play a role. The Dutch Scientific Council for Government Policy (WRR) comes to the conclusion that values can take concrete forms, dependent of the object to which someone refers.

Anything can be the object of valuation, such as things, cultural heritage, individual people, the nature of relations between people (e.g. trust), or social principles (e.g. freedom) (WRR 2003: 46). Concrete values are readily recognisable from a spatial planning perspective, like specifically defined key natural resources that define the natural values worthy for conservation. These key natural resources are laid down in nature conservation legislation in scientific terms of species and habitats. Other values can concern the quality of land for various purposes of land-use, which may simply be defined as land value in terms of money.

Other distinctions can be made between types of values. Values can be nested in deeply rooted religious beliefs or can be moulded by political frames. Values can be personal and therefore objective, or can have a joint cultural origin. The latter will considered as being values of a general nature. Values may refer to substance or to more procedural matters, such as routines or ways in which we wish to do things properly.

Values therefore are abstract concepts expressing an ideal for what is considered to be the ‘good society’. Abstract values are beliefs. Deep felt opinions or desires for what is considered ‘the good life’. Certain values are recognisable as political values. These values are principles concerning the desired mechanisms and structures of society that can be related to views of political parties or political social movements. In the practice of spatial planning and ways of working to deal with spatial development issues, may be specific process values can be discerned. Guiding principles on the way in which the desired spatial development, design and use of land or urban territory needs to be realised. Or procedural principles, which reflect the preferred role of government and its instruments, such as statutory planning, that usually concern the desired division of responsibilities between government and private developers or individual citizens.

3.3 Sets of values

One of the pitfalls of value-oriented research is that it may appear attractive to design a hierarchy of values, e.g. based on the distinction between concrete values and abstract values. In such a hierarchy, abstract values would than be ranked higher than concrete values. Concrete values are often considered being derived from an abstract value. Urban density can be a value that guides decision-making on an urban redevelopment scheme. In spatial planning this normally means that a densely built-up area is thought to create a distinct metropolitan atmosphere. The abstract value behind it can be 'diversity' or 'growth', as denominators for a highly dynamic, busy and mixed city life.

In the reality of the practice of planning and decision-making on spatial development or urban design, actors will draw upon a mixture of concrete and abstract values. High density as something that creates a good and vibrant city may be linked to a preference for innovative and modernistic designed high-rise buildings, as well as with a specific notion of mixed residential use, corporate businesses and small-scale creative industry. Density may even be defined as a concrete norm, in terms of the number of dwellings per hectare, yet may be combined with rather indicative design references. In actual decision-making, actors may wish to deliberate on these values and norms vis à vis values that are linked to concerns with global climate change or social cohesion.

Defining a hierarchy of values is principally impossible and add will no new insights. The distinction between abstract values and concrete values in the value-oriented research approach is therefore analytical distinction only. It helps to construct the relevant sets of values that play a role in basic decisions on spatial development issues. Values can be grouped in terms of their substantive similarities, creating an insight in more or less congruent sets of values that appear to be applied in basic decisions on spatial development and the design and use of land and urban territory. For this particular research, one of the main challenges was to define a categorisation of possible sets of party-political values.

4. Value-oriented research strategy

In order to find the sets of values that are relevant in a process of dealing with spatial development issues, two research strategies can be followed. First, a rather strict empirical research strategy can be followed for analysing a spatial development process. Based on document analysis and loosely structured interviews with key actors, the dominant storylines of an elaborate policy process can be described. After that, the challenge for the researchers is to identify the underlying sets of values for each of these storylines. Experience with practice of planning processes and insight in a broad field of related policy fields such as transport, nature protection and recreation and rural development, also in terms of research, will be necessary to select the viable textual elements for defining values.

This may prove to be a laborious research strategy, but with little previous value-oriented research in the field of spatial development processes and planning this may seem to only viable research strategy that helps avoid bias. Yet, another research strategy can be considered. In this strategy, a categorisation of values or types of values is defined beforehand on the basis of theory, relevant literature from other fields and/or outcomes of related research. This then should help to find the

sets of values in further empirical analysis of spatial development issues and planning. In order to prevent a bias to predefined values, it should be avoided that it becomes a theory-driven research. Theoretically defined types of values of value categories need to be used heuristically, to help understand the empirical material.

In the research of party-political values, the research starts with a categorisation as such. Not all social and professional values concerning spatial development and planning are searched, but political values. This is a first defining effort that helps limit the field of research. Further theory and literature is available to help define possible categories of political values or sets of political values. For this reason, this second research strategy was followed, in which practical political experience was structurally mobilised as part of the analysis in a series of expert meetings in which political thought on issues was analysed and preliminary outcomes tested.

4.1 Categories of political values

The research into the most relevant party-political sets of values on Dutch spatial planning started off with some exploratory interviews with national and local politicians and with practitioners and scientists with links to political practice[2]. Next, a large number of political documents were analysed (around 80). By the start of the project it proved difficult to continue on a preliminary indication of four dominant storylines on spatial development issues and planning of the four political 'families' (Buunk 2010: 34). Instead, the document analysis looked at five elements: (1) the preferences on spatial concept or urban development pattern (if at all), (2) political problem definition of the underlying social issues behind perceived spatial development issues, (3) the role of central and/or local government vis a vis private parties or social organisations or individual citizens, (4) preferred instruments and (5) specific moral-ethical anchorage for spatial development issues and planning.

In two sessions with representatives from political parties and civil servants and policy advisors, the political views on different cases that are typical for Dutch spatial planning on a central government level and on local government level were discussed. With the use of mind mapping software, the landscape of political values on spatial development issues and planning was mapped. The main challenge proved to be finding the backbone of this map, the legend so to speak, by which political values can be categorised. With the rich body of political thought, categories like 'socialist', 'social-democrat', 'liberal', 'green' and 'christian-democratic' appeared inadequate. A variation of three citizenship styles defined by Dutch research bureau Motivaction (Gijsbers & van der Lelij 2010) and the German research bureau Sociovision (de Vries 2006) was considered. This notion of the variety of attitudes people can have towards government and society, daws on extensive lifestyle research with long-term surveys that produce cross sections of socio-economic stratification and moral orientation. In confrontation with the analysis of political

[2] The research was carried out by the author of this paper, together with Marloes van der Weide Msc and with support by De Argumentenfabriek, a consultancy agency specialised in analysing complex issues with mind mapping software and clearly designed overviews of results.

documentation, five categories of political values were constructed but finally rejected as inadequate for a categorisation of party political values.

The choice was finally made to take basic moral orientations as starting point for categorisation. Moral judgements, it is often thought, in essence concerns what is considered the just course of action. In this line of thought of what is 'just', the concept of justice is the dominant value. Justice is often seen as pivotal, as the mother of all values in modern society (Sandel 2011). Ancient societies were characterised either by honour and respect (Greek and Roman ethics), or by guilt (Christian ethics). In modern society, justice is a formal principal in legislation, rather than guide choices in day-to-day life (Kinneging 2005: 100-114). Political philosophers like Michael Sandel show how competing definitions of justice are visible in legislation and in the way society is used to deal with dilemmas. There is one school of thought in which welfare is considered important, another in which freedom prevails and a third in which it is all about personal virtues. For making proper choices in their own lives and in society, people need to be aware of these fundamental differences and need to reflect on that (Sandel 2011: 26, 306).

The variety of party-political values that may play a role in basic decisions on spatial development and on the design and use of land and urban territory are wider than three varieties of the concept of justice. Two approaches were considered. The first is the model of ten or eleven personal moral values by Schwartz c.s. (2003, 2006). The distinction proved hard to apply to the variety of political values, notably because political values are predominantly about what desires people have towards group dynamics or how they desire society to be organised. This is somewhat different from the personal moral values, aimed at ones own behaviour or attitudes that Schwartz emphasises. This insight led the researchers to the work of moral psychologist Jonathan Haidt c.s., five basic moral positions can be defined, which people can hold distinctly in their judgmental argumentation: (1) the position in which *care* for others and preventing from *harm* being done to others dominates (2) the position in which *fairness* dominates, also in the meaning of *reciprocity* of behaviour, (3) the position in which *loyalty* to ones own group (*ingroup*) dominates, (4) the position in which respect and authority are dominant, and (5) the position in which the *purity* of ideals and the *sanctity* of beliefs are dominant (based on Haidt & Graham, 2007: 105-106. Also see Haidt & Kesebir 2010: 822)[3].

4.2 Normative positions in political views on spatial policies and planning

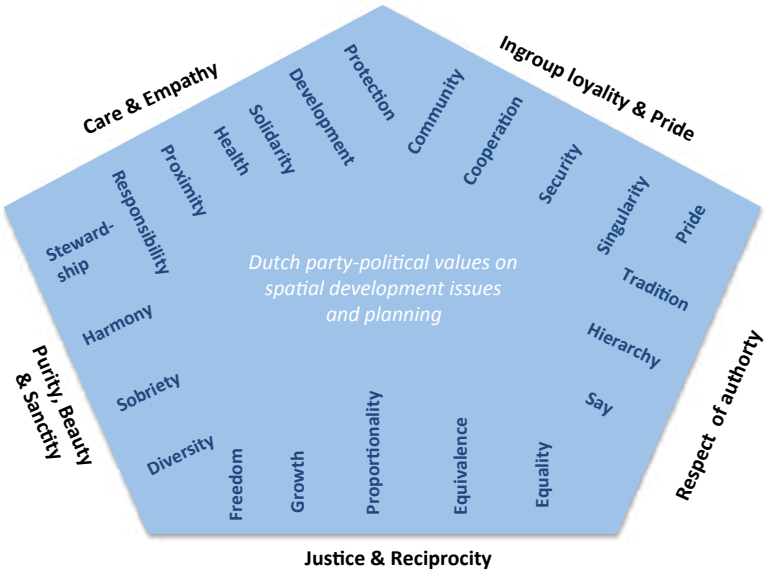
With five basic normative positions it appeared possible to analyse the empiric material of the document analysis of some 80 political documents of all Dutch parties represented in parliament. These documents were first analysed looking at their preferences for the spatial development pattern (if at all), the issues that are defined in terms of spatial policies, the preferred policy instruments for spatial policies (such as the instrument of planning) and the scope of government influence,

[3] Haidt c.s. have based their distinction of five categories of normative positions on insights in human driving forces in their social behaviours as found in psychological surveys in combination with moral philosophy and evolutionary biology. They have hypothesised these basic normative positions and keep testing them in moral psychological research.

and the political/moral/ethical views that are expressed in relation to spatial policies and planning. This material was then re-analysed with the five normative positions as a frame of reference by the researchers, and further refined in two working sessions with representatives from political parties and practitioners that are used to work on the fringe of practice and political decision-making[4].

The five basic normative positions were thus reformulated with a view to the Dutch political landscape of spatial development issues and planning. On the basis of expressions that were found in political documents or that were expressed in the working sessions, a set of 23 political key values could be defined in the normative playing field that is demarcated by the five normative positions (figure 1).

Figure 1 Dutch political values on spatial development



Each of these values is concisely defined in one word and a short explanation to further typify it. For the purpose of this paper they will not all be mentioned here, but a short indication is given for each of the five normative positions.

Care & Empathy is a normative position that is reflected in political ideals of solidarity, caring for others as recognisable in preferences for social housing, in protecting weak interests in spatial planning (e.g. *Protection*) or in urban design of neighbourhoods (e.g. *Proximity*) that allow people to care for each other (e.g. *Solidarity*);

Justice & Reciprocity are reflected in notions of fairness of the regulatory land use mechanisms (sometimes critically) (e.g. *Freedom*), fairness of housing allocation (e.g. *Equality*), as well as notions of spatial development opportunities for (economic) growth and individual freedom in landuse

Loyalty & Pride are reflected in loyalty with the own community, neighbourhood or town (e.g. *Cooperation*), and feelings of security that go

[4] Using the mind mapping software in a series of more than ten iterations in preparation of the sessions with politicians and in reporting on the results, the research team has selected these 23 key values.

with that. It concerns notions of regional identity and pride on ones own living environment (e.g. *Singularity*), and in negative terms a fear of changes to that.

Respect for authority may be generally not be a stronghold in Dutch political thought, yet is clearly reflected in the acknowledgement of state involvement in planning issues and in the relatively strong ideas of the hierarchy of the spatial planning system, albeit in different preferences in terms of the extent of central government involvement (e.g. *Say* for individuals vis a vis government).

Purity, Beauty & Sanctity is recognisable in a variety of rather distinct ideals, such as Christian notions of stewardship and of harmony that needs to be restored (e.g. *Sobriety* for an eco-friendly living standard), holistic ecological political ideals (e.g. ecological *Diversity*) and the beauty of architectural or urban design. The concern is with the integrity of the ideal as such and the adaptation of human behaviour it requires.

The 23 key value s – as an expression of a political motive, incentive, desire or ideal – is characterised by the researcher by a word that is always not necessarily found in the documentation or expressed explicitly by interviewees, but which the researchers consider to be representative. Each of the 23 key values (words) is further described by a sentence that indeed was found or can be found in similar form in documents of political parties or was expressed by interviewees.

5. Reflection

The research has resulted in an overview of the key party-political values of Dutch politics that can expected to play a role in decision-making on spatial development issues, projects and in processes of planning. This is particularly the case, when this decision-making takes place in the formal institutional arenas of political debate in municipal councils, regional councils and parliament. In order to support this practice, a clearly designed map of the Dutch party-political landscape is made[5]. This is meant to help analyse and understand the background of political questions and the course of political debate. The results of the research and the use of this overview deserve some remarks and caution.

The 23 political key values only characterise the Dutch political landscape. In other countries, the result of such an analyses will be different, if only for the choice of words that can be considered suitable to characterise a similar sort of value. The five basic normative positions may prove to be useful frame of reference for interpretation more or less similar to this Dutch research.

The 23 political key values should not be seen as being derived from a basic normative position. Values like 'protection' of weak interests and 'solidarity' with those that have a weak social position are merely a (more or less strong) reflection of the normative position of care, depending on the way such a value is expressed and used by someone. Whereas 'say' for individuals in matters of land use vis à vis central or local government shows a concern with issues of hierarchy and authority,

[5] To be published on http://www.windesheim.nl/lectoraatareadevelopment

it is weak or even negative reflection of the normative position of respect for authority.

The 23 political key values are the result of interpretation of the researchers. Values are words that can (and will) have a different meaning to different people in different contexts. In practice, many varieties can be found of similar normative meanings with different words. It requires some practice to recognise what is meant. Politics is often rhetoric. Questions are answered by questions, or with many words not answered. Sometimes the opposite is said of what is meant. Recognising the underlying value(s) will always require interpretation. Politicians and other people have flexible minds and hearts, and may be ambivalent in their preferences or adhere to seemingly contradictory preferences, desires and underlying values. Points of view, such as a support for sustainable development, may be linked to rather different underlying values (e.g. *Diversity*, *Solidarity*, *Sobriety*, *Fairness*).

The political turn in the Netherlands in government views on spatial development policies and planning suggest a break with a longstanding support with a core element of the Dutch planning system: the comprehensive strategic spatial planning approach by central government. With a view to the key political values, this tradition is understandable as it can be linked to six key values. The political document reveal as underlying values for spatial planning that *Protection* of weak interests of social democratic and socialist parties, *Stewardship* and *Harmony* of the Christian political tradition, the acceptance of *Hierarchy* in this policy domain (all parties, even liberal parties), and the strive for *Equality* of the social democratic and socialist parties and *Equivalence* (liberal parties). These values can be recognised form 4 of the 5 basic normative positions. Despite this almost all round support, it also reveals that is not supported by one recently more influential set of political values that can be recognised from the basic normative position of *Ingroup loyalty* & *Pride*. This seems to be a normative position and set of values to which spatial policies and planning and its practitioners have little linkages to. An insight that may give rise to many more new research questions.

THE RURAL VILLAGES IN PERIURBAN SUZHOU. BEYOND THE COUNTRYSIDE MODERNIZATION OF CHINA

Giulio Verdini [1]

Abstract

Among the top priorities of the political agenda set by the Chinese government during the last years, there is a rising need of achieving a balance between economic growth and environmental protection reducing, among the other things, urban–rural conflicts and building a "new Chinese countryside".

Especially in coastal China, and in the area of Suzhou that is used as a case study, a strongly land-consuming urbanization model is affecting the residual agricultural areas with a drastic reduction of farmland, causing at the same time a process of decline of a complex system of rural villages still existing around or within the urban areas (Liu et al., 2010; Verdini et al., 2011).

While the task of urban growth containment in China has already been addressed and, given the complexity of the issue, some strategies have been put forward (Zhao et al., 2010), the goal of a "new countryside" is still quite controversial. Behind the willingness of achieving the efficiency of agricultural areas creating meanwhile "clean and tidy villages" and a "civilized social atmosphere", lies the obsolete ideology of countryside modernization (Long et al., 2010).

The aim of the present paper is to point out the contradictory effects of these actions in the peri-urban belt of Suzhou in Jiangsu Province, reporting the preliminary results of a research work supported by the Suzhou Social Science Foundation in 2011, which is still ongoing. According to the fieldtrips and the first questionnaires realized in the summer and autumn 2011, an articulated and transitional reality becomes apparent. The system of villages studied reveals how most of them are threatened today either directly by the urbanization pressure or indirectly by the application of relocation schemes for local villagers. Moreover, the social structure is facing a problem of gradual expulsion of the young workforce towards the urban areas that will cause a phenomenon of the local population ageing in the medium-long term.

The understanding of the social and economical issues of the system of peri-urban

[1] Department of Urban Planning and Design, Xi'An Jiaotong – Liverpool University, Suzhou, People's Republic of China – giulio.verdini@xjtlu.edu.cn

villages can be considered a first and important step for outlining the potentials of these areas setting new policies for a real urban-rural integration of functions between the current model of urbanization of the Asian city and the surrounding rural fringes. The maintaining of a system of rural settlements can be strategic for reducing the social pressure exerted in some central and over-crowded locations of the city, moreover keeping the human-scale and the complexity of social formations of this kind of environment.

From this perspective it seems urgent even for the Asian city to rethink the paradigm of urban growth, reconsidering the role of rural settlements around the city.

1. Planning the urban fringe in China

The studies devoted to the understanding of the governance structure for farmland conversion at the fringe in today's China demonstrate that the system appears land consuming, strongly centralized and relatively complex, despite efforts by the central government to reduce rural areas being converted into urban areas, and to protect farmers' land rights by promulgating new laws and directives (Feizhou Z., Bourguignon C., 2009). The planning system is still mainly based on command-control planning instruments (Pieke F., 2002) and moreover it seldom encourages people's participation in the decision making process without avoiding the widespread and dramatically long-lasting phenomenon of illegal farmland conversion.
In China the quota systems, controlled by the upper levels of (provincial and national) authority, and the featuring of "acquisition with compensation" do not guarantee an equal distribution of advantages and disadvantages of development among farmers but often generate discretional allocation of land with a strong attribution of power to rural committees unable to ensure transparency to the rural-urban conversion process.

Urban fringes in China, especially in coastal areas, belong to a complex and transitional area between the city and countryside hosting the major contradictions of the so called "countryside modernization". Several rural villages, around the dense urban areas, are still densely inhabited by local villagers or new migrants, living, in some cases, in poor housing conditions. The proximity to the city can guarantee, on the one hand an alternative household income not just depending on agricultural production but, on the other hand, urban demand for underdeveloped areas can be a pre-condition for a relocation scheme supported by local government.

From this perspective the goal of urban growth containment and open space preservation (say farmland protection in some official documents of the Chinese government) seems to be, for example, in open contradiction with the several schemes of relocation, often put in practice by local government as in the case of the city of Suzhou.

In the prevailing literature on urban growth management in Western Countries urban containment policies have for a long time been at the centre of attention. This is due to the widely recognised negative impact of urban growth on farmland reduction, unsustainable urban sprawl, loss of environmental quality and rural landscape transformations (Altermann, 1997; Pendall, 1999).

Nowadays this has apparently emerged as a new concern of the China public agenda of sustainability, producing, among the other things, a huge reform of the national land management law by the end of the '90s with the clear purpose of drastically reducing urban growth.

In spite of this, the conversion from rural to urban land use in the Eastern Coastal Area of China seems to continue unabated due, in particular, to the dangerous combination of a land-consuming economic growth, more evident in areas like the Yangtze River Delta in Jiangsu and the peculiar urban policy structure that encourages local governments in transforming land, often illegally, increasing their revenues from the transaction itself (Lichtenberg E., Ding C, 2006; Huang, 2011).

Considering the current high rate of economic growth of China and the forecast of growing countryside-city migration, this will be clearly one of the most critical side effects of the urbanization process for coastal China.

The future of fringe rural areas lies at the crossing of different but interrelated strategic questions still open: the challenge of urban-rural governance in China inside a centralized land management system; the raising of a still timid local demand for inclusion in the decision-making process, especially in the rural villages or peri-urban settlements around the cities; the still unclear definition of urban-rural integration policies and countryside modernization, today unable to distinguish between underdeveloped areas in the west and more complex transitional rural areas in the urbanized east of the country (Long et al., 2010).

2. The system of rural villages in peri-urban Suzhou: recent trends

The area of Suzhou currently classified as "urban district" is almost 1/5 of the entire prefecture-level city (Fig.1)[2]. In the recent years the districts of Suzhou have concentrated most of the population growth of the entire area. From 2001 to 2008 the districts' population increased from 2.094.600 to 2.382.100 (+ 13,7%) while the "non agricultural population" rose from 1.170.600 to 1.580.600 (+ 35%). These data register not only a high rate of immigration but also a strong process of internal conversion of land from rural into urban. For example in the case of the recent development of the Suzhou Industrial Park (SIP), only in this area almost 60.000 farmers' households, equal to 200/250.000 people have been relocated in a

[2] The current administrative structure of the prefecture-level city is formed by 5 counties plus 5 urban districts: Xiangcheng District, Suzhou New District, Old City, Suzhou Industrial Park and Wuzhong District, together equal to 1.650 sq.km.

neighborhood called Lotus Village nearby the new industrial areas of the city.
In general terms the dramatic reduction of cultivated land from 1996 to 2010 can be estimated around 1/3 of the former agricultural area of the whole region[3].

If obviously the core of the city has been strongly affected by the urbanization process, an important part of the urban districts, especially at the fringe is still characterized by agricultural activities and by the presence of a complex system of rural villages, functionally integrated in the city of Suzhou but still keeping a strong local identity.

Figure 1. The prefecture-level city of Suzhou: counties and urban districts.

The entire loss of rural villages (Xiang), within the urban districts, is impressive. From 2001 to 2010 the number of villages was reduced from 720 to 213 (-70%), merged in the new urban areas or were simply demolished and are today waiting for a new land use. Just in the SIP area 72 villages have been demolished and today officially there are no longer villages in that area apart from some scattered relicts of rural housing.

[3] The cultivated land in 1996 was equal to 3.300 sq.Km decreasing to 2.216 sq.Km in 2010 (Prefecture-level city).

But while the SIP area is located in a highly urbanized area in the middle of the Suzhou–Shanghai conurbation, the west part of Suzhou is characterized by a different environmental and morphological structure, being close to the natural area of Tai Lake.

According to the current Master Plan of the city of Suzhou approved in 2007, there is an entire green buffer zone, along the lake coastline where several villages are still located. This area is delimited by a clear buffer between the built areas, especially of the Suzhou New District and the lake, statutorily not involved in the new urban development process of West Suzhou.

If the risk of urbanization is relatively low and not comparable with the trend of those areas located along the development corridor Wuxi-Suzhou-Shanghai where it's still easy to find "ghost villages" recently abandoned (Fig. 2), some relocation schemes have been applied or are willing to be applied even along the lake.

Figure 2. The "roofless village" in north of Suzhou Industrial Park. Picture: Qianqiu Li, July 2011.

It would be rather difficult to have a comprehensive picture of the technical or political motivations behind these choices, given the scarcity of information, but the case study of Jinshi Village and its surroundings, close to the lake and belonging to the Suzhou New District, has in the last years surely provoked strong local protests against the relocation (Fig.3).

However, the tourist potential of the area and consequently the real estate development that is taking place require a suitable environment producing, on the one hand, a high competition for land use allocation. Hotels, housing developments for holiday and leisure time, parks and greenery, infrastructures, amusements parks, but also technological parks and new residential areas no longer match the local agricultural landscape and, consequently with the relatively poor living conditions of the rural villages. On the other hand, it is rather clear that several economic activities

still ongoing in the area like local food production, fishery, embroidery, just to mention a few, are particularly in demand by the local tourism economy.

Figure 3. The riots between the police and the villagers during July 2010 in Tong'An Town and the surrounding villages due to a rising dissatisfaction for the compensation policy. Source: Jinan Times, Local Newspaper of Shandong, 18th Aug 2010).

Is not the goal of the present paper to evaluate the potential benefits of the residual rural areas in Suzhou for strengthening and diversify other forms of economic activities more embedded in the local development path and more sustainable from the socio-environmental point of view, as this has been explored elsewhere (Wang Y., Verdini G., 2012).

The intention of this paper is to reflect upon the rationale behind the "modernization" of the countryside" prioritizing the social impact of the rural villages' abandonment and considering whether the maintaining of a system of peri-urban settlements can be strategic for reducing the pressure exerted in some central and over-crowded areas of the city. Moreover it is intended to link the issue of relocation to the topic of population ageing, that will strongly affect China in the next 15-20 years, arguing whether improving or even upgrading the current situation can be considered suitable for the complexity of the existing social formations, keeping the human-scale of the environment and the social networks of local residents.

3. The case of Jinshi village: results from 14 in-depth interviews

During the last year a research group of the Department of Urban Planning and Design of XJTLU has been involved in several activities aimed at achieving a deep knowledge of the fringe areas of Suzhou and especially of the study case of Jinshi Village under the jurisdiction of Tong'An Town.[4]

[4] The research group is coordinated by Giulio Verdini (PI) and Yiwen Wang (CI) with the support of several year 3 students involved in the undergraduate programme of Civic Design at XJTLU. The work is supported by the "Suzhou Social Science Programme 2011" (11-B-08). The

The area where the village is located is one the cases selected for the high risk of abandonment and relatively high multi-functional value[5]. The village, as most of the similar settlements of the region, developed historically in a linear way along a canal directly connected with Tai Lake (Fig. 4).

Figure 4. The current land use of Jinshi village and a picture of the historic part of the village (Source: Planning Methodology. UPD Dept. XJTLU, Year 3 students, Group A Poster, Dec. 2011).

The old part is today semi-abandoned while more recently, in the last two decades, new scattered developments have flourished around the village together with a new commercial area along the main north-south road connection. The population trend shows a strong increase of population till the beginning of the 80s (+ 36,4% between 1964 and 1982) and a gradual decline afterwards (Table 1).
During the 80s the population is almost stabile, with a decreasing rate of population equal to – 1,1% and a relatively stable household's size (around 4 members each family). In the last two decades the village has lost more than 10% of population each decade, counting 2.149 inhabitants in 1990, 1.901 in 2000 and almost 1.706 today. In the last ten year the loss of household has been even more critical: from 560 to 484 with a reduction of the household's size up to 3,5 members each.

research granted is "Assigning open space non-market values as a tool for planning the urban-rural fringe of Suzhou. Moreover the selected study case of Jinshi Village has been the case of the Module "Planning Methodology", during the first semester of the academic year 2011/12, coordinated by the two lecturers, with the involvement of 24 students.

[5] One of the outputs of the first research report presented in November 2011 is the comparative evaluation of the environmental, agrarian, aesthetical and recreational value of a number of rural villages in Suzhou. Jinshi Village has been classified, using a multi-criteria matrix of evaluation among the category of "high risk, high value" (Verdini et alii, 2011).

Table 1. Population and household's size trend from 1964 to 2010

Jinshi Village (population and total amount of households)	**1964**		**1982**		**1990**		**2000**		**2010***	
	1.592	383	2172	541	2149	521	1901	560	1706	484

*Estimation (the official data is still not released)										

While during the last year Suzhou, as most of the metropolitan areas of China, has experienced a strong population growth in the urban and peri-urban areas, especially in those urban settlements in rural areas driven by the Township enterprises (The "Zhen" normally addressed in literature as "Town") Jinshi village has declined both in terms of population and households. According to the series of pilot interviews, conducted at local level, a gradual expulsion of population towards the central locations of the city has been taking place and moreover the village has been also affected by some relocation schemes. The combination of the two processes has left locally an aged population no longer involved in agricultural activities, very often retired or employed in informal jobs. Most of the agricultural land around the village in fact is today rented outside to migrant workers while the young people are almost all employed in the local factories.

In order to have a better understanding of the current socio-economic condition of the village, the results of 14 in-depth semi-open interviews to local households are reported here. The methodology uses is the household survey based on a sample of 14 households randomly selected. The information obtained from those interviewed about their relatives (considering only the people sharing the same house) allows, moreover, the sample to be extended up to 51 people, adopting the logic of the "snowball" survey.

The surveyed household size is 3,7 which is in line with the current situation of the village, and slightly higher than the Suzhou average size of 3,2. Furthermore, the pro-capita income is almost 1.173 RMB/month, in line with the per capita net income of rural residents of the city of Suzhou (1.221 RMB/month)[6]. The average age of the people included in the survey is 40,7 and 13 households have at least one family member older than 50.

[6] Even if some of the people interviewed are currently employed in the secondary sector, most of them are involved in informal or not stable work. This is the reason why the average income that comes out for the survey is far from the average wage of staff and workers at the city level (3.797 RMB/month), regardless of their status of rural or urban residents. Actually the majority of people living in Jinshi Village seem to own an urban *hukou* (residents permit). In general terms the correspondence between the household's size and net per capita income is assumed as a provisional indicator of reliability of the selected sample.

The proportion of the employees by type of industry is as follows: 21% working in primary industry (almost all in fishery due to the proximity to the lake), 41% in secondary and 38% in tertiary (in this case mostly involved in small retail at local level). A number of people, even if formally unemployed, are involved in home-based informal jobs (37 % of the total amount of working force surveyed) like tailoring or embroidery, particularly flourishing in the whole area. Another source of household income is from pensions or rural insurances.

As shown in the table n.2 the total monthly income of the sample comes mainly from formal jobs (77 %) nonetheless with a considerable component coming from informal jobs (almost 11 %). The welfare system accounts for another 11,3% of the disposable income of the local population. Considering only the formal jobs most of the income is produced either by industrial (33,1 %) or tertiary activities (39,5%).

Table 2. Surveyed working force of Jinshi Village (46 people). March 2012.

Employment structure 2012	**Surveyed working force**		**Total monthly income**		**Income produced in Jinshi Village**		**Income produced outside Jinshi Village***

* Income produced outside Jinshi Village refers to the income of commuters who spend from 20 to *Fom 20 to 60 minutes daily to go to work.								

One of the central research questions raised during the fieldtrips is about the level of integration (or self-containment) of the local economy in the surrounding areas or, in other words, the amount of income produced outside or inside the village.

In order to calculate this, the income of local commuters who travel 20 to 60 minutes daily (one way) to go to work has been compared with other workers who are employed locally. Most of the income produced in the factory system comes from the industries located either in Tong'An or Dongzhu Town (63,6%) and this is even more evident in the case of the tertiary activities (74,5%) despite the fact that some of those interviewed run their own shop in Jinshi

Village. This depends on the low profitability of local commerce that pushes the villagers to have other source of income, like in the case of a family owning a small centrally located grocery, who also host on the second floor a Mah-Jong club, (a traditional Chinese game).

In general terms the total income produced outside from formally employed working force is equal to 64,9%. Considering on the other hand the informal component, that is entirely produced internally, the ratio between inside and outside income changes substantially bringing the outside quota to 56,9%. Eventually adding the component coming mainly from pensions the quota reaches 50,5%. In a way the total income is almost equally dependent on inside and outside activities.

4. Some considerations and some preliminary conclusions

The results of the 14 in-depth interviews demonstrate that the economic life of Jinshi village seems to be functionally integrated with the surrounding productive and economic system, keeping at the same time a certain level of autonomy.

The model of development of the Chinese fringe driven in the last twenty years especially by the township and villages enterprises, has created a scattered development of industrial areas across the countryside especially concentrated in the towns. This model, highly impacting from the environmental point of view, as pointed out in literature, has kept alive a system of pre-industrial settlements that today, even if threatened by some internal (ageing) or external factors (urban development), retain their own identity.

In the case of Jinshi village it means that some local activities like fisheries, to some extent certain residual agricultural activities, and especially home-based embroidery still count in the final household's monthly income (16% in the selected sample). These activities are locally embedded and hardly replicable elsewhere due to contextual factors.

The case of the embroidery is particularly interesting because it is developed all over Suzhou in productive clusters, some of them located in some semi-peripheral areas around the city centre and some of them in smaller clusters in the Tai Lake area along the west fringe of Suzhou, as shown below (Fig. 5).

The physical removal of the villages might mean the disappearance of these alternative sources of income especially for some marginal households. In these families the quota of income coming from embroidery can in fact vary from 15% to 30% of the total household's income. Moreover, it can erase part of the cultural capital of the villages, being difficult to reproduce the same local conditions elsewhere.

Figure 5. The clusters of embroidery in Suzhou (Source: Planning Methodology. Group B Poster, Dec. 2011).

The paradox of relocation can be clearly seen in the extreme case of Mr. Yang who was interviewed the 5th of March 2012[7]. The family was relocated in 2003 according to the last relocation scheme applied in the village. By that time the husband, who is now 57 years old, was running a family metal workshop located in Jinshi village nearby their home. Nowadays, the household lives in Tong'An Town, the daughter is employed in a local factory such as the daughter's husband while her father became a commuter spending every day 20 minutes by e-bike (almost 8-10 km) to reach his workshop in Jinshi.

The relocation that is normally associated with a sense of displacement, shows in this case a certain lack of planning rationale. If this can reveal just a paradox, that might occur under the application of these kind of schemes today at the fringe of Suzhou, the data provided before show that part of the income locally produced cannot be replaced elsewhere, being locally embedded and moreover representing an important intangible cultural asset, potentially strategic for a more equitable and sustainable local development in the near future.

It was argued that underlying the idea of countryside modernization is an obsolete ideology of clearance of the rural villages, today still associated with poverty and deprivation and definitely in contrast with the image of the new China. It's also clear that a sacrifice for modernization requires the fast transformations of huge portions of land and this is the case of the new Suzhou Industrial Park given the high rate of disappearing of rural villages in the last ten years.

[7] The name is invented. The household got as a compensation two medium sized apartment in Tong'An Town of 90 sq.m. and 60 sq.m. plus 220.000 RMB. During the in-depth interview the husband declared his unsatisfactory due to the economic treatment and for the distance that today stands between his working and living place.

What is under discussion is whether some of the already developed areas of the east, strongly urbanized, have now reached their limit of sustainability given the emerging contradictions that have been pointed out. If this is true, then there is a clear need to introduce a new paradigm for understanding the urbanization growth of the east of China in order to avoid just a mechanical reproduction of the models so far applied.

This might mean reconsidering the role of the scattered villages around the city as a suitable living place for a variety of social formations: from aged households still active in informal jobs and involved in the local community life to households sharing their working and living time between the village and the urban edge of Suzhou. For those situations the relocation of these people to urban areas might mean the cut of some of their cultural and also some of their socio-economic roots, creating in the long term an increasing dependency on the new "urban life style".

The degree of adaption to the new living environment deserves an ad hoc investigation, especially for those areas which have been inhabited by displaced farmers for a long time, but it seems evident that keeping the same trend can generate problems and, especially for the more fragile social formations, less willingness to readjust to the new environment. So far the problem of ageing has not been clearly pointed out, especially in China, but it is clear that the effects of the "one child policy" applied in the last years will soon become apparent. At that time a deep consideration of the spatial implications of ageing will lead to a rethinking of some of the current policies, and among them the gradual urbanization of the rural villages at the fringe of the Chinese cities, which are still suitable living places for most of the local inhabitants.

4. Acknowledgements

The research project is supported by the "Suzhou Social Science Programme 2011" (11-B-08). This work has been made possible through the continuous support of my colleague Yiwen Wang together with our students from XJTLU especially: Xinyuan Yang, Qianqiu Li and Feiran Huang. The kind advices received from Paolo Ceccarelli, Xiaonan Zhang, Ying Chang and Shen Dhong, such as the proof reading from Arian Wildschut, are also gratefully acknowledged.

How to benchmark public transport accessibility in European cities

Abstract

The development and communication of land use-transport integration measures has become increasingly critical for successful stakeholder engagement in sustainable transport planning in recent years. Similarly, the dissemination of best-practice examples in public transport infrastructure and service planning and delivery has been an important contributor to improvements on the ground that led to a growing share of public transport in the mobility mix in many European cities.

In this paper, we will provide an overview of different strategies to implementing best practice in public transport and land use integration at the scale of entire urban networks, in their real-world context of urban settlement patterns. We draw on the first comparative results from an application of the Spatial Network Analysis for Multimodal Urban Transport Systems (SNAMUTS) tool to a sample of six European cities between 2009 and 2011 (Amsterdam, Copenhagen, Edinburgh, Hamburg, Oporto and Zuid Holland).

Highlighting some of the challenges that accompany the collection of public transport supply and land use data that is robustly compatible between different cities, we will outline a categorisation of the nine cities with regard to the policy environment determining land use planning and public transport provision, as well as accessibility outcomes that can help test the efficacy of such policies. This context will also illustrate and critically review elements of best practice in land use-transport integration from the nine cities, and conclude with some reflections on the relevance of international benchmarking exercises in this field.

Keywords: Accessibility, Public Transport, Land Use-Transport Integration, Benchmarking

Introduction

Successful European cities, like their overseas counterparts, are experiencing deteriorating road congestion as well as increasing public transport usage as a result of growth in population, greater spatial clustering of economic and discretionary activity, as well as intensifying regional and international inter-dependencies between cities. These trends translate into mounting pressure on cities to expand the capacity and improve the service quality of their transport networks. In this context, allocating a greater proportion of limited investment funds for public transport projects offers a critical alternative to continued reliance on a dominant role for the

car in urban mobility. It is recognised that there are significant opportunities for public transport to gain further market share from the car, thus reducing road congestion as well as addressing the social and environmental impacts associated with excessive car dependence.

In many European cities, growth in public transport usage has outpaced population growth over the past decade. This trend is an expression of a fundamental transformation, following the growing recognition of public transport by all tiers of government as a critical and desirable contribution to people's mobility within cities, and its evolution from a dual orientation, focussed on central city job commuting and the provision of a social safety net, towards a service that is capable of catering for all urban passenger transport needs across metropolitan areas (Mees, 2010).

Several cities have set specific, numeric targets of increased mode share for public transport in the urban mobility mix. These are set within a new understanding of the need for transport planning to deliver accessibility rather than simply mobility. Policy aspirations for city planning framed around accessibility rather than mobility have long been promoted by the academic community (Cervero, 1998; Vigar, 2002) and are now being embraced in planning practice. Mobility planning assumes that city dwellers will gain access to services required to support their daily needs through a transport system based on high levels of mobility by car, regardless of the relative location of land uses. In contrast, by planning for accessibility the approach considers proximity of land use as well as the transport network itself.

City planning framed around public transport accessibility raises the question of what quality of public transport system can deliver this objective. Public transport for urban mobility in developed cities varies greatly, from just over 2% of all trips in Atlanta and Los Angeles to between 26-31% of all trips in Barcelona, Vienna and Singapore (Kenworthy and Laube, 2001). The European cities discussed in this sample have public transport mode shares in the 10-20% range and thus does not (yet) contain the 'top performers' mentioned above. The variation in public transport mode share is influenced by historic and current policy priorities for infrastructure and service development as well as settlement form, and the competitiveness of different transport modes (Newman and Kenworthy, 1999; Mees, 2000; Mees, 2010).

To meet such an objective where public transport can offer a real alternative transport mode choice to the car requires a new approach for planning and evaluating public transport accessibility. It requires a method that can also serve stakeholders and decision makers as they deliberate on the best public transport network configuration, service levels and capacity upgrades. In many cities, however, there has been a relative absence of such an approach designed to usefully inform key policy objectives about the future public transport network in relation to accessibility improvements (Curtis et al, 2010). Instead strategic planning for public transport has often been unambitious, with most proposals offering incremental improvements to existing networks based on demand forecasting rather than future planning in the context of meeting policy objectives (Curtis et al, 2010).

There are parallels here to the situation in Australia, where the development and establishment in practice of methodologically robust and user-friendly accessibility tools for integrated land use-transport planning in Australasian cities and regions has become an urgent endeavour in the context of recent changes to policy priorities at Federal and State level (SSCRRAT, 2009). Only during the last five years, the Commonwealth Government has identified the significance of public transport

investment in cities and stated its intention to greatly increase its contributions for funding these pivotal items of infrastructure, while clearly tying such contributions to a satisfactory integration of strategic planning in land use and infrastructure at state level (IA, 2009). This contrasts with the situation in Europe where national and EU-level contributions to public transport infrastructure development in cities have been commonplace for many decades. However, such European funding schemes face a similar challenge to their Australian counterparts in incorporating the more recent principles of land use-transport integration and accessibility performance within their parameters. Given the multi-billion dollar/euro scope of infrastructure proposals, the substantial costs to regional economies and the environment implied in making sub-optimal or poorly informed decisions for infrastructure investment (where it fails to deliver alternative accessibility to the car and therefore fails to reduce car-based transport emissions and other externalities), this quest for greater rigour of assessment is vital to allow for the most efficient allocation of government resources and the greatest benefit to the public. Our ongoing work in the development of a new accessibility tool provides one way of evaluating the extent to which cities offer the potential for residents and employees to have accessibility by public transport (Curtis and Scheurer, 2010). The application of our tool in planning practice in Perth and Melbourne has demonstrated its useful role in forging constructive collaborations between transport and land use planning agendas. Considering this work within the context of the above national and super-national policy agendas for evidence-based public transport investment has brought to the foreground the need to establish appropriate benchmarks for public transport accessibility for cities world-wide.

As we explore the notion of benchmarking we expose many different ways of considering it. To go back to basics, benchmarking can be defined as, “a standard or point of reference against which things may be compared” (Oxford Dictionary). At this level of definition we might be asking simply – how do the public transport systems of European cities compare? To take the idea a step further, in the context of the policy imperative ‘future public transport planning’, the definition, “a standard of excellence, achievement etc., against which similar things must be measured or judged” (Online Reference Dictionary) adds the dimension of excellence or best practice. So in the context of this paper this suggests the need to establish a benchmark, or metric, for an excellent public transport system.

The idea of benchmarking in this paper is conceived in two dimensions: current and future. In the first, our interest is in how current public transport systems in European cities compare. Exploring this dimension enables us to assess the merits of the SNAMUTS indicators in different contexts and with differing data availability. In this way we can consider whether it is even possible to apply a universal benchmark. In the second dimension, our interest is in what the benchmark, or standard of excellence, for a public transport system in European cities should be. Our overarching metric is derived from regional, national and European policy objectives and our interest in sustainable accessibility, in this case a public transport system that provides an alternative mode choice to the car for the city’s metropolitan residents.

While our benchmark is based on public transport accessibility for all, others have chosen different metrics. For example, it is common for governments to use ‘public transport patronage’ as a measure that reflects the concern that investment in the public transport network ‘paid off’, or that demand forecasts were met. Others might focus on the cost of operating the public transport network, or the costs of

construction. We assert that the choice of metric is dependent on what policy objective is being considered. All too often the choice has been based on the cost of public transport framed around the storyline of 'public transport subsidy' (Curtis and Low, forthcoming) rather than being based on the need to implement policy imperatives.

The context: Public transport usage and mode share patterns

An important consideration in understanding any application of a benchmark must be to consider the SNAMUTS outputs for different cities in their broader context (Table 1). Before presenting our SNAMUTS outputs, therefore, we compare population, employment, the geographic size of the city, the intensity of residential and employment uses. All of these factors have an impact on the public transport task and are important considerations in the context of our later accessibility findings. In addition we report mode share and public transport use; both factors may well be the product of the extent to which public transport accessibility is achieved.

Table 1: Metropolitan population and jobs, urban density and public transport boarding and mode share data from seven Australasian cities in 2006 and 2010.

Contextual Data	København (2009)	Hamburg (2010)	Amsterdam (2010)	Zuid Holland (2010)	Edinburgh (2011)	Oporto (2009)
Metropolitan population	1.85m	3.37m	2.16m	3.46m	1.27m	1.23m
Metropolitan employment	0.99m	1.66m	0.96m	1.30m	0.58m	0.52m
Urbanised land in sq km	734	1,492	952*	919	342	360
Residential density per urbanised hectare	25.2	22.6	32.0*	37.6	37.1	34.2
Employment density per urbanised hectare	13.5	11.2	14.2*	13.1	17.0	14.4
Annual PT boardings	397.6m	676.3m	NA	NA	149.0m	NA
Annual PT boardings per capita	215	201	NA	NA	117	NA

* Urbanised area figure relates to the entire provinces of Noord Holland and Flevoland, which stretches beyond the Amsterdam metropolitan area definition (combined residential population in 2010: 3.04 million).

Some of the data presented in Table 1 is not beyond contestation in terms of compatibility between cities. It is likely that there are differing definitions on what constitutes a job (full-time, part-time, self-employed, marginal employment) and on what is counted as urbanised land and what is not, the detailed exploration of which is beyond the scope of this paper. However, the figures can be taken as a general guide to highlight the differences between cities or, to be more precise, metropolitan regions. The two northernmost cities, Copenhagen and Hamburg, are characterised by the lowest settlement density in the sample, while average densities in the Dutch cities, Edinburgh and Oporto are remarkably similar. The largest conurbations in terms of population are Zuid Holland and Hamburg, though they differ quite dramatically in settlement form: Zuid Holland is a polycentric region with two

separate primary urban centres (Rotterdam and Den Haag) and a number of secondary ones (Leiden, Delft, Zoetermeer, Gouda, Dordrecht). In Hamburg, the hierarchy of centres, while not free from polycentric elements, is far more traditionally structured with the primary centre at the geographical and functional heart of the metropolitan area and the secondary ones acting as satellites. Amsterdam, too, shares some multi-nuclear settlement characteristics with its immediate neighbour, while similar-sized Copenhagen, located on an island, only developed a significant functional interdependency with neighbouring Malmö during the last decade, following the opening of a fixed crossing across the Øresund. Edinburgh and Oporto are the primary centres of metropolitan regions of roughly similar size, though Edinburgh shares commuting catchments with neighbouring Glasgow in ways that have no equivalent in stand-alone Oporto.

Robustly comparable public transport usage data remains patchy at this stage, but it is obvious that Copenhagen and Hamburg can boast of a much higher rate of public transport journeys per capita than Edinburgh. However, at a level of just over 200 per year the two Northern cities (as well as Amsterdam and Zuid Holland, which we expect to have roughly similar usage rates to their Danish and German counterparts) are still likely to be 'mid-fielders' in a European comparison, where figures of 300 or more journeys per capita per year are not unheard of in places such as Vienna (Kenworthy and Laube, 2001).

SNAMUTS: An overview of the accessibility tool

This section is intended to provide the reader with a broad overview of the tool prior to the discussion on 'current benchmarks'. A full explanation of the tool can be found in Curtis and Scheurer (2010). The Spatial Network Analysis for Multimodal Urban Transport Systems (SNAMUTS) is a GIS-based tool designed to assess centrality and connectivity (primarily) of urban public transport networks in their land use context, and in their market position among multimodal travel options. In particular, SNAMUTS endeavours to identify and visualise a land use-public transport system's strengths and weaknesses of geographical coverage; the ability and efficiency to connect places of activity; the strategic significance of routes and network nodes; and the speed competitiveness between public transport and car travel in a coherent mapping exercise. The tool is intended to aid discussion and to lend weight to decision making within the fields of land use planning and transport planning, particularly where outcomes leading to more sustainable transport options are needed.

The tool is designed to reflect a vision of world best practice in public transport that has consolidated from the contributions of numerous scholars and practitioners over the years and is most comprehensively documented in the European Union HiTrans project (Nielsen et al, 2005). In geographical and operational terms, the most critical success factors relate to the integration of public transport services as a coherent, legible network, offering travel speeds competitive to the road system and service frequencies on a significant number of routes that make timetable consultation unnecessary (see also Mees and Dodson, 2011).

SNAMUTS breaks down the land use-transport system into a set of activity nodes and route segments derived from the hierarchy of activity centres identified in strategic planning documents, and the location and service standard of public transport routes. In particular, SNAMUTS makes the following definitions:

Minimum service standard

SNAMUTS defines a minimum standard for inclusion of a public transport route into the analysed network, normally requiring a service frequency of 20 minutes (or better) during the weekday interpeak period (about 10.00 to 15.00) and 30 minutes (or better) during the day on Saturdays and Sundays. This level is referred to as SNAMUTS *20* and has been used in all international SNAMUTS comparisons to date. It was chosen to reflect a reasonable minimum for public transport to be perceived as having a full-time presence and attracting usage for a variety of both planned and spontaneous journey purposes.

Activity nodes

These refer to a list of higher-order activity centres across a metropolitan area that appear in strategic planning documents or have been identified by on-site observation, with some adaptations to the configuration of the public transport network in order to also capture major transfer points and some linear corridors along high-frequency surface lines. Each activity node is assigned an exclusive catchment of residents and jobs located within walking distance from the associated rail station(s) (800 m) or tram/bus corridors (400 m). Wherever two or more of these catchments overlap geographically, the residents and jobs are distributed in equal parts among the associated activity nodes. In effect, every resident and job within walking distance from a minimum-standard public transport service has been assigned to one, and only one, activity node catchment.

Travel impediment

SNAMUTS measures spatial separation, or spatial resistance (a proxy value for distance) by relying on the units that are closest to the user experience, namely travel time and service frequency. Each route segment is labelled with an impediment value consisting of the average travel time divided by the number of services per hour, separately for each direction, and multiplied by a factor of 8 to arrive at more readable numbers. The travel impediment (proxy distance) between any two activity nodes on the network is thus made up of the sum of the impediment values on each route segment traversed along the path.

Weekday interpeak

SNAMUTS' network performance measures refer to the service levels offered during the weekday interpeak period (roughly between 10.00 and 15.00 on Mondays to Fridays). This is considered to be the time when the greatest diversity of travel purposes over a daily and weekly cycle coincide, and when the potential of public transport to offer a viable alternative (or not) to the 'go anywhere, anytime' convenience of the car is most critically determined.

Benchmarking: How do current public transport systems compare?

Applying SNAMUTS to European cities incurred the consideration of varying methodologies on how transport operators and public agencies in different cities report (or do not report) public transport and land use data, and the challenge to convert the findings into a format that allows for valid and robust comparisons between cities. These data items include public transport timetables and maps, geographically fine-grained records of the location of residents and jobs, and some

operational parameters such as average load factors on different public transport modes.

Timetables and maps

SNAMUTS timetable databases are compiled from public-domain material. This is a deliberate choice as the intention is to evaluate public transport accessibility from a user perspective. It is therefore important to rely on the passenger information that all users can access. In each European city in the sample, such material is available both as printed timetable brochures as well as an online format. However, only in Hamburg are timetables and maps published in an annual, network-wide compilation across all public transport operators covering the entire metropolitan area. In the Dutch cities, a similar booklet is available for the regional and intercity rail system, while timetable folders for urban public transport are usually only available on a line-by-line basis, and in some cases only in electronic format. Similar standards prevail in Edinburgh, Oporto and Copenhagen (though in the latter case there are also folders covering the entire rail system, or the entire express bus system).

Definition of activity nodes

SNAMUTS indicators are derived from an origin-destination matrix based on activity nodes, ie. places with geographical concentrations of trip origins and destinations (urban activities) that are linked through the public transport system. The number and location of relevant activity nodes requires careful definition and needs to contend with the differing urban structure and public transport network configuration in each case study city.

In the denser inner sections of European cities where mixed land uses prevail and there is thus a more or less spatially contiguous presence of trip origins and destinations, it is usually most straightforward to define every intersection of public transport routes as a separate activity node. In more suburban locations, however, particularly those from the post-war era when segregation of land uses was the norm, it is necessary to be more discriminating. In the Danish, German and Dutch cities, it was found that most post-war suburban housing estates contain shopping and service clusters that usually offer good walking and cycling access within the neighbourhood and are also generally well served by centrally located public transport stops. Such centres were included on the list if they either had a significant spatial concentration of residents – manifest, for instance, by clusters of multi-storey apartment blocks – or a concentration of employment that went beyond that of a service and retail centre with an exclusively local catchment area (for example if there was a hospital, tertiary education facility or business district in the same neighbourhood). In Edinburgh, the spatial co-location of housing and non-residential uses in post-war city extensions appears to be much weaker than in the continental cities: many housing estates appear to lack even basic shopping and service facilities, while on the other hand, there are numerous larger commercial centres outside an easily walkable context from residential areas, but often supplied with dedicated bus terminals. In Edinburgh, activity node allocation outside the older parts of the city thus refers more to such ‘stand-alone’, mono-functional facilities. In Oporto, there is a greater mixed-use building tradition even in suburban areas than in the northern cities as well as the presence of some large-scale retail centres, meaning that the technique from the inner cities of defining public transport interchanges and termini as SNAMUTS activity nodes could generally be extended to the entire network in the Portuguese city.

In some cases, activity centres that are located on the public transport network have multiple, not always functionally connected access points (such as where spatially separate rail stations and tram or bus corridors service the same activity centre within walking distance). In such cases a separate activity node was assigned to each of these access points, resulting in the division of some suburban activity centres into two or three SNAMUTS activity nodes.

Geographical distribution of residents and employment

A SNAMUTS land use database ideally consists of residential and job figures at as fine-grained a geographical level as possible, to allow for a best-fit allocation of their locations to the 400/800-metre catchment areas of public transport access points.

The Danish, German and Dutch cities conduct the continental European tradition of a council registry, ie. a local government office where citizens are obliged to register their residential address and which in turn enables the collation of a frequently updated and quite accurate database of residential population and its geographical distribution. Employment data, in turn, usually relies on business surveys taken at less frequent intervals. In Copenhagen and Hamburg, residential and employment output data is available at a sufficient level of geographical detail, based on travel survey zones. In Hamburg however, whose metropolitan area stretches over three federal states and two state statistical departments, the reporting standards differ from one jurisdiction to the next, and privacy legislation prevented the release of the full list of job figures per statistical unit within the territory of the city-state of Hamburg. In these circumstances, we resorted to estimates based on average job densities in the surroundings of the missing units in Hamburg itself, and to an assessment at the municipal scale for data in the surrounding states of Schleswig-Holstein and Lower Saxony.

In the Dutch cities, residential data is available at an exceptionally detailed geographical scale based on six-digit postcode areas, each of which sometimes only extends to a single city block and occasionally only a single building. Employment data, however, is only available for free for statistical units based on the first four digits of the postcode.

In Edinburgh and Oporto, we relied on census data for both residential and employment counts. While both cities delivered this data in sufficient geographical detail for SNAMUTS purposes, the level of spatial precision was much higher in Oporto than in Edinburgh.

Current Benchmarks – Comparing European Cities

This section presents the results for six SNAMUTS indicators: service intensity, closeness centrality, degree centrality, network coverage, contour catchments and nodal betweenness. In so doing we highlight important differences and similarities between the eight case study cities, allowing for a new understanding of public transport accessibility and for the identification of specific trends and patterns in land use and transport integration.

Service intensity

The SNAMUTS timetable database, compiled for each case study city at the SNAMUTS *20* minimum service standard during the weekday inter-peak period, provides us with an estimate of the numbers of public transport vehicles that are

required to be in simultaneous revenue service in order to deliver the public transport network that is operated at this standard (Table 2). Note that the figures for the actual numbers of vehicles required by the operators are somewhat higher than that, as the SNAMUTS calculation does not make provision for service breaks at the termini, contingencies for delays or disruptions, non-revenue journeys, and for vehicles undergoing scheduled or unscheduled maintenance. Nor do these figures reflect the usually greater numbers of vehicles required to operate peak hour services.

Table 2: Service intensity in the European case study cities

SNAMUTS *20*	København (2009)	Hamburg (2010)	Amsterdam (2010)	Zuid Holland (2010)	Edinburgh (2011)	Oporto (2009)
Number of trains/ S-Tog/S-Bahn	81	47	50	36	13	4
Number of metros/ U-Bahn/LRT	16	54	23	36	-	30
Number of trams	-	-	136	182	-	1*
Number of buses	329	439	398	308	158	271
Number of ferries	2	5	1	-	-	-
Number of services (total)	426	545	607	562	472	305
Metropolitan population	1.85m	3.37m	2.16m	3.46m	1.27m	1.23m
Services per 100,000 inh	23.1	16.2	28.1	16.3	37.2	24.8

*Cable car

The SNAMUTS *20* standard imposes a restriction on what proportion of each city's public transport network actually enters the analysis. For instance, in each European case study city, there are regional rail lines that are operated at frequencies of 30 minutes or 60 minutes and thus do not meet the minimum service standard. The same is usually true for a sizeable proportion of the bus network, especially outside the contiguously urbanised areas. Conversely, metro, light rail and tram routes generally consistently meet the SNAMUTS *20* standard, with only a few minor exceptions in Oporto.

Relative service intensity (ie. 'services per 100,000 population') reveals some variation across the sample. The most frugal cities on this index appear to be Hamburg and Zuid Holland, while Copenhagen and Oporto occupy an intermediate position. Of the continental European cities, Amsterdam has the highest number of public transport vehicles in simultaneous revenue service per capita, while the highest level in the sample, by quite a significant margin, is on record for Edinburgh.

The service intensity indicator is influenced by the propensity of public transport agencies and operators to provide resources to run the system as well as by its efficiency: a dominant role for fast high-capacity modes, particularly heavy rail, will depress relative service intensity figures, while a large number of high-frequency, slow-moving surface routes tends to inflate them. The intensity figure also increases where settlement areas are dispersed or separated by geographical barriers, thus

lengthening journey distances and times between places of activity. High service intensity scores are therefore not necessarily indicative of better service. It is, however, reasonable to suggest this indicator as a benchmark, hereby using it as a focus to examine the public transport effort in cities with low service intensity scores. The examination could be conducted by cross-reference to other SNAMUTS indicators (see later) to ascertain whether accessibility benefits in relation to operational inputs into the public transport system could be lifted to a level commensurate with peer cities.

In this context, it is unsurprising that Edinburgh, home to the most bus-dominated public transport network in the sample, comes out with the highest service intensity figure and Zuid Holland, the most rail and tram-dominated region, comes out with the equal lowest. Part, though not nearly the full extent of Edinburgh's steep figures on this index are related to the deregulation regime governing public transport delivery across the UK, leading to the provision of competing services by several bus operators along some of the same corridors. The difference between Copenhagen and Hamburg, however, both of which have comparable roles for rail and bus-based modes, is mostly due to Copenhagen operating a far denser and more multi-directional bus network than Hamburg, an observation that will occupy us further in subsequent steps of the analysis.

Closeness and Degree Centrality

These two indicators are designed to capture the structural properties of the public transport networks; they do not incorporate a land use dimension beyond defining the number and location of activity centres. Closeness centrality considers accessibility in a way most closely described as 'ease of movement'. An average score for travel impediment (travel time divided by service frequency), or ease of movement, is calculated between any two activity nodes on the network. The final figure for each activity node represents the average impediment score for all journey possibilities between this node and all others on the SNAMUTS *20* public transport network. Degree centrality considers accessibility by public transport from the perspective of number of transfers required to make a journey between any two centres. The figure given for each node thus describes the average transfer intensity for journeys to or from all other nodes on the network (Table 3).

Table 3: Closeness and degree centrality in the European case study cities

SNAMUTS *20*	København (2009)	Hamburg (2010)	Amsterdam (2010)	Zuid Holland (2010)	Edinburgh (2011)	Oporto (2009)
Number of activity nodes	128	176	132	205	97	94
Average Closeness Centrality	25.6	35.3	36.4	45.1	47.0	35.8
Closeness (lowest value)	14.3	19.6	20.6	26.5	24.8	19.6
Closeness (highest value)	78.9	92.9	89.9	146.6	125.7	122.0
Average Degree Centrality	0.80	1.07	1.14	1.60	0.99	0.91

For both indicators, lower figures indicate greater metropolitan public transport accessibility in principle. Comparisons, however, need to be seen in a broader context to allow for valid conclusions across the sample. Firstly, on both closeness and degree centrality we should expect average results to increase with city size (measured here by the size of the public transport network and its number of activity nodes within the 20 minute service frequency zone) and the resulting complexity of the public transport network. On this basis, all other things being equal, smaller networks will invariably return better average, lowest and highest closeness values than larger networks, as well as lower counts of degree centrality (ie. transfer intensity). From this perspective, it should come as no surprise that Edinburgh and Oporto, the two smallest cities in the sample, return lower average degree centrality values than their larger Dutch and German counterparts. Similarly, smaller network size explains part of Copenhagen's superior performance on the closeness index compared to Hamburg and Zuid Holland. But even within this limited six-city sample, there are a lot of deviations from this pattern.

Other factors influence the closeness centrality score and can provide a useful insight into where improvements to accessibility can be made. Closeness centrality is measured by travel impediment, which in turn is composed of travel time and service frequency. Cities where activity centres are spaced further apart (in terms of public transport travel time, not necessarily metric distance) or in other words, cities with more dispersed settlement patterns and more convoluted links between places of activity are at a disadvantage for public transport accessibility compared to more compact ones or ones with faster public transport systems. Compactness, in this context, is not necessarily equivalent to density: Part the reason for Copenhagen's low (good) average, lowest and highest closeness scores can be found in the city's location on an island, whose coastline effectively contains the settlement area and ensures that outward growth can only occur within an approximate 135-degree segment of a circle. While all the other case study cities also have coastal access, nowhere else does this circumstance provide such a compelling constraint to urban expansion as in Copenhagen.

Conversely, the relatively high (poor) average, highest and lowest closeness centrality scores in Zuid Holland are linked to this conurbation's multi-nuclear form without a single overarching centre. Since the closeness matrix treats every origin-destination pair on the network as equally weighted, the spatial separation between dispersed centres, even where these might have compact and contained settlement areas in their own right, is making itself felt here. This is also manifest in the high average transfer intensity of Zuid Holland's network, where several individual cities (Leiden, Den Haag, Rotterdam and Dordrecht) operate self-contained urban networks which are only connected by a limited number of rail and metro lines between them at a regional scale.

On the other hand, it is such fast rail connections that work to bring the closeness average down in each case study city where they exist, and thus compensate for the effect of settlement dispersal to some extent. Copenhagen and Hamburg stand out on this aspect as their rail and metro systems are not only speed-competitive with road travel, but also operate at very high frequencies during business hours (5 minutes or even better throughout the inner areas). In the Dutch Randstad, such frequencies are only achieved on metro trunk lines (in Amsterdam and Rotterdam) whereas the regional rail system operates a mix of overlapping all-stop and intercity trains, which each stopping pattern typically operating every 15 or 30 minutes and

thus usually adding up to frequencies of between four and eight trains per hour on each route (less for minor intermediate stops, some of which consequently do not meet the SNAMUTS *20* standard). In Edinburgh and Oporto, the maximum rail frequency tends to be four trains per hour, and there are several suburban lines that operate only half-hourly and thus do not enter our analysis. The low frequencies on the rail system, as well as on bus routes to outer suburban and regional centres, also explain the breakout highest closeness values in the two smaller cities, which overall appear to be less successful than Copenhagen, Amsterdam and (to a lesser extent) Hamburg in offering a uniform standard of public transport accessibility throughout their urban region. Instead, they seem to be allowing some outlying areas to contend with long travel times and/or low-frequency services, a situation that helps to push up average closeness centrality values for the entire network.

Oporto's advantage over Edinburgh appears to be almost entirely related to the presence of a light rail network in the Portuguese city, with two mostly underground inner-city trunk lines providing travel speeds through the urban core that have no match in the congested streets in the centre of the Scottish capital, some of which need to cope with more than 200 bus movements per hour even outside the peak period. Also incorporated in this index, though with only minor effects in this case, is the circumstance that Oporto offers fully integrated fares with free transfers between light rail and buses, while in Edinburgh most fares are operator-specific, ie. even a transfer between bus routes of different operators incurs an additional cost to the user.

Lastly, Copenhagen's top performance on the degree centrality index merits an explanation, given that the public transport network in the Danish capital, not unlike Hamburg's, is organised around a hierarchy of modes where rail picks up the primary corridors and buses the secondary ones, as well as feeder and distributor functions to the rail system. But why does Copenhagen outperform Hamburg (as well as Amsterdam) so dramatically on this index? In Amsterdam, the core explanation can likely be found in a circumstance similar to what was said about Zuid-Holland earlier: the metropolitan region is multi-nuclear, and the neighbouring secondary centres of Haarlem and Almere operate their own, relatively self-contained urban bus networks that are connected to Amsterdam only through rail links and some express buses, resulting in the near-inevitability of two or more transfers between places located in different cities away from the rail network. But in Hamburg, the greater transfer intensity can primarily be traced back to the much lower density of the surface network in the inner areas, as well as the less developed nature of orbital bus links in the outer areas than in Copenhagen. This observation is also supported by the lower service intensity figure for Hamburg. Both Nordic cities converted their once-extensive tram systems to bus operation in the 1960s and 1970s, but while Copenhagen retained practically each and every former tram route as a bus link (and then added some further ones), Hamburg abandoned a significant number of tram routes without full bus replacement, 'thinning out' its inner urban network in the process and making public transport movement much more dependent on transfers between modes, even for some relatively short journeys, than its Danish neighbour. Or in other words, Copenhagen's bus network alone provides a 'random-access grid' (Nielsen et al, 2005; Mees, 2010) across the inner area and supplements this function with fast, high-capacity rail and metro links servicing some of the same corridors, while in Hamburg, only the interplay of rail and bus modes on different corridors achieves a comparable network configuration.

In contrast, the uneven comparison of both cities' outer urban orbital bus networks boils down to geography rather than policy (notwithstanding the fact that there remains scope for some easy-win network extensions in Hamburg). Hamburg's only significant geographical constraint to outer urban expansion is the linear Elbe estuary which connects it to the North Sea nearly 100 km to the west, and which has no fixed transport crossings west of Hamburg. This leaves nearly 360 degrees of a circle for orbital travel in outer suburbs, compared to, as mentioned above, only around 135 degrees in Copenhagen. The provision of a full set of orbital links is thus much easier to achieve in the Danish capital than in its southern neighbour.

Network coverage and contour catchments

The network coverage indicator is designed to query the land use patterns of the metropolitan area in question, and in particular identify those parts of it that are serviced by public transport at the minimum service standard. It measures the percentage of residents and jobs that are located within walking distance (800 metres around rail or metro stations and ferry terminals, 400 metres along tram and bus corridors) of at least one public transport service that meets this standard, and expresses them as a percentage of the total metropolitan number of residents and jobs.

The contour catchment index uses the same approach to measuring land uses, but identifies the average percentage of residents and jobs that can be accessed from each node by way of a public transport journey of 30 minutes or less. This time window can include up to one transfer as long as both legs of the transfer journey are operated at least every 15 minutes, and with a penalty deducted that is equivalent to the average transfer time across the network from arrival of the first vehicle to departure of the second vehicle. The index adds a further dimension to the network coverage assessment, in that average 30-minute contour catchments are also influenced by the density and concentration of urban settlement, the speed of public transport and the spacing of activity nodes within the metropolitan area, which can be read as a proxy measure to its degree of compactness or dispersal (Table 4).

Table 4: Network coverage and average 30-minute contour catchment in the European case study cities

SNAMUTS *20*	København (2009)	Hamburg (2010)	Amsterdam (2010)	Zuid Holland (2010)	Edinburgh (2011)	Oporto (2009)
Network Coverage	1,927,000 (71.9%)	2,749,000 (54.6%)	2,446,000 (78.3%)	2,965,000 (62.3%)	1,037,000 (55.9%)	1,086,000 (62.0%)
Average 30-min contour catchment	879,000 (32.8%)	880,000 (17.5%)	599,000 (19.2%)	521,000 (11.0%)	259,000 (14.0%)	346,000 (19.7%)

Across the sample, network coverage ranges from a low of 55% and 56% in Hamburg and Edinburgh, respectively, to a high of 72% in Copenhagen and 78% in Amsterdam. Some of this variation is explicable when considering the figures in conjunction with the service intensity index discussed above: cities that put more resources into public transport operation should be able to provide a larger network (relative to city size) that services a greater percentage of its urbanised area. This pattern is clearly present in the comparison between Copenhagen and Amsterdam with Hamburg. But it does not yet explain why Hamburg falls even behind Zuid Holland despite having a comparable level of service intensity. A possible reason,

also observed in future SNAMUTS case study cities such as Vienna and Munich, is that historically, public transport provision in Hamburg has been a local government responsibility, meaning in this case the city-state of Hamburg which in 2010 comprised only just over half of the metropolitan area population. Hamburg may have been a pioneer in the conception of the first integrated public transport agency as far as back as 1965; however, only during the last decade did this governance model grow significantly beyond the city-state borders to encompass the seven neighbouring counties in Schleswig-Holstein and Lower Saxony in their entirety. And while some metro and regional rail services have since been improved and extended to regional centres, on the whole the outer metropolitan area remains characterised by a legacy of urbanisation that was either focussed on regional rail services with frequencies too low to meet the SNAMUTS *20* standard, or without much public transport orientation at all. Zuid Holland is by no means free of comparable settlement and public transport service patterns, but its multi-nuclear nature ensures that there is a lower number of regional centres than in Hamburg without services that meet the SNAMUTS *20* standard, and that these tend to be smaller than their northern German counterparts.

In Edinburgh, the second lowest network coverage figure paradoxically coincides with the highest service intensity figure, for reasons that resemble those discussed in the context of Hamburg: a high level of penetration of the core city with bus services at reasonable frequencies is countered by a very patchy network in the wider metropolitan region, including only a minority of regional rail lines that meet the SNAMUTS *20* standard.

On the average 30-minute contour catchment size, Copenhagen delivers another breakout performance within the sample that reflects several observations already made earlier, namely the high speed and frequency of its suburban rail and metro network and the dense grid of bus routes in the inner area. The combination of these two factors maximises both the number of destinations that can be reached within the time window, and the number of trips for which no transfer is necessary. At considerable distance, the figures for Oporto, Amsterdam and Hamburg are relatively similar, considering that this index, like closeness centrality, can be expected to decline with growing city size and geographical complexity (and the ensuing difficulty to provide short travel times across a large settlement area). The reasons why Edinburgh and Zuid Holland trail the sample on this index are also quite straightforward: in Edinburgh, the slow average speeds on a bus-dominated network and the patchy configuration of public transport services outside the core city conspire to depress the average contour size, while in Zuid Holland, the dispersed nature of settlement across a multitude of spatially separated urban centres is the key driver for the low figure.

Betweenness centrality

The last SNAMUTS index compiled for all six case study cities tries to measure the geographical distribution of travel opportunities across the networks' nodes and route segments as generated by the land use system and the configuration and service levels of the public transport network. Betweenness is a dynamic index, acknowledging that fast and frequent services between a pair of centres will be more attractive for urban movement than slow and infrequent services between another pair of centres of similar size. The index is designed to highlight which centres and public transport routes are 'at the crossroads' of movement across the metropolitan

area, and how well different modes fare in terms of attracting such movement opportunities, not least with a view to their varying passenger capacity. The global betweenness index represents an attempt to benchmark the attractiveness of the public transport system as a whole to facilitate movement and accessibility across a case study city, and may allow for an insightful comparison within our six-city sample (Table 5).

Table 5: Betweenness centrality in the European case study cities

SNAMUTS *20*	København (2009)	Hamburg (2010)	Amsterdam (2010)	Zuid Holland (2010)	Edinburgh (2011)	Oporto (2009)
Global betweenness index	2,173	1,612	1,726	844	677	736
Average nodal betweenness	83.4	51.6	55.2	24.1	33.3	34.5
Average catchment (residents and jobs) of typical path length	74,000	88,000	78,000	85,000	51,000	51,000
Segmental betweenness – | rail/S-tog/S-Bahn	49.3%	27.8%	24.5%	32.4%	8.7%	1.9%
Segmental betweenness – metro/U-Bahn/LRT	10.6%	33.5%	14.1%	17.6%	-	27.3%
Segmental betweenness - tram	-	-	21.9%	30.7%	-	0.0%*
Segmental betweenness - bus	39.1%	38.3%	39.4%	19.4%	91.3%	70.7%
Segmental betweenness - ferry	0.0%	0.3%	0.0%	-	-	-
Segmental betweenness – CBD area	32.0%	24.6%	29.1%	21.3% (Rotterdam) 18.9% (Den Haag)	44.0%	46.9%

The global betweenness index appears to divide the sample firmly into two groups. It suggests that Copenhagen, Amsterdam and Hamburg (in this order) are characterised by a much higher presence of public transport travel opportunities throughout their metropolitan areas than Zuid Holland, Oporto and Edinburgh (again in this order). In the case of Zuid Holland, this is not surprising, since this index strongly rewards compact, dense and contiguously urbanised settlement areas and penalises spatial discontinuities, regardless of whether they are generated by topographical constraints or result from policy decisions or historical trends. On the other hand, the poor results for Zuid Holland as a whole could also be read as an indication that the region is characterised by two dominant and only partially compatible public transport accessibility trends: on the one hand, it continues to provide quite favourable conditions for intra-urban public transport movement within each of its centres, especially Den Haag and (to a lesser extent) Rotterdam. On the other hand, the proximity of these centres to one another generates a high volume of inter-urban travel flows. This observation invariably raises the question, already posed in previous work (Scheurer and Straatemeier, 2011) on which scale of public transport accessibility is in fact the most relevant for the Dutch Randstad in representing a ‘daily urban system’: the core city, the sub-region (Amsterdam or Zuid Holland in this sample) or the Randstad region in its entirety?

Yet, the difference in the figures between Zuid Holland and Amsterdam, where polycentrality is less pronounced than in Zuid Holland but still a critical feature of the

settlement pattern, remains striking. With a view to with Copenhagen's outstanding performance on this index, it is likely that both cities benefit strongly from a relatively intact interplay of a dense surface public transport network (dominated by trams in Amsterdam and buses in Copenhagen) and a functional pre-war, originally transit-oriented, mixed-use settlement pattern in their inner areas. In contrast, Rotterdam and Hamburg, both extensively damaged during World War II, significantly departed from this pattern during post-war reconstruction in favour of a more functionally segregated urban form with reduced urban density compared to the pre-war stock.

The influencing factors of land use density and network compactness/dispersal can both amplify and neutralise each other on this index, for which reason it is useful to devise a measure that is capable of separating the two. This is being attempted by the 'catchment of typical path length' index, which multiplies the average nodal catchment across the network by the number of activity nodes an average weighted node-to-node path passes through (a number that varies between cities according to the spacing of activity nodes, the travel impediment between them and the ability of the network to provide a choice of routes). This measure thus compensates for the compact/dispersed properties of the network in question and focuses more exclusively on land use concentrations and network coherence. As a result, Hamburg and Zuid Holland have a narrow lead over Amsterdam and Copenhagen (both pairs in this order) precisely because their networks (in the case of Zuid Holland, particularly the Rotterdam component) are configured to facilitate longer journeys on faster modes rather than the short-range opportunities that central Amsterdam's and Copenhagen's extensive surface networks excel in. Edinburgh and Oporto, where slower modes dominate to an even greater extent, follow the larger cities at a quite considerable distance on this index.

It is remarkable that Copenhagen and Hamburg have a near-identical distribution of travel opportunities between rail and bus modes, underscoring the aforementioned significance and superior service standards of the suburban and metro systems in both cities. In contrast, in Amsterdam surface modes play a much greater role, which may be partly related to a comparatively small heavy rail network length (in relation to population) in Amsterdam as well as in neighbouring Zuid Holland. Zuid Holland, in contrast, appears to have relegated buses into an auxiliary role while Den Haag's and Rotterdam's extensive tram systems clearly dominate travel opportunities among surface modes.

Edinburgh and to a lesser extent Oporto remain strongly dependent on buses for the bulk of their public transport system's ability to service mobility needs arising from the land use system. In Oporto, the metro system, developed only over the last 15 years, arguably remains incomplete and is in fact subject to ambitious expansion plans. In Edinburgh, the role of its relatively extensive heavy rail infrastructure for frequent suburban services remains underdeveloped, though here too, plans are underway to address this (as well as introduce a light rail system).

The segmental betweenness scores for the CBD area – percentage of travel opportunities to, from or passing through the central city - can be expected to drop with growing city size and polycentrality, as well as a network configuration that offers attractive alternative travel paths for cross-suburban journeys. Within our sample, high-capacity orbital transport links are arguably best developed in Amsterdam, yet it is Hamburg that comes out with the lowest segmental betweenness figure for the CBD, perhaps primarily due to its larger size and a flatter

hierarchy in network significance (nodal betweenness) between the dominant CBD node (both cities' respective Central Station) and other rail hubs in its vicinity in Hamburg than in Amsterdam.

Discussion and Conclusions

The SNAMUTS analysis of the land use-transport systems in six European city regions has shown Copenhagen to achieve a top ranking on every accessibility indicator with the exception of network coverage, on which it comes second after Amsterdam. But does Copenhagen's stellar performance in this assessment elevate the Danish capital to the status of a model city, a benchmark for European best practice in public transport accessibility?

Some of Copenhagen's success factors can be traced to more immutable features of urban form, such as its position on an island which effectively limits its possible outward expansion to less than half the city's circumference, and the absence of major geographical or administrative barriers on the land side of the island that would impede the existence and effectiveness of high-quality orbital links to complement the radial corridors that shaped the city's historic development.

But there are also public transport network and service planning choices behind Copenhagen's good standing in the comparison of SNAMUTS results. The three most critical factors in this regard appear to be:

- the presence of an expansive heavy rail (suburban rail and metro) network with high service frequencies – every 5 minutes or better during business hours on all routes in the inner area, and every 10 minutes or better practically everywhere else – a standard that out of the six-city sample, only Hamburg can match;
- the presence of a random-access grid of surface routes covering the medium- to high-density, mixed-use inner neighbourhoods without leaving deliberate gaps where parallel rail lines exist – a standard also found in Amsterdam and Den Haag (mostly tram-based), Edinburgh and Oporto (mostly bus-based), but not in Hamburg and Rotterdam.
- the presence of fast orbital routes in middle and outer suburbs whose service frequency matches that of radial train lines, and whose travel times are shorter than those of transfer trips through the central city using the radial routes.

This is not to say there was no room for improvement in Copenhagen's public transport system – there remain conspicuous geographical gaps in the rail system, and some bus routes are congested or insufficiently prioritised over motorised traffic. Some of these shortfalls are being addressed by metro extensions currently under construction, and by plans to convert the busiest orbital bus route to light rail.

The comparison between the two medium-sized cities, Oporto and Edinburgh, demonstrate some of the shortfalls associated for cities in this category from relying excessively on buses for urban public transport. Edinburgh has by far the highest operational input but produces what is arguably the poorest accessibility profile in the sample. A comparative look at Oporto illustrates the efficiency gains in terms of operational resources as well as accessibility performance that can be achieved by

introducing light rail as a higher-capacity mode for the city's key corridors (a step Oporto only took during the 1990s and which remains far from complete).

Some open questions remain. For instance, what would be the outcomes in terms of accessibility performance if public transport service intensity per capita in Hamburg was lifted to the level of Copenhagen (a more than 40% increase)? Would Hamburg draw even with or even outperform its northern neighbour? And further, how does Rotterdam's and Hamburg's failure to provide a full random-access surface network across their inner areas relate to the unique characteristics these two cities share – namely, accommodating Europe's two largest seaports within their boundaries as well as, out of the sample examined in this paper, being precisely the two cities that suffered a major discontinuity to their urban development in the mid-20th century due to wartime destruction and subsequent rebuilding in a very different form?

Future SNAMUTS investigations and an expansion of the European sample to incorporate Barcelona, Munich, Vienna and Zurich will serve to address these questions in more detail.

Abstract

The EU has been involved in influencing major infrastructure in the fields of transport and energy mainly by means of the TENs programme begun in the 1990s. Other macro planning and wider spatial planning exercises, including the ESDP, made reference to such infrastructure systems, particularly in relation to the need for connectivity and mobility, but normally did not attempt to intervene in an area seen as one of the prerogratives of national states. Much more important have been the wider programmes of liberalisation pressed by the EU since the 1980s, but these have had no specific geographical content.

A revision of the TENs programmes since 2008 has led to proposals to increase the role of the EU, by drawing up continent wide schemas indicating needs for future investment in many fields of both transport and energy, and introducing new procedures to streamline decision making by designating projects as of European interest. The initiatives in transport and energy are described here, including the two Regulations currently under discussion within the EU institutions. These include major proposals for cross European multi modal transport corridors within an EU core network, and regional schemas for energy drawn up primarily by energy industries and government counterparts. Both are likely to be of real significance for spatial planners throughout the continent, and have major impacts on the shapes of future infrastructure networks.

These proposals are analysed, as cases of the rescaling and re-ordering of government, giving more force to the EU in these fields, and reinforcing sectoral or silo based decision making. The relationships to spatial planning are examined, partly in terms of the degree of "soft" planning styles. It is argued that somewhat different outcomes will result in the few areas, such as the Baltic, where long term macro-regional collaboration has been present, from the rest of Europe, where these sectoral programmes may complicate further the mix of planning impacting on each region, making even more confused the accountability of governance. Suggestions are made for the careful assessment of these schemas by national and regional governments, and for the creation of some spatial planning analytical capability at

EU level, which could examine proposals such as these with powerful spatial impacts.

Introduction

Large schemes to transform transport and energy infrastructure have been recently under consideration across Europe, following national level investment in several fields since the 1990s – in high speed rail, motorways, ports and airports, as well as gas, wind and other energy generation sectors. Whilst such continental wide schemes have a long history[i], the present round was spurred in part by the highly successful pressure of leading business executives in the 1980s, who identified "missing links" in all European transport systems (European Round Table 1984, 1991). The making of the single market project thus came to carry with it an interest in boosting the capacity of European transport systems. This combined with, or in part was inherent in, the liberalisation of the industries, mostly state owned, which for several decades had managed these infrastructure systems. This liberalisation became a core EU goal in the 1990s. Other more material factors were involved of course, such as the increasing freight movement across the world, impacting on ports and much else. One result was the creation of the TENs programme in the early 1990s, seen as a part of the Delors package which sought to modify or tame the single market programme. Unlike the social programme also promoted by Delors, which was beaten off by neoliberalising governments, the TENs packages were progressively detailed and, on the transport side, given significant EU funding support. In 1994 priority transport schemes were listed. Most of this top set were rail schemes, with limited support for road and aviation, although these figured strongly in the sets of schemes in the rest of the listings. This leaning towards more environmentally desirable modes was another part of the political drive of the policy zone, ensuring some support from political groups interested in environmental gains. The TENs scheme for energy also advanced through the 1990s, but with less political drive and little financial support.

At the same time, spatial planning was making its bid to impact on EU policy making, by means of work on a cross European spatial framework, finally issued in 1999 as the European Spatial Development Perspective (ESDP), as well as through work on mega regional planning overviews, and support for cross border iniatives via INTERREG programmes. The now clear accounts of this story (Duhr et al 2010, Faludi and Waterhout 2002, Faludi 2010) show how variable and often limited the integration of this spatial planning work was to key policy areas – the big funding programmes, transport and energy policies, competition policy and so on. However, the work on spatial planning, now generally rebadged as territorial cohesion policy, continued through the 2000s (CEC 2008c), and so was present when the moment

arrived, when a major review of the TENs policies was launched, in 2008. The first purpose of this paper is to investigate any links between the continuing aspirations for some sort of territorial integration in the EU, and the TENs reforms which were worked up in 2008-2011 and are now in the process of being hardened into firm policy, including Regulations in the transport and energy fields. A second purpose though, even in the absence of such linking, is to reflect on the importance of the TENs reforms for the changing European geography, that is to think about what major initiatives like this do "behind the back of planning", in generating the future shapes of urbanisation and environmental futures, and how the future territory of Europe is imagined.

Understanding the changes

A third purpose, alongside these more policy or substantive concerns, is to discuss how we may best understand these policy developments, from the range of lenses available from diverse disciplines. Geographers and political scientists have long considered the shifting of scales underway since the 1980s (Brenner 2004, Jessop 2002, 2008), whereby the EU has taken on more "meta governance" roles, whilst leaving the states, and in some cases regions and city authorities, with major powers over the levers of economic and social change in their territories. The single market project, and the associated "annexes" mentioned above, were critical ingredients of this shifting kaleidoscope which has made the EU such a core element of government in the last two decades – as the post 2008 economic crisis has made ever clearer each year. This rescaling is linked to the dynamics of declining democracy underway during the same period, and can be seen as an attempt to depoliticise key decision making areas. As was argued long ago, rescaling is often deeply political (Swyngedouw 1997). This change in vertical articulation of governing can also be usefully linked to the horizontal question at the core of all planning, given the powerful "silo" effect in most governing systems, which, we will see, is strongly present in the TENs reforms. Between them, changes in scaling of governing and the extent of sectoralised policy making are critical dimensions of the way major infrastructure is governed in present day Europe. This assemblage of mechanisms, which work to some extent together, forms the first lens used later for reflecting on the case considered here.

A second lens will be useful in helping to understand the style and characteristics of the planning emerging or which may emerge. Given that this is sectoral planning, the question is how that form is understood, as well as how that relates or may relate to spatial planning in the more integrated sense. I will consider here the usefulness of conceptualising this in terms of "soft" processes or spaces, a perspective enjoying some interesting development at present in planning theory. It has been argued that

soft processes (Faludi 2000) and soft spaces are becoming more influential within states (Haughton et al 2010), and that this can be usefully linked to policy making at EU level (Faludi 2012). Such soft approaches are open to quite varying definitions, emphasising different aspects. Often soft spaces are seen as "in-between" spaces of governance existing alongside or beyond formal, statutory or official spatial planning, with planning less and less applied to fixed areas, and more fuzzy in its application. Faludi (2010) considers that at the European scale, planning can only be soft, if it is to be anything at all – a relevant argument, given the locus of TENs policy making. A further relevant discussion is that of Metzger and Schmitt (2012), looking at recent EU leadership in the Baltic Sea Region. They emphasise the time dimension of changes in such harder or softer planning, seeing the EU Baltic strategy as solidifying earlier soft spaces. They also suggest that planning can in such cases become an important element in regionalization, or the constitution of new metagovernance of regions, in part by processes of institutionalization. They note the importance of the EU coordinator roles in this case, something we will see echoed in the TENs packages – possibly a soft governance form with some harder edges. This lens therefore has several dimensions which can together help to put some aspects of the TENs reforms in a wider perspective.

With these two lenses we can see how new forms of policy making are being institutionalised and naturalised, by the shifts in scalar governance, and by the forming of organisational structures, deliberately created as policy silos. It can be argued, at the highest level of generality, that this policy making form is a good fit for the regime of politics dominant in Europe in recent years, and which has always characterised the EU – weakly democratic, dominated by economic goals. Clearly this is a political interpretation which will not be to the liking of all readers, and cannot be proven within a short article, or even probably within a massive tome. All analysis in planning is framed by political stances.

The rest of the paper is in three parts. Firstly I give a relatively concise description of the reforming of the TENs programmes, and their (non) linking to spatial planning thinking. This is followed by interpretations of this process, relating it to the themes discussed above. The concluding section reflects on where the overall forging of infrastructure systems is going, under the impact of the TENs reforms and other forces, and how this might (or might not) be usefully linked to some input from spatial planning ideas of some kind. The paper is based on interviews conducted in the European Commission in Brussels in late 2010, some updating discussions in early 2012, and analysis of the extensive documentation of the EU directorates involved.

Reforming the TENs systems 2008-2012

My original interest in TENs was to see whether they might, in reformed guises, make up for the weak major infrastructure steering capacities or desires in most European states. Such weakness was observed in Germany for example, where the planning of energy systems showed little direction, arguably hindering the possibility of serious progress to a lower carbon society. Equally there were many German criticisms of government inability to adopt a more strategic approach to transport planning, as against the business as usual of the federal transport plan (BVWP).

This is examined here separately for transport and energy (telecoms is omitted, much less significant from a planning perspective). The idea behind TENs was that more traffic of all kinds would flow between countries and that transport and energy systems, like productive systems, ought to be harmonised and opened up to competition, to cope with the greater movement. In 1994 a priority list of 14 big transport projects, mostly for high speed rail but also with one airport scheme and some road projects, was agreed. There was a commitment to some financial support, mainly via loans – in fact the EU paid 29% of the total invested 1993-2006, with a similar proportion expected in 2007-2013 (CEC 2008a). Apparently the EU was committing 230 billion euros to transport infrastructure between 1996 and 2013 – a major contribution, most channelled by regional funding (CEC 2011e). As Duhr et al explain: "The process of selecting priority projects was a highly political exercise 'from the bottom up', characterised by pressures from national governments or industrial lobbies pushing for their national wish lists" (2010 p. 300, also Peters 2003).

The energy TENs were less high profile, but gradually picked up momentum, mostly to ease cross border links in gas and electricity transport, to facilitate the single market in these products being introduced at the same time. Both programmes had a "fill the gaps" approach, rather than one in any way related to strategic cross European planning. Given the slow progress with even this level of intervention, there was for years quite enough for the EU to do in trying to get effective implementation. By 2008 some of the original priority projects had still hardly begun. Nevertheless, it was felt the time was right to review progress and adopt a more ambitious approach. The account here reflects policy making up to April 2012.

Transport

The TEN-T programme review began in 2007-8, and resulted in a final Commission proposal for a new policy in 2011 (CEC 2007, 2008a, 2009a, 2010b, c, e, 2011a, b, Fischer and Sykes 2009). The primary innovation was the making of a "core network" of routes, in multi-modal form, across the EU and connecting with third countries. This would supercede the project based approach used since the creation of the TEN-T in the early 1990s. The core was to include all modes, with a study

identifying 57 ports or port complexes which should be the key port links to the terrestrial transport system (NEA 2010). The 30 projects agreed at the last revision in 2005 would mostly slot into such a core network, along with some more, but this time the result is supposed to be a genuine base network for the whole continent, not a patchwork of projects. Underlying this, the "comprehensive network" will continue, slightly amended, this being the main existing transport systems marked on a map, and showing the "missing links" still seen as needing connections or improvements. It must be remembered that this is a substantial existing project, which there is no intention of reducing, on the contrary it will be added to somewhat. As a working document (CEC 2010e) said:

"*Today the comprehensive network comprises altogether 95,700 km of road links, 106,000 km of railway links (including 32,000 km of high-speed links), 13,000 km of inland waterways, 411 airports and 404 sea ports. It has to be noted that most of these links and nodes already exist. However, almost 20,000 km of the road links, over 20,000 km of railway link (overwhelmingly high-speed lines) and 600 km of inland waterway links remain to be built or substantially upgraded*".

The choice of the core network was based on a much more planned approach, through a methodology worked up in 2010-11 by an expert group, essentially based on linking key nodes of the European transport system. This meant in particular a big emphasis on ports and on freight, and the resulting ten corridors concentrate especially on rail links, with a major aim to encourage modal shift from road to rail and water. The core network was to be given priority, with a chance to get some of the 50 billion euro Connecting Europe Facility announced at the same time (31 billion for transport, 9 billion each for energy and telecoms). It was also targeted for completion by 2030, as against 2050 for the comprehensive network.

The new way of dealing with the core network was through the creation of "Corridor Development Platforms", consisting of a European Coordinator appointed by the EU to lead the work on that corridor, and of member states and relevant interests. They were to draw up a corridor development plan within six months of the entry into force of the Regulation. This was to be submitted to the Commission, who would give its opinion, and particularly say in what way it was going to support implementation. As an example, Corridor 2 runs from Warsaw to the English Midlands, and needs upgrading of rail lines along much of the route, as well as inland waterways works in Germany and at the Amsterdam locks, and port and multimodal platform works in England. Here four states will be involved, but in some corridors such as the north-south ones, governance will be more complex still.

This is a major new initiative which is itself a sort of spatial planning and will impact on spatial planning. The system design from above, on a relatively rational planned

basis, is a radical departure for the EU, as is the form of implementation. Clearly it is an essentially transport silo/sectoral initiative, which will empower the rail and port operators and transport ministries in particular, but the planners on each route will surely also wish to be involved in the platforms, to adjust the plans to their objectives, or learn how the transport schemes impact on other proposals. Although routes and implementation will be contested, it is most likely that planners will have to take these schemas as a committed starting point, as they are used to doing in most states when handed down big transport decisions by national governments. But they will sometimes be able to adjust schemes, especially when these become politicised and negotiating on land use issues becomes critical.

These transport infrastructure proposals (and much more) are now presented in a Regulation, the form of EU legislation which, if approved, becomes directly binding on members. There will then be little scope for deviation, in principle, and all future investment should be guided by or be taking note of the TENs schemas – in principle for the coming decades, though we may fully expect regular revision. Of course the Regulation may not be approved, at least in its current form, though for the moment the timetable is for passing it by the end of 2012. Under the co-decision procedure, first the European Parliament needs to give its approval. At the time of writing there were several elements that looked controversial, with the Council preferring a more government (transport ministries) centred governing mechanism, and pressures from Green interests in the Parliament against other elements of the package.

In substantive terms, it is important to note that the Commission and the EU remain very much on the "missing links" track, rather than seeking a radical comprehensive low carbon mobility strategy for the long term. Certainly parts of such an agenda are referred to in the transport White Paper (CEC 2011a), but rapid growth remains a core part of the EU approach, which appears very hard to square with low carbon rhetoric. Such contradictory aims have equally been at the heart of the Lisbon and Europe 2020 strategies created to guide the EU overall since 2000 (CEC 2010a).

Energy

For the TEN-E field, policy development began by 2008 (CEC 2008b, Ramboll/Mercados 2008) and Commission documents were published late in 2010, including on energy infrastructure (CEC 2010f, i, j), followed by the final policy package in October 2011 (CEC 2011c). The final TEN-E proposals are wide ranging and significant, though in a different way from those for transport given the very different context of energy policy making. The infrastructure strand of energy policy relates strongly to the coming into force early in 2011 of the Third Energy Package liberalising fully European energy systems (full unbundling of transport systems in particular). Here there are two strands of special interest to spatial

planners (CEC 2011c, the proposed Regulation, contains most details, but much related documentation is on the Energy directorate webpages for the October 2011 announcement). The first strand is the designation of projects of common European interest (PCIs) and how these are identified. This is again a strong stepping up of the EU role, responding to the worry that a liberalised pan European energy work will simply not have the technical infrastructure to work, particularly given the low carbon and security goals that the new competitive industries are also supposed to achieve. The projects are chosen by the Regional Groups for each fuel body, those created under the Third Package, ENTSO-E for electricity and ENTSOG for gas. These groups have been doing planning work since their formation in 2009, in the Gas Regional Investment Plans (GRIPs) for example, and this is set within the overarching Ten Year Network Development Plans (TYNDPs) now prepared for both electricity and gas by their respective bodies (Entso-e 2010, Entsog 2011). ENTSO-E is working on the second iteration of its TYNDP, due to be finalised in mid 2012. So the energy field also has priority corridors, based on the ENTSO work, there being 4 for electricity, 4 for gas, and one for oil, as well as three thematic areas, for smart grids, electricity highways (a long term super grid) and a cross border carbon dioxide network.

The TYNDP for gas of 2011 (Entsog 2011) followed the Entso-e approach the year before by not just listing the responses of the transmission operator of each country, but carrying out a "top down" research of the matching of supply and infrastructure systems to 2020. It admitted this was full of important uncertainties, but concluded that if the committed investments went ahead, there were only relatively limited areas of major risk in the event of disruptions, mainly on the eastern borders affected by Russian gas risks. These "Plans" were described in the gas case as intended to "provide stakeholders with signals that can be further investigated in their decision-making processes for market triggered investment or for European funding" (Entsog 2011 p. 51). But the evidence now is that the planning is getting a little less cautious, reaching at least indicative status, even though the TYNDPs are definitely not binding documents. In due course it is expected that the Entsos will be able to take over all the planning and prioritising role, though in 2010 their limited resourcing (30-40 staff for electricity but only 4-5 for gas) did not allow this.

One key is attempting to leave the planning, or at least parts, to the private industries required to cooperate in the Entsos. Another is the regionalising approach, identifying areas like the North Sea, south west Europe, central and south eastern Europe and the Baltic as areas where European "added value" was most obvious or feasible. The regional approach leaves scope to play across to the regional iniatiaves of DG Regio (see below) or perhaps in due course to elsewhere. However it was clear that the Commission is operating largely by individual sectors. Certainly all

Commission work is relatively collegiate, working by inter-service groupings, with all COM documents agreed across the Commission. But the regional cross-sectoral implications are not considered much by the Energy directorate in this reform drive. The main aims are sectoral, rather than integrated or territorialised.

It is clear then that the process is somewhat different from that for transport. The work is ongoing, less a "big bang" one of setting of future directions at one moment. These dierections for energy are set essentially by the industries themselves and brought together by the Commission, and depend on the Regional Groups for both designing priorities and implementation. The extra element is some funding help, for the priority corridors. It is more difficult to gauge the significance of interaction with spatial planning concerns, though these are clearly present, for example in marine spatial planning, and in the implications for the long run sustainability of different sorts of regions. It is not so likely that planners will get involved in these regional groupings which are likely to be dominated by the major companies, and their ministry expert counterparts. However, when difficulties emerge in implementation, planners may find themselves involved. This is particularly the case given the second important strand in the package, on permitting.

Energy companies, and to some extent governments, have long been pressing loudly their concerns at delays in giving consent to schemes which they see as essential to getting relevant new investment, especially in electricity transmission lines. Several national governments, including the UK, Netherlands and Germany, have reformed their procedures to make such permitting easier and quicker (at least that is the aim). This can involve the appointment of "independent" authorities, as was tried with the Infrastructure Planning Commission in the UK, aiming to depoliticise decisions. This therefore links directly to one wing of neoliberal thinking, to remove key decisions from electoral democratic arenas, as in the creation of autonomous central banks. The EU decided to make this a big element in its infrastructure package, and commissioned a study in 2011 from Roland Berger, a management consultancy, to work out how this might be done (Roland Berger 2011 for their final report). The result is a section in the Regulation to alter procedures in all EU states, towards what is seen as best practice, including a one stop shop for authorisation, cutting overall maximum authorisation periods to three years (including one year for the offical consent process) and introducing more effective overseeing of the processes at both national and EU level. There is scope for an EU appointed coordinator to intervene in cases where delays are serious, for projects of common European interest. Much of this is advisory, as it would depend on national legislative change, but it represents a strong push to the sort of approach implemented in the UK with the Planning Act 2008, seen by the consultants as very much a template for desirable reform.

From a planning perspective, this is a very interesting initiative, representing one of the first times that the EU has dared to tread into such national regulatory territory. Whilst it is likely that a relatively soft approach will be used, perhaps not forcing member states in such permitting reform, a style of procedures is likely to be set by the Regulation which will gradually infiltrate national practice, especially where EU funding support is hoped for, support which will doubtless be dependent on moving towards the recommended model. The energy corporations can be expected to put maximum pressure on states who do not move to an expedited approval model. Whilst this is unlikely to be the precursor for the much discussed harmonisation of national planning regimes across Europe, it does represent a significant step for this rather special category of projects.

As in the case of transport, the Regulation is not yet approved. But there is a very considerable head of steam behind this reform, with the European Parliament committees having already in June 2011 given a more or less green light to the proposals. It may be even more likely than with transport that the essence of the Regulation will be approved within 2012.

It may be noted that a significant exercise in institutionalisation has been taking place in this policy process. Both fields will now have European coordinators, with potentially strong brokerage power. The Corridor Development Platforms for transport and the Regional Groups for energy are important new bodies. The Commission will be advised by a new committee for TEN-T, and the energy field already has ACER, the grouping of European national regulators. The European Railway Agency created in 2006 is the nearest thing to institutionalisation in the transport field. The drive for a single national competent authority for infrastructure projects will affect national institutions as well. All this is strongly sectoralised, and largely invisible to the public view, as is the norm at EU level, but they are already, or will be, important actors in infrastructure making.

So the EU approach in this field is potentially powerful, creating a genuinely multi-level system for energy network planning, with the locus of much decision making probably shifting for some countries to these collaborative European institutions. Countries like France may resist such a shift, but given liberalisation and takeover processes affecting the network industries, such resistance may not be long lasting.

In terms of substance, the schemas point in mixed directions: to a considerable extent to business as usual, continued growth in the physical networks, but with some emphasis on the promotion of modal shift in the core network, away from the highest carbon generators (road and air). Similarly in energy, there is big support for fossil fuel generation systems (gas, oil), as well as nuclear, but equally a drive to promote

transmission support for renewables. Clearly this fits the double sided EU objectives, for growth but in principle with low carbon goals too.

The extent of integration with the concerns of the Regional Policy directorate (Regio) and with spatial planning

We now turn to the question of the linking to spatial planning, by examining first the position of the regional directorate in the Commission, which has been the one dealing with territorial issues, and so to some degree, touches on spatial planning, and then thinking about what other ways spatial planning may interact with these new policy directions. The main focus is on the regional strategies developed in recent years, and what their relationship is to the evolving infrastructure fields.

The regional directorate of the Commission is in some ways a powerful one, given its large budget, and the task of ensuring this is spent, and spent well. But it is clear that DG Regio is not seen as any sort of planning body in a substantive sense. The DG was hoping in 2010 to be able to strengthen its position within the Commission by aligning regional policy more tightly with the Europe 2020 strategy (CEC 2010a, g). The DG's role is primarily procedural, ensuring the guidelines are followed, and cooperating with sectoral directorates like transport and energy to make sure that they are content that the criteria they set for their areas are also observed. There was little sign of much cooperation on energy issues with that directorate. With transport there was some contribution to the working on the recent TEN-T reforms, with Espon material drawn to the attention of the policy makers there. Given that Regio has itself no independent remit on which to take a view of the proper spatial development of Europe, there was no strong base on which to advise Transport in its drawing of the core network. However, Espon did provide some valuable data foundations.

The direct input to the TENs reforms from Regio was thus limited, even though normal lines of consultation remained fully open. The linking of Regio to the reviews was primarily in relation to its core concerns of funding regional policy, and hence to major parts of the EU's support for infrastructure. So the discussion of the new funding instrument (Connecting Europe Facility), and how this related to the 2014-2020 budget, was a very important cross Commission theme, much more significant than any geographical implications.

The greatest hopes have been in macro regional working, which has been seen to give real scope for integration in the future (CEC 2010h, l, m). The Baltic strategy is seen as the model here, being the first of a new breed (it was hoped by DG Regio) of macro regional stategies (CEC 2009b, 2010d). Faludi (2010 p.182) calls it "an exemplar in planning for soft spaces". It was prepared by a score of directorates-

general in the Commission, with DG Regio as moderator – the ideal institutional architecture for EU action, in Faludi's view. This built on a lot of work in the region since the 1990s, some of which has had a strong spatial planning component. Baltic state planning ministers had started on a Vision and Strategies for the Baltic Sea Region (VASAB) in 1992, completing the strategy in 1994, and pressing on with much use of EU funds to the present. The latest VASAB strategy (VASAB 2009, 2010) had energy and transport as part of its three core areas, and laid out long term perspectives to 2030. The EU Baltic strategy benefitted from this spatial planning tradition and did have significant transport and energy elements. In the transport sphere this involved re-emphasising long standing priorities like the Rail Baltica link up from Germany through the Baltic republics, and the Fehmarn-belt link from Denmark to Germany, as well as stressing shipping improvements, but with VASAB's help this was placed in a spatial planning context. Nevertheless, as so often, when one examines the regional policy funding, the biggest sums go to road building (over 18 out of 27 billion euros in the 2007-13 ERDF were for this purpose – CEC 2010n). For energy the Baltic Sea Region Energy Cooperation, set up in 1999, had also prepared the way, and the Baltic Energy Market Interconnection Plan of 2008 was a cornerstone, intended to reduce the energy isolation of the Baltic republics. So in both areas the spatial elements and understandings were well developed, and a supranational sphere does appear to be in real flow, even if resulting actions are judged to fall well behind these understandings.

A Danube strategy was launched at the end of 2010, at the request of the European Council. This may also develop important implications for the transport and energy fields, though at present the content of the Action Plan concentrates on issues easily linked to the Danube itself, such as the river's navigation, and hydro power possibilities of tributaries of the river (CEC 2010k). One does not get the impression of anything like the same developed spatial elements as in the Baltic. Given that many of the bordering states are not EU members, and with the more difficult cohering role of just a long and winding river, this is not surprising. Experience will show whether this second macro region develops a strong momentum, particularly in being able to cohere infrastructure plans. The Baltic may be odd. Larger states like France, Germany, Italy, Spain or the UK are not likely to be cooperative in this way, and they naturally dominate many of the powerful networks in the continent. For the moment it looks as if seas may be the most fertile places for regional cooperation (Baltic, North Sea, possibly parts of the Mediterranean).

However the TENs reforms are far from the final steps in policy making around new infrastructures and cross European policy changes. The schemas laid out in both transport and energy are indeed much more detailed than those attempted before, and, if these survive the process of horse trading between member states, and

pressures from other lobbies, this does leave rather less scope for subsequent detailing for planners at regional and urban levels. However such scope will still exist, and will be played out over the coming years as schemes get near to implementation, whether through the leadership of states, developers or in some cases EU brokered deals. This will in many cases mean that the integrating skills of spatial planners will come into the frame, as a major infrastructure scheme for say a rail line or transmission line, only sketched in broad terms in the TEN-T or TEN-E core networks or regional corridors, comes into the political jurisdictions of particular states or regions or cities. So even in the majority of the EU where no stronger macro regional working is present, there are likely to be opportunities for modest input to detailing of TENs schemes, and sometimes, where conflict emerges, more major roles.

Interpreting the TENS reforms in relation to territorial futures

Significance

I would argue that these reforms are highly significant for planners – and for all citizens. They lay out geographical templates in a way that has never been done before at the continental level in Europe. The move to designate a core network in transport, and articulating this as corridors, and the making of regional schemas in electricity, gas and to some extent for oil and for forms of storage, places an infrastructure overlay on the map of Europe. The authors of the ESDP might be green with envy, had they been able to integrate such an overlay with other forces affecting locational change. Transport infrastructure in particular could be extremely important over coming decades in locking in certain geographical patterns and dynamics, giving locational advantage to some regions and disadvantage to others. The same will apply in the energy field, but how this plays out is very uncertain, as the marketisation of energy investment is considerably more advanced than in the transport field. Although the potentially radical decisions affecting any transition to a low carbon Europe will be extremely important in the long run, I have doubts whether the TEN-E process will actually lead in this direction, rather than solidifying existing fossil fuel based and to an extent nuclear geographies. Decisions in the key national states will be vital, especially in Germany and France, influenced by their large energy corporations.

So, potentially, this is a major shift in the governance of two key features of the future of Europe. Following on from the single market drive of three decades, and the liberalisation drive of roughly the same period (above all in infrastructure industries), these schemas give the EU an important role in the way big systems evolve in the future. As usual, this is not creating a direct transfer of powers to the EU, but increasing the diagonal nature of decision making, whereby states,

Commission, major corporations, and other important lobbies interact in the advancing (and inevitable modifying, as circumstances change) of the investment streams proposed. The reasons this became necessary were precisely related to the single market and liberalisation drives, which left European states without instruments to guide investment in these key industries to achieve their key goals – maintaining supply, skewing to low carbon priorities, and increasing competition where practicable, including between suppliers of the major fuel, gas. The 2012 packages, if passed, are intended to provide the new instruments, alongside the efforts of the states and corporations. There may be doubts as to the efficacy of these instruments, but ineffectiveness will be in a sense a political failure by the states, not supporting what they have created.

Rescaling, democracy and siloised governance

Rescaling is variable across policy fields, as any text on the EU makes clear. What we see here is a move to recalibrate governance in one field, and one relevant to the interests of planners and territorial specialists. The peculiar melange of forces that is the polity of Europe (states plus the EU's institutional formulas and behaviours) has moved on again – in my interpretation completing the work of the 1980s and 1990s. Seen as a whole, this can be seen as a further distancing of decisions from wider political and democratic control. This is inherent in the project of neoliberalisation, which is in its essence hostile to properly democratic control of major decisions – such as the future shapes of countries, industries, ways of life. If these can be hived off to economic decision makers remote from electoral or pressure group influence, and where necessary, if powers can be allocated to governance assemblages and polities which are equally difficult to understand, track and affect, then there is more scope for the "powers that be", and less for "the many" within that governance machine. As I see it, the new structures created in the TENs systems have much of this character.

It may be said that schemes will be locally resisted, that depoliticisation never really works, that pressures pushed aside at one level will burst out elsewhere. This may be true, but it leaves a highly uneven spread of resistances, which may have high societal costs, and may result in a pattern of investment to the liking of hardly anyone, and inefficient in achieving wider agreed goals. The result may not be depoliticisation of investment decisions in the full sense, but certainly the removal of effective democratic steering over the key long term patterns of life. In the long run, de-democratisation generates depoliticisation, or perhaps simply the narrowing of political life to the activities of a small range of elites.

There is a great deal more to be said on the issues of democratisation or otherwise in the EU and in planning, going beyond the discussion of representative and

deliberative elements, to consider the claims of different publics and actors (Saward 2010), but this is not the place to enter these complex areas of political discussion.

The strongly siloised or sectoralised character of the TENs schemas is another major ingredient which acts to form the governing ensemble managing infrastructure sectors now. In this it mimics normal state behaviour (Marshall 2012a). It is normal for policy making for energy or transport to be highly sectoralised, often subsectoralised (for just roads, rail, ports, or just for gas, nuclear, renewables, oil etc). There are exceptions, where a more integrated approach has been taken, as in the famed Dutch national spatial planning, or the work of the Grenelle in France to try to integrate across sectors. It is true that the EU TENs efforts have strived to at least integrate above subsectors. The TEN-Ts schemas are remarkable for really trying to integrate freight routes, linking rail and ports above all. And the energy schemas do try to make connections between different fuels and storage needs, going above the individual fuel sectors. But, as we have seen, there is not much integration beyond this in a geographical sense, so sectoralism remains dominant.

Soft spaces and silo governance

As with all fresh conceptual development, discussion of soft processes and spaces has elasticity, in fact it may be seen as conceptually soft. My interpretation is that where these characteristics are present, they represent a weak form of planning (if they really qualify to be called such), with loose framing, fuzzy relating to precise geographies, and loose implementation structures, often highly dependent on private developers, generally large corporations. As such perhaps the London Docklands in the 1980s might be seen as a forerunner of soft spaces, responding to the ups and downs of market actors. This sort of planning may be especially characterised by siloised governance, which avoids integrated debate on alternative futures, and so is disconnected from the decisions of elected democratic authorities. The National Infrastructure Plan 2011 in the UK takes this form (Fischer 2012, Marshall 2012b), treating each area of infrastructure largely on its own and avoiding links to any explicit geography.

First of all, how far does this apply to the TENs schemas in themselves? Sectoral planning, like spatial planning, may have softer or harder features. I would judge that both in energy and transport, there is a mix of characteristics. Simply because they are EU level policy initiatives, they have a certain soft form, dependent on indirect implementation mechanisms, and consisting of carefully crafted text and macro sketching on maps at large scales, making exact geographical impact sometimes hard to identify. Faludi's insistence that spatial planning can only be soft at the EU level applies in part, for the same reasons – subsidiarity, essentially. And

the Regulations concerned may get softer during the discussions of 2012 or even 2013.

However, it can also be argued that the reforms have a hard edge, like many EU sectoral instruments, and that for perhaps the first time, this has a major geographical component. Identifying quite clearly ten continental transport corridors is not really soft planning, any more than the drive to persuade states to reform their planning processes for critical major infrastructure - here not so geographical, but impinging on what is normally seen as the domestic policy sphere of planning systems. The policy making for TENs is marked by weak links to formal democratic structures and a tendency to bypass standard national or local decision making approaches. They are definite top down interventions led by EU and national governments together. A phrase like "the hard fist in the soft glove" comes to mind to try to catch the mix within this sectoral planning (and there are of course significant differences between transport and energy, which could be detailed from the account above).

The second question is then: how does this mix relate to the spatial planning with which it comes into contact and which it is going to affect? I have suggested that this is going to be an important encounter in many parts of Europe. On occasions it will be with the soft styles of macro-regional planning (Knippschild 2011, Stead 2011), where there has surely already been implicit two way interaction between these EU stimulated soft spatial strategies and the TENs corridors and regional programmes, and that such a two way process will continue. The harder edge elements of the TENs schemas may further the process of solidifying of macro-regional strategies identified by Metzger and Schmitt (2011). There may be an interesting, possibly not entirely smooth, relationship between the more integrated approaches being developed in the Baltic and Danube cases by appointed coordinators, and the more single minded goals of transport corridor coordinating groups or individual transport or energy coordinators. Of course where no macro-regional strategies exist, such scope for possible friction will not exist.

Elsewhere the encounter is with in part "standard" spatial planning, the regional or even national planning strategies of a hard kind, alongside the softer forms perhaps emerging in many city regions around Europe. Here I would argue that the effect will be to further "soften" planning, in the sense of making it more difficult to tell, for citizens, where policy is decided and who is to be accountable for it. Areas with "hard plans" may find themselves in a stronger position (just as currently in England, where local authorities with approved plans will be able to resist imposed developments more easily than those without up to date formal plans). But even here localities may find their planning softened up for development, with national governments seeing good reasons to go with the flow of the TENs schemas.

In part therefore here I am using the distinction to point to the possible hopes of developers to find soft territories, giving little resistance to major transport and energy developments. Spaces may thus be made soft by non-integrated planning and top down corporate led governing arrangements, where the major actors are ultimately the largest energy and transport corporations and agencies, backed by governments. Clearly this is giving the concept multiple layerings of meaning, but this appears appropriate when applying in this case: soft in definition, soft in process, soft in (expected) impact.

Referring back to the Metzger and Schmitt discussion of regionalization, the TENs transport corridor institutional development may build its own dynamic of cooperation and lobbying geographies, though perhaps not with the same force that something like the Baltic strategy work has had, building as it did on multiple forms of cooperation regionally over many years. The energy regions may over years build up some regionalizing force, at least within the policy community of specialists, whereby companies and governments come to know the regional systems well within that zone of Europe, and are to a degree less linked to other regions.

So as a whole the TENs schemas may be seen as complementing and possibly reinforcing the tendency to soft space styles of planning present in some European planning contexts, whether locally or at the mega-regional scales. Putting it the other way round, they probably on balance give little comfort to those who might wish to reinforce more classical forms of firm national or regional spatial planning. The point is made tentatively, because, as the above discussion indicated, there are two or more steps in the process, with softer and harder forms of both sectoral and spatial planning interacting to create the overall effect in any national or regional context.

Impacts on ideas and imaginaries

The "real" impacts on geographies are likely to be very considerable, if these packages are approved and implemented over the coming decades. They are meant to be for the long term, with schemes to be reviewed in 5-10 years time, but looking at the horizons of 2020, 2030 and 2050, as is no doubt appropriate for investments of this range and type. Given the long life of most infrastructures of this kind, they are likely to be therefore framing life into the twenty second century – or involving some extremely costly write off of mistaken investments, which took the continent on multiple wrong tracks. Many of the elements of the schemas are likely to be contested, from contrasting positions on the political or philosophical spectrum – too green, not green enough, too directive, not market sensitive enough and so on. However, if approved, they may over time impact on the shape of the continent and also how people think about that shape and shaping. If one imagines the changes

wrought in recent years by essentially unplanned changes in the transport systems, such as low cost flights from different national locations, or the evolving high speed rail networks, it is clear that these have changed how we think about Europe (Jensen and Richardson 2004, McNeill 2004). The freight corridors and proposed energy geographies may be somewhat less near to the thinking of most people or opinion formers, but over time, the fact that say half the energy supply came from wind farms on and off shore, often within the jurisdiction of other countries, would create one way of thinking about our interdependencies, as would a similar shift to locally based solar or related electricity generation – a downscaling of imaginaries and spatial linkings.

My study of national planning and its absence made me reflect about the forming of such ways of thinking about big scale geographical change. Such thinking appears to have a continuing national presence in some countries, such as the Netherlands and France, and, if in much more negotiated and conflictual ways, in Germany and Spain, reflecting their federal or proto federal natures. It is generally resisted in the more peculiar mongrel UK state, as in some other countries which cannot perhaps "afford to" speak or think openly about their geographical nature and balances. The impossibility of an intelligent debate about the HS2 project (high speed rail line) in the UK, in the absence for over three decades of a mature spatial framing, shows how critical such absences can be in real world decision making. At the continental level, there is little, I would imagine, in the way of a shared imaginary, with horse trading between member states largely taking the place of any explicit consideration of what could or should be done where – hence the nature of EU spatial planning or its absence. However, the TENs schemas do seem to be a first example of placing very definite prioritising of corridors on maps. In debating them, fighting them, implementing them, many people will come into contact with the idea that say the north-south freight route across the Alps is important to European functioning, and its planning might usefully be shared (Hesse 2010). Equally, a shift to a genuinely low carbon future has a massive geographical component, alongside the issues of principle about fuels, external security and so on. If there is to be a sensible use of the energy potentials of the North Sea, for example, planning will be unavoidable – though that does not mean that such planning will occur, as the large obstacles in its path make clear (House of Commons, Select Committee on Energy and Climate Change 2011). Maritime spatial planning is emerging as a new practice, and though it will have specialised and technical elements, the effect over time on how everyone thinks about seas and their "services" to states near them, must change our geographical imaginings. I am not arguing that the TENs schemas in themselves will start to make explicit thinking about geographies more central to politics. I suspect that such thinking goes too near the bone of numerous power interests and threatens to open too many democratic and radical questions to wider view. However, the

simple fact of the EU getting involved in such areas may impact on what national states (or regions) feel they may need to do – perhaps even reinventing national spatial planning in the Dutch or Scottish mode. The making of National Infrastructure Plans in the highly liberalised UK may be one sign of an understanding of the need for new kinds of national steering (HM Treasury 2010, 2011).

Responding to the TENs reforms

This paper is not primarily intended to sketch possible responses to these new ways of managing infrastructure investment in these two fields. Like many observers, I am sympathetic to some of the substantive content (such as the goal to shift freight to more environmentally friendly modes, and some aspects of the facilitation of a low carbon energy world), less so to other parts. The question here is rather what links to spatial planning might be valuable, if any, and how that might be progressed. The difficulty here is that the European polity is such a difficult species, that it is hard to think of a way that might usefully link together real life concerns of populations and their democratic representatives and these very high level proposals. In principle both the whole schemas and the details in each corridor should be examined by national and lower authorities, in the full view of the public sphere. This would, in many countries, be very difficult to do with any real evidence base, given the dismantling of planning capacity at most levels in many cases. If critical views were extensive, this would be a message that the schemas needed reworking, making more integrated links to national and regional development aspirations. Again, such reworking would be difficult, as now I suspect that many European states and regions do not have clearly based goals formed from competent spatial planning processes. Such national and regional strategies would be needed, in principle, so that the corridor proposals could be checked as to their sense in relation to these schemes – in the same manner as the Raumordnungsverfahren process in Germany. Another way of putting this would be to subject the schemas to Territorial Impact Assessments, if such an instrument ever comes to exist (Bohme and Eser 2008).

Beyond such a procedure, it would clearly be valuable if the EU developed some analytical spatial planning capacity in order to influence the making of such sectoral schemas. Whilst this might have been seen as an unnecessary luxury in the 1990s, the degree of impact and intervention envisaged in the TENs reforms does point to the value of such a capacity. Although for the moment this might be a case of closing the stable door after the horse had bolted, there may well be further such initiatives with major spatial implications, and the formation of such planning capability, well beyond the valuable but essentially research based input of Espon, would easily prove its worth in that case.

Macro-regional strategies, as mentioned above for the Baltic and Danube, might be one ingredient of a more integrated approach, but it is unlikely that such strategies will become widespread, given the logical resistance of larger states to such stronger collaboration. A fuller examination of the Baltic case and the links to current TENs packages should reveal the value of a continuing integrated spatial planning over many years. But we should not hold our breath with the idea that such strategies will emerge elsewhere as containers for future planning of big infrastructure. If that is to happen, it is more likely to occur at the national level, through a return to some sort of national spatial planning. In a neoliberalising world, however, we know the real and ideological barriers to such a return.

Of course at a wider level, the debate is always a political one about what sort of Europe is desired. Should it be a minimal budget and economy-driven model as at present (the Anglo Saxon form blended with some Rhineland elements, as Faludi and Peyrony 2011 have it), or something more like their European model, with far stronger EU policies and territorial cooperation? Should it be economic growth driven and based on market dominance, or with more social and environmental priority? Infrastructure industries are increasingly in the marketised zone, and so more resistant to spatial planning, and so the current TENs packages fit into these givens of the EU political economy. For the moment realities seem to be that the main scope for a meeting with spatial planning will be in the detailed regional working – the Corridor Development Plans, the regional energy packages. Planners would do well to keep their eyes on how these new forms develop.

AWARENESS-RAISING FOR EUROPEAN TERRITORIAL COHESION IN PLANNING EDUCATION - WITH REFERNECE TO ITALIAN AND GERMAN EXAMPLES

Kirsten Mangels[1], Giancarlo Cotella[2]

Abstract

In recent years the "territorial cohesion concept" found its way to the centre of the debate over European spatial planning, until its inclusion in the recently ratified Treaty of Lisbon as a supplement to the economic and social dimension of the EU cohesion objective (Treaty on European Union, Art. 3 (3)). In turn, this strengthened the importance of spatial planners among the experts in this field of action, putting them in charge of the realisation of territorial cohesion. The fact that planning professionals are more and more involved in EU initiatives in their everyday practice and have the chance to take over leading roles in related EU policies and programming should find adequate expression in spatial planning study programmes. This contribution aims to explore whether and to what extent young planning professionals are nowadays trained to play a role within the European territorial cohesion process and related programmes and projects. It shortly introduces the actors that may potentially play a role within the heterogeneous European spatial planning network, and analyses the appropriate knowledge they should bring if they have to contribute to the realization of EU territorial cohesion. Selected Italian and German spatial planning education programmes are analysed in the light of these information. A mixture of both quantitative and qualitative analyses is adopted, focussing both on the number of obligatory and facultative study courses dealing with EU spatial planning related issues in Bachelor and Master Programmes as well as on the different ways EU-related issues are accommodated and integrated within these course and programmes. The provided evidences suggest that, despite the progressive homogenisation of the organizational framework of spatial planning education programmes in the EU as a consequence of various pan-European initiatives – e.g. the Bologna process – a real 'European turn' in terms of contents is still far from occurring.

1. Introduction

Graduates in Spatial Planning are active in the public service, in semi-public and private institutions as well as in professional and non-governmental organizations. They work on different spatial levels (from city neighborhoods to regions, to the state level, to the transnational and global contexts) and in different professional fields (land use planning, urban design, urban development, regional development and formal regional planning, sector planning disciplines e.g. transport, landscape planning, promotion of businesses, real estate management, etc.). Within the public sector they are employed in a highly heterogeneous set of bodies (e.g. planning departments, environmental departments, promotion of businesses, etc.) of municipalities, county administrations, regional authorities, national and federal ministries as well as European institutions. In private institutions they may hold positions in large companies as well as in small planning, architecture or engineering offices, in real estate companies, housing associations, consultant firms, site select consultants, research institutions etc.

Despite the lack of formal competences on the matter, the influence of the EU on the spatial development of its member states and regions is enormous. On the one hand, such influence is exerted through the continuous production and re-production of ideas, concepts and storylines by mean of an ever-expanding set formal and informal strategies and documents that are then often taken on board by Member states' actors (at the various territorial level) during the formulation of domestic policy documents and initiatives.[3]On the other hand, the EU contribute to influence Member States planning and development through economic conditionality, i.e. by providing economic rewards attached to the fulfillment of specific substantive and procedural conditions (as for instance through the former Community Initiatives and through the EU Cohesion Policy. Cf. Schimmelfenning and Sedelmeier, 2005; Adams et al. 2011). Last but not least, additional pressure derives from those EU's sectoral policies that, despite not being strictly 'spatial' in their focus, results in a series of planning and development constrains and impact once they are taken on board in the various Member States' domestic contexts (Cf. Dühr, S. Colomb, C., Nadn, V., 2010)

Keeping in mind the above considerations, it is possible to agree with Dühr et al. when they argue that "the European dimension in spatial planning has become an essential part of the work of planning practitioners and academics" (Dühr, S. Colomb, C., Nadn, V., 2010, p. 1). It is therefore relevant to explore whether young planning professionals are nowadays trained to play a role within the described ever-Europeanized professional scenario, in other words to what extent are they equipped with the necessary means to interface with the whole set of implications brought about by the consolidation of the EU territorial cohesion process. To shed some light

[3] For a detailed analysis of the process of discursive integration and the influence of the European spatial planning discourse in the Member States see: Bohme 2002; Adams et al. 2011; Stead and Cotella, 2011.

on this issue, the present contributions briefly introduces the possible professional careers of spatial planers focusing on their European dimension as well as on the related necessary knowledge that should be provide by universities (section 2). It then present some general information on the present situation of planning education in Europe (section 3), to provide the background for the empirical analysis that follows. Sections 4 and 5 analyse the activities of four planning education faculties (two from Germany and two from Italy) focusing both on the number of obligatory and facultative study courses dealing with EU spatial planning related issues in Bachelor and Master Programmes as well as on the different ways EU-related issues are accommodated and integrated within these course and programmes. A conclusive section rounds off the contribution, reflecting on how the analysed spatial planning education programmes meet the introduced requirements, and suggesting possible ways forward.

2. There is nearly no way around EU initiatives for planning professionals!

Spatial Planners working in public services on local, regional or national levels in the above mentioned positions need to deal with the spatial impact of EU policies, as well as with the operational implications that EU programming initiatives have in their everyday practice. There are some sectoral policies with direct impacts on spatial planning and development, like e.g. environmental policy and its transformation in legislations with impacts on all spatial levels, competition policy and its impact on building activities etc. Additionally, there are sectoral EU policies with an indirect influence on spatial decisions like e.g. energy and transport policy. And a strong influence on spatial planning and development is exerted by the EU through its regional policy as well as through its territorial cooperation initiatives and urban programmes.

Concretely, due to the increasing internationalization of location decisions of residents and companies they need to manage the competition between cities and regions and elaborate strategic concepts about the positioning of there are of competence. To be able to succeed in these new tasks, they need profound knowledge about how to develop, manage and implement those strategies, in other word to prove able to attract funding and to manage them effectively in times of ever-decreasing public budgets. Because of increasing opportunities to participate in consultation processes in the elaboration of objectives and regulations e.g. concerning the new cohesions policy period 2014-2020, planners active within the various domestic contexts also need to know the architecture of this policy area. Additionally, as numerous local and regional authorities and respective spatial planners are partner in transnational, cross-border or interregional cooperation projects developed within the framework of the European territorial cooperation objective, in order to be able to participate in those projects one needs to know how to network with the other partners active within a potential cooperation areas as well as how to prepare projects' applications and to successfully manage projects as well as their implementation and financing.

Practitioners active in the private sector work either in specific fields like real estate development, housing associations etc. or act as external experts or consultants for public administrations. In the latter case they need the same knowledge that spatial planners being employed in public administrations plus perhaps knowledge about the management of projects in the European Territorial Cooperation because often public lead partners of the projects contract private consultants to conduct the project management. As practitioners in a specific sector they should be able to assess the impacts of EU policies on the sector and know basic rules for accessibility to EU funding. This extends to spatial planers working for non-governmental organizations too.

The short review of fields of work, possible positions and functions of graduates in spatial planning on the one side and of the corresponding necessary knowledge in EU issues shows, that there is a certain need for spatial planning education programmes to provide at least the basis for a preliminary understanding of the new opportunities and constrains brought forward by the EU in the field. Despite one could always argue that not everything can be covered by university courses and that training activities and actual work may fill-in the gap, the provision of some fundamentals should indeed be present.

2. A brief glimpse at the planning education in Europe

In 1995 AESOP recommended a list of core requirements for a high-quality European planning education based on the understanding that AESOP should provide "orientation for the elaboration of programmes or defining core qualifications which need to be achieved in individual programmes" (Ache, 2008). An orientation for the restructuring of degree courses following the Bologna 3+2 or 4+1 cycle was regarded as useful not only to ensure a certain quality of education but also to ease mobility of students. The list is divided in three parts:

- acquisition of due knowledge in e.g. the nature, purpose, theory and method of planning; the history of planning; cultural differences in planning in Europe and international, economic and social impacts of planning; the political, legal and institutional context of planning practice at national and EU level; instruments of planning and planning implementation.
- development of practical competences in e.g. methods for problem definition and problem-solving in multidisciplinary settings; thinking in terms of concepts, instruments and measures; techniques for data collection, for data analyses, valuation etc.
- development an attitude i.e. a feeling for the cultural embedding, the value dimension of planning, the orientation towards solving the needs of the society etc. (Geppert and Verhage, 2008).

For the purpose of this article, it is important to stress the point that AESOP recommended that students in planning education programmes should acquire due knowledge in "cultural differences in planning on a European and international

level" and in the "political, legal and institutional context of planning practice both at the national level and at (evolving) international i.e. European level" (Geppert, and Verhage, 2008, p. 24).

At this point, it should not be discussed whether the implementation of the Bologna Process in planning faculties lead to better or worse education programmes and graduates or whether the Bologna objectives were achieved or not. More relevant is that, while restructuring the degree courses to Bachelor and Master according to Bologna, the European planning faculties should also define new, consistent education programmes aiming at providing graduates for professional life after three or four year courses with the option of an additional two or one year Master. The question here is whether in those new education programmes the two above named qualifications are considered or not.

In 2006 and 2008 AESOP realized two surveys mapping the experiences AESOP member schools had had with the new structured degree courses according to the Bologna Declaration (Ache, Jarenko, 2010). The 2008 survey results in the reported advantage of the process, the need to rethink and the possibility to internationalize curricula. On the other hand, a reported negative effect is that in several cases the domestic, cultural flavour resulted of the programmes resulted severely weakened (Ache, 2010). These two issues stressed in the report's summary give rise to the assumption that cultural aspects in planning on European level and the political, legal and institutional context of planning at European level is part of the education programmes and planning graduates have due knowledge to be active parts in the implementation of European territorial cohesion, to shape European policies and programmes and to use those programmes in planning practice.

In order to verify this assumption, planning education as it manifests within four different university institutions (two from Germany and two from Italy respectively) will be reviewed in the following sections, paying particular attention to the obligatory and facultative contents offered in the respective Bachelor and Master degree course.

3. The EU dimension of planning education in Germany – Evidences from Dortmund and Kaiserslautern

Two spatial planning education faculties in Germany will exemplarily be reviewed concerning to European Spatial Planning and European Cohesion Policy contents of the provided study courses. The faculties are introduced briefly before the provided study courses are short and crisp displayed and analysed whether there are obligatory or facultative offers for students in the regarding field.

The reason for the selection of the two case studies is motivated by the fact that each of these two Universities host a faculty of spatial planning offering distinct study courses in spatial planning since more than 40 years. Both have some years of

experience with the Bachelor and Master system, so that Master courses are already running.

4.1 Education in Spatial Planning in Dortmund[4]

The Faculty of Spatial Planning at the University of Dortmund consists of fourteen departments. Measured against number of students and number of departments the faculty is currently the largest educational institution for spatial planning in Germany. Its educational profile is characterized by a multidisciplinary and integrated understanding of spatial planning and is organized as a so called "project study" course. In the winter semester 2010/2011 the faculty had 1,260 registered students, where circa 150 students start each winter semester.

In implementation of the Bachelor –Master system, the Faculty of Spatial Planning at the University of Dortmund decided for a 4+1 cycle format. The Bachelor of Science in Spatial Planning is a four years (eight semesters) programme in which the students need to mature 240 Credits according to the European Credit Transfer System (ECTS). Graduates which wish to proceed with a Master at the Faculty have the choice between a one year Master of Science in Spatial Planning with six different areas of specialization, a two year Master in Spatial Planning for Regions in Growing Economies (SPRING) and a one year Master in Spatial Planning in Europe.

4.1.1 Bachelor of Science in Spatial Planning at the University of Dortmund

The Bachelor of Science in Spatial Planning at the University of Dortmund covers all spatial levels (neighbourhood, city, region, state etc.) and content areas of spatial planning. It qualifies students for working in the field of spatial planning and accomplishes the requirements to subsequently register to the Chamber of Architects (Urban Planer). It enables students also for further studies in a Master degree course. The Bachelor degree course is structured in basics, sector planning issues, cross-section modules, methodological and practical modules. Currently the Bachelor is structured in a four year course, subdivided in a first part (1st till 4th semester) and a second part (5th till 8th Semester) and is completed by a Bachelor Thesis.

Table . Bachelor of Science Spatial Planning at the University of Dortmund - Structure

	Modules		ECTS	
Part 1 Semester 1 to	1	Introduction in Spatial Planning	8	125
	2	A-project	19	
	3	Basics in Spatial Planning I: law and environment	11	
	4	Basics in Spatial Planning II: Society	9	

[4] All information concerning the Bachelor and Master degree courses underlain this chapter, are published on the web page of the faculty http://www.raumplanung.tu-dortmund.de/rp/wichtigbsc.html, (accessed 5 May 2012).

	5	Basics in Spatial Planning III: Economy	10	
	6	Empirical analysis and inquiry	10	
	7	Computer graphics and analysis	11	
	8	Regional planning	9	
	9	Urban and regional concepts	12	
	10	Land policy and management	9	
	11	Concepts for city quarters	12	
	12	Study fundamental	5	
Part 2 Semester 5 to 8	13	F-project	22	115
	14	Research methods in spatial planning	8	
	15	Cross-section module: theory of spatial developments	9	
	16	Cross-section module: planning theory and planning processes	12	
	17	Cross-section module: methods, processes and instruments	9	
	18	Sector planning	12	
	19	Current challenges for spatial planning	8	
	20	Urban design	11	
	21	Spatial planning from experience (internship, excursions etc.)	12	
	22	Bachelor Thesis	12	

During the first part students receive an introduction in spatial planning and work in groups with average twelve to fourteen members in a so called A-project to solve a problem- and practice-oriented spatial question (Module 1, 2). The basic modules (3, 4, 5) explain fundamental relations between landscape ecology, environmental protection and spatial planning, introduce students in juridical, sociological and economic issues of spatial planning. In Module 6 and 7 attain knowledge in choosing and implementing suitable inquiry and analysis approaches and in computer graphics and analysis (GIS, CAD and cartography). The development of regional and city quarter concepts is core topic of modules 8, 9 and 11, while in module 10 necessary aspects for implementation of these concepts is imparted. In module 12 students can choose any courses that are provided at the university according to their interests.

The second part of the degree course is different structured. During the fifth and sixth semester, students work on the F-project (advanced project). In the cross-section modules the specific and methodological competences are trained according to the needs of planning processes in real live. Sector planning is provided as an offer of six possible areas (e.g. landscape planning, transport planning, gender planning etc.) from which three needed to be chosen. Urban Design is obligatory and covers also urban design history and cultural heritage preservation.

It has become apparent that – analyzing the information material in the internet – the Bachelor degree course at the University of Dortmund contains not directly a lecture or course in European Spatial Planning or European Cohesion Policy. Nevertheless especially the F-project (advanced project) offers the possibility to integrate those contents in the Bachelor programme.

4.1.2 Master of Science in Spatial Planning at the university of Dortmund

As already described above, the faculty currently offers three different Master degree courses:

A. Master of Science Spatial Planning (one year programme, 60 ECTS) with six possible areas of specialization:
   1. Strategic urban- and regional development
   2. Urban design
   3. Local and regional economic policy
   4. Real estate management
   5. Comparative European Planning studies
   6. Planning in developing countries

B. Master of Science Spatial Planning for Regions in growing Economies (SPRING), two year programme (4 Semester)

C. Master of Science Spatial Planning in Europe (one year programme).

Unfortunately the Master Spatial Planning with the specification in Comparative European Planning studies will not be offered from winter semester 2012/2013 on. The Master of Science Spatial Planning in Europe is not yet running and no information material is provided on the web page. The Master Spatial Planning for Regions in growing Economies (SPRING) has a different focus and is a cooperation project with partner universities in Tansania, the Philippines, Ghana, and Chile and closely linked to growing Economies.

The Master Spatial Planning should prepare students for leading positions on all planning and decision making levels. It enables students to take over the leadership in multidisciplinary teams and allows students a research career and the possibility to make a PhD. It consists of four modules in which 60 ECTS need to be acquired. The new description of the modules for students which will start the Master degree course Spatial Planning in winter semester 2012/2013 contains a new structure and provides not any longer the possibility to choose the specialization in “Comparative European planning studies”. It will be structured as follows:

- Module 1 impart knowledge of current spatial research and planning on regional, national and international level (8 ECTS)
- Module 2 is the master project or master concept (selection of project or concept) in which complex problems in spatial planning should be solved with scientific methods. The master project put am emphasis on theoretical-analytical or conceptualization of a current question in spatial research and planning. The master concept stresses more the conceptualization and a practical design task. (12 ECTS)
- Module 3 is the specialization module in which students can select: transformation of post-industrial regions, strategic urban- and regional development, urban design, environmental planning, spatial and mobility research, real estate management, renewable energies.

- Module 4 is the Master thesis (20 ECTS).

The module manual of this new structure is not fully developed and described so far, so that only rough information about contents of the specializations is provide. Currently only in the specialization module transformation of post-industrial regions the description of contents names “European experience in transformation processes”. But it is likely that the facultative offered courses of today will be offered from winter semester 2012/2013 on, too. In this list of facultative courses one can find: Urban Regeneration in European Countries, European Spatial Planning, national planning systems in Europe.

The number of ECTS and related the effort students put to European contents in this Master of Spatial Planning with the specification in “transformation of post-industrial regions” cannot be quantified yet. The number of students dealing with EU contents can be much higher than the number choosing the specialization, considering the fact that also Master project and Master thesis can deal with European issues.

4.2 Education in Spatial Planning at the University of Kaiserslautern

The Faculty of Spatial and Environmental Planning at the University of Kaiserslautern consists of ten departments and educates students in spatial planning since 1971. It provides multidisciplinary and cross-section oriented study courses in spatial science: Bachelor of Science Spatial Planning, Master of Science Urban and Regional Development, Master of Science Environmental Planning and Law, Bachelor of Education Geography (the last one will be not part of the review in this article). People with their spatial requirements which find expression in the basic needs like working, living, recovering and supplying are central for the degree course design. Since the winter semester 2007/2008 the faculty have provided the Bachelor Spatial Planning, since the winter semester 2010/2011 the Master in Urban and Regional Development and since winter semester 2011/2012 the Master in Environmental Planning and Law. Currently circa 450 students are registered while the Bachelor usually starts with circa 90 students, and the Masters with 25.

In implementation of the Bachelor – Master system, the Faculty of Spatial and Environmental Planning at the University of Kaiserslautern decided on a 3+2 cycle format. The Bachelor of Science in Spatial Planning is a three years, six semester programme in which the students need to get 180 Credits according to the European Credit Transfer System (ECTS). Graduates which want to proceed with a Master at the Faculty have the choice between the two already mentioned two years Master of Science (120 ECTS). The review will focus on the Bachelor Spatial Planning and the Master Urban and Regional development, because the Master Environmental planning and Law is conceived as a specialized Master, educating experts in environmental planning, concepts and resource protection. Nevertheless, students studying this Master obligatory need to attend a lecture in European Regional Policy.

Graduates are like the ones from the University of Dortmund active in public, semi-public and private institutions and have jobs not only in traditional planer contexts but also in the real estate market, in promotion of trade and industry, in transport, research etc. But it should be mentioned, that Bachelor Graduates prefer to proceed with a Master because the new graduation system is not fully accepted by the employers, yet.

4.2.1 Bachelor of Science in Spatial Planning at the University of Kaiserslautern

The Bachelor of Science in Spatial Planning at the University of Kaiserslautern should equip the students with competences as planning professionals for all spatial levels and for formal as well as informal planning cases. Additional to the basic skills for spatial planers knowledge in planning and environmental law, environmental protection, real estate management, and sociology are also gained as sector planning issues, like transport, sewage etc. The Bachelor degree is a first qualification for the planning profession and enables students also for further studies in a two year (or 120 ECTS) Master degree course.

The Bachelor course is structured in 17 modules (two of which are facultative), one study project and the Bachelor Thesis. The modules are divided in urban planning, regional planning, general conditions and key qualifications.

Table 2: Bachelor of Science Spatial Planning at the University of Kaiserslautern - Structure

	Modules		**ECTS**	
Spatial planning at urban level	I	Planning methods, concepts, basics in landscape planning	10	40
	II	Basics in architecture, urban environment, urban land-use planning	10	
	III	Design, concepts, strategic environmental assessment	10	
	IV	Informal planning instruments, governance, urban planning and law	10	
Spatial planning at regional level	I	Settlement development, socio-economic changes and demographic development, basics in spatial planning	9	27
	II	Spatial planning law, concepts and instruments, new informal instruments	9	
	III	Analyses of spatial structures, processes, locations, valuation methods, basics in regional economic	9	
International spatial planning		international urban planning (1,5), international planning systems (1,5), European Regional Policy (3), planning in developing countries(3) (students need 6 from 9 ECTS)	6	
Legislation	I	Land use planning, European law, administrative law	11	21
	II	Urban planning legislation, environmental law	10	
Economy		Regional economy, regional policy	7	59
Sociology		Regional and urban sociology, empirical research	8	
Environmental		Ecology of/in settlements, green space concepts	9	

planning				
Infrastructures		Transport, sewage, water supply systems, waste management	11	
General conditions for spatial planning		Real estate developments and financing, climatic geography, climate modeling	8	
Key competences	I	Presentations, press release, media, moderation, mediation	6	
	II	CAD for urban and regional planning, statistics, GIS in urban and regional planning	10	
Bachelor project			13	
Bachelor Thesis			14	

In the modules spatial planning at urban and regional level necessary knowledge is imparted concerning methods, instruments and conceptualization of spatial planning inclusive links to sector plans. Multidisciplinary aspects are included in exercises and the Bachelor project. In the Bachelor project students apply the gained competences and knowledge to solve a practical planning problem in a group of up to ten persons. In this context students should also train social competences, team management and presentation techniques.

During the Bachelor degree course at the University of Kaiserslautern students have the opportunity in the module international spatial planning to choose facultative a course in European Regional Policy. This is the only offer with reference to European issues. But the Bachelor project offers the opportunity to integrate European spatial planning issues in the study programme, also the Bachelor thesis.

4.2.2 Master of Science Urban and Regional Development at the University of Kaiserslautern

The Master Urban and Regional Development is the consecutive continuation of the Bachelor Spatial Planning. The four semester course prepares students for high-qualified jobs, the leadership of teams, a research career and is the precondition for a doctoral dissertation. It is structured in ten modules, a master project and the master thesis. Students need to collect 120 ECTS.

The modules are structured in spatial planning specific modules concerning urban and regional planning and development to deepen and round out the already gained knowledge. Scientific methods, the design of adapted planning processes in different spatial contexts (from rural areas to metropolitan areas and from urban to European levels) and the implementation of urban and regional development strategies and concepts are the main focus. Additional economic, social and legislative aspects to deal with multidisciplinary tasks in spatial developments are imparted.

Table 3: Master Urban and Regional Development at the University of Kaiserslautern – rough structure

	Modules	**Contained European or international contents**	**ECTS**
	Urban development	International urban development	27
	Regional development	Spatial development in Europe	18

	Economy		8
	Sociology	International developments	8
	Legislation		10
Facultative (1 of 3)	Economy 2	European Regional Policy	9
	Real estate developments		9
	Mobility and transport		9
	Key competences		12
	Master project		12
	Master Thesis		16

In one of the modules in regional development one lecture is about "spatial development in Europe". One of the ten modules is to be chosen out of a choice of currently three (from summer semester 2013 on four) facultative modules: economy 2, real estate developments, mobility and transport, (international planning systems from 2013 on). The module economy 2 contains one course in European Regional policy. The planed module "international planning systems", starting in summer semester 2013, will consist of three courses: international urban and regional development lab, European Spatial Development: Policies, Concepts, Strategies and methods of comparative planning.

The number of ECTS and related the effort students can put to European contents are in obligatory courses 2 ECTS (from 120 ECTS – 1,7 %) and in facultative courses currently 4 ECTS (together 6 ECTS – 5,1%), (from 2013 on 5 ECTS are possible – together 7 – 5,8%).

5. The EU dimension of planning education in Italy - evidences from Torino and Milano

Following the presentation of the spatial planning Bachelor and Master programmes activated by the above German universities, the present section focuses on two Italian universities: Politecnico di Torino and Politecnico di Milano, this being both the main Technical University of the country as well as among the few Italian University institutions running both Bachelor and Master programmes related to the field of spatial planning[5]. As with the German cases discussed in the section above, the provided study courses are presented after a short introduction of the institutional contexts they are active in. In particular, the extent to which Bachelor and Master programmes in these institutions includes elements related to European Spatial Planning and European Cohesion Policy will be explored.

However, before moving to the case studies, it is necessary to mention that the contextual conditions for spatial planning education (as well as for spatial planning profession) in Italy substantially differ from the German context. Here the planning

[5] In the academic year 2001/2012, as few as XX University institutions were running autonomous bachelor and master programmes in planning (Together with Politecnico diTorino and Politecnico di Milano: XXXXX)

field developed as a declination of the professional figure of the architect and continues to be strongly attached to,and competing with the latter. Since its inception, the emancipation of the urban planner as an autonomous professional figure has been subjected to more or less open conflicts, and the first planning courses appeared in Italian univeristies only since the end of the 1970s. Within this context, Architecture faculties become the stage of a more or less explicit clashes focusing on the opportunity to revise the role of urban planning within or outside architecture education. Beside its cultural roots, this position is also underpinned by issues related to professional accreditation, as within the Italian legal framework, architects are officially entitled to redact and sign urban plans.

5.1 Education in spatial planning at Politecnico di Torino

As far as the Politecnico di Torino is concerned, spatial planning education is promoted within the two former Faculties of Architecture (Faculties were abolished as a consequence of the Higher Education reform on 2011) through two different channels: (i) through specific Teaching Units that constitute essential part of the pedagogical experience of the Bachelors and Masters degrees in Architecture and (ii) through a Bachelor and a Master course specifically dedicated to the education of spatial/urban planners (respectively accounting for XX and XX students in the academic year 2011/2012). A synthetic description of the main features and elements that characterize the latter is provided in the text below.

5.1.1 Bachelor of Science in Territorial, Urban, Environmental and Landscape Planning at Politecnico di Torino

The course is intended to train “territorial technicians” able to collaborate in all activities of territorial, urban, landscape, strategic and environmental planning, using the tools – programmes, plans and design projects – that serve to define and manage the organisation of a city or territory, and that guide the use of resources, environment and landscape[6]. Taking into account the expanding changes that urban, territorial and landscape planning must address, students graduated from this course are expected to work together with different specialists, and hence needs a multidisciplinary background that enables them to understand the languages of the various specialists and work with them in an integrated manner. Course graduates will be able to collaborate in the preparation of plans and programmes, to undertake the necessary analyses semi-autonomously, with particular attention to environmental and landscape aspects, to manage technical and administrative procedures, and design and manage territorial information systems which are today an indispensable means for the conduct of any planning activity.

[6] For full syllabus see:
https://didattica.polito.it/pls/portal30/gap.a_mds.espandi?p_a_acc=2011&p_id_cdl=&p_sdu=82&p_cds=5&p_header=&p_anno=0&p_info=&p_lang=EN

Graduates seek employment with local authorities (municipalities, provinces, regions), municipal utilities and companies, professional firms and engineering firms operating in the field of territorial, urban, landscape and environmental planning. They can also pursue free-lance activities and enroll, after passing a state exam, in section B of the professional order of Architetti, pianificatori, paesaggisti e conservatori with the title of " junior planner", and are qualified to conduct research on or to apply existing knowledge to planning, conservation, restoration and renewal of urban areas, territory and landscape.

The programme follows three tracks, providing core modules on key disciplines as well as practical hands-on experience: (i) territorial government and town and land-use planning, (ii) landscape and environment and (iii) geographic Information Systems. It is organised in two series of teaching modules:

a) Teaching units, which cover foundation subjects of a mono or multidisciplinary nature;
b) Teaching units consisting of multidisciplinary ateliers. These focus on activities relating to actual local situations, allowing students to apply knowledge acquired in the Teaching Units. The ateliers are coordinated by a central disciplinary area, but contain other subject input as well. They last one semester and conclude with a single examination.

The relationship between core knowledge provided in the Teaching units and its application in the Atelier characterises the approach of the degree course.

The objective of the first two semesters is twofold: i) to teach the student that territory, city, landscape and environment are complex phenomena, the product of different forces, to be investigated from various disciplinary viewpoints, and ii) to provide the first analytical tools. The necessary background in the evolution of urban thinking, in planning tools and the institutional system for territorial government, is accompanied by history and geography studies addressed to the analysis of landscape and environmental characteristics, the fundamentals of mathematical tools, representation and cartography. The first year studies conclude with a practical experience in the Atelier, which allows students to apply the knowledge gained. The third and fourth semester activities provide students with skills in urban design (proportionate to the employment opportunities provided by the three-year BSc degree), an understanding of the field of territorial planning and its practices, and the other needed skills. These include the ability to set up a statistical survey and interpret the results, and the techniques and methods of spatial analysis using GIS. Urban design skills and knowledge relating to territorial planning practices are developed through two interdisciplinary ateliers, the first dedicated to urban design, with input from the fields of infrastructure planning and urban morphology, the second dedicated to regional planning, with elements of ecology and hydrogeology. These experiences are supported by two multidisciplinary modules providing basic knowledge, one in energy efficiency of human settlements and their environmental impact, the other in mobility and transport. The fifth and sixth semester activities help students to understand the complexity of implementation processes and to

acquire the necessary skills in this field, to experience real working conditions through an internship, and to develop a capacity for independent work in the final exam. The experience gained in the interdisciplinary atelier about local development and urban regeneration programmes is supplemented by units providing skills for evaluation of economic feasibility and strategic environmental assessment of plans and programmes, and basic knowledge of social factors that influence the territorial organisation and of the role of social participation in defining and implementing programmes.

The actual number of ECTS credits devoted to European/International issues is hardly quantifiable. However, some modules touch upon these issues and contribute to provide at least for some basic elements of EU and international planning, often in relation to their local declination. For instance, the module "institutional system for urban and territorial governance introduce the different territorial level somehow having a say in the planning activities among which the EU. Furthermore, the Atelier "Integrated programmes for local development and urban regeneration" focus on programmes of clear European inspiration. Additional insights on EU Environmental regulation are provided by the unit focusing on strategic environmental assessment.

Table 4: Bachelor of Science in Territorial, Urban, Environmental and Landscape Planning at Politecnico di Torino - Structure

Year (term)	Module	ECTS
1(1)	Planning Thought and Practice	6

5.1.2 Master of Science in Territorial, Urban, Landscape and environmental Planning at Politecnico di Torino

The Master-level course trains "planners" able to coordinate design teams engaged in territorial, urban, landscape, strategic and environmental planning[7]. As most of the key issues concerning people's lifestyles and development prospects nowadays involve urban, territorial, environmental and landscape planning and their ability to respond to crucial problems in the environment, planners' training focuses on the development of a solid multidisciplinary background that may provide them with the capability to facilitate cooperation among the various approaches, integrating the contributions of each and managing the resulting complexities. Besides, the growing importance of development models that enhance local identities in response to globalization processes, requires that planners develop strategies, policies and projects for urban and territorial transformation focusing on a proper use of local resources and involving all stakeholders (institutional, economic, social). The planner must therefore also be able to interact with non-experts and encourage their participation in the planning process. Thus the course objective is to train a figure with a broad, multidisciplinary background and a solid awareness of all the economic, social, institutional, environmental and ethical factors involved in a planning process. Graduates must pay particular attention to innovations in the institutional and regulatory frameworks governing the activities of administration, planning and design of cities, territory and landscape in both national and European Community contexts, as well as the consequent redefinition of planning processes and tools and their relationship with local development programmes.

The typical fields of activity for MSc-level graduates are free-lance practice and employment in public, private and non-profit organisations involved in the transformation and government of cities, territory and environment. Employment opportunities include local authorities (municipal, provincial, regional), municipal

[7] (For full syllabus see: https://didattica.polito.it/pls/portal30/gap.a_mds.espandi?p_a_acc=2011&p_id_cdl=&p_sdu=82&p_cds=9&p_header=&p_anno=0&p_info=&p_lang=EN)

companies, engineering firms operating in the fields of territorial, urban, landscape and environmental planning, as well as free-lance professional practice. The programme trains professional figures able to undertake research activities, or to apply existing knowledge in the fields of planning, conservation, restoration and renewal of cities, territory and landscape, performing functions that involve supervision, management and coordination of activities.

The programme centres around two formative experiences: urban planning and landscape and territorial planning. The professional profile outlined above requires the training programme to provide students with a variety of disciplinary input, as well as develop their capacity to integrate these into a global vision of complex problems. With this aim the programme is organised in two teaching modules:

a. Teaching units providing systematic knowledge that builds and expands on the diversity of disciplinary approaches needed; these units may be monodisciplinary or consist of integrated multidisciplinary courses leading to a single examination;
b. Multi-disciplinary ateliers focusing on the definition of tools for planning at different scales, and simulating, by means of input from various subject areas, the integration of a plurality of viewpoints which is required of planning teams. The ateliers have strict attendance requirements and lead to a single examination.

The activities in the first semester are designed to give students a solid background in areas closely related to the formulation of local planning policies: regulatory issues associated with planning activities, urban and regional geography and sociology of the environment. Students must also understand aspects of network and single-point infrastructures linked to solving energetic, acoustic and environmental issues, and how to integrate these infrastructures into the urban fabric. In the second semester students will simulate a process for drawing up a plan at the local level, in addition to completing their knowledge in subject areas closely related to the formulation of planning tools, such as transport planning, and gaining a solid understanding of the role of the European Union in urban and territorial policies.
During the third semester, students will gain specific knowledge in the field of land protection and water management, allowing them to address regional and landscape planning issues and interact with specialists. They will also expand their knowledge of policies and processes for territorial and strategic planning, and will simulate a process for drawing up a territorial and landscape plan. The fourth academic period is wholly dedicated to thesis preparation. Students are given an alternative between a theoretical thesis or a practical thesis which entails an internship period.

Also in this case the focus on EU and International planning issue in spread among several modules. However, it is interesting to notice how, the Master programme features also specific modules with a clear EU and International focus, as for instance Urban and Territorial Policies in Italy and Europe and Policies and tools for environmental sustainability (suggested).

5.2 Education in spatial planning at Politecnico di Milano

5.1.1 Bachelor of Science in XXX at Politecnico di Milano

5.1.2 Master of Science XXX at Politecnico di Milano

6. Do the reviewed Spatial Planning education programmes meet the requirements concerning necessary EU knowledge? Conclusive remarks and future perspectives

Before formulating some conclusive remarks, it is worth to shortly assess and compare whether EU spatial planning and regional policy issues matter in the reviewed education programmes in a way that they provide graduates with basic knowledge.

An overview about obligatory and facultative contents about required knowledge in “cultural differences in planning on a European and international level” in “political,

legal and institutional context of planning practice at international and European level" could be gathered from the table below:

Table 4: Summarized results of the case studies – AESOP requirements

Yes(E) – yes for European Level None (E)
Yes(I) – yes for international level None (I)

All in all, contents in the study programmes dealing with international and European issues are less marked than expected, though present to a reasonable extent. In the German Bachelor degree courses, Spatial Planning students are not necessarily confronted with European Spatial Planning or European Cohesion Policy issues. There is the opportunity that facultative, if a certain interest is existing, projects and/or the Bachelor Thesis can deal with those topics. With regard to the fact that Bachelor graduates can decide to start professional life without continuing studies, it is questionable if this arrangement provides them with the necessary knowledge and skill to deal with EU level issues. On the other hand, without offering any specifically devoted module, Italian Bachelor seem to be more sensitive to these issues, that are touched upon within the framework of several teaching units. This difference between the two national realities may depend both on the role planners play within them as well as on the traditional features of planning education. Furthermore, it has to be stressed that it is very rare that Bachelor graduates in planning terminate their studies, as their employment possibilities are very low due to the peculiar Italian situation.

Master programmes offer, in the German case, contents to gain knowledge in cultural differences in planning on a European and international level and in political, legal and institutional context of planning practice at international and European level, but also to a very limited extent. As far as the analysed Italian Master programme is concerned, it presents several modules touching upon EU issues, together with two

specifically dedicated modules. Whereas this provides graduates with a solid knowledge background on EU Cohesion Policy and related programmes and projects, it has to be noted that only one module is characterized by a broader perspective that goes beyond the EU borders. In respect of leadership roles of Master graduates in spatial planning working, it is strongly advisable to provide obligatory due knowledge in European spatial planning and regional policy.
In conclusion, the contents of the reviewed spatial planning study programmes seem to stress the need for specific, methodological, multidisciplinary and national legislative knowledge and turned so the scales of European contents in the new Bachelor – Master programmes. This is partly also a result of existing and binding standards study programmes need to meet concerning national associations and standards for public careers.

Nevertheless, at the next opportunity it is advisable to check whether European content could be strengthened in the curriculums. Evaluations of degree courses and graduates-surveys are good opportunities to ask students and graduates if and if yes how contents could be changed to have space for obligatory European contents.
Especially graduates-surveys should be used to get to know if they missed European issues or if training omn the job was an appropriate approach.

A short-term realizable approach to get degree courses more strengthened in terms of European issues, is to provide targeted Bachelor and Master projects and thesis topics linked with European spatial planning and cohesion policy

POLICY STRATEGIES AND DESIGN PROCESSES: COMPETING LOGICS?

Laura Coucill [1], Dr. Maria Caserio [2], Prof. Tom Jefferies [3]

Abstract

The future urban environment comprises the political trademarks of sustainability; renewable energy, high performance architecture and low carbon transport (DECC, 2008). Although polling confirms public agreement with the requirement for such trademark sustainable practices (Carrington, 2011), their physical manifestation in the landscape is often contentious and unpopular. Society's unwillingness to accept some of the more obvious impacts of sustainability policies on lifestyle and the visual appearance of their surroundings is especially illustrated by the reaction of individuals and organisations to wind farms (Chancellor, 2011; CPRE, 2010) and eco-towns (Peterkin & Hope, 2008). This dissension highlights a cultural disconnection between the causal drivers of sustainability policy and the design solutions those policies deliver.

Policy strategies for sustainability are intended to eliminate the risk of further environmental degeneration. However, written in isolation, policy objectives often incentivize sustainable economies (DCLG, 2012) relegating culturally meaningful design in favour of profit (Carmona, 2009). The effect of these priorities leads to design solutions that, although satisfactory in terms of policy requirements, foster cultural ambiguity, and are subsequently rejected by society (Hatherley, 2010). Whilst it is increasingly feasible that development in technologies, materials, infrastructure and techniques, can satisfy the performance requirements of sustainability policies, the questions remain: What are the consequences of target driven design? How does policy inform the practice of design? And, how are these schemes received by society?

Moreover is our sustainable future destined to be a windmill shaped cliché, or, can design make a difference?

1.0 Introduction

Sustainability is a principal concern in the production of architectural and urban form. Although it would be difficult to place an architectural practice that did not "profess passionate commitment to 'green' buildings" (Sudjic, 1996, p.7), as a mark of contingency and commitment toward climate change, planning policy advocates regulations and codes that set benchmarks for building design.

[1] Birmingham Institute of Art and Design – laura.coucill@mail.bcu.ac.uk
[2] Birmingham Institute of Art and Design – maria.caserio@bcu.ac.uk
[3] Manchester School of Architecture – t.jefferies@mmu.ac.uk

Regulations and codes comprise “a combination of written and graphical rules” (Street, 2006: 7) and, with regard to the design of architectural and urban form, are formalised during the design processes conducted by architects and designers. Rowe (1987, p.1) identifies that “the design of buildings can be viewed in a number of ways”. In general terms he suggests that “design appears to be a fundemental means of inquiry by which man realises and gives shape to ideas of dwelling and settlement” (ibid). To do this, design thinking requires the ability to synthesise, evaluate and resolve often conflicting requirements and objectives that comprise the design problem.

Inevitably, the products of architects’ practices are manifest in urban form and therefore have indirect implications for the societies and cultures supported by it. This raises the following questions: What impact does sustainability policy have on architectural and urban form? How does it affect architectural and urban form in terms of typology and materiality? And what are the implications for cultural representation and social use?

Historically, inquiry into the consequences of policies, codes or political ideologies has relied on the retrospective evaluation of the architectural edifices and urban patterns they have informed. Carmona & Dann (2007) note a rise in support of supplementary codes in planning policy. Often these are place-specific codes with the intention of creating desirable place (real-estate). Ostad-Ahmad-Ghorabi & Collado-Ruiz (2010) articulate that the pivotal need to address sustainability issues has led to the unquestioned application of performance-based parameters, without any indication of the efficacy of these, or, how they reconcile with the processes of the designers that formalise them.

Parallel to this, Guy & Moore (2007; also see Guy, 2000; Moore, 2007) propose that sustainability has been dominated by technical and economic performance parameters evident in policy. Principally, they suggest that this detracts attention from the social and cultural implications of design and therefore question whether performance parameters are commensurable with end use. Viewed in this way, sustainability has many dimensions and Guy & Famer (2000) indicate that for these reasons it is not measurable with the simplicity that policy implies.

Circumstances such as these indicate the imminent need to examine the effects of sustainability policy strategies ahead of retrospective opportunity (Imrie & Street, 2011). This research contributes to study in this area by examining the structure of sustainability code in the context of the design process. The research draws analogies between the structure of policy strategies and modernist rational design processes. It considers possible tensions between the two paradigms, looking specifically at the consequences of this for typology and materiality of design solutions.

2.0 The Structure of Policy Strategy

Stemming from a global concern for climate change, the need for sustainable architecture and urban form originates in international agendas to reduce harmful emissions. At the building scale, this has resulted in the emergence of regulations and codes that set performance efficiency benchmarks as an aid to substantiate claims of 'green' building. According to the Building Research Establishment [BRE], their Environmental Assessment Method [BREEAM] is the "leading and most widely used environmental assessment method for buildings" (BRE, 2012a). Dwellings are commonly assessed using the Code for Sustainable Homes [CSH], also initially developed by BRE. Both are endorsed by legislative planning policy (DCLG, 2012; BRE Global, 2010), which encourages their adoption in the early stages of building design.

BREEAM	Score
Outstanding	85
Excellent	70
Very Good	55
Good	45

CSH	Score

Pollution	10	2.8
Total	100	100
Innovation (additional)	10	

Figure 1. BREEAM performance ratings, categories and credit weightings.

The categories presented in figure 1 provide the framework for a point-based system that measures performance. The system has "three main functions: simplification, quantification and communication" (Kirkpatrick, 2009, p.18). Effectively, they are designed to provide a comprehensive construct of reality (ibid) and in doing so it is assumed that point-scoring is causal. This means that the complexity of reality is reduced to a linear system in which the code implies more points equate to greater sustainability, regardless of design processes or subsequent utilisation (Carmona, 2004).

In summary, sustainability codes are "de facto measure[s] used to describe a building's environmental performance" (BRE, 2012a). To do this they simplify and quantify expectations of reality in order to make predictions about the performance of a building; offering certainty that emissions will be reduced and therefore the resultant building minimizes its negative impact on the environment. In turn, this validates that progress is being made towards meeting overarching targets such as the Climate Change Act. In short, the relationship between cause (the targets of

objectives) and effect (the consequences of meeting targets) is linear for the purpose of comprehensibility and predictability: The primary effects of objectives are therefore the raison d'être of policy, explaining the significance and emphasis of codes as planning and design devices.

3.0 The Structure of Design Processes

Design process refers to the sequences followed by designers to arrive at a design solution. Design methods are descriptions of the tasks performed during the sequences. Whilst "designers are traditionally identified not so much by the problems they tackle as by the solutions they produce" (Lawson, 2006, p.53) the design process initiates with the design problem.

For architects, the client commonly delivers the design problem. Lawson (2006, p.58) points out that, "design problems are both multi-dimensional and highly interactive" and he suggests that the requirements of the client form only part of the problem, with other stakeholders in addition to the site context and policy requirements contributing to the many dimensions and the complex relationships between them. Forty (from Clark & Brody, 2009, p.16-19) adds to this his conception of design solutions as expressions of society and politics: He considers the designer as the translator of these ideas into objects. From this, it is visible that there are many considerations and constraints in the design problem; too many to map, and some that are never consciously conceived.

During the mid twentieth century, a body of research emerged that specifically addressed design problems in a search to establish a universal method for problem resolution (see, Broadbent, 1969; Moore, 1970). This was sparked by Herbert Simon's (1947) conviction that the human mind was limited in its ability to resolve multifaceted problems that arose in modernizing society. Consequently, a plethora of theories emerged; from Alexander's (1964) formulaic tracing of all components and subcomponents in a problem, to Rittlel's (Protzen & Harris, 2010) concept of wicked problems that acknowledged large areas of uncertainty in design problems. This modernist movement of design methods seemed to prove that the human mind was not necessarily limited in its capacity to solve problem, as much as it was limited in its ability to identify every aspect of large complex problems.

Wahl & Baxter (2008) identify that the wicked nature problems (in terms of problem ambiguity) is still prevalent in design issues that arise from the desire for sustainable architectural and urban form. Defining design solutions is therefore an ineffable task that involves complex, non-linear thinking (see Teal, 2010) to resolve multiple constraints.

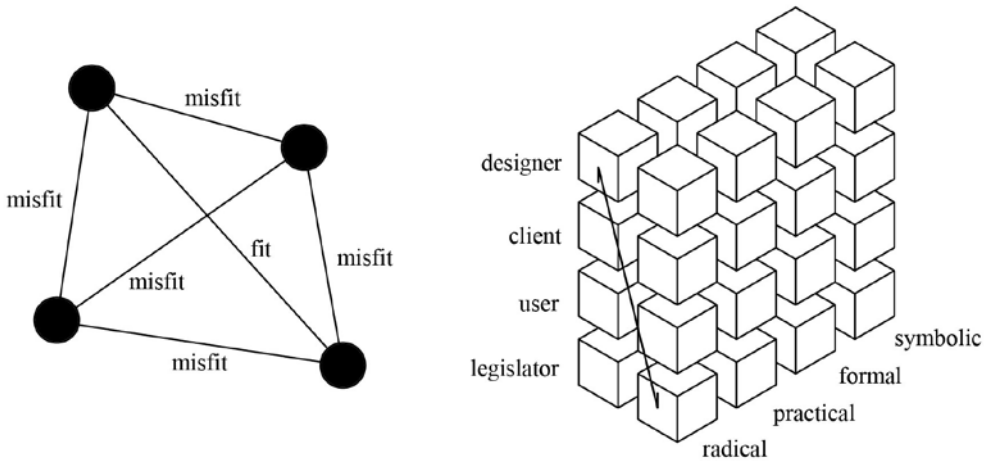

Figure 2. Paradigms of Design Problems
Left: Christopher Alexander's perception of design problems (1964, p.2).
Right: Lawson's model of constraints that structure design problems (2006, p.106).

4.0 Comparing Structures

The view of the architect as "heroic form giver" (Bentley, 1999, p. 28) supports the misconception that the architect operates autonomously. This is a sentiment recently resonated by Professor Carlos Ratti where he described the Le Corbusier as having the "hand of god"[4] (Ratti, 2012). The purpose of this was to point toward increasing integration of technology in design process and inevitably in design solutions. In a similar vein, Yaneva (2009, p.102) conveys; "the master architect is not a lone genius", they are in fact supported by the design team that surrounds them and importantly for Yaneva, the materials they use.

For Imrie (2007, p.926) this misconception of the role of the architect obscures the reality that architects and urban designers are dependent on external forces (discussed in section 3.0) and with this he makes specific reference to the "rules and regulations that codify and regulate architects' practices". These two perspectives present "architecture [as] a dependent discipline" but also "as [a] profession and practice … which does everything to resist that very dependency" (Till, 2009, p.1): A paradox which suggests that design and policy have perennially been at odds.

[4] Professor Carlo Ratti put forward this view of Le Corbusier in a presentation made at the Smart Cities Conference, University College London, 20th April 2012.

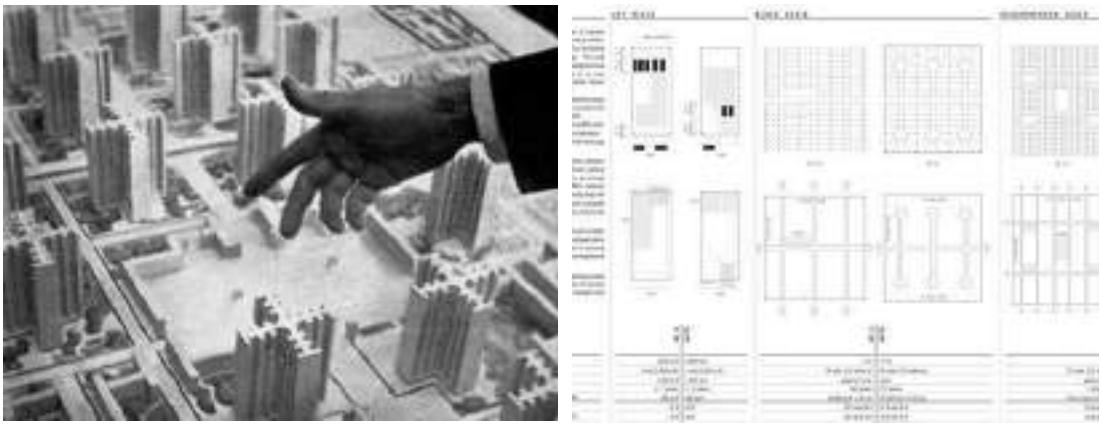

Figure 3. Who's in Charge Here?

Section 2.0 presented the structure of policy: Revealing how current objectives for sustainability are predicated on comprehensive, deterministic logic and deriving optimum solutions. In this regard, it addresses the design process as a 'black box' (Jones, 1992), and assumes that the output from the box will perform in the manner anticipated by the input.

Section 3.0 presented the ineffable nature of design process: It showed that present understanding of design problems were predicated on models that referred to the relative flexibility of constraints within those problems, of which, legislation was the most rigid.

This builds up a picture of two contrasting logics: Of the linear and deterministic objectives of policy, and of the entangled complexity, minimally structured, processes of design. Furthermore, it is a contrast analogous to the tension between "biological determinism … and free expression" that Colquhoun (1969, p.73) observed during the height of the modernist design methods movement.

Rational design methods, Colquhoun identified, were derived from biological determinism: This is the idea that the genotype of an organism is the sole informant of its behaviour and its development. It contrasts with the findings of D'Arcy Wentworth Thompson's (1917) allometric study, which indicated that environmental forces were determinants of an organism's structure. Nature, seen to 'design' itself (freely self-regulate and adapt), has frequently served as an ideological model of design as both noun and verb. Therefore, applied to design method, for design theorists such as Tomaś Maldonado (1972) biological determinism defined the need to map the genetic makeup of design problems in order to derive the optimum solution.

The problem with this was that the process of defining the whole design problem was untenable. The consequence of this for design solutions was that "without sharper tools for analysis and classification, the designer tends to fall back on previous examples for the solution of new problems" (Colquhoun, 1969, p.71). Putting forward a remedy, Colquhoun contended that the "exclusion" of conventions, would challenge the "reduction" of traditional typologies that prevailed in solutions.

"*The process of change must involve a dialectical relationship between those parts of the system that are resistant to change (because they are conventional) but changeable (because they are arbitrary); and those parts of the system which depend on natural laws which progressively come to light under the pressure of new technology*."

(Colquhoun, 1969, p.74)

In contradistinction to Simon's (1947) conviction that human intuition was incapable of dealing with the complexities that comprised modern design problems, Colquhoun proposed that intuition, unleashed from convention could address consistently changing circumstances.

Policy criteria could be considered analogous to Alexander's (1964) rational methodology: In *Notes on the Synthesis of Form*, the design problem is aggregated into constituent components that make up the whole. Any sub-problem in this system can exist in the binary states; 'fit' or 'mis-fit'. Each problem must be resolved to an equilibrium in which all components 'fit'. Although Alexander later readdressed this proposal (Alexander, 1966), Lawson (2006) discredits the original for its equal weighting of problems because he considers that designers often make unconscious judgments about the relative significance of issues to be resolved.

Whilst rational design methods may have been discredited, their formulaic approach to design is analogous to the performance-based parameters defined by sustainability polices and codes. Referring to the US LEED system, Garde (2009, p.438) points out that assessment methods for sustainable development often evaluate factors of the built environment equally, "because it is difficult to determine the relative importance of criteria" out of context: He conveys that the variation in location and design requirements make it difficult to tell how much specific objectives in the code will contribute to sustainability in a specific circumstance. Notwithstanding this, the point based system of codes weigh parameters equally.

Parallel to this, Wahl & Baxter (2008) argue that the parameters set by sustainability policies pursue environmental performance objectives potentially at the expense unquantifiable requirements. They recognize that the environment undergoes continuous adaptation, identifying that sustainable development is commonly appreciated as equilibrium between society (and its systems) and nature: It is considered a process of communication and adaptation analogous to that of evolution. In this respect sustainability cannot be explicitly determined as a sequence of objectives that represent social, economical and environmental requirements,

because the nexus of values it constitutes are constantly evolving. (ibid, p.72-73)

5.0 Design Workshops

Taking precedent from studies of the effect of constraints on the design process (see, Chan, 2001; Ostad-Ahmad-Ghorabi & Collado-Ruiz, 2010) a series of workshops were conducted to gather data that would allow further inquiry into of the implications of policy strategies and design processes.

Three workshops were held in 2009 and 2010. Two of the workshops involved undergraduate, cross-disciplinary art and design students in their second year and one comprised postgraduate students in architecture who also had experience in working practice. Many of the postgraduate students studied part time, working in practice for the majority of the week. Postgraduate and undergraduates participants were specifically sought for their anticipated distinction experience and knowledge.

Workshops took place in the first semester of the year and spanned a twelve-week period, meeting for three hours each week. During the meeting hours, design activities were conducted, which included group discussions and brainstorming for generation of ideas. Participants were provided with a framework within which they would generate their own design brief including the context which it addressed. This was intended to resemble the format of the RIBA Plan of Work (2007; illustrated in Figure 4).

	RIBA Plan of Work (to stage E)		Workshop Framework
Preparation	A	Appraisal	Define Sustainability
			Acknowledge Legislation
			Explore Problems
			Examine Precedents
	B	Design Brief	Compare Problems and Precedents
			Identify Design Task
Design	C	Concept	Generate Design Proposals
	D	Design Development	Design Development
	E	Technical Design	Solution Justification

Figure 4. Workshop format in the context of the RIBA Plan of Work (2007).

Outside of the workshop hours participants progressed their designs, documenting thoughts, research and analysis that helped formulate ideas and formalize design solutions in design reports. Progress was presented and discussed each week. Finally, at the end of the workshops, participants produced a 500 word summary of their design and the reasons they considered their design to be sustainable in accordance

with the code. These presentations and written statements form part of the data, combined with notes that document verbal presentations.

Central to setting their own design brief, participants were required to identify the problem to be addressed. At the outset, this involved asking participants to provide personal definitions of sustainability. Parallel to this, all participants were encouraged to consider what sustainability meant for society in the context of urban form. No limits to the term 'urban form' were implied and as a result of this, the solutions produced were naturally varied. A total of 31 projects were produced, of these, 17 concerned building production or physical changes to urban form. This equated to 50% of undergraduate designs critically focussed on built form, compared to 80% in postgraduate proposals.

Figure 5. presents key information about workshop participants and the solutions they produced. Firstly, it provides a breakdown of the mix of disciplines involved in the workshops. Over half the participants involved studied architecture, and although roughly the same amount of designs produced concerned architectural and urban form, the type of solution produced did not necessarily correspond to the discipline of the participant.

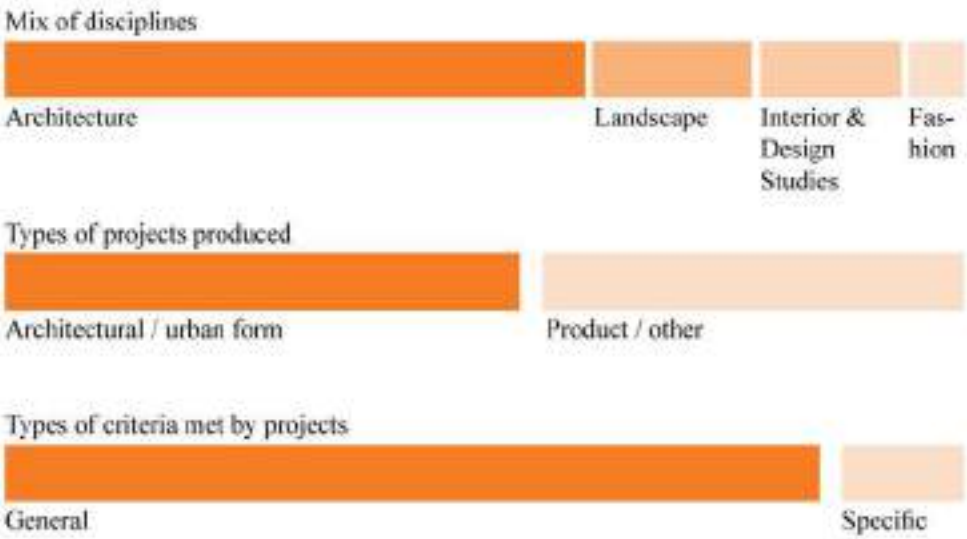

Figure 5. Quantitative summaries of participants and solutions.

Solutions could be divided into those that met general criteria, and those that were more specific about responding to particular regulation and code criteria. Here, 'specific' refers criteria derived from the technical documents of the Building Regulations, BREEAM and CSH. 'General' refers to umbrella targets, such as the Climate Change Act (2008).

5.1 Outcomes of Specific Criteria

Postgraduate participants took a greater interest in the specifics of code, with a 50/50 split between general and specific in this group. It is assumed that this related the more advanced experience and knowledge of practice and the discipline in general of postgraduate participants: Therefore, the codes they explored and the solutions they proposed were a consequence of the nature of the problems they typically address on a daily basis.

Only one undergraduate project met with specific criteria. This project met specific criteria by making a polemic statement about the nature of policy: They projected that the most simple method by which to meet policy criteria was to replicate existing precedents. In this case the participants proposed that new buildings could be designed by compiling elements already proven to satisfy regulation, taking into account only generic contextual conditions, most of which related to climatic conditions. Additionally, their work stretched to suggest a sample of retrofitting techniques that could bring existing building stock up to current specification. Building variations and components were proposed in a catalogue from which prospective clients could affectively assemble their own building from prerequisite, BREEAM certified parts. Solutions that comprised contextual interventions were not so far removed from this polemical statement:

The Compositional Paradigm
Materials and technology were prevailing concerns in three of the four projects that followed specific criteria. From the projects collated, it was clear that in addressing specific criteria certain building materials and technologies implicitly related to meeting particular code criteria: In these circumstances, the process of design becomes one in which relevant materials and technologies are assembled in the best possible way in relation to the site. A compositional design paradigm, therefore, provides the predictability necessary to acknowledge (measure) direct links between input (code) and output.

From the workshops it emerged that there were two consequences of this (see Figure 6): Designs either appear indistinguishable; often adopting desirable vernacular typologies and relying on materials to improve energy efficiency and performance, or, design adhere to contemporary typological conventions, incorporating often visible, technological additions that satisfy policy criteria. This is an observation which is not only visible in the design solutions produced in the workshops, but on that is also prevalent in built examples of sustainable architectural form, in particular the examples displayed at the BRE Innovation Park (see Figure 6).

Figure 6. Exemplar sustainable homes at the BRE innovation park:
Left: The undistinguishable - The Prince's House, The Prince's Foundation (BRE, 2012b, p.26-27)
Right: The conspicuous - The Sigma House, Rexel Energy Solutions & Stewart Milne Group. (BRE, 2012b, p.20-21)

5.2 Outcomes of General Criteria

Consensus among projects that explored general criteria acknowledged sustainability as a need to reduce greenhouse gas emissions. Not only did they generalise their proposals to this broad target, but also in doing so, they adopted or challenged no more than four approaches to reducing emissions (see Figure 7).

With general criteria, there was also a clear link between input and output, which drove subsequent design processes. Participants defined sustainability at the outset of the workshops in one of two ways: Providing descriptive definitions of problems, or by identifying precedent solutions. Those that provided descriptive accounts of sustainability tended to focus on society's relationship with emissions. Much of this work made observations about the tensions between the need to propose fundamentally different strategies for future living, within the existing urban context. Solution-orientated definitions in many cases included popular building precedents marketed for high BREEAM, LEED and Green Star ratings.

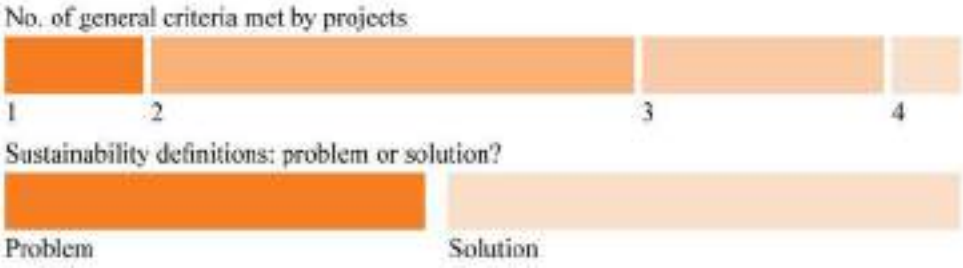

Figure 7. Sustainable criteria and definitions

Participants with descriptive accounts commonly observed problems and proposed problem specific solutions. This paradigm will be referred to as the observational paradigm. In contrast, participants that provided solution-orientated definitions of sustainability went on to produce designs that that shared remarkable similarities with the precedents identified and explored in the first week. This paradigm will be referred to as the iterative paradigm.

The Observational Paradigm

In the observational paradigm participants examined existing theories and definitions of sustainability in the first week, expressing tensions between these and current social and cultural attitudes towards sustainability. Design processes in this paradigm examined the tension identified and explored a variety of design fields searching for precedents of similar problems, rather than looking for solution precedents (as can be seen in the iterative paradigm). The outcomes in this paradigm displayed varied characteristics and consequently, these types of solutions divided relatively equally between built and urban proposals and otherwise, though this corresponded to 55% of participants producing a solution that didn't reflect their original discipline (see Figure 8).

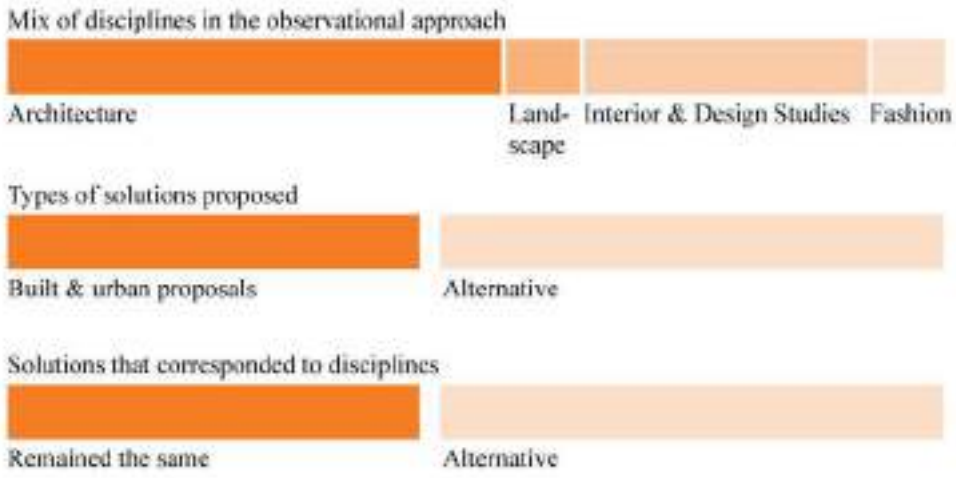

Figure 8. Solutions and comparative disciplines of the observational paradigm.

The Iterative Paradigm

Designers that followed the iterative paradigm presented solution-orientated precedents of design (in a variety of scales and products; from buildings to household items) already nominated 'sustainable'. They tended to present key facts concerning these artefacts and edifices, as though these were definitive descriptions of, or solutions to, sustainability. Following their exploration of sustainable precedents in the first week, designers that followed the iterative paradigm sequentially produced variations on the themes addressed by their selected precedents. Notably, their design

solutions, deconstructed into components, showed in many cases, marked similarities to the images that had been presented at the outset. Accordingly, solutions tended to be built or urban forms since built form prevailed at the outset. In marked contrast to the observational paradigm, participants that demonstrated the traits of the iterative paradigm, tended to produce solutions within the realm of their original discipline.

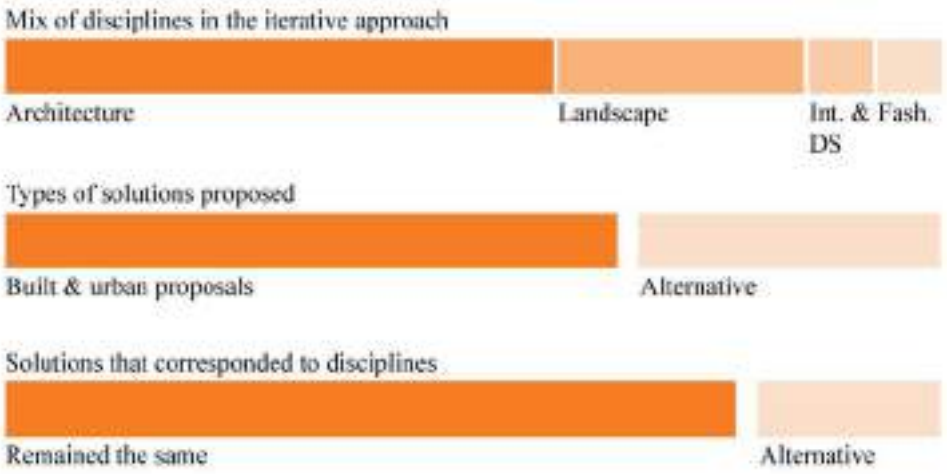

Figure 9. Solutions and comparative disciplines of the iterative paradigm.

5.3 Discussion and Evaluation

Coleman's (2005) inquiry into *Utopias and Architecture* articulates how design ideals for architectural and urban form are preoccupied with uniting fragmented theories and forms as well as providing contingency. The theoretical appetite for coherency stems from the often incomprehensive-messiness of reality (in this case specifically of cognitive design processes. Till, 2009). Referring to Zygmunt Bauman (1991), Till (2009, p.28) argues that ideals are born out of a fear for uncertainty, therefore, the ordering of architectural and urban form is a means of making sense of civilization and shaping a more predictable future (Bentley, 1999, p.27). The results of workshops carried out support the principle that codes and coherency are idealistic bedfellows.

In similar research, Clevenger & Haymaker (2011, p.449), in addition to Ostad-Ahmad-Ghorabi & Collado-Ruiz (2010), provide statistical analysis to show a link between sustainability codes and a reduction in creativity. Their statistical approaches require the quantification of creativity, and as such these examples have particular interests in examining the cognitive processes as much (if not more) than the outcomes of those processes. They consider that the nature of design policies, as "incremental approaches" is isolated from the creative and predominantly social process of design (ibid, 2010, p.480). They argue that design policies for sustainability are predefined by existing technological conventions that influence typology, materials and function. They suggest that policies (or 'eco-design strategies' as they refer to them) are driven by economics and the requirements of the

market. As such, these forces encourage the specification of materials, the reduction of material consumption and performance targets such as strength or capacity to retain heat. Simply put, they infer that the object to be designed is often predefined and that code is simply used as a means of environmentally considerate refinement and measurability.

Predictable design outcomes are useful for measuring sustainability. However, as Guy & Farmer (2000) indicate, it does not necessarily respond well to user requirements or future needs, nor, as this study has shown, do they produce the most innovative results.

6.0 Conclusions

The research set out to examine the consequences of sustainability codes for design. It identifies that codes present well-defined problems. For example, they refer to specific building elements, and impose targets or limits on the performance of that element. In this regard, sustainability codes are predicated on a form of logic that demands linear and causal outcomes, enabling design solutions to be measureable against those outcomes. In contrast to this logic, the paper has also shown that the design processes of architects and urban designers are ineffable activities in which sustainability codes are formalized. This presents a 'black box' in which code is input in the setting of the broader design problem, its constraints and requirements.

Workshops provided a test bed for the hypothesis that architects and designers in the construction industry would produce more predictable outcomes when responding to policy criteria. Trends in the data indicate the validity of this hypothesis, and suggest that certain methodological approaches to design, in addition to cross-disciplinary influence, tend to produce more innovative solutions to sustainability policies. It follows from this that the logics of policy strategies and design thinking play a principal role in driving sustainability. Consequently, this paper suggests that the complex and non-linear process of design thinking could be said to conflict with the linear mechanisms and causal expectations set out in design codes:

Research findings suggests that where a greater number of specific design codes are imposed on the design process, the design outcome appears to be more predictable (conventional), meaning that the design solution often looks familiar and uses technologies and materials in a intended manner. Where targets were less specific, design solutions tended to demonstrate a broader exploration of the fundamental problem and propose designs based on observations of how domestic and urban environments were currently utilized by society. Rather than exploring how to apply conventional technologies and materials, designers appeared to explore alternative fields in order to produce unique solutions. This aligns with Lawson's (2006, p.43) view of design as a solution finding process. Lawson proposes that, by comparison to scientists, who tend to "[focus] their attention on understanding the underlying rules" architects can be seen to focus on "achieving the desired result" and with this

technique, designers are suited to solving ill-defined problems (see, Horst Rittel's definition of wicked problems in Protzen & Harris, 2010).

The results of this research show that codes, set out in a format that specifies many specific performance requirements, encourage the scientific problem solving method: This means that code, forces designers to pay attention to the underlying rules (defined by the code) of sustainability. In this context, codes are supplemented by guidance produced from within the professional institution and elsewhere that indicate suitable approaches, technologies and materials that can help meet code criteria. Consequently, design outcomes embody these techniques and at the same time are constrained by the possible combinations of solutions offered by these techniques. The benefit of this is that design is more easily measurable, but nevertheless, predictable.

Predictability, as Colquhoun (1969) proposed can be considered as the repercussions of the competing logics of rational methods (in this instance policy) and the reliance on the knowledge of past solutions as function of traditional design technique. In contemporary circumstances it could be argued that precedents and tradition are further encouraged by guidance provided professional institutions and QANGO's.

Sustainability requires drastic change. However, policies pursue rather incremental changes. If design process and code remain in conflict such changes are unattainable. This research provides proof of principle that design can make a difference.

Integrating the water demand approach in the planning practices to face drought risk in the Potosí district (Bolivia)

Guido Minucci[1], Lorenzo Chelleri [2]

Abstract

There is not agreement with reference to drought definition (Palmer, 1965; UNCCD, 1994; Wilhite, 2002; Mishra and Singh, 2010) and it has direct consequence in the lack of a common and shared strategy to cope with such hazard. Nevertheless, drought can be considered as a typical slow-onset phenomenon, which operate at different temporal scales, from days to years and these are relevant depending on water resources and uses of interest. The traditional supply-driven water management approach views the water needs of the community as "requirements" that must be met and not the "demands" that are changeable (Gleick, 2000; White, 2006; Kampragou et al., 2010). This traditional approach has led to over-use of the resources, overcapitalization, pollution and others problems of varying severity (Pahl-Wostl, 2007). With reference to our case study, we illustrate the analyses of different applied measures related to the water demand approach to increase the resilience of the community in the area of Uyuni and Tomave (Potosí district, Bolivia) to face droughts and desertification. On one hand, the local knowledge integrated with expert knowledge have been used to develop an early warning system in order to monitor and provide early warning of an emerging drought to avoid or reduce the impacts of a drought event. On the other hand, within the water demand approach, a water pricing policy and a water meter campaign have been put in place to count the amount of water used by different users and to reduce wastage of water. Moreover, international support programs are implementing both irrigation systems to support the rain-fed agriculture and a more sustainable land use management to cope with future drought events and climate change effects affecting, in particular, water availability in this area. Consequently, the study highlights how the need to built resilience in water demand poses the challenge of building integration between the water sector and development planning, which are traditionally separated domains. Moreover, it underlines the importance of a shift from a reactive approach, which is still widely applied in Bolivia, to a proactive hazard management in order to cope with future events.

1. Introduction

A clear, universal and shared definition of what can be labeled like drought has not been achieved yet (Palmer, 1965; UNCCD, 1994; Wilhite, 2002; Mishra and Singh, 2010). Nevertheless, looking into drought definitions, two main categories can be highlighted: conceptual and operational definitions. The former states in relative terms (e.g., a drought is a long, dry period), while the latter aims to identify the onset, severity, and termination of drought periods. Drought is often referred to as a creeping phenomenon due to the fact that the onset as well as the end of a drought are difficult to determine, the impacts of a drought increase slowly, often accumulate over a considerable period and may stay for years after termination. Consequently, it is necessary a change in the way of managing water as well as its integration within a participated spatial planning to assess the implications for water of new developments, proposed changes in land use and to adopt a proactive approach in order to face such risk.

2. Description of Study Area

The municipalities of Uyuni and Tomave lie in a plain at an elevation of 3,700 m above sea level in the (Potosí district, Bolivia) in the Southern Bolivian Altiplano. The altitude of the plateau as well as the presence of the Uyuni Salt Flat with a surface of 12.500 km2 affect the weather and define many of the ecological aspects of the area. The area is characterized by an arid climate, with extreme temperatures that range from -20°C to 30°C. The air is thin and transparent, thus the irradiation is high, while humidity is low reducing heat diffusion. Furthermore, winds in the region are very strong (can reach speeds exceeding 90 km/hr) all year, which have a relevant impact in terms of soil erosion. Consequently, a negative evapotranspiration and a deficit in rainfall (around 150mm per year) bring prolonged drought, cause a very irregular rainfall. The probability to have a drought event in this area is one every two years (Statistic Service of Potosí District, 2011). Moreover, a high solar irradiation combined with wind cause rapid evaporation.

3. Climate Change Effects

The Bolivian population has always been exposed to extreme hydro-meteorological and climate variability, particularly the influence of El Niño (ENSO), which regardless of climate change occurs periodically in different areas of the country (World Bank, 2010). According to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC), arid and semi-arid regions are particularly sensitive to possible decreases in rainfall. The IPCC (2007) estimates that increasing the temperature to South America will be between 1.8°C-4.5°C and precipitation changes from -12 to +12% by 2080. Although the manifestations of climate change in Bolivia are still little studied, the contributions are based on: a) scientific observations point b) local perceptions little systematized, and c) generated according to climate models that still have high levels of uncertainty. Besides

demonstrate acceleration in the increase of temperature, Vuille & Bradley (2000) and Francou et al. (2003) observed a clear relationship between the melting of glaciers and El Niño events. Also, a study of the National Climate Change (NPCC, 2007) complements this temperature rise in the Andes from observations on the incidence of malaria in highland communities. The IPCC (2007a) adds that the increase in atmospheric temperature has led to an acceleration of glacier retreat in the Andean region, with consequent impacts on water availability and the generation of hydroelectric power. According to Ramirez et al. (2001), higher temperature increases in the coming years will affect considerably the Andes. This statement has is sustained by a recent report regarding the effects melt glacier phenomenon on the communities living in the Bolivian Altiplano (Agua Sustentable, 2010). Whereas, in a study related to the impacts of climate change on the rainfall trends in Bolivia, Seth identifies a decrease in precipitation in spring (September-November), which would affect the water resources. This trend is coherent with what has been observed by a study conducted by the PNCC (2000) based on the Normalized Difference Vegetation Index (NDVI) showing a reduction between the months of September to October and increased in the month of November, which evidence of a shortening of the rainy phase. Consequently, such decline would be exacerbated by lack of management strategies, information on climate change and institutional constraints. Therefore, in this context, mitigation and adaptation mechanisms for sustainable management of water resources are critically needed.

4. Water Management: Changing Paradigm

The traditional supply-driven water management approach views the water needs of the community as “requirements” that must be met and not the “demands” that are changeable (Gleick, 2000; White, 2006; Kampragou et al., 2010). Gilbert White (2006): “The old paradigm of designing the cheapest reliable supply with little attention to demand determinants, pricing structures, and financing policies is no longer suitable. Moreover as it has been recognized that the traditional approach is unable to cope with rising water demand and meet changing standards in water uses (Kampragou et al., 2010). This traditional approach has led to over-use of the resources, overcapitalization, pollution and others problems of varying severity (Pahl-Wostl, 2007). Gleick (2000) underscores the significance of demand management, as a tool for adaptive water management, since the construction of large-scale water supply is hindered by social, economic and environmental constraints. Furthermore, given the nature of developing nations, much of the “saved” water will immediately be used by others, most obviously by “tail enders” on the irrigation canals or those with inferior riparian rights, or by women and small farmers who previously had less water than they needed for their livelihoods (Gumbo et al., 2005). A shift toward a water demand management approach may produce important impacts, such as enhancements in economic, social or gender equity, although the direct outcome is not an absolute reduction of water use. Hence, WDM do not aim just to change quantities and distribution of water, but if realized in appropriate ways it may have even impacts on the environment as well as enlarge participation in decision-making process.

4.1. Water Monitoring and Water Pricing

In the planning documents of the municipality of Uyuni which defines the vision for the future of the city, it is underscored how the sustainability of the water distribution service is still very fragile due to lack of investment to cover the largest percentage of claims and further the cost of water is based only on a low water consumption (PDU, 2007). Any differences in prices due to water usage in peak-hour usage or exceed amount of water consumed can be underlined and such regulatory practice is not taken in consideration for the future. Water pricing should be considered as a mechanism aiming to financial sustainability instead of a tool to regulate water allocation. Only if the financial costs are recovered can an activity remain sustainable (Savenije and van der Zaag, 2002). In 2007 the Water Cooperative of Uyuni (WCU) distributed through the pipeline water to 3,300 homes with a fee of 6.00 bolivianos (Bs) per five cubic meters of water. As underscored by WCU during the interview (09.2011), since 2007 to July 2011 the fee increased to 10.50 Bs for 8cm3, while, today, the price has risen at the quota of 13 Bs per eight cubic meters of water, which is the monthly average consumption per a family composed by (4-5 people). Furthermore, in 2007 only the 30 % of beneficiaries had a water meter, whereas since July 2011 a project (ending in 2013), which aims to install water meters in order to cover all the beneficiaries and to monitor the water consumption, has been up in place in Uyuni. Indeed, as pointed out by WCU the actual fees do not cover service costs. Thus it is necessary to regulate consumption (billed authorised consumption and unbilled authorised consumption) and revised the apparent losses unauthorised consumption and metering inaccuracies due to lack of investment to cover the largest percentage of claims and the cost is considered low for water consumption.

4.2 Education and Capacity Building

The Water Cooperative of Uyuni in collaboration with the municipality of Uyuni have identified and listed the priorities both for urban and rural area which aim to strength drinking water requirements, minimum equipment support for operation and maintenance as well as tracking and monitoring to ensure water quality (drinking). While, in rural as one of the main priority is to develop information campaigns to improve the sustainability of water projects and to involve a wider number of communities to contribute to exchange experiences between different programs working in drinking water and sanitation in the rural area. Notwithstanding, as stated by Gumbo et al. (2004), an important element in water demand management is to examine skills and the training needs of who compose and carry out water management programmes. Consequently, trained users and manager are a key factor to develop a worth conservatory plan. Since 2011 a project to increase the awareness of stakeholders, mainly with reference to householders and tourist facilities owners, has been promoted by the Water Cooperative of Uyuni. The campaign based on advertisement shows how the water-saving devices can contribute to saving water and promotes their installation. Awareness of rights and obligations by water users is

usually not so high. Thus, information campaigns on water-saving options at home, education programmes in schools and financing educational programmes among different stakeholders can stimulate a more active public participation in water-saving effort.

4.3. Water Management: The issue of water quality

The difficulties in the lack of coverage and quality of drinking water is a cause for the municipality low health profile, even if some differences can be highlighted between urban and rural area (PDMU, 2007). In the municipality of Uyuni the percentage of potable water coverage by pipes is around 69.32% while the different boroughs have the following drinking water coverage: 48.33% Coroma, Chacala 50%, 25% and Pulacayo Sows 90% (INE, 2005). Furthermore, the water supplied is not secure, there is neglect in the chlorination and disinfection, residual chlorine do not guarantee a permanent, operation and maintenance are not adequate, which means a growing deterioration of drinking water systems. Water pollution is one of the main problems and due to it is estimated that 80% of diseases are waterborne, childhood diarrhea are the leading cause of death (PDMU, 2007). Uyuni belongs traditionally to the mining sectors and the characteristic of such activity is to have a highly polluting discharges of acid mine drainage.

Table 1 – Housing Conditions in Uyuni (INE - Statistic Municipalities Atlas, 2005)

Furthermore, as it can be seen in the table 1 there is a relevant lack of a proper sanitary sewer system. In the town of Uyuni the extension of the water net is around 33%, while household connections reach 22% and the municipality does not have any wastewater treatment. It is worth noting that, on one hand, the municipality does

not have any wastewater treatment; while, on the other hand, even if 60% of the garbage is organic matter, the remaining 40% is composed mostly by solid waste such as household, commercial, hospital, industrial, which are deposited in rivers, streams aw well as vacant lots and uncontrolled dumps resulting in an overall deterioration of the environment. While in the rural area *"curaca cobrador"*, who is elected by the community and is in charge for one year, has to manage and control of water distribution. In the rural area of Tomave, water to people living in villages is provided by two different systems: on one hand, piped system distribution, which delivers water to 1671 houses located in a village (44.8%); on the other hand, *"mingitores rusticos"* (well), which serves 685 houses located in a village (18.3%); whereas people do not live in villages extract water mainly from streams (36.1%) or *"ojos de agua"* (springs) (Table 2).

Table 2 – Housing Conditions in Tomave (INE - Statistic Municipalities Atlas, 2005)

Furthermore, the data related to number of houses having a kitchen or a bathroom should be read in favor of the presence in the house of a kitchen as result by informal interviews done to local people in 2011 in the municipality of Tomave. Quality is a major problem even in the rural areas due to lacks both of quality management trainings to people and water quality instruments. The quality of water distributed is low because of its provenance from wells or springs and so it result not to be drinkable (chlorine) and to be sources of infection for people living in this region. Moreover, a decrease in precipitation, along with climate warming, may affect negatively the quality of water in rivers. Reduced water levels mean that pollutants

from point sources will become more concentrated. Consequently, in an area where the availability of water is already scarce, the amount of water available is unknown and a such situation of low water quality, an early warning system plays a key role in order to reduce the degree of the impact of a drought event, which has a probability to occur one every two years in this area (Statistic Service of Potosí District, 2011).

5. Quinoa, land degradation and desertification

Contemporaneously, the cultivation of quinoa, a grain-like crop farmed primarily for its edible seeds, is provoking changes in the land use with direct effects on the quality of the soil and indirect effects increasing drought vulnerability. Quinoa has been one of the main ingredients at the base of the Andean farmers' diet for thousand of years. Traditionally, the cultivation of quinoa was aimed at auto-consumption and the whole production process was conducted manually according to a well-defined methodology, which schedules to leave the land uncultivated for a long time. Such fallow period, around one year, has different purposes, such as restore soil fertility after harvest, and reduce the probability of disease. Although the most relevant is to accumulate water in the soil in order to sustain quinoa production characterized by using 2 years of rainfall during its growth period. This process requires at least 10 years due to the slowness of biological processes at this high altitude (Joffre and Acho, 2008). Nowadays, the role and the strategies to cultivate quinoa have been changed completely. Nevertheless, as consequence of this appraisal, a remarkable spread of the cultivation is imposing a relevant transformation in the land use of the countryside and in the social behavior. The high demand of the international market for this crop has increased the international prices. The price of quinoa sold by the farmer has almost tripled from 1999 to 2008, up to USD 2300/t (MDRyT, 2009). It pushes the producers to an extensive and unsustainable exploitation of soil and water due to a widespread and intensive one-crop agriculture in favor of the quinoa's export. Consequently, farmers' communities are loosing the sense of being a community, which was characterizing this region, in favor of a more individualistic (or family) interest. Further, farmers prefer selling it and buying less nutritious food for themselves (Hellin and Higman, 2005). Moreover, people attracted by the high price at the market of this product comes back in their villages of origin from the Bolivian cities for some months to cultivate quinoa to gain some money by selling this product without any kind of respect for this vulnerable land. Such attitude belonging to these people leaves the local communities to deal with the consequences of an inappropriate way of cropping, which is reducing the pastures and water for lama as well as accelerating the land degradation and desertification process. As result from the study developed by the Ministry of Planning for Development (Ministerio de Planificacion del Desarrollo), the desertification phenomenon covers 100% of the Potosí Department (MDSMA, 1996). Furthermore, to satisfy the rising world market demands the cultivation strategies have been changed. Firstly, crop-farming approach is moving from the ancient manual practices toward mechanized production system. Secondly, the increased use of tractors, especially with the disc plough and the sowing machine, has led to a severe degradation of soil fertility (PIEB 2009). Such practises have triggered a series of

changes that have aggravated the problem. These changes are: a) the rapid expansion of the agricultural frontier, b) the degradation of the vegetation and soil, increase in wind erosion, c) changes in surface albedo, d) increased frost and increased attacks on crops from pests and insects. All this has had adverse effects on agricultural yields and has also contributed to the process of desertification (Monasterio and Andresen, 1996). In 2010 several local institutions in coordination with local farmers have developed a project base on the plantation of *thola*, a native shrub that covers much of the southern Altiplano plain, to face the situation of accelerated degradation of soil and natural resources in the region due to the common erosive winds. Moreover, in 2012, two organizations of quinoa organic producers (ANAPCHI and ARPAIAMT) have defined for their affiliated farmers a set of rules and standards of production with reference to organic farming. Such norms tie the purchase of quinoa from these two organizations to the way of cultivation. Thus, a maximum extension for the cultivation of quinoa (30% for cropping and 70% for grazing) is established in order to reduce soil erosion and degradation. Those agriculture practices should be able to reduce in the long run the velocity of the process of soil compaction, which would permit a better percolation of water through the soil. Nevertheless, It is worth to underline that 20% of quinoa has been produced according to organic practices between 2010 and 2012.

6. Drought Early Warning System (DEWS)

It is often possible to provide early warning of an emerging drought due to the characteristics of such natural hazard. This information allows for a shift from reactive to proactive hazard management and represents a change in focus from disaster recovery to disaster prevention. A survey conducted by ISDR Platform for the Promotion of Early Warning discovered that early warning systems for drought are more complex than those for other hydro-meteorological hazards and are consequently, relatively less developed globally (ISDR, 2007). Augmenting forecast and early warning information with decision support capabilities to provide information on options for reducing vulnerability to drought enhances local coping capacities and provides an important mechanism for reducing drought risk. Promoting the inclusion of indigenous or local groups and knowledge in drought monitoring and early warning systems is essential for developing appropriate local drought indicators, verifying the occurrence of drought, and communicating the warnings to local populations. Furthermore, although all types of droughts are due to a precipitation deficiency, it is not sufficient to rely exclusively on this climate element to evaluate severity and subsequent impacts because of factors identified previously. Effective DEWS must combine rainfall and other climatic parameters with water information such as stream flow, groundwater levels, reservoir and lake levels, and soil moisture into a comprehensive assessment of present and future drought and water supply conditions. With reference to the case study, in 2009 the Potosí district developed an Early Warning System which provide hydro-meteorological information regarding the probability to have a natural or human induced disaster, which could have impacts on a municipality, a region or the whole district, in order to be able to face such event in an organized and appropriate way.

Such system is based on three levels (FAO Bolivia, 2009). The first level is composed by the institutions that generate information through monitoring points (weather stations or others) that are in various communities in the department. This level includes the National Service of Meteorology and Hydrology (SENAMHI), which monitor the weather conditions of the department. On the second level there is the Departmental Monitoring Centre, which belongs to the Department of early warning system, implemented within the Risk Management Unit of the Prefecture. This unit is responsible for the reception and dissemination of meteorological and hydrological information as well as of disseminated the alert level at the departmental and municipal levels. The third level is made by the users of the System Department of Early Warning System, Municipal Early Warning, communities and those responsible, who are the Prefect of the Department and the Mayor, according to the law 2140, for the activation of operation centres (EOC's) at the Departmental and Municipal level. The developed early warning system has been applied to crop-graze production in various municipalities of the Potosí district and between those even Uyuni and Tomave. Such system combines the expert knowledge with the local knowledge (COMPASUR, 2011). The former bases its assessment on ten weather-monitoring stations, which check: a) weather temperature; b) precipitations; c) wind. Furthermore, through 120 stations widespread in the land dedicated to farm quinoa the susceptibility to wind erosion and the soil humidity are evaluated. Whereas, the latter takes in consideration with reference to a monitoring calendar forty-three bio-indicators divided in three categories: 1) vegetation; 2) animals; 3) clime and stars. Currently, an emergency plan to respond to the EWS alerts is what is lacking.

7. Water and Spatial Planning

Land uses and water have been strongly interconnected in the past but somehow such link has lost its relevance that nowadays water sector and spatial planning are deemed as two domains traditionally separated. The lack of a truly territorial approach in which water and spatial planning could be integrated and considered interdependently has been due to a traditionally sectorial view of hydraulic policies (Valenzuela Montes, 2008) as well as to uncontrolled growth and an unplanned development. Available water resources are menaced by human activities in different forms, such as diffuse agricultural, urban pollutions and over abstraction of groundwater. Hazards related to climate change, which will influence the hydrological cycle of different regions in different countries, may intensify water resource challenges in the future. Hence, a shift towards a planning system based on a proactive approach is necessary (Carter, 2007) not to be only aware of water and correlated problems (environmental, economic and social) but to act in order not to restrict development activities and opportunities in the future. The Bolivian National Developing Programme recognizes the basin river management and the integrated water resource management (IWRM) approach as processes that promote a coordinated development between water, land and related resources to maximize social and economic equity in order to guarantee the sustainability of vital ecosystems (PND, 2009). Notwithstanding such integration has not been

accomplished yet and the IWRM has not been applied yet due to many difficulties. Firstly, a too large scale which does not fit in a region where day-to-day decision-making on water development and management are in the hand of users and communities. Further, local communities do not know and they do not know the modality to express their ideas and concerns when they have to refer to an authority, which is not close to their reality. Thus, it would be necessary a lower scale in order to be able to attract interest of different stakeholders and to manage possible conflicts in the water management. IWRM should not be applied only to river basin management unit, but it should be applied to all different scales (from a village to trans boundary level) cause water stress reveals itself at all levels and needs to be addressed through a combination of bottom-up and top-down measures (Lenton and Muller, 2009). Secondly, a lack of decentralization and cooperation among the different sectors as well as of a fully defined legal framework are at the base of problems in applying such policy. Furthermore, at the national as well as at the local level, policies and solutions are still established to solve punctual or emergency issue lacking thus of a long-term planning vision. With reference to the policy of "Para el Bien Vivir" (for Living Well), the National Plan for the Integrated Territorial System of the Central-Sur Altiplano (Complejo Territorial Integral de La Region del Altiplano Centro – Sur) developed in 2009 draws a strategic agro-industrial development (MPD, 2009). It is based on the combination of enablement of 1 million hectares of agricultural land for organic production of quinoa to reach a production of 1 million of tons per year, production of compost thanks to lamas' droppings, tourism activity, petrochemical production and lithium abstraction in the Salar of Uyuny. Such plan do not consider at all the high drought risk which characterized the regions and the impacts of the increasing water demand due to tourism and land use changes as well as the effects of the implementation of a petrochemical and lithium abstraction systems on the aquifer and superficial water. Furthermore, both of investigated municipalities, which will be part of this project, lack of a proper planning system, environmental control system (according to the Environmental Law 1333), stakeholders participation despite of the law 1551/94 (Ley de Participación Popular) which promotes it widely.

9. Conclusions

Climate Change and the high drought risk call for a change in the Bolivian water management. The adoption of the river basin management approach as leading policy marks a relevant step for the future water management in Bolivia and for a more integrated development. Notwithstanding, the selection of a more operative scale would be helpful in the process of participation and decision-making. Indeed, the IWRM should not be considered as a box of reforms and rules but more as a philosophy, which should influence the strategy of projects and programmes instead of being built on them. Furthermore, the high awareness of Bolivian people towards the environmental issue should be valued as a resource to build an integrated system and no as an obstacle to this and to the development. Therefore, more space and chance should be given to local communities to express their ideas and concerns regarding the future development and water management in order to support a

bottom-up approach. Participation could be strength, further, linking sanitation and hygiene sector to IWRM, since such themes claim the attention of people, in particular in developing countries, since they improve enormously the quality of live. Consequently, local initiative should be encouraged by the government in order to invest in a cooperative approach between top-down and bottom up policies. In turn, if on one hand, international development projects in developing countries could represent a valuable tool to favour an improvement in the participation of the communities in the decision making process and in the collaboration among various entities; on the other hand, those projects are characterized by a short-, medium-term plan and are developed mainly in areas where the success rate is higher. Consequently, a shift from a planning and management system based on punctual and emergency interventions to a system based on a more strategic and long-term vision is needed in order to create a room to foster the construction of connections and coordination between the different elements composing the system. In turn, it is not possible to predict in advance that such coordination will be sustainable and equitable but lighter forms of integration (which could be seen as early wins) could constitute the base on which build a higher-level of integration, as in the case of water management and spatial planning. Furthermore, a shift from a reactive approach, which is still widely applied in Bolivia, to a proactive hazard management, is essential in order to cope with future events. According to this, a drought emergency and a communication plans should be developed and linked to the existing early warning system in order that the EWS works at its best and accomplices its functions to warn the population about the risk and to put in place the necessary measures to face the emergency.

HOUSEHOLD RELOCATION AND THE RESTRUCTURING OF SOCIAL RELATIONSHIPS: INSIGHTS FROM SHARJAH, UAE

Shaima al Harmoudi[1], Varkki Pallathucheril[2]

Abstract

Over the span of a few decades, cities in the Arabian Peninsula have not only grown in size but they have also changed qualitatively. In a recent study set in the city of Sharjah, Al Harmoudi (2010) found a significant deterioration of the public realm in residential neighborhoods. In this paper, we provide some preliminary assessments of how the social health of residential neighborhoods has also changed, and how these changes might be related to changes in the physical fabric. We report on a study of 11 households that relocated from an old Sharjah neighborhood in the 1970s and 80s to newer neighborhoods. We find a significant diminishing of social capital accompanied this relocation that appears related to changes in lifestyle and physical fabric and interactions between the two.

1. Introduction

Herbert Gans (1959) documented how changes in the physical fabric of the city, in the form of havoc rendered by urban renewal projects in American cities, had major negative consequences for social relationships and individual welfare in those cities. Across the world, the physical fabric of cities continues to change in ways that could likewise weaken the social fabric and diminish welfare. Unlike the case of urban renewal, however, dramatic changes may be experienced by people and households voluntarily relocating to neighborhoods that are very different from where they used to be located.

Over the span of a few decades, cities in the Arabian Peninsula have witnessed an astonishing transformation. They have not only grown in size but they have also changed qualitatively. Elsheshtawy (2008) and others have studied the role of globalization in this transformation. The city of Sharjah, the third largest in the United Arab Emirates, is no exception to this trend. While house form and urban fabric have changed dramatically over time, this evolution has also been accompanied by transformations in social relationships and lifestyles (Mahgoob, 1999; Coles and Jackson, 2007; Al Harmoudi, 2010).

In a recent study, Al Harmoudi (2010) found that residential neighborhoods in the city of Sharjah from three different eras spanning six decades have very different morphological characteristics from each other. The net result of these changes appears to be a significant deterioration of the public realm. Al Harmoudi (2010) speculates on some of the factors driving these changes: rising expectations as a result of increasing affluence, the push for modernization, and the approach to urban planning in Sharjah. She left for later a set of questions regarding the consequences of these changes.

In this paper, we provide some preliminary assessments of how the social health of residential neighborhoods has changed, and how these changes might be related to changes to the physical fabric. We report on a study of 11 households that relocated from an old Sharjah neighborhood in the 1970s and 80s. We establish through structured interviews the social relationships that existed when they were resident in the neighborhood and how these were tied to the physical fabric of the neighborhood. We identify their new locations in the city and explain the factors driving this relocation. We then assess a number of aspects of their current situation: What is the extent and nature of social relationships within the new neighborhoods? How is this tied to the morphology of the new location? What are their interactions with their former neighbors?

In the next section, we briefly review the evolution of Sharjah and its neighborhoods, the literature on measuring the social health of neighborhoods, and linkages among social health, physical fabric, and lifestyle changes. In Section 3 we lay out the question that motivated this study, explore our methodological choices, and describe the research design underlying our work, which is summarized above. Section 4 presents details of what we learned about the spatial patterns of relocation and the experiences of women who moved between these neighborhoods. We conclude with what we learned about possible drivers of changes in individual social capital through relocation, some policy and planning responses, and an agenda for future research.

2. Background

In this section, we provide background on the city of Sharjah as well as the morphological evolution of residential neighborhoods in the city. This raises the question of the social consequences of this evolution. We briefly look at the literature on how the social health of communities has been characterized. This leads us to consider the links between social capital, the physical fabric, and lifestyle.

2.1 Sharjah and Morphological Evolution

Sharjah is the principal city in the Emirate of Sharjah, the third largest of seven emirates that make up the United Arab Emirates. Sharjah's economy was traditionally based on pearl harvesting in the gulf waters, nautical trade, and a small amount of farming and animal breeding on the scarce arable land surrounding the city. This changed when oil

was discovered in the region in the early 1970s, and the region grew wealthy as a result. Federation of the seven emirates in 1971 reinforced this inflection point in Sharjah's development trajectory as the new nation gained economic and political stature. Three decades later, a massive growth in the UAE's sovereign wealth resulted from a surge in oil prices. As a relatively stable setting, the UAE attracted much outside investment in real estate and other businesses. Dubai was the principal beneficiary of this boom, the effect of which was also felt in next-door Sharjah, where many of those employed in Dubai make their home.

In this timeframe, Sharjah has grown physically in a linear fashion from the original settlement, located along the shores of the Arabian Gulf, inland towards the desert. Older neighborhoods are closer to the shore and newer neighborhoods are further away. Neighborhoods along the shore, however, have been largely demolished and redeveloped as high-density residential areas; only scant traces remain of neighborhoods from before the discovery of oil. Sharjah's residential neighborhoods are quite segregated even as its public places reflect the great diversity of people and families drawn from around the world. UAE citizens, or *Emiratis*, live in neighborhoods made up of single-family dwellings. Expatriate households are typically located in neighborhoods with multi-family dwellings.

Sharjah neighborhoods have changed over time. When Emirati households are granted land in new neighborhoods at the edge of the city, they rent their current houses to expatriate families and move into newly constructed houses. As houses in old neighborhoods age further, expatriate families move out and are replaced by increasingly large groups of single expatriate men who work as laborers. When these houses are extremely dilapidated, they are torn down and replaced by multi-story apartment buildings.

Rapid economic and physical development in Sharjah has been accompanied by dramatic social change. The traditional, simple Emirati lifestyle has acquired many trappings of the West. Modernization, growth and consumerism in cities crowded with modern buildings or skyscrapers, polluting industries and huge shopping malls. Stable, historic neighborhoods are threatened by the sprawl that resulted in order to accommodate the growing demand for all forms of land uses, new modes of travel, new house forms, and new expectations.

Al Harmoudi (2010) studied the morphological evolution of residential neighborhoods in Sharjah. She demarcates three eras in this evolution using two inflection points: 1.) discovery of oil accompanied by unification of the UAE, and 2.) the spurt of wealth and development at the turn of the 21st century. In her morphological comparison across these three eras she found that 1) the organic pattern that is observed in older neighborhoods becomes much more regular and of a much coarser grain in newer neighborhoods, 2) houses and lots are much larger in newer neighborhoods and meet the need for privacy in different ways, 3) the connectivity of the street decreases with each passing era and neighborhoods appear less internally

integrated, and 4) the shorter and more connected streets in older neighborhoods generate more interesting dynamic experiences than is the case when moving through newer neighborhoods. The net effect of these changes is a diminishing of the quality of the public realm even as it is occupying a larger portion of the neighborhood. Al Harmoudi (2010) speculates that this evolution was driven by rising expectations caused by increasing affluence. The rising expectations were shaped and directed by a push to be modern. Finally, this push for modernization was manifested through the particular approach to urban planning that has been prevalent in Sharjah.

Al Harmoudi (2010) leaves for further research the question of the social consequences of this morphological evolution. There is anecdotal evidence that the public realm is playing an increasingly smaller role in the social lives of neighborhood residents. For example, children are less likely to be found playing in public areas in newer neighborhoods. Conversations with residents of the newer neighborhoods suggest that they are less socially connected with their neighbors than in the past. Not all these consequences can be linked to changes in the physical fabric. Some of these are probably driven more by changes in lifestyle. Most activities that used to take place in the public realm in residential neighborhoods are now conducted either within people's homes, which are walled off, or in privately-controlled public areas such as shopping malls which are away from the neighborhoods. Another observation to be found in Al Harmoudi (2010): households in the older neighborhoods were likely to be from the same family or at least the same tribe. This is much less true in the more recent neighborhoods.

2.2 Social Health of Neighborhoods

How might we measure the social consequences of these changes? Along what dimensions might these changes be measured? There has been a large amount and a wide range of research on the social health of residential neighborhoods in the United States and other western contexts that could provide a degree of guidance in answering these questions. Some of the constructs used to measure social health include neighborhood satisfaction, sense of place or community identity, and social capital. As the following discussion shows, each of these constructs seems to progressively shift the focus further up Maslow's hierarchy of needs.

Neighborhood satisfaction appears to be the earliest of these constructs to be deployed in measuring the social health of neighborhoods. Speare, Jr. (1974) proposes the notion of residential satisfaction, which is undergirded by individual or household characteristics, location characteristics, and social bonds. Social health plays only a small part in this measure; the index that emerges from a regression analysis does not include any explicit measures of social bonds. More recently, neighborhood satisfaction has become one of the bases for comparing urban quality of life in several world cities. Oktay et al. (2009) describe application of this measure to Famagusta in North Cyprus. In addition to

individual, household, and location characteristics, that study measures community participation and involvement, neighboring, and safety.

The notion of sense of place includes a greater focus on social health of the neighborhood. Shamai (1991) expresses dissatisfaction with earlier formulations of sense of place but does not break down the construct any further. He proposes an ordinal seven-point scale to measure sense of place using linguistic categories: ranging from no sense of place to located, belonging, attached, identifying with, involved, committed (in ascending order). Deutsch and Goulias (2009) use a formulation that subsumes the notion of neighborhood satisfaction. They also use measures of neighborhood attachment (person-environment bond), dependence (person-place association), and identity. Tapsuwan, Leviston, and Tucker (2009) use a similar set of measures and explain that identity refers to feelings about the physical fabric and how it provides meaning and purpose. Cuba and Hummon (1993) find that participation in the social life of the community is essential for community identity. Axford and Hockings (2005) use an expanded set of measures that additionally includes sense of belonging and commitment to the neighborhood.

Despite intellectual roots that reach back to Adam Smith and Max Weber (Bjørnskov, 2006), social capital is the more recently formulated measure of social health. It is also one of the few that has been applied in the Arab world (El-Said and Harrigan, 2009). Bjørnskov (2006) traces the term social capital to James Coleman, though it gained wider circulation through the work of Robert Putnam. At its simplest, social capital is the net effect of trust, reciprocity, and association with others; like other forms of capital, social capital is generally thought to facilitate economic advancement including the production of public goods and services such as health; Ferlander (2007) notes that social capital may have negative consequences. Much of the research based on this construct attempts to put a number on this net effect. Extensive critical discussions about social capital and its possibilities and limitations can be found in Durlauf (2002), Ponthieux (2004), and Ferlander (2007). Ferlander (2007) distinguishes between two levels (individual and collective) and two forms (bridging and bonding) of social capital.

El-Said and Harrigan's (2009) contribution is particularly useful because they provide a fascinating qualitative discussion of the evolution of social capital in Jordan starting from the tribal society that existed before independence from Britain in 1946 up until the present. They do not quantify social capital but the rich descriptions they provide are hugely valuable to those who seek to study social capital in Arab societies. They introduce two terms in Arabic that to a large extent represent social capital: *wasta* (political influence; a form of bridging) and *takaful al Ijtima'I* (social solidarity; a form of bonding). They list a number of components of social capital: "satisfaction with life; formal and informal associations and membership in and quality of participation in local community; generalized norms of trust and reciprocity; political engagement and perception of government institutions; communications (including variables related to media and proximity variables); everyday sociability; family, friends, and neighborhood connections; and the level of safety and crime" (p. 1237).

In the context of this list, the literature on neighboring could be useful. Key (1965) provides an early list of signs of neighboring: speaking acquaintanceships, casual visits, visits in the home, borrowing or lending things, doing other favors, parties and activities outside the neighborhood. Skjæveland, et al (1996) find four factors that subsume individual measures of neighboring: supportive acts, annoyance, attachment, and social ties. Lee, et al (1991) use a survey instrument with four categories of items: acquaintanceships, content and frequency of contacts, dealing with neighborhood problems, and judgments about neighbors. Campbell and Lee (1990) find that women exhibit more signs of neighboring.

2.3 Links to Changes in Physical Fabric and Lifestyle

The literature on the social health of neighborhoods contains virtually no discussion of how this might be related to the physical fabric of neighborhoods. One exception we encountered was in Kuo, et al (1998) who argue that neighborhood social ties may substantially depend on the informal social contact that occurs in the public realm of neighborhoods. The data they gathered on residents of urban public housing projects suggested that the use and characteristics of common spaces may play a vital role in the natural growth of community.

In this context, the detailed observations that Al Harmoudi (2010) presents on the ebb and flow of the level of privacy afforded in the neighborhoods she studied could be relevant. In pre-oil Sharjah, the neighborhood did not afford a great deal of privacy and there did not appear to be a great need for privacy. The mixing of families and tribes in post-unification neighborhoods triggered a greater need for privacy that was reflected in the configuration of houses and walls. Contemporary neighborhoods allow greater surveillance of the public realm from within the house but the houses themselves are still very private because they are set back and have tinted windows. It would seem likely that these changes have affected neighboring and social capital.

Despite these possible links, the literature points mostly to lifestyle drivers in changes to social capital. For example, Putnam famously refers to the propensity for Americans to go bowling alone rather than in groups. He also points to longer commutes as diminishing social capital. Care must, therefore, be taken to ensure that any findings of links to the physical fabric of neighborhoods are not confounded by parallel changes in lifestyle. Figure 1 captures the relationships described here.

Hunter (1979) warns of another way in which links to the physical fabric might be confounded. He writes of studies that focus too narrowly on the neighborhood and do not grasp the effect of its context end up with descriptions not explanations for observed phenomena. When societies evolve from rudimentary occupational, transportation, and communication systems to more complex systems, Schwirian (1983) writes that such cities witness greater social and spatial differentiation with profound implications for the social make-up of neighborhoods. If any changes are found in the social health of neighborhoods, some of these changes may be driven by evolution of the broader system rather than observed changes to the physical fabric.

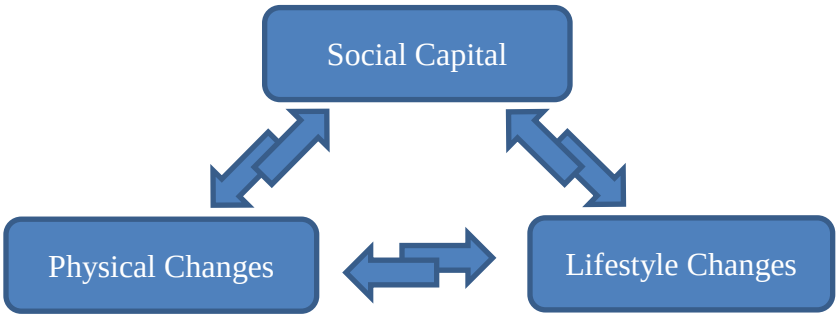

Figure 1: Inter-relationships among social capital, physical changes, and lifestyle changes

3. Research Questions and Method

The primary question we seek to address in this paper is as follows: What have been the impacts of morphological changes in Sharjah neighborhoods on the social health of neighborhoods? Al Harmoudi (2010) has already delineated some of the changes to the physical fabric. To understand how changes to the physical fabric in Sharjah neighborhoods have affected social health, we must identify and measure the changes that have taken place in social health of neighborhoods.

Two research designs for answering this question present themselves. The first would involve measuring social health in two or more neighborhoods with different physical fabrics. (This would be along the lines of Al Harmoudi's [2010] research design.) This design has the advantage that broader contextual factors remain comparable when measurements are taken. A second research design is made possible by the pattern of residential relocation common among Emirati families in Sharjah. As discussed earlier, families that lived in pre-oil neighborhoods relocated to newer parts of the city to take advantage of new housing or grants of land and money for new house construction. Recounts and assessments by individuals of their experience in different eras would provide data that can be used for comparisons between the different neighborhoods they lived in and inferences about the changes.

We opted for the latter research design primarily because there are no prior studies of social capital in our context, and there is not an available instrument we could apply. Our research requires generating hypotheses rather than testing them. We expected to gather richer data to generate hypotheses through this research design. In the 1970s and 80s, the area of Sharjah we chose to study was a tightly knit neighborhood that has today been completely replaced by high-rise apartment buildings. Families that used to live in the neighborhood have now moved to other parts of the city. We located 11 of the approximately 30 households that used to live in the neighborhood. We gathered two types of data. First, we traced the relocation pattern for each household. The locations of each household during each move were recorded on Google Earth. These data points

were then imported into ArcGIS and some very elementary spatial metrics computed: area of spread, average distance between locations, etc.

Next, we assessed any changes in social capital that paralleled this relocation. To do this, we recorded the experience of one woman from each of seven of the 11 households. We interviewed women because they exhibit the most signs of neighboring (Campbell and Lee, 1990) and are the ones to most likely feel the impact of changes in social health. Interviews were carried out in Arabic and then translated into English with every effort made to capture the spirit of the original. We engaged the women through semi-structured interviews, which sought to ascertain:

- What social relationships existed when they were resident in Al Nabba?
- How were these relationships tied to the physical fabric of the neighborhood?
- What factors drove their relocation?
- What is the extent and nature of social relationships within the new neighborhoods?
- How is this tied to the morphology of the new location?
- What are their interactions with their former neighbors?

Our conversations with these women attempted to cover the measures included in the idea of social capital. Among those constructs reviewed above, social capital is likely the best fit for our purposes because it covers more of Maslow's hierarchy of needs and focuses outside the realm of physiological needs. However, a major obstacle in using social capital as a measure is the lack of prior experience with applying it in our context. It is also typically applied using broad metrics generated from national data sets. Still, we believed that conducting this research would bring to the surface several hypotheses about social capital in this context that could be tested and refined in future research.

4. Results

In this section, we summarize the two sets of data that we gathered. We first report on the spatial patterns that we found, and then on our assessment of change in social capital.

4.1 Spatial Patterns of Relocation

Recording the different places where households have located since they moved from the original neighborhood reveals spatial patterns and allows us to see some similarities and differences in these patterns. Figure 2 summarizes these patterns. All distances mentioned below are approximate, measured as the crow flies and not along the road network.

The 11 households originally clustered in area roughly 125 x 200m. After the first move, 7 of these families clustered in a new area roughly 250 x 500m (more than four times as large as the previous area). Two families were within 500m of this cluster. In a second wave of moves, members of some families began to live in separate households. Four of these second-move families clustered in an area roughly 125 x 200m (just over a third of

number originally but in the same area) with a fifth family 700m away. A second group of four families clustered in an area roughly 60 x 80m (about the same density as originally) with a fifth about 600m away. The original 11 households are now 17 households.

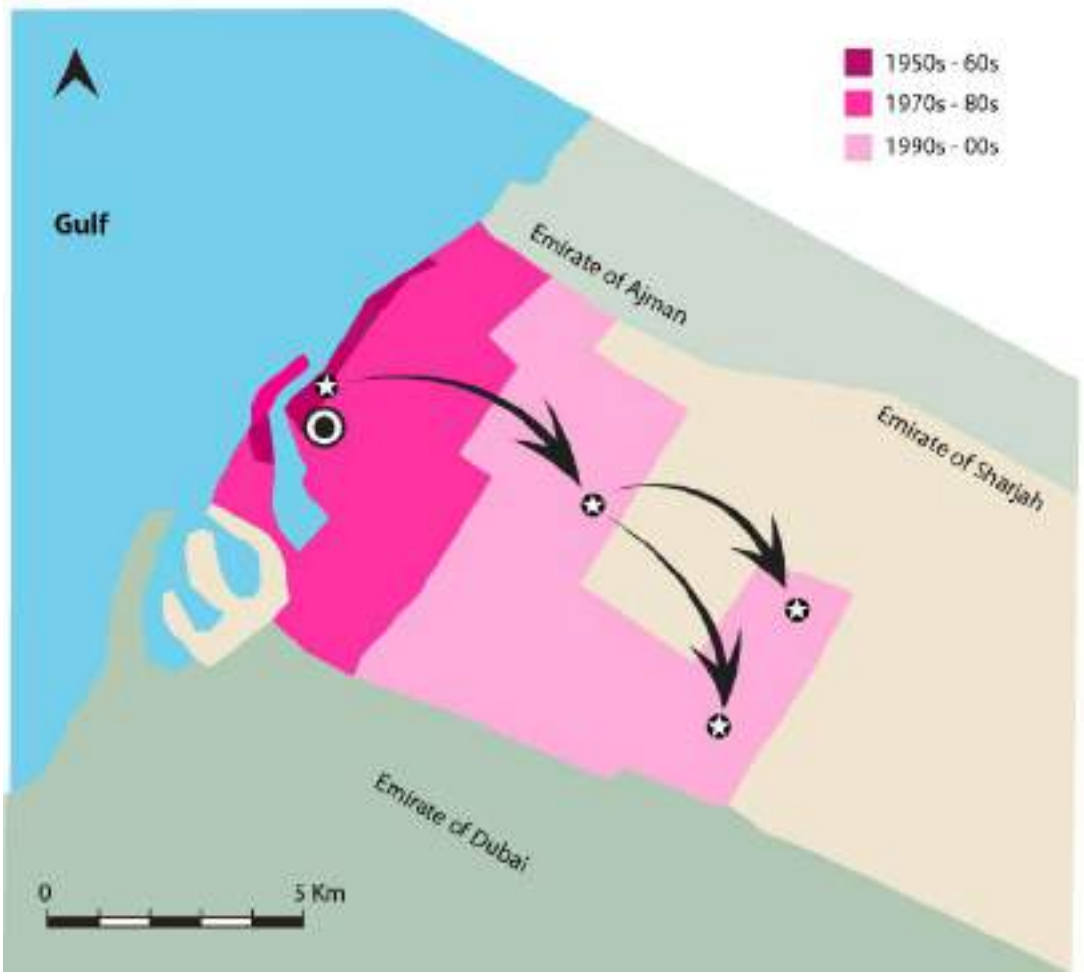

Figure 2: General Relocation Pattern

Five of the households we studied (2, 7, 9, 10, 11), just under half, moved only once and they moved to roughly the same location. Of these five, four remain clustered but not as tightly as they used to be. The average distance between these four families was just over 100m in the old neighborhood but now is more than 4 times that (about 440m). The remaining six households moved more than once, typically two times. As mentioned earlier, members of four of these households began to live separately. Three households in this group (3, 5, 8) are living increasingly apart from each other. Originally, they were on average just over 100m away from each other; after the first move, they were about

220m away from each other, and today are about 1,740m away from each other. The maximum number of moves was four and only one family moved this many times.

One household remains an outlier in that it has a much more complex relocation pattern than the others we studied and this is captured in Figure 3. This household was the first to move out of the old neighborhood and it was to a different area than that to which the other families moved. Two members of this household formed separate households and located away from each other. In their next move, they relocated close to each other and to other offshoots from one of their former neighbors in the original neighborhood. One of the two separate households then relocated one more time back to a location close to the old neighborhood.

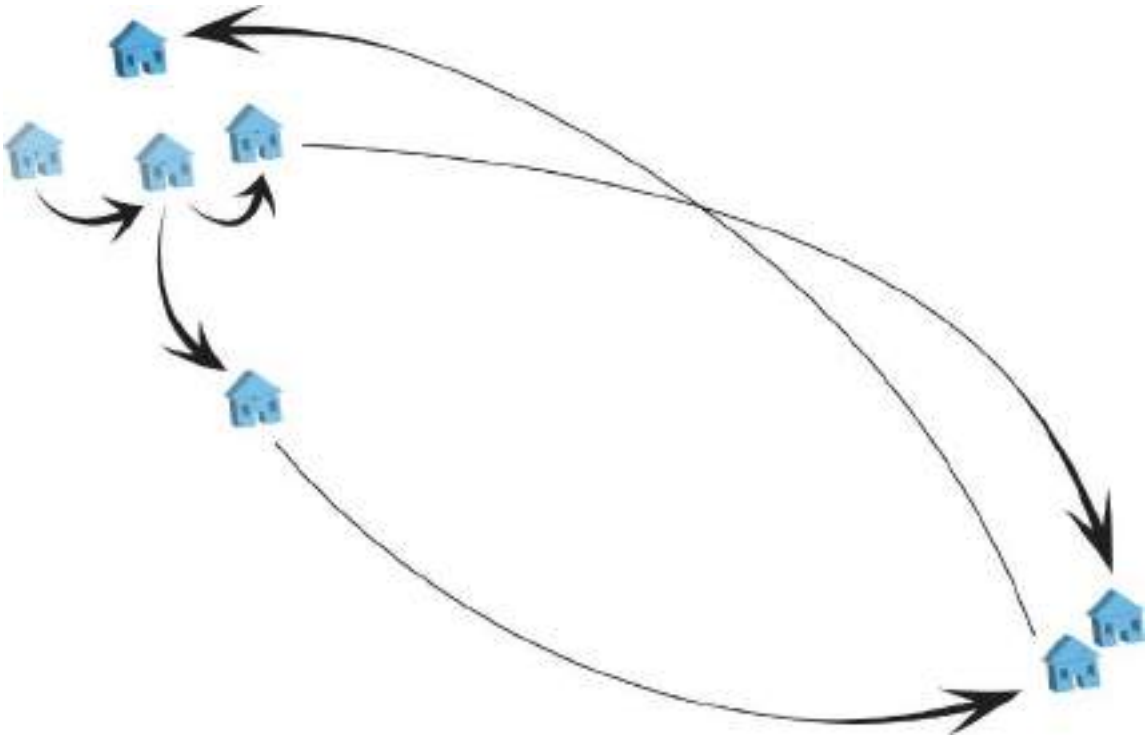

Figure 3: Relocation Pattern for Family 1 (Lighter is Older)

While the overall pattern from these results suggests a spatial fragmenting of the set of households we studied, the results also indicate a surprising amount of clustering. Many of the households ended up close to each other but not as close as they were originally.

4.2 Changes in Social Capital

The overwhelming sense from talking to women in these households, who experienced this relocation first-hand, is of a significant loss of social capital.

4.2.1 Original Social Relationships

All the women we spoke to recalled their days in the old neighborhood with fondness and great affection. Participant 5 noted, “Our neighborhood was home; it was our shelter. We felt we were a big family living in a big house.” Participant 1 recalled, “We spent most of the day socializing with others, sharing news and stories.” Some adjectives frequently used to describe the neighborhood: nice, interesting, friendly, simple, exciting.

The bonds between households were strong, and there was a high level of trust and reciprocity. Participant 2 remembered, “When my brother-in-law returned from a fishing trip, we would share fish with all of our neighbors. My husband used to be a trader, so whenever we got new goods we would share some with our neighbors.” Participant 3 noted, “If you didn’t show up at a neighborhood gathering, your friends would be knocking on your door asking about you, worried that there might be something wrong with you or your kids.”

The relationships among households ran very deep. Several respondents noted how in the absence of the man of the house, other men in the neighborhood would provide support. Participant 6 recalled, “My husband was in the armed forces and used to be away from home for long periods. I never felt lonely or in need. Everyone, from the grocer to the eldest man in the neighborhood, helped me and took care of me and my children.” This was particularly important in the case of households headed by women who were widowed or divorced.

Not everyone saw this as being completely positive. Participant 6 described social relationships differently, “But there was no privacy, as I said earlier. People knew every tiny detail about your life. They used to get involved in your problems and private matters.” Participant 4 was more positive about this, “We had a lot of quarrels but they were easy to solve.”

4.2.2 The Physical Fabric

We found that the women we interviewed were generally unable to make direct connections on their own between social relationships and qualities of the neighborhood’s physical fabric, even when pressed. However, many women talked about walking around the neighborhood, and how this affected the quality of social relationships. Participant 1 recalled, “We used to walk on our errands and talk to people that we passed by even if they were men.” Similar remarks were made by almost all the other women, some of whom noted it was different for young, unmarried women whose movements were restricted. The public realm appears to have played a role in enabling and fostering social relationships.

To help participants make the link between social relationships and the physical fabric, we asked them about some specific physical attributes that Al Harmoudi (2010) mentioned: proximity of houses; high boundary walls; quality of the public realm. With these prompts, participants were able to make some connections. All participants without exception described how having houses close to each other helped them feel

connected. Participant 7 said, “The houses were small and close, as if we were all living in one big house.”

Participant 3 provided more detail, “Houses were close to each other: a door next to a door and a window facing a window. It was easy to communicate; we did not need phones. We would chat with each other standing on the roof of our houses; that’s when we arranged to meet later in the day. The houses were that close!” She explained that the roofs of houses were used for drying laundry, drying dates and onions for use out of season, and for sleeping on hot nights. Participants 4 and 6 linked proximity and spatial configuration to sense of safety. For example, “Our doors faced each other and the street separating us was very narrow… [this made it] easier and safer to communicate and visit.” Another commented that because of proximity “it was very easy to visit our neighbors. It also made me feel safe when my husband was away. I never felt as though I was alone in the house.”

Almost all participants acknowledged the role of the height of the boundary wall; they mentioned that having low walls facilitated communication and made them feel close. Participants 1, 3 and 6 recalled that they were calling each other across the wall, chatting or asking for help. Participant 6 said, “If I needed anything, all I had to do was to shout to them; they could easily hear me and would come straight away.”

When women were asked about open space in the neighborhood they immediately made the connection with social relationships associated with children playing outside the house. Almost all of them noted how children played outside the house because it was safe and there was natural surveillance. Participant 4 recalled, “The *baraha* (open space) in front of our house was easily watched by all of our neighbors. Even if I was busy doing something, I knew that someone else would be watching, whether it was women from the rooftop of the houses or men sitting in chairs next to main door of the house.” She explained that all houses had one or more chairs outside next to the main door. Men used to gather and sit there after they had their afternoon nap. Participant 1also recalled children at play, “They used to play with rocks and sand as well as cans [for football]. It was very simple but they enjoyed it a lot.”

4.2.3 Reasons for Relocating

Without exception, participants cited the need for more space as their reason for relocating. Participant 6 told us, “Our house was very small and we were a big family. One room for four kids was very uncomfortable. We didn’t have much privacy in the home.” While we did not ask directly why they did not just construct larger houses in their original neighborhood, most provided us the reason: new housing was provided at no cost by the government. One participant gave us the sense of a slightly different motivation. Participant 6 said, “We wanted to experience the new lifestyle.” This suggests a desire to be modern.

4.2.4 New Social Relationships

All participants spoke of declining social relationships in each successive move. The first move saw a slight decline in the quantity and strength of social relationships. Participant 1 explained, "The second neighborhood was like [the first] but it was more private. We used to socialize, but only with close neighbors." After the first move, there was still quite a bit of socializing outside the house. Participant 7 recalled, "We used to socialize every day in the late afternoon while our children played outside together." But there was a decrease in the amount of time spent outside. As Participant 5 remembered, "We were less comfortable about kids playing outside; this decreased our daily meetings with neighbors."

As some participants tell it, bonds were almost as strong as in the old neighborhood but were spatially limited. Participant 7 observed, "The bond was very strong…but only with families that lived around our house." Participant 2 also felt there were limitations on social bonds. She referred to "a lot of new families that we did not know." She maintains that women were comfortable with other women of the new neighborhood but not the men.

After the second move, the decline in social relationships is more pronounced despite, as Participant 6 noted, all the new communication tools available. For one thing, most participants felt that maintaining social relationships is becoming hard work. Participant 4 told us, "We rarely see each other unless we receive an invitation. After issuing an invitation, people spend a lot of time and effort preparing for the visit. Visitors responding to an invitation also go to great lengths to get ready for the visit. All this makes visiting less pleasant. In the past, we only had to knock on the door and we were made comfortable." This view resonated in responses from other participants.

We also found many participants now spend less time in the neighborhood outside their houses because they 1.) do not feel safe, and 2.) use their cars to move around. Participant 2 said, "Now it's not very safe to [walk in the neighborhood]. There are a lot of laborers working in and walking around the neighborhood. I never let my daughters walk outside the house." This fear of strangers and outsiders pervaded our conversations with most participants. Participant 3 appeared less concerned about safety but told us "We drive cars. In a car, we are less likely to meet others and chat." With regard to mobility, Participant 6 noted that women nowadays have a greater spatial range of movement than they did in the past. This broadening of vistas was noted by Participant 4 when talking about young women, "[These days] they talk to men at work and in the market, but they never talk to their neighbors. It doesn't make sense!"

We followed up with participants about the quarrels that used to take place in the old neighborhood. Are there still quarrels in the new neighborhoods? All participants agreed that there are fewer if any quarrels between neighbors in the new neighborhoods. Only two participants, however, thought this is a good thing. The other participants thought that the quarrels were not very serious. Participant 3 recalled, "[The quarrels] were actually part of our lives. One day we get angry, the next day we are drinking tea and eating dates together." For them, the value lost in neighboring outweighed the value gained through fewer quarrels.

4.2.5 The New Physical Fabric

As indicated earlier in Section 4.2.2, when reminded of some of the morphological changes in neighborhoods, participants were able to describe ways in which they see these changes relate to changes in social capital. A number of participants linked the changes described above to the growing degree of separation between houses. Participant 1 noted, "Houses nowadays feel more separated; perhaps because of the high walls and the big front and backyards?" Participant 2 added, "It used to be very easy to visit your neighbor seven houses away. Nowadays, because of the size of the land and houses, going three houses way is quite a journey!"

Participant 7 highlighted the role played by wide streets. She said, "Nowadays the houses are … separated by roads. It has made the houses very separate and private. It's not nice this way." She also appeared to the very linear configuration of the public realm: "Nowadays the houses are … all lined up next to each other." How this is tied to the sense of separation is among houses is not very clear.

Women were asked to talk about the reason behind children playing indoors more often than in new neighborhoods. Without exception, all of the participants related it to the danger in playing outside due to the presence of paved roads and cars. Participant 1 noted, "They still love to play outside but the problem is with roads and cars. It's not safe at all; we don't allow them to play outside the house." Participant 2 complained, "The neighborhood is filled with cars and crazy drivers." Participant 4 noted, "Only two men in the old neighborhood had cars. When they drove, the kids used to run after the car. It was like a game to them." Participant 7 was particularly angry about the current situation, "How can they play outside? The roads are full of speeding cars. In the past, the *baraha* was sandy; it was not paved. The worst injury was being hit by a rock. Nowadays we hear about all kinds of accidents. That's why they play inside and get fatter and fatter. Poor children!" Could it be because of indoor forms of entertainment? Participant 6 did not think so. She said, "They always want to play football [outside] no matter how many video games they have."

Some participants seemed to think that increase spatial extent of the neighborhood played a role in this change. They mentioned that the new neighborhoods appeared bigger, accommodating a larger number of families that they did not know. Participant 2 said, "The [new] neighborhood was bigger with a lot of new families that we did not know well."

4.2.6 Interactions with Former Neighbors

Most participants said that they rarely interact in person with their former neighbors. They only meet face-to-face at family events such as weddings, births, and funerals. They call each other once every two weeks if they belong to the same family, whereas they talk only once or twice a year to former neighbors who are not family. By way of

explanation, as alluded to earlier, these interactions feel more and more burdensome because they have become more formal.

5. Discussion and Conclusion

Our conversations with the women who lived in neighborhoods from different eras reveal an extensive degrading of social relationships and social capital over time. These changes parallel the morphological changes that Al Harmoudi (2010) revealed. To simply attribute the former to the latter, the earlier reviewed literature suggests, would be naïve. Any such inferences would be confounded by the influence of 1.) lifestyle changes and 2.) social changes driven by evolution of the broader context, the city, from rudimentary to complex.

The city of Sharjah has grown tremendously over the past four decades. As Schwirian (1983) predicts, this growth was accompanied by a transformation from a more rudimentary to a more complex urban system with greater social and spatial differentiation. This is reflected in the mixing of households in new neighborhoods referred to by many of the participants. As importantly, we believe it is also reflected in the lifestyle changes they describe. As a result, we propose that the model in Figure 1 is sufficient to explain the changes in social capital. This suggests three possible explanations for observed changes: they are because of 1.) physical changes alone, 2.) lifestyle changes alone, and 3.) the combined effect of physical and lifestyle changes.

Let us first consider the lifestyle changes that have driven down social capital. First, an increasingly auto-oriented lifestyle has meant less face-to-face contact but greater spatial reach. Social relationships reach further distances but are less intense. Second, more formal standards of etiquette have meant that social relationships have become more burdensome and there is less motivation for engaging others. Third, there is a pervasive fear of strangers and others, and becoming a victim of crime, which makes people less inclined to venture out into public. In the past, construction and maintenance work used to be done by men of the neighborhood. Now, most of this is done by low-wage expatriate laborers who as a result have access to residential areas. Overall, there appears to have been a shift from outdoor living (use of roofs and public open spaces) to indoor living.

Let us next consider how two changes in lifestyle interact with changes in the physical fabric. First, a significant change has been wrought by an auto-oriented lifestyle but in a manner different from that discussed above. The public realm in neighborhoods increasingly privileges the automobile, discourages pedestrian use, and displaces activities, primarily involving children, which help build social capital. The automobile also diminishes social capital through its impact on the public realm. Second, the sense of fear discussed above may be related to the spatial structure of neighborhoods. Al Harmoudi (2010) found that old Sharjah neighborhoods were more spatially integrated with the surrounding urban fabric while new neighborhoods are more segregated. One possible explanation for heightened fear in new neighborhoods: Hillier and Shu (2000) find that integrated areas of a city had fewer crimes. But Nubani and Wineman (2005)

find these areas have more crimes, and suggest the difference could be because the areas they studied are automobile- rather than pedestrian-oriented. We did not find studies that looked specifically at fear of crime.

We can next consider physical changes that appear for the most part to have directly diminished social capital. The changes that have had the most impact appear to be those that have increased the physical separation among households: larger plots, wider streets, high boundary walls. Diminishing of social contact is only to be expected as a result of these changes and participants confirmed this expectation. Some participants also perceived newer neighborhoods as larger, which diminished the sense of belonging. In this case, perception is indeed reality. The city block containing the original neighborhood is just 0.10 sq km in area, while the first neighborhood to which households moved is in a block just under 0.50 sq km, and the most recent neighborhoods are in 1 sq. km superblocks.

The spatial patterns of relocation that we recorded lead us to a final conclusion. While the overall pattern we observed suggests a spatial fragmenting of the households studied, the results also indicate a surprising amount of clustering. As noted above, several families (2, 7, 9, 11) located close to each (though more spread out than before) after they moved for the first time. Despite this proximity, the women in these households still feel that social capital was diminished after the move. Al Harmoudi (2010) pointed out that a major difference between the old and new neighborhoods lies in the proximity of households from the same family or tribe. Our finding here suggests that the forces of change described above were probably of greater consequence than proximity.

Lifestyle changes discussed above are not easily addressed through public policy and design initiatives. Changes to the physical fabric, on the other hand, are probably more likely to be amenable to policy and design intervention. The design of streets, the public realm, and land parcels can be altered to reduce the sense of separation among households. Design controls can encourage better visual connections among houses. Policies of households growing in place rather than relocating may also help build social capital. Ultimately, however, the impact of lifestyle changes may be too great to overcome by managing physical changes. Recently, the Ruler of Sharjah announced that housing plots from now will be allotted so as to locate members of a family close to each other. Our research suggests that proximity cannot overcome physical barriers or lifestyle pressures.

The loss of some valuable aspects of social relationships noted above must not diminish the value of progress made in other respects. As participants pointed out, they now live in houses that better accommodate their families. Increasing affluence today means the new generation does not have to experience some of the hardships faced by the previous generation.

Our research has uncovered several hypotheses about relationships between social capital, lifestyle changes, and physical changes that must be rigorously tested. A series of related unanswered questions also deserves attention. As noted earlier, the fear of

being victimized in the public realm appears to preoccupy the women we surveyed. Is this fear of crime based on perception or reality? What factors underlie this fear? To what extent is fear of crime related to the spatial structure of neighborhoods?

Targeted Public Participation in Sustainable Mobility Planning: A Case Study of Aalborg, Denmark

Authors: *Patrick Arthur Driscoll, Aalborg University, patrick@plan.aau.dk; Vladimir Mrkajic, Autonomous University Barcelona/University of Novi Sad, vmrkajic@gmail.com.*

Abstract

There has been consistent agreement in both the academic literature (e.g. Banister, Pucher, Tolley) and in the policy guidance literature from the European Commission (e.g. PILOT, CIVITAS, Eltisplus) that broad public participation and stakeholder involvement in sustainable mobility planning projects is necessary in order to ensure their successful implementation and to generate sufficient political support for further measures. However, the results of a recently completed case study of the planning and implementation of a high volume cycle 'motorway' in Aalborg, Denmark, suggest that targeted public participation may be more widespread than is commonly presumed. This raises important questions about transparency, efficiency, democratic process, and fairness that will be outlined within this paper.

Through a study of relevant planning documents at the municipal, national and supra-national levels and in-depth interviews with the planning staff working for the city of Aalborg, the authors found that the planners responsible for the implementation of the bicycling measures implement through a EU-funded sustainable mobility project possess a more nuanced appreciation of the need, relevance and usefulness of public participation than is commonly thought to be the case within academic, planning, and policy communities.

Key words: public participation, sustainable mobility planning, bicycle infrastructure

1.0 Introduction

Across many European countries, extensive public and stakeholder involvement within sustainable mobility planning processes has been promoted as a way to build political legitimacy and increase the acceptance of sustainable mobility measures (Banister, 2008; Pucher & Buehler, 2008; Wolfram & Bührmann, 2007). Some of the more common rationales for doing so include: 1) public participation and stakeholder involvement strengthens democratic planning, in turn supporting a more engaged populace; 2) more transparency in the decision-making process yields more widespread acceptance of contentious policy and planning measures; 3) the knowledge exchanged within the public participation process helps to strengthen the policies and plans by exposing them to public comment, criticism, and revisions; and 4) public participation and stakeholder involvement builds trust between planners, politicians, and citizens.

Policy guidance from the European level also mirrors much of what the academic literature advocates. For example, The GUIDEMAPS handbook from the EU CIVITAS sustainable mobility project asserts that:

'There is a growing belief that communities would support transport schemes more readily if they were more actively involved in designing them. They would better understand the need for the project and perhaps be more willing to accept compromises, and they would be able to suggest ways in which the

proposals could be better adapted to meet their local needs. In short, they would 'own' the scheme, instead of regarding it as having been 'imposed' on them from above.' (Kelly, Jones, Barta, Hossinger, Witte, & Wolf, 2011, p. 20)

While there may be elements of this sentiment that hold true, much of the rhetoric surrounding public participation and stakeholder involvement often belies reality, particularly when it comes to the ways in which planners themselves perceive public participation (Bickerstaff, Tolley, & Walker, 2002). While limited consultation and one-way communication with affected communities is a relatively low-risk proposition for planners, more extensive power-sharing processes that allow citizens to actively shape plans, procedures, and outcomes tend to inflame latent tensions between competing roles that planners must negotiate today between what Tore Sager terms the dialogic ideal and neo-liberal reality (Sager, 2009).

It is within this space, between the communicative ideal of the deliberative practitioner (Forester, 1999) and the actual practices of planners today, that this paper will explore. Despite the extensive amount of research and policy attention that has been directed toward the issue of how planners *ought* to perceive public participation and stakeholder involvement, to date there has been comparatively little attention focused on how planners *actually* perceive public participation and to what extent it is desirable or effective (Laurian & Shaw, 2009), particularly in the field of sustainable mobility. This matters for two reasons. Firstly, many of the measures necessary to achieve sustainable mobility, such as congestion road pricing, capacity reductions for motorised transport, modal shift to non-motorised forms of mobility, and parking restrictions, are often politically unpopular (Isaksson & Richardson, 2009; Lee-Gosselin, 2010; Driscoll, Theodorsdottir, Richardson, & Mguni, 2012). Therefore the encouragement of public participation may in fact retard more progressive sustainable mobility strategies that seek to lower greenhouse gas emissions, decrease social exclusion, encourage compact urban development and reduce air, noise and water pollution from motorised transport. Secondly, the shifting (and often countervailing) tensions in planning as practised opens up a more nuanced theoretical space in relation to what the authors have termed targeted public participation, where the planners are able to exercise their expert judgement in choosing which particular "publics" that they choose to engage with.

In this paper, the authors are particularly interested in cycling since, despite its importance within a sustainable mobility strategy, there remains a lack of in-depth research regarding participation in planning of cycling infrastructure. Moreover, public participation within planning has still not been widely accepted among many EU countries, particularly among the southern and eastern EU member states. One of the goals of the paper is to contribute to a better understanding of the role and significance of public participation within the sustainable mobility planning process in a Scandinavian context. Additionally, understanding planners' perspective on public involvement is important for the research community since planners often have a very different perception of public participation than researchers and policy analysts do. Although there have been previous studies on planners' perception of public participation in transport planning (Bickerstaff, Tolley, & Walker, 2002; Laurian & Shaw, 2009), the literature review did not reveal previous peer-reviewed studies into the planning process of bicycle planning and public participation.

The remainder of this article is structured into four main sub-sections. Firstly, a state-of-the-art review of the literature pertaining to sustainable mobility planning and public participation is developed. This includes documents such as EU White Papers and other policy guidance from the European Commission and the EU-funded CIVITAS and Eltisplus sustainable mobility projects as well as peer-reviewed literature. Secondly, the main research methods used in the data collection and analysis are presented, including key limitations of the study. Thirdly, the relevant outlines of the case study are analysed and discussed, including a comparison of the normative participatory framework and the actual practices of the planners. Fourthly, and finally, three main conclusions will be established that are relevant to researchers, planners, and policy makers going forward: 1) planners' own perceptions of public participation differ in important ways from the manner in which they are typically presumed; 2) the use of targeted public participation is a defensible, although ethically sticky, means of guiding sustainable mobility strategies and plans through the thicket of potential opposition; and 3) that for more far-reaching measures that reduce individual mobility options, particularly car-based ones, it is practically unavoidable that planners will more and more be faced with the 'tension of inclusivity' as to who and how the "public" will be involved in the decision-making process.

2.0 Sustainable mobility and public participation: The state-of-the-art

What is sustainable mobility?

For the purposes of this article, sustainable mobility is defined by the European Commission White Paper 'Roadmap to a Single European Transport Area-Towards a competitive and resource efficient transport system' (2011) that states the sustainable mobility challenge *"is to break the transport system's dependence on oil without sacrificing its efficiency and compromising mobility"*, with a notable emphasis that "*curbing mobility is not an option*" (European Commission, 2011a, p. 5). Leaving aside the question of the feasibility of achieving such ambitious (and contradictory) policy goals, such as a reduction of greenhouse gas emissions from the transport sector by 60% in the 2050 without significant reductions in overall mobility levels or the imposition of road pricing, sustainable mobility is understood as a system of movement that is not reliant upon fossil fuels, but also takes into account relevant social and environmental considerations such as equal accessibility, safety, and reduced air, noise, and water pollution.

Interestingly, a search of both the White Paper and the accompanying Impact Assessment (European Commission, 2011(a)(b)) revealed that neither document mentions public participation in any form in within the policy recommendations or strategic aims. In a comprehensive review of sustainable transport planning in the United States, the European Union, and Canada, researchers claim that "*acceptability is an essential (yet often neglected) element of sustainable transport*" (Banister, Pucher, & Lee-Gosselin, 2007, p. 36). Within the European Commission, this message apparently has yet to be heeded, for perhaps understandable reasons. People generally react quite strongly and aggressively toward travel demand reduction measures that restrict their personal mobility, in the absence of emergency situations such as wartime rationing or energy shocks such as those experienced in the 1970's (Lee-Gosselin, 2010). Although there are notable differences between North America and Europe regarding public acceptability of state regulatory interventions, even

within the EU there is frequently strong resistance to impositions and restrictions on mobility, particularly if private motoring is at stake (European Commission, 2011b).

The lack of public engagement and absence of participatory mechanisms within the European Commission in relation to transport planning is not mirrored in the guidance and policy documents that are produced by the European Parliament. In a 2010 report delivered to the Committee on Transport and Tourism entitled 'Sustainable Urban Transport Plans', the authors state that:

One of the core elements of SUTPs [Sustainable Urban Transport Plans] is public participation in its preparation. Undeniably, ensuring comprehensive citizens' involvement at the planning and evaluation stages offers the opportunity to raise awareness of the objectives and substance of the strategy and measures of SUTPs. Besides the contribution in terms of transparency and accountability of the process, public participation may facilitate mainstreaming, ensuring a common approach to policies that affect residents' quality of life and the urban area's growth perspectives. Finally, with respect to SUTPs, public involvement should also be aligned to the modalities of public participation set out in Article 2 of Directive 2003/35/EC (EC, 2003). (Trasporti e Territorio, 2010)

Here the linkage between public participation and sustainable mobility is claimed to be essential. Many of the rationales (transparency, awareness-raising, accountability, and acceptability) are frequently encountered in both academic and policy circles, with little in the way of critical assessment of what type of public participation is being discussed and how exactly the planners themselves encounter and perceive public participation.

What is public participation?

Following Sherry Arnstein's (1969) well-known conceptualization of the ladder of citizen participation, public participation here is understood as citizen involvement in the actual decision-making processes with the underlying goal of affecting the outcomes and influencing choices (Arnstein, 1969). There is a key distinction to be highlighted in Arnstein's work, that public participation in the broadest sense is not equivalent to holding workshops, communicating with affected citizens, and producing promotional brochures describing the benefits of a given plan or strategy. Rather, it is the more radical notion embedded within the progressive planning tradition that citizens have the right and the responsibility sit at the same table as politicians and planners when decisions are taken. Within the European Union, there remain large differences in how municipal planners understand and apply public participation in sustainable mobility planning, and the idea of citizens wielding real political power within the planning system is still quite a radical notion.

There is a spectrum of citizen involvement that covers a distance from manipulation to one-way distribution of information from the authorities to the citizenry, through widespread inclusion of the public during the entire process of formal decision-making, to handing over authority to the public to decide how plans will be decided upon (Arnstein, 1969, p. 217). However, as noted in the EU-funded CIVITAS handbook on stakeholder involvement, "*politicians tend to have an ambivalent attitude towards participatory approaches*" (CIVITAS Secretariat, 2011, p. 8). In fairness to politicians, they are not the only ones with ambivalent attitudes towards participation. Much of the planning guidance to be found on how to engage with citizens to develop and implement sustainable mobility plans also demonstrates a certain wariness as to who, when, and how planners should pick those who participate

in the process. Within the same CIVITAS handbook on stakeholder involvement, planners are encouraged to screen the potential actors using a two-by-two influence/interest matrix (see Table 1 below for an example). Not surprisingly, most of the measures discussed in the handbook, ranging from mobility management, clean fuels, bicycle measures, collective transport, and safety measures, listed public authorities, politicians, and transport authorities as the key stakeholders in the "high influence/high stakes" category that are central to a public involvement strategy (CIVITAS Secretariat, 2011).

Table 1: Sample influence/interest matrix

	Low influence	**High influence**
Low stake	• NGOs • Consultants	• Presidents of local associations and organisations • Local celebrities • EU • Citizens
High stake	• Trip generators (schools, hospitals, etc.) • Companies • Public transport providers	• Local government • Politicians • Transport authorities • Media

The stated purpose of such a screening process is to help planners decide how to target the different "publics" that are relevant to a given sustainable mobility measures. Additionally, such practices reveal what Bickerstaff, Tolley and Walker call the 'tension of inclusivity' (Bickerstaff, Tolley, & Walker, 2002, p. 71), where planners face difficult dilemmas concerning representativeness (how can they be certain that special interest groups speak for society at large, and how can the presumed or actual spokespeople of the special interests groups speak for the group?) and inclusiveness, since it is practically impossible to include every potential stakeholder and affected citizen at each stage of the planning process. This raises an uncomfortable issue regarding the ability of well-connected, articulate minority groups to capture the agenda when it comes to participation and planning, something that Todd Litman, among others, contends can lead to biases and distortions favoring mobility over accessibility and an undervaluation of non-motorised forms of travel (Litman, 2002). Lastly, the tension of inclusivity also opens up sticky ethical and moral questions such as: 1) within which planning contexts is it justifiable for planners to selectively engage the public; 2) what are the implications for democratic decision making, transparency, and fairness when planners actively suppress participation of citizens that are opposed to certain measures or goals; and 3) is it justifiable that planners engage in targeted public participation in order to achieve sustainability goals that would otherwise be disrupted or destroyed by wide-spread public engagement (for example, road capacity restrictions, road pricing schemes, removal of free parking, and increased fuel taxes).

What is targeted public participation?

For the purposes of this article, targeted public participation is understood as a selective approach by planners to engage specific segments of the public for specific purposes at specific times.

3.0 Methodology

The research design is a single critical case study using qualitative data sources including: relevant local planning documents and reports, European Commission documents, and expert interviews with three planners directly involved in the planning and implemenation of the planning connected to the construction of a 'cycle motorway' within ARCHIMEDES[1] project (Achieving Real Change with Innovative transport MEasures Demonstrating Energy Savings) in Aalborg, Denmark. What makes this case critical is the bringing to empirical ground some key theoretical assumptions about the way in which planners ought to perceive public participation in sustainable mobility projects. Furthermore, Denmark has a well-deserved reputation for strong public and state support for sustainable mobility planning in general and bicycling provision in particular. One of the guiding hypothesis of the research is that given the positive pre-disposition toward sustainable mobility strategies and plans, coupled with strong traditions of democratic control and transparency, then planners in Denmark should possess strong inclinations toward extensive public participation.

The interviews were semi-structured and lasted for approximately 1 hour. All interviews were recorded and transcribed. In addition to the responses of the participants, background data on participants (educational background, position and main responsibility, time spent in current position) was collected. The analysis and interpretation of the data was conducted through the use of structured queries developed by the authors using a syncretic method combining EU-level policy guidance and best practices for sustainable transport/mobility planning in combination with an analytic frame derived from key academic contributions in the field of sustainable mobility planning and public participation.

3.1 Limitations of the study

As with any case study, particularly single case studies, there are of course issues with the generalizability and validity of the findings. The transferability of the findings from a Scandinavian context is also untested. One of the next steps in the research is to extend the methods to a number of different bicycling projects that have been realised within the CIVITAS program, looking at cities that have different levels of transparency, divergent planning cultures, and differences in political and social systems. Another caveat to this study is that since the planners interviewed were working within an EU funding framework, it is not entirely clear that ordinary municipal planners working on other sustainable mobility projects have similar attitudes to targeted public participation.

[1] ARCHIMEDES is a part of larger EU-funded CIVITAS sustainable mobility project

4.0 Case description and analysis: Planners' perception of public participation in bicycle planning in Aalborg, Denmark

Even though Denmark is one of the most bike-friendly countries in the world, with excellent cycling infrastructure and strong public support for bicycling among citizens, planners and politicians, the overall levels of cycling in many Danish cities has been generally stagnating or declining while car ownership rates and per capita vehicle kilometres travelled are rising (Statistics Denmark, 2010; Lautrup, 2011). In order to reverse this trend, many Danish cities have implemented various plans and strategies that address barriers to cycling. Aalborg, the fourth largest city in Denmark with a metropolitan population around 120.000, is one of those cities. The Municipality of Aalborg developed a Cycling Action Plan in 2008 with the aim to prioritise a list of cycling infrastructure projects to be completed by 2020. The plan was approved by the City Council at beginning of 2009. Also, in the same year, eager to demonstrate a strong political commitment to cycling in the city, the city council approved the project Cycling City Aalborg, co-financed by the Danish Ministry of Transport. The project focuses on commuting cyclists, aiming to provide high-class cycling commuter routes.

Additionally, Aalborg has participated in multiple generations of the sustainable mobility project CIVITAS (CIty-VITAlity-Sustainability), funded by the European Commission. The project was launched in 2002 in order to encourage cities to introduce transport measures and policies that support sustainable urban mobility. The City of Aalborg has participated in two out of three phases of the CIVITAS project (CIVITAS I from 2002-2006, and CIVITAS PLUS 2008-2012). Each CIVITAS project involved between 4-6 European cities in research and demonstration projects. In the CIVITAS PLUS project, Aalborg participated with 5 other cities within the ARCHIMEDES project. One of the primary goals of the ARCHIMEDES project for Aalborg is to put a particular focus on cycling mobility aiming to become a Cycling City. One of the key measures related to cycling improvements that Aalborg implemented is the construction of a cycling motorway.

Through this cycling motorway, the city centre is linked with University campus located 6 km to the southeast. This stretch of the cycle motorway was chosen since it represented one of the primary routes for cyclists traveling on the city centre-university axis. Prior to the construction of the grade-separated bicycle motorway, there were only painted cycle lanes, creating shared space between motorised and non-motorised traffic. An investment for infrastructure work, of approximately 1.2 million Euros has been financed outside of the ARCHIMEDES project (Lautrup, 2011). However, the project contributed through staff time to design, plan and manage the implementation of the measures.

4.1 The need for public participation

Unlike binding legal requirements for Environmental Impact Assessments or Strategic Environmental Assessments, there are no EU requirements for public participation or consultation in transport projects (Trasporti e Territorio, 2010; European Commission, 2011b). When planning the cycling motorway project in Aalborg, the planners interviewed stated that they did not have a binding legal requirement to include the public in the planning process of building the cycling motorway.

However, in light of the fact that the project was nested inside of a larger cycling strategy, Cycling City Aalborg, there was 8 weeks of public comment/communication space set aside where planners held workshops and other public events to communicate the goals of the cycling motorway. As noted by one of the planners within the municipality, *[t]his is part of an EU project and we do not have any requirements for doing this [public participation] in particular. But of course, the European community is very interested in having these experiences with citizen engagement. And that way we are kind glad that we did this. Because, now we can say in Europe, this is the way that you can have a good process about planning for cyclists* (GF).

Another rationale for public participation that is often put forward is that involving the public can *"get new ideas for the project but also to hear whether there are certain specific problems that were relevant for the people that are cyclists within in city*" (AMLN). In the case of the cycle motorway, the planners interviewed agreed that public involvement here was also important to avoid costly and divisive conflicts further down the road. As one of the planners explained:

'*If you do not spend the time and money at that point (early planning) you could easily spend later on. Because if you do not involve people in the beginning of the planning process then you could easily spend all the time and money on people complaining. You have to respond to every complaint that enters the municipality. So, in that way you will spend the time in some point anyway. Why do not do it at the beginning where it is positive involvement, instead of the negative feedback later on...It takes some resources but you would have spent, from my perspective, these resources anyway.*' (MV)

4.3 Targeted versus comprehensive public participation

"I think this might sound weird if you have a theoretical background in public participation, but if we had a very large number of people who will just come in because we had a public advertisement for this for instance, we would also have a lot of ideas that would not be practically possible. We could not stand with one hundred different ideas out of workshop. So we worked with small target groups – to make it more specific."(GF)

While our research shows a high degree of agreement with much of the academic and policy literature on the value of public participation for conflict avoidance and engaging citizens in planning, it is when we turn our attention to which publics participate and in what fashion that the empirical evidence tells a different, and more nuanced, story. The quote above illustrates quite clearly the 'tension of inclusivity' (Bickerstaff, Tolley, & Walker, 2002), whereby planners are often restricted in their ability to have a completely open process due to time, resource, and practical constraints. Since most of the ARCHIMEDES projects were already committed to specific outcomes prior to the public consultation period, the planners decided to forego more open public consultations that would have elicited ideas and comments that were unworkable or impossible to implement given the project schedule and budget. So whom to choose and how should they be chosen? A response that emerges from this case study is that planners use a combination of expert knowledge and agenda-setting power to include the groups that fall within the high influence/high stakes end of the sustainable mobility stakeholder matrix: professional planning staff,

consulting engineers, transport authorities, and key civil society interest groups that have a strong disposition toward supporting the project. The list of stakeholders that participated in the planning process of building the cycling motorway is shown in Table 2.

Table 2 Stakeholders involved in the cycling motorway project

Government/Authorities	Businesses / Operators	Communities/Local Neighbourhoods	Others
Local transport authority	Engineers/contractors (COWI - consulting firm)	Local interest groups (Vejgaard Samråd)	University (Aalborg University)
Traffic police	Transport operators/providers (Public transport unit, Aalborg municipality)	Cycle group (Danish Cyclists' Federation)	
Planners		Transport users	
Professional staff (designers, engineers, health and sustainable departments)		Citizens	

When questioned as to how participants were invited to a workshop organised by the municipality in order to finalise the design and placement of the cycle motorway, a planner for the municipality noted that "*it was very pragmatic process of choosing who should be in it, and it was made in the Archimedes Project Secretariat at that time, and we decided who should be invited in the workshop. And they were invited directly. It was not that we made a broad announcement of the workshop-it was made internally*."(GF) The use of targeted public participation in this context can be seen as a good strategy to engage specific citizen groups and stakeholders that have a strong interest in realising the project while avoiding the typical pitfalls of open-ended public participation processes of multiple rounds of discussions, meetings, map making and the like that ends up ultimately being ignored when the plans are decided between the technical and political actors within the municipality and powerful stakeholders. Another reason that the planners gave for using this type of engagement is that they frequently encounter a lack of interest from the public, and therefore more precise engagement with motivated actors avoided long delays in the planning process. The workshop was the most proactive point of interaction of the project team with public and stakeholders.

As to the question of when the public was included within the planning process for the cycle motorway (see Table 3), it is readily apparent that there were relatively few opportunities for active public involvement over the 4-year project time span. In Arnstein's ladder of public participation, this type of involvement could be reasonably located within the degrees of tokenism, somewhere between informing and placation.

Table 3 Stages of planning and public participation for the cycle motorway project

Stage/ Name	Actions	Stakeholders	Time
Stage 1 **Development of "tool box" with innovative bicycle initiatives**	• Collection of possible initiatives (measures) on the route • Inspection of the topology of the route in order to get 'an impression' of the route and possible initiatives. • Vision workshop with different groups of stakeholders and public	Representatives of all four stakeholders group (see Table 2)	Autumn 2008 / Summer 2009
Stage 2 **Design of the route and project engineering.**	• Finalizing the planning and drawings • Contacting the manufacturers of technical equipment and signing the contracts • Sending the application to the Danish Road Directorate in order to get approval for the lane light project (since this initiative, as a new and untried solution, needed an exemption from existing Danish legislation to be implemented) • Obtaining the approval to implement the project for a test period • An ex-ante count of cyclists	• Professional staff • Project managers • Danish Road Directorate	Autumn 2009 / Summer 2010
Stage 3 **Implementation**	• Establishing of the initiatives on the route • Informing the citizens	• Engineers/contractors (COWI - consulting firm) • Project managers • Transport users • Citizens	Summer 2010 / Summer 2011
Stage 4 **Evaluation**	• An ex-post count of numbers of cyclists • Evaluating average speed of the cyclists • Evaluating cyclists' attitude about implemented measures	• Project managers • Professional staff • Transport users • Citizens	Summer 2011 / spring 2012

Using the framework of the decision-making process set up by (Kelly, Jones, Barta, Hossinger, Witte, & Wolf, 2011), the role of the public and stakeholders in this project is identified. As Table 4 shows, in the process of decision-making (problem definition, option assessment, and formal decision-taking) there were little to no public participation, other than small groups engaged by the planners themselves. Even if the theory suggests that engagement is desirable in all stages of decision making process, here, in this case could be seen that from the planners' perspective, there was little compelling reason to engage the wider public in any significant way.

Table 4 The Stages of the decision making process and main actors involved

Stage	Actors
Problem definition	Project team
Option generation	Project team, stakeholders (targeted)
Option assessment	Project team
Formal Decision taking	Project team
Implementation	Project team, stakeholders (targeted)
Monitoring and evaluation	Project team, stakeholders (targeted)

5.0 Discussion

A reasonable person may ask: so what? What are the practical ramifications for planning that emerge from this study? The answer (or set of possible answers) has a few dimensions worth noting. Firstly, it may be necessary to re-visit both the theoretically- and policy-driven guidance regarding public participation and stakeholder involvement in sustainable mobility planning. Despite more than two generations of exhortations from planning researchers and practitioners, participatory approaches to planning have limits and those limits ought to be more clearly discussed as to how, when, and where public participation is employed. Transparency and fairness (both perceived and actual) are important planning values, but they should not come at the expense of abandoning professional expertise and insight developed through years of experience. One of the interesting tensions that emerged from the study is that the planners who were responsible for the cycle motorway project were all younger planners educated at a program at Aalborg University that places a strong emphasis upon on public participation and collaborative decision-making. Yet when faced with the constraints of real-life planning, there was little visible reluctance to engage in a much more specific and narrowly defined version of public participation, whereby the planners themselves chose which publics should be heard.

Secondly, the relentless focus the presumed need for public participation as a means to secure political support for sustainable mobility measures ought to be examined more critically. While this may be true for small-scale changes in transport modal shifts, when it comes to more contentious issues such as road pricing, removal of parking and capacity restrictions for motorised transport, broad public participation will likely encourage a continuation of the status quo rather than a shift toward non-motorised and energy-efficient modes of transport. If urban planners are serious about realising sustainable mobility goals, then they will have to, sooner rather than later, become more comfortable with the idea that large segments of the population will be strongly opposed to ANY restrictions on personal freedom in the material expression of the automobile. The recent planning disaster in Copenhagen regarding the

proposed implementation of a congestion ring neatly illustrates the point. The idea generated virulent opposition not only from predictable political corners, such as the conservative, free-market parties, but also from many of the Social Democratic municipalities that are located on the periphery of Copenhagen. Despite strong central government support, the city had to abandon the plan due to overwhelming public opposition.

Thirdly, and finally, there are a number of ethical paradoxes that are raised here. Denmark, along with the rest of Scandinavia, has a long history of democratic governance, and public participation and engagement have been integrated into planning system for many decades. The planning culture in Denmark recognises the significance of public participation, even if there are no legal requirements for doing so. Customs and norms of democracy and participation are also embedded in planning practice, even in the absence of formal legislative or regulative measures. Moreover, Danish citizens generally have a high level of trust in authority and there is culture of communication between citizens and planners at the local level, creating more space for planners to operate and decide without constant consultation with citizens and stakeholders. In political cultures that are more corrupt, contentious, or litigious, targeted public participation can easily assume a more ominous character, where existing power imbalances between the expert and the citizen are amplified by the ability of the planner to freely choose the particular public that they wish to engage.

Conclusions

How planners actually perceive public participation and how they ought to perceive it, according to both policy guidance and scientific literature, is not necessarily the same thing. One of the main conclusions to be drawn from this study is that from both a research and practice perspective, more empirical work needs to be conducted that seeks to understand how exactly planners today engage with the public. If we collectively are to realise our goals of living and moving in a more sustainable manner, then radical changes will have to be made in our current patterns of mobility and consumption. These will not be popular changes in the near term. Empty exhortations of “collective decision-making” and “public participation” often serve to mask the reality that the key decisions have often already been taken and what is required from the crowd is merely to give the thumbs-up or thumbs-down. Human beings are quite clever is sorting out the rules of the game and most people do not really enjoy being a part of a consultation process that is, at root, a charade of democracy.

The tension of inclusivity is also emerges quite strongly in the current paper. In the space between the communicative ideal and the difficult choices that need to be made in real life, what kinds of tools, practices, and ethical guidance will be required to make these difficult choices in a defensible manner. There may be little in the way of clear-cut right and wrong, but if planning wishes to move away from an elite exercise, then more work needs to be done to clarify exactly how and in what ways the public ought to or even wants to be involved in these decisions.

PLANNING FOR SUSTAINABILITY IN NORDIC TOURISM DESTINATIONS: Case Ylläs, Lapland, Finland

Tiina Merikoski [1], Kaisa Junkkonen [2]

Abstract

Many tourism destinations are struggling with simultaneous needs to protect natural environment and to meet the needs of tourism. Depriving natural assets, growing numbers of visitors, and fast construction and development all strain the carrying capacities of these communities. Planners are working in the crossfire of different demands, interests of several operators, and needs to preserve nature and its limited resources. Yet, planning for sustainability in tourism destinations remains rather vague.

MATKA Sustainable Tourism Destinations - Land Use, Architecture, and Energy (2009-2011) was a multidisciplinary research project investigating sustainable solutions for Nordic tourism destinations in terms of land use planning, energy systems and architecture. MATKA project aimed to…. MATKA was a joint project between the Aalto University Departments of Architecture and Energy Technology, and Finnish Forest Research Institute (Metla).

The case study site of this project located in the Finnish Lapland, Ylläs – one of the fastest growing ski resorts in Finland. The case study site was a roughly 1200 ha new development next to the existing ski center on the northwest slopes of Ylläs fell. At the time of the research, a master plan for the site had been prepared and approved by the municipality, and it waited to become legitimate. The municipality, together with other developers of the site, held a planning competition in 2010. The goal of the competition was not only to get a variety of optional plans for the site but also to find new solutions for a sustainable tourism resort. In 2011, planning the site continued with the winning team.

This paper will describe the results of the MATKA project together with the design process of the competition proposal and the further developed plan for the site. Furthermore, this paper will describe the observations drawn from reflecting the research and practice. Authors of the paper represent both ends: the research as well as the practice. Key questions of the paper are:

- How the research and practice met in this particular case study, and

[1] Aalto University School of Engineering, Centre for Urban and Regional Studies (YTK), Espoo, Finland – tiina.merikoski@aalto.fi
[2] Eriksson Architects Ltd., Helsinki, Finland – kaisa.junkkonen@eriarc.fi

- How did the different demands for sustainability integrate in planning the new resort community in Ylläs?

The analysis of Ylläs case study showed that meeting the demands of sustainability easily become secondary to the variety of short-term stakeholder interests, and that moving towards detailed planning the aims for sustainability do not concretize. The analysis suggests that strong cooperation between planners and researches from early phases of planning until the more detailed planning would be one way to ensure that aims for sustainability are considered through out the process. Also, this way the conversation between different stakeholders and decision-makers could be facilitated by the researchers, and therefore the possible disputes in the community lessened.

1. Background

Global concern on the sustainability of our development began already in 1960's with better understanding of the environmental changes and the effects of these changes on our living environment. Despite of being recognized and discussed already for decades sustainable development remains a vague concept and difficult to apply in practice. The aims for sustainability and the tools to achieve these aims are a challenge for everyday life as well as for policies, decision-making and land use planning.

There are many guidelines and criteria for sustainable planning (LEED etc.), and these guidelines are appreciated as tools for planners and designers. However, applying those to the often very specialized conditions and demands of tourism destinations may be difficult or even impossible. Many destinations are located in extraordinary natural environment, which is sensitive to erosion, and slow to restore. In addition, Nordic resort communities are often rural and remote destinations.

Natural environments as well as communities are in a constant change. There are many reasons for change, and not all is due to our actions or under our control. In resort communities the change is driven e.g. by customer demand, growing numbers of visitors, increasing traffic and fast construction which all have direct and indirect effects on the environment. With nature and landscape as their main assets, they struggling with simultaneous needs to protect natural environment, to meet the growing needs of tourism and to assure the social and economic well-being of the community (Shawn & Williams, 2004). With development and new construction tourism destinations reach for increased economic benefits and better competitiveness. But the growing numbers of visitors and fast construction strain the natural as well as the social carrying capacities of the communities. Changing environments require systemic approach to planning, and new thinking is needed in order to review the values behind development.

1.1 Case study: A new resort community in Ylläs, Lapland

The case study site of MATKA project located in Ylläs[3], in the western parts of Finnish Lapland (Fig.1). The site lies next to Äkäslompolo village and Ylläs-Ski ski center on the northwestern slopes of Ylläs fell. Ylläs fell (718 m.s.l.) is part of the third largest national park in Finland, Pallas-Ylläs National Park. It is the most southern fell of the park. The fells in Lapland create a unique mountainous landscape in Scandinavia, and also Ylläs is appreciated for it's far-reaching scenery and extraordinary Nordic nature. Like in many Nordic destinations, tourism in Ylläs is based on the exclusive natural environment.

Figure 1. Location of Ylläs (source: Google maps)

The case study site was altogether a roughly 1200 ha indicated for new development (Fig. 2). At the time of MATKA research, a master plan (Ylläs II Master plan) for the site had been prepared and approved by the municipality, and it waited to become legitimate. The master plan together with other legal documents and strategic plans

[3] Ylläs is one of the most visited ski resorts in Finland. Of the individual ski resorts in Lapland, Ylläs has had the second most registered overnight stays during 2004-2010. In 2011 Ylläs held over 12% market share of the nights spent in Lapland. (Statistics Finland & Regional Council of Lapland, 2011; 2012)

indicated the aims for development and growth for the site. The master plan consisted of a dense new village center connected to the existing ski center and an altogether 334 ha holiday housing and accommodation area. For hotel, tourism businesses and services the master plan allows up to 284 000 sq m of new construction (10 200 bed units), and for holiday housing approximately 50 000 sq m (2 500 bed units). Other guidelines for planning were set by the existing topographical, ecological and micro-climatic conditions of the site (Fig. 3).

Many strategic plans and development projects considering the future of the Ylläs site have been made during the last years and decades. Part of the long-term development was a planning competition that was held in 2010. The goal of the competition was not only to get a variety of optional plans for the site but also to find new solutions for a sustainable tourism resort. In 2011, planning the site continued with the winning team. Based on the winning entry, a *resort master plan* for the site was finalized in December 2011. A resort master plan is a combination of guidelines of the legitimate master plan, aims of the service providers and other actors. In the near future, the development of the site will continue with detailed planning.

Figure 2. The part of the Ylläs II Master plan that concerns the new resort development site as it was at the time of the MATKA project. (Source: Kolari municipality)

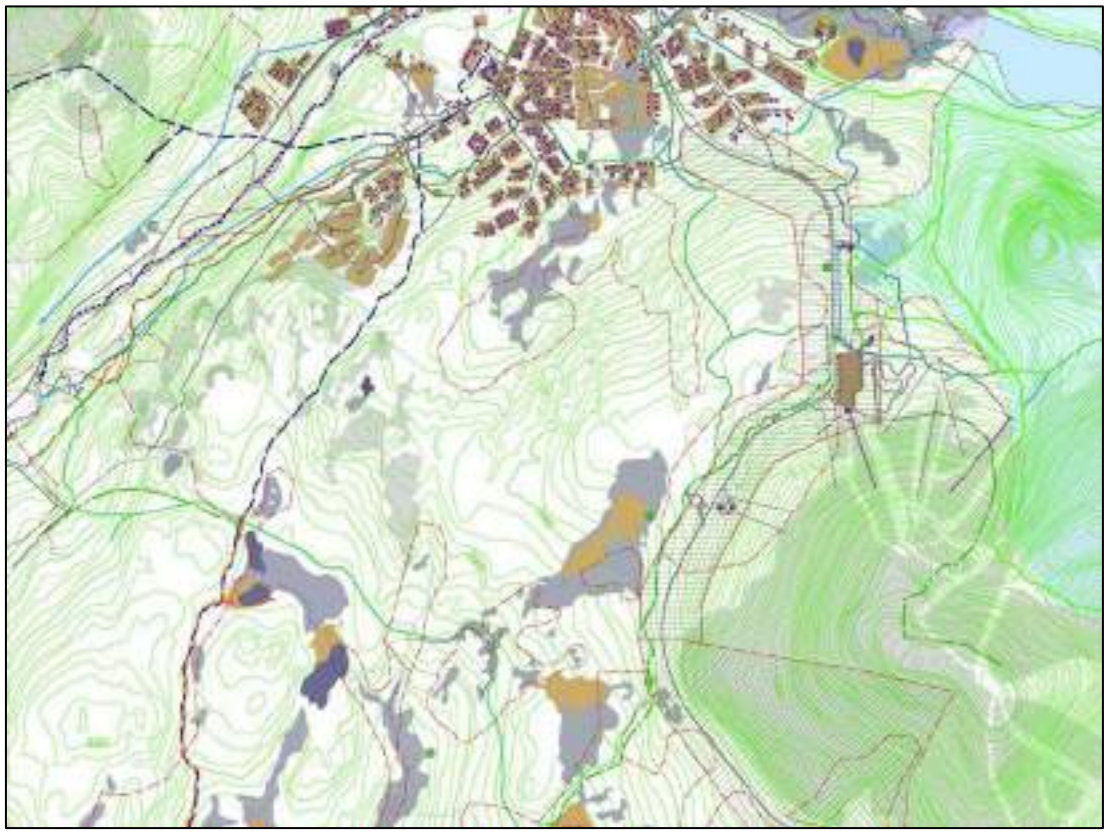

Figure 3. Ylläs case study site's topography and ecological conditions together with the existing infrastructure.

2. Methodology

MATKA project was based on pragmatic action research methods. During the project, MATKA researchers worked together with the project partners[4] that represented the entire value chain of stakeholders of the case study site. The ongoing planning process of the case study site framed the research through out the process. Different planning documents, policy papers and other relevant agreements, plans and reports were studied and analyzed in terms of sustainability. In addition, local actors and residents were interviewed, and a visitor survey conducted, in order to find out a shared vision for the development of the specific site. (Merikoski, 2010; Staffans & Merikoski, 2011)

[4] The project partners were Kolari municipality (the planning authority), Laatumaa (land owner), Lapland Hotels (tourism industry, one of the key developers of the site), Lemminkäinen Talo Oy (holiday house constructor and developer), and Fortum Power & Heat (energy company).

MATKA project was also linked with a planning competition held for the site. The aim was to enhance understanding in integrating sustainability in planning, and to find solutions for evaluating and comparing alternative plans. The researchers created principals for planning the site in a sustainable way for the competition program, and evaluated the proposals in terms of the given guidelines. For the evaluation it was considered how the given principals were articulated in the proposals, how the different dimensions of sustainable community were emphasized, and how had the guidelines been translated into planning solutions. Features, such as land use and infrastructure, of the proposed plans were investigated by layering the features of different proposals on top of each other. This way the differences between proposals were easier to understand and the effect of visual representations alleviated. (Fig. 4)

- KUVA -

Figure 4. Features, such as land use and infrastructure, of the proposed plans were investigated by layering the features of different proposals on top of each other.

For this paper the results of MATKA project were examined together with the design process the case study site. Authors of the paper represent both ends: the research as well as the practice. The authors aimed to identify some of those factors in a planning process that support long-term sustainable development.

2.1 Design sciences

Since this paper describes research and conversation over a planning process, it is necessary to have a look at *the design sciences* as a concept. Van Aken (2004) distinguishes three categories of scientific disciplines: *the formal sciences*, *the explanatory sciences*, and, *the design sciences*. By design sciences, van Aken refers to academic disciplines such as engineering and medical sciences. The design sciences aim to develop knowledge for the design and to solve or improve problems in e.g. construction or planning (van Aken, 2004). As van Aken indicates (2004, pp. 225), the final objective in design sciences "…is to develop valid and reliable knowledge to be used in designing solutions to problems." where as formal sciences such as philosophy or math aim to build systems propositions that are internally logical and consistence. Explanatory sciences, on the other hand, aim to describe or explain observable phenomena. (Van Aken, 2010, pp. 224).

Straatemeier et al. (2010, pp. 578) note that research in planning is not only concerned with understanding the current practices and processes but also with creating change. They argue that in order to generate innovations in planning, a particular research approach is needed. The traditionally used research methodologies (e.g. comparative case study analysis) are static and do not allow interactive development processes that are necessary in order to generate change.

Straatemeier et al. (2010) introduce a methodology called “experiential case-study analysis”. The methodology suggests that innovations for planning practices can only be developed through iterative testing, reflection and adaptation. (Straatemeier et al., 2010)

3. Key findings of MATKA project

MATKA project was a multidisciplinary research project investigating sustainable solutions for tourism destinations in terms of *land use planning*, *energy systems* and *architecture*. In terms of integrating sustainability in planning tourism destinations, the key findings were:

- A shared vision is needed in order to identify common values that all stakeholders and community members are committed to promote
- There is a need for more flexibility in detailed planning, and more commitment to value-based, strategic planning
- Competitions offer a viable tool to investigate sustainable planning solutions but it has to be ensured that they respond to the current needs and the ongoing planning process

3.1 A future vision of a sustainable community

Vision integration is being adopted for strategic development and planning in many cities and municipalities through various methods and with divergent results. It has been understood that evaluation of future direction in planning is often based on an analysis of the process that has lead to the current situations, and planning responds to guidelines set by the past. However, future community planned this way may not be the one we envision for ourselves. (Staffans et al., 2008; Merikoski, 2010) A shared vision is seen as a tool to "create the future we [the community] choose" (RMOW, 2007).

Figure 5 illustrates how the vision of a sustainable community was understood as a combination of national and global aims for sustainability and local condition and values in MATKA project. What the local community and stakeholders need and value in their business and living environment set a local frame for *the features for sustainable communities*. Together with the global demands for sustainability they form a framework for *a future vision* for the community. A shared vision responding to the key features of sustainability is a tool to identify objectives, and to develop criteria for planning and design principals. The built environment and its use and maintenance need to be monitored in order to verify the results and effects. Vision becomes reflective to new knowledge and results of implementation due to the ongoing evaluation. (Staffans & Merikoski, 2011; Merikoski, 2010)

Figure 5. Key features for a sustainable community are a combination of local values and global aims for a sustainable community. The features are necessary for envisioning a sustainable future for the community. Guidelines for planning can then be created based on the shared vision. (Source: Staffans & Merikoski, 2011)

Tourism destinations are communities with a variety of stakeholders. In addition to residents, tourism industry and municipality, the stakeholders include visitors, seasonal workers, second home owners and the services and business outside of tourism sector. Therefore, planning and developing these destinations means balancing between many different, and even conflicting interests. (Beritelli, 2011; Merikoski, 2010)

The discussions with Ylläs stakeholders indicated that in the end, interests of different stakeholders were not as conflicting as they were perceived. Old disputes in the community reflect on current atmosphere for cooperation and discussion. Sometimes the key aims are not heard or they are misunderstood by others because of prejudice or merely because common discussion turns into an argument on secondary topics. When future visions and development interests were discussed in small stakeholder groups common understanding as well as different points of views were easy to identify and the discussion was open minded. On the other hand, these discussions showed that in the end, the key interests were shared (Table 1).

Table 1. Shared values identified from stakeholder discussions in Ylläs. (Staffans & Merikoski, 2011)

LOCAL ENVIRONMENT: NATURE, LANDSCAPE, COMMUNITY **Respecting and protecting the natural systems**	
BUILT ENVIRONMENT	**COMMUNITY AND WELL-BEING**
A well-planned community (quality of	Needs of residents, community life and

planning, design and construction)	well-being
Sustainable mobility, trails (promoting car-free travel)	Partnerships and participation
Architecture	Identity, culture and cultural heritage
Sustainable energy solutions	Methods of guidance, know-how (towards sustainability)
Managed and controlled growth and development (carrying capacities of the community and nature; year-round tourism)	Tourism as part of larger economic system
Successful operational environment for tourism	Healthy and diversified tourism economy
SUSTAINABLE COMMUNITY, QUALITY	

A shared vision can be seen as a common agreement on the basis of future development. It is also a link between the often quite abstract aims of sustainability and the local context. However, these value-based key interests as guidelines for planning and development require commitment from all stakeholders. In addition, it is necessary that the stakeholders are able to trust on each other's commitment. The trust can be created only by long-term cooperation, and the experience from MATKA project suggested it might be enhanced by research partnerships.

3.2 Commitment to strategic planning

The National Building Code of Finland underlines the different aspects of sustainability, and all planning and building construction should promote ecologically, economically, socially and culturally sustainable development (MRL 2000, 1 §). Nevertheless, in land use planning as well as in building construction the legally binding, quantifiable regulations are only barely met, and it is left to the commitment and will of stakeholders whether they will aim more ambitiously towards sustainability.

Ylläs case provided examples on how aims for sustainability do not concretize towards detailed planning. The site for the new development sits next to the Pallas-Ylläs National Park, and the unique natural features typical to the area exist on the site as well. National parks in Finland are well protected by the law and the natural values of the site have been recognized in the Ylläs II Master plan as well: several levels of protection give guidelines for future planning. However, only a few of them are obligatory, and e.g. wetlands are only partly appreciated. Meanwhile, wetland and water body conservation is a required feature in many internationally renowned indicator systems, such as LEED 2009 for Neighborhood Development (USGBC, 2012). (Merikoski, 2010)

For successful resort development, the shared value-based aims for sustainability have to be identified and supported by all actors and stakeholders. Also, due to the lack of means to bring sustainability into practice in detailed planning, there is a need for more flexibility in order to implement new technologies and to promote innovations (Fig. 6). (Staffans & Merikoski, 2011)

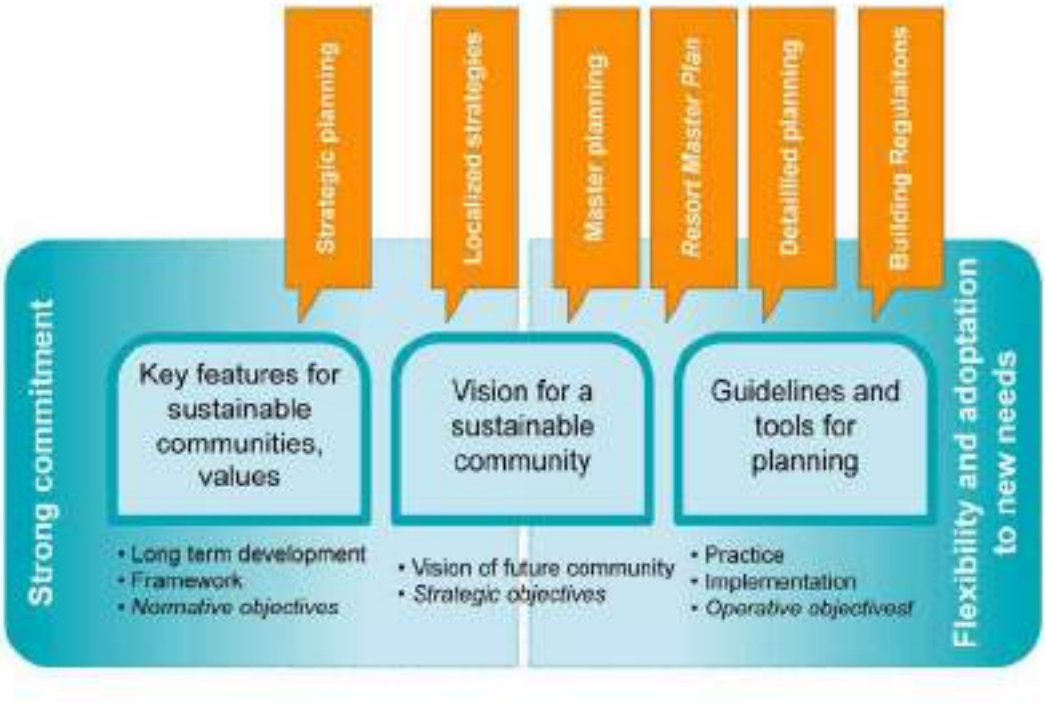

Figure 6. Current land use planning in Finland puts emphasis on detailed planning by legally binding regulations and rather slow transformation processes whenever revision is needed. More commitment is needed to strategic planning, and at the same time, more flexibility in detailed planning. (Staffans & Merikoski, 2011)

3.3 Competitions as tools for sustainable development

Design and planning competitions seem to offer a viable tool for investigating sustainable solutions for one particular site. (Staffans & Merikoski, 2011; Merikoski et al. 2012) With a competition, different options can be studied and stakeholders will understand already before the commission what to expect. Nonetheless, competitions have to be programmed in a way that the results respond to the current planning process and to a particular need. It has to be understood what can be solved with the competition, and clarified what is sought after. (Merikoski et al. 2012) It seems that in Ylläs, the planning competition would have been more successful if it had been held earlier in the process. Now, although considered flexible the legitimate master plan for the site set major limitations for new ideas for sustainability.

(Staffans & Merikoski, 2011) Figure 7 shows how Ylläs competition was positioned in the long-term planning process for the site.

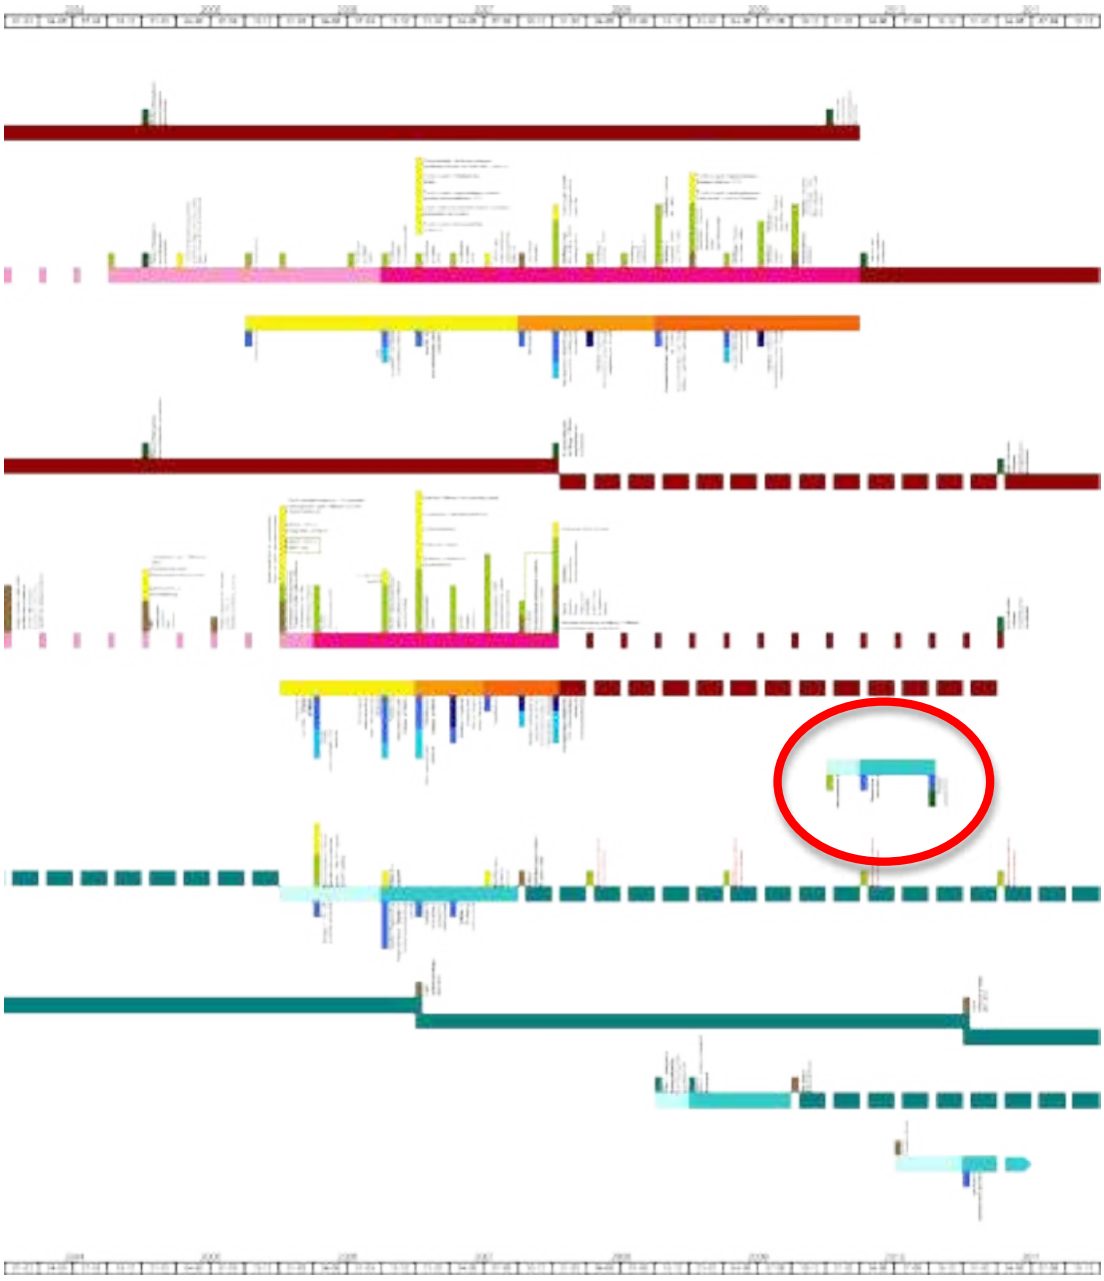

Figure 7. The evaluation of the Ylläs competition suggested that it might have been more successful in terms of finding innovations for sustainable resort communities had it been held earlier in the planning process. (Staffans & Merikoski, 2011)
KUVA MUOKATAAN SOPIVAKSI

4. Ylläs competition: guidelines for sustainability

Ylläs planning competition was launched in April 2010. The objective of the competition was to investigate optional planning solutions for the new resort community. Five multidisciplinary design teams were invited to propose a plan for the site, and to find new solutions for a sustainable tourism resort.

MATKA project took part in programming the competition by introducing a vision and key principals for sustainability as guidelines for planning the site. These guidelines were based on six features for a sustainable resort communities identified in MATKA project (Fig. 8). The vision was developed together with the various stakeholders of the case study site. In all, five group discussions were organized with different stakeholders: municipality representatives, business and tourism industry representatives, residents, land use and infrastructure actors, and second homeowners. During the process, local values, sustainability objectives and the future vision of the site were discussed.

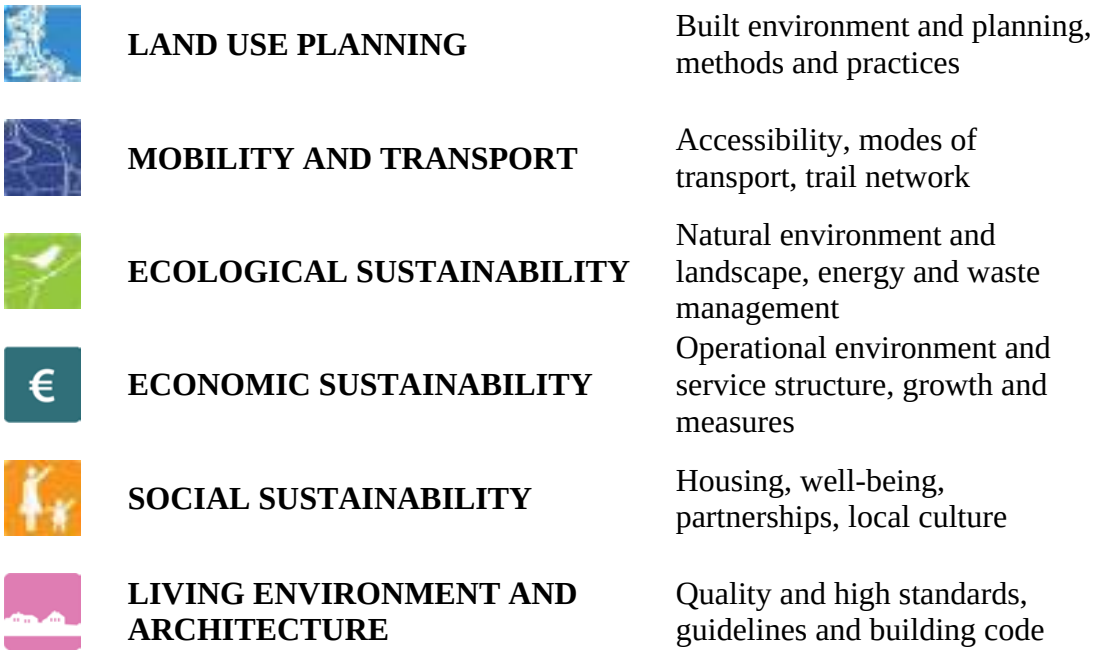

Figure 8. Six key features for a sustainable Nordic tourism destination identified in MATKA project. (Staffans & Merikoski, 2011)

Decisions made during early phases of **land use planning** have long-range impacts in terms of sustainability. Regional structure and built environment effect on future opportunities to adopt sustainable solutions. Planning also affects on how natural resources are employed and what kinds of uses and activities are encouraged – or

feasible. Planning practices are linked with social sustainability through participation and open communication.

Needs of **mobility and transport** in tourism destinations are two-folded: accessibility of the destination and mobility within the community. All stakeholders in Ylläs mentioned traffic planning, sustainable modes of transport and accessibility as key elements for a sustainable future. The trail networks (cross-country skiing, hiking, motor sleds, dog sleighs, etc.) were considered as one of the core attractions of Ylläs. Within the resort, accessibility includes physical and visual access to nature, as well as pedestrian environment (allowing access to tourism services and encouraging car free tourism). Sustainable mobility in a resort community has to respond to the needs of the residents and workers as well - in addition to visitors. The built environment sets the frame for different modes of transport: what kind of mobility is possible, and how sustainable and soft modes of transport can be adopted. Fast and sustainable transport (such as rail connection) to a destination will be an asset in the future because of the significant environmental effects of air and car traffic. (Staffans & Merikoski, 2011; Merikoski, 2010)

Protecting biodiversity and sustaining ecosystems are global concerns but for nature-based Nordic resort communities, **ecological sustainability** also means ensuring their own success as tourism destinations. Strong winds, heavy rains and weather conditions that change quickly require climate responsive planning and architectural solutions. (e.g. Luthe, 2009) Pollution, waste and other substances spread and stored in water, ground and air have a direct effect on the attractivity of the destination (RMOW, 2007). In addition, climate change needs to be considered in Nordic tourism destinations. It may mean changes for winter activities and the possibilities to perform different winter sports. If winters become more moderate in the future, year-round visitors and activities will become more important for ski resort communities. (Luthe, 2009) Already ski resort communities in Finnish Lapland struggle with significant imbalance between seasons that are not **economically** or **socially sustainable**. At the same time the operational environment has to support tourism business and encourage the sustainable practices, as well as economically profitable activities. The growth of the resort has to in balance with the carrying capacity of the natural environment and the community. Finally, in tourism destinations, the well-being of the local community is important also for tourism. The residents as well as the visitors will appreciate high quality **living environment** that reflects the local culture. As an example, the key objectives for *sustainable land use planning*, *mobility and traffic*, and *ecological sustainability* summarized for the competition are listed in Table 2.

Table 2. The key objectives for *sustainable land use planning*, *mobility and traffic*, and *ecological sustainability* summarized in MATKA project.

Sustainable land use planning	• A shared vision for sustainable future
	• Balanced development: new

	development, existing conditions and carrying capacities
	• Nordic nature and conditions as the basis for planning
	• LCA / Regional life cycle assessment
	• Multidisciplinary expertise integrated in all planning
	• Communicative planning and participative methods as a common practice
Mobility and traffic	• Sustainable access to resort
	• Balanced transport and route planning: carrying capacity, future demand, flexibility
	• Ensuring routes and trails for all users
	• Physical and visual accessibility of nature
	• Encouraging sustainable mobility and car free tourism
	• Accessibility and pedestrian environment
Ecological sustainability	• Protecting natural environment and biodiversity
	• Planning from local conditions: ecology, climate, topography and landscape
	• Energy and material efficiency in planning and construction
	• Local and sustainable waste management
	• Landscape-based planning

Although different dimensions help to understand the complex aims and demands of sustainable communities, they are interconnected. Moving towards a sustainable community in long-term may mean tradeoffs in short-term development. It means that taking a step forward in one area may mean lack of development on another area - or even negative impact in terms of sustainability. These tradeoffs must be recognized, and they can be seen as stepping-stones toward long-term sustainability. (RMOW, 2007) Vision-based planning is a feasible approach in order to illustrate and understand these interconnections and trade-offs.

Figure 9. Competition proposal “Luppo” suggested a strong ecological approach. This proposal left most of the site untouched and suggested radically less construction than Ylläs II master plan allowed. It was found unrealistic in terms of the site developers’ aims especially since it left the highest parts of the site – with the most sensitive nature – unconstructed. In the master plan, half of the resort center and a 10 000 sq m hotel are to be built to these parts of the site.

The competition proposals were submitted in early fall 2010. MATKA researchers analyzed the proposals in terms of the given guidelines. Overall the proposals suggested only variations of plans that were fitted well into the Ylläs II Master plan. Innovative approaches to sustainability were not found and only one of the five proposals, “Luppo”, suggested a plan with a strong statement for sustainability. It proposed radically less construction than the master plan allowed leaving as much land unconstructed as possible (Fig. 9). Even so, it was considered unrealistic in terms of developers’ aims for the site. “Noitarumpu” offered an interesting approach to organizing traffic and the core of the resort (Fig. 10). However, the proposal was not economically feasible.

Figure 10. In the competition proposal “Noitarumpu” the center of the resort was resolved in a very characteristic way. It was found interesting and reflecting the local culture in an innovative way but considered economically unrealistic to realize.

The competition was resolved in December 2010. The analysis and findings by MATKA researchers were available also for the competition jury to support their decision-making. “Kuura” by Eriksson Architects was announced as the winner (Fig. 11). It was considered the best compromise of all the guidelines and aims. The plan was carefully studied and it responded well to the architectural guidelines for sustainability, such as the composition of buildings in the landscape and topography. However, it was considered too spread out in terms of land use, and the jury suggested that in the future, it would need to be developed more compact. Further planning of the site was commissioned to the winning team, and the resort master plan finalized late in 2011 was based on the winning proposal.

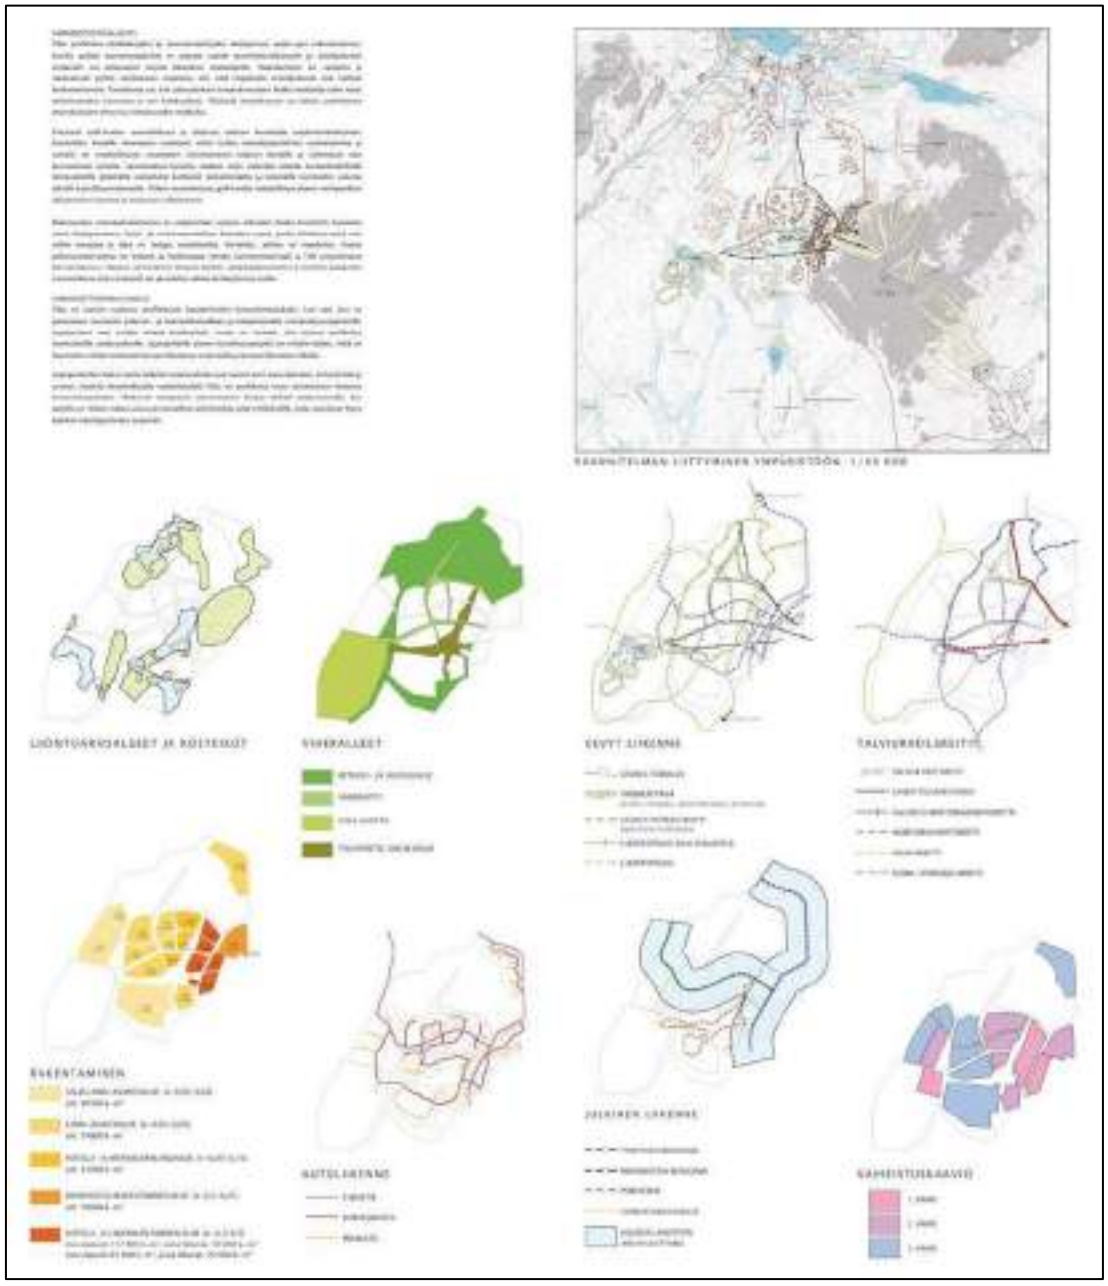

Figure 11. Competition proposal “Kuura” was considered carefully studied, and it responded well enough to all the different aims and guidelines of the competition. MATKA researchers appreciated the proposal for taking well into account the architectural guidelines for sustainability such as the composition of buildings in the landscape and topography.

5. Planning process

5.1 The competition proposal

The guidelines for Ylläs competition included the existing Ylläs II Master plan and the principals for planning a sustainable tourism destination given by MATKA researchers. The master plan was considered flexible but at the same time problematic in terms of the aims for sustainability. For instance, the different densities of construction set by the existing plan were seen problematic: in certain areas the density seemed too low for an effective infrastructure or public transportation system. On the other hand, the dense new resort center was to be built on the most challenging topography and the most vulnerable natural environment.

In planning competitions, the teams balance between the restrictions set by realism and the totally new approaches to planning the site. Proposing a plan that offers a new approach includes a risk of not becoming rewarded. Often competing teams aim for a compromise where the proposal is a combination of realism that the organizers are assumed to be looking for, and new thinking to some extent (Merikoski et al., 2012). What the approach will be in a particular competition is a decision that has to be made in a very early phase of the design process.

In spite of the aims for sustainability that might have provoked for new thinking, as well as the challenges in the existing master plan, in this case, the planning team still chose to follow the major guidelines of Ylläs II Master plan as it was given as the base for the planning.

Figure 12. Winning entry “Kuura” by Eriksson Architects Ltd.

One of the challenges of the competition was how to ensure easy access to sustainable modes of transport and to different trailheads as the new construction and development would take more and more land area. Guidelines such as limiting new construction within walking distance from main roads were suggested in the Ylläs competition program. It was demonstrated by the MATKA researchers that while it would still allow same amount of development (sq m and bed units) with the same average density as the current master plan, public transport would be accessible, and nature and trailheads would be always at walking distance. (Staffans & Merikoski, 2011; Merikoski, 2010)

Nevertheless, the planning team deemed that new ideas for sustainable transportation and traffic came out easily for the competition proposal. In the proposal, access to pedestrian, skiing, hiking and biking routes was kept easy with the aim to reduce the need for a car. Two lifts were also placed on the resort area to enable the ascent to the slopes directly from holiday accommodation. Reindeer and husky taxis were proposed as alternatives for traditional taxis. It was also easy to use creativity in the energy issues in the competition phase as the planning team included an energy expert: for instance the energy collected by cooling the slopes was proposed to be utilized in heating the holiday houses.

The most challenging task in the competition – and also later in the planning process – was to place the required amount of square meters of new construction on the steep slopes of the site. These northwest slopes will be challenging to construct but they are also valuable in terms of nature and landscape. However, the amount of new construction was justified by the close proximity of tourism services and lifts that made the new center easily accessible.

In the proposed plan, the given densities were mainly achieved. The best possible solutions to place the maximum capacity of construction on the site were studied, and the main idea was to leave as many of the unique geological formations untouched as possible. The existing master plan included instructions to leave “the most valuable parts” of these geological formations untouched, yet it didn't state which parts of the slope these actually were. There seemed also to be a conflicts between the allowed square meters, given floor heights and the overall area of the site. It was almost impossible to leave parts of the site unbuilt with the required amount of square meters.

Although considered flexible, Ylläs II Master plan set major limitations for new sustainable ideas. The planners found it difficult to follow the given guidelines for sustainability while the existing master plan was in so many ways contradictory to them. The widely spread structure of new construction and the dense new center situated over the most vulnerable and geologically valuable environment, were considered as the most challenging components of the existing master plan. The biggest change to the existing master plan in the proposal was the relocation of the

new main road connecting the village and the new resort together. The road was moved further north in order to leave the most central area of the site for pedestrian and recreational use only. This green corridor, "The Winter Park", also included a ski-in-out route and a lift that permitted straight access from the cabins to the slopes. This solution made the pedestrian traffic superior compared to vehicle traffic, and was considered one of the most important ecological components of the proposal.

When the proposal "Kuura" was announced as the winner of the competition, the same challenges, the lack of preserved natural areas and the fragmentation of the land use, were criticized in the jury's feedback. The timing of a planning competition in terms of the long-term planning process seems to be crucial when new and innovative planning solutions are sought after. The realism and the knowledge of the ongoing planning process may limit the competitors' will to take risks and propose something against what has already been decided.

5.2 Further planning: a resort master plan

Further planning of the site was commissioned to the winning team, and the resort master plan finalized in late 2011 was based on the winning proposal. A particular *resort master plan* is used in planning resort communities, and it means a comprehensive development plan of a center for travel, leisure, trade, business or another action. It typically consists of a study and a plan of the needed investments, economy, financing opportunities, marketing and sales of an area, as well as the locations of the main facilities. However, the Ylläs resort master plan was not realized to that extent. It concentrated on the volumes of the new infrastructure and the viability of planning solutions for the areas that were to be realized first.

The feedback from the jury of the competition as well as some useful ideas from the other rewarded competition proposals were utilized in the resort master plan as much as possible. Yet, some ideas proposed in the competition, especially considering the sustainable lifestyle of the new resort, seemed to be unrealistic at this stage. Many of the earlier strategic plans of Ylläs, and the different interests of operators were also studied more carefully at this point. In addition, the results of the MATKA research project were available. However, further cooperation with the researchers was not possible because of the schedule and the limited resources.

The goal of the resort master plan was to concretize the long-term goals of sustainability and create a base for the detailed planning in the future. Even though, many of the questions remained unresolved and were left for detailed planning. The future will show how the long-term aims for sustainability will become visible in the new resort.

For planners, working in the crossfire of the different demands of sustainability and the aims of several operators is challenging. Many times the final plan ends up a compromise, and not the first priority of anyone. The demands of sustainability are easily left secondary to the other interests. The further the planning process is from

legitimate and detailed planning, the easier the goals of sustainability can be seen. The commitment to sustainability is tested when the actual resources for implementation become at stake. There are no means to bind these aims legally when moving towards detailed planning and construction. If there are no measurable qualities, it's also hard to evaluate how well the goals of sustainability are reached in the plan (e.g. Junkkonen, 2011).

Figure 13. Resort master plan by Eriksson Architects Ltd. finalized in December 2011.

6. Analysis: how the research met practice in terms of sustainability?

During the research (2009-2011) and after it, the discussions for creating a new *sustainable* resort community in Ylläs faded gradually. After the competition and the researchers involvement the focus in planning shifted towards short-term stakeholder interests. Also, the discussion continued involving only the active partners of the new

development instead of all community members. At the same time, tight schedule for planning did not leave enough room for planners and architects to further investigate how to combine the aims for sustainability and the demands of stakeholders in the new resort master plan. Architectural and planning offices, even if specialized in sustainability, can develop their knowledge only to a certain extent. Therefore cooperation with researchers in planning would offer a way to gain access to latest research in integrating aims for sustainability in planning.

The analysis of Ylläs case study suggests that meeting the demands of sustainability can easily become secondary to the other stakeholder interests. In the competition, innovative approaches for sustainable communities had been left second to the demands of the existing master plan. The further the planning process is from legitimate and detailed planning the more aims for sustainability are present. At the same time there are no means to have these aims legally binding and they do not effectively transfer into practice when moving towards detailed planning and construction. The closer the process gets towards realization the more regulations begin to emphasize measurable and quantifiable qualities. For sustainability, it means that only regulations such as for energy systems or energy efficiency can effectively be included.

7. Conclusions

Planning sustainable tourism destinations requires a combination of different fields of expertise, such as land use and traffic planning; energy systems engineering; architectural design, landscape planning and ecology expertise; climate planning; tourism sector; and understanding in cultural and social environments. Planning means compromises and trade-offs, and it is case-related what kind of emphasis is put to the aims for sustainability. Nevertheless, planning sustainable Nordic tourism destinations begins with protecting natural environment and biodiversity.

MATKA project argued that new guidelines for planning are needed, as well as knowledge of sustainability and how to bring it into practice. Especially municipalities in remote areas with small resources may have a limited access to the information and skills needed to develop local sustainability. At the same time these communities may depend on tourism that appreciates the nature, as it is the case in Ylläs. Resort communities also have a plethora of stakeholders, and therefore a mutual understanding of the terms of development may be difficult to find. All have their short-term interests, and the compromises may mean mediocre design. Aims for sustainability are easily left secondary when stakeholders insist on their own interests without committing to common values. At the same time, many decisions made during early phases of land use planning have long-range impacts in terms of sustainable development. Regional structure and built environment create the frame for future opportunities to adopt sustainable solutions.

Working in the crossfire of different stakeholder demands was more than enough for the design team. Tight schedules do not leave opportunities for the planners and

architects to effectively introduce latest knowledge and research of sustainability into their work. Strong cooperation between planners and researches from early phases of planning until the more detailed planning would be one way to ensure that aims for sustainability are considered through out the process. Also, this way the conversation between different stakeholders and decision-makers could be facilitated by the researchers, and therefore the possible disputes in the community lessened. Interests of different stakeholders may not be as conflicting as they are perceived.

It can be argued, that at least in Finland developing new tools and methods for planning for sustainable communities depend much on research projects. Planners, municipalities and stakeholders lack the time, financing and other resources for effectively develop the practicalities needed. It is critical to look at the points in planning processes where research projects end: how the planning continues and how the findings in research are implemented. Unfortunately, quite often the development does not continue and the results are not undertaken. To solve this we'd need to ensure that project's ending does not mean the end for cooperation. Also in term of design sciences and the academic benefits of design research, long-term cooperation and iterative process development are needed.

There seems to be many opportunities in developing partnerships where design research could develop new ways of interaction and cooperation through iterative processes as well as investigate the integration of aims for sustainability in land use planning. Correspondingly, planners, architects as well as all stakeholders would have the latest research knowledge at their reach. Competitions offer one tool for these partnerships. However, interaction should be taken further and continued after the competition is resolved. Researches can provide material and guidance for the competition and throughout the process. In addition, involving research partners directly in planning processes, and exceeding the cooperation in one particular project, offers another approach to a more intensive conversation between planners and researchers.

MATKA project and Ylläs case study could be seen as part of an experiential case-study analysis (see Straatemeier et al. 2010), and the next step would be to adapt the methods to another case study. Only then the lessons learned and reflections done would help to further develop the practices for cooperation as well as the vision integration in order to consolidate and implement aims for sustainability in planning.

PARTICIPATION ENCOURAGED BY LAW – INTERVENING NEIGHBORHOODS, MUTUAL LEARNING AND EMPOWERMENT

Sandra Viña [1]

Abstract

Neighborhood, community and city development have become a matter of growing interest in terms of investigation and practice throughout the last decades (see e.g. Thackara, 2005; Fuad-Luke, 2009; Augé 1995; Carmona et. al, 2003; Gehl 2010). However, one of the challenges of city design deals with the application of participatory design and user-centered design approaches and, in making governments to accept the importance of user involvement in design activities and community development.

The paper aims, above all, to discuss how a political top-down decision in the higher educational system of Venezuela could bring about new perspectives, discourses and ways of doing in the field of architecture. In 2005 the government of the Bolivarian Republic of Venezuela decreed a new law: the community service for higher education students. The law aims to regulate community service work for students of higher education that, at undergraduate level aspire to practice any profession. The community service work is understood by the activities students should develop in communities by applying the knowledge acquired during their studies for the benefit of neighborhoods. The new discourse focuses on local development and neighborhood empowerment based on social design and participatory approaches. The paper illustrates three intervention cases which are part of the service community work by students of architecture and urbanism of the Central University of Venezuela (UCV). The cases illustrate the relation of the local macro-micro level changes especially in the field of design and architecture and their relation to community development, empowerment, and social design.

The three case studies shed light to design interventions as a tool to reflect and build dialogue through participatory means. It facilitated mutual learning between ordinary people and students of architecture about concepts and practices of architecture and cultural heritage. The design interventions offered locals a possibility to reflect about their local environment and the importance of social and cultural events as part of their identity and value in the society. It empowered people from the neighborhood to deal with local knowledge and local development.

1. Introduction

Neighborhood, community and city development have become a matter of growing interest and research in terms of investigation and practice throughout the last decades (see e.g. Thackara, 2005; Fuad-Luke, 2009; Augé 1995; Carmona et. al, 2003; Gehl 2010). However, one of the challenges of city design deals with the application of participatory design and user-centered design approaches and in making governments to accept the importance of user involvement in design activities and community development. The aim of this paper is above all to discuss how political and top-down decision-making can help to generate new perspectives and ways of doing in the higher educational system of Venezuela, the field of architecture in particular. The new discourse seems to be focusing on local development and neighborhood empowerment based on social design and participatory approaches. This paper shows through three design interventions how mutual learning between future professionals and local people develops; reflections on the notions of architecture; and, community empowerment. The three intervention cases are created by students of architecture and urbanism of the Central University of Venezuela (UCV), they illustrate the relation of the local macro-micro level changes especially in the field of design and architecture and their relation to community development, empowerment, and social design. The paper also presents how top-down decision-making can help to discover new methods, methodologies, approaches and experiences in the area of design for social well-being. According to John Thackara "we need to design macroscopes, as well as microscopes, to help us understand where things come from and why" … "Macroscopes can help us understand complex systems" (Thackara, 2005, p. 6). Thus, a zoom is required to look how changes take place at all levels of social change and communities collaboration.

Generally, the regeneration of a city looks into ways to rebuild and redefine the city image through new urban entrepreneurialism or city marketing (Paddison, 1993). However, the new renaissance of cities is connected with the social and cultural aspects of regeneration, thus questions of heritage, tradition and authenticity are putted forward. In late 1960s a reaction against modernist environments took place and new policies came into existence that protected historic areas, and thus preservation became an integral part of urban planning. Cultural and historic buildings and environments were observed to serve and support urban life and activity in contrast to modernist environments. These experiences also gave light to the uniqueness of places, styles, their history, and a great concern about contexts, continuity of local patterns and typologies. (Carmona et al, 2003).

Research in the contemporary landscape of urban politics or urban governance uncovers a decline in the community power, urban managerialist and collective consumption debates. The current post-political consensus appears to be absorbed with economic growth combined with an explosion of entrepreneurially oriented governing regimes (MacLeod, 2011). Nevertheless, what seems to be lacking in the current understanding of city development and community building is a stronger

discussion on how and why designers/planners and architects ought to utilize participatory design approaches, social design thinking and design interventions as part of their learning design process. Moreover, it is relevant to study the relation between macro level decision-making and changes in the micro level of the professional field, as urban planning and architecture in this case.

Throughout the presidency of Hugo Chávez Frías the constitutions and strategies of the country have changed. The shift moves towards the 21st Century socialism, which is a revolutionary socialism directly linked to the philosophy and the Marxist economy. The vision of the current government is to establish, promote and support participation and collaboration among different communities. In the year 2005 a new presidential decree was decided in the Bolivarian Republic of Venezuela: the law of community service for higher education students which runs under the country's constitutional principles of solidarity, social responsibility, equality, cooperation, responsibility, participation, humanitarian assistance and otherness. This decree attempts to drive changes in the structures, functions, knowledge systems and knowledge sharing of communities, giving strength to local knowledge, empowerment to communities and local development. It focuses on the practice and implementation of interventions as driver of change, participation and for growing awareness about the new discourse.

At the macro level this nationwide change towards citizen participation through the presidential recognition of participatory approaches to drive social cohesion and well-being bring about the discussion of scale and social design in city design and local development. Participatory design deals with considerable challenges not only in new processes of formation and education but also in the paradigm shift of higher educational disciplines and governmental system. Participation encouraged by a presidential decree to students of higher education can be seen as design, social and participatory design moving into the public space, into the area of social innovation, social change and social well-being.

According to Björgvinsson, Ehn and Hillgren (Proc. PDC 2010, p. 41) a major challenge deals with what is being design as an object or service; or, as a "sociomaterial assembly that deals "matters of concern"". The shift of design towards sociomaterial touches upon communities and the engagement with environments where user centered and user inspired design can develop. Taking participatory design to the streets and to public spaces has the fundamental difference of working with the public and communities rather than within organizations. Ezio Manzini's experiences, in the so-called developing countries, during his workshops appoints new attitudes and designs about daily life where objects are being replaced by fascinating events. The shift towards a more sociomaterial thinking includes the design of "activities and environments in which energy and material consumption is modest and more people are used." (in Thackara, 2005, p. 6).

Within the law community is illustrated in the social context of national, state or municipal level where the institutions of higher education will actualize the

community service. Community is thus defined, in its widest sense, as a group of interacting people living in some proximity; or, sharing common values. The cases illustrate in this paper were explored through on site visits, interviews to students, community members and professors and, the analysis of students' reports. Each group focused on one community or concern within the area of San José situated in Caracas. The first group concentrated on a public primary school and worked with teachers, staff and children in order to make sense of cultural heritage and the service community work. The second group intervened the school of medicine of the UCV and involved various groups of students in the sector. Finally, the third group of students functioned as supporters, catalysts and promoters of their classmates' interventions and San José's cultural and social richness.

2. Demanding participatory democracy, social integrity and changes in the higher educational system

The law of community service for higher education students decreed by the President of Venezuela Hugo Chávez in 2005 brings forth a great variety of experiences for students, professors, and the communities where the service community work is delivered. The decree is an incentive by the government of Venezuela to drive change in this decade. The vision of the government is to move to a social model that drives principles of self-development and independence through incentives and subsidies for the growth of productive and educational activities to overcome the traditional livelihood systems and, to increase social well-being especially in rural and low-income communities.

The social model of the country is the 21st Century socialism, which sustains four axes: the regional democratic development, the economy of equivalence, participatory democracy and protagonist and, grassroots organizations. This vision is also a product of Karl Marx on the social dynamic and the class struggle. Also, the country supports independence from capitalism by promoting cultural independency; moral power; politics of liberation; and, the growth of the country must be in complete unity. The ideology structure of the revolutionary socialism lies in self-management and the idea of creative communities and sustainability, ideology by Ezio Manzini and the Design for Social Innovation towards Sustainability (DESIS). Thus, there is a strong link between politics and design; ideology and product; intellectual and practical knowledge. The current shift in Venezuela tries to move individuals and communities towards sociomaterial interactions; participatory and proactive approaches; and, puts emphasis on local culture and local development as foundation for social cohesion and wellbeing.

According to Tony Fry (Fry, 2011, p. 38) "what design brings into being not only influences the nature of the world we human beings inhabit but equally affects what we become as actors within that world as its makers and un-makers." We can also think of individuals as being passive, active and pro-actives. Reaching social stability, wellbeing and harmonious conditions with nature and the built-environment requires proactive communities and "a radical mind that moves away from the notion

of perceptual growth towards a situation in which quantity is displaced by quality (itself redefined, elaborated and culturally infused)." (Fry, 2011, p. 64). The implementation of the service community work as a top-down approach to neighborhood regeneration and community building can help to re-establish values and principles in the country. The political vision also comes together with practical tasks that tackle the micro level, participatory and inclusive performances, and social design thinking that future professionals should gain knowledge of and consider for future design interventions; and, in the macro level a re-conceptualization of production and consumption of places, as it is articulated to what Fry describes as "responsibility for what is produced (contributing not just to sustaining the bio-physical environment but equally to skill and knowledge, and thus to a social ecology)." (Ibid.)

The law of community service for higher education students positions individuals, communities and especially students in a design effort that contributes to the transformation of Venezuela. I can suggest Fry's 'design as politics' where "design-led changes is tremendously important, and will become ever more so – as a means to essential change." (Ibid, p. 3) Fry proposes that "design has to be made overtly and proactively political. Design has to become a politics. For design to become politicized, it has to directly confront politics." (Ibid, p. 7). Integrating the power of design as an agency of social transformation in the strategy of a country is already a huge step to a friendship where politics and design communicate.

Thus, one can regard designers, planners and architects as 'actors' of social change. According to Bruno Latour "An 'actor' in the hyphenated expression actor-network is not the source of an action but the moving target of a vast array of entities swarming toward it. … To use the word 'actor' means that it's never clear who and what is acting when we act since an actor on stage is never alone in acting. … By definition action is *dislocated*. Action is borrowed, distributed, suggested, influenced, dominated, betrayed, translated. (Latour, 2005, p. 46). In this sense, one of the challenges of the service community law relates to its fully recognition among teacher, professors, students and researchers. Some teachers feel that the service community project is an obligation rather than an opportunity to explore the design field and come about with new methods and methodologies for instance. Also, some students feel as 'actors' forced to behave in a certain way (interacting and exchanging with specific local knowledge and communities); performing in a stage not familiar or out of their preference (usually low-income communities); and not fully understanding the core story (design as agency of change).

The new opportunities of design in the public sector open doors to a great extent of emerging areas in design that can be explored. According to a survey done by Design Council in United Kingdom the 22% of the complete clients for design businesses are public administration, health and education. Moreover, there is a "rise in the number of design business doing work for public sector and non-profit clients over the past few years." (Julier, *Proc. NORDES 2010, p.* 77). The rise of design expertise in the public sector can be seen as part of a package shift in the public sector in

which citizens become consumers of state services, (Julier and Moor, 2009), protagonist of participation in design and, overall helps to build platforms for students and professionals to collaborate and learn with ordinary people about real problems and design opportunities.

This new opening to students of higher education shows the idea of design moving towards an innovative and distinguished practice, which also become embedded into governance. We can steadily recognize then, that the local government and authority of Venezuela are moving forward greater systems of innovation based on building synergies between communities and social design approach. The shift of design practice and design initiatives in the public sector is also visible in the Reforming Higher Education by the UNESCO in 2009:

"*Higher education itself is confronted therefore with formidable challenges and must proceed to the most radical change and renewal it has ever been required to undertake, so that our society, which is currently undergoing a profound crisis of values, can transcend mere economic considerations and incorporate deeper dimensions of morality and spirituality."*

Design education and governance as actors of social integrity, social change and social well-being touch upon the shift of higher educational paradigm. Young-Gil Kim proposes (Kim 2010, p. 76) that "revolutionary change of educational paradigm with scientific development from the industrial era to the knowledge age of the twenty-first century, toward a trans-disciplinary education which integrates rather than isolates the academic disciplines." Also, the shift integrates three essential attributes of the twenty-first century education: "*globalization, humanization,* and *futurization*". (Ibid. p. 75) *Globalization* refers to "the movement from finite-borders to infinite-borderless", *humanization* defines "human advancement beyond materialism", and *futurization* puts "an emphasis on future-eternal values rather than immediate results."

3. Law of community service for higher education students

In 2005 the government of the Bolivarian Republic of Venezuela decreed a new law: the community service for higher education students. The law aims to regulate community service work for students of higher education that, at undergraduate level aspire to practice any profession. The law is ruled by the constitutional principles of solidarity, social responsibility, equality, cooperation, responsibility, participation, humanitarian assistance and otherness. The vision of the current government is to establish, promote and support participation and collaboration among different communities. The geographic scope of the community service comprises areas in the national territory that each institution of higher education determines.

The community service for higher education students is understood by the activities these students should develop in communities by applying the knowledge acquired during their studies for the benefit of communities and, to cooperate to achieve social well-being according to the establishment of this law in the Bolivarian Republic of

Venezuela. Students of higher education should apply their scientific, technical, cultural, recreational and humanistic knowledge during the service community interventions.

The law defines community in the social context of national, state or municipal level where the institutions of higher education will accomplish the community service. The community service can be eligible after the actualization of, at least, 50% of the total academic load; the community service consists of 120 hours of work and it is mandatory for obtaining the degree of higher education. The community service aims to: 1) nourish solidarity in the student and the responsibility with the community as an ethical and citizen norm. 2) Create an act of reciprocity within the society. 3) Enrich the higher education activity through the service-learning period and apply the knowledge acquired during the studies years. 4) Integrate institutions of higher education to communities in order to contribute to the development of the Venezuelan society. 5) Educate through the service learning the national social capital.

The law also brings about changes in the area of teaching and training, it touches upon the role of professors in particular, as they are required to be pro-active in the search and understanding of communities and their requirements. Professors work as mediators between students and communities, and they are responsible for teaching new approaches and topics of interest. Overall, they can drive social change. Moreover, professors and the administration of higher educational institutions are responsible to develop seminars, workshops and/or courses that deal with the topic of communal reality. These aim to educate the academic staff and students about their responsibilities, the viable execution, coordination and objectives of the community service.

The projects execute during the community service should be elaborated answering to the necessities of the community, offering solutions of methodological scope, and considering municipal development plans, at state and national levels. There exists various ways how to originate a community service project, the following entities can be the drivers: 1) The ministry of higher education; 2) Institutions of higher education; 3) Students of higher education; 4) Trade associations; 5) Public institutions; 6) Private institutions; 7) Organized communities. Each community service project should deliver a report where the problem is illustrated, how is approached and solved. The report also should include a justification, objectives and a methodological focus together with any specific requirement demanded by the educational institution.

4. Context of design interventions and methodology

Following I present three case studies accomplished during the year 2010-2012 by one of the service community classes of the School of Architecture and Urbanism of the Central University of Venezuela. This class was selected because the projects and design interventions where happening during my stay in Venezuela and they were dealing with social and participatory approaches. The projects were examined by the

realization of interviews to students, professors, and people from the community where the service was delivered; on site visits to the community was helpful to understand the conditions of the neighborhood; and, a study of students' reports also assisted for this investigation.

The three intervention projects were accomplished in the area San José situated in central-north part of Caracas. San José has a population of approximately 40.000 inhabitants, and it was funded in 1889. The realization of the community service in this community originated in response to the specific necessity of saving San José's flower market in 2009, which was thread to be demolished by governmental entities in order to construct the main stop of the Bus-Caracas. Under this circumstance the community of San José approached the school of architecture and urbanism (UCV). The school organized a forum where experts, intellectuals, people from the community affected and the municipality discussed matters of cultural heritage and how it relates to the possibility of destroying the flower market. The decision to demolish the flower market was dropped, bringing forth dialogue about the essence of the flower market as a cultural heritage and, its meaning to the community.

In first place the community of San José wanted students of architecture and urbanism to design a new building for the flower market. However, the current value of the flower market does not reside in the edifice as such but in the activities generated and social dynamic in it, also the essence of flowers as being ornamental and medicinal. Nonetheless, the service community class began by examining the case of San José, not only the flower market but the entire neighborhood, they focused on the notion of patrimony starting with an open discussion of what cultural heritage means not only in the architectural or physical level but also in the immaterial one. This can also be translated to the soft assets and hard assets describe by Thackara (2005, p. 79). "Hard assets include natural beauty and features; shopping facilities; cultural attractions; and building, museums, monuments and the like. Soft assets are all about people and culture: skills, traditions, festivals, events and occasions, situations, settings, social ties, civic loyalty, memories and the capacity to facilitate learning of various kinds."

After the concept of heritage was discussed the class made an excursion in the community of San José with the professor and the local tutor. This is the first real contact with the community, students were invited into peoples' houses and key places in the area were visited, the local tutor told stories about the community and he explained the importance of places to the community and outside of it. After meetings of discussion to evaluate and understand the essence of San José and map how design interventions can be useful in the community, the community service group decided to create a series of interventions that could inform the general public about the existence and importance of the flower market and other valuable assets and, disseminate San José's tangible and intangible cultural heritage in various ways. They came up with the idea to study and construct with the community the concept of San José's cultural heritage. The class of students divided into four groups in order to go deeper into the topics of hard and soft assets that fully consider the local

culture and local development of the neighborhood. Simultaneously, each group selected particular communities within San José in order to develop the concept of their design intervention. One of the four groups designed a new building for the flower market; they delivered three-dimensional drawings and a small-scale model together with a description about the work. This case is not presented here because it is considered to be an ordinary project within the professional career of architecture and urbanism in Venezuela. The focus of this paper is about the use of design interventions as tools of reflection and for comprehending new discourse and approaches in the professional field of spatial planning.

The methodology utilized by the professor in the service community class consists of participative, reflective and socially oriented approaches. The methodology also resides in handing down the information gathered and created by one group to another. The projects in the service community class are encouraged to be continued by a following group, in this way there is not need to start from scratch, making it possible to achieve a proper design intervention and connection with the community. Information and experiences are recycled and used later by different students in the community service class. This methodological approach has a re-interpretative character as different student groups have to make sense about the project and find (new) ways to sustain it. Also, it drives community service projects ahead, towards concepts and happenings into communities that cannot be actualized in only 120 hours. The cases illustrated in this paper are initiators and others followers. The course holds a total of four generations of work; so, four communal service classes took place in the community of San José dealing with aspects of cultural heritage and social wellbeing in the neighborhood.

4.1 Case I: medicinal garden for the school of medicine, San José

This case was carried out by two groups in two different classes. The initial group started the community service in San José in 2010. Currently, the second group is finishing the actual design intervention, which is the beginning of a new initiative in the area. The first group interviewed the director of the school of medicine and other professors in order to map out the problems and necessities in the school's facilities. The group decided to retake an old project about a medicinal garden in the abandoned internal garden of the school of medicine proposed by an architect in the year 1997. This group generated besides the final report also a catalogue where the design idea was illustrated, this worked as a tool to present their idea to the community. It included a selection of medicinal plants, budget plan, concepts, improvements from previous plan, and further development. One student of architecture donated to this group a series of modular structures made of cement, which were meant to function as plant pots and furniture for the medicinal garden. These were the material gathered for the next group to continue.

Thus, the follower-supporter group was from the beginning clear of their aim: revitalize the internal garden of the school of medicine by making a medicinal garden with and for the community. The personnel and students of the school of

medicine of the UCV responded actively and supportive to the second group. The only challenge was the lack of economical resources to construct the garden. Thus, students of medicine collected money by asking people from the community to collaborate. (see picture 1).

4.1.1 The design intervention

The effort of both groups to complete the medicinal garden can be broke down in two phases; the investigation and design phase and, the implementation and maintenance respectively. The first group set the problem and how to solve it, delivering an informative brochure about the area of San José, and an accurate plan about medicinal plants and a budget plan for the construction of the medicinal garden. Moreover, the cement modular structures were available for the construction phase. The second group thus, dedicated time and effort to make and sustain the medicinal garden.

In the participatory opening of the medicinal garden (see picture 2) the cement structures were placed; and the ecological brigade of a nearby school came to plant the plants together with the local tutor and students of architecture. Every Tuesday, Thursday and Friday students from nearby primary and elementary schools will visit the garden to learn about agriculture, gardening, medicinal plants and to maintain the garden. The space will also be used for other recreational activities.

Figure 1. Intervention for money collection.

Figure 2. Participatory opening of medicinal garden.

4.2 Case II: planimetric survey of O'Higgins school

This group contacted the Bolivarian Primary School "Bernardo O'higgins", where they wanted to accomplish their community service project. They taught children in the school about cultural heritage and they studied together the colonial architecture of the school building. It was built in 19th Century and was the house of the Dr. José Izquierdo who was the funder of the School of Medicine of the UCV in about 1910. Thus, the house was designed to serve as a familiar residence rather than a school.

The methodology applied consists of interviews to the personnel and documentation of the building with the help of children. Questions helped students, teachers and personnel to reflect upon the notion of cultural heritage and its value in the area.

4.2.1 The design intervention

The group approached the service community project from an architectural point of view, starting to observe, document and illustrate the colonial elements in the architecture of the school building. The group created documents where specifications, functioning and valuable elements of the house were illustrated. Their report also includes a historic review of the building, its current conditions and ways to improve it. They illustrate the house and how its different constructions through years have transformed the essence of colonial architecture into a mixed of styles and uses. Thus, its status as cultural heritage has been damaged. The group aimed to create awareness to the community about the school's value as part of Venezuelan cultural heritage. A floor plan and architectural drawing were also created and delivered to the university and the school Bernardo O'higgins.

The design intervention was based on educational material; the group gave a lecture to children about the history of the house, the function of spaces, Venezuelan colonial architecture, its value as cultural heritage and in the sector San José and, ways to preserve its value. The group also supported local events by documenting them. For further development teachers of the primary school suggested students of architecture to develop a game around a small-scale model of the school that can be utilized as educational material for children, as they can exercise and learn aspects about Venezuelan colonial architecture and its significance.

4.3 Case III: Disseminating information on capital and social assets

This group aimed to disseminate the values of San José's cultural heritage, both tangibles and intangible. The community of San José did not fully recognize their immaterial cultural values. Thus, the group was challenged to utilized design interventions to make local people understand and realized their intangible cultural assets. For this they appointed the identity and cultural assets of San José through residents' testimonies. The specific programs of the group were, first of all, to ensure a positive impact into the community through events developed with and for the community.

4.3.1 The Design Intervention

The group delivered a series of design interventions, results and products. 1) Visual tools: informative brochures communicated historical reviews and current perception of tangible and immaterial local patrimonies; game cards for children were designed, they promoted the search for local heritage in San José. Also, posters representing the current areas of work by the community service class were illustrated. 2) Recreational games: this helped students of the community service to reach the younger people in the area to communicate in a didactic and recreational way the

values in it. 3) Supportive actions: facilitated to have a real contact with the community, it consisted of documentation and communication of local events through different social networks in the Internet (blog, facebook and twitter) emphasizing the cultural and social dimension of San José. Moreover, this group helped to clear out the site and uproot the old plants for the construction of the medicinal garden (case I). The group also organized educational and playful material including a workshop. They appropriated traditional games, which were adapted to topics of cultural patrimonies and aimed to inculcate children about the integrity and preservation of cultural and social capital. The group also created a mural in the public library of the community.

5. Design interventions as drivers of reflection and action in the higher education system – towards integration, participation, social well-being and new ways of doing and learning

This paper aims, above all, to discuss how a political top-down decision in the higher educational system of Venezuela could bring about new perspectives, discourses and ways of doing in the field of architecture. Based on the cases presented previously one can position architecture and urbanism moving towards the re-arrangement of activities and surroundings focusing on social matters, local development and local knowledge in neighborhoods for example. In the three cases presented, students of architecture reflected through their design interventions that the role and notion of architecture is not only the profession of designing buildings, as it is often understand, but architecture as the structure or design of anything. The art of architecture and its wide range of meanings consist of the arrangement and organization of things. This can be the re-structure of the discipline itself; organization of spatial arrangements; or sociomaterial assemblies that deal with relevant issues for the society and culture as shown in case I, II and III. It includes the architecture of communities, open areas and other artificial constructions and environments. Usually, architecture deal with aspects of aesthetical effect, however, the current shift in the field of architecture is towards social and participatory design, being humans and their interactions at the heart of design. It also is viewed from the perspective of human activities and environments rather than material consumption and style.

Taking design to the streets, so to speak, have the powerful character of design intervening with the public, with communities, ordinary people, and entities. Conventional ways of learning are usually interactions in the classroom and based on individual work rather than teamwork and in real context situations and with real people. The implementation of the service community work is a new way of teaching and learning; it provides professors, students and researchers to make sense of the field of study in a wider perspective as it explores new functions, capabilities and relevance to the society and, neighborhoods in particular. At the macro level, the community service for higher education students not only serves to re-conceive the role of disciplines as such, but also contributes to build new ways of exchange between future professionals and “ordinary” people. The community service focuses

on the public sector rather than the private; common people and communities rather than investors and clients; usually low-income neighborhoods rather than wealthy communities; and it is based on social and collective responsibility rather than individual and commercial benefit.

At the micro level, the community service for higher education students in the field of architecture bring forth new way of doing and acting which is based on design interventions, an approach and tool that facilitate designers to directly interact with the public, and try out ideas. Helping to improve people's everyday life in neighborhoods through design interventions is a new way to perceive and experience the world, especially in regards of the study field. The three case studies have shed light to design interventions as a tool to reflect and build dialogue through participatory means. It facilitated mutual learning between ordinary people and students of architecture about concepts and practices of architecture and cultural heritage. The design interventions offered locals a possibility to reflect about their local environment and the importance of social and cultural events as part of their identity and value in the society. It empowered people from the neighborhood to deal with local knowledge and local development, as seen in case II. Also, students learnt besides the regular research and design process also the implementation and maintenance of the design work. In case I students dealt with logistics, budget plan, making and community building. In case II students learnt how to deal with new topics and practices in architecture as it is the realization of planimetric study. This serves as a justification and starting point to the school Bernardo O'higgins to request the municipality the renovation of the building. Also, this group learnt the importance of architectural education to audiences not familiar with the topic. Moreover, the case studies illustrate the significance to communicate information about design through design. Above all, design interventions in the area of community service work make small-scale architecture and significant ideas palpable, visible and able to be experienced and evaluated. There is a long journey to fully understand the role of social design and participation in architecture in the southern hemisphere. Decision making in relation to the macro-micro perspective, local and global experiences can help to make sense of new discourses and practices in the conventional professional field.

PLANNING LAW AND THE RIGHT TO CITY PLANNING: A CASE STUDY OF 'WALLED BUILDINGS' IN HONG KONG

Mee Kam NG[1]

Abstract

Planning-related laws as part and partial of a planning system could be a double-edged sword: they could guarantee people's planning rights but they could also behind the 'equality before the law' façade privilege certain actors' rights at the expense of others. Hence, the coverage and ingredients of planning-related laws could be potential subjects of contention. This paper attempts to tell the story of 'walled buildings' in Hong Kong through the lens of planning-related laws and people's awakening to their right to city planning.

Walled buildings are not new in compact Hong Kong. However, "high-density slab-block style buildings" in new reclamation areas maximizing stunning harbour view, depriving old lower-rise urban areas of natural ventilation and sunlight, is a relatively new phenomenon. Through a critical examination of the delayed amendment of an outdated Town Planning Ordinance (originated in 1939 and amended partially to broaden participation in 2004) and a Buildings Ordinance that 'promises' huge development potential, this paper first investigates the conditions that have given rise to the "walled building" phenomenon in Hong Kong. If "walled buildings" are common place in Hong Kong, then what are the specific circumstances that have led to the emergence of a right to city planning movement to counteract this faulty urban form? The paper adopts a three-pronged approach to answer this research question: the role of the 2005 amended Town Planning Ordinance in sensitizing people of their right to city planning; the roles of networked stakeholders in mobilizing information, resources, opinions in re-problematizing the "walled-building" phenomenon; and the wider evolving socio-economic context with embedded transforming hard and soft institutions that increasingly recognise people's right to the city.

1. Introduction

The following first discusses the relationships between planning law and the right to city planning, followed by an overview of the characteristics and evolution of planning-related laws and regulations in the city of Hong Kong that render

[1] The Chinese University of Hong Kong, Hong Kong--meekng@cuhk.edu.hk.

substantial development rights to property developers, very often at the expense of the urban environment. Through a case study of a 'walled building' controversy, the paper examines the significance of the community's awakening to their right to city planning and the implications to the established institutional setup.

2. Laws and the right to city planning

Alexander (2007, p.114) identifies two types of planning rights: positive planning rights are recognised claims in a planning system through 'laws, regulations, and court decisions that have set the norms of institutional practice' that are different in diverse constitutional, political, legal and institutional contexts; potential planning rights are claims that have yet to be 'recognized or proven through legal confirmation, enforcement or practical effectuation'. Socio-political transformations may be required to translate 'potential planning rights' into 'positive ones' (op cit., 2007, p.114).

Wesley Hohfeld (2000) identifies four basic legal rights: claim rights, liberty rights, powers and immunities, the latter two being 'secondary rights' for 'individuals and groups to alter, override, or ignore existing legal entitlements'. This argument can be compared interestingly to what Attoh (2011) describes as 'a moral right to break the law' or what Dworkin (1977, p.672) argues that 'rights are best understood as trumps against democratic tyranny'. And in certain situations these rights are necessary to realize the potential planning rights of citizens.

Besides breaking laws or challenging the tyranny of the majority, perhaps rights to city planning can be seen as a way to realize 'generational rights' (Waldon, 1993). Waldon (1993) argues that first generation rights, traditional human rights, which would mean very little without second generation rights such as rights to housing… to mobility, employment etc. (all related to urban planning) or what Attoh (2011, p.672) calls 'socio-economic entitlements' especially for the disadvantaged. In discussing what constitutes the right to the city, Harvey (2008, p.23) argues that 'it is a right to change ourselves by changing the city' through 'greater democratic control over the production and utilization of the surplus' (p.27). Purcell (2002, p.102) puts forward two principal rights: 'the right to participation and the right to appropriation' and the latter includes 'the right of inhabitants to physically access, occupy and use urban space' (p.103). Agier (1999) simply calls it a right to 'invent' the city (cited in Capron, 2002, p.222). But to borrow from Alexander (2007), these can be called 'potential planning rights'.

Borja (2001) suggests four approaches to transform 'potential planning rights' to real planning rights: grassroots struggles against marginalization; empowering grassroots initiatives; implementing the right to the city through the legal framework; and public policy and planning. And the processes would involve patient explanation of the values that underlie these rights; civic mobilization to create and legalized the institutionalization of effective rights; and a political-

institutional process 'to formalize and consolidate these rights' in order to implement them! All these point to the moral obligation of those who possess such reflective knowledge to act as 'advocates for potential planning rights'!

3. Planning-related laws and regulations in Hong Kong

Hong Kong is a densely populated city. A population of seven million occupying a land area of about 1,108 km^2, population density is often quoted as 6,318 per km^2. However, reference to Table 1 below shows that less than 25 per cent of the land in Hong Kong is built up land and in fact, public housing that accommodates about 48 per cent of the population used up only 1.4 per cent of the land, giving rise to a density of 210,000 per km^2. As can be seen below, Hong Kong has a rather crude urban land use zoning system without detailed urban design rules or regulations.

Table 1. Land Use Distribution (as at end-2010)

Class	Approximate Area (km²)	%	Remarks
Residential			
Private Residential	25	2.3	Residential land developed by private developers (except village houses, HOS/PSPS and temporary housing area)
Public Residential	16	1.4	Includes HOS/PSPS and temporary housing area
Rural Settlement	55	5.2	Includes village housing and temporary structures.
Commercial			
Commercial/Business & Office	4	0.4	
Industrial			
Industrial Land	7	0.6	
Industrial Estates	3	0.3	
Warehouse and Storage	16	1.4	Includes open storage areas.
Institutional/Open Space			
Government, Institutional & Community Facilities	25	2.3	
Open Space	24	2.2	Includes parks, stadiums and playgrounds.
Transportation			
Roads	40	3.6	
Railways	3	0.3	
Airport	13	1.2	
Other Urban or Built-up Land			
Cemeteries and Crematoriums	8	0.7	
Utilities	7	0.6	
Vacant Development Land/ Construction in Progress	16	1.4	
Others	21	1.9	
Agriculture			
Agricultural Land	51	4.6	
Fish Ponds/Gei Wais	17	1.5	
Woodland/Shrubland/Grassland/Wetland			
Woodland	254	22.9	
Shrubland	303	27.3	
Grassland	178	16.1	
Mangrove and Swamp	5	0.4	About 4 km² of Mangrove and Swamp, which is below the High Water Mark, is included in this figure. This 4 km² should not be counted in the total land area of the Territory.
Barren Land			
Badland	2	0.2	
Quarries	1	0.1	
Rocky Shore	4	0.4	
Water Bodies			
Reservoirs	25	2.3	
Streams and Nullahs	5	0.4	
Total	1 108	100.0	According to Lands Department, the total land area of the Territory, i.e. land above the High Water Mark, is 1 104 km²

3.1 Development density controlled by Buildings Ordinance not Town Planning Ordinance

Positive planning rights are rather limited in Hong Kong. The Town Planning Ordinance (TPO) was first enacted in 1939 when the plot ratio then was set around 3 (80 feet in height with less than five stories) by the 1935 Buildings Ordinance (BO) (HKBRTPI, 1973, p.1). Population in the 1930s was less than one million while the city's current population is seven million. In other words, the urban context has been completely transformed. Yet, the TPO even with the latest amendments has not been fundamentally changed. Throughout these decades, the Town Planning Board (TPB) has been entrusted to 'make provision for the systematic preparation and approval of plans' only but NOT the power to implement its plans. As argued by Cuthbert (1997, p.299), the Planning Department 'is not allowed to implement the plans which it prepares… Implementation procedures are enshrined with the Buildings regulations and Crown lease conditions, and there is no mandate that statutory plans must be carried out'.

As stated in the Hong Kong Planning Standards and Guidelines, 'the Buildings Ordinance, including its associated Building (Planning) Regulations, is the only statue which explicitly sets density limits and provides for their enforcement (Planning Department, Chapter 2, p.3). As a result, 'population estimates and the resultant provision of services and reservation of land for road, government, institution and community purposes have had to be based upon full development under the Buildings Ordinance' as no one would doubt that developers will not build to the maximum density permitted by law (HK Branch of RTPI, 1973, p.42). So how reasonable is the BO in guiding urban development and growth?

As mentioned above, the 1935 BO allowed for a plot ratio of 3. However, this level of development could not satisfy the needs arising from rapid urban growth in the post war years. For instance, in 1945 Hong Kong's population dropped to 0.6 million and then in 1956, the number rose to 2.4 million. As a result the Building (Planning) Regulations (B(P)R) was changed in 1956 and building height then was controlled by the width of street, that is, the wider the street, the taller the buildings and development bulk. Hence, the permitted development plot ratio was extremely high: about 18-19 and the subsequent population density of about 7,000 persons per acre, a big challenge for the Government then to provide enough land for social amenities (HK Branch of RTPI, 1973, p.2).

Because of this, the B(P)R were changed in 1962 and instead of having a fixed development height, it became a function of plot ratio and site coverage. Hong Kong was divided into three density zones (Figure 1, Planning Department, 2012, p.28) and site coverage and plot ratio were defined according to three

classes of sites (Table 2, op cit., p.19) and Figure 2 (op cit., p.19). As a result permitted maximum development was reduced by about 25 per cent. This slashing of development right was not implemented immediately. In fact, a long grace period of four years were given for implementation and in the interim, the number of private resident units shot up from 11,300 in 1962 to 29,000 in 1965, an increase of 160 per cent (Fung, 2011, p.96). This development gut had led to a banking crisis in the mid-1960s, a time of turmoil in China and other parts of the world. It should be noted that the First Schedule of B(P)R (Table 1) was enacted in 1976 and the specification more or less stopped at 61 metres (about 21-storey) as buildings higher than that level was hard to imagine then. Hence, while the B(P)R are outdated, these have continued to be used as the basis to direct urban growth and development, sustaining an ultra-high density regime in the urban areas.

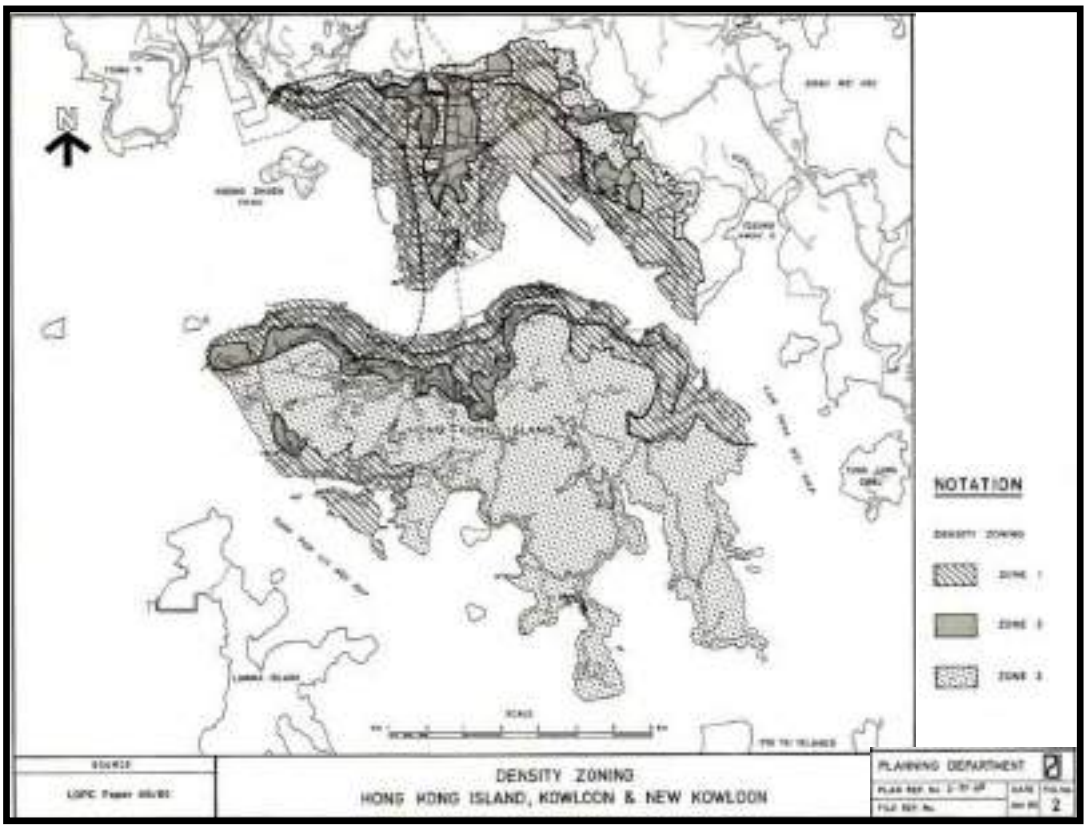

Figure 1. Density Zoning in Hong Kong

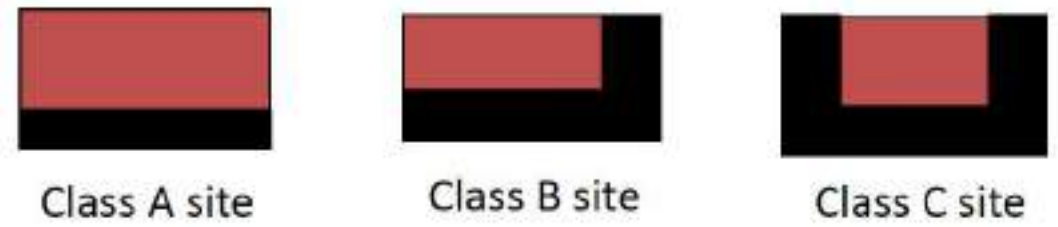
Table 2.Maximum permitted site coverage and plot ratio in relation to building height for domestic buildings under First Schedule of B(P)R

Height of building in metres	Maximum site coverage (%)			Maximum domestic plot ratio		
	Class A Site	Class B Site	Class C Site	Class A Site	Class B Site	Class C Site
up to 15	66.6	75	80	3.3	3.75	4.0
up to 18	60	67	72	3.6	4.0	4.3
up to 21	56	62	67	3.9	4.3	4.7
up to 24	52	58	63	4.2	4.6	5.0
up to 27	49	55	59	4.4	4.9	5.3
up to 30	46	52	55	4.6	5.2	5.5
up to 36	42	47.5	50	5.0	5.7	6.0
up to 43	39	44	47	5.4	6.1	6.5
up to 49	37	41	44	5.9	6.5	7.0
up to 55	35	39	42	6.3	7.0	7.5
up to 61	34	38	41	6.8	7.6	8.0
over 61	33.33	37.5	40	8.0	9.0	10.0



- Class A site means a site, not being a Class B site or Class C site, that abuts on one street not less than 4.5 m wide.
- Class B site means a corner site that abuts on two streets neither of which is less than 4.5 m wide.
- Class C site means a corner site that abuts on three streets none of which is less than 4.5 m wide.

Figure 2. Classes of sites in the First Schedule of the B(P)R

Besides relying on the B(P)R to 'guide' the formulation of the level of development intensity in the statutory plans, the implementation of plans also

depends on the Building Authority who can disapprove a building plan if 'the carrying out of the building works… result in a building differing in height, design, type or intended use from buildings in the immediate neighbourhood or previously existing on the same site' (Section 16(1)(g), BO). The Building Authority, however, possesses discretionary power in exercising his/her development control responsibilities and the guideline is not particularly useful in green-field sites such as newly reclaimed land.

3.2 Failed attempts to introduce implementation and enforcement power to the Town Planning Ordinance

The problems of the TPO have long been identified by planners in the city. As early as 1973, before the introduction of the development application system to the TPO, the Hong Kong Branch of the Royal Town Planning Institute undertook a thorough review of the TPO and put forward a number of pertinent recommendations which are still valid to this very date. In 1991, after the establishment of the Planning Department (before this, urban planning was housed under the Works Department), a comprehensive review was done by the Government and many suggestions were put forward to enhance the 'openness, fairness, certainty, efficiency, effectiveness, affordability and comprehensiveness' of the TPO (PELB, 1991). Unfortunately, as can be seen in Table 3 below, most of the recommendations of these two thorough reviews have not been accepted in the various minor and major amendments of the TPO.

Table 3. Amendments made at the 2004 Town Planning (Amendment) Bill when compared to suggestions put forward in the 1973 HK Branch of RTPI Report and the 1991 Comprehensive Review of the TPO

	1973 HK Branch of RTPI Report	1991 Comprehensive Review of the TPO	2004 Town Planning (Amendment) Bill
Planning study	The public to be consulted before & during the preparation of plan… period of public exhibition to be extended to 3 months	A planning study to be prepared & published for 3 months for public comments	n.a.
Submitting representa-tion	n.a.	Any member of the public would be able to submit representations to be published	Any member of the public would be able to submit representations to be published

	1973 HK Branch of RTPI Report	1991 Comprehensive Review of the TPO	2004 Town Planning (Amendment) Bill
Exhibition time	n.a.	Would be extended from 3 to 6 months	•2 months for making representations •3 weeks for commenting on the representations
Plan review	To be reviewed at least once every five years	n.a.	n.a.
Planning permission	Regulations to be introduced to replace the notes… requiring material changes of use… to be submitted to the planning committee	•Written consent or notice to owners required •Planning applications published for public inspection & comments •Consideration from 2 to 3 months	•Written consent or notice to owners required •Planning applications published for public inspection & comments •Consideration within 2 months
Interim develop-ment control	n.a.	Deferred consideration for sites as subject of objections	n.a.
A register of all planning applications	n.a.	A register available for public inspection	A register available for public inspection
Established use certificate	'Established use certificates' to be issued by the planning authority	Planning related provisions in the BO should be consolidated in the new Planning Ordinance. Planning certificates issued by the Planning Authority	n.a.
Building density	Include density and development control etc. in the TPO	Control on development density (reg.19 to 23 & B(P)R)… consolidated in the new Planning Ordinance	n.a.

After a thorough consultation of the general public on the 1991 Comprehensive Review, the Secretary for the then Planning, Environment and Lands Bureau (PELB) reported that there were 65 written representations and except the developers, the general public supported wider consultation in the preparation of statutory plans and in the planning process (HK LegCo, 1992, p.1355). Secretary for PELB also pointed to the 'misguided fear' of the proposed planning certificate system and explained that the proposal was simply to 'enable the Planning Authority to deal directly with the planning aspects of buildings works rather than indirectly through the Building Ordinance as at present' (op cit., p.1356). Five years after the 1991 Comprehensive Review came another consultation document the 1996 White Bill which maintained most of the recommendations put forward in the previous review. Legislator Albert Chan then questioned strongly the Government's change of attitude and queried why a consultative White Bill instead of a promised Blue Bill was published (HK LegCo, 1996, p.147). To the Democratic Party that Chan then represented, 'the proposals [in the White Bill]… still lack transparency with regard to the composition of the Town Planning Board, the decision-making process in planning and the appeal procedure… it is imperative for the Government to introduce… the Blue Bill into this Council for scrutiny asap' (op cit., p.150). Other legislators criticized the design of the whole mechanisms as biased towards the interests of 'the Government, the public utility organizations and the property developers' (op cit., p.155).

The long delay in introducing an amended TPO also prompted the Hong Kong Institute of Planners (HKIP) to question 'the Government's sincerity of introducing new planning legislation to revamp the much out-dated TPO' (HKIP, 1996). However, on the contrary, the Hong Kong Institute of Architects, Hong Kong Institute of Engineers and the Hong Kong Institute of Surveyors put forward a joint paper criticising the White Bill (1997, pp.1-7):

1. The White Bill would delay the development process.
2. The White Bill would create uncertainty because of the discretion power left to the TPB.
3. The White Bill would deprive landowners of proprietary rights without compensation.
4. The White Bill would impose from above another layer of bureaucracy in relation to land development.
5. The White Bill would provide excessive power to the Planning Department.
6. The White Bill would be an expensive endeavour though there was no financial and economic assessment of the proposal of White Bill.

And naturally, these Institutes suggested that planning permission should only be required 'in exceptional cases' and that 'no planning certificates should be required' (op cit., p.7). In other words, these professionals with their vested interests in the development rights of land owners guaranteed by the existing BO and the B(P)R had joined force to thwart attempts to return the

responsibility of urban planning to the planning profession. Although the HKIP urged repeatedly (1997, 1998) the Administration to release the compiled public views on the White Bill and publicize the Blue Bill as early as possible, the requests were not entertained.

In 1998, an interim amendment was made to the TPO to expedite the drafting of plans through limiting the processing time of objections to nine months (LegCo, 2003, p.1). The HKIP declared that it would only support the Bill in principle if the Administration undertook to introduce a major Bill to revamp the TPO in the first half of the following legislative session and requested once again the release of assorted views expressed on various controversial issues related to the TPO (Provisional Legislative Council Secretariat, 1998, p.2).

In 2000, a Legislative Council Brief on the TPO reported that:

> 'Green groups, Municipal Councils and District Boards, professional institutes and the Law Society support proposals that would make the statutory planning system more open and involve the public more extensively in the entire planning process… Real estate developers, business sector and other professional institutes such as the Hong Kong Institute of Surveyors, Hong Kong Institute of Architects, Hong Kong Institute of Engineers have expressed concern over whether a more open system would lead to further delay to the development process' (p.2).

Because of these controversial stances, the Government had continued to consult, review and address the concerns of different parties and hence the revised Bill was not tabled until 16 February 2000, four months before the end of the legislative session. At the 9th meeting, the Bills Committee came to the conclusion that 'it would be unrealistic to complete the scrutiny of the Bill within the current LegCo Session' (2000, p.4). That was extremely unfortunate though instead of the shortage of time, the crux of the matter was probably due to the fact that 'while planners called for the early enactment of the Bill, architects, surveyors and real estate developers had indicated their preference for adhering to the existing legislation over putting in place a new Bill hastily passed without careful scrutiny' (op cit., p.4).

When the Town Planning Bill was raised again in the Legislative Council, it was 2002, 11 years after the publication of the 1991 Comprehensive Review of the TPO. This round, the Government's determination to introduce comprehensive changes had evaporated. Instead of enacting a comprehensive Bill, the Government proposed to amend the TPO in stages and planned to introduce the relevant legislative proposals into LegCo in March 2003 (PPLW, 2002, p.6). The amendment was eventually passed by the Legislative Council on 7 July 2004. As can be seen in the Administration work schedule in amending the TPO below, the prospect of placing development control and implementation mechanisms back to the hands of urban planners is dim (HK LegCo, 2003, p.2):

(a) Stage One - to streamline and shorten the town planning process, enhance openness of the planning system, and strengthen enforcement control on unauthorized developments;

(b) Stage Two - to amend the TPO regarding the operation of TPB, designation of Special Design Area, Environmentally Sensitive Area and Designated Development; and

(c) Stage Three - to review the highly controversial proposals such as interim development control and planning control on building development.

Again, the HKIP was the lone voice to urge the Government 'to include issues covered by Stage Three amendments in Stage Two and streamline the whole amendment process' (2003, p.1). And in fact, since the stage one amendment of the TPO, the issue of further amending the TPO seems to have faded away in the agenda of the LegCo.

As can be seen in Table 3 above, while the 2004 Town Planning (Amendment) Ordinance has indeed made the plan making and development application systems more transparent, the fact that TPO lacks implementation power persists and the city has continued to rely on the BO and the B(P)R in directing high density development. In other words, the 'positive planning rights' rendered by the planning-related laws and regulatory regime even after the fight by the planners and some of the democratic legislators have not much been expanded. In the long and rather futile road to amend the TPO and behind the facade of many technical jargons, complicated procedures and behind the scene administrative practices, Hong Kong saw the rise of many 'walled buildings' in the newly reclaimed areas, scrambling to capitalize on the stunning sea-view of Victoria Harbour but shutting off the older more modest urban fabric from natural air ventilation, sunshine, visual and physical accessibility. While the professional planners have failed to regain their planning power, the civil society has mobilized itself to fight for its own right! The following uses one such case to illustrate the civil society's efforts in expanding/regaining their right to city planning.

4. 'Walled buildings': the case of Tai Kok Tsui

The case in point lied on the western part of the West Kowloon reclamation, a massive piece of then newly formed land from the sea in 1990 the size of which amounted to one third of the Kowloon peninsula. It was one of the ten core Airport Core projects undertaken by the Government in the late 1980s as a 'rose garden project' to boost the confidence of Hong Kongers after the June Forth massacre in 1989 in Beijing (Ng, 1993). The reclamation served strategic planning purposes (TDD, 1992, p.2-3):

- To provide space for the construction of two Airport Express stations which serve to bring the Airport in Lantau Island back to the heart of the city in 25 minutes.
- A strategic transport corridor linking Hong Kong, Kowloon and the northwest New Territories including the Lantau Island.
- Re-provisioning of waterfront facilities.
- New secondary office and hotel centre.
- Housing land.
- Solution space to restructure land uses including the 'thinning out' of congested residential and industrial areas in old Kowloon.
- Meeting local district level needs to make up deficiencies in open space, GIC uses, etc.

However, as statutory plan lacks implementation power and has to rely on the BO for development control, residential developments on the reclaimed land where there was no neighbouring uses were therefore allowed to develop to its 'fullest extent' allowed in the First Schedule of the B(P)R. Figure 3 is the statutory plan for the site and the reclaimed areas are zoned into distinctively massive blocks very different from the human scale street blocks in old Kowloon. Worse still, when monstrous residential tower blocks emerged and very often, on podium structures, their prominent presence turned the old Tai Kok Tsui inland into a 'walled city', being 'robbed' of sunlight, ventilation and visual access. Figures 4 and 5 show the various phases of high-rise development in the reclaimed areas and the corresponding birds' eye-view. Figure 6 is a photo that shows the location of the site, described as the only breathing gap for the old urban area. The emergence of these massive property developments and socio-economic changes in the post-colonial city saw the rise of civic activism that criticizes the 'walled buildings' severely.

Figure 4. Development of 'walled buildings' in Tai Kok Tsui

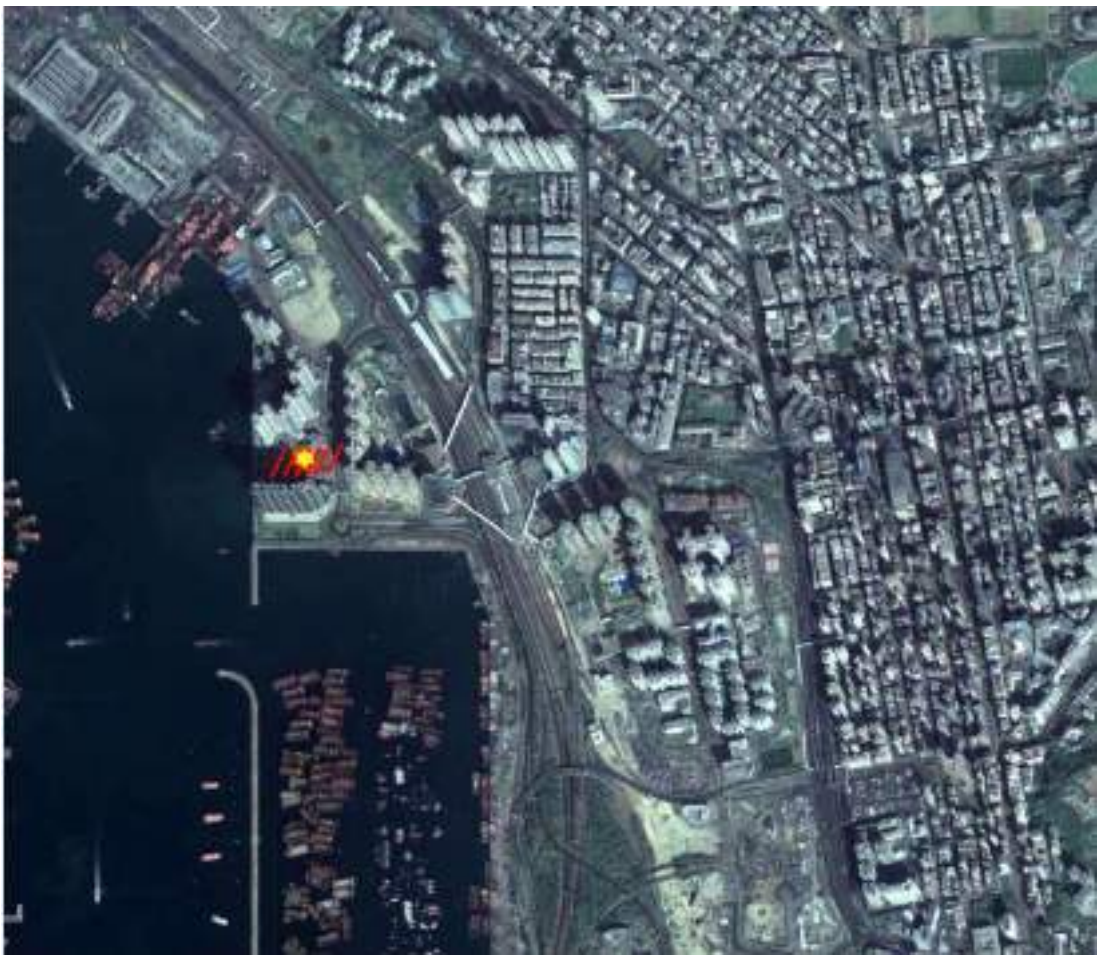

Figure 5. Walled buildings in Tai Kok Tsui.

Figure 6. The subject site described as the only 'breathing space' for old Tai Kok Tsui

Many people in Hong Kong think that the founder of a civic group, Green Sense, Roy Tam coined the term 'Walled Buildings' (direct translation from Chinese should be 'screen' buildings but 'walled buildings' are more popular in the English media). However, according to our interview with him, he first noticed a similar term in another protest activity surrounding the Hopewell Mega Tower where the proposed development was described by local residents as a 'screen' blocking their views. And his concern about 'walled buildings' was triggered by a picture that he saw on the newspaper about another site above a mass transit station (Figure 7). He found the proposed development unreasonable and was concerned about its impacts on the surrounding community and this concern triggered his campaign, among others, against 'walled buildings'.

Figure 7. Above station development in Nam Cheong, West Kowloon

The late 1990s and early 2000s was an interesting era in the ex-colony. The return to Chinese rule in 1997 coincided unfortunately with the Asian Financial Crisis and Hong Kong entered into an economic recession that was further hit by the SARS crisis (Ng, 1995; 2000; 2008a, 2008b; 2011). The economic downturn allowed many to have time to reflect on their life styles, the city's mode of urban development and their rights to city planning. The dense urban living and the ideology of growth at all costs have increasingly been challenged and questioned by the general public especially among the younger generations,

commonly called the 'post-80s' (born after 1980) who do not have the tolerance of the previous generations towards the Government and refuse to give it the credit in transforming Hong Kong from a poverty-stricken refugee-filled city into a modern metropolis. Hence, the city's economic downturn was contrasted with the rise of civic activism challenging the conventional wisdom of development such as harbour reclamation, urban redevelopment and the removal of heritage sites to further growth. And it is against this background that the battle to save the last breathing space in Tai Kok Tsui took place.

The campaign started in 2003, before the enactment of the Town Planning (Amendment) Ordinance when there was no provision in the TPO for rezoning of land uses in statutory plans. The application of rezoning the residential site into open space was made to the TPB administratively and was rejected as according to the Board, there was enough public open space and the site should be used for residential purposes 'to optimize the use of valuable urban land'. In 2004, the local advisory District Council passed a motion to request the change of land use from residential to open space or government/institution/ community (GIC) use (Green Sense, 2009). In 2005, the site was included in the List of Sites for Sale by Application, that is, the site was ready for sale by auction should a developer opt to put a price to the land lot that was agreeable to the Government. With the Town Planning (Amendment) Ordinance in place, the local resident filed in two more planning applications to change the residential site into either open space or GIC uses but both were rejected by the TPB.

In 2007, the Lands Department announced that the site was successfully triggered for sale under the Application List system with a price of HK$4.2 billion (HK Government, 2007). Local district councillors on one hand petitioned the Lands Department and on the other hand organised various civic actions including the launching of the 'Blue Windwill Action' to protest at the land sale; Green Sense filed yet another rezoning application to request the reduction of plot ratio and appropriate air ventilation (Green Sense, 2009); and the filing for a judicial review by a local resident which was refused by the Court as information provided was too sparse and unclear. Nevertheless, the land was successfully bid by a developer and building plans were submitted in July 2007.

In August 2007, a professional town planner belonging to the Democratic Party and a representative of Green Sense submitted yet another planning application requesting the maximum permissible domestic plot ratio to be reduced from 6.5 to 5 as well as introducing a 10-metre wide wind corridor but both requests were again rejected. Eventually, in 2008, the building plans were finally approved and the building height was reduced to 130 to 140 metres with 32 to 34 stories, about 10 stories less when compared to neighbouring sites. The Chairman of the TPB, a government official, made the following remarks:

> '[Th]e OZP might not be the most suitable tool for the control of the design of individual buildings. As building design and layout were largely

> governed by the Buildings Ordinance, the Buildings Ordinance might need to be reviewed and, where appropriate, amended to give regard to air ventilation factor… the proposed 10m wide non-building area… was provided voluntarily by the developer' (TPB, 2008, p.14).

To the civic activists, this cannot be a victory but to the developer, perhaps this was a big concession. The developer's willingness to make such a concession might have to do with the fact that the bid price was much lower than its neighbouring sites due to uncertainties introduced by local civic actions (Sing Tao Daily, 2007).

5. Conclusion

Where does Hong Kong stand with reference to the earlier discussions on laws and the right to city planning? Obviously, the recognized rights to city planning offered by the planning system through laws and regulations are rather limited. In fact, as can be seen in previous paragraphs, the procedural TPO offers no statutory power for implementing the formulated plans. And the scale and intensity of development allowed in the plans are constrained by the First Schedule of the B(P)R which have been taken as the promised development rights by the built-environment related professionals. Indeed, the vested interests of developers and related professionals (except some of the town planners) have led to the delay of the amendment of the outdated TPO and the resumption of the urban planning responsibility to the planning profession. In other words, the planning profession has failed to help realize the 'potential planning rights' of the citizens as the Government seems to have sided with the interests of the developers.

On the other hand, civic activism sprang up to try to challenge the biased system at the grassroots level. Various attempts were made to use the amended TPO to change the land use zoning but to no avail. Although eventually, the community actions had succeeded in lowering the height of the development project and enforcing a 10-metre wide ventilation corridor, the fundamental of the biased planning and building regime remains intact.

This story shows us the importance of having conscientious professionals who are willing to put public interest before self-vested interests. In other words, to borrow from Alexander (2007), Hong Kong needs 'advocates of potential planning rights', planners or related professionals who are willing to use their knowledge to patiently explain the 'hegemonic bias' (Borja, 2010, p.24) of the current system and to point out the importance of institutionalizing planning considerations in the development process, the return of planning authority to professional planners, the review of the First Schedule of the B(P)R, the empowerment of the civil society of their rights to city planning and the

formalization of appropriate mechanisms to facilitate their participation throughout the plan and decision making processes.

This paper has attempted to reveal the mechanisms that have given rise to 'walled buildings' in compact Hong Kong and hopefully, it also points to a need to explore possible alternative futures that will simultaneously be contested but open to democratic control and management!

Urban network, regional change and regionalization process in Turkey

AESOP 26th Annual Congress – 11-15 July 2012 – METU, Ankara (Turkey)

Track 7. Regional Change and Resilience : Plans, Institutions and Concepts

Prof. Marcel BAZIN, University of Reims Champagne-Ardenne (France), EA 2076 – Habiter

Abstract

Turkey has undergone since 1950 a vigorous urbanization process resulting in a well-developed and hierarchized network of urban central places, with a strong trend towards metropolization in favour of the three biggest cities Istanbul, Ankara and Izmir. Thus a number of metropolitan and regional centres have progressively shaped, through regional directions of administrations and high level commercial, health and education facilities, *de facto* polarized regions, whereas several regional development plans have been engaged by the State Plan Organization, but without creating regions as political units and territorial collectivities. In response to European Union incentives, Turkey has adopted in 2002 NUTS 1 and NUTS 2 regional units and created Regional Development Agencies at the NUTS 2 level. The paper will analyze the criteria used to delimit these units and discuss how far the implementation of Development Agencies in this framework can be a first step in a regionalization process in Turkey.

Keywords : urban network – regionalization – NUTS 1 and 2 – Regional Development Agencies – Turkey

1.Introduction

This paper intends to explore the links between urbanization and regional development in Turkey. This country has undergone a vigorous urbanization process which has not only reversed the urban/rural ratio but also created a hierarchized network of urban central places **(2)**. How far has this process led to the rise of regional identities in a cultural area where regional units were an almost unknown concept ?. Beyond broad natural regions, could the higher levels of the urban hierarchy develop *de facto* polarized regions, and did the government take such units

into account as a framework for development projects **(3)** ? Among a great number of reforms adopted in Turkey in order to meet the standards for entering the European Union, NUTS 1 and NUTS 2 statistical units have been created, and the latter have given the spatial framework for Regional Development Agencies. How far can these constitute a first step towards a true regionalization process in a country with a strong tradition of centralization **(4)** ?

2. A vigorous urbanization process leading to a well-developed urban system

Like many other developing countries, Turkey has started in the 1950s a strong urbanization process which must be analysed both in its quantitative dimension, the global growth of urban population **(2.1),** and in its qualitative one, the differenciation of several hierarchized levels of central places **(2.2).**

2.1 The global shift from rural to urban

Although a significant number of urban places had shown a remarkable continuity since the Antiquity, the young Republic of Turkey, proclaimed in 1923, was fundamentally a country of peasants, with 75 percent of the population living in villages at the time of the first general census of population in 1927. This rural/urban ratio remained the same until 1950, while the total population of the country gradually increased from 13.6 million to 20.9 million. In 1950 started both an acceleration of the global annual increase rate (from 2.17 percent in 1945-50 to 2.77 percent in 1950-55 and 2.85 percent in 1955-60) and an outmigration movement from villages to cities, resulting in a sharp discrepancy between the annual increase rates of urban and rural populations, respectively 5.57 and 1.75 percent in 1950-55 and 4.92 and 1.95 in 1955-60. Some peasants had already experienced seasonal or temporary work migrations to cities, especially from the Black Sea region towards Istanbul, as observed by Xavier de Planhol in 1950. Thus a “chain migration” process was developed, the first migrants helping relatives or neighbours to come.

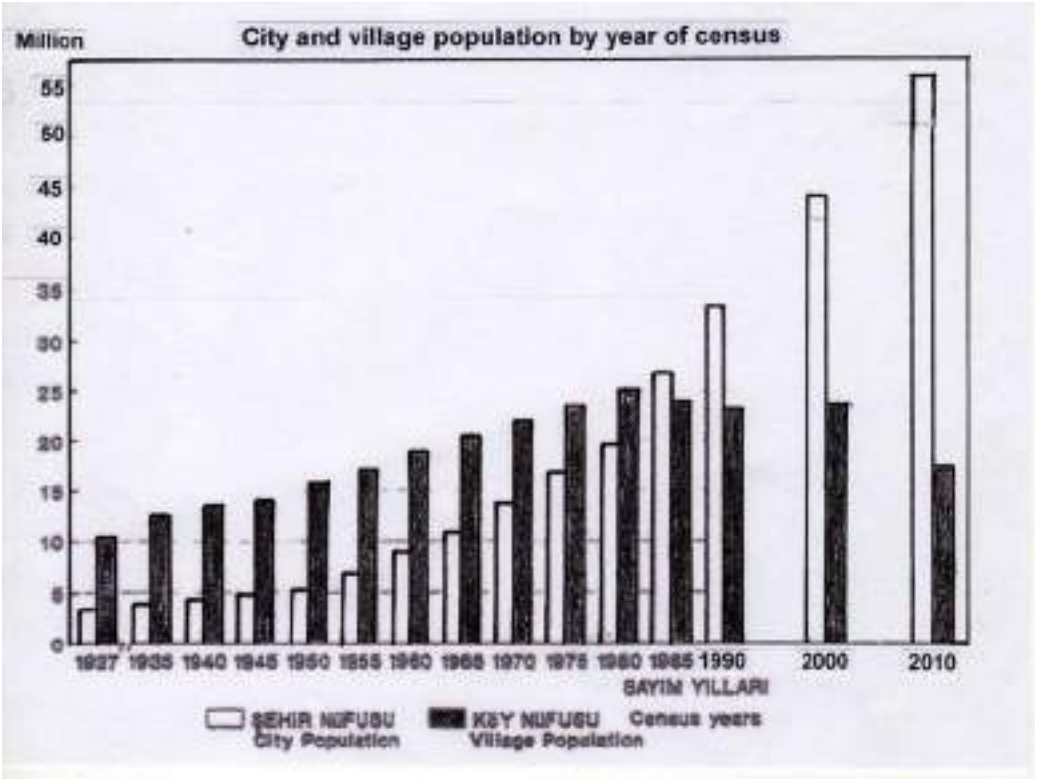

Fig. 1 – Evolution of the urban and rural population of Turkey (source DİE)

During the two next decades, this rural/urban migration process went on, not only towards Turkish towns and cities but also to foreign countries, mainly Germany together with other West European countries and oil-producing Arabian countries. The rural population as a whole was still growing, but much slower than the urban population, and reached its maximum at the 1980 census with 25 million people (56 percent of the total population of 44,7 million).

Then the rural population began to decrease, rather distinctly between 1980 and 1985 because the administrative reform creating the metropolitan municipalities for the biggest cities revised their limits in order to include actually urbanized former villages. Thus at the 1985 census urbanites became the majority, being 53 percent of the total population of 50.6 million. The rural population stabilized for a while between 1985 and 2000 and underwent a sharp decrease during the 2000 years, falling to 17,5 million, while the urban was strongly increasing, up to 56,2 million out of a total of 73.7 million on 31/12/2010, i.e. 76.2 percent of the total population. Actually, a new method of counting the population has been used since 2007, the Address Based Population Registration System, one may question wether it has introduced some discontinuity in statistical series or not. Anyway, as a whole, the proportion of villagers and urbanites has been reversed in just forty years.

2.2 The development of a hierarchized urban network

This urban growth has been distributed between a great number of cities, big and small, with differentiated functions, many of which give them the role of central

places for bigger or smaller areas : administration, education and health services, commerce, personal services. Turkey has thus built the most developed urban network of the Near East (Bazin 1997), the only Middle Eastern country having a comparable hierarchized urban network being its eastern neighbour Iran.

The first publication I devoted to this question (Bazin 1986) distinguished five levels in this hierarchized urban network :
a) The two capitals: At the top of the pyramid, the Turkish urban system appears to be bicephalous., due to recent history : Ankara has been appointed as the capital of the new Republic of Turkey in 1923, but the former Ottoman capital Istanbul, as a bimillenary world city (Stewig 1964), has kept a great part of its functions and demographic importance. Thus nation-wide functions are shared between the two cities : Ankara is the official political capital, with the Presidency of the Turkish Republic, all the organs of government, the Great National Assembly and the foreign embassies, and also the center of military power and of State-owned economic sector, whereas Istanbul has kept the roles of first harbour and commercial place, first industrial center, capital of the private economic sector and capital of academic, intellectual and artistic life. Of course, Ankara, being a very small town (25,000 inhabitants) when it became the capital, has undergone a very rapid growth (Pérouse 1997) while Istanbul, a city with more than 600,000 inhabitants when it lost its title of capital, was growing at a much slower pace until it accelerated its growth in the 1980s (Yerasimos 1997).
b) Regional metropoles: Three big cities following in the size-ranking list, Izmir center of the Aegean façade of Turkey, Adana in the Mediterranean region and Bursa in the southern Marmara region, have all begun to develop their industries together with their commercial role in the late Ottoman period, and have kept their advance.
c) Regional centers: a dozen of cities were identified as exerting a number of higher level functions, with regional-rank administrations, universities, a large hospital and many specialized services, and a strong commercial center. Contrary to the two upper levels present only in the western half of the country, they were scattered all over the national territory, and completed by half a dozen of centers with a less complete set of such functions.
d) Province (or Departments) centers: The province (or rather Department, *il* in Turkish) is the basic administrative unit in Turkey and corresponds to the French "Département" since Atatürk followed the French model of the Third Republic when he reorganized the administrative grid of the country. All these departements but four are named after their chief-town, which plays a prominent role in spatial identities : when a Turk says "I am from Sivas", this means that he lives either in that city itself or in any township or village located in the department, and uses the numerous administrations, services and facilities of the city. Thus the remaining department centers (i.e. those having no significant regional-rank equipments) constitute the basic level of the urban network. The State is represented at that leve by the *vali* or "prefect".
e) Districts or "arrondissements" centers: under the departemental level, Turkey is also characterized by the great number of small towns and townships, chief-towns of the inferior administrative unit called *ilçe*, equivalent of the French

“arrondissements”, the towns being the equivalent of French”sous-préfectures” hosting a subprefect. The multiplication of these smaller agglomerations is quite important : having a few administrations, a grammar school, a health center, a weekly market and a group of permanent shops, they offer to the inhabitants of surrounding villages the first contact with urbanity. Some of them have grown bigger thanks to the presence of industrial plants or touristic activity.

Compared to this situation of the mid-1980s, the urban network has kept its main characteristics and undergone a number of significant changes.

- The metropolization trend has boosted the biggest cities, governed since 1984 by metropolitan municipalities (*Büyük Şehir Belediyesi*, “municipality of the Great City”), especially Istanbul, now a megacity of 13.3 million inhabitants (end of 2011, see www.citypopulation.de) with important international functions, but also the capital Ankara with 4.3 million people.

The “club” of regional metropoles can now include, together with Izmir (2,7 million), Bursa (1.7 million) and Adana (1.6 million), a new member, Gaziantep (1,376,000) as a very important industrial center and the leader of developing Southeast Anatolia.

Most of the regional centers have reinforced their role and become quite large cities, five of them have more than 800,000 inhabitants : Konya (1,073,000) and Kayseri (844,000), “Anatolian tigers” with great industrial development in a socio-political conservative atmosphere ; Antalya (964,000), motor of the touristical boom ; Mersin (859,000), major industrial harbour, and Diyarbakır (875,000), leading city of the Kurdish Southeast. Some cities classified as uncomplete regional centers in 1986 have completed their functions, like Denizli in inner Aegean (511,000), Adapazarı east of Istanbul (429,000) or Van in remote mountainous Southeast (353,000). Only two of these cities have undergone demographic stagnation or slight decrease, Zonguldak with the decline of its coal mines and Edirne facing conjonctural changes at the Bulgarian boundary.

As for the province chief-towns, their total number (including the three above-mentioned categories), after having remained stable between 1955 and 1989, has increased in successive stages from 67 to 81 in 2000. Most of these are mid-size cities, or even very small, like Bayburt (25,000 inhabitants) or Ardahan (18,000), often at the head of a small declining area, and generally owe to political considerations their accession to this higher rank.

The number of smaller district centers has gone on increasing as well, they are more than 700 now, including in 2011 22 mid-size cities between 100,000 and 200,000 inhabitants, mostly industrialized cities, and 192 towns between 20,000 and 100,000 inhabitants.

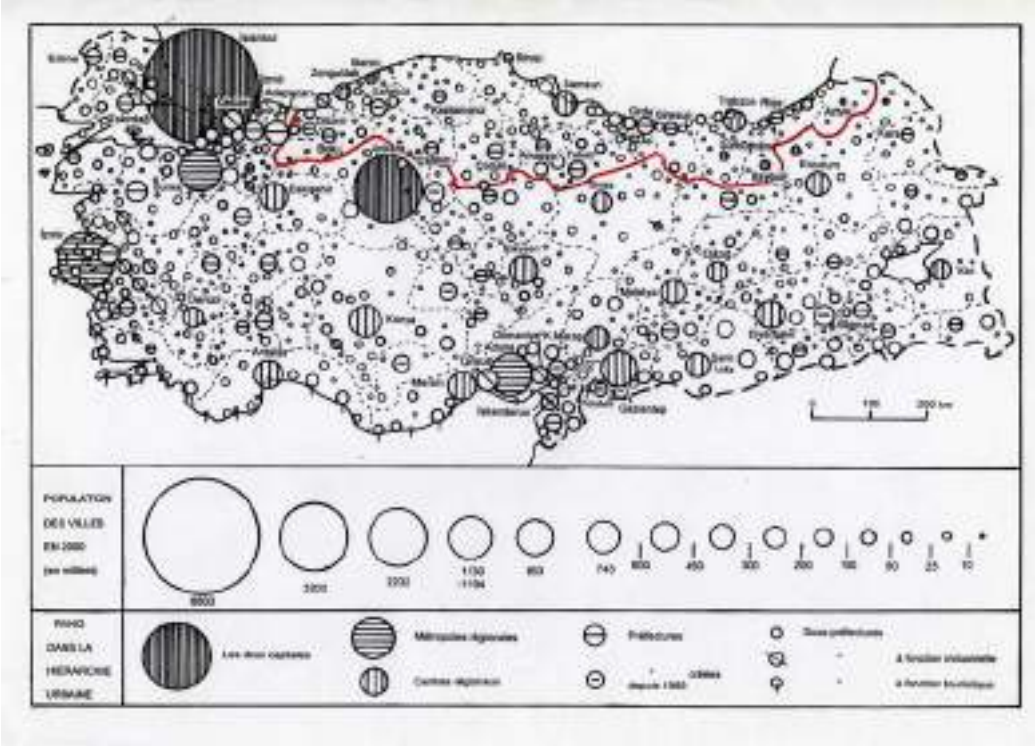

Fig. 2 – The urban network of Turkey in 2000

3. Regional centers and regional identities

The paradox of Turkey is that this country has numerous and strong regional centers, but no regions, or more precisely no regions identified through the influence of urban centers, but only natural regions **(3.1)**. To what extent can these dynamix regional centers contribute to develop regional identities **(3.2)** ? A step further has been attained by a number of development projects at a regional scale **(3.3)**.

3.1 The “unknown region”

I used this expression (in original version “La région, cette inconnue...”) to underline the lack of regional units in Turkey and the Turco-Iranian cultural area (Bazin, 2000), an analysis which was more recently invoked and completed by Benoît Montabone (2011) in his excellent PhD thesis about the stakes of regional development in Turkey. In fact several words exist in Turkish to designate intermediate spatial units between the local place of everyday life and the national territory. The most often used one, *bölge*, is a neologism derived from the verb *bölmek*, “to divide”. Another word derived from the same verb, *bölüm*, is used for smaller units, especially subdivisions of the latter. *Yöre* is in turn used for even smaller local units.But if several common nouns designate different levels of spatial entities, very few specific proper nouns are in use. Administrative units themselves are usually named after their chief-town, it is the case of 77 of the present 81 provinces (*il*) and of the totality of the districts (*ilçe*).

However, a few regional nouns are used in Turkey. In fact the lack of such names had led orientalists and cultured travellers to use regional names of the classical Antiquity, such as Lydia, Phrygia, Cilicia etc. For instance, the thesis of Xavier de Planhol *De la plaine pamphylienne aux lacs pisidiens* (1958), which marked the beginning of his rich work on the cultural geography of the Middle East, was devoted to Pamphylia and Pisidia which had no other contemporary names than “the plain of Antalya” and “the lake district” or the “provinces of Burdur and Isparta”. Most of those antique names had totally disappeared from the daily use of people, to the exception of Thrace, *Trakya* in Turkish, which had remained well identified within the Ottoman empire for its partly Greek population, and has kept its name after the exchanges of populations in 1923. Other antique names have been brought back into use for regions having a high touristic value, first Cappadocia (*Kapadokya*) with its unique association of natural landscapes carved in volcanic tuffs and cultural heritage of medieval Christian populations, which you can admire now from the nacelle of a balloon, and later Lycia (*Likya*) for its original funeral monuments which you can discover by walking along the pedestrian Likya route : antique names as a marketing argument for new products !

Another name, purely Turkish, designates a very well identified regional unit: it is the Çukurova, the”hollow plain”, i.e. in the heart of the antique Clicia a large alluvial plain surrounded by the chains of Taurus and Amanos and irrigated by the two rivers Seyhan and Ceyhan, mainly for the intensive cultivation of cotton. Thus it associates clearly perceivde physical features and agricultural speciality, well-known through the novels of Yaşar Kemal.

In fact, one set of regional units has been identified for the whole national territorry, by the first national congress of Turkish geographers held in Ankara in 1941, and is still taught in elementary and secondary schools, memorized by all the population, and used in everyday life, for instance in the meteorological bulletins : seven natural regions (*doğal bölge*) characterized by a combination of physiographic and bioclimatic features (fig. 3). Four maritime regions are named after the four seas around the country, Black Sea, Marmara, Aegean and Mediterranean regions, and three interiol regions are all called Anatolia completed by an adjective of position : Central Anatolia, Eastern Anatolia and Southeastern Anatolia.

Fig. 3 – Natural regions of Turkey

This definition and delimitation of seven natural regions has been validated and precised by Oğuz Erol (1983) who used a modern approach based on the identification of geosystems and established a subdivision of every *bölge* into three levels : *bölüm, yöre* and landscape units. This division into natural regions is systematically used as the framework for regional descriptions of the country in atlases and handbooks. For instance the *Büyük Atlas* (Great Atlas) first produced in the late 1930s by Prof. Faik Sabri Duran and constantly reedited since that time, reported at once the limits of the natural regions on the four regional double pages (Duran, 2010, pp.24-31). Similarly, a new atlas of Turkey for the general public (Çiringel, 2010) devotes a substantial second part (pp. 53-85) to the presentation of the seven regions, the limits of which are also superimposed on most maps of the general part. Giving the first role to these natural divisions - which have not produced any administrative entities - underlines the unitarian vision of the Turkish territory.

3.2 *De facto* polarized regions versus centralization ?

However, the affirmation of regional centers rests upon a number of realities which are gradually building *de facto* polarized regions : people from the surrounding departments increasingly frequent these bigger cities for administrative affairs, for educational and health services, for shopping and leisure.

If the department (*il*) remains the basic level of administration in Turkey, with departmental directions (*X... il müdürlüğü*) for every State administration and public organizations, this scale has been quite early judged too narrow to treat many problems. Thus a number of State administrations and public companies have created regional directions (*Y... bölge müdürlüğü* or *baş müdürlüğü*) covering a number of adjacent departments. Although the need to address to this supradepartmental level is not very frequent, it gives a reason to go out of the usual departmental environment to a bigger city.

FIG. 3. — Erzurum, capitale régionale.

1. Et ve Balık Kurumu (usine de viande, aire d'approvisionnement). 2. Raffinerie de sucre de Ilıca (aire d'approvisionnement). 3. Toprak Mahsulleri Ofisi (produits de la terre). 4. P.T.T. 5. Devlet Su İşleri (eaux). 6. Toprak Su (Sols). 7. Karayolları (Ponts et Chaussées). 8. İller Bankası (en partie aménagement du territoire). 9. Orman Baş Müdürlüğü (Forêts). 10. Merkez Bankası (Banque Centrale).

Fig. 4 – Administrations and public organizations bound to Erzurum in 1966 (Bazin, 1969, p. 293)

However, as I checked it in the case of Erzurum in my first research work (Bazin, 1969, pp. 292-293), all these regional directions did not cover the same area – that was the same situation in France under the Fourth Republic -, which obliged the population to frequent several urban centers for different purposes. But this may have begun to be at least partly harmonized since that time.

High level social services such as most specialized health equipments or higher education can also play a significant role to make the population of an area to focus on a regional center providing these facilities. But in the Turkish case, the situation is quite different in these two fields of services. Actually, the contribution of universities to a regional identity is weaker in Turkey than in many other countries, for two opposite reasons. On the one hand a recent boom in higher education has led to the multiplication of universities : there were in 2011 (according to a list given on the website of the French embassy in Ankara) 75 universities and other higher education institutions located in 38 different cities, i.e. not only in regional centers, whereas the three main cities still concentrate more than half of these institutions (25 in Istanbul, 10 in Ankara and 5 in Izmir). If universities are almost exclusively hosted by regional centers in Black Sea region, Eastern Anatolia and Southeastern Anatolia, in the western part of the country a number of mid-size province centers have also their own university now, for instance Çanakkale, Kocaeli, Bolu, Kûtahya, Kırıkkale, Niğde or Isparta. On the other hand the repartition of students between the universities is still organized in a much centralized way through a national interdisciplinary and interuniversity competitive exam. Thus every university receives students from all the regions of Turkey, and some of them a significant number of students from foreign countries as well. In fact, it always contributes to enhance the social animation and cultural life of cities, but only very partly in relation with its regional environment.

Health services, on the contrary, follow a logic of relative proximity, except for very rare illnesses. Big public and private hospitals are more numerous and have a bigger capacity and more complete equipments in regional centers, which offer as well a larger panel of specialists. The same logic applies to commerce and private services too. Together with concentrations of shops in the city center, which may be partly in a traditional bazaar and partly along the main avenues, important cities have begun to widen their commercial offer to two new forms : hypermarkets on peripheric locations and big commercial malls called *alış veriş ve yaşam merkezi* ("Shopping and lifestyle center), often with a monumental architecture like the glass pyramid of Zafer Plaza in Bursa.

An important condition to the development of this regional attractivity is to improve the accessibility of these cities, and Turkey has in fact seen during the last two decades a real boom in transportation facilities. In terms of time-distance, in the 1980s regional centers were central places which one could reach in one day, nowadays you can go there, do your business or administrative formalities and come back home within the same day.

But shifting from this *de facto* growing polarization to a true regionalization reveals to be quite difficult. Centralization is deeply rooted in the political tradition of the Turkish Republic, and any attempts to decentralization are quickly perceived as a threat to the unity of the country. It is symptomatic to notice that the first step towards decentralization has been undertaken at the lower scale of departments by transferring some competences to "departmental special administrations" *(İl özel idaresi*) and to metropolitan municipalities.

.

3.3 First experiences of regional development projects

In a more pragmatic way, a number of regional development projects have been undertaken, still in a centralized context under the impulse and control of the State Organization of Planification (*Devlet Planlama Teşkilatı,* DPT).

The most ancient one was also the most ambitious, the Southeastern Anatolia Project (*Güneydoğu Anadolu Projesi,* GAP), an hydraulics-based integrated development project which has been subject to passionnate discussions. It was launched in 1977, soon after the completion of the Keban reservoir-dam at the junction of the two upper branches of Euphrates, the Karasu and the Murat Su. The idea was to built a system of 22 dams on upper Euphrates and Tigris and tributary rivers combined with 19 hydro-electric power plants – including the biggest one in Turkey, fed by the Atatürk dam on the Euphrates, with an installed capacity of 2,400 MW -, in order to turn into intensive irrigated lands some 1,800,000 ha of extensive pluvial fields and steppic pastureland and to develop industries transforming regional mineral resources and agricultural products, especially cotton.

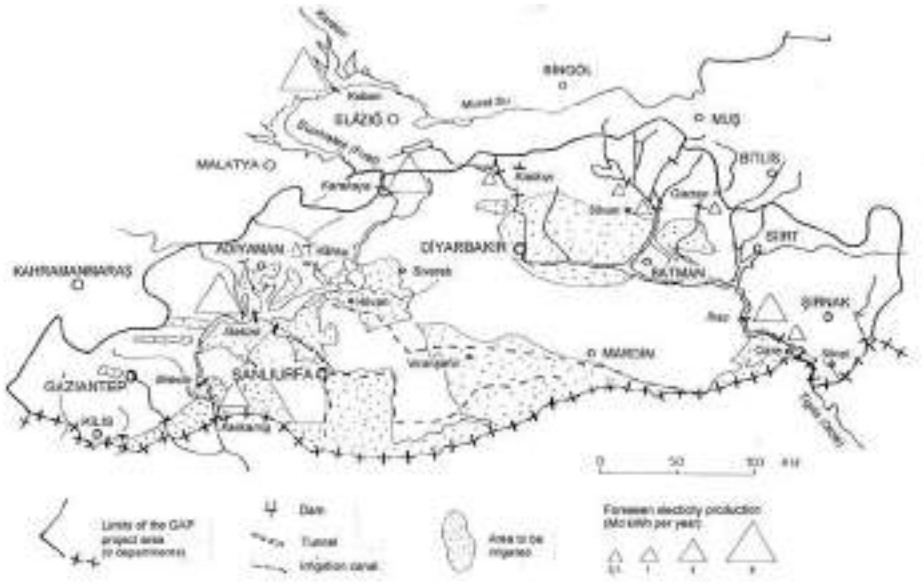

Fig. 5 – The Southeastern Anatolia Project (GAP)

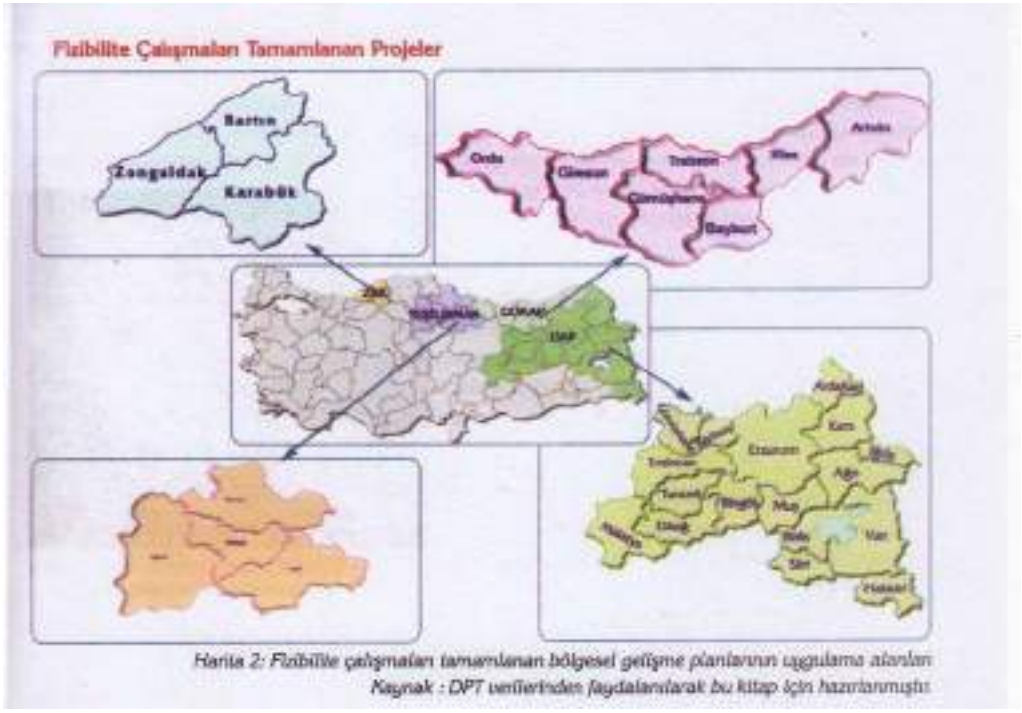
The main objective of GAP was to seek a global remedy to the deep underdevelopment of Kurdish Southeast and to reduce spatial unequality by providing new infrastructures, increasing agricultural production thanks to irrigation and developing industry thanks to hydroelectricity. If the hydraulic programme and the extension of irrigated land is not achieved yet, Southeastern Anatolia has engaged deep changes, especially along the axis linking Gaziantep to Şanlıurfa.

Another set of more sectorial plans have been implemented during the successive five-year plans since 1970. Six rural development projects have successively been engaged by the Ministry of Agriculture and Rural Affairs, and more precisely by its General Direction of Rural Services, in order to favour the growth of agricultural production by improving infrastructures, in areas covering one or two departments each, all in the northeastern part of the country. The last one, designed for the Erzincan-Sivas area (2005-2012), shows a new trend towards support to small familial holdings and sustainable development (Montabone, 2011, pp. 146-148).

The most interesting initiative, once again engaged by the DPT, concerns four Regional integrated Development Plans (RDP), all located in the north and east of the country (fig. 6) and adaptated to the specific problems of these areas (Montabone, 2011, pp. 148-152) :



Harita 2: Fizibilite çalışmaları tamamlanan bölgesel gelişme planlarının uygulama alanları
Kaynak : DPT verilerinden faydalanılarak bu kitap için hazırlanmıştır

Fig. 6 – Regional development plans as presented in a secondary school handbook

-The Zonguldak-Bartın-Karabük RDP(1996) aims to favour the restructuration of coal mines and iron and steel industry.
- The Eastern Black Sea RDP (acronym DOKAP, 1998) is a long-term plan prepared with a Japanese cooperation agency, based on a detailed territorial diagnosis and proposing ten structural programmes.
- The Eastern Anatolia RDP (acronym DAP, 2001) encompasses the poorest areas of the country. Elaborated by a pool of regional universities, it has ambitious but very general objectives of sustainable development and reduction of unequalities.
- The Yeşilırmak Basin Development Project (2004) takes its originality from its pecular logic : organizing a catchment basin in order to lessen the pollution discharged into the Black Sea, which compels by retroaction to improve numerous aspects of economic and social life. Alas, it includes only the four departments located downstream, but not the upstream valley located in Sivas department.

As a whole, these plans have suffered from questionable delimitation, from the incapacity to mobilize the necessary financing resources, and form the lack of an institutional body ready to implement the plans, that remain virtual as for now. But they have opened an interesting way towards regionalization.

4. From new statistical units to a real regionalization process ?

In the framework of the large pre-adhesion process engaged to meet the Copenhague criteria for claiming membership in the European Union, Turkey has adopted two levels of supradepartmental units NUTS 1 and NUTS 2 **(4.1)**. Although their

delimtation is criticizable in many cases, all the NUTS 2 units have been provided with Development Agencies **(4.2)**. Can we consider the creation of these DA as the first step towards a real regionalization **(4.3)** ?

4.1 The introduction of regional units between EU incentives and national concern

As in many other fields, Turkey has been facing strong EU incentives concerning the chapter 22 – Regional policy of the pre-adhesion process. The first *Partnership for adhesion* adopted in March 2001 indicates namely among the three priorities concerning the development of an efficient regional policy the elaboration of a NUTS classification. This objective met some actions separately engaged in Turkey, such as the above-mentioned Regional Development Plans and reflections about a reform of governance.

Thus two levels of statistical units have been defined and delimitated in 2002 between the State and the existing departments, that have been subsequently labelled NUTS 3 units. The result is the official Classification of Statistical Regions (*İstatistik Bölge Birimleri Sınıflaması,* acronym İBBS) and the corresponding maps (fig. 7) :
- 12 NUTS 1 (*düzey* 1 = level 1) big regions, which respect as much as possible the contours of the 7 natural regions and are named after them ;
- 26 NUTS 2 (*düzey 2*) regions, counting from one to six preexisting departments ;
- and 81 NUTS 3 (*düzey 3),* the existing departments.

Fig. 7 – The new NUTS 1 and NUTS 2 regional units in Turkey

The delimitation of NUTS 2 regions has apparently obeyed to several conctradictory logics : having a comparable demographic weight ; constituting an homogenous natural or economic entity ; being polarized by one big city. The combination of these criteria results in a rather confused typology :
- Regions made of one single department : the three metropoles Istanbul (TR10), Ankara (51) and Izmir (TR31), a choice which avoids too big regions, but cuts the metropoles from their immediate environment ;
- Regions polarized around one single regional center : TR21 Edirne, TR22 Balıkesir, TR32 Denizli, TR33 Manisa (not so clear), TR52 Konya, TR61 Antalya, TR81 Zonguldak, TR83 Samsun, TR90 Trabzon, TRA1 Erzurum, TRB2 Van, TRC1 Gaziantep ;
- Bipolarized regions (often with a different weight of the two cities) : TR41 Bursa + Eskişehir, TR42 Izmit (Kocaeli) + Adapazari, TR62 Adana + Mersin, TR63 Kahramanmaraş + Antakya ; TR72 Kayseri + Sivas, TRB1 Malatya + Elâzığ, TRC2 Diyarbakır + Şanlıurfa ;
- Little polarized interstitial regions : TR82 Kastamonu-Çankırı-Sinop, TR71 Kırıkkale- Aksaray-Niğde-Nevşehir.
- Little polarized peripheric regions : TR42 Kars-Ardahan-Iğdır-Ağrı, TRC3 Mardin-Batman-Şırnak-Siirt.

4.2 The creation of Development Agencies

After having been for some years just a new statistical grid – adopted at once by the Turkish Statistical Institute (*Türkiye İstatistik Kurumu,* TÜİK) -, this new territorial division of the country has suddenly increased its importance with the creation of Development Agencies (DA, *Kalkınma Ajansları*) in the territory of the 26 NUTS 2 regional units, in three steps : two pilot-agencies were created in 2007 in Izmir (TR31) and Adana-Mersin (TR62) ; 9 others, including Istanbul, in 2008 and the remaining 15 in 2010. Thus these new institutions cover the whole national territory. Benoît Montabone has focussed his research on this innovative institution (2011, chapters 4 and 5, pp. 155-217). The law n° 5449 published in the Official Journal on July 6, 2006, which has launched their creation defines their main functions: planification at the regional scale, including the elaboration of strategic plans : financial support to development projects ; support to innovation and external investments.

Initially called Regional Development Agencies (*Bölgesel Kalkınma Ajansları*), these DA have followed – after a number of preparatory visits and inquiries, for instance in West Midlands and in Alsace – an international and especially european model, defined by Halkier and Danson (1997) as private or semi-public organizations gathering together strategic stake-holders of a territory in order to favour innovation and improve economic governance. Several new members of E.U., such as Poland, Czech Republic and Hungary, have in fact adopted this formula during their pre-adhesion period. But Turkish DA also take place in a much wider legislative package

launched in 2004 and aiming to give more autonomy to local levels like Departmental Special Administrations and Metropolitan Municipalities. They can thus be interpreted as the result of a convergence between a european demand and a national evolution.

One of the most important innovative features of DA is the creation, beside the usual Management Board (*Yönetim Kurulu*), of a consultative Development Council (*Kalkınma Kurulu*) of 100 members representing the economic and social forces of the region. In addition to the institutional personalities present in the Management Board, i.e. the prefects of all the departments composing the regional unit, the mayors of the chief-cities of every province, the presidents of the Departmental Special Administrations and those of the Trade and Industry Boards, they include representatives of municipalities, of State local administrations, of Trade and Industry Boards, of Organized Industrial Estates, of professionnal associations, of universities etc. Resting on the experience of a few pre-existant growth coalitions, for instance in Gaziantep, these new DA allow bottom-up mobilization for nation-wide recognition of regional competitivity and attraction of investments.

4.3 A first step towards real regionalization ?

If Elise Massicard (2008) remained somewhat sceptic about the trend towards regionalization, speaking of "impossible regionalism" and "improbable regionalization", her study dates back to the very beginning of the creation of Development Agencies., and she had not had the possibility of appreciating the first results of this innovation process, as Benoït Montabone has done.

The latter has chosen three examples to make field studies and inquiries, the DA of Istanbul, Izmir and Karacadağ covering the two departments of Diyarbakır and Şanlıurfa. The two former examples have in common the fact that the choice of a NUTS 2 unit limited to one single department weakens the possibilities of strategic planification which should be elaborated for a much wider metropolitan area. In fact, in the case of Istanbul, where the authority of the metropolitan municipality covers now the whole territory of the department, the DA stands in concurrence with the Istanbul Metropolitan Planification board (*Istanbul Metropoliten Planlama*, IMP) directly bound to the municipality, which has actually produced a reflection at a much wider and more appropriate scale, that of the whole Marmara basin (fig.8).

In Izmir, where the DA was installed earlier, its strategic development plan has taken into account documents previously elaborated by the metropolitan municipality and by the Board of Trade, and explicitely proposed to extend the reflections to all the departments of the Aegean region, actually under the metropolitan influence of Izmir.

As for the Karacadaĝ DA, its territory depends greatly of development programmes engaged at the broader scale of GAP, which encompasses as well the two neighbouring DA of Gaziantep (*İpek Yolu,* "Silk Road") and Mardin (*Dicle*,

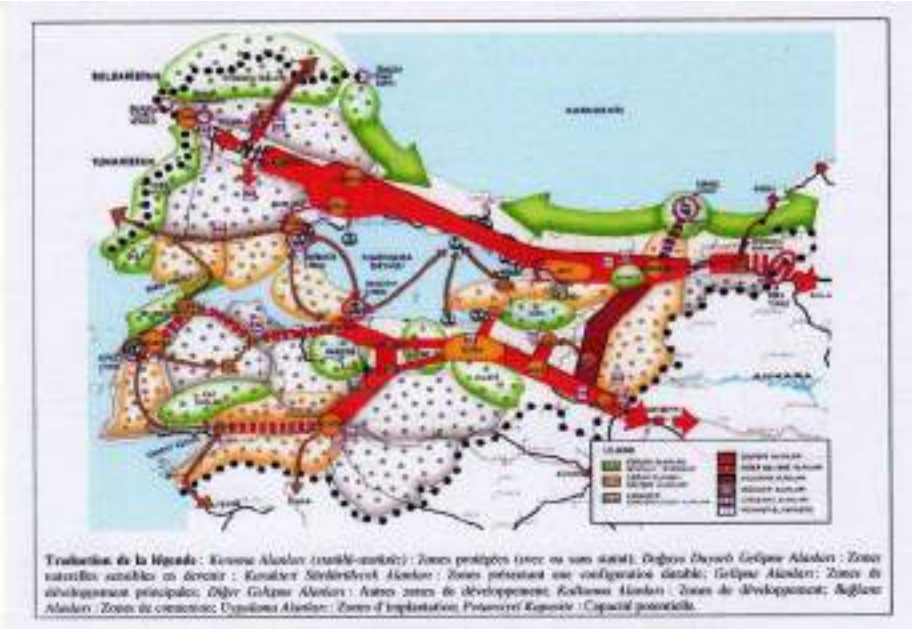


Fig. 8 – Spatial vision of the Marmara region proposed by IMP, 2006 (Montabone, 2011, p. 265)

"Tigris"). It suffers also from the political rivalry between its two big cities, Şanlıurfa with an AKP (the party of the present govertnment) municipality has been chosen as the regional center and the seat of DA although Diyarbakır is quite bigger (875,000 inhabitants against 515,000) but has a mayor from the pro-kurdish Party of Peace and Democracy (*Barış ve Demokrasi Partisi,* BDP).

In spite of these difficulties which result from the delimitation of the three above-mentioned DA rather than from their organization, the 26 agencies as a whole have begun to play a significant role in involving regional actors in development projects and favouring territorial appropriation. Thus, they can, in my view, be a starting point to a gradual evolution towards regions as true territorial collectivities. I invite the pessimists to consider the example of my own country, France, where regions were first created in the late 1950s as "Circonscriptions d'Action Régionale" (Regional Action Areas), so with a regional planning approach in a strongly centralized state. Who could have imagined then that they would become, a quarter of century later, the masterpiece of the decentralization process in France ? So, good luck to "alaturka regionalization" as well !

Hierarchy, Negotiation, Competition and Protest:

Multi-Actor Interaction in Building High-Speed Railway Oriented New Town in China

Guowen DAI g.dai@uva.nl

University of Amsterdam

The Netherlands

Key Words:

High-Speed Railway oriented New Town (HSR-NT), Actor-centered Institutionalism, Interaction mode

Introduction

High-Speed Railway station area development might be a platitude in the practice and academia of the western world (Peters and Novy, 2012). Those cases in Europe are evolving from property capitalization towards urban mega-project and till TOD (Transit Oriented Development) (Bertolini, et al, 2012). However, the similar topic in Chinese context can be interpreted differently into local scenario.

HSR-New Town Nationwide Fever

The strategy of using the railway station as a growth pole of a new town/district in China is considered as the major policy response to HSR embedding. With the operation of HSR stations, the processes in majority of cities have moved onto the actual implementation phase. However, this HSR-New Town (HSR-NT) development is gradually turning from a heat to a 'nationwide fever'. Before excavating the insight, it is important to be aware of the problematic situations in the planning and implementation of current HSR-NT in China as follows:

- Tendency of turning from a golden opportunity for city re-construction to just a gimmick of land enclosure:

  Since most of those HSR stations have been put in to use recently, the majority of the land and road system around stations are almost ready for secondary land development (if there is such). In other words, the land enclosure in urban periphery has been almost finished. The institutional parameters that drove local government to keep the 'production line' of urban space are revealed.

- Lack of sustainable engine for further urban development:

  The increasing fiscal burden to pay back mortgage in the primary land market is strongly restricting the land development around station. Not to mention with the challenge of changing political and financial background, the missing market interest is gradually growing. The international crisis is exacerbating domestic inflation in China, while the Chinese national policy on housing and land is tightened up. Therefore, what is the future sustainable engine to keep the 'growth machine' running?

What caused the current problematic situations? Who are hidden behind the curtain? What collective action problems are involved in the process of planning and implementation? Those raise the necessary of getting anatomy insight of the process of making HSR-NT. In order to actor-centered institutionalism will be introduced. The main research question will be formulated as: **How can interactions between actors**

embedded in the Chinese context effect the decision-making and implementation process of making High-Speed Railway oriented New Town? The case of Wuhan station area development will be taken as a case study. Two trips of fieldwork to Wuhan have been conducted. One was from October 2010 to February 2011, and the other is from January to February 2012. Twelve structured in-depth interviews to key actors involved in this case have been made, including transport planner, urban planner, civil servant, urban designer, and architect, etc.

Wuhan railway station area development: a new sub-city center

Wuhan, the capital of Hubei Province, locates at the inner part of China. The urbanization history can go back to 3500 years ago. It was merged from three counties - Wuhanchang, Hankou and Hanyang - on both banks of Yangtze River in 1949. According to the old version of City Master Plan (1996-2020), it is regarded as an important city in central China, vital industrial base and transportation node (B1). The population was planned to be 5.05 million by 2020 within the area of 8467 km2. In the reversion of City Master Plan (2006-2020) its position has been raised to be a central city in central China, a national historical city, vital base for industry and science education, and integrated transportation node. Wuhan has been playing more and more important economic and social role in nationwide. It is one of the two metropolitan areas, which are approved to be the comprehensive pilot area to build 'Two-type Society, that is Resource-saving, and Environment-friendly Society' in 2007. Two years later, it is regarded as one of National innovation pilot cities.

Wuhan holds a strategic position within national water and railway transportation network. It is planned as one of the four national conjunction nodes in the National Railway Network Plan. Billions has been invested into the twelve railway related infrastructure projects in Wuhan during the 11th Five-year Social and Economic Development Plan, including the case of 'Wuhan Station' to be discussed here. There used to be two railway stations, Wuchang and Hankou stations. Although Wuchang station is not connected into HSR network, it is considered as the nodal station organizing multi-direction railway transportation to all over the country. Hankou station is connected into the HSR network, providing the CRH trains which head for Yangtze River Delta in the east. The name of the new 'Wuhan station' emphasizes the symbolic importance of Wuhan station as a municipal transportation node. The high-speed trains departing from it will head for north and south. This new periphery station is far away from the city centers: 17 km away from Hankou station, 12 km from Wuchang city center, and 22 km from Hanyang city center (see Fig. 1).

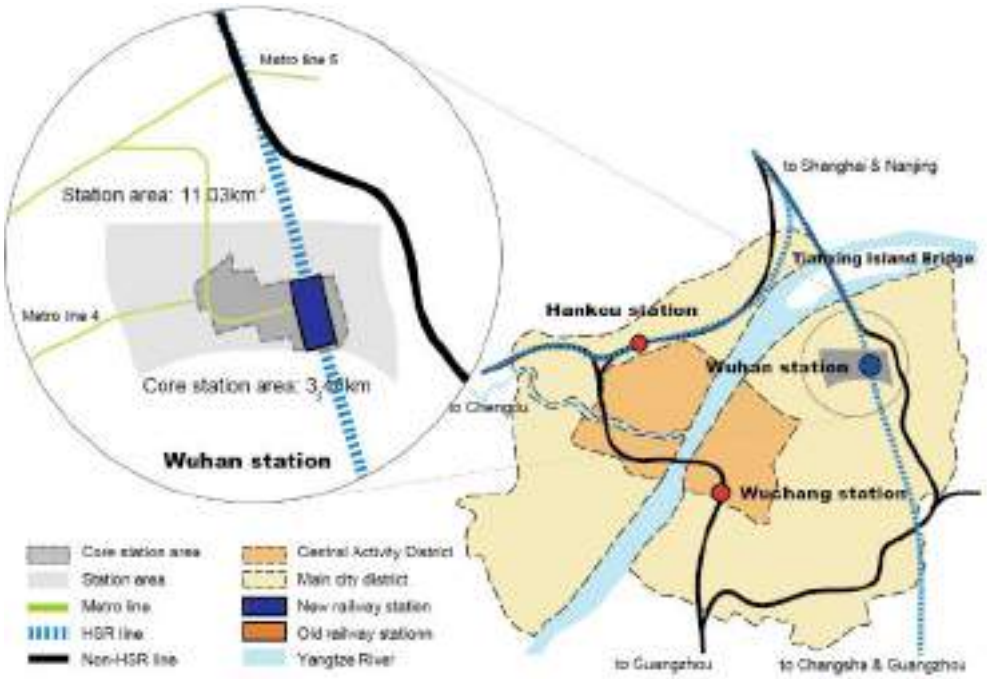

Figure 1: Wuhan railway network and location of Wuhan Station (source: author made)

The whole process from 1995 until January 2012 involved at least 13 official plans or researches. They are 1 architecture design, 4 infrastructure plans, 2 city master plans, 3 conceptual plan and urban designs, and 3 regulatory plans. Two more plans (research) are being conducted at the same time. During the past fifteen years, there were some crucial moments that determined the direction of decision-making process (see table 1). One is the official approve for the final proposal of Beijing-Guangzhou High-Speed railway line as well as the Wuhan Station by MOR and National Develop & Reform Commission in 2004. Another is the official statement of building Yangchun-lake sub-center around Wuhan Station in the revision of City Master Plan of Wuhan in 2006. (The detailed illustration of timeline can be found at http://timeglider.com.) The whole process can be divided into three phrases according to the crucial moments: First is the planning of HSR route and location of station from 1995 to 2004. Second phase is the making of spatial plan of station area and construction Wuhan station from 2004 to 2008. Last but not the least is the preparation of Wuhan station and implementation of station area plans from 2008 until now (May 2012).

Time	Event	Significance
09/1997	MOR's approve on Wuhan Railway Network Plan	Decision on plan and construct Tianxing Island Bridge and the new Wuhan Station
17/05/ 2004	Official approve by MOR and National Develop & Reform Commission (the first agreement between province, municipality and MOR was reached on 26/09/2003)	Final decision-making on Beijing-Guangzhou HSR route and periphery location of Wuhan Station
2006	Official approve for City Master Plan of Wuhan (2006-2020) by State Council	Firstly establishing the planned role of Yangchun-Lake sub-center, in order to form multi-centered metropolitan area in Wuhan
2007	Integration of five plans after the international competition of urban planning and design	Plan for Yangchun-Lake sub-center settled down and the future vision began to take shape
12/2009	OCT Co. Ltd. won the land, P(1009)113, with the function of 'housing, entertainment & tourism' in the bidding by 4.3 billion RMB	Official involvement of Wuhan OCT project

Table 1: Crucial moments in the process of Wuhan station area development (source: author made)

Key Collective Action Problems in Making HSR-New Town

Context matters in defining the key collective action problems in the HSR station area development. There are some shared commonalities. Based on the European experiences during last two decades in 20th century, a series of relevant dilemmas were elaborated. For instance, Bertolini and Spit summarize the spatial, temporal, functional, financial, and management dilemmas (1998). As the economic and political context change, new dilemmas emerged during the past decades, such as the discussions on the difference of TOD and TAD (Transit Adjacent Development), understanding the failure of some station area development projects, and decline of lesser stations. Etc. (Peters, D., Novy, J., 2012; Speck, 2012). This paper sets forth four collective action problems that are characteristic in Chinese context: location and route choice of railway line and station, transport intermodality with other transportation modes, functional diversity, and social integration with local context. And specific features defer in individual

cases. In this case of Wuhan, the ecological accountability stands out as the fifth issue. The majority of those issues are attached to the acclimatization of this new potential 'growth pole' into existing Chinese city context.

- Where to locate the HSR and station?

  The decision making of the route of railway and location of station layouts the keynote of future station area development. The choices include redeveloping/enlarging the existing central-located station, building a new central-located station, and building a new periphery located station, etc.

- How to connect railway with the other transportation modes?

  The buzzword of 'intermodality' is one of the most important issues which all sectors need to take into consideration. It not only refers to the connectivity with other transportation, including airplane, metro, city bus, inter-city bus, private car and pedestrian from station itself, but also the accessibility to station from surrounding area.

- What functions to be facilitated?

  Functional diversity in urbanized area is no doubt the key for spatial quality as J. Jacob indicated. But it might be opinionated to come to the judgment that it is always necessary to promote diverse space in station area. The situation differs depending on the orientation of station itself, which can be pass-by station, property-led station, and nodal integrated station, etc.

- For whom is the plan made for?

  Social integration is a common issue to produce spatial quality in new towns. It indicates the identity of local residents, the external image of community, as well as the embedding of new dwelled community with original ones, etc.

- To what extent can environment vulnerability be taken into consideration?

  With the growing emphasis on ecological sustainability from either normative or political motivations, the accountability of urban plans for protecting public resource becomes more out loud, especially in such a hilly and lochy city like Wuhan.

Chinese Characteristic Action Arena for Building a HSR-NT

Actors embedded in institutional settings

The theoretical approach in this paper is mainly adapted from the 'Actor-centered Institutionalism' from Scharph (1997) and 'IAD (Institutional Analysis and Development framework)' from Ostrom (et al. 1994).

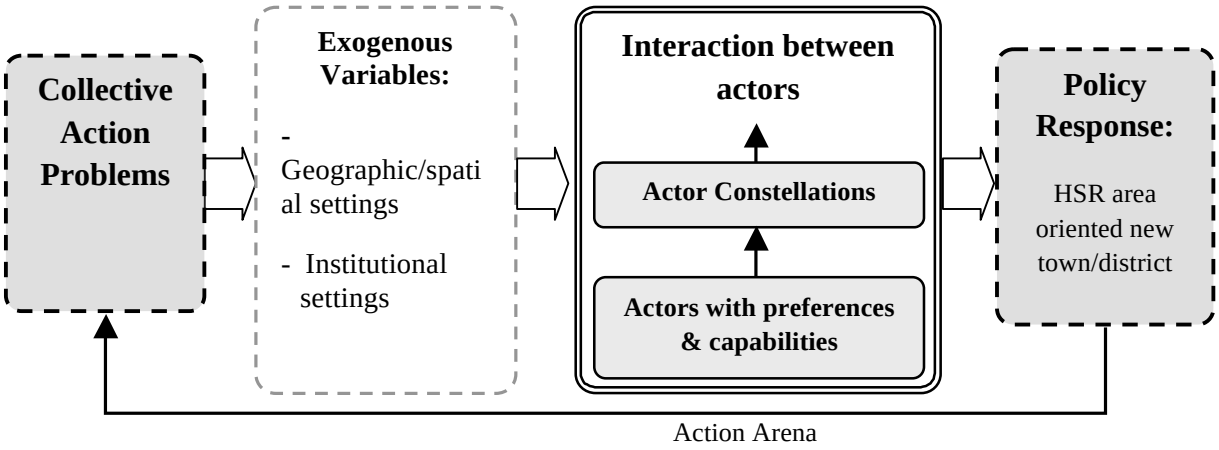

Figure 2: Conceptual framework (source: author adapted from Scharph and Ostrom)

The general institutional arrangement of transportation and urban (spatial) development in HSR station area development in China is shown in table 2. The power and interest continually shifts not only on scalar dimensions, but also at differentiated phases along the process of planning and implementation. The horizontal continuity shows the involvement of public and private sectors, while the vertical axis represents the time sequence of process. This shares some commonality with other mega-project development in the centralized institutional arrangements of China.

	Transportation development (As 'node')				**Urban development (As 'place')**			
	Actors			**Accountability**	**Actors**			**Accountability**
	Macro	**Meso**	**Local**		**Macro**	**Meso**	**Local**	
Decision-making & planning	MOR	--	--	Make plan for HSR route and station location	MG	--		Make spatial plan for station area development
Implementation & construction	MOR	--	--	Construct railway track and station architecture	--	--	MG, DG, ASDO	Municipal government entrusts construction office and district governments to conduct
Management & service	--	LRD		Maintain daily function of station and the commercial space within it	--	--	MGP	Attract investment and provide preferential policies for station area

Table 2: General actor constellation of mega transportation infrastructure in China (source: author made)

(MOR: Ministry of Railway, LRD: local railway department, MG: municipal government, DG: district government, SADO: station area construction office, P: private developer/investor)

Preferences and Capacities of Actors

Built upon the understanding of institutional settings, different preferences (individual and organizational self-interest, and normative obligations and aspirations) of actors and their capacities will be explained.

- Dominant position of public actors

Firstly, the dominant role of MOR in the decision-making process for location and route is un-doubtful. Unlike in the other countries, MOR is independent of Ministry of Transport. It is responsible for the formulation of the railway network planning, the implementation and the evaluation of railway infrastructure, and the management/ regulation of state-owned railway property. It is known as the most enclosed 'kingdom' left by the Socialist Planned Economy, which means the system of decision-making and implementation is relatively independent from other social and economic sectors in Chinese society. Wuhan has its own subordinate office, which directly runs the railway investment and construction company in cities around Wuhan. It is famous for the capability both in technique and political aspects because of the extremely strategic position of the city in national railway network. Another hidden factor is that the director of Wuhan Railway Bureau is the younger brother of Minister of Railway, which provides possible closer relationship within ministry. To conduct the practical financing and investment of railway infrastructure construction, Wuhan-Guangzhou HSR Ltd. Co. is established. The whole line is financed by Guangdong, Hunan, and Hubei province, and Wuhan municipality entrusts district governments to take in charge of replacement and demolishment. The argumentation of 'three pillars' (Amos, P. & Bullock, R., 2011) can be seen as the vivid metaphor for the governance and structure of railway industry into Chinese context: not enough join-up governance of the transport sector in a single ministry; the separated roles of policy-making and transport services delivery (in all modes, including railways), and independently regulate the industry (whether by ministry or agency).

Secondly, local Wuhan subordinate railway Office acts with its own interest during the implementation of plans. One typical example is the 'illegal ' restaurants and shops under the ramp of Wuhan station in east square. There was no such commercial space in the legally approved architecture design. However, the Wuhan railway office realizes the huge hidden profit margins of involving retail and restaurant, as well as the consumption demand from the passengers. Another example is the changed function part of Wuhan station area management office building. The building was originally oriented for only the office function. However, the management office changed part of building into hotel without application for official approval from Wuhan government. It is obviously illicit but accepted throughout the time.

Thirdly, Wuhan municipal government entrusts the construction office to be in charge of the land development. According to the Constitution, the government is not allowed to participate in the market activity directly, which raises the necessary of Wuhan City Construction & Investigation Ltd. Co. It is the subject who is in charge of the financing and developing real estate of the land except the station as representative of government. The similar state-owned enterprise exists almost in every city and has been considered as the main financing platform for urbanization in China. In the case of Wuhan station area development, a Wuhan Railway Stations Construction & Coordination Office was founded to organize the spatial development as well as municipal facilities around the three railway stations. Wuchang (2008) and Hankou (2006) station are located within the third ring road, and therefore, Municipal City Construction Committee is in charge of them. And Wuhan station is under the charge of Municipal Transportation Committee for it is located outside of third ring. The mechanism is as follows: The land around the station was collected into the Land Reserve Center of Wuhan ever since the decision-making of periphery location was made in early 2000s. Cooperating with Land Reserve Center, the City Construction & Investigation Company hypothecates the state-owned 'raw land' to banks in order to get mortgage as investment for site development, such as road and sewage construction. After repaying the mortgage and finishing the site development, the company then leases the 'mature land' to developers. In this sense, there is no specific procedure of station area that is differentiated from other land development. One unforeseen event, the Wuhan OCT thematic park project, needs to be mentioned. This project changed the mechanism of the Staion Area Construction Office: In order to re-capture the new potential profit from land price appreciation brought by OCT, Wuhan municipal government withdraw the development right of the station area besides the core area back from the office.

Last but not the least, district government has slightly saying in the decision-making process but significant role during implementation. The station area involves two administrative districts, which are Hongshan District as the main part and Qingshan District involved just a tiny proportion. Only the west part of this area is urbanized with the majority community of industrial workers ('Danwei'), such as

Wuhan Steel Plant as well as other factories. This area used to be one of the fully facilitated neighborhoods when the factory workers were the middle classes in Chinese society back then. Nowadays, this area is considered as not so popular in housing market because of the industrial pollution and social segregation. During the whole decision-making process, neither of the district government was involved. However, since they have the land or administrative power to operate the development, it is difficult for Wuhan Railway Stations Construction & Coordination Office to implement the plans in practice. Therefore, in this stage, district (esp. Qingshan district) is involved. Their role is to operationalize the demolishment and replacement of residents and functions under the order from Wuhan Railway Stations Construction & Coordination Office (A9).

- Missing the coalition or platform between spatial development and railway sectors

However, the role of a collaborate coalition or network platform in this case is missing. First of all, there is slight negotiation between spatial and railway sectors. The typical example is the decision-making of the location choice in the early phase. Only in some rare cases, most of which are mega cities with bigger right in anatomy, spatial actors can negotiate with transportation actors in the decision-making/planning phase. It is indeed this case that the municipality and MOR succeeded to achieve a relatively win-win situation. But the whole process was fragmented and not so transparent. During the phase of construction, they also do not cooperate well. City public facility departments complained that they always need to wait for the final plan from railway sector to start their own construction. The competition/fight for the shared construction site also happened sometimes (A9). Another typical un-cooperated example is the transfer between different transportation modes. The planned two metro lines are still under construction two years after the establishment of station. And the bus connection provides less capacity than nowadays demand, not to mention the requirement of the planned sub-city center.

Secondly, there is also missing cooperation between spatial development sectors on both city and regional level. At city level, the whole land operation procedure is planned on the city level and managed through Wuhan Railway Stations Construction & Coordination Office. It has higher legitimized power than two involved district governments, Qiangshan and Hongshan District. The speed and quality of district government's work on clearance of land in advance will strongly affect the implemented outcome of the plans. Besides, at regional level, the relationship between cities on the HSR corridor still remains as competition rather than cooperation.

Thirdly, the land ownership is quite tricky. Generally speaking, there is clear definition for the station area according to the national regulation that is the railway sector can obtain the ground land of the station architecture from local authorities. In this case, Wuhan railway department required a bit larger area around the station for the construction of ticket office in the contract with local government. In total, it covered 330-thousand m2 land with 120 thousand m2's floor area. And Wuhan government owned the land excluded that part in the station area. However, during the practice, it turned out that the land needed for ticket office was exaggerated. Therefore, the actual development right of the extra land was given back to Wuhan municipality and Wuhan railway department is only in charge of drip line area of the station architecture.

- Bonded market behavior of public actor with private actor

The public-owned company makes the government's participation in market realized and legalized. As both rule-maker and participants in this game, public actor is acting just like other profit-making private actor. Real estate developers and enterprises are only brought in the game during the public bidding for leasing land use right after the infrastructure is implemented. Unlike some other station area development, there is no specific legitimated coalition or platform to facilitate private market behavior. The main reason of it is that only two relatively economically 'weak' districts are involved in the process, which seems no necessary of creating new coalition. It also shows that the ever-surviving developers in Chinese re-structured market in the post-financial-crisis era are mostly public-owned. They also want to bond their

own interest with public actors so that they can participate earlier in the process of primary land market in order to gain more profit from land leasing. It is a huge gap that they haven't been involved more in-depth for they are the actually users of the potential boomed urban space.

- Strong intervention of flagship project developer

Wuhan OCT project is the biggest investment in the history of OCT company as well as in Chinese entertainment tourism industry. After attracting such a flagship project, Wuhan government, especially municipality, shows clear confidence in realizing this Yangchun-lake sub-center. The government came to be aware of the possible enormous profit hidden in the rise of land price of this area in the coming future. The interesting response is that the land development right around the station was then taken back to municipal authority (municipal land resource center) from the Railway station area construction and coordination office in the middle of the development process. The frequency of politicians' inspects on the progress of the project and the countdown sign in the OCT construction site show the high attention from government.

- Slight involvement of civic actor

The interests of civic actors, such as local community, industry or NGO are slightly involved. Most of the local communities are the farmers living on the collective-owned land. They are asked to move out of origin housing to a new collective built public housing by local government. The same situation does not apply to the big industry within the site, such as Wuhan Steel Plant. Unfortunately, there is no such NGO involved in the whole process. It is a relatively a supply side approach. The opportunities for housing and office development in the station area seem to sprout from the planning perspectives. The content of the plans seems to be very much driven by design and regulation oriented planning as opposed to forms of interactive or communicative planning.

Furthermore, the previous mentioned media attention on Wuhan OCT is the only case that the voice of civil actors could be heard. And their opposition, to some extend, contributed to the positive change of the way of dealing with public space in the future Yangchun-lake sub-center (A12). However, the reliability of the media reports still needs to be further invested. Because of social contradictions in rapid urbanization, this type of critic on government and real estate developer is easy to resonate citizens. In this case, there is not enough evidence that can fully prove the report.

Facing Collective Action Problems in Wuhan Yangchun-lake Sub-center

The five previously mentioned collective action problems are involved on different levels and will evolve with the change of exogenous variables in institutional settings. They are assorted according to both temporal and scalar dimensions (see Fig. 3). The scalar dimension (vertical axis) refers to the governance level from national, regional, municipal till project levels, while the temporal dimension (horizontal axis) indicates the three phases from planning, implementation and management. The actor constellations and the interaction among them in those five issues will be described as follows.

Figure 3: Important issues in temporal-scalar scheme (source: author made)

Location choice

Location choice is the most fundamental dilemma. The outcome lays out the keynote of future development, on which the others will be path dependent: The discussion dated back to the vision for railway network in City Master Plan in 1995. The idea is to build the new Wuhan-Beijing Passenger-dedicated Line as one of the major north-south corridors. It was planned to be laid next to the old Beijing-Guangzhou line. And a new station, Wuhan North Station, was proposed on the second road ring in the

northeast part of Wuhan. It was not considered as High-Speed line yet. At that time there was only one vehicular bridge available for railway to cross over the Yangtze River, that is, Wuhan Bridge. In this version of City Master Plan, the new Tianxing Island Bridge for both railway and car was planned. It is then known as the main channel connecting the HSR Wuhan station to the north bank of the river nowadays. However, the abuses of that proposal gradually emerged. Four specific problems were discussed: The technique criteria of railway construction become the first problematic issue: the western proposal would go through the highly urbanized area and might limit the high-standard designed train speed. The second problem is from the ecological perspective: it would affect the ecologically sensitive environment along the corridor. Wuhan is also known as 'City of Hundred-lakes' and therefore it is famous for the rich ecological resources. The west route is rather close to the beautiful inner city lake, Sha-Lake, where locate the Museum of Hubei Province, Hubei Provincial Government, Wuhan University, as well as other exclusive hotels and housings. Railway station is always not the favorite public facility in the civic opinion for the old negative image, such as unsafely, insanitation, and disorder. Not to mention the possible noise, air and visual pollution caused by the project. Protests from academia, politician and citizens have been heard after the publicity of that plan. Thirdly, correspondingly to the second problem, cutting through the existing blocks would leave even more inefficient and fragmented land ownership along the corridor. It requires large amount of demolition or replacement of housing, universities and office, which will raise the fiscal and time cost. On the contrary, northeastern periphery area connecting directly with Tianxing Island Bridge is still vacant with no complicated land problems. Last but not the least, the original intension of the central location within the city was to attract more internal passengers of Wuhan. However, considering the unexpected rapid growth of regional transfer, it might lose the external regional passenger from other cities around Wuhan in the bigger picture. Therefore, a new east (periphery) proposal route was then raised. It is proposed to locate the station at northeastern outskirt and to lay the HSR line along the east side of the biggest inner city lake, East-Lake. Not only the route choice but also three possible options for the station location were intensively discussed.

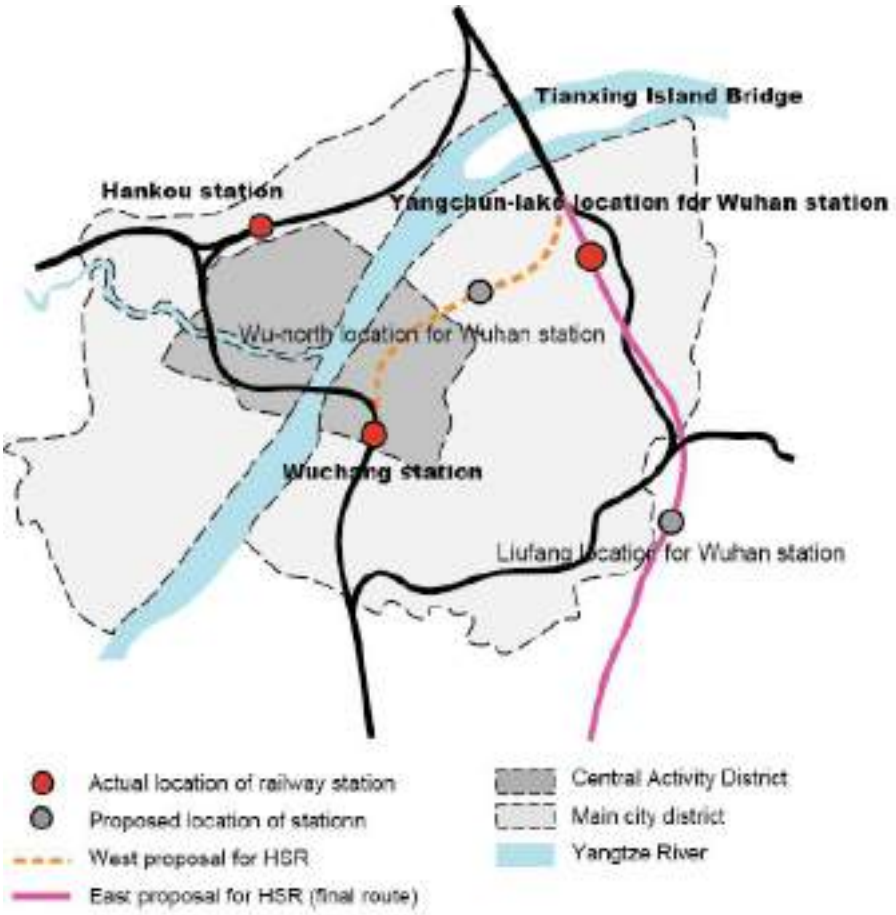

Figure 4: Two proposals for route and location for Wuhan station (source: author made)

The major discussions were focused on the following issues: From the technique perspective, east proposal is easier to operate to HSR than west line for it's new railway track. The high frequency of CRH trains in every 10-15 minutes might strongly restrict the city public transport, visual connection, and spatial expansion toward the east. And the turning radius of west line is not easy to be realized and be sufficient than east line. From the implementation perspective, west line can provide better accessibility to the urban center but more difficulty for construction. From the connectivity perspective, the east line is farer away to central city road system but easier to connect the three major parts of Wuhan by the third ring express road. Besides, it makes few sense of re-using the old Beijing-Guangzhou railway corridor since the old line has already been planned to remove in the long-term perspective anyway. In the revision of Wuhan Network Plan, the eastern periphery route was officially chosen under the condition of keeping environmental balance of East-Lake. On 17th May 2004, MOR and NDRC (National Development & Reform Commission) officially approved the proposal of locate HSR station next to Yangchun Lake in the northern edge of city. The new station is named as 'Wuhan Station' in order to distinguish from the existing two central stations, Hankou and Wuchang (see Fig.4).

Why and how did the crucial change from central to periphery location happen? As shown in Fig. 5, negotiation is the most effective way of communication between railway and urban sectors in this case. Of course, the negotiation here is different from the western definition. Its Chinese conception combines two types of activity: 'mobile warfare' and 'joint quest'(Faure, 1998). It is interesting that the frustration continued for 2-3 years and was soon replaced by the rational reasoning on the possible east alternatives until coming to the final agreement. the involved actor constellations include railway and urban sectors on municipal, regional, and local levels. The superficial reason is that the specific regional department, who makes the plans, locates right at Wuhan. That provides much more opportunities for both sides to communicate. However, the deep reason is their shared interests:

On one hand, the Ministry of Railway (MOR) plays as almost the role of top-down decision maker left by the previous planned-economy. The most important orientations are to maximize the space enclosure, minimize the fiscal and technical input of construction, and eventually maximize railway revenue. It It is one typical fossil of 'Danwei'. Even after the economic reform since 1978 and several attempts of internal institutional innovation since 1980s, it remained its independency by owning the subsidiary regional department/office, public security, judicature agency, hospital, school, and research institution. It is also separated from Ministry of Transport (MOT). MOR makes decisions in the planning of passenger and freight railway transport on national level, while the regional departments are in charge of the construction, management and daily service on local level. They have the legal ownership of land in the railway corridor and under the roof of station. The revenue of MOR mainly consists of the construction fund from freight railway transportation, ticket profit, mortgage from bank by impawning land, social insurance fund, insurance company investment, etc. Therefore, at the beginning the west central proposal is a bit more preferred for it re-uses the old railway track corridor and can therefore minimize the demolishment and construction cost. Besides, the eastern part of Wuhan is rich in landscape resources and knowledge industry. This sensitive eastern proposal next to the national scenic park, East-Lake Park, might make the construction more difficult if the balance between infrastructure and ecological environment is asked to achieve. However, the criteria for location choice changed and made. Firstly, it is better that the HSR line to cross the Yangtze River at the new Tianxing Island Bridge for the old bridge is not qualified for the new HSR from the technique perspective. Secondly, the integration between railway station and metro line as well as other transfer modes has also been taken into consideration. Thirdly, the new location should also provide the best connectivity and accessibility as terminal and nodal station in the national railway network. Based on those criteria, two optional proposals for the line route and three proposals for the station location were proposed. One was the west line (also called Sha-lake line), which use the original Beijing-Guangzhou railway corridor through the old town of Wuchang. The other choice was the east line, which will avoid the existing urbanized area and go through the east side of East Lake.

On the other hand, urban development sectors have their own orientations. Despite of the rather top-down process, the voice of Wuhan municipal government and Hubei provincial government can still be traced. From the normative obligation of Wuhan government, the east periphery proposal is more acceptable. Because the railway station is always considered as one rare opportunity to re-organize the urban structure and optimize the spatial extension. It is especially crucial for the metropolis like Wuhan, which covers the area of 8494 km2 with the population of 9.79 million (November 2010[1]). From the self-interest of local governments, even if the development might not be realized according to the plans, the enclosure of cheap rural land will bring big fortune to local government (G.Dai, et al, in press). To conclude, the Chinese version of negotiation within top-down institutional setting plays the major role in making the decision for peripherylocation.

Figure 5: Interaction between actors on problem of location choice (source: author made)

Transportation intermodality

The word of 'intermodality' not only refers to the connectivity with other transportation (including airplane, metro, city bus, inter-city bus, private car and pedestrian) from station to city center, but also the accessibility from surrounding area (namely the planned Yangchun-lake sub-city center) to station itself. Firstly, the interchange with other transportation modes is not sufficient enough. Take metro as an example. The plan for metro system was earlier than plan for Wuhan HSR line and it was not integrated considered at the beginning. Eventually two lines are connected to the underground of railway station and the construction caught up with each other under the coordination of municipality. However, the detailed plan and construction were almost separated. Wuhan metro company owns the land in the underground, which is part of the Wuhan Municipal Transport Group. And the land above ground of station architecture is owned by railway sector. During the construction, both groups even 'fight' for the construction site. The railway station was put into use for two years while the metro line is still under the phase of facilitating metro equipment and decoration. Secondly, the accessibility from surrounding area to station requires enhance as well.

Fig. 6 illustrates the involved actors in promoting transport intermodality, which are Wuhan government, municipal transport company, Wuhan Railway Department. The communication channel on the same level is sometimes blocked and it is somehow even more efficient to deliver the message through higher authority. The lack of corporation between transport and urban sectors on the local level reflects the segregation between MOR, MOT and MOHURD (Ministry of Housing and Urban-Rural Development) on national level. The major hidden mechanism is that the accountability systems in MOR and MOT are differentiated: On one hand, within the centralized MOR system, the local railway departments are the direct detached offices of MOR on meso and local level. The organization of local offices is not necessarily correspondent to the municipals. For instance, Wuhan Railway Department is in charge of the planning, construction and management of six provinces around Wuhan metropolitan area. There are twelve local offices over the country in total. Therefore, the Wuhan Railway Departments in this case is only accountable for MOR instead of Wuhan municipal government. On the other hand, the local departments for other transportations are less dependent on the MOT but more relied on the local economy development. In the sense, they are more accountable for being consistent with municipal government. As to the role of urban sector in the interaction process, is more likely as a coordinator in between. To conclude, the actors' corporation in making the transportation intermodality of Wuhan case is not effective enough.

Figure 6: Interaction between actors on problem of transport intermodality (source: author made)

Functional diversity

[1] See online data of 6th National Population Census from Hubei Provincial Bureau of Statistics, http://www.stats-hb.gov.cn/structure/xxgk/tjgb/rkzw_347_1.htm

Fig. 7 shows the actor constellations embedded in producing functional diversity. Municipal government and its construction office, the metro company, as well as the Wuhan Railway Department are the involved actors. It can be interpreted from the following three aspects in Wuhan case: introducing flexibility in land development, flagship project benefiting from/to station area development, restrained involvement of commercial space in station.

Figure 7: Interaction between actors on problem of functional diversity (source: author made)

- Introducing flexibility in land development

It can be seen as the amendment or supplement to the hierarchical way of arranging actors' behavior. The basic idea of flexibility in the program was developed from the key concept of 'white land' in the international competition for the station area. And it was adapted into the regulatory plans, namely the un-fixed land use. It shows the local government's concern that to what extent can the station attract local and even regional economic dynamic, and how big is the role of regional function of station area should play within the agenda of sub-city center. The flexibility is reflected in the 'dual-core' structure of central station area in the plan: one core is aiming for the local function of sub-city center such as local cultural facility, sport and medical facility, commercial retail, and housing, the other core is oriented for regional activities, such as headquarter office, high-end hotel, and tourism (theme park) etc. The layout of public facilities relates to this basic idea. However, to conclude, this interaction between actors remains within the restriction of traditional centralized 'blueprint' planning. Very few developer or any other market forces are involved.

- Flagship project benefiting from/ to station area development

Since the developers are mentioned in last point, it is inevitable to discuss their interaction with other actors. The flagship project has mutual beneficial with HSR station: On one hand, it is attracted by the accessibility improvement brought by HSR station. It was originally persuaded by Wuhan government to move from other alternative locations to this area for two reasons: Firstly, Wuhan Station is providing good accessibility for customers from other cities to the theme park. Secondly, East-Lake's environmental advantage will attract further interest for the future housing development. It is the outcome of competition with other economic active pole, such as CBD.

On the other hand, it will trigger the development of sub-center around the station area. It seems that apparently not all sub-city center functions will be realized within the boundary of station area according to the direct implementation of the sub-city center plan. Instead, the spatial development starts from the flagship project outside the station area. The crucial example in this case is the OCT project, namely 'Huaqiao City'. OCT Enterprise Co. is attached to the State-owned Assets Supervision and Administration Commission of the State Council (SASAC). It is known as the leading enterprise of cultural tourism, which refers to the combination of Chinese theme park tourism as well as related cultural and service industry. The cultural industry development started from the foundation of Chinese first cultural theme park-Splendid China in 1989. After that, it has successfully built a series of theme parks such as Chinese Folk Culture Village, Window of the World, and Happy Valley, etc. Besides, it also established cultural facilities, such as Chinese Art Center, He Xiangning Art Museum, OCT creative cultural park, and Chinese art gallery, etc. Its successful marketing has been copied to other major Chinese cities. On 26th December 2009, the Wuhan OCT started its formal operation, which includes the theme park of Happy Valley, water parks, metropolitan entertainment and casual zones, themed hotels and housing. It stresses the combination with local historical culture of Chu. It is the biggest investment ever and one of the most important links in the chain operation involved in the company's development strategy in central China. The detailed program of OCT can be seen from its official website[2]. To conclude, competition is the thematic way of involved actors to realize functional diversity by introducing flagship project.

[2] See the official website of OCT, http://www.octwuhan.com/

- Restrained involvement of commercial space in station

The mixture of commercial space is also considered as one of successful operationalization of functional diversity. The former minister of MOR, Mr. Liu Zhijun, was in favor of efficiency for mobility. That is because to solve the problem of crowd in station area during the Chinese New Year is considered as one of the most important political achievement as well as a normative mission. Pure transport function and huge scale of waiting space in the hall is the corresponding result. The idea of adding up a whole floor of shops was vetoed because the unique architecture structure requires much more cost than usual design. And the huge parking space is regarded as the major profitable space rather than retail space in the mind of railway sector. Therefore, in the early version of station architecture design, there was only a few retail shops planned in the underground floor (A8). However, the there is indeed enormous demand for more retail function: on one side, the passengers have the demand to eat or communicate or just shopping while waiting for train at hall. On the other hand, the involvement of more commercial space will surely bring more profit the landowner, which is the local railway sector. Therefore, the idea of mixed function was adopted a bit during the implementation. One main way is to add more restaurants in the second floor of waiting hall. However, the indoor ventilation system for smoke and oil is not qualified enough for too many commercial function. Then, another 'illegal' way emerged: the local Wuhan Railway Department added two small buildings under the ramp of entrance of east square with the 4000 m2. The restaurants such as KFC and other quick food shops are providing place to eat and relax for the passengers. Those shops are always full once it was put into use. This situation is known by urban planning sector, but they couldn't response because the land under the ramp is still owned by local transport sectors. That situation becomes more and more common. To conclude, the missing platform between transport planner, urban planner, and developer makes the making of commercial space quite secretive.

Social integration and ecological accountability

The building of local identity in this new sub-center is not explicit yet for there has not been a solid local community of HSR-NT. However, the involvement of Wuhan citizens in the seemly scandal of privatization of public waterfront in thematic park reflects some tension of social integration. Therefore, the social integration and ecological accountability are discussed together in this case. Specific geographic location of Wuhan makes the ecological accountability a significant element in conducting the Yangchun-lake sub-center. The attentions for environmental sensitivity and public resource from government are especially significant in this case. From political perspective, it can be seen as a spatial operationalization of the political promotion of 'Two-type Society', Resource-saving, & Environment-friendly Society, in Wuhan. Fig. 8 illustrates the interaction between actors on these issues. Protest is the main interaction mode between actors to pursue the social integration and ecological accountability. The centralization feature of Chinese planning and political system prevent this kind of interaction mode from the other dilemmas of collective actions. It can be reflected in two sub-issues: one is concern on the ecological sensitivity around East-Lake park in the thematic park (Wuhan OCT), the other is the discussion of the (re) placement of heavy industries in the east.

Figure 8: Interaction between actors on social integration and ecological accountability (source: author made)

For the first issue, As the national scenic park, East-Lake is labored to be city brand of Wuhan, the 'city of lakes'. The East-Lake Management Committee was set up to make future trajectory and to manage the daily issues of this area. Master Plan of East-Lake was made and approved by State Council in 2009, in which involved the potential economic effect of Yangchun-lake sub-center development. When Wuhan OCT project was proposed to the public, there was a big debate among civic, government and Wuhan OCT developer on whether the case should be located at such an ecologically sensitive location. It started with one journalist's exposure of a seemly scandal of privatization of East-lake shore on 25th March 2010. That report claimed that the land and even lake in between Wuhan station and East-lake was leased to OCT for a profit-making urban function without taking civic interest into account not all. Then it attracted a series of media attention. After the explanation in press conference and field tour for public, the program

of this thematic park and housing development began to be more transparent and more public facilities such as art museum and concerts are planned. And the final plan was adapted according to the Master Plan of East-Lake Park. It furthermore labeled itself to be the 'eco-cultural tourism park' of China by planning to open public facilities next to the park. To conclude, the outcome of this interaction, to some extent, contributes to the possibility of avoiding an exclusive, elite-oriented community.

As to the other sub-issues of (re) placement of heavy industries in the east of station, it is also considered as crucial issue in all plans of station area. Different from other Chinese HSR station area, this area involves heavy industries, such as state-owned Wuhan Steel Plant, which is important backbone for Wuhan local industry. Besides, there are also small-polluted industries such as cement factory, construction material factory, and landfill, which are planned to be removed from this area. The statements of cleaning up the factory chimneys and high-voltage electricity wire in station area can be seen repeatly in the planning documents. However, to beautify the skyline can be quite different from to actually decrease the productivity of industry. It relates to the future industrial structure of the Yangchun-Lake sub-city center. On that issue, no civic or other voice has been heard.

Conclusion and Discussion

This paper starts with the two major problems of the 'nationwide fever' of using HSR railway station as a growth pole of a new town/district in China: the tendency of turning from a golden opportunity for city re-construction to just a gimmick of land enclosure, as well as the lack of sustainable engine for further urban development. Wuhan Yangchun-lake sub-city center development is taken as in-depth case study. Five collective action problems are characteristic in Chinese context: location and route choice of railway line and station, transport intermodality with other transportation modes, functional diversity, social integration with local context, and the ecological accountability. Those five are inter-related on both temporal and scalar dimensions. In order to dissert the process of decision-making and implementation of HSR-NT, the actor-centered institutionalism perspective is introduced. The specific institutional settings in Chinese infrastructure project shape the orientations and capabilities of actors involved in the action arena. The features include: the dominant position of public actors, the missing the coalition or platform between spatial development and railway sectors, bonded market behavior of public actor with private actor, strong intervention of flagship project developer, and slight involvement of civic actor.

The action arena and interaction modes between actors (constellations) differ in each collective action problems. Firstly, hierarchy remains the major featured interaction modes in Chinese mega infrastructure development and the spatial development around it. MOR and municipal governments are playing the dominant role in this infrastructure-driven spatial development. In the process of railway infrastructure development, MOR is the sole decision maker despite of the few involvement of local government in the location choice. Once the choice for location is made, the construction of infrastructure is completely exclusive towards the other actors. The situation is similar in the implementation of urban plans. Bottom-up actors are restrained at the end of the 'production line' of urban building environment. Small private developers as well as the other market forces are excluded in the key process of land development. Only state-owned developers are likely to hold more secured position in making the decision whether to invest, because they could be closer to more information from public stakeholders. Therefore, even there are indeed some interests from developers and rigid consumption demand for housing from young couples, developers show even more cautious when the policy atmosphere starts to change and market demand starts to shrink.

Secondly, negotiation exists between transportation sectors and urban sector. On the dilemma of location and route choice of railway line and station, it is interesting that it took not so long time of frustration to come to the agreement on the periphery location between MOR and local government because of the shared interests of both sectors. On the dilemma to gain functional diversity, the transportation sector, including metro transport, inter-and inner-city bus system, and road transport, have the chance to negotiate with each other on sub-issues, such as the integration of metro space, the involvement of the commercial

space in the station architecture, etc. Most of those negotiation processes are realized under the coordination of municipal government or the Railway Construction Office. Of course, the actors involved are not totally free to express their preference. The extent of expressing either self-interests or normative obligation differs. In this case, the outcomes of negotiation on both dilemmas are relatively positive.

Thirdly, competition usually exists within the same institutions without long-term vision. That could lead to malignant outcome. Within transportation system, the railway sector namely MOR and other transportation sectors MOT and its local institutions are always under the competition for land, investment, and even political priority. The most direct result could be the low intermodality of station area. Even within urban development system, competitions also exist on many levels: At the municipal level, the planned new sub-center has to compete with the existing CBD as well as other economic active spots within the city. At the district level, the pressure under the pro-economic growth baton from municipality make the district governments take into account of the financial balance while implementing HSR-NT plans.

Last but not the least, protest only happens on the recessive dilemmas, such as social integration and ecological accountability. The top-down feature of Chinese planning and political system prevent this kind of interaction mode from the other dilemmas of collective actions. The outcome of this interaction, to some extent, contributes to the possibility of avoiding an exclusive, elite-oriented community.

CONTOUR. Consolidate ownership negotiation tool for urban restriction. The case of Põhjaväil.

Damiano Cerrone [1], Panu Lehtovuori [2]

Abstract

This paper, based on the author's entry in the Street 2020 competition, explores possibilities for a new urban development model in Tallinn. Using the planned urban highway Põhjaväil as our case study, we provide insight and fresh thinking in studying the city and the site to find its real potentials, and addressing the gaps and weaknesses of the current planning system and real-estate process to delineate a new tool of urban management. We call this tool CONTOUR, a localised, actor-oriented tool to foster public good. While the concept is new, the tool is based on solutions and regulations that, in other contexts, have managed to mediate public and private interest and ensure high-quality urbanism. In the site of the "Street 2020 competition - the case of Põhjaväil", the question is how to turn the threat of unnecessary inner-city highways into an opportunity to create an attractive urban area reaching to the seaside. The spatial solution, based on interlacing flows, is the driver for a rich variety of urban landscapes and programmatic mixes.
The economic incentives and negotiation tools of the proposed CONTOUR facilitate the preservation of key values of the site, while opening new development opportunities. The process is characterised by managing built volume and land rents to reach a win-win for landowners and the broader public.
Public projects, such as public space and transport, or art and events, sustainably receive their share of the added value.

Key words: urban planning, transfer of development rights, Põhjaväil, negotiation, planning tools, Tallinn.

1. Introduction

The Põhjaväil, as shown in the competition background documents, is framed by the city centre, Kadriorg district and the sea, making the site one of the most lucrative in whole Tallinn. Despite the competition was closed in the summer, the

[1] Estonian Academy of Arts. Tallinn, Estonia - damianocerrone@gmail.com

[2] Estonian Academy of Arts. Tallinn, Estonia - panu@livady.fi

inner-city highway project was already visible on the cadastral map of Tallinn months before. Some landowners along the planned road have united their plots to be able to propose larger single projects, such as a massive 5-story shopping centre, or housing.
Furthermore, Tallinn harbour (starting point of the road) is experiencing growth in traffic volumes, not least because of the Helsinki-Tallinn twin-city scenario. Part of this growth will focus on the city centre harbour (passengers and Ro-Ro), while part will go to Muuga (cargo). For tourists, the site is the gateway to Tallinn and the face of the city. The harbour administration has strong interested in having this road as main exit of the port to drain out cars and trucks unloaded by the Ro-Ro ferries.

In our site observation of the seaside, we recognised three types of mobility: pedestrian, biking & sports, and cars. These flows naturally have different speeds but, more importantly, they transform different types of environment and atmosphere from alternative, even marginal, to urban. In Goffmannian terms, the site has both ‘front’ and ‘back’ side, increasing its urban variety. The three flows are a key potential towards varied streetscape. Tourists are a very visible and important flow, and the current situation of unsolved and empty transit space between terminals and the city is bound to change. Harbour, Tallinn University and WTC add clear international connectivity, flows of money, ideas and people.
The built environment has both practical and symbolic / heritage values. The building stock is analysed in terms of historical and cultural value (red), potential when change of use (orange), potential and historical value when renovated (brown) and others, such as TLÜ camps (yellow).

The site has some of the last remaining old limestone harbour buildings. Some of these are listed, but the urban potential as a dense network of small streets and squares remains to be recognised. The area has also a number of singular buildings of high quality and symbolic value, such as 1950s Seamen’s dance hall, 2000s synagogue and the Tallinn University complex built in several phases.
Tallinn University campus has a certain quality already, to be developed further.
Seaside park from Russalka statue towards the harbour edge is actively used. It is a natural connection from the historic Kadriorg park to the sea, but also has its own character as a somewhat wild and unregulated urban greenery. The park lane from Russalka towards Tuukri Street is the start of an active biking and sports route. The old harbour buildings and yards at the western edge of the site, an ‘atmospheric jungle’, have great local potential to be enhanced as urban park.

Figure 1. Map of potentials

2. A future scenario

The area described above is regulated by detailed plans, like the rest of the city. Building such a big scale infrastructure as this urban highway has not come together with the introduction of special tools or comprehensive plan that we may expect in such a case. As detailed plans are submitted by developers to the City administration, approved and made public one by one, our first aim was to collect those developer's proposals and picture them together along the planned highway, an attempt to understand how the new "city assembled" will look like.

Figure 2. Scenario, based on approved detail plans - June 2011

3. Gaps

Using the ordinary planning tool established in the city of Tallinn together with lucrative private initiative, we can observe 2 main Gaps resulting in the case study of Põhjaväil:

3.1 Gaps in the planning system

By looking deeper at the volumes and characteristics of those detail plans attached to Põhjaväil, it emerges how all the developers had the freedom to fulfill their properties with housing and commercial activities, regardless of anything but their

own economic interests, without considering other issues like public interest and sustainability.

The roots of this speculative phenomenon had to be observed thorough history: along with the dissolution of the USSR in 1991, a new planning system had to be thought. The process of independence led to change the all-soviet centralized planning system into a market based mechanisms, offbeat with the previous establishment. “The reform of urban planning has been a difficult and controversial task. Market euphoria and the consequent support for a sharp reduction in public administration had been defeated, eroding the legitimacy of planning" (Thornley, 1993), giving the opportunity to developers themselves to lead the city planning.

Still today the master plan of Tallinn in force is a coarse 1:45000 map with related documentation and studies, giving outlines for macro zones. The regulations expressed by the master plan find the most visible gap in its facility to be changed and being “developer ruled”. Indeed, by detail plans, developers can propose variations to the master plan, that we observed were easily granted. District focused plans have been released this year but clearly those are reports of developers intention, following the detail plans submitted to the city administration. The approbation machine can be shortly summarized here:

1) Developers present the intention to realize a project

2) city administration gives out the guidelines to draw the first detail plan draft, announcing it on at least one main local newspaper and one daily national newspaper or webpages to facilitate the discussion.

3) Developers submit the first detail plan draft to the city administration

4) Citi administration review the detail plan and sends it back to developers with corrections and changes

5) Developers submit the corrected detail plan to city

6) City administration announces a public meeting to show the detail plan for open discussion

7) If there is no argument against it, the City administration proceeds to approve the plan.

9) In case strong arguments against the plan persists, then the City administration is sending back the plan to developers for other correction and changes.

10) When the latest detail plan drawing is presented to city, the project can be officially approved is all the arguments are clearly solved. In particular case or sensible areas, another public meeting can be arranged.

Acknowledging the real complexity of this procedure and the actual timespan from start to end, participation here is meant only as second voice or reviewer of the plan. This kind of inclusion of the public opinion is quite generic and simplistic as the opinions are not actively included in the public debate. In order to reach a smarter and a more adequate practice to face current demands and problems of the city, it is crucial to include NGOs, locals’ association, visionaries and experts’ knowledge in the planning process itself.

Other perspectives aiming to have a more touristic focused seaside are forgotten here, apart for the vision made in Paljassaare (on the eastern side of the city), where mixed uses, wide promenade, sailing harbour, mall and other potentially touristic-focused services will give added value to the project, in terms of creating jobs, having better utilities and perhaps having a new thriving centrality beside the city centre.

3.2 Gaps in the landscape

Gaps in planning system, generates gaps in the urban landscape.
When the project it is designed to give benefits only for its own purpose, all other typical aspects distinguishing the surrounding are left apart. Parks and shores are considered just as local elements for real estate speculation but nothing is done to preserve and include them in the project vision. Mostly the edge buffers of those projects are likely to suffer the lack of a comprehensive vision, as the boundaries are not defined considering the landscape but by rather mere ownership net borders.
The planned road of Põhjaväil in this segment defined in the competition, will be the most representative gap for the site and perhaps for the urban shore of Tallinn and its users. According to the detail plans and the expectation of the city administration, the road will be designed for 3plus3 car rows with related safety spaces and pedestrian way. This urban highway that can be 45meters wide, will run for one fourth of its length on top of the current shore and rocky shore, passing just in between the water and a spectacular urban park. It will not only turn the rocky shore into concrete but it will significantly break the peculiar dune buffer between the park and the sea. This intervention is aiming to have better and more fluent exit traffic from the harbour and reduce traffic jams of commuters coming up east from Viimsi municipality.

4. Gaps for good

4.1 How gaps in the planning system can be used for good practices

Gaps and weaknesses off course are the leak in the system but as developers can exploit them for economic interest, in the other hand, cracks can be used to infiltrate good practices and smart solution in the process of planning, according to overcome restrictions and incapability to handle negotiation.

4.2 C.O.N.T.O.U.R. - Consolidated Ownership Negotiation Tools to Overcome Urban Restrictions

At first, planning can start from a larger scale in order to describe and understand the overall scenario and relate the single plans to the bigger vision of “opening

Tallinn to the sea side". Plans and actions on the coast from Viimsi to Kakumäe (West and East end of the city) are organised through thematic development agencies, aiming for spatial innovation and public social good. We call these agencies CONTOURS – Consolidated Ownership Negotiation Tools to Overcome Urban Restrictions.

Each CONTOUR is a public-private enterprise with both social and economic aims. All landowners touched by the proposed street have to join. Also other actors can become active stakeholders with the same rights and obligations, if they are linked to the theme of the particular CONTOUR.
Landowners and other stakeholders pool their resources, so that each CONTOUR has real powers to partake in public discussion, make investment decisions, negotiate land rights and curate public programmes and space, independent of plot borders. Through pooling of resources, including social and cultural capital, each agency is expected to produce added value to all stakeholders, thus becoming real driver of the development of urban landscape.

Connectivity along the seaside is the common thread of all CONTOURS. Through a combination of urban design to reach unique local aims and policy-measures to encourage public transport and light traffic along the whole seaside, they can negotiate complex and sometimes conflicting desires, building a positive alternative to the unnecessary inner-city highway project (Põhjaväil).
Thus, the street is not only an element of urban landscape, but rather becomes its driver. The proposed tool has potential to define the conditions of the production of urban space, reaching towards new model of planning and real-estate development in Tallinn.

4.3 Localised TDR

"Local governments undertake transfer of development rights (TDR) programs to use the market to implement and pay for development density and location decisions. TDR programs allow landowners to sever development rights from properties in government-designated low-density areas, and sell them to purchasers who want to increase the density of development in areas that local governments have selected as higher density areas. TDR programs appear to offer many advantages to local governments that want to control land use but also compensate landowners for restrictions on the development potential of their properties. TDR programs can be easier to implement than typical zoning programs; they make development more predictable and use the market to compensate landowners for lost property value. TDR programs are also more permanent than traditional zoning regulations. Although TDR programs appears to be a potentially powerful land-use tool, few communities have had success in

using these programs because of the associated challenges . TDR programs do not reduce the need for zoning and can actually be more complex to administer. Communities may not support TDR programs, and local governments may have to invest in community education programs to explain them to the public. Lastly, although the permanency of TDR programs can be an advantage, it may also be a liability, since a community's land use needs change over time"(Transfer of Development Rights Program - Jason Hanly-Forde, George Homsy, Katherine Lieberknecht, Remington Stone).

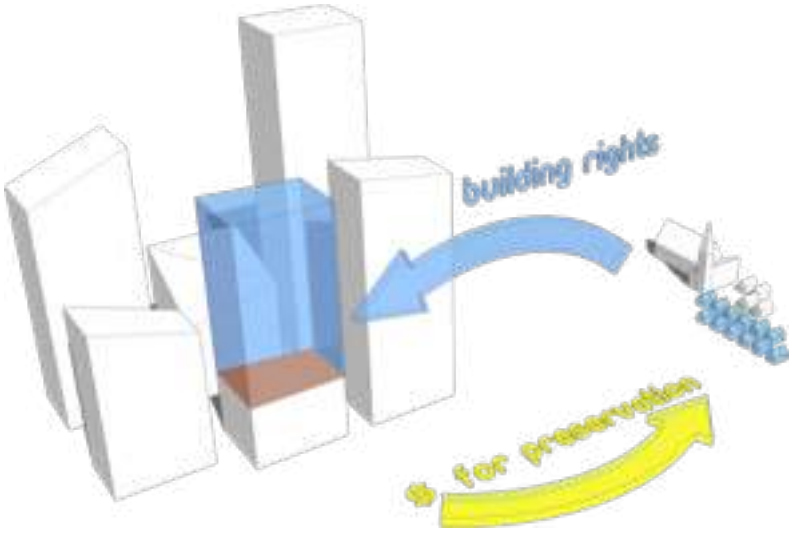

Figure 3. TDR

The concept of TDR will be localized within the CONTOUR boundaries as key tool to negotiate the land use and using incentives for leading developer to preserve values and potentials that locals' associations together with activists and experts together will identify on the site. Therefore the areas or objects to preserve will be the Sending Site (the slice of land from which development rights will be transferred) of those rights, that together with an added incentive component, will be transferred to the Receiving Site (sites to which development rights are transferred or added to existing ones).
Building rights sent by a Sending Site and incentives should be transferred to a Receiving Site with strong market demand in different fields like commerce, real estate, tourism or production in order to guarantee economic efficiency and mixed uses.

Figure 4. Localised TDR

4.4 Building rights

Managing the building rights in an equal and economically beneficial way is a key element of the process. The distribution of built volume starts from the theoretical FAR 2.0 for each plot. The building right is then shifted inside the COUNTOUR to reach both optimal new urban qualities (based on varied FAR co-efficients for different types of street exposure) and agreed preservation targets. An incentive of 10% is given by the Board of the CONTOUR in case of shifts for preservation. Land rent is managed by the CONTOUR and distributed following the theoretical building right of each owner, including the City. Thus the CONTOUR provides sustainable funding for public projects for public space, public transport, art and events.

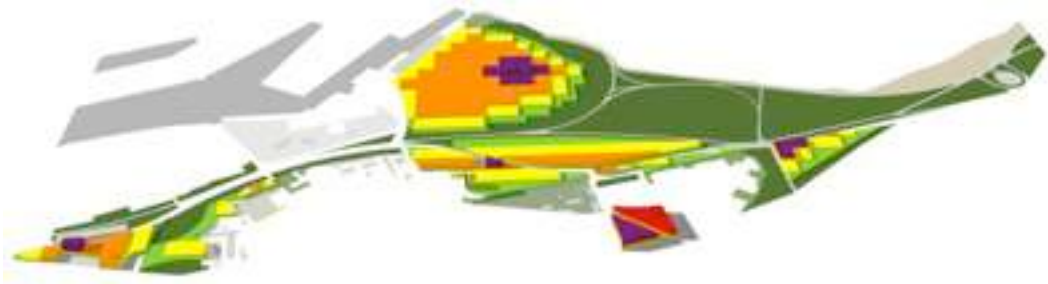

Figure 5. Building rights matrix

4.5 Mixing programs between public and private

Programmes are located to support street and park-level activities regardless of land-ownership. Special focus is given to the Tallinn University Knowledge Campus and attractively urban street sequences where many user-groups can

meet. Taken together, the process, as exemplified by this thought-experiment, will lead to a diverse set of urban districts: Urban Synapse, Knowledge Campus, New Seaside District and Parklife.

Figure 6. Resolution, flows interlaced

Figure 7. Resolution, flows interlaced

5. Conclusions

5.1 Unifying land for comprehensive plan

Unifying land to design a comprehensive plan of larger scale is going to create better possibilities in many aspects regarding the plan. Spatial planning will be able to feed landscape with volumes demanded in more efficient way and international competition should be set to guarantee the openness of the process. More significant ideas can be found to follow the ongoing city administration's vision "Opening the city to the sea side". Infrastructure projects will be more efficient in serving the different developments taking part of the CONTOUR with smart ideas to manage traffic flows, proposing new ways of mobility rather than bigger roads that would not exclude any side of the build, avoiding dark zones. It would be fundamental to have projects like a sea promenade (already proposed by the city administration) or green

corridors to reconnect the vegetation patterns currently blocked by the central figure of the port. Realizing them with the current trend of developing plot by plot, however, sounds nearly impossible. Following the logic of unifying the land onto a CONTOUR will give the right environment and tools to define greater ideas. When the area begins to be considerable big in the city scale as the COUNTOUR defined by us is, public interests is going to be more active, giving more guarantees on the legitimation of the plan.

5.2 Resolution example. Flows interlaced

In the spirit of Street 2020, the varied, locally embedded and regionally connected network of streets, bike routes and pedestrian paths is the driver of developing the site. Each plot offers multiple faces to the streets and routes, creating gradients in density and programme. Different types of mobility require different environmental qualities and benefit from different types of connectivity. The car streets are as central and rational as possible, while seaside pedestrian routes may be oblique and leisurely. In the most urban parts of the site, different mobilities converge to create full-blown urban streets with elements of shared space.

5.3 Building on key values

The analyzed values of the site in terms of Green, Built, Flows and Interests are the starting point of development process. The negotiations of the CONTOUR should always enhance values, modifying and re-placing programs according to need.

Abstract

This paper aims to investigate the design thinking strategies that are applied to solve growing urban conflicts in developing countries as an unavoidable side-effect of urbanisation throughout the world. This analysis is based on the human factor as an inter-medium, thus becoming a design element in the process of urban development. Furthermore, the individual is viewed not as a mere passive pawn, but rather as a potential vector of spontaneous social change. This can be summarized in: "How to transform the negative into the positive from what occurs as an unavoidable large-scale side effect and to make such an effect an overall positive aim by engaging average citizens to deal with urban conflicts, express their creativity and diversity, and initiate an impetus of development?"

Rapid globalisation in the 20th century has considerably changed the morphology of cities in developing countries. Based on the assumption that the western urban planning paradigm proves inefficient in developing environments, these cities tend to lose their substance as an urban phenomenon through the ill-decoded application of western models. Moreover, modern urban thought could be stuck in this rut, inducing negative background effects on the strategy and management of urban planning. A possible solution lies in involving the entire community into these processes, on grounds which exclude a specific "plan", as its statutory basis derived from urban planning examples of developed countries, and beginning to investigate less formal methods (creativity, knowledge, skills and originality), on which developing environments could be constituted, by altering the traditional structure and concept of cities. This issue is rooted in the idea that the benefits and prosperity of cities could be derived from resources such as style, brand, design and aesthetic values. What may be even more challenging is embracing uncertainty as a formation which seeks out opportunities to add value to "options" in order to represent these as a range of "opportunities" that are not static but iterative.

This new pattern of "participatory urban design" presents a community-driven, flexible method of small steps with the aim of finding compromises and consensuses between urban actors, all of whom are mobilized to willingly integrate their customs

and needs in order to creatively track their cultural identity and to contribute to a common base of knowledge on urban patterns and processes, so as to initiate "positive feedback" in the city's self-creation as an organic, and not mechanical, surface. This is achieved through an open and dynamic system, which integrates different scales and partial urban actions in the creation of urban spaces, events and experiences.

The method outlined herein constitutes a challenge in the redefinition of the scientific approach to urban conflicts through a creative, dynamic and iterative process of design thinking within developing environments. Its technique – involving holistic thinking, flexibility in developing strategies as well as human-centred and user-friendly concepts – blurs the boundaries between various disciplines and stakeholders, rendering a wide range of potential solutions for recombination and application, and finally generates a new vision of cities that better suits developing environments.

1 Introduction

This paper aims at investigating design thinking strategies applied for solving current urban conflicts through participatory processes. The analysis is based on a participatory action research process (**of)**which focuses onhow the individual perceptions of average city dwellers and their creative potential could be applied in the creation and re-creation of city structures and urban planning procedures. This concept is further elaborated through a methodology of participatory design thinking workshop. This issue is grounded upon current trends, which suggest that the city encompasses culture and creativity and applies it in physical and social regeneration through participatory urban design processes.

A new era dominated by creativity, knowledge, skills and originality has totally changed the traditional structure and concepts of development and has become a new research focus. The modern definition of society therefore focuses on a simultaneous orientation towards these capacities as the resources of the future through innovative and creative investigations and actions. In these terms, society is interpreted as something organic, constantly mutating and emitting new elements; a living system through which new combinations are brought, fragmented and recomposed. This drivingforce within an urban environment is shaped and formed through cultural activities. The city acts as a playground for creativity, while culture is a part of the city's soft infrastructure (Louise Nyströom, City and Culture: Cultural Processes and Urban Sustainability). Furthermore, culture is here meant to include values, assumptions, norms and behaviours that define life situations in particular settings, which also includes* people's feelings, wisdom, intelligence, knowledge and scientific methods (Fred Fisher: Building Bridges through Participatory Planning).

Meanwhile, the focus of these processes and their immediate effects have moved to less developed and poorer regions of the world as a potential market for material and intellectual goods, as well as alternative places of production. According to the imbalance of circumstances between "the old and new world", urban processes must address developing problems, which may be identified as the following: economic problems of imbalanced development, spatial problems of rapid urban growth, environmental deterioration, and cultural collisions caused by the juxtaposition of tradition and modernity. Although the urban conflicts faced by developing countries seem particularly serious and complex, the possible solutions are not radically different from those in developed countries. Moreover, the principles and aims are the same.

Finally, urban conflicts can be resolved through creativity, by applying various understandings, perspectives and interpretative keys. From this standpoint, changes and involvement in city development should not be spectacular; they are more often the results of everyday work. This is a creative process, which involves inhabitants and encourages them to participate in designing the place/environment where they live. Additionally, it provides the opportunity to rescue citizens by inserting them into society, including them into economic affairs and drawing assets from their background, culture and roots. This concept engages ordinary people from a social and cultural point of view: it involves their identity and individuality (i.e. their feelings, intellect, morals, knowledge, memory and every other human capacity), fosters positive emotional response (enjoyment, excitement, feeling of freedom, self-importance and affiliation within society) and demonstrates the coherence and cooperation of inhabitants with their immediate surroundings.

2 Analysis

2.1 Conceptual framework

- *Theory about urban development and developing environments*

The rapid development of cities in the 20th century has considerably changed the morphology of cities. What is therein produced is a city as "a collection of conceptually ill-decoded enigmas" which in the process of planning has lost its substance as an urban phenomenon*(Jean-Claude Bolay 2004).* Moving forward from this concept, the city is defined as "the point of maximum concentration for the power and culture of a community"*(Mumford 1961).*

According to one of the leading urban theories of David Harvey and Manuel Castells, urban planning cannot be seen as an autonomous process, but as one that is constantly overlapping with current economic and social changes, which are

momentarily grounded in the development and expansion of industrial capitalism, neo-liberalism and consumerism. Urban areas are and have always been the spatial and symbolic manifestations of broader social forces *(Giddens and Birdsall 2001).*In the scope of the rise of liberal capitalism, economic conditions are the most common triggers of social actions, which increase or reduce social and environmental well-being. Production, exploitation and consumption of goods arethe generators of social relationships and possible conflicts.

Therefore, the city is regarded as the most complex social phenomenon on one hand, and on the other, it is a highly-structured economic phenomenon. Every urban issue (spatial distribution, social relations and social structures) is inextricably linked to the economy, as today cities are exposed to global economic changes. Since they host the largest concentration of finance, industry and manufacturing and constitute primary markets for all products, cities are viewed as the main driving forces of development *(Sassen 1991).*

- Developing environments

The formation and re-formation of modern cities unfold through urbanization (territorial and social), globalization (of the economy, of culture, of ideologies) and change (social, innovative, potential change and spatial, territorial change).An urban setting in a broad sense, and a city as its physical and social manifestation, outwits any human attempts to imagine it. Within the compass of developing countries' environments, cities are viewed as multi-dimensional integrated systems composed of qualitatively different and semi-autonomous processes.

The theory of the modern city lends dynamism and innovation to cities of the Western World (developed countries) while modernity in cities of the South is almost exclusively reduced to development (Robinson 2006). According to the latest statistics, about 2 billion people now live in the urban environment of developing countries and almost one third of this population is estimated to be poor. Development may be therefore circumscribed as an initiative to improve the life of the poor in these cities. Moreover, the scope of the Millennium Development Goals (Goal 7 target 11) emphasises the importance to relieve the basic precarious conditions (access to water, sanitation, secure land tenure, and adequate housing space), which these poorest city dwellers live in.

Such an approach addresses the poor as a problem in urban environments and reduces their role in the urban environment and society they live in. Conversely, if they could be seen as a human capacity, which aggregates the diversity and complexity of cities, their competences and capabilities would be considered in addressing current urban conflicts and in planning the future of their cities.If every

city is a complex polygon of interactions between urban actors and actual space, then urban life is the sole product of the inventiveness of urban dwellers.Circumstantially, the city is a place which tells the story of one society and its development, its framework for social life and its subsequent collective identity milestones. It is a cultural phenomenon which, in terms of incompleteness of cities in developing countries, gives them the opportunity to constantly renew themselves.

2.2 Contextual analysis

- *The constitution of a modern urban actor*

The core definition of society refers to social actors, social practices (policies and processes),and the production and reproduction of social order.The role of an urban actor is constituted on these basic items; our reality is in constant constitution and restitution and while we continuously transform the world, we also transform ourselves *(Slater 2003).*These processes in an urban environment imply production anddealing with urban conflict, which thrive on inequitable power relations, cultural differences, and a set of colliding perceptions within a city and germinate from an individual level towards a socio-urban dimension.

Individuals or constituted groups within the city are the actual actors of these urban conflicts. They produce their urban environment, governed by their different values, their logical processes, influenced by their relationships and representations and driven by their aspirations. This may refer to the city as an urban phenomenon and "as the objective product of the reciprocal actions of the actors involved." [1]

This conceptof society is conspicuously dependant on communication and the process of exchanging goods and knowledge, which requires the creation of networks of objects and subjects constantlyin flux. Such social structures are dynamic, potent and open-ended systems, ready for any kind of innovative activities providing that they do not jeopardize their functional balance.

- *Culture and Creativity – a personalized engine for urban growth*

Modern society has evolved from a relatively rigid system to multi-dimensional and unstable social, economic and industrial entities. These systems require a new approach based on dynamics so that they can)operate in their full complexity. Conversely, culture is a focal point, the "knowledge in context", which simultaneously relates to new information and communication technologiesand substantially addresses modern social conflicts in a real context.

[1]The definition of George Simmel interpreted by Yves Pedrazzini, Jean-Claude Bolay in Social practices and spatial changes(Jean-Claude Bolay 2004)

Generally speaking, human creativity exceeds the singularity of personal production of novelty and actually arises from the synergy of many different sources. It is a systematic rather than an individual phenomenon, which evolves from the interaction between personal activities and a socio-cultural context, and is directed towards a positive future,social change and the satisfaction of human needs *(Csikszentmihalyi 1996)*. Effectively, creativity attempts to impose a human vision of the future on reality, to reformulate everyday forms of life, and struggles to respond to social problems and to build a better society.

Creativity is a process, not a status. Society is the venue where creative actions are concentrated,induced and gradually built, and creativity can be observed only in the interrelation of the system within the social boundaries where it manifests itself *(Csikszentmihalyi 1996).*Intellectual and social networks are the core stimulus of applied creativity, with adequate social mechanisms that exceed known patterns, recognize creative potential and spread innovative ideas. Creativity therefore thrives in places where there is an overall understanding of new ideas. A complex, stimulating environment, with a greater density of interactions of novel and original ideas and information, is a common ground for new insights, an inspiring setting for pursuing creative endeavours, and a stimulating factor for an open-ended approach towards the richness and complexity of the future. So, creative powers tend to gravitate toward nodes of vital activity and spatiotemporal contexts, where their capacity to generate a positive future is more likely to succeed.

Creativity thus re-shapes immediate surroundings, activities and patterns, and affects the cultural patterns in which in which it takes place. Conversely, traditions are in essence conservative in their tendency to preserve the achieved social order. So, it takes effort to allow creativity to express itself and to make it accessible to a broad base of people, and to prevent the stagnation caused by centrality within tradition. The process of continuous flows of information as well as active, formal and informal learning leave open the possibility to generate and develop creativity.

- *The modern city – a venue for applied creativity*

The city slowly developed into a place of consumption as soon as it started to decline as a manufacturing centre. In due course, the city has become the spatial expression of globalisation, attaining in this process its economic independence and importance*(Miles 2010).*Society and social development are gravitated by: non-material goods, commodity aesthetics, mediation of goods and non-material functions of production, and the city is a respective venue for people to express themselves ascitizens of a consumer society*(Slater 2003).*

On the other hand, the city of consumption represents a city of built environment. As Marshall Berman puts it, the city is a symbolic expression of our present time, and human factor in the city is represented in the places we build. Consumption plays a mediating role between our human self and society and provides a bridge between the social and the individual. Consumption dominates the city, and it seems that the individual experience of that city is filtered through the processes implied by consumption*(Miles 2010).*

This apparent domination of the non-material transforms human encounters with cities into a sheer perception and representation of images: a never-ending circulation of signs*(Slater 2003).*This commodification robs cities of their particular identities and turns them into clones*(Miles 2010).*Conversely, "the city has always been the world's incubator of innovation" *(Savitch and Kantor 2002).* If innovation is defined as a design approach inside material culture, the city may be presented in light of the "creative city", where innovation is generated and exploited through the incessant process of subject-object interrelations, based on the process of generating and exploiting knowledge as a non-renewable resource. City provides a quality base for the exchange of ideas and information.

Cities as creative centres provide an integrated, open, free and diversifying"habitat", where all forms of creativity (artistic, cultural and technological) can take root and flourish. Culture should expand, share and celebrate humanity and human values *(Rifkin 2000),* should be more accessible for an average user/citizen. In other words, culture and the arts, the fields of expressed creativity, constitute the identity of cities and make them competitive on the global stage.

- *Design thinking activates urban actors in the urban realm*

In view of the accelerating development of modern society and liberal capitalism, the traditional role of the designer needs to be reviewed to respond to a growing number and widening range of needs. The design process has henceforth been slowly and gradually reformulated to designate human-centred, creative activity within the modern consumer society, which aims at tackling complex social problems and conflicts in order to create an even better system. In order to achieve such high-standard demands, design has become both a problem-seeking and a problem-solving activity; a complex, future-orientated decision-taking procedure with one ultimate goal: to improve the quality of human life.

By placing the human in a central position, design thinking occupieswith not only detecting and responding to a wide range of consumer-related and social needs, butit is also actively engaged in formulating their needs, as part of current subject-object relations. This interrelated process favours social interactions, continuous adaptivity

and perpetual innovation. It represents a modern “social game”, where human creative and emotional powers are captivated to identify social pattern, express the innatepart of human nature and apply functional solutions to social problems or conflicts.

Design thinking corresponds to the group and develops within groups, but in a way that liberates individual creativity instead of suppressing it through the group’s united spirit. This emphasizes a high level of effectiveness, where collaboration is carried out transversally among equally valuable fields and individuals, enabling free access and open–mindedness. Correspondingly, ideas are common property and responsibility. Problem-solving extends beyond specialized fields and urges to find collective solutions that work as bridges for realms of ideas*(Brown and Katz 2010).*

3 Explanation of the methodological approach

3.1 Generating creative activity

In terms of thesubject-object relationship (product/designer) and vice versa,creativity can be defined as an activity which generates new working (operational) problem-solving concepts*(d'Agostino 1984).*The integration of design in the knowledge economy isa challenge, which affects the physical environment, reflects human needs and generates a more vibrant built environment.

All urban actors integrate their customs and needs from their past in order to creatively trace their cultural identity. Yet, what is necessary in actual urban environment is to activate such unconscious creativity and develop it through adequate professional supervision *(Nyström 1999).* But the major problem in participatory urban planning is to providea common base that is suitable for integrating comprehensive and interdisciplinary, explicit (expert) and tacit (local stakeholder, experience), knowledge on urban patterns and processes. Professionals should only coordinate and articulate this process of collective planning procedure (Bolay 1996) byconducting/ teaching in order to initiate “positive feedback” in city self-creation, dependant at least as much on the individual's direct experience, as on a sense of well-being. Defining the identity of a city and leading its own development is a way to actualize the self-understanding, self-creation and self-representation of an operating urban environment. What may be crucial here is that through social practices, individuals can be indirectly thought to take an active part in urban developing processes and in the design of structures and spaces within a city.

3.2 City as a system based on creativity

The prerequisites for the development of creativity include an open-minded approach, risk-taking, clearly focused long-term goals with an understanding of strategy, the capacity to embrace local differences and cultural diversity, and willingness to accept continuous change and learning. These strategies are approaches that use participatory processes to generate an action plan for city development to achieve an agreed vision, goals and priorities for a city, a set of strategies and action plans, and to establish institutional mechanisms for implementation, monitoring and evaluation.*(Fisher 2001)*

The design thinking approach in urbanism aims at the maintenance and development of certain indicators which denote urban quality: social order, production of space/place, continuity of development, richness of experience, completeness and belonging*(Peter Buchanan, (What is Urban Design? 2011))*[2]. On the other hand, planning has hitherto been mainly concerned with urban forms: analysing, organizing and shaping them in order to respond to inhabitants' needs.

Bearing in mind that the design process has already surpassed its traditional scope and it actively serves in forming modern society, the shift in urban planning towards participatory design could offer more flexibility and involvement through the summary of small movements, partial approaches and real-time responsive actions. Therefore, the ultimate goal of "designing the urban" is to solve urban conflict and produce a better city. Concerning consumer society and its needs, this process is actually a dynamic interdependence and mutual development of both city and citizens.In other words, creative interventions guide cities' growth and change, giving them unique identities.The inclusion ofdesign within cities enhances the quality of lives and multiplicity of lifestyles, fosters cultures, promotes artistic activities, enablesinformal learning and generates development.

Participatory urban design involves obeying to economic currents, cooperation and partnership among different actors and stakeholders and setting up guidelines and standards for zoning, building, historic revitalization and reconstruction. Moreover, it is a collaborative and interdisciplinary process of shaping not only a physical, but also a social, component of cities. Design in an urban contexttransfers the spatial component into a broader framework in reference to time.[3]It exceeds its main purpose of place-making and encompasses all the activities and events which denote a certain space.

[2](*What is Urban* Design*?* 2011)

[3]Peter Webber defines urban design as 'the process of molding the form of the city through time'(*What is Urban Design?* 2011)

From this standpoint, the city is not merely a venue but a dynamic and complex system – a network of subjects, objects and activities where the human component is nestled. City is a reality, a situation where social practices take place and where urban design structures these activities, frames them and puts them in a wider spatial and social context. So, participatory urban design actually is the articulation of human life in an urban realm which urges for active citizenship.

In terms of the already mentioned variability of modern contexts and the importance of individuality and humanity in all of this, finding such a way of fighting urban deterioration with appropriate non-intrusive, creative measures can only be obtained with a clear understanding of every particular context: society/ city and its actors/ their social background. Moreover,indirect conducting/teaching through participation encourages individuals to take an active part in urban developing processes, which cohere with society's scientific and technological advance and the design of structures and spaces within a city.Additionally, the aesthetic factors of a city's architecture and space design is responsible for qualitative actualisation in urban development. As soon as international design fails to respond to one's local comprehension of needs and demands, the design should indicate that a different course is necessary. In this way, continuous and simultaneous participatory actions and interpretation based on momentum and flexibility allow not just for a visual solution, but also one that includes time, action, and uncertainty.

4 Application of participatory urban design

4.1 Design thinking methodology

Design thinking is an exploratory process for transferring and adjusting ideas into models that are compatible with reality while constantly examining, re-evaluating and validating them. This method treats reality as a dynamic system of interactions among individuals and groups, which aims at generating a common behaviour to complement human needs and desires. It should encompass a range of plans and actions, from managing risk to fostering innovation in order to, eventually, lead to a set of opportunities. Finally, when it is socially-orientated, the core (crux) of design thinking is in fact a social problem/conflict to be resolved through this process.

In current social contexts, such a process should be organized as a project with a clear goal, operational framework, action plan and corrective measures for process updating. Clarity, goal-orientation, definition of weaknesses and boundaries, constant evaluation and updating, inclusion of risk and serendipity at any point of research and creation process are the qualities which enable a project to generate and maintain creative energy and to apply it effectively in practice.In order to choose the model

which best corresponds to the defined social problem/conflict, a design thinking process is coordinated in three overlapping and back and forth looping stages:

- *Inspiration: motivating the search for solutions from a hierarchical set of mental constraints*
- *Ideation – Conceptualization: generating, developing, and filtering,testing and iteratingideas*
- *Implementation – Realization: prototyping and turning ideas into actual products and services that are again tested, iterated, and refined.*

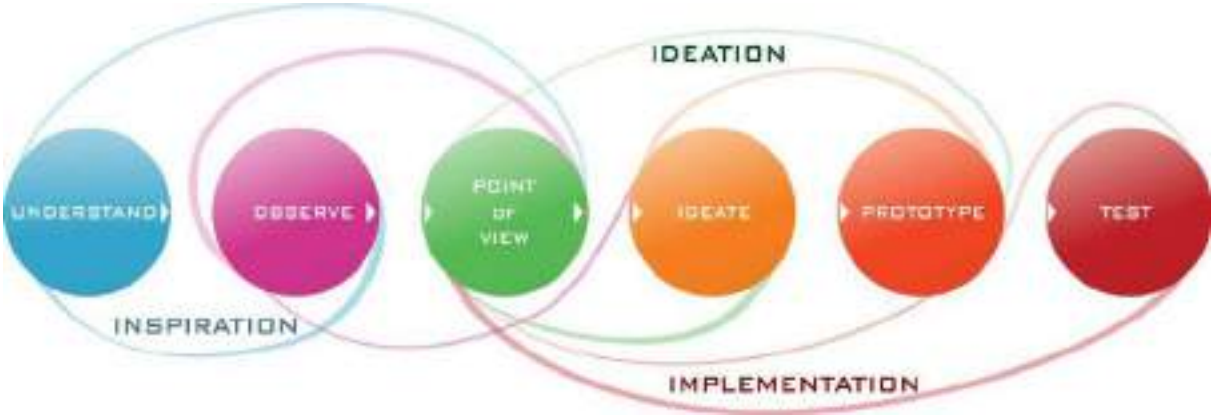

Figure 1: Process of Design Thinking. Original picture available at: http://www.pferdt.de/archives/572[4]

The final step is orientated towards a communication strategy, particularly through multimedia, which makes the solution accessible for a diverse set of stakeholders. To sum up, design thinking uses designer's sensibility and methods to match human needs with what is technologically feasible and economically viable*(Brown and Katz 2010).*

4.2 Ideology of design thinking in urbanism

Design thinking aims at articulating the spirit of a place, while leaving its realization to consumers / citizens. In urban terms, it may signify that it is design which leads to planning and then to development, integrating decision making to maximize innovation and render opportunities*(Professor Laura Lee,(Value of Design 2009)*[5]).In this sense, urban planning is reduced to branding: it defines the spirit of a place and then lets others (consumers / citizens) articulate that spirit.Citizens/urban dwellers are engaged within their environment, and professionals develop only a set

[4](Pferdt 2009)

[5](Value of Design 2009)

of performances based on outcomes that foster a dynamic model rather than automatically assume a product*(Professor Laura Lee,(Value of Design 2009)*[6]). The idea is to exchange the notion of a place for (the) place itself; space is not a product of creative process, but a venue for creative experience.

The design thinking method in urbanism could be seen as a step forward from a traditional planning process – instead of designing the urban in reference to space, this new instrument articulates the urban in reference to time, which energizes a public process of urban planning by using the lowest common denominator; an active urban actor. This means that an average urban actor is encouraged to participate in the decision-taking process concerning its immediate surroundings and to take an active part in designing it.

In order to achieve it, design thinking addresses individual cognitive potential by involving urban actors in the "story" and the "scenario" of place-making. It tells a story about what space could be and initiates the empathy and emotional correspondence of all participants in urban planning and designing processes.This story signifies the cooperation between professionals and average city dwellers (consumers), erasing the differences between them and making them equal in the process of place-making.

This collaboration in a wider sense shows what transdisciplinary approach in urbanism may be – a field between the abstractions of planning and the concrete specifics of architecture and design. Not only defines it that aesthetics and consumerism is a new driving potential for solving urban problems, but also it is the emphasis of collective intelligence, common logic and broad-band solutions which lies in the heart of the design thinking approach to this new paradigm of urban development.

4.3 Implementation of design thinking in urbanism

The main idea of the implementation of design thinking in urbanism is based on the statement that design is a creative and productive activatorfor articulating human needs in a certain built environment. Put differently, the value of design lies in catalysing the impact of built environment on the quality of urban life and activating creative human potential for solving urban and social conflicts. This actually means that "participatory urban design" refers to strategic planning not as a procedure for generating a product - "urban plan", nor as architectural aesthetics of cities, but as an integrated process of timing, rating and locating urban development in accordance with human needs and desires in order to generate an integrated vision, strategic

[6](Value of Design 2009)

techniques and viable opportunities in urban planning, and to produce a functional and aesthetically valuable built environment.

According to the herein elaborated theory of creative potential as an impetus for solving social problems, the design thinking process is used to producea creative environment, a place-shaping framework, a creative experience and an incubator for ideas.Design thinking makes the process of urban development and the production of social order feasible in such a way that ideas arepitched and then city and citizens respond to them in their own way.

In accordance with Sorkin's assumption that urban planning tends to prove inefficient on a very large scale and that urbanism could be stuck in it, the shifting point of "participatory urban design" is a functionalist idea of the city as a symbolic concept - an open and dynamic system of integrated scales*(Interview: Michael Sorkin 2005)*[7]. It practically means that the urban development of a city as a whole is brought through small-scale, partial urban actions and urban venues of different scales, which take care of the social and the public and create urban spaces, places, events and experiences.

In the course of urban planning, design thinking therefore encompasses a range of scientific and practical activities that all together form the continuum of innovation for solving urban conflicts. These activities are clearly structured in three stages within participatory urban design processes:Problem definition,Problem solving strategyand Product identification.

These successive stages serve to facilitate and improve identification and agreement over: an integrated human-centred vision of built environment or socio-urban context, explicit objectives of different time-frames, guiding principles for achieving them as well as tools, strategies, and methods to most effectively deliver them.The quality of such a gradually developed and looping process lies in its flexibility and dynamics to allow for a wide range of modifications or replacements to easily take placeand change the course of the project and final product according to human needs and desires or to restrictions and constraints.

- *Problem definition - Identification of an urban conflict*

The initial phase of the process consists of agreeing on the vision of positive urban future, identification of an urban conflict to be treated and solved, analysis of all urban actors involved, the input of guiding principles and the definition of long-term and short-term objectives.Regarding the scale and the character of these conflicts,

[7](Interview: Michael Sorkin 2005)

urban actors involved in the process are identified among average urban dwellers, different public and private stakeholders and professionals.[8]

In line with legal, economic and social constraints, urban actorsagree upon guiding principles and develop objectives. In general, they have to fulfil these basic requirements of participatory urban design ideology: high aspiration commitment (cultural identity, sense of place, human-centred considerations), collective and collaborative actions, constructive engagement and constructive criticism, knowledge network and integrated design education (ensure environmental experience literacy for urban actors), practice-based/use-inspired (optimistic approach to existing reality) and intelligent investment. These principles should be well accustomed to each case individually andits current socio-urban context, they should address all socio-economic aspects and foster innovation and development in a defined urban environment.

- *Problem solving strategy- definition through action-orientated methodology of design thinking*

Problem solving in design thinking is processed in three steps (inspiration, ideation and implementation), which are included in a circular process of solution generation. All of these steps should involve reflection, contextualization and action on different models for problem solving. This process isdivided in six sub-actions:collaboration on idea, acceptance with empathy, synthesis through integrative thinking, stoke ideas, positive approach toward the selection of ideas, experimentalism in prototyping and testing results. This looping procedure iterates until the best solution is found.

[8]Now, if this pattern is applied, the actors of these cities (seen in a great number as being poor, excluded, marginalised, outsiders) can also be the actual “makers of the city”(Jean-Claude Bolay 2004).

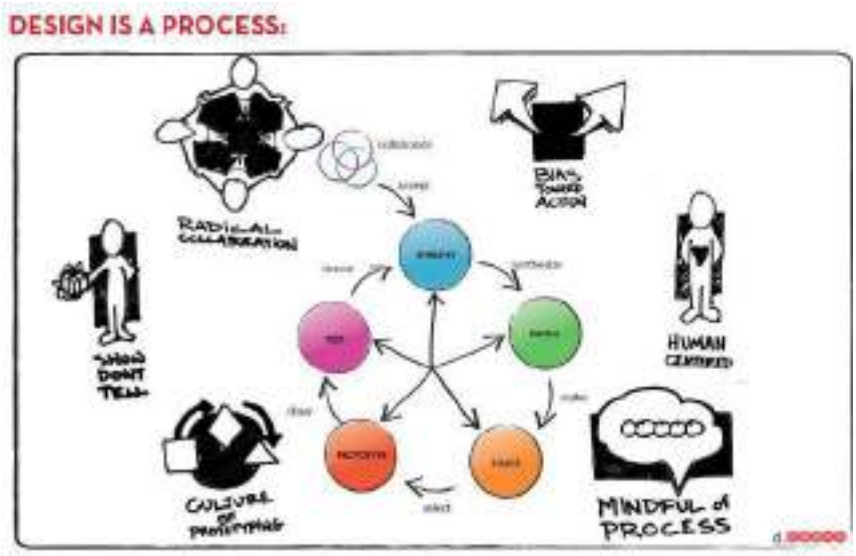

Figure 2:detailed procedure of design thinking[9]

In urbanism this process is transferred in a model of six basic steps[10]:

Step 1 - Research: explore spatial factors (urban environment) and investigate social aspects (human experience). These activities may be depicted through Lynch terminology and methodology (interviews and spatial landmarks)*(Mary Foyder / courtesy IDEO*).

Step 2 - Case Studies: communicate the essence of space or community through a creative process of functional analysis of human needs and urban identity of the environment, in order to define the issues at stake in very simple terms.

STEP 3 - Design Brief: translate ideas into action so as to experiment with possible solutions in the current context, while preserving positive aspects, cultural heritage and identity and promoting collaboration, creativity and a do-it-yourself approach.

Step 4 - Design Principles: transform the passive and ignite the active through the participation, densification and diversificationof cultural models and identities in a spatial framework. The essential broad principles are to be articulated as specific guidelines and then broken down into services or strategies.

Step 5 - Design in reference to time: design around the behaviour and experience of urban actors

[9](Ford 2009)

[10]The variations of this model have already been used in the urban design approach of the city of Adelaide in Australia (Value of Design 2009) and in urban designs of IDEO group in Kansas City(Mary Foyder / courtesy IDEO) .

Step 6 – Design in reference to space: reflect understanding of human desires and correspond to human needs concerning spatial aspects.

Figure 3:participatory urban design process. Based on integrated design thinking process for the city of Adelaide, Australia[11]

- *Product identification– decision making and place-making in urbanism*

This final stage articulates the chosen model in practice in order to achieve reliable long-term results. Depending on the nature of the problem (urban conflict), applied methods and tools, these models could be implemented in decision-making or place-making strategies in urbanism.Additionally, according to these factors, models are formulated in terms of performance qualities, facilitation of innovation and impact in order to address the target group and produce the best outcomes.

5 Discussion – Wider social context

5.1 Results

Following the thesis that our current social context can be identified as a consumer society in a postmodern framework, it becomes apparent how economic values come to triumph over social ones in the practice of everyday life. Such social framework

[11](Value of Design 2009)

imposes pressure on the human environment, threatens social order and performance of social practices and produces social conflict. When we refer to these problems inside any urban environment (city), we define it as an urban conflict, a rupture in an urban system – symbiosis made of human environment in a built environment framework. These systemic problems need systemic solutions, which address not only spatial and social conflicts, but problems of urban actors as well.

Participatory urban design relies on human capability to generate novelties (new systems, organizations or fields) by using a wide range of human capacities (ability to be intuitive, to recognize patterns, to construct ideas that have emotional meaning as well as being functional, and to express in media other than words or symbols)*(Brown and Katz 2010).*Accordingly, urban actors are actively involved in processing scenarios for solving urban conflicts. When this individual potential is carefully directed toward solving individual social conflicts in an urban environment, it may produce benefits for individuals (by involving them in meaningful social practice and encouraging them to solve social conflicts) and for society (by forming a built environment and producing social order). The idea is such that urban actors participate in creating a harmonious, meaningful environment in space and time, one that will correspond to their needs and desires and obey the scientific and social rules defined by professionals.

The social goal is not only to validate best ideas and produce best results in the urban environment but also to inspire people to live a creative personal life and to be useful to their community and urban environment. Moreover, letting people intervene in their immediate surroundings produces positive social effects: it gives meaning and importance to their human existence, reduces the effects of alienation common in modern consumer society, and involves them in informal learning which broadens their human capacities and improves their lifestyles. Conversely, they will act upon their immediate surroundings and participate in production in the urban environment that best fits their requirements and in doing so reduce urban problems and social conflicts.

5.2 Impact

The key issue that participatory urban design could reduce the negative effects of consumerism, a by-product of liberal capitalism, is elaborated by emphasizing the importance of individual creative potential in solving current urban conflicts. This idea presents the “urban actor potency” to freely influence and choose its immediate surroundings.

Furthermore, according to new visions of urbanism in relation to consumer culture, the issue at stake is an “urban consumer” – an individual between citizen and

consumer – and the collision between the roles of an urban actor and a consumer.In brief, this is a social struggle of 'ethics' and human nature over the production of everyday life, which challenges the modern social discourse.The sphere of cultural reproduction is also coming to be overflown by the postmodern pursuit of the self, where social relations, activities and objects are offered to be consumed as commodities*(Slater 2003).*

Namely, individuals unavoidably tend to conform to the expectations of their immediate social surroundings. In their pursuit of identity, self-realization and self-fulfilment, they are torn between the limits or boundaries of their needs and the possibilities to satisfy them, so that the whole system functions in a vicious, never-ending loop*(Slater 2003).*In terms of urbanism, there may be a risk that urban actors fail to participate actively in the herein presented new approach to strategic urban planning.

Additionally, consumer culture has already spread its tentacles into visions of the modern city.We witness nowadays the transformation of cities into products of consumerism and for consumption, venues for the production of public spectacle. Citizens/ individuals are not only the human capacity which build cities, but they are also consumers of cities. This relation identifies the city as a place of consumption, entertainment and services.In sucha diverse urban realm, already threatened by liberal capitalism, participatory urban design could be, conversely, seen as a strategy that crosses the traditional boundaries between public, for-profit and non-profit sectors, and introduces a new transdisciplinary field which can be applied to all realms of city planning.

The other crucial point of this methodology is its participatory nature– the idea of urban development as a democratic process, where the "user-orientated" strategy surpasses the decision-making process and aims at involving users in an empathic version of place-making*(Brown and Katz 2010).*

On the other hand, its potential flaw lies in the question as to whether this form of economy is really a solution for urban problems and to what extent this concept is actually applicable in different environments.Namely, a human-centred approach and orientation toward a unique cultural context conspicuously bring social benefits; its experimental nature is a source of personal development through learning for urban actors who participate in the process. But it is actually difficult to assess whether the specificity of solutions and possibility of failure in experimentation prove to be profitable as well.

Finally, individual human potential could also be interpreted as a possible threat. In terms of the evolutional development of human race, the importance of novelty has

been recognized as a propensity to explore and invent in order to better cope with the unpredictable conditions that threatens its survival. But the force of entropy, another antagonistic force that also strongly motivates humans, tends to prevail over the urge to create. The collision of these forces may also reduce the success of this method when it comes to application in practice.

6 Conclusion

Participatory urban design poses a challenge to the redefinition of a scientific approach to urban conflicts and corresponding urban planning procedures, through a creative, dynamic and iterative process of design thinking within an urban setting. Participatory urban design – a human-centred, user-friendly concept, which fosters holistic thinking and flexibility in developing strategies – blurs the boundaries between various disciplines and stakeholders, as well as their mutual endeavours to provide a wide range of potential solutions of recombination and application in certain environments, and finally, generates a new vision of the city that suits current scientific and cultural trends.

Key words: "participatory urban design" method, design thinking, creativity, developing countries

Sticky stories: how civic initiatives connect to regional planning agendas

Hetty van der Stoep [1], Noelle Aarts [2]

Abstract

In this paper we aim to contribute to understanding complex change processes that result from a myriad of social, physical and political processes in which both governmental and non-governmental actors try to achieve ambitions. We focus on the role of self-organizing civic initiatives and how they relate to the construction of regional planning agendas by local and regional governments. How do civic initiatives connect to local and regional governments and how can we understand the consequences?

We addressed these questions by focusing on whether and how civic initiatives enable issues and ideas to spread through social networks and mobilize supporters. Agenda-setting theory and framing theory point to the construction of realities in social interactions. Strategic framing of issues, selecting certain aspects and ignoring others, is considered a powerful agenda-setting strategy. When framing gets the form of 'sticky stories' chances are enhanced that promoted issues reach a tipping point.

The findings of two case studies in the Netherlands suggest that stories become sticky through an interplay between conversations (that enable the construction and travelling of stories), concurring circumstances, and 'connectors' (people who are able to connect people, ideas and informal and formal contexts). Civic initiatives can perform crucial roles in the generation and spreading of 'sticky stories'. They are sometimes better than professional planners and policy makers able to create the right contexts, to connect the right people and storylines. 'Adaptive' attitudes of planners, asked for in debates about dealing with complexity in planning, may involve embracing and enabling forms of self-organization and connecting to unfolding 'sticky stories'.

1. Introduction

Collaborative planning faces dilemmas with respect to the promises of a more democratic practice, more efficiency and effectiveness. Some authors speak of a new crisis in planning in which new ways out are searched to deal with increasing complexity (non-linearity) of socio-spatial changes (for example De Roo, 2010). In such a view, change is viewed as the highly unpredictable and often unintended outcome of a myriad of social, physical and political processes in which both

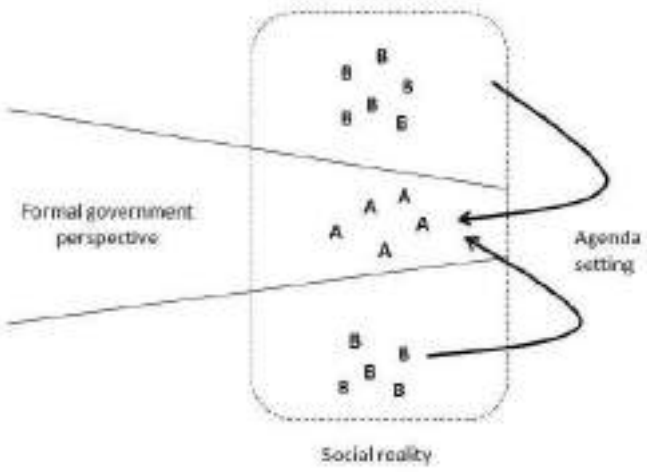
[1] Radboud University Nijmegen, Geography, Planning and Environment, Netherlands – h.vanderstoep@fm.ru.nl
[2] Wageningen University, Communication Science / University of Amsterdam, ASCoR, Communication Science, Netherlands – noelle.aarts@wur.nl

governmental and non-governmental actors try to achieve ambitions (Innes et al, 2010). The challenges for planning and governance lie in the understanding of complex change processes as well as developing 'adaptive' attitudes to deal with complexity.

We aim to contribute to a 'complexity perspective' on (collaborative) planning by focusing on understanding socio-spatial change from the perspective of local-regional civic initiatives who engage in local-regional planning practices. Civic initiatives for improving the quality of public space sprout everywhere as potential 'seeds of change' in urban and rural planning (for example Horlings, 2010; Boonstra and Boelens, 2011). We assume that they contribute to spatial change and change of planning agendas in more or less subtle ways by their efforts to get (government) support.

Some of these initiatives successfully connect to other (government) initiatives to get access to required resources and regulations. Other initiatives are not so successful and fade away. It is argued that most civic initiatives will at some point need a form of engagement of government actors to achieve goals (Aarts et al, 2007; Horlings, 2010). But getting attention of government actors is often a difficult process (Wagemans, 2002; Turnhout et al, 2010; Jones and Baumgartner, 2005). Government only has eye for that part of social reality that has meaning within the perspective of government. This is illustrated in figure 1. Initiatives B are not part of the perspectives of the government and therefore they are, to the government, irrelevant and meaningless. If initiatives want to be heard, they need knowledge of dominant policy frameworks as well as a great deal of "communicative skills, creativity, and guts" (Turnhout et al, 2010).

Figure 1. Self-referential perspective of government on social reality and effort of civic initiatives to get inside that perspective conceptualized as agenda-setting (adjusted from Wagemans, 2004)



This raises the question of what civic initiatives do to achieve goals. How do they connect to governments and how can we understand the consequences in terms of agenda setting? How do ideas and issues of civic initiatives 'travel' to policy arenas (Healey, 2006) sometimes leading to policy and governance change?

2. Theoretical and methodological approach

2.1 Storytelling and framing

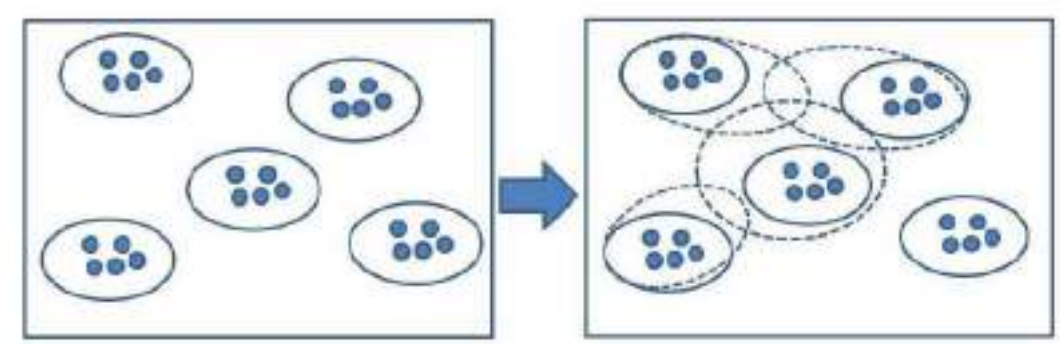
We addressed the questions above by focusing on whether and how civic initiatives enable issues and ideas to spread through social networks and mobilize supporters in a process of agenda-setting. Agenda-setting theory and framing theory point to the construction of realities in interactions. Strategic framing of issues, selecting certain aspects and ignoring others (cf Entman, 1993) is considered a powerful agenda-setting strategy (Jones and Baumgartner, 2005; McCombs and Shaw, 1993). Issue frames are continuously produced, reproduced, transformed and replaced in social interactions (Gray, 2002; Benford and Snow, 2000; Dewulf et al, 2009). Consequentially, a study of agenda-setting should not only focus on the role of trigger events and policy entrepreneurs in the opening of 'windows of opportunity' (cf Kingdon, 2003), but should also address a micro-level analysis of framing processes in social interactions.

Through the process of issue-framing a 'normative-prescriptive' story may emerge that provides a sense of what the problem is and what should be done about it (Rein and Schön, 1996). Storytelling plays an important role in disseminating a vision or a message and is considered a potential catalyst of change (Throgmorton, 1996; Sandercock, 2003; Baker, 2010). Storytelling is a way of ordering and constructing shared meaning (Hajer and Laws, 2006). Stories contain a plot with a more or less logical course and coherence of events. Such a structure provides an explanation to listeners about 'what happened' or 'what can happen if' (Baker, 2010). It is a framework for interpretation that invites listeners to attach their own understandings, experiences and emotions (Baker, 2010). This way, storytelling, the interactive framing of issues into plots, enables dealing with ambiguity and coordinating different realities (Throgmorton, 1996; Van Dijk, 2011). Stories also contain moral tension and motivation for action (Sandercock, 2003; Hajer and Laws, 2006). Therefore, the packaging of ambitions into clear stories can mobilize or 'galvanize' people into action (Bate, 2004; Rein and Schön, 1996; Hajer and Laws, 2006).

Although stories have various properties that influence policy making and the construction of social realities, they cannot cause change themselves. The concept of storytelling emphasizes that stories emerge in interactions between people and that they are constantly being reshaped in those interactions (Hajer and Laws, 2006). 'Stories are elastic' (Baker, 2010: 169) in the sense that listeners and tellers reshape stories while (consciously or unconsciously) interpreting and discussing them in interactions. Listeners are invited to incorporate the story within their own frames

and then pass it on to others in ways that are meaningful and relevant to them. Elasticity enables stories to travel through a wide network. In the context of policy agenda setting, elasticity is a critical condition because novel ideas need to 'fit' into current policy 'stories' to get inside of the self-referential view of policy makers (Jones and Baumgartner, 2005; Van Dijk, 2011). New stories may need to be stretched to fit into prevailing policy stories. This is visualized in figure 2.

Figure 2. Interactive alignment ('fitting') of frames and stories to build supporting coalitions



The activity of 'fitting' and 'stretching' stories can be understood as frame alignment strategies (Benford and Snow, 2000). The four basic alignment strategies are: bridging (linking ideologically similar frames), amplification (idealization, exaggeration, or reinforcement of frames), extension (including concerns of potential supporters which extend primary frames), and transformation (changing frames into new understandings and meanings). Storytelling can involve each of these strategies depending on the level of receptivity of targeted actors. Sometimes stories do not have to change much to persuade listeners to join in while sometimes the plot needs to be transformed to get the required (political) support.

Alignment of stories can thus be enhanced by framing stories into the 'latitude of acceptance' of listeners. This is done by providing credible, salient, concrete and emotive stories (Benford and Snow, 2000; Heath and Heath, 2007). Stories are perceived as credible when they are consistent with everyday experiences, and when storytellers are considered credible (cf. Benford and Snow, 2000). Salient, 'memorable' stories, connect well to the personal beliefs, values and experiences of listeners as well as the culture with which listeners identify themselves ('cultural resonance').

In the context of agenda setting, issue proponents face the challenge of fitting their stories to the existing policy stories by using alignment strategies. The mechanism of 'strategic fitting' (Benford and Snow, 2000) implies that stories are continuously reproduced, adjusted and 'resemiotized' (Van Herzele and Aarts, forthcoming 2012) through social interactions. Some stories become 'sticky' (Heath and Heath, 2007; Gladwell, 2000) in the process of storytelling and frame alignment, while others fade

away. We analysed the process and conditions in which stories become sticky with the help of two case studies about civic initiatives who tried to bring unsolicited proposals for local-regional development to the attention of relevant governments.

2.2 Case-studies: civic initiatives in Heuvelland and Gouda-Krimpenerwaard

As examples of agenda-setting processes in which local-regional civic initiatives bring forth unsolicited proposals that concern agendas for regional development we selected two case studies in the Netherlands: New Markets Heuvelland (Heuvelland) and Landscape Development in the urban-rural Fringe Gouda-Krimpenerwaard (Gouda-Krimpenerwaard). In table 1 we have summarized the characteristics of the two cases.

In the cases we first identified tipping points in the agenda-setting process[3]. Next, we analyzed what preceded tipping points: 1) the construction of stories around the proposed issues through the interactions between initiatives and potential supporters in the region; 2) the events and contexts that enabled the spreading of stories, and 3) the role of individual agents who connected people, frames, resources, and contexts, and thereby also enabled spreading of stories across a wider network. The analysis of framing processes, and roles of events and individual agents was executed through interviews with key actors and content analyses (policy documents, newspaper articles, reports of meetings of initiatives, and e-mail and letter conversations).

In short the plots of the cases can be summarized as follows: The initiative of citizens in the Gouda-Krimpenerwaard fringe area led to successful agenda-setting of landscape values throughout a period of 20 years. The initiative started when there was only fragmented attention of governments for the area at stake (‘tunnel visions’) which the initiative perceived as a big threat for natural and historical landscape values. After twenty years attention and support of local and regional governments was mobilized which resulted in the investment of millions of euros in the protection and development of landscape values. The Heuvelland case actually contains two stories that in the end competed with each other for attention and (financial and political) support. Both started with the New Markets initiative to build a community of ‘capital rich’ entrepreneurs who would invest in landscape qualities through new product-market combinations which were assumed to generate economical returns (improved tourism). However, this initiative could not sufficiently mobilize support of entrepreneurs and relevant governments and stagnated while at the same time a story about Regional Branding emerged around which the participating entrepreneurs self-organized. This latter initiative was very successful in mobilizing support and, like the Gouda-Krimpenerwaard case, resulted in investments of millions of euros into a regional branding campaign.

[3] Tipping points, agenda-setting factors and framing processes are described in detail in ‘case narratives’ in Van der Stoep (doctoral thesis, forthcoming in 2012).

Table 1. Characteristics of the two case studies of civic initiatives

Cases / characteristics	Gouda-Krimpenerwaard	Heuvelland	
Where?	Southern urban-rural fringe of city of Gouda, connecting to polder region Krimpenerwaard Local-regional level	Region South-Limburg Regional level	
Initiative (labels used in this paper)	Citizens: "WGK-initiative"	Experts, entrepreneurs: "New Markets initiative"	Entrepreneurs: "Regional Branding initiative"
Reason for starting initiative	Lack of government vision for urban-rural fringe Gouda-Krimpenerwaard	Lack of government vision on how economical activities can improve landscape quality	Strategy for regional (economical) development should be based on a good marketing (branding) strategy
Ambition	Getting attention and (financial and political) support for the protection of landscape values (nature, historical landscape structure, monumental lock)	Integrated improvement of (tourist and rural) economy and landscape quality: founding of a business community around New Markets	Establishing a regional brand and a 'branding' campaign to attract businesses and employees (dealing with shrinking and 'silvering' population)
Ambition achieved?	Yes	No	Yes (branding campaign was performed)
Connection to what sort of government agendas?	Local and regional development plans	Regional development plans	Regional economic development visions
Duration of process	1985-2010	2006-2009	2007-2012

In the following we aim to explain these outcomes by analyzing and comparing how and why stories did or did not become sticky over time.

3. Case study findings

3.1 Stories and ambitions that 'fit'

In the theoretical part we suggested that clear ambitions are an important part of bringing across messages and constructing a strong plot of a story. In the Gouda-Krimpenerwaard case this condition was met very well. Initiatives in Gouda-Krimpenerwaard had a clear and stable ambition throughout the 20 years of campaigning. Even though the story shifted to an emphasis on the advantages of landscape protection for economical and nature development, the original ambitions,

that is the plot of the story (renovation historical lock and nature-oriented recreational development) remained the same. Many of the ideas that were developed in the 1980s were achieved throughout the 2000s without serious alterations.

The New Markets initiative in the Heuvelland-case however had many difficulties in establishing a clear ambition. And as there were no stable ambitions, no sticky story emerged from the interactions between the participants. There was continuous discussion and disagreement between entrepreneurs and experts about the organization of the project which deviated attention from constructing an ambition for development of landscape qualities and economical activities. No storyline or plot emerged from the discussions. Finally, entrepreneurs self-organized around another storyline: that of regional branding of the region. The regional branding story became very sticky and not only the initiating entrepreneurs, but also other entrepreneurs and local and regional governments clustered around it. Once the regional branding story had 'tipped', many resources and supporters flowed to it from all kinds of budgets for regional development. The story, with the motto "Zuid-Limburg: Bright site of life", became a million-euro-story.

It was suggested earlier that to get inside the self-referential perspective of governments, stories have to be fitted to existing policy stories. This idea was confirmed in both cases. In both cases initiatives connected their ambitions and stories to governmental agendas for regional economic development. Strategies of initiatives were aimed at stretching 'the latitude of acceptance' of relevant government actors. Initiatives did not present their stories as alternative ideas, but as something that fitted into existing policy frames. So initiatives focused on 'bridging', 'extending' (Benford and Snow, 2000), or in other words 're-semiotizing' (Van Herzele and Aarts, forthcoming 2012) their stories and frames to connect to existing policy frames. New ideas and stories were connected with and fitted to 'existing stories' (cf. Van Dijk, 2011). Through this process, existing policy stories were reconfirmed and reproduced. Existing policy stories only became a bit 'wider' to include new ideas as part of the story.

Besides having 'clear ambitions' and 'a fit' with current (policy) stories, another condition for a successful story was assumed to be found in the qualitative properties of the story. It was suggested that stories, in order to be attractive, should be experienced as clear and concrete, credible, salient and emotive. These conditions were not met for the New Markets-initiative in the Heuvelland case, but they could be recognized in the Regional Branding initiative and the Gouda-Krimpenerwaard case. The regional branding story won at the cost of the Transforum-story because it was considered more attractive by entrepreneurs. The message of Regional Branding connected well to their personal concerns and ideas about what the regional economy needed. Moreover, the Regional Branding initiative and the civic initiatives in Gouda-Krimpenerwaard used many symbols that spoke to the imagination of the listeners. For example for the Regional Branding initiative, the regional products (beer, sirop etc), culture (gastronomy, festivals, art) and the name of the group of entrepreneurs (Black Riders, after the local beer brewery and pub where they met

each other). For the Veenvaren-initiative in the Gouda-Krimpenerwaard case, a strong emotive symbol was the historical boat in which one of the initiators sailed the waters of the polder Krimpenerwaard representing the ambition of reintroducing boating in the polder.

These examples show the relevance of using symbols to construct strong appealing stories to connect to the personal life experiences of targeted audiences. The active construction and shaping of stories shows that credibility, salience, emotion etcetera are never inherent qualities of stories. A story is not sticky in itself. A story becomes sticky because of what people do with it. When we want to trace how a story becomes sticky, we should ask 'who is telling what to whom, why and in which context?' In the following we focus attention on interactions and other conditions in which stories become sticky.

3.2 Conversations that trigger change

The case findings suggest that stories are made sticky by creating and using various opportunities for conversation which enables learning about different 'life worlds' and frames. Reframing and re-semiotization (Van Herzele and Aarts, fortcoming 2012) in conversations increase the chances that frames are aligned and that stories become sticky.

In the Gouda-Krimpenerwaard case many opportunities for conversation were used and created. The strategy of civic initiatives was aimed at conversing at all times everywhere and in every way. Throughout 20 years of campaigning, proponents of the initiative to protect landscape values in the fringe attended many meetings in the region about related topics, they talked informally on the street, they wrote letters to governmental representatives and potential supporters, contributed to newspaper coverage, held informal meetings, used channels of formal public participation, and more. This resulted very slowly in resonance of the story in a large network of regional stakeholders. In Heuvelland, one of the problems for the initiative of the experts to advance a sticky story about area development was a lack of opportunity to discuss it in formal or informal conversations. There were some formal meetings, but process managers were not able to create conditions for informal conversations with entrepreneurs in which decisions in formal meetings could be prepared. In fact, they were excluded from informal conversations between the engaged entrepreneurs. As a result, stories of the experts and entrepreneurs developed separately and competed with each other. Ambitions did not become clear so a story could not emerge from the interactions that did take place.

The spreading of a story through a network on the one hand requires a quantity and variety of conversations, but also asks for certain connecting qualities of conversations. Through framing processes alignments are established between stories and frames of issue proponents and the 'life-worlds' and stories of targeted audiences. In conversations reframing takes place as the intended or unintended result of framings of conversation partners. This is how stories can shift subtly.

Baker (2010) argues that conversations can 'catalyze change' when they provide a context of trust, respect, curiosity and hope. Other conditions are acceptance of differences and patience with respect to the process. Such properties of conversations are supposed to create an advantageous situation for people to open up their minds, become receptive and come out of their comport zone. The case study findings confirm that acceptance and curiosity towards differences as well as patience were important in frame alignment and coalition building. It requires from conversation partners to take time to ask questions, listen to responses, share experiences and share stories to illustrate ideas, and access intuitive and tacit knowledge.

We found in Gouda-Krimpenerwaard case that frame alignment was achieved when conversations provided room not only for telling stories, but also listening. Connecting to personal 'life-worlds' of targeted listeners requires a certain amount of empathy and ability to 'listen'. Successful storytellers were very empathetic with prospected supporters and could relate to their everyday lives very well. By listening tellers became knowledgeable about the frames with which they had to align their own story. Storytelling requires a great deal of listening. Or in other words, strong sticky stories are told by great listeners.

In contrast, the analysis of Heuvelland suggests that the process managers, the experts, were focusing too much attention on building the right coalition according to their own beliefs, and were unable to create a situation in which they could 'listen' and 'empathize'. Although meetings and an interactive website were set up to organize joint fact finding and to provide a platform for the articulation of concerns, interests and ideas, this did not give enough opportunity for listening and storytelling. In Heuvelland, informal 'one-on-one' conversations were an essential vehicle for creating sticky stories and connecting different 'worlds' and networks. The process managers did have the intention to carefully listen to concerns of entrepreneurs, but they were excluded from those informal conversations with entrepreneurs. The findings suggests that the closedness of the community of entrepreneurs and government executives was hindering 'outsider' actors to 'listen' and 'empathize'. This way 'outsider' participants were unable to align frames and start a 'sticky story'.

These conclusions about conversations show parallels with a growing body of literature on the role of conversations in organization management (Ford, 1999; Baker, 2010; Van Herzele and Aarts, forthcoming 2012). The activity of conversation is viewed as the key process through which forms of organizing are reproduced and changed. We can conclude that conversations are needed to start, shape and spread a story. Conversations have to provide room for both telling, listening and empathizing to achieve frame alignment. It depends on the context what type of conversation works best and whether and how one will be considered a good conversation partner. Building on the empirical findings as well as literature we argue that stories are made sticky in human interactions through 'catalytic conversations' (Baker, 2010). That is, conversations in which people are open to new perspectives for several reasons and take time to listen and 'empathize'.

3.3 Concurring circumstances

The cases showed that specific circumstances and contexts played decisive roles in enhancing the stickiness of stories. For example, the opportunity of the 'crisis law' in the Gouda-Krimpenerwaard case, enabled the attachment of emotion and urgency to the story of the civic initiative by stressing that 'it was now or never', a unique opportunity which could not be missed. This enhanced the perceived urgency of the issue (to local and regional governments) to such an extent that the story about renovation of the monumental lock became sticky and 'tipped'. In Heuvelland triggering events could also be recognized. In the case of Regional Branding changes in political circumstances were used to make the story more sticky. The story aligned well with the existing policy story about the regional economy that was faced with the threat of young people leaving to other parts of the country.

In both cases we found that 'trigger events' could only trigger because they were interpreted by people as triggers (windows of opportunity). Trigger events are given meaning as triggers in light of previous events and interactions. They can trigger change when they concur with past events in the eyes of people who frame a particular event as a trigger event, a window of opportunity. To other people, the same events may have no meaning at all. This means that a triggering events are preceded by a large number of events and interactions that happened in the past. It is a matter of 'filling the cup', or in the words of Kingdon (2003), a matter of 'softening up' prospective adherents. When the cup is filled, it only takes a small drop more to make the cup run over. This is in line with a complexity perspective on change. Small and seemingly irrelevant or unimportant changes can have large effects (Morgan, 1986).

In the case of Gouda-Krimpenerwaard the initiators used various opportunities to bring alternative plans for the fringe area to the attention. Over a period of 20 years they used design competitions, formal participation procedures around government plans for the region, the project Masterplan Stolwijkersluis, as well as their own yearly 'dawn walk' to suggest alternative plans and many other occasions. The variety of contexts in which they prompted their ideas enabled a slow 'softening up' of the policy system. The only thing required to actually implement the ideas was resources that had to flow from the provincial government. That happened when the province realized they needed just a few hectares more to achieve their ambitions for nature development. To solve that 'problem' the provincial government could use the ' solution' that had already been floated by the civic initiative in the fringe area. The province's sudden interest in the area was the small drop that was needed to make the cup run over and implement the ideas for a nature-recreational development of the fringe area. But it was preceded by a filling of the cup with many small drops. This was achieved by introducing small novelties in many different places and moments which could then reinforce each other. The right context was created to make the story stick.

The analysis of Gouda-Krimpenerwaard provides many examples about changing circumstances and events, also the more subtler and smaller circumstances that could still trigger change. One of these is the role of the discussions and heavy debates about the construction of the bypass around Gouda in the tipping of ideas about renovation of the historical lock and reintroducing boating in the polder Krimpenerwaard to give an economic stimulus. The passionate engagement of the citizens group "Werkgroep Gouda-Krimpenerwaard" led them in a coalition with stakeholders from the polder Krimpenerwaard. These contacts remained and helped the "Werkgroep Gouda-Krimpenerwaard" to know a lot about the beliefs, concerns, interests and values of people in the Krimpenerwaard. They understood through ongoing conversations with Krimpenerwaardians over a longer period of time that the nature-agriculture controverse was the major concern also for the province who were responsible for solving the conflicts. So they knew exactly how to deal carefully with the political culture in the Krimpenerwaard and how to use that to get to the province. Their engagements in the Krimpenerwaard led them to contact and alignment with the "Veenvaren"-initiative. A sticky story was created out of it in which renovation of landscape values in the fringe (such as the monumental lock) and recreational possibilities were connected to a story about the economical opportunities of introducting boating in the polder Krimpenerwaard. At first glance, the conflicts and discussions about the bypass by the end of the 1990s and the beginning of the zeros seem to have little to do with the story about "Veenvaren" and the restoration of the lock. However, the story of Veenvaren and the role of the lock in that story could only become sticky as a result of the previous engagements of the "Werkgroep Gouda-Krimpenerwaard" with Krimpenerwaardians around the issue of the bypass. Often little things matter a lot!

3.4 Connecting stories, people, events and resources

In the case of Gouda-Krimpenerwaard we found that special individuals, who we call 'connectors', are able to connect ambitions, storylines, people, resources, and events and contexts. Those 'special individuals' resemble 'innovation brokers' (for example Klerkx, 2009) and policy entrepreneurs (cf Kingdon, 2003), but as we emphasize 'connecting' qualities we prefer to use the term 'connectors' (after Gladwell, 2000). By these connecting activities they enable the emergence, strengthening, spreading, adapting and fitting of stories. In other words, connectors can make stories 'sticky' in a number of ways.

First, the cases contained connectors that had central positions in networks and could therefore connect different networks and groups. Examples in the Heuvelland case are the 'leading' entrepreneurs who used their informal executive networks effectively. They were able to bridge the entrepreneurial network and the relevant policy networks. In the Gouda-Krimpenerwaard case we found that connectors can also be people who just like to spread and share knowledge with many others and this way make ideas spread rapidly through a wider network (similar to Gladwells 'mavens', 2000).

An individual can also operate as a connector when he or she is considered a credible storyteller by other people or when they are able to mobilize credible storytellers ('frame articulators'). In Gouda-Krimpenerwaard we identified a number of credible frame articulators who had status or were considered experts in the field and as such were able to persuade influential actors in their network. However, credibility of storytellers was not only exclusive to people who were considered to be authorities. Sometimes, storytellers had a good claim to a hearing because they were considered genuine as their background and knowledge was consistent with the culture and concerns of people living and working in the region. The Gouda-Krimpenerwaard case provides the example of the initiator of "Veenvaren" who was considered as a credible conversation partner by crucial political actors in the Krimpenerwaard. This way the Veenvaren-initiative enabled an effective connection between decision makers in the Krimpenerwaard and the civic initiative in the Gouda-Krimpenerwaard fringe area.

In Heuvelland credible frame articulators were people that were assigned with authority. This worked out positively for the Regional Branding initiative. Tor the New Markets initiative this was a delimiting factor as the experts themselves were not part of the select club of individuals who were considered to have authority. Here, they would have needed other connectors that did have the right cultural background and position and that could reinforce the story and pass it on.

A third 'connecting' quality is being able to empathize and listen to stories of conversation partners (see also section 3.2). In Gouda-Krimpenerwaard we see that also regular citizens, who were not part of a powerful managerial network, could operate as connectors. Crucial connectors were people who could empathize with and listen carefully to potential supporters. Moreover, key players were connectors who liked to share information and knowledge to help other people. And by being very knowledgeable about different contexts they could bridge different networks and reach other connectors whose connecting qualities lay more in 'selling' and 'networking' the story.

A fourth 'connecting' quality is being sensitive to circumstances and contexts that provide opportunity to connect and align stories and people. For example, the self-organizing entrepreneurs in the Regional Branding initiative were continually scanning the context and looking for the right circumstances. They built an informal network and provided for a suitable context for informal conversations. They seized political opportunities and tried to create ('nudge') the right context. The same happened in the Gouda-Krimpenerwaard case in which initiatives continually searched for contexts to promote their messages and tell their story. Awaiting, searching and creating the right (conversational) context required a great deal of knowledge and sensitivity about various contexts as well as patience and perseverance. Connectors know how to 'nudge' contexts, that is signal, use and create context to a certain extent. This way, connectors are critical agents in the construction of a sticky story or the other way around, they may also weaken a competing story. That said, connectors are always dependent on the interactions in

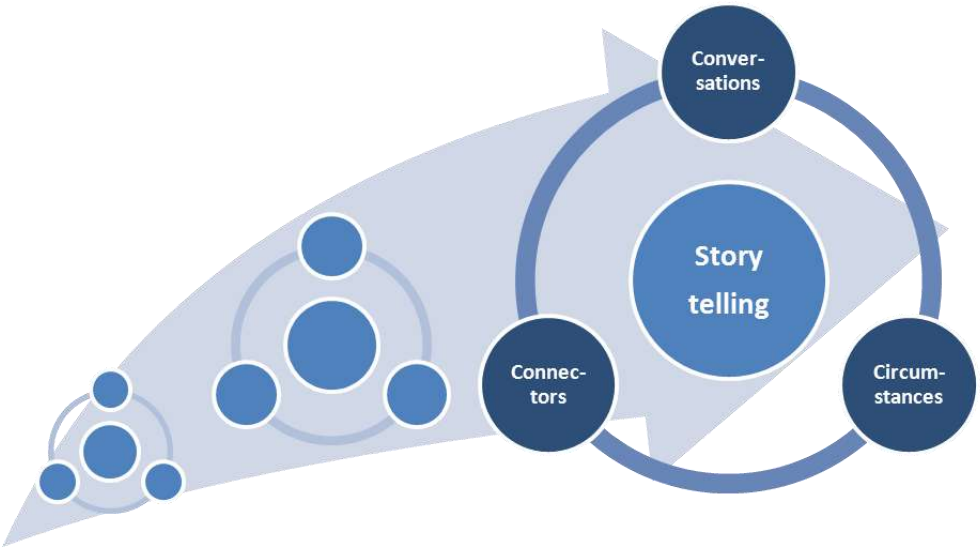
the wider network of which they are part, so 'nudging' is all they can do. Still, 'nudging' may be all that is required to 'tip' a story.

It is impossible for a single person to have or perform all qualities discussed above. Connecting qualities in the Gouda-Krimpenerwaard case varied from person to person but together they created a strong spreading effect for the story about landscape values in the fringe. Therefore we conclude that the label 'connector' is not exclusive to a particular person but depends on the context (time and place). Persons can perform as connectors at certain moments while at other moments leaving others to this task. There can be several connectors at one time. There is no single change agent that can be identified. Individual people can perform as connectors at different moments depending on the specific context and the qualities that are needed at a certain moment.

3.5 Sticky stories: conversations, circumstances and connectors

Sticky stories that are remembered and that connect people and ideas to each other in coalitions become sticky through human interactions. Our empirical findings demonstrates that stickiness is influenced by an interplay between (everyday) *conversations* that enable the construction and travelling of stories, concurring *circumstances*, and *connectors* who are able to connect people, ideas, events and various conversational contexts. This interplay is schematized in figure 3.

Figure 3. The process through which a story becomes sticky



The previous sections demonstrated that social interactions in the form of conversations matter a great deal in the mobilization of support. Conversations form the vehicle for framing ambitions into stories. Conversations provide means to listen, empathize and tell and thereby to connect stories to the emotions and frames of

conversation partners. Therefore, conversations are an essential condition in the unfolding of a sticky story. Creating opportunities for conversations in which knowledge and information are shared can enhance innovation and self-organization of people around stories that link various ambitions. Conversations open up windows to new possibilities in particular situations and contexts which can be created to a certain extent.

Conversations can bring forth sticky stories in particular circumstances. Many conversations together build up a momentum, they 'fill the cup', and when this concurs with a triggering event the cup will run over, or in other words the story becomes so sticky that it ‘tips’ and leads to change. ‘Connectors bring together people, ambitions, resources and meaningful events through conversations in specific (concurring) circumstances. Connectors do not only connect people and ambitions, but they also connect ‘events’ and construe them as ‘windows of opportunity’. Moreover, connectors develop an antenna for creating a conversational context that enables collective storytelling and coalition-building, or in the words of Baker (2010), that ‘can catalyze change’.

4. Conclusion: storytelling and adaptivity

In this paper we discussed how we can understand the process and outcomes of attempts of civic initiatives to connect to local and regional governments to achieve goals. The comparison of two case studies resulted in an analytic model in which successful agenda setting and mobilization was defined in terms of storytelling. A successful story is a story that can self-multiply and travel rapidly through a wider social network, or in other words a story that is ‘made to stick’. Stories become sticky in a process of ongoing social interactions in which (interplaying) conversations, concurring circumstances and connectors are critical conditions.

Successful initiatives in the cases were able to achieve goals and change planning agendas by navigating on the self-referentiality of governments. They managed to get inside the self-referential view of governments on social reality, while governments embraced ideas as part of prevailing policy stories. Beneath the surface new coalitions between government actors and civic initiatives emerged out of interactions, and stories shifted slightly. Initiatives and formal plans of governments were ‘enriched’ with ideas of civic initiatives. Change happened, but it was subtle and non-linear.

Apparently the ‘world out there’ about which government has a self-referential view provides opportunities for change and innovation. The case findings confirm that it is not a static world that can be mended to governments ‘will’. Civic initiatives try to achieve goals and try to be noticed by governments. The interactions that flow from these efforts leads to generation of new stories and reproduction or adjustment of existing stories that guide action. So what can we learn about planning in complex change processes from the findings and the proposed model for analyzing agenda-

setting and storytelling? What starting points were found for more 'adaptive attitudes' of planners called for in the planning debate?

Planners may try to develop an antenna for self-organization of people (public and private actors) around emerging stories and make use of these self-organizing movements to connect own ambitions to them. If planners also look for stories that will 'stick' and guide change, then the conditions for stickiness may be helpful in deciding on actions. That means that planners, like civic initiatives, could try to create and engage in 'catalytic' conversations in which there is room for differences, diversity, and for 'listening' and 'empathizing'. They could try to signal events that provide momentum for action or try to create the right context for constructing a story and making it sticky in conversation with other actors ('nudging contexts'). And related to 'creating the right circumstances' and 'engaging in catalytic conversations' planners could identify and make use of 'connectors' that can link stories from different social networks and 'life worlds'. The research suggests that connectors, may be people with authority (in line with studies about policy entrepreneurs) but just as important are 'local' people who are very knowledgeable about various relevant contexts (historical, policy, political, social, geographical) in the area and who like to share knowledge with other people.

Creating and engaging in catalytic conversations, looking for and using connectors and 'nudging contexts' are adaptive attitudes that can contribute to a form of planning in which complexity is not considered a problem but an opportunity for innovation.

Culture Counts – How Cultural Differences impact Strategic Planning Processes towards Urban Resilience

Jenny Atmanagara (atmanagara@igp.uni-stuttgart.de), Christoph Hemberger (hemberger@igp.uni-stuttgart.de), Walter Schönwandt (igp@igp.uni-stuttgart.de)

University of Stuttgart, Institute for the Foundations of Planning (IGP)

Abstract

Against the background of global change and transformation processes and an increase in international and interdisciplinary cooperation, the need to better understand cultural differences in strategic planning processes towards urban resilience becomes apparent. In particular, with regard to climate adaptation, cities and regions around the globe are looking for alternative approaches and new strategies in order to strengthen their resilience and their capability for innovation.
Based on the definitions of the key concepts "culture" and "resilience" as well as on the planning model of the "third generation" (Schönwandt, 2002) and the "cultural values model" (Stephenson, 2008), this paper discusses the impact of cultural differences on strategic planning processes towards urban resilience.
Examples from regional workshops on climate mitigation and adaptation in South-West Germany illustrate how these concepts are actually lived in strategic planning processes and how diverse planning cultures and approaches influence the different planning steps, starting from the definition of the initial problem up to the development of solutions. Appropriate tools and approaches that can help to overcome cultural misunderstandings and barriers are presented. Finally, the cultural determinants of strategic planning processes are analyzed and recommendations are deduced in order to raise cultural awareness in international and interdisciplinary planning projects as well as in political decision-making.

1. Introduction

Strategic planning processes have gained new popularity against the background of climate change adaptation and resilience of urban areas. Since these challenges can be no longer solved on regional (or national) level or by a single discipline only, international and interdisciplinary cooperation has increased significantly. This goes along with multiple cultures and approaches which are characterized by manifold mental models, values, attitudes and interests.

In order to cope with the complexity of transformation towards a resilient and climate friendly society the German Advisory Council on Global Change ("Wissenschaftlicher Beirat der Bundesregierung Globale Umweltveränderungen") has recently called for a knowledge-based process on transformation, inter- and

trans-disciplinary cooperation, a systemic perspective, social and technical innovations, and more research and education on transformation processes (cf. WBGU 2012). The need to further consider cultural issues in political governance and decision-making has been lately emphasized for example by a policy statement of the United Cities and Local Governments on "Culture as the Fourth Pillar of Sustainable Development" (UCLG 2011). Both documents underline the need for an intensified cooperation between science and society, including diverse disciplines and manifold stakeholders. Hence, the need to understand cultural differences and to find a common language will further increase.

This paper aims at analyzing the interrelation of culture and resilience in strategic planning processes based on the definition of the key concepts "culture" and "resilience" and theoretical foundations. Examples from regional workshops on climate mitigation and adaptation illustrate the diversity of planning cultures. Suitable tools and thinking approaches how to overcome cultural misunderstandings and barriers are presented. Finally, the results are reflected and used for recommendations on cultural awareness in planning and decision-making.

2. The Interrelation between Culture and Resilience – Core Concepts and Theoretical Foundations

The concept of culture has diverse meanings in different countries ranging from achievements in science, technology and art, via social boundaries due to different interests, attitudes and values, to "culture as the fourth pillar of sustainable development" (UDLG 2011). In our context we use the concept in the sense of "planning culture" which can be considered as a discipline-specific sub-culture within the overall concept of culture. In this sense, "planning culture" is associated to those occupational groups who deal with the design and future development of space and environment, e.g. spatial planners, urban and regional planners, architects, landscape planners, and neighbouring professions such as geographers, civil engineers, sociologists etc. They are characterised by a more or less common framework on how to deal with planning issues. Knieling & Othengrafen (2009a) explicate that these members of the planning profession "[...] are producing and sharing cognitive frames, practices, knowledge, beliefs, norms and rules, values and codes. […], all actors involved in planning processes are conditioned by the system of planning they act in, including the acceptance of rites and power structures etc. [...], planning is embedded in a specific cultural framework, which is composed of interactive processes among involved actors, their cultural cognitive frames and the particular planning procedures and instruments. In this sense, planners and planning systems need to be responsive to their cultural contexts." (Knieling & Othengrafen, 2009a, pp. 42-43) These professional biases of planners, i.e. certain planning approaches they use, narrow the perspectives and quite often hinder them to develop alternative solutions. Because these "glasses" through which a planner sees a given situation determine the way he/she constructs the problem, analyses the causes of a problem and deduces strategies and measures to solve the problem (Kuhn, 1981; Bunge, 1996; Schönwandt & Voigt, 2005).

These cultural issues also affect strategic planning processes that aim at enhancing urban resilience. Originally, the concept of resilience stems from the science of ecology and describes the ability of ecosystems to absorb shocks and other disturbances and to further exist preferably without prejudice (Holling, 1973 and Folke, 2006; in: Birkmann et al. 2011, p. 17). In recent years, the concept has been further developed and applied to socio-economic and socio-ecological systems (cf. Birkmann 2008). In the context of climate change the concept is often understood as "robustness" or "resistance", i.e. the ability of a system to sustain its central functions even after the occurrence of natural hazards. Moreover, a second essential feature of resilient systems is the ability to restore the initial state after external disturbances or shocks. The concept of "engineering resilience" emphasizes the "coping capacity" (Hollnagel et al., 2006) that measures the time period until then the initial state is recovered. The more resilient a system is, the faster it recovers from the impact of a crisis. Previously focusing on robustness and coping capacity, the term has been recently extended to the learning capacity of a system (among others Folke, 2006), i.e. that the system is able to learn and to adapt itself to changing environmental conditions. Hence, a resilient system or a resilient society possesses a high capacity for adaptation and has the ability to adapt itself reactively and proactively to changing environmental conditions. Therefore, a resilient spatial planning aims not only at the development of robust and resistant structures, but should - in the sense of reorganisation - support changes towards an adjustable spatial structure (Birkmann et al., 2011, p. 17). Finally, the debate on the notion of urban resilience is still ongoing. Generally, the concept is understood "as the degree to which cities are able to tolerate alteration before reorganising around a new set of structures and processes" (Seventh Framework Programme, 2011).

In order to capture the influence of culture on strategic planning processes towards urban resilience, the planning model of the "third generation" is used which was elaborated by Claus Heidemann (Heidemann, 1992) and further developed by Walter Schönwandt (Schönwandt, 2002). This model is based on systems theories and helps to analyze the determinants of strategic planning processes by mapping the planning cycle and its steps of procedure. Thereby, it is essential to note that the several components that together make up the "third generation" planning model never exist in isolation but always interact with one another (see figure 1): Based on their individual and discipline-specific mind-set (methods, concepts, theories, world-views etc.) planners build a "planning world" that is composed of specific approaches and operates within the environment of a "life world". This "life world" is where particular agendas, i.e. several points of political discussion or dispute, are worked out by actors in an arena. This interaction of "planning world" and "life world" forms the basis of a planning cycle that we can deconstruct into the following interconnected steps of procedure: "comprehension of the situation", "elaboration of instructions", "communication about behavior", "interventions", "spatial, social, ecological, economic, and political-administrative settings", as well as "outcomes". The outcomes can give rise to a new comprehension of the situation, which, in turn, can initiate a new planning process (for further details see Schönwandt, 2002, pp. 30ff; Schönwandt, 2008, pp.19ff). Since the understanding of these steps and the specification of the related attributes usually differ in diverse cultures, there is the

need for an overall theoretical framework that can integrate these. Due to its systemic approach, the planning model of the "third generation" provides an appropriate analytical tool to map the manifold aspects related to the concepts of resilience and culture. Further details on this issue and illustrating examples will be outlined in the following chapters.

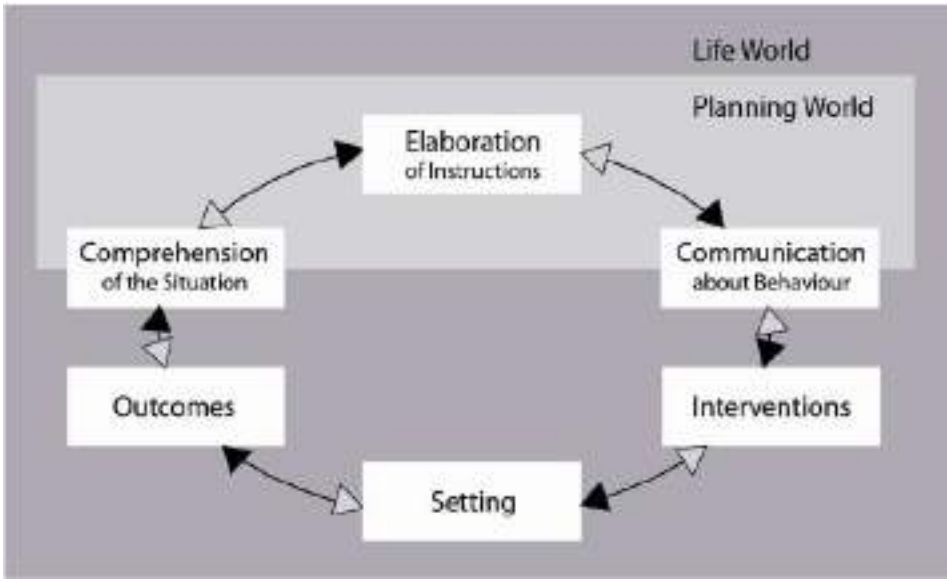

Fig. 1: A planning model of the "third generation" (Schönwandt, 2002, p. 47, modified)

With regard to cultural differences and their impact on the adaptation to environmental conditions, quite often non-European countries have more and longer experience, because they have faced the challenges of large-scale migration much earlier and those migrants have been exposed to extreme environments. For example, Stephenson (2008) studied how the Maoris and the European settlers in New Zealand perceive their environment and everyday landscape. She found out that the settlers mainly realigned to the "surface values" (perception of physical landscape elements, forms, relations and practices), whereas the natives oriented themselves more on "embedded values" (awareness of inclusive values, narratives, symbols, memories and emotions). Based on the results of her empirical study she developed the "cultural values model" (Stephenson, 2008, p. 136; see fig. 2) that incorporates three basic landscape constituents (forms, practices/processes and relationships) as well as temporal aspects (cultural dynamics and relationships). Such case-studies in non-European countries can serve as laboratories that can provide knowledge and lessons learnt with regard to cultural diversity.

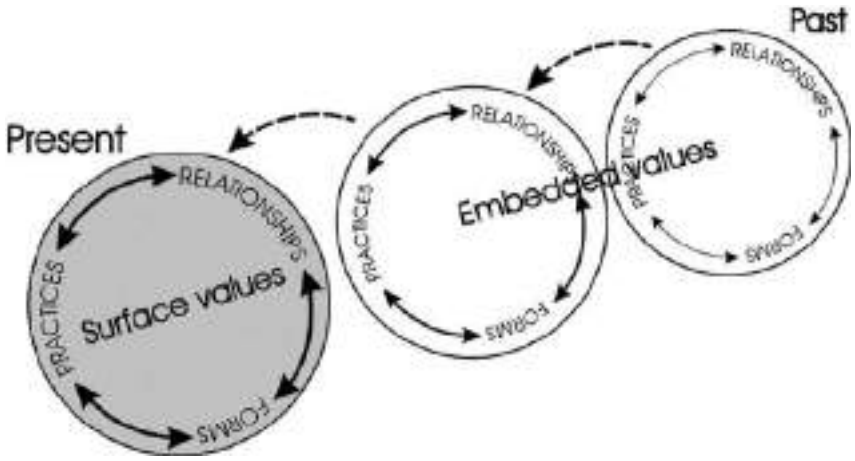

Fig. 2: "Cultural Values Model" (Stephenson, 2008, p. 136)

Taking recourse to the planning model of the "third generation" (Schönwandt, 2002) and the "cultural values model"(Stephenson, 2008), the interlinkage between the concept of culture and the concept of resilience can be explained in more detail: Firstly, there are cultural differences in the way planners think and act, i.e. there are diverse planning approaches depending on the knowledge and professional background of a planner. Secondly, the "life world" consists of manifold stakeholders with diverse interests, attitudes, and values that act within different arenas and incorporate diverse agendas. Thirdly, within the planning cycle itself there are cultural differences with regard to the comprehension of a situation and its assessment (problem definition), the communication of the behavior, and the implementation, i.e. the interventions (for further details see Jung, 2008). Fourthly, planning never takes place in a vacuum, but is situated in certain cultural contexts that can change offer time, especially when new individuals or group of individuals enter the scene; thus planning issues are treated in different ways in diverse cultures and over time.

Keeping this in mind, it can be concluded that tension arises between the aim of finding common or transferable solutions for resilient urban areas and of considering cultural differences. For the development and implementation of strategies and measures towards urban resilience that respects cultural features, we have to be aware of the common characteristics of the two concepts of culture and resilience; they:

- are multilayered, i.e. a high number of aspects are to be considered;
- focus on the process;
- are temporal dynamic (not static);
- comprise interrelated components that depend on each other;
- involve a high number of stakeholders with competing interests.

Restrictively, it has to be mentioned that the interrelation between (planning) culture and resilience needs to be further explored. Can resilience really be attained by (formal) planning? Or is it more or less the result of a sum of determining factors,

among others the culture of a region/country or a specific discipline? So far it can be concluded that the characteristics listed above underline the high complexity of strategic planning processes. This aspect can be regarded as one of the main reasons why the concepts of planning culture and resilience are less incorporated in planning practice until today. In the following chapter we will exemplify this intermediate result by providing practical examples from the workshops conducted within in a project on climate mitigation and adaptation.

3. Initial Tools and Approaches in Strategic Planning Processes and their Practice within the Project ClimateMORO "Spatial Development Strategies for Climate Change"

The impact of cultural differences on strategic planning processes towards urban resilience can be exemplified by three initial tools that determine these processes and can be a source of misunderstanding between diverse stakeholders involved; these are:

a) the problem definition and the problem shifting (part of the planning step "comprehension of the situation in the planning model of the ´third generation´"),
b) the use of key terms / language that plays an important role at all planning steps and
c) the planning approaches which are the core element of the "planning world" in the model.

Some cognitive tools or thinking approaches can help to overcome difficulties evoked by cultural differences. These tools were taught to the participants of three workshops on climate change adaptation with relevant stakeholders in the region of "North Black Forest / Middle Upper Rhine", South West Germany. Those workshops were part of the project "ClimateMORO" (2009-2011) which was commissioned by the German Ministry of Traffic, Construction and Urban Development. Examples from the discussion are given below (cf. Hemberger, forthcoming; see also RV NSW/MO, 2011).

Ad a) In the beginning of a planning process it is necessary to clearly define the problem to be solved. Otherwise we cannot develop a coherent argumentation from the problem to its solution. In our understanding a problem is the description of situation (A) plus the negative assessment by an individual resp. group of individuals – in short: A(-). Thus, the assessment of a problem is a subjective interpretation, i.e. it is "socially constructed" and depends on the perception and the background of the stakeholders involved (profession, ethnic group, etc.). At this point the cultural differences regarding values, attitudes, interests etc. become apparent (see above chapter 2).

If someone does not consider the components of this simple thinking approach, A and (-), it will certainly result in difficulties: For example, during one of the three workshops on climate change adaptation mentioned above the topic was discussed

that the arboreal range of species will change due to climate change. But what is the definite problem thereby? After a long discussion it turned out that different reasons were relevant for the stakeholders in order to assess this fact as problematic/negative; these were:

i. the existing technology of the wood-working industry cannot cope with the type of wood that is produced by new tree species (economic reason);
ii. the loss of the traditional landscape scenery (cultural reason);
iii. the decrease of tourist numbers due to the loss of the landscape scenery they are used to (economic reason);
iv. the changing arboreal range of species itself is seen as a problem (ecological resp. ethical reason).

Each of these problem definitions (respectively negative assessments) depend on different planning cultures and will lead to different action and specific measures in order to solve the problem. Planning cultures that are determined by the conception that nature is an economic resource for business (see above point (i)), will lead to measures that adapt the equipment and machines of the wood-working industry to the new conditions. In contrast, those who judge nature as a value on its own (see above point (iv)), will develop measures for the protection of the existing arboreal range of species. Hence, within interdisciplinary planning processes it is important to precisely define the problem to be solved and to attend the respective cultural imprint of the stakeholders involved. Only to examine the same state (arboreal range of species) is – as shown above ! – not sufficient, in order to clarify the problem and to introduce appropriate measures.

In addition, it might be helpful not only to define a problem, but to shift it by analysing the possible outcomes of this particular problem. For example, with regard to climate change the strategies and measures will firstly focus on avoiding or decelerating this phenomenon, e.g.:

i. avoiding climate change by reducing CO2 emissions;

However, if we consider the complex interrelations of this problem and its causal effects, for instance the heat island effect in urban areas and its effects on the health of elderly people, we will certainly come to further and more specified strategies and measures, e.g.:

ii. technical and other planning solutions such as air condition, white coloring of the buildings and facilities, tree planting to increase the coldness by evaporation;
iii. physical training, especially of elderly people, to make them more resistant against heat effects.

The first strategy (i) includes an approach of avoiding negative impacts of climate change, the second strategy (ii) focuses on technical solutions, and the third strategy (iii) ask for the capability of the people to adapt to the changing environmental conditions. Each of these approaches is determined among others by the diverse

cultural expressions of the stakeholders involved which make its implementation a challenging task.

Ad b) Another essential task is the appropriate handling of the language and the definition of key concepts. Since in international and interdisciplinary projects planners will meet a great variety of stakeholders from diverse backgrounds, it is necessary to define key concepts and terms. In doing so, the communication on the contents and the procedure of the project is facilitated. Such definitions must be beneficial to the key question or the problem examined because they determine the planning actions by opening or closing search areas for solutions. Today, planners too often suppose that the professional concepts they use are well-defined and understood in the same way by all parties involved. Moreover, planners have to be aware that concepts are not "true" or "false", but rely on agreements and on the backgrounds of the people who use them (for further details see Schönwandt, 2002).

An example from the workshops mentioned above is the definition of "age" regarding sensitivity against heat. During the discussion it turned out, that not the age counted by years is meant, but an umbrella term that cumulates certain attributes related to the heat sensitivity, i.e. lack of fitness, being bed-ridden, poor living situation, dehydration, lack of air condition in retirement homes, social isolation etc. Because the data collection is less costly for only a single indicator these attributes are summarised and ascribed to all people at the age of >75 years (PIK, 2005). In this way, the relevant data can be easily collected from the statistical offices and forecasted by demographic scenarios. However, for architects and planners this low level of granularity is a disadvantage because it hinders the development of suitable measures aligned to the more detailed attributes mentioned above, for example installation of air condition, physical training of elderly people etc. Often certain disciplines, in this case architects and planners, borrow broad definitions from other disciplines without being aware of the potential for further solutions if a more detailed level of definition would be used.

Hence, it is important to find the appropriate level of granularity for each discipline, in order to sharpen up communication in international and interdisciplinary projects and to reach successful cooperation and results in planning processes. With increasing complexity, this is even more important for strategic planning processes towards urban resilience.

Ad c) A planning approach comprises a set of four bonded and interdependent components: the problem(s), the objective(s), the method(s) and the specific background of a planner, particularly his/her ethical positions, values etc. (Kuhn, 1981; Bunge, 1996). Planning is never based on objective world views, as these depend on the observer and his/her point of view – the "glasses" through which planners see a given situation. According to the paradigmatic approaches of their discipline, planners construct the problem, the factors that cause a problem and the deduced strategies and measures in a discipline-specific way. This professional bias leads to the narrowing of perspectives since each planning approach only allows for a limited range of problem definitions, objective settings and problem solutions (Schönwandt & Voigt, 2005). Moreover, planning approaches can transform over

time, when the underlying philosophical and ethic positions change. For example, Davy (1997) discussed the controversial viewpoints of "social justice" and "liberalistic justice" (Davy, 1997) that affect many planning topics regarding the living conditions in regions and municipalities. Such paradigm change often modifies the understanding of planning and the development of strategies and measures.

To exemplify this, we revert to the example given above with regard to problem definition (ad a)), where the diverse viewpoints on the value of nature play an important role. On the one hand, there is the position that nature possesses an intrinsic value and men should protect nature (see above the protection of a certain arboreal range of species). On the other hand, there is the position that men are superior and nature presents a useful resource to him (forestry and wood-working industry). These opposed positions illustrate the diversity of values and how they influence planning (see also fig. 3).

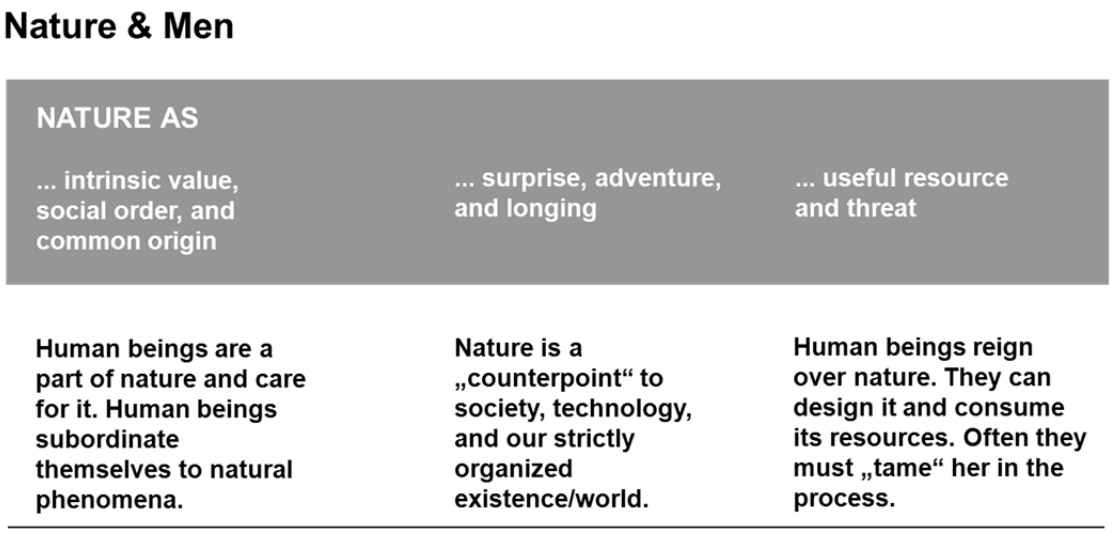

Fig. 3: „Nature and Men" (Gill, 2003, p. 54; modified)

With these three initial planning tools – problem definition (comprehension of the situation in the "planning model" above), key concepts, and planning approaches – cultural differences go along. As shown above, they can be a source of misunderstandings between different stakeholders in planning processes.

4. Cultural Determinants of Strategic Planning Processes towards Urban Resilience

There are several links where cultural issues interact with the pursuit of resilient urban areas and societies. Facing the challenges of climate change adaptation and urban resilience, innovative strategies and measures are necessary. With the

increasing number of stakeholders and interests included the complexity of strategic planning processes increases significantly. The cultural factors that determine these strategic planning processes can be summarized as follows:

a) the background of the individual resp. group of individuals involved (education and profession, mental models, values, attitudes, interests) - see workshop examples above;
b) the interaction of the personal and social identity, the belonging of an individual to a certain group, and the "collective memory" of a society influenced by historical experiences and traditions – these issues and their influence on spatial planning processes has been studied for example by Hasselsberger (2010) who analyzed two regions at the Austrian-Slovenian and the Austrian-Italien border (cf. Hasselsberger, 2010).

In addition, with regard to strategic planning processes towards urban resilience other cultural factors become apparent:

c) the institutionalization of values in planning processes (legal framework, rites etc.);
d) the political will for adjustment and innovation; and
e) the cultural context in which a planning process takes place.

How diverse the latter is in different countries and how much this determines the basic pre-conditions for strategic planning can be imagined if we look for example at the different education systems that provide (or does not provide) knowhow and skills to the stakeholders (cf. OECD, without date). Another determinant is the sense and handling of time which differs to a large extent in diverse cultures as it has been studied for example by Levine (2004) who analyzed the speed of pedestrians in different cities around the world (cf. Levine, 2004). Summing up, both aspects – education and sense of time - will certainly influence the way, how the stakeholders involved can develop and implement strategies and measures towards urban resilience.

5. Conclusions and Outlook

Based on the planning model of the "third generation" (Heidemann, 1992; Schönwandt, 2002) and the "cultural values model" (Stephenson, 2008) as well as on the definitions of the core concepts (culture and resilience), this paper explicates how cultural differences, both in terms of ethnic and discipline, influence strategic planning processes towards urban resilience. Examples from workshops with practitioners illustrate this issue. Moreover, certain tools are introduced that show how international and interdisciplinary cooperation can be enhanced.

From the aspects outlined in this paper it can be concluded, that if spaces often form physical barriers for a certain behavior, multiple planning cultures add yet another barrier to planning processes, because they steer the thoughts and actions taken. Planning cultures always comprise a set of social perspectives of a problem, the

envisaged objectives, the methods used to solve a problem, and the ethical positions and moral concepts of the stakeholders involved. With cultural plurality these elements of planning cultures are going to increase.

Due to the cultural plurality as well as the multilayer structure, processing, dynamics, and interrelation of components, strategic planning processes towards urban resilience are getting more and more complex. This concerns both the tasks of spatial planning as well as the framework conditions. The latter includes the multiple planning cultures which vary according to ethnical, discipline-specific, value driven, historical and other factors. According to each planning culture the action a planner takes will differ. Particularly with regard to complex problems, such as the interdisciplinary planning of a resilient city, the high diversity of planning cultures needs to be paid more attention to. Because more and more disciplines and thereby planning cultures work on more complex and cross-linked planning problems.

In this process, certain cognitive tools and thinking approaches can help to put away or at least to diminish cultural barriers and further obstacles. For example, the professional bias regarding the value of nature certainly impacts the planning result. Finally, for planning processes, political decision making, as well as international and interdisciplinary cooperation this means that

- more effort should be spent on cultural awareness in planning and decision-making;
- planning processes must consider more intensively the diverse backgrounds and approaches of the stakeholders involved;
- possible misunderstandings and barriers must be traced right from the beginning of a planning process;
- beyond the tools and approaches mentioned above, further work techniques and ways of proceeding should be researched in order to avoid such misunderstandings and to initiate learning processes among stakeholders;
- a paradigm change in society needs to be fostered that assess cultural plurality as enriching and a potential basis for innovation.

However, open questions remain that need to be further explored:

- Can urban resilience really be attained by (formal) planning? Or is it the result of a sum of determining factors including culture that can hardly be influenced?
- Are there groups of stakeholders, e.g. certain professions or ethnic groups that present typical mental models, interests, attitudes, and values? And how do these components of diverse planning cultures affect the thoughts and action of these stakeholders?
- Which policies and best practices to achieve urban resilience are already used in different regions and countries and how are they evaluated?
- How probable is the development and implementation of an integrated transition strategy towards urban resilience against the background of diverse cultures and approaches?

These questions and other topics will be further studied in the ongoing research projects COST IS1007 "Investigating Cultural Sustainability" (www.culturalsustainability.eu/; cf. COST Secretariat 2010) and FP7 "TURaS – Transitioning towards Urban Resilience and Sustainabilty" (www.turas-cities.eu/; cf. Seventh Framework Programme 2011).

REGIONAL PLANNING FACING GLOBAL CHALLENGES: ISSUES AND PERSPECTIVES IN THE ITALIAN CASE

Giuseppe De Luca[°] e *Valeria Lingua*[°°]

1. Introduction

This paper focuses on the models and practices of regional spatial planning activated in Italy in recent years, in order to evidence the innovations that occurred and challenges that Regional planning institutions are facing. Just after the devolution of local power in Italy in 1977, spatial planning competences began being organized into Regional Institutions. Each of the twenty new Regions must make a Territorial Regional Plan (Piano territoriale regionale) together with a Regional Landscape Plan (Piano paesaggistico), possibly in connection with a Development Regional Program (Programma regionale di sviluppo).

The first experiments in regional planning, carried out in the 1980's and 1990's, have led to the formation of territorial plans with an indicative planning setting, the development of special regional areas, and the planning of infrastructure, such as road networks and railways.

The new millennium opened with two important changes that have considerable influence on the nature and form of regional planning:

- the amendment to Title V of the Constitution (2001) that, by incorporating the principles of subsidiarity, adequacy and differentiation, has reversed the institutional hierarchy in favor of municipalities, making it urgent to reflect on the role of the Region and its planning territorial instruments;
- the approval of the National Landscape Code (2004), which has modified the landscape issue in the statutory of national and regional regulation.

These changes have generated important revisions of legislation at the regional level. A review of the regional spatial plans reveals that although the plans have different forms and work according to different timelines, they address one common need: to overcome the traditional approach to regional planning system with a set of innovations.

In this direction, the latest experiments abandon the traditional approach to regulatory coordination, turning to a regional territorial plan . A mixed model, characterized as strategic, structural and operational at the same time, the regional plan is required to convey an idea of the future, a common goal, and a shared vision. It is supported by a set of guidelines for the protection and enhancement of the elements of identity in the region and is made explicit in specific territorial projects. From a multilevel governance perspective, the local and provincial bodies are called on to share and specify both the regional

scenario and the operational scenarios. This specification must also be accomplished through the coordination of bottom-up and sector-based planning in terms of coherence and conformity to the directions defined at the regional level.

Together, various cases of recently formalized planning (Veneto, Emilia-Romagna, Lombardy, Tuscany), some cases-in-progress (Friuli Venice-Giulia, Piedmont), and the case of an interregional experience of coordination of regional spatial strategies carried out by eight Regions under the name of *Padano-Alpine-Maritime Area* can provide a framework for these reflections.

The paper addresses these innovations.

2. Nature and form of the new Italian regional planning

Through experiences in regional planning coming to fruition at the turn of the late 1990's and the new millennium, we can identify three major trends:

- the first, expressed mainly by Regional Territorial Plans of the Valle d'Aosta and Umbria, seems to still be strongly anchored to the model envisioned by the traditional Law no. 1150 of 1942: a unified plan to coordinate and address, giving an overview of the issues of territorial government, through a subdivision of land for fields and an explanation of the program lines in the region, in close connection with the regional program development
- the second, a strategic concept of regional planning, is made explicit through the construction of shared vision and cooperation of the scenarios of perspective, as in the case of the Territorial Indicative Plan in the Marche Region and/or of the Piedmont Regional Spatial Plan
- the third, a structural approach to regional planning, is one in which the regional plan is considered a real "warranty" actor for all of the choices which are considered to be priorities for the land, landscape and environment. The indications of the plan are aimed to build consensus among the institutions in order to ensure resource quality and resilience of the reference system. This approach is developed in the experiences of the Tuscany and Liguria regions.

These three trends give rise to different forms and characters of the regional plan, as well as different modes of interaction, each having various limitations and opportunities.

All offer meaningful forms of interaction: the first, a hierarchical system, allows a clear distinction regulatory apparatus which enables public and private entities to have a clear awareness of their responsibilities and the scope of their autonomy. The second involves the construction of a coherent vision of the region among the various institutions, reinterpreted in a unique strategic vision. The third identifies factors to be considered as spatial structures of territorial identity (be they physical or intangible resources, social or cultural capital) and, as such, be subject to rules and performance criteria to allow for protection and reproducibility over time.

In all cases, the interaction required to give form to the regional plan involves critical issues: the joint rules of the Regional Territorial Plan of the Valle d'Aosta and the Regional Territorial Plan of Umbria assume that all of those involved in the governance of the territory are cooperative and willing to work together. This is because the objectives are not local, but

are of general interest. It also requires that the regional and local authorities take an active and constructive role in the process of transformation and development.

In the case of strategic regional planning, the likely limits are related to present interests within the political market, without taking into account possible future interests. While moving away from more traditional territorial coordination plan, in fact, collective interest can be considered as pertaining only to the interests of so-called "strong", that is, those who are organized and structured.

Structural regional planning also tries to consider the interests of the weaker parties. This gives rise to an instrument consisting of a set of elements characterized by the nature, dynamics and different degrees of uncertainty and inconsistency. As a result, the instruments sometimes penalize the design aspirations, reducing them to tools for defining "structural invariants".

However, the latest plans, newly approved or soon to be adopted, appear to show a decided movement toward the reconciliation of these trends in the same instrument landing. A new trend may herald the desired formation of a mixed system of planning that contains within it both structural and strategic elements.
The "mixed" nature of the regional plan seems to resolve the dichotomy between strategic and structural planning which is highlighted in the experiences at the turn of the 20th century and the beginning of the 21st century. Rather than being considered an element of incoherence of a structural plan, the presence of elements with cogency and different degrees of uncertainty creates a point of strength when inserted in a strategic plan. The term strategic refers a sharing process which helps define a shared regional vision. It also refers the product of such sharing, that is, a plan which is broken down into strategies, goals and actions to be followed accordingly, in a more or less prescriptive manner.

In this sense, it is possible to find consistency between a strategic vision which is more focused on economic development and visions which are more oriented to the protection and enhancement of the environment and landscape.

Most recent regional plans, therefore, are not only strategic or structural, they have a mixed valence in which there is predominant tendency i towards a balance among the different natures. Balance that comes from "eclectic" processes of formation of the regional facility, which offers some form of institutional cooperation, participation and inclusion of very different interests, results not only in creating regional legislation, but also the political and technical imprint given to the plan.

In relation to finding a balance between the three dimensions of the regional planning (strategic, structural, land-use oriented), we will highlight some common issues and experiences in the emerging regional planning in progress, all converging towards the identification of appropriate forms of cooperation:

- the construction of strategic vision with multimedia tools and methods, as is reflected in a plan aimed at defining the vision, objectives and actions that revolve around the strategies outlined in the form of intriguing slogans (as in the case of Emilia-Romagna and Veneto) and involve the interests increasingly marked by experiment, in addition to traditional instruments (Lombardy), and modes of participation involving citizens in a broader sense (Veneto, Apulia, Tuscany).
- the relationship between spatial planning and landscape planning, which assumes very different shades because of how the two dimensions are conceived in the regional legislation. The regions, in fact, may choose to provide a landscape plan in addition to the regional spatial plan, or they may choose to merge the two

dimensions (landscape and territory) within the spatial plan. In any case, to avoid the excesses typical of strategic planning (non-inclusion of weaker interests and future interests), the identification of identity elements (structural invariants) and the definition of strategies for the protection and enhancement (landscape quality objectives and guidelines) involve a wide cooperation and the capability of acknowledging and addressing the complexity of territorial interests.

- finally, the operation of the plan is resulting in the identification of design areas at the regional level (Lombardy, Marche, Campania, Liguria) which are able to stimulate public interest and private agencies, both in terms of the local practices of area-wide planning (inter-municipalities, unions of municipalities, etc.) and through the identification of possible areas of inter-institutional cooperation (Friuli Venice-Giulia, and Piedmont).

The current experiments evince a new turn towards co-planning, and while the activation of widespread participation practices is still in an embryonic stage, there are episodes of great interest. In particular, the theme of the landscape seems to imply a close search for consensus on the resources to protect that, at the regional level, requires more consideration of both the weaker and more general interests. It should be noted, in light of the first experiments, that the regional level necessarily implies a selection of interests and actors through a process which can occur in several ways:

- through self-selection, when meetings, conferences, etc., are called which involve institutional entities, citizens and associations. As already noted for conference services, the very act of attending the conference and presenting the plan would entail the consideration of its contribution, while non-attendance has the value of self- exclusion
- randomly, when the process is based on the extraction of a larger representative sample of participants, as in the case of the town meeting
- through a combination of the aforemented approaches, for cases in which sample-areas and pilot projects are identified, and the use of localized participatory practices is activated.

Finally, the operation of the instrument is one of the main characteristics of the newest generation of the regional territorial plan. This involves implementing strategies which more and more oriented to the identification of contexts for regional or thematic projects.

In most cases, the regional level foreshadows programs and integrated projects covering a range of topics and areas of particular weaknesses and particularly problematic. If at first, this orientation to the project seems more evident in those plans that promote a strategic approach to planning, it is now an integral part of most more recent regional plans. Already, the regional territorial plans of Liguria, Marche, Umbria and Campania provided for an extensive use of operational tools with multiple definitions and objectives (regional initiative projects, pilot projects, integrated projects, project areas in the Regional Territorial Plan of Liguria, shipyard projects in the Marche region, field projects in the Campania Regional Territorial Plan, and plans and programs in the Umbria Region). Today, the latest plans make extensive use of tools and programs that include character design, as well as inter-institutional cooperation and the intervention of the private sector.

It is clear that the identification of areas of regional planning involves the activation of a direct relationship between the region and the specific interests that focus on the design theme identified on the scope or area defined in the plan. Strongly related to this way of understanding the operation of the plan, through thematic or territorial projects at the

regional level, is the identification of areas for for intervention or co-planning above the local level.

In some regions, in fact, there is an evident link between territorial cooperation and the operation of the regional plan, for which the identification of geographical areas based on historical characters, and socio-economic identity is not only aimed at the specification of objectives and policies of the plan, it is also the basis for how to activate co-planning and institutional cooperation. It is the case, for example, in the Piedmont Regional Territorial Plan (PTR), approved in 2011, which identifies 33 Areas of Territorial Integration (AIT) and defines them as supra-regional systems. These areas represent the aggregation of systems against economic social, and territorial decline.

To these areas, the plan takes an compliant approach to urban spatial planning , in order to provide for "government guarantees" (environmental protection, standards, monitoring tools, etc.). This is a multilevel governance which activates a process of interpretation-design-decision to be implemented both in each regional system and at the local level. Decisions may result from governments' specificity, from traditions and from values expressed by local communities.

In summary, the current experiences show a common issue related to the possibility of implementation of the regional plan: the strategic vision conveyed by the spatial plan necessarily requires an effort of integration among policies for large areas, including financial policies. The Regional Spatial Plan, in fact, suffers from two problems. Firstly, it needs to include estimates of regional development in a framework that offers increasingly globalizing trends. On the other hand, the regional plan is affected by difficulties affecting some industries more than others, difficulty reconciling the need for effective correspondence between the policies of the regional plan and the provisions of the Regional Development Plan (PRS). The political will to implement certain actions rather than others still determines the emergence of the strongest themes (mobility, living, renewable resources, etc.), since they are better funded and supported at the political level, as opposed to issues such as weak rural areas and the landscape.

In this case, the experiences in Tuscany and Piedmont seem the most interesting while the regional program development one developed in Apulia is more strongly bound to the political landscape with.

The years 2007-2013 were marked by a strong period of ~~of~~ hybridization between the two dimensions in the construction of regional strategic frameworks. While in some regions (Emilia Romagna and Lombardy), the strategy was built through policies and actions related to the programming of resources to planning, in other cases (as Tuscany, Umbria and Marche) the strategies were built together, so there has been a real territorialization of policies. Throughout this last experience, however, the relationship with the State has been inconsistent and sometimes it did not take into account both the national strategies and the possible interregional strategies.

Despite being characterized by advanced tools, spatial planning systems (Plans and regional) of the regions of central Italy failed to generate a collaborative process. Collaboration was not possible even when the Ministry of Infrastructure and Transportation had proposed "regional platforms" as strategic areas of cooperation, within the *National Strategic Framework 2007-2013*.

3. Horizontal forms of governance: the inter-regional table of *Padano-*

Alpine-Maritime Area of the North Italy

The definition of an interregional experience of coordination of regional spatial strategies was mainly driven by the need to shift some weight away from the European context. The approach can be considered a particular and significant one for the evolution of the regional plan in Italy: the process of collaborative governance organized around an Interregional Table which aimed to develop a Padano-Alpine-Maritime Zone in Northern Italy.

The Interregional Table was created in 2007 and included the regions of Veneto, Emilia-Romagna, Friuli Venice-Giulia, Piedmont, Lombardy, as well as the autonomous provinces of Trento and Bolzano. It served as a moment to capitalize on the institutional learning conveyed by their participation in the EU's Metrex network. This new cooperative form was intended as a technical working community, firstly aimed to build a shared cognitive framework within which strategies could be generated for the sustainable development of the first so called "Adria-Po Valley".

The Interregional Table is a committed that was designed to identify a system of coherences and to promote the competitiveness of the regions concerned, both in the new context of European development and within the media planning. In practice, it was created as a space for discussion and exchange of knowledge in the process of construction of instruments of regional planning, with the aim of promoting, on an ongoing basis, initiatives for the comparison of relevant inter-regional issues.

The Interregional Table also aimed to acquire a role as a forum for the sharing of a common position regarding the construction of the Territorial Agenda of the European Union, an agenda which is also based on the sharing and dissemination of results of trans-national and trans-border cooperation activities .

This committee, politically motivated, is supported by a technical committee which prepares materials and activities for the Interregional Table itself: in fact, after the signing of the Charter of Venice, it soon became clear that the real promoters of the Table were those of the technical regional administrations, appointed for the formation of governmental instruments for the territory (regional territorial plans and regional landscape plans).

The Interregional Table forAdria Po Valley was then immediately established for a "technical discussion", in which the revision of spatial planning instruments became the common theme of the exchange. Many regions were preparing the new regional territorial plans and this forum facilitated comparison during the meetings, as evinced by the themes for discussion: «the protection and enhancement of the natural environment and the strengthening of the economic system and the networking of excellence; the development of cities as engines of the future; strengthening the connections and intangible assets; the promotion of innovation activities and research and the promotion and enhancement of best practices to reduce energy consumption and combat climate change» (Interregional Table, Venice Charter, 2007).

The first results of this experience, presented in July 2008, led to the creation of three landscape- related charters for a shared vision of the Padano-Alpine Area, concerning the system of ecological structures, the layout of infrastructure networks and the system of urban polarity.

This vision was built expressly to form an intermediate level of knowledge between the European level (usually borrowed from the ESPON program) and the regional level. For this purpose, there has been an analysis of the area of the relationships and influences of some urban centers and infrastructure systems and systems of other nuclei and, in general, the

spatial contexts of belonging, which often go beyond the regional borders. The vision, which has been defined as a “gentlemen's agreement”, was inserted directly in the planning tools through a sharing process at the technical and political meetings, which were held in each region. Between 2008 and 2009, those regions with more active participation have formalized their instruments: Veneto, Emilia-Romagna and Lombardy have received approval, and Piedmont has adopted the plan. In all cases, the scenarios prepared have been incorporated into the plan, particularly in the cognitive frameworks.

The year 2009 is considered a stagnant period, due to a change of legislature in almost all regions which led to a lack of sharing at the political table. After launching a committee which emphasized balance between politicians and lobbies at the European level, the political participation (and therefore the interest) seemed to slowly wane. The technical component, however, continued to meet regularly, both for the promotion of initiatives in cross-border and transnational cooperation (participation in tenders ESPON and Interreg), and for the sharing and dissemination of the results of project activities. In addition, interregional coordination (in its technical component) has been indicated as a reference for the ministerial committee appointed to integrate the requirements of the Leipzig Charter.

The technical component has thus promoted the continuity of the committee, which first took the political path on October 12, 2010 through the signing of the *Pact for Sustainable Development of interregional Padano-Alpine-Maritime Area*, and then through the signing of *Bologna Agreement*, January 27, 2012. In fact, a new program of committee activities is set to begin under the new administration , based on the following objectives:

- promoting the area of the Mediterranean basin as the most important macro-region for central Europe (with its 120,000 square kilometers and 27 million inhabitants, the production of more than 54% of Italian GDP, the largest share of research and for its innovation)
- sharing policies for the regional territory and the landscape, through the definition of strategies and objectives for the recognition of the importance of macro-alpine region of the Po Valley in the European context and at national level, in particular relating to landscape matters
- implementing coordination in the strategic planning of large areas, which comprises development, environment, landscape, location of major functions and infrastructure, defining common rules to ensure efficient use of resources, and the containment of land consumption
- building a map for landscape identity in order to link the policy of protection and enhancement of landscape with strategic environmental assessment
- spreading good practices.

The final goal, therefore, is the certainly the need to transform a common vision (at the time, more oriented towards knowledge than to projects) in a model of self-representation and of a strong and valid territorial marketing in order to compete in the European space.

It is necessary that this vision be reinforced by other Italian regions, especially those of Central Italy, even if it is not yet fully realized.

4. Conclusion

The focus of the paper are the theories and practices of regional spatial planning activated in Italy in the last 20 years, in order to evidence the innovation which occurred and the challenges that regional planning institutions are facing.

Compared to a theoretical framework and regulatory environment that tends to separate the different areas of planning (landscape, land, cultural heritage), the evolving experimental framework outlined by the most recent experience of regional planning is characterized by pluralistic approaches in which, in the face of the widespread use of strategic rhetorical orientation, different aspects of planning seem to prevail at various times (alternatively, strategic, structural, or both).

The new regional plans, therefore, are not only strategic or structural, but have a mixed valence in predominately striving for a balance between the different natures. The balance comes from eclectic training processes of regional facility, which offer some form of institutional cooperation, participation and inclusion of very different interests, resulting not only in regional, policy and technical legislation, but also the political and technical imprint given to the plan.

The problems of consistency of views on the one hand, and social equity and distribution on the other, seem to find a synthesis when the following elements are identified within the same regional territorial plan:

- a vision for the future with fewer in strategic objectives, so the nature of the regional plan has a long-term time horizon
- structural elements which are required for performance and quality criteria, with medium to long- term horizons, especially in reference to the system of landscape protection understood as a cultural product and identity;
- operative projects and programs that collect instances of the territory of the meeting and therefore involve a feasibility of short-medium term.

In a context dominated by globalization, the future vision, as well as operational programs and projects, necessarily require a leap in scale that allows for movement outside the regional boundaries and into to macro-regional areas located in a specific European space. In this sense, regional authorities have already recognized that the notion of 'legal region' is weak; and that a new "soft" association is the future strategy. In this context, interesting examples of intraregional and interregional cooperation are maturing: the example of the Interregional Padano-Alpine-Maritime Area in Northern Italy is one that has possibilities.

The experience has provided a unique opportunity to activate a process of co-planning at the supra-regional scale- planning that is characterized as bottom-up and not imposed from above. The simultaneous preparation of spatial plans in each region allow for the representation of the area as macro-region through a shared vision and common indicators. At the same time, it allows regions to work together on common themes, translating them into a set of skills and strategies that have a common language for all the regional instruments.

However, the potential of this approach does not seem to be fully explicit: the regional planning documents, for the most part, treat the vision as a piece of a cognitive framework, without a real inclination to the project. This is due to the lack of an approach geared to action, which will lead to an , effective coordination expressed by the various plans, if not an actual strategic plan. While this coordination is indicated in the objectives of the new cycle of the Interregional Table, it should have emerged earlier during the phase of drafting the instruments- instruments that are by now institutionalized and, therefore, not subject to

revision.

If this weakness emerges at the national level, within the EU, it is likely to be amplified. The degree to which weakness will be amplified will depend on the nature of cooperation, the size and characteristics of the partnership, and relations with the European Union.

To free itself from the characterization as a community-based project and really project itself in Europe, against the local marketing done by creating a shared vision, there should be a strong political marketing operation of the committee, to boostits value and capability as an instrument of interregional co-planning in the broader landscape of European development...

In this sense, institutional arrangements for the partnership must be established. These may be based the European model of the EGTC, or even without creating new institutions, as envisaged in the recent macro-regional experiences. Such arrangements will give legs to the table, through formal agreements on inter-regional strategies that are able to project Northern Italy in the the competitive system of the European Union.

The other regional experiences seem too weak and little prepared to set up macro-planning experiences in Central or South Italy. In this sense, only the Northern macro-region, which has already taken wing, can be a real example of competitiveness in the European system.

Competition must be built, nationally and across regions, through a substantial effort to integrate the regional spatial planning and development policies so that there is a profitable relationship between local-regional and global.

In this framework, the Regional Spatial Plan can play a key role in providing a regional development strategy for the next season of the Structural Funds (2014-2020. It is the tool that - when integrated with the Regional Development Plan - can provide a territorialized vision of development strategies, to meet the objectives of territorial cohesion with place-based strategies (Barca Report, 2009) and inter-regional strategies, based on shared projects and geographical areas that go beyond the institutional boundaries.

To take on this ambitious task, the Regional Spatial Plan can only assume a cooperative nature, made explicit through processes marked by inclusiveness and capable of :

- systemizing, the different options of the regional government, in particular the different interests and the different governing options they have pursued;

projecting these options into the broader framework of the relevant macro-reference area (in Italy we can speak of north, central or south) through inter-regional planning experiences like that of the Po Valley -Alps-Maritime. A thorough national strategy based on its regional cooperation will facilitate entrance into the system of European territorial cohesion.

Stronger political support, as well as the development of innovative practices provided by operative interregional projects, can play an important role in improving and strengthening the interregional tables, leading to a real cooperation of a scope in which geography and economy converge to develop the necessary requisites of competitiveness and sustainability in an European and global panorama.

URBAN POLICIES AND PLANNING DURING THE GREEK DICTATORSHIP (1967-1974). CONTINUITIES AND RUPTURES IN POST-WAR DEVELOPMENT OF THE GREEK CITY.

Paschalis Samarinis[1]

1. Abstract

The Greek dictatorship has been a particular form of authoritarian regime. Many scholars question its totalitarian dimension and underline its military and oppressive character and its ideological contradictions. Its ideological premises were mainly shaped by post-war Greek-orthodox nationalism and a vague idea of economic modernization. Expressing certain interests of economic elites as well as the need for political legitimization, the regime appeared as the guarantor of capitalistic growth, promoting the idea of a private-sector-driven economy. The spatial consequences of such a political agenda have been crucial.

The dictatorship influenced in various ways the identity of Greek cities, their built and cultural environment. With the country already going through a phase of unprecedented economic growth and intense urbanization, the major role of the construction sector in economic activity was further promoted. An overproduction of legislative regulations, resulting in the loosening of public control, encouraged the intensification of investments of small and large capital in land and construction. Cities expanded, densities and building heights increased, industrial complexes and huge hotel buildings rose in ecologically sensitive areas of the country. Regarding urban planning, the regime's contradictory ideological background favoured a variety of proposals, from those reflecting a superficial perception of local identity to strictly technocratic ones.

Through an interdisciplinary approach, the research seeks the connections between the socio-economical, political and cultural transformations of the time and the mutations in urban theory and planning. In this context, it approaches the specific dynamics of the urbanisation process and the new trends in urban space production, by using material from the public discourse-media, bibliographic sources and planning projects of that time. The central question regards the continuities and

discontinuities in urban space production related to the violent political change from a democratic state to an authoritarian regime. Did the conditions for planning and implementing plans change and in what way? What has been the actual role of planners and the scientific community in this context? And, finally, in what ways have the policies of the dictatorship affected the public discourse on the city and planning in particular, after the return of democracy and during the period of democratic consolidation?

These questions refer, on the one hand, to the particularities of the historical and geographical context of Greece in the post-war period. On the other, they provide some key elements for discussing critically the political nature of spatial transformation, an issue highly important today.

2. Introduction

This paper is part of my ongoing PhD research on the crucial, for the Greek urbanisation process, post-war period, focusing on the years of the dictatorial regime, from 1967 to 1974. In the following pages, I will try to give an outline of my research plan and my theoretical and methodological choices. My focus here is on discussing the existing historical/academic knowledge for the period, on presenting the main questions that arise from a critical perspective of our recent history and on proposing a research process for answering these questions. Finally, I will give a brief outline of specific case studies so as to describe how this research framework is applied in certain cases. I should also note that since my research is still in progress, the paper has a "non-finito" character and the conclusions are more likely to be questions open for discussion.

2.1 Post war period and the urbanization of Athens: a general context.

Before moving to the issues described above, I will give in points a general framework of the first post-war urbanization of the Athens area. My emphasis is on the processes and dynamics I consider important for understanding the urban transformations and the planning ideology and practices, during that time.

Despite its ancient history, Athens as an urban system did not have a continuous, "glorious" history in time. The urban complex of Athens is actually a new city, built, mostly, during the 20th century and the post war decades (Biris, 1966). During that time it expanded rapidly, and to some extent uncontrollably, due to massive internal migration for economic and political reasons.[2]

[2] For demographic data, tabulations and mapping of the post war urbanization of Athens see the official source of the National Statistical Service of Greece (NSSG), and the work of research centres like the Center of Planning and Economic Research (CPER), the National Center of Social Research (NSGR) or the Athens Center of Ekistics (ACE). Lila Leontidou gives in her book on the urbanization of Athens a fascinating description of Athens' changing geographies by combining

This demographic and spatial transformation happened amidst an unprecedented dynamic of economic growth, starting in the early 1950s and lasting for almost two decades, until the international crisis of 1973. An extensive program of public investments in basic infrastructures steamed a particular process of spatial and economic modernization, while new fields for private investments opened in tourism, industrial activities and the service economy. The construction sector and the housing market obtained a central role in this process (Antonopoulou, 1991; Stathakis, 2000; Iordanoglou, 2003). Although the Greek "economic miracle" resulted in an overall rise of economic indicators, it also led to various forms of social and spatial imbalances, expressed in all different scales, from national territory to particular urban areas. As Lila Leontidou notes

> "Greece developed not through the organic transformation of indigenous productive forces, but from the penetration of capitalism of developed countries. This produces a polarization of its economy expressed in the national territory and intensified in the last 50 years. […] We witness in Greece a process of economic polarisation which is the exact opposite of the process of rationalization observed in the West." (Leontidou, 1977)

Important characteristics of Greece's particular modernization process have been the co-existence of a "modern", "formal" economic sector with a "traditional", "informal" one: the first, represented symbolically by large scale capital investments in public infrastructure, industry or energy production, while the second by a highly dispersed, small scale, private entrepreneurialism. These two "economies" developed over time a variety of interrelations and along with the administrative role of the capital city, explain Athens' strong attraction to new populations. It is not my intention to describe the structure of Greek post-war capitalism at this point, though its understanding is a precondition for discussing the state's spatial policies. I am referring instead to the crucial differences of Greek regional and urban structures from the cities of western or northern Europe. In the case of modern Athens the role of informal economies, of small scale land ownership and small construction capital has been decisive.

The rapid urbanization of Athens (and secondly Thessaloniki) has been a significant, though neglected by traditional economic research, factor of the "Greek economic miracle". According to recent research, its role in boosting the Greek economy, by channelling small and medium size capital in a chain market that involved from construction-materials industries to small time contractors, technicians, workers etc, has been crucial (Stathakis, 2000). In Greece, like in many countries of the "south", urbanization did not come as a consequence of the concentration of economic activity, but, rather reversely, through the concentration of people and capital it created the conditions for economic growth. This particular nature of the Greek post-

---

statistical with qualitative data and by emphasizing on strategies of allocation, and social and economic segregation (Leontidou, 1990).

war “urbanization without industrialization” is a key in understanding the state’s spatial interventions and policies over time (Leontidou, 1990).

Under the pressuring needs of this social, economic and spatial transformation, a “planning ideology” gradually gained support, initially among technocrats, then in certain political circles and eventually in public administration (Vasenhoven, 1995). Special reference should be made to Konstantinos Doxiadis and his pioneering work on the post-war reconstruction programs from 1945 to 1951. These programs, though, were policies dealing with a state of emergency (Vasenhoven, 1995).Again, it was in the 1960s that this “planning ideology” was recognised as an element of official policy making. The Centre of Planning and Economic Research (CPER) was established in 1959, and in 1964 its objectives widened so as to include the preparation of short, medium and long-term development plans, regional plans etc.[3] Around the same time academic institutions like the Laboratory for Urban Planning Research in the National Technical University of Athens launched their first regional development proposals (Vasenhoven, 1995).

The possible futures of the growing region of Athens became a serious issue among specialists from the late 1940s, when Constantinos Biris and Doxiadis presented their first proposals. In 1959 Professor Prokopis Vasileiadis was assigned to elaborate the Regulatory Plan of Athens and in 1960 Doxiadis presented his first plan for Athens implementing thus his theory of “Ecumenopolis” (Technical Chamber of Greece, 1974). In 1964 the American firm Wilbur Smith and Associates was invited by the government to elaborate a Transport Plan for Athens (Sarigiannis, 2010; Mitaraki and Basoukea, 2001). An active society of planners, many of whom were transferring their knowledge and experiences from abroad, was growing, promoting the idea of a systematic regulation of urban space to administrative circles and the public. Numerous plans for cities around the country were presented from 1960 until 1967, and issues of urban development and planning increasingly found their ways to the technical press and the public media.[4] This public debate had its “symbolic moment” in the 5th National Conference of Greek Architects under the title “The Problems of the Greater Athens’ Area”, where the alternative and sometimes opposing scientific and political proposals were presented (AGA, 1974).[5] The conference took place in Athens in the winter of 1966 just one year before the coup.

[3] The CPER was established by Prime Minister and iconic leader of the Right Konstantinos Karamanlis. Karamanlis invited Professor Andreas Papandreou, from Berkeley California, to be the first President and Scientific Director of the Center. http://www.kepe.gr/EN_Pages/home.htm.

[4] For a presentation of this public discourse as well as some of the development proposals of the time see the 1977 Annual Review of *Architecture in Greece*, in the chapter City and Regional Planning in Greece - a historical survey.

[5] D. Filippidis makes a distinction between a “rightwing” and a “leftwing” planning ideology. The first constructs “ideal models of modernization and national development with a gigantic capital city as the symbol of progress and dynamism”, while the second, “isolated from the centers of political power”, either totally denies central planning or introduces alternative perspectives with an emphasis on decentralization, spatial justice, reorganization of production activity and redistribution of resources. The first is politically dominant through the 50s and the 60s and between 1967-1974, while the second appears in a coincidence with the periods of social movement and claims in the mid ‘40s

This intensive activity of the planning community was perfectly reflecting the general context of the time both in Greece and abroad. On the social field, the rise of the newly urbanised populations and the consequent changes in the production structure, consumption patterns and social expectations coincides with a wave of social, political and cultural radicalization. This wave made a dynamic appearance in the urban public sphere from the early 1960s, pushing for progressive reforms of political and economic life, and consequently leading to the destabilisation of the traditional political system.[6] It was interrupted in many ways by the coup in 1967, to return as a historical factor in 1973, and during the years of the democratic consolidation (Hatzivasiliou, Rigos and Seferiades, 2008) But when discussing the conditions that allowed the establishment of a planning community and ideology in Greece in the first post war decades, we should also consider seriously the international context. Modernization as "Europeanization" has been a dominant political and technocratic conception in Greece throughout the 20th century and this had a serious impact on the ideology and the practice of urban planning. It has been noted that Greek planning has been a systematic import of ideology, methods and practices, from the context of the "advanced West capitalism", to a social and geographic formation that has been the outcome of highly differentiated historical processes (Leontidou, 1990; Vaiou, Mantouvalou and Mavridou, 2000).

This condition created over time a particular status which has been described as a clear disparity between theory and practice, between the produced plans and the actual spatial transformations (Filippidis, 1990). The post-war urbanization of Athens has been a characteristic example of this "not planned" spatial growth. Despite the intensity of the city's growth and despite the highly elaborated proposals for a city master-plan even from the early 1960s, the first (and last) Regulatory Plan of Athens was established only in 1985. This mismatch would consequently lead us to a problematic concerning the actual role of the central state and the local authorities in the building of the Modern Greek city. And as I am not keen in adopting the popular simplistic concepts of the "absent or weak or incapable state", I propose that we should look for the alternative political and economic mechanisms that were introduced to handle urban growth.

2.2 "What for?" Some thoughts on the objectives of this particular research.

The aim of this short introduction is to highlight the complexity and the multiple implications of post war socio-spatial transformations in a country of the European

---

and the mid '60s (Filippidis, 1990, p. 16). Although this distinction may be schematic, it describes a range of approaches characteristic of the scientific and ideological discourse of the time. This range of approaches was fully exposed in the 1966 Conference, in the form of highly elaborated proposals, a proof in all of the dynamism of the planning community at the time.

[6] It would be impossible to describe this progressive pluralistic social movement and the violent reaction of the coup without referring to the structure of political power and political representation that was inherited from the past and crystallised after World War II and the civil war that followed. A political state that has been described as a "cachectic democracy" (Nikolakopoulos, 2003) characterised by the systematic violation of political rights and a permanent status of institutional crisis (Alivizatos, 1986).

south like Greece, with a focus on its capital city, Athens. The main question of my research is what has been the role of the violent institutional change in this process and what have been the consequences from the implementation of the authoritarian regime to urban politics and planning, of the time. This question sets a theoretical challenge, since the thematic opens up equally to theories originating from various disciplines. It requires a conception of space as a field of social, political and economic relations with historical, ideological and aesthetical dimensions and not just as a technical construction. Additionally it refers to major discourses, like the spatial dynamics of modernisation in the countries of the "periphery", or the spatial politics of the totalitarian regimes of the 20th century. Therefore, I am following an interdisciplinary approach, drawing material and methodological tools from social, economic and political sciences and of course geography, urban history and theory of urban planning. I prefer the term "spatial politics" than the term "planning" as it highlights the profoundly political character of the post war urbanization of Athens and is in accordance with the fact that the city grew besides the norms of official planning.

Concerning the handling of historical time, the analysis uses the notion of continuities and discontinuities, which I find appropriate for deconstructing the popular and simplistic perception of the dictatorship as a "parenthesis" in our modern history. It is also a schema that allows correlations between different periods of recent history and thus introduces historical research as a critical tool for the understanding of contemporary and future possibilities (Hobsbawm, 1997). We could also see in this perception of history an implementation of the theoretical and methodological idea of genealogy that would translate here to a genealogy of post war spatial politics and planning ideologies.

In this context, I mention four reasons why I find the study of the dictatorial regime's urban politics, still fruitful for a contemporary discussion, in a "greek context", but probably in a comparative perspective as well:
- The first one being that it, obviously, highlights the socio-political parameters and thus the complexity of spatial politics and urban planning in particular. The coup d' etat has been arguably the most violent political rupture in the second half of the 20th century. A comparative approach of the authoritarian versus the democratic state offers an ideal context for the evaluation of the role of the central state in the production of urban space. What makes the story even more interesting is the contradictory evaluations of the period of the junta concerning urban and environmental issues.[7]

[7] The idea that the period of the Junta has been a "catastrophic" one, considering urban environment and the identity of Greek cities and natural landscapes throughout the country, is widely accepted and commonly expressed by the majority of professionals, academics and the public. At the same time, the opposite argument is commonly expressed by those nostalgic for the era and some ultra conservative social groups. The slogan "the Junta constructed roads and brought electricity to every village of the country", has been as famous as the one praising the "law and order ideal of the colonels". But we can also trace much more sophisticated "disagreements", which are right to the point of this study. Like, whether the period between 1967-1974 has been a "productive" one, concerning the reformation of the legislative framework and planning proposals (Filippidis, 1990), or not.

- Secondly, urban space as a material, social and economic field, still carries distinctive and in many cases binding elements of the regime's policies. Extensive urban areas in Athens and elsewhere have been constructed or transformed during the period of the Greek dictatorship, or due to legislative regulations proposed at the time. Certain legislative arrangements, even today, are rooted in the dictatorial period.
- In connection to the above, it is interesting to evaluate if and how the specific politics of the period of the junta have affected the wave of reformations that followed, in the period of the democratic consolidation and even later.
- Lastly, there is a theoretical and political aspect that surpasses the boundaries of the specific historical geographical context and is becoming highly important today, once again: it concerns the technocratic ideal of governance and its interrelations with different forms of political authoritarianism.[8]

In this direction, in my research I have been working on questions like the following:
- What have been the ideological background and the hegemonic complex of principles and ideas of the regime? In what ways has this background affected specific policies, especially the ones concerning spatial and urban planning?
- How did the constitutional change affect the process of designing and implementing spatial policies?
- What has been the scientific and political personnel involved in this process during the years of the dictatorship and under what conditions and terms have they executed their work?
- What kind of public consciousness and public dialogue around the issues of the city and spatial policies has been constructed?
- Finally, what have been the continuities and discontinuities in the field of urban policies, considering the preceding period and the one that followed immediately after, during the years of the democratic consolidation?

Another reason for working on this thematic, one that I consider really important, is a clear historiographic interest. I could even describe it as a sense of "historiographic duty", as there is hardly any attempt of documenting historical information for the period. Very little research has been done on certain policies, on the process of producing and implementing spatial planning, on the specific political and scientific actors involved. There is minimum academic work and relevant literature, with the exception of dispersed references in general studies for the Modern Greek city.[9] Furthermore, Greek historians and political scientists (among others Konstantinos Tsoukalas, Ilias Nikolakopoulos and Christina Koulouri) have pointed out that this lack of historical knowledge for the junta is a general phenomenon and that the

[8] We could examine, for example, how the heterogeneous works on reactionary modernism (Herf, 1993), totalitarianism, "Bureaucratic Authoritarianism" (O' Donnel, 1977), "Authoritarian Statism" (Poulantzas, 1980) find meeting points with the problematic of the democratic deficit in "neoliberal times" (Harvey, 2005).
[9] Again, particularly interesting information is provided in the work of Lila Leontidou (Leontidou, 1990), and that of Dimitris Filippidis (Filippidis, 1990)

period of the dictatorship is, from a historiographic point of view, one of the darkest periods of our recent history. According to Christina Koulouri:

> "Up to this time, the approach of the dictatorship is attempted through two main roads: Through the published testimonies of people who lived during that time and were involved in the resistance against the regime, or by political scientists in a perspective of comparative analysis with the regimes of Latin America and southern Europe. Historians have not dealt with the period… and we should also examine what this seven years period passed over to the following one". (Ta Nea, 22/04/2005)

An important part of knowledge for the period is in the form of public history. The period is still present in collective memory, as broad social groups had an immediate experience of it. This consciousness, of course, is fragmented according to a range of different experiences and backgrounds: from the "silent masses" in rural and urban areas of the country for example, to the technocrats who collaborated with the regime and those who participated in the resistance, were arrested, tortured and exiled. The experiences of these people are an extremely rich but also "vulnerable", non-documented source of public history.

The lack of systematic knowledge has been a great burden but at the same time a challenging condition for the process of my research, as it has /led me to various sources of primary material, like the state's archives, the public press or interviews with the "protagonists": planners, academics and members of the state's apparatus. The collection and documentation of this material constitutes a first goal of my research project.

3. Building an approach: between historiography and theory.

The aspects mentioned in the previous chapter describe a perspective that stands between a historical analysis and a theoretical approach of urban transformations and politics. The research is organised in four sections:

a. In the first section, the socio-economic framework of post war urbanisation is examined in relation to a corresponding system of political and technical mechanisms. The material for this study comes from bibliographic sources.[10] I keep two important outcomes from this section. The first refers to the particularities of the urbanization process of the city of Athens as opposed to a dominant north-western example. As mentioned in the introduction, significant elements of this particularity have been the dispersion of small scale land ownership, small construction capital and the co-existence of "modern" and "pre-capitalistic" forms of housing production.

[10] A number of researchers in the late 1970s and early 1980s contributed largely in documenting the process of this cumulative, spontaneous development of the Greek city and introducing a theoretical perspective on the geographies of Greek capitalism. Particularly helpful in my study has been the work of D. Emmanouil, D. Economou, C. Hadjimichalis, M. Mavridou, M. Mantouvalou, D. Vaiou.

The first dominated by private building activity under the mechanism of "antiparochi" and the architectural form of the multi storey block of flats (Papamichos, 2000), and the second expressed in the extended areas of illegal housing (Leontidou, 1990). The second outcome is the need for a distinction, between the actually implemented urban policies and the rise of a planning ideology in circles of academics, technocrats and some members of the political system (Vaiou, Mantouvalou and Mavridou, 2000). In the first category we should include political tools that had an immediate and organic role in urban development, like the tax system, the general building regulations, the introduction of financing mechanisms in the house market, the political handling of informal activities like illegal housing, programs of public or social housing etc. If we wish to examine the consequences of the Greek dictatorship in the urbanization process we definitely need to turn to this category. "Official" planning, on the other hand, although it seemed to express the dominant post-war discourse of modernization or even a possibility for redistributional policies, remained an external factor to this process, as it was not connected with economic and social interests of certain groups.

b. In the second section, I approach the different historical and political interpretations of the coup, and the recent literature on the regime's ideological characteristics, political practices and relations with the pre-existing social, political and economic system. This study allows for the urban politics to be evaluated as a part of a broader political program and social context. Furthermore, it has been important, from a theoretical and methodological point of view, as it introduces the possible frameworks for a comparative analysis of the Greek case. For example, would it be a justifiable choice to compare the Greek junta with the European totalitarian regimes rooted in mid-war fascism? For those regimes, by the way, there is a rich academic literature and ongoing research, concerning spatial policies, urban planning and architecture.[11] However, the analysis of the junta's policies and ideology have shown that it has been a particular form of authoritarian regime, with a military and oppressive character on the one hand, but bearing more differences than resemblances to fascism, on the other.[12] Most notably, it lacked a structural relation with the Greek society, in the form of a political party, a labour organization or an organised youth sector, all characteristic elements of fascist regimes. And although the colonels defined the coup as a "National Revolution", they never expressed the will for a radical social and economic change. Instead, the faith in the "primal role of the private economic sector" and the "principle of free competition" were repeatedly expressed in public speeches and programmatic documents.[13] The regime appeared as a guarantor of the "proper function" or even the "modernization" of certain fields

[11] For a comprehensive analysis and literature on urban development projects and unimplemented planning proposals in the case of fascist Rome, see the recent work of Federico Caprotti (Caprotti, 2007) and Aristotelis Kallis (Kallis, A., 2011).

[12] For a review of the theoretical and historical interpretations of the Greek regime see (Sakellaropoulos, 1998)

[13] See, for example, the introduction in the Program for the economic development of Greece, 1968-1972 (Ministry of Coordination, 1968).

of the Greek capitalist economy. It adjusted rapidly to the basic economic principles all post war governments had followed (Iordanoglou, 2003), it "adopted the European perspective" of the country (Pesmazoglou, 1999) it maintained the basic structure of public administration (Meletopoulos, 2000), it reproduced the organic relation of the state with the economic elites and further introduced a paternalistic clientelism as the dominant form of relation with the middle and lower classes (Sotiropoulos, 1999). It did so in a violently imposed context of "silence, order and security", of hysterical anticommunism, of persecutions and censorship. The regime attempted to impose total control in the public sphere, including the media, the universities, the trade unions, the structures of local representation. And while the state apparatus continued its legislative, judicial and executive work, these basic functions were isolated from participation or public control mechanisms.

c. Although telegraphic this description implies some answers to the main question of this paper on the continuities and discontinuities of spatial politics of the dictatorship. And along with the idea of the parallel contexts of actually implemented spatial tools and official planning ideology, it has provided me with certain logic for the third, and main, section of my research. This third section approaches the policies of the regime that were immediately related to the production and regulation of urban space.

Additionally to the limited relevant literature, I have been using three main sources of primary material:

- Relevant articles from selected editions of the technical press ("The Newsletter of the Technical Chamber of Greece", "Architectural Issues"), the economic press ("Economic Postman") and the daily press ("To Vima"). Especially for the "Economic Postman" -a significant edition on economic, technical, and administrative issues, with a continuous history over the post war decades- I have made a systematic documentation over the complete digitised archive for the period from 1965 to 1975. The outcome of this work is a register of almost 600 articles, in chronological order and organised in 4 thematics (Urban planning, Economic and Regional Planning, Housing Market, General technical issues).

- Archives of various branches of public administration (like the Technical Services of the Municipality of Athens or the Ministry of Public Works), the proceedings from the meetings of the Consulting Committee of the Junta (in the Central Library of the Greek Parliament), and material from the private Archives of Konstantinos Doxiadis.

- A series of semi-structured interviews with people that held a significant role in planning and policy making around the period of the dictatorship (members of research institutes (3), academics (3), professionals working in the private sector (2), members of the Ministry of Public Works (1), the Office for the Regulatory Plan of Athens (1) and the Ministry of Coordination (1).

My study up to this point has focused on:
- Reformative attempts concerning the land and construction system and the housing market.
- Specific proposals for the restructuring of the urban area of Athens, with an emphasis on attempts to introduce a representative architecture or urban planning, particular to the period of the regime.
- Changes in the legislative framework of planning, particularly concerning the Regulatory Plan of Athens
- The "active subjects", people or groups of people that were involved in spatial policy and urban planning. Their experience and evaluation of the period and the conditions under which they performed their work

The facts show that the state apparatus during all seven years of the dictatorship was particularly active in reforming the legislative framework that actually affected the development of the urban area of Athens. Furthermore, the model of speculative urban growth was systematically exported to all regions of the country, particularly in the middle-size peripheral towns and tourist resorts.(Filippidis, 1990). Over the post war period some issues have been particularly decisive for the housing market and the construction economy: the regulation of building heights, the General Regulatory Plan, and the incorporation of peripheral urban areas in the official city plan. Only one year after the coupe the regime introduced the Compulsory Act 395/68 "On buildings' height and unrestricted construction building". According to the CA 395/68 the Floor Area Ratio (FAR) increased from 25% to 40% in urban areas around the country, adding more floors to existing buildings and increasing the heights of new constructions. As expected the construction sector was triggered end the private housing market boomed. In 1972, a new General Regulatory Plan was implemented. The implementation of the CA 395/68 has been used as a particular case study of my research as it reflects all the range of issues discussed in this paper.[14]

Equally decisive has been the policy of the regime in the case of informal settlements and illegal housing: In three years only, from 1968 to 1971, about 2.700 ha were integrated in the city plan of Athens, involving more than 150.000 people[15]. Leontidou describes this "legalization" process as a successful instance in the 'modernization' and expansion of Greek speculative urban capitalism. A success, of course, that involved the repression of settlers, demolition and arrests (Leontidou, 1990). The expansion of the structured urban market was related to the systematic promotion of credit financing in the housing market and contributed to the rise of a competitive speculative construction sector. Law 1003/71 "On active urban planning", was another tool for facilitating this construction sector and further

[14] In what could be called as "the genealogy of the CA 395/68", I am working in the register of articles and in other archives to document the process from the early appearances of the issue in public discussion - to the formation of certain social pressures - to its official implementation – to an evaluation of its impact.
[15] Data from the common study of the National Statistical Service of Greece (NSSG) and the National Center for Social Research, elaborated and presented by L. Leontidou (Leontidou, 1990).

attracting the investment of large scale private capital in urban development. Its logic was transferred faithfully in Law 947/79 of the second democratic government.

4. (c) Conclusions

The building euphoria lasted until 1972. In 1973 and in the context of the international crisis the construction sector collapsed. Around that time the consequences of the construction frenitis were obvious in the urban environments. A renewed interest appeared in the public sphere and the media, on issues of environmental protection, historical identity and quality of life. This turn was later expressed in the progressive Constitution of 1974 and the reformative wave that followed during the first two years of the democratic consolidation. The state's efforts turned to other directions and emphasized on more democratic methods of implementing policies. But the "modernization" of this particular urban capitalism remained the structural dynamic that transformed the Greek city.

As this research is still in progress, the questions of continuities and ruptures in the period of the dictatorship are still open. Up to this point, the analysis of the legislative framework, of the actually implemented policies and the micro-histories of people or social groups involved, reveals the existence of persistent dynamics and processes that cross the boundaries of different political periods.

Indeed the dictatorship continued the 'modernization' of the speculative land and construction system, which of course was not a neutral process but a conflictual political one. The most obvious difference in the case of the regime has to do with the loosening of social control that led to a rise of arbitrary practices. The regime introduced an idea of laissez faire to favour all kinds of investment activities, partly as a mean for gaining the necessary legitimisation

Another point has to do with the "scale" and intensity of urban transformation processes. This doesn't simply imply the "natural tendency" of authoritarian regimes towards gigantism (a tendency that had its reflections in the form of proposed development projects for Athens too). It may refer for example to the systematic promotion of large-scale capital investments in an urban economy that was traditionally characterised by small scale and self-financing practices.

Furthermore, the idea that the negative consequences of the dictatorial policies were the outcome of technical and administrative inefficiencies of the government or the state apparatus, although very popular, proves to be misleading: the urban policies of the period should be judged in relation to their actual objectives and social functionalities. But this, of course, is a major challenge in general.

Capitalist logic and the production of spaces of inequality: the case of organised food retailers in Ankara

Based on the works of Marx (1859, 1867), Engels (1845, 1873), Harvey (1973, 1982, 1985) etc. the present research has the major assumptions that the capitalist system, from its nature, has always the tendency to produce socioeconomic crisis and inequalities. Although within capitalism there are some moments where these crises and inequalities were masked by collective efforts (like at the moment of 'Glorious 30s'), the system continuously produces its contradictions. The neoliberal era is considered as a specific moment within the long history of capitalism in which special advantages are given to specific parts of the societies so that the accumulation of capital continues. With reference to some particular researches this paper first tries to illustrate how urban space is utilised within the capitalist system. Secondly, the research focuses on the signs of social and economic injustices that became subject of different urban researches. Finally, the case of organised food retailers in Ankara is analysed through a series of statistical procedures if this specific case can be seen as a contemporary example in the production of urban injustices.

1. The capitalist logic

The classical interpretation of capitalist system, mainly based on Adam Smith's ideas, provides an early picture of a political economic system which emerged in the last few centuries. Classical economics conceptualise the capitalist system as a circular system whose main actors are capitalists, labourers and landlords. As time passed, new facets of capitalism were discovered and political economists interpret these new facets according to different viewpoints. Karl Marx made a major contribution to the understanding of capitalist system by making the 'critique of the political economy'. He falsified the circular logic of capitalism and introduced a linear logic which is based on exploitation of labour power. Within this conceptualisation the accumulation of wealth is realised only in one direction and due to its unequal nature the system is assumed to be prone to perpetual crisis. Marx's objections on classical economic interpretation of the political economy have both theoretical and practical bases. On the theoretical side, not separate from practical observations, Marx questions the creation of surplus value and its distribution among classes. This constitutes the primary source of inequality in Marxist understanding which leads to the creation of supporting institutions, social and economic crises, and temporal solutions to these crises. On the practical side, Marx focuses on social and economic inequalities that affect the living condition of millions of workers in industrialised countries like Germany, France and England. Human exploitation under the cover of economic freedom and the production/consumption processes leading most of the populations into misery backed his theoretical formulations. The way how Marx conceptualise the capitalist system not only helps to the realisation of a more accurate description of capitalist system but also shed light on the nature and logic of capitalism. Application of this perspective becomes essential to the present research primarily because it is argued

that the locational inequalities are internally based on the capitalist logic guiding that guide the spatial strategies of organised (food) retailers. Secondarily, Marxist perspective provides a framework to distinguish the role of state mechanisms and more specifically the role of planning, as ‘external factors’ influencing retailers' spatial decisions.

The capitalist system has a major linear form indicating production, circulation and consumption of commodities on one side and the accumulation of wealth and labour power towards the other. This general process continues until capitalists find ways to extract more surplus value (profit) out of the production/consumption process. This move out of primary circuit has two other paths that capital can follow. In the secondary circuit, the capital is diverted to the space, in the form of investments invested in the built environment. These investments are thought indirectly beneficial to the primary circuit as they enhance the production and the consumption sides of the primary circuit. Through the investments in the built environment (as will be discussed more in the following section) capitalists diminish the spatial barriers. Sometimes space is considered as a commodity and investors benefit from its exchange value. The third circuit of capital has two target areas. In the first one, the third circuit investments are directed to overcome the problems directly related to the production process that lies at the beginning of the primary circuit. Through the development and application of new technologies and organisational structures the efficacy of the production process is enhanced. The cost of production may decrease and potential for excess profit may increase. The second option within the third circuit covers the investments directed to social expenditures. These investments, rather than focusing on the production process, target the consumption part of the system. Through these investments, the reproduction of labour power is enhanced and sometimes investments aim to enhance labourers’ purchasing capacities as a part of welfare policies (Harvey 2006(1982)).

(Graphic 1) and (Graphic: 2)

1.1. The space in the accumulation of capital:

> "Land serves not only as a means of production but also as a 'foundation, as a place and space providing a basis of operations', space is required as an element of all production and human activity" (Capital Vol.3: 774).

For Marx space, mostly referred as land, plays a double role both as a condition and as a mean of production. Through this dual role, space becomes the symmetrical image of the capitalist system and reflects i) circuits of capital, ii) perpetual crises, and iii) patterns of exploitation and injustices. Policies developed to sustain capitalism not only aim to increase efficiency and utility of the system but also to facilitate the extraction of surplus value from space through its commodification. This focus on efficiency and profit, as seen before, becomes the source of increasing inequalities and injustices, and makes space one of the key areas to observe these externalities.

From its nature, space is a functional necessity for the basic movement of labour, commodities and money. In other words the circulation of capital within the primary circuit (encompassing production, exchange and consumption - line 1) can only realise on space. Harvey (1985) giving a more detailed explanation on the utilisation of space for the capitalist accumulation, argues that depending on the level of development of societies, capitalism creates the necessary spatial composition that meets its needs and that enables the circulation of capital in the most profitable way. The technological capacities together with the material possibilities of the society determine the character of the necessary spatial structure. Harvey further argues that, in the course of time, the requirements of capitalist system change. Once-enabling physical structures start to limit the flow of capital along space and force capitalists to create new spatial organisations. At these times of constraint, demolition of old spatial elements, production of new ones, and consequential restructuring of urban structures (often called "creative destruction" of the built environment) becomes unavoidable for the future of the capitalism.

The effect of space is analysed in detail within the secondary circuit of capital. As now known, the productive capital stuck within the primary circuit can be diverted into the secondary circuit, in the form of investments in the built environment (line 2). On the side of production, as a part of fixed capital, such investments contribute to the enhancement of the production processes. Construction of new production centres together with the production of necessary infrastructure for the production, and renewal and upgrade of these facilities are the examples of fixed capital investments concentrating on the built environment. At the more concrete level, production of newer facilities, newer product and organisational designs and application of more efficient production mechanisms together with the utilisation of more responsive transportation and communication systems that respond to the needs of the new mode of production can be seen as parts of the fixed capital investments. Such developments of the built environment are not only realised within the sphere of production. The sphere of consumption offers alternative built environment investments to capitalism as well. (Re)organisation of everyday life around shopping centres, introduction of e-retailing (decreasing the fixed costs of construction), appearance of new small-scale retail formats, their diversification and specialisation are the effects of spatial investments aiming to revitalise consumption of commodities. Through such investments in the built environment, the capital originally following the path of the primary circuit moves out of the circuit but is always utilised for obtaining the surplus value. The only difference for the capitalist is that such investments in the built environment necessitate longer turnover times than are required for the production and consumption of most commodities. For this reason, capitalists first try to function within the field of primary circuit of capital and move to other circuits only when these circuits become more advantageous considering turnover times and profit levels.

In his analysis of the circuits of capital, Harvey separates the investments

contributing to the production and consumption of commodities (secondary circuit) and those serving the reproduction of labour power (tertiary circuit). Within the framework of this research it is also argued that it is not easy to separate the consumption for reproduction from other consumption activities. This not only includes utilisation of services like schools, libraries, sport facilities, green spaces, etc., but also covers the consumption of goods (as in the case of retailing). In addition and far beyond the necessary consumption of basic needs, in a consumerist society the activity of consumption starts to occupy an important position in people's lives and contributes to their reproduction from a much broader perspective. On the side of the utilisation of space, as mentioned within the spatialisation of primary and secondary circuits, capital directed to the tertiary circuit need to be spatialised as well in order to be concrete (line 3).

(Graphic: 3)

The utilisation of space out of the circuits of capital is realised during the moments of crises. As mentioned previously, the capitalist system is always prone to crisis and spatial interventions are frequently utilised by capitalists to overcome such moments of crises. According to Harvey the ‘spatial fix’ is necessary for the continuation of capitalism and especially important to overcome the location specific character of all the crises of devaluation (Harvey, 2006[1982]). For Harvey, after the investments on production and consumption, spatial investments are seen as a second option to solve the problem economic crises. These interventions can take different forms. Creation of new urban structures, elimination of spatial barriers and spatial integrations made to increase mobilisation of capital on the land can be seen as possibilities to overcome the crises happened in first and second cuts. On the side of excess surpluses, both the capital and labour power are all spatial entities. Both of them can be 'disposed of and remunerated by entering into external relations with other regions' (Harvey, 1985b)

1.2. Capitalist political economy and its reflections on space:

Marx and Engels, later Poulantsaz (1968, 1973), Lefebvre (1972, 1991[1974]) and Harvey 2006[1982], 1985) argued that the capitalist economy which had many contradictions needs to be backed with a political system. This system not only provides solutions to economic problems and crises but also guarantees necessary spatial policies that contribute to the accumulation of capital through various ways. The theoretical framework provided above is utilised for the very brief analysis of the neoliberal policies that started to be enacted with the 1980s. Additionally, the framework provides the basis for the understanding of food retailers’ economic and locational behaviours.

With the 1980s, neoliberal policies started to be implemented in most of the developed countries which are then followed by many other countries aiming to follow the path for the ‘development’. Although the implications of neoliberal doctrines differ according to “scale and scope of state intervention, forms of labour

market regulation, the constitution of institutions of social regulation, patterns of historical resistance and political incorporation, and do forth" (Peck and Tickell, 2002: 387-8), researches illustrate that neoliberal political economic restructurings are commonly consisted of policies aiming the deregulation of state control over principal industries, reactions against organised labour, reduction of corporate taxes, decreasing the functioning of public services and their privatisation, dismantling of welfare programs, facilitating the mobility of international capital, increasing competition between localities, and criminalisation of urban poor (Brenner and Theodore, 2008[2002]:3).

1.3. The production of retail environments, continuation of inequalities:

> "theorising retailing contributes to our understanding of the whole capitalist system" (Ducatel and Blomley,1990:207).

Conventional interpretation of retailing considers the activity as a self-governing system that is based on the efficient usage of distribution channels and that connects producers to consumers. With the advances in the production and diversification of demand, the existence of intermediary agents became necessary. Distributors and retailers have become vital for the continuation of the economic system. With the advances in the capitalist economy, specialisation on retailing increased. This brought further efficiencies within the circuit of capital, facilitated consumption and indirectly contributed to the continuation of production. Despite its unique and important position within the economic system it will be misleading to consider retailing as a pure economic activity only linking production and consumption processes. Here, the retail activity is selected as a special case as it is believed that retailing represents more than a simple economic activity. Here, it is argued that the contemporary shape and dynamics of the retail system is capable to reflect both social and political aspects of capitalism and its contradictions.

Similar to other layers forming the urban landscape (like industry, housing, infrastructure, etc.) retailing on the one side contributes to the continuation urban daily life and on the other side, plays a key role for the (re)production of the capitalist system. Social importance of retailing, especially the one of organised food retailing is discussed in relation with the social production of wants and needs in contemporary urban societies. To begin with, I would like to focus on the commercial capital or more precisely on retail capital which determines a specific instance within the general circuits of capital (Marx, Capital vol:3/17; Lamarche, 1976; Ducatel and Blomley, 1990). By realising this, it becomes possible to contextualise urban retail systems within the general political economic discussions. And, after reaching this point, the problems related to social needs and injustices can be identified accurately and solutions to such problems can be developed much correctly.

As in other branches of activity, retailing is a sector in which there is a tendency to the concentration of capital: some capitals expand by taking over or

displacing smaller ones. There is evidence that the concentration of capital (and thus of power) in retailing tends to be particularly marked and this in turn can weaken the relative power of upstream capital (agricultural and other food producers) and of (downstream) workers who are the consumers of the retail product. These concentrations of power have an evident spatial dimension and it is spatial monopolies and oligopolies which affect consumers and perhaps spatial monopolies which affect upstream capital.

1.4. The retail system within the circuits of capital:

When Marx refers to commerce, he calls all commercial activities 'parasitic', considering that merchants obtain profits just through organisation of services without directly contributing to the production process. But in practice it is seen that retailing occupies an important role not only in the production process but also in the continuation of capital accumulation. Retailing represents specialisation within the circuit of capital and increases efficiency by reducing the costs of producers, by internalising the commercial functions and by decreasing the turnover time. Ducatel and Blomley (1990). Before selling the product in the market the retailer makes an investment and takes risk by directly buying the commodity from producer. The risk that retailers took through this exchange returns them as profit and the risk involves the key features of the consumptive sector which are the volatility and unpredictability (Harvey, 2006[1985]: 215).

The importance of retail activity for the capitalist economy can also be understood on the basis of its positions within the circuits of capital and its functionality during the moments of crisis. On the circuits of capital, it is possible to position retailing at all three circuits. The primary circuit of capital is about the production of goods and their consumption. The continuity of the circuit necessitates good functioning of the activities of production, distribution, selling (for the part of retailers) and consumption (for the part of consumers). The contradictory activities of production and consumption are existing in a dialectical way and linked to each other through the activities of distribution and retailing. In the normal functioning of the activities and in normal conditions of accumulation money invested in the means of production, labour power and raw materials return to producer capitalists with some surplus value and this becomes their basic motivation. But the necessary conversion of commodity capital into money capital becomes a point of friction for producer capitalists needing to use money capital for productive purposes or as the basis for further investments. So, the commodity capital that represents an intermediary stage needs to be transformed into money capital to become efficient for the circulation of capital. It is the merchant capitalist that facilitates this duty of transforming commodity capital into money capital.

(Graphic: 4)

Retailing in the primary circuit of capital: From the point of view of circuits of capital, it is possible to observe that retailing's contribution to the accumulation of

capital is not limited with the increasing efficiencies and decreasing turnover times. At the moments of crises, the capital, which is stucked in the primary circuit of capital, needs to be diverted to other circuits so that the accumulation of capital continues. For the case of secondary circuit, it can be transferred to the productive processes in the form of fixed capital or to the consumption activity in the form of consumption fund. Investments directed to productive materials to increase the productive efficiency are out of the focus of this part (despite its important spatial implications). Instead, here it is argued that those investments grouped under the name of consumption fund have direct effects on retail practices. Construction of shopping centres and retail outlets together with infrastructures that such buildings need can all be seen investments directed to increase consumption of commodities and reproduction of labour power.

Retailing in the secondary circuit of capital: The primary circuit of capital offered the most direct way of surplus creation. As mentioned previously, due to the internal contradictions of the capitalist mode of production there happens some moments (i.e. at the moments of crises) that investments in other circuits is considered to be more profitable. Those investments made for the enhancement of the production and consumption side of the circuit of capital. As seen before, Harvey separates those investments into two, one side being the fixed capital investments realised on the production side and the other side consisting of investments on the consumption fund. To be more precise I would like to focus on the part of consumption fund separated for the construction of built environments and the appearance of retail activity as a part of it. Investments on retail environments can also be beneficial for the production as they enable the discovery of new markets and new consumption patterns and may help reduce costs for the transportation of goods. Through such developments on the one side producers find new ways to eliminate over produced commodities but on the other side and may be more importantly investors discover new investment opportunities that have higher rates of return on investment with their excess capital (Feagin, 1987; Harvey, 2006[1985])

Despite having the capacity to offer solutions against the effects of the crises in the primary circuit of capital the secondary circuit has its own set of contradictions. Heavy and fast investment in the built environments combined with the deregulated legislative framework can cause another crisis of overproduction, at a different circuit. On the side of retailing it is possible to observe these dynamics. Considering the limits of the purchasing power, overproduction of shopping malls leads to higher vacancy rates on older ones and causes the disappearance of small scale retailers who cannot resist on conditions of crises. Different from housing sector and office construction, retail sector represents more dynamism and adaptability to the changing economic conditions. Although for some capital-weak retailers the crises represent a drastic moment, for more powerful ones these moments offer opportunities for development through mergers and acquisitions.

Retailing in the tertiary circuit of capital: At the moments when primary and secondary circuits are less profitable, investment opportunities covering

technological and social investments are considered as a third alternative for the accumulation of capital. Although, compared with primary and secondary circuits, the turnover time of the third circuit investments is long, capitalists accept to divert investments into the third circuit and agree to receive revenues in the long run in order to avoid devaluation of their capital at the present time. Considering the case of retailing, the third circuit of capital becomes important both in direct and indirect ways. In the direct side, technological developments and investments to enhance the human capital working in the retailing sector covers considerable part of organised retailers. The competitive nature of the sector necessitates these kinds of investments as they can bring long term competitive advantages to retail firms. On the side of indirect relations, investments in the retail sector, especially in food retailing can be considered as investments contributing to the reproduction of labour force especially when they are addressing disadvantaged neighbourhoods. Despite the emphasis given to major public services like education, health, etc. considering the contemporary importance of consumption, accessibility to retail facilities becomes as important as accessibility to public services. These issues will further be discussed within this section under the title of the social production of needs.

The third circuit of capital encompasses social investments and investments in science and technology. Leaving aside the investments in science and technology I would like to focus on the social investments which basically aim at the social improvement of working classes, their more active participation to the economy and enhance their contribution to the flow of capital in an indirect way, from the point of view of capitalists. Out of capitalist point of view, benefiting from such investments is considered to be a precondition for a just urban living with equal accessibility to social amenities and unrestricted participation to socio-cultural practices. Despite the acceptance of interrelation between different circuits of capital and their influence on the retail development process, the research emphasises the importance of the third circuit of capital in the reproduction of labourers. Knowing that in the world of advanced capitalist societies the (in)accessibility to retail facilities causes the formation of food deserts, disadvantaged consumers and various health problems, putting the problematic of accessibility at the core of the research was necessary. To underline the importance of this part and despite the risk to move focus away from the production of urban retail environments, the author wants to discuss the activities of consumption, its relation with labourers' reproduction and the social production of needs and wants; before returning to the point of urban land rents and formation of values which is considered to be the principal factor affecting locational choices of retailers and thus to their accessibility.

2. Food retailing, disadvantaged consumers and food deserts:

Due to the collective nature the activities and in relation with the ways of provision of these activities, Marxist literature focuses more to the collective means of consumption than individual ones. Two writers' works are important considering the establishment of the interrelationship between urbanity and means of collective consumption. Both Lojkine (1977) and Castells (1977), following the path of the Marxist approach, define the speciality of urban space as being the place of

concentration of services of reproduction. Considering the provision of food products, this was something historical and started with two processes happened hand in hand: the maturation of capitalist political economy and development of the industrialisation of food markets. Steel refers to the Charles Booth's survey 'Life and Labour of the People [of London]' dated 1903 and points out that 97.5 per cent of city's population lived in grim conditions whereas 30 per cent of them had to live under the bread line. She than concludes that:

> "What was becoming clear was that leaving the food supply solely to the 'hidden hand' of commerce had its downside. While the nascent food industries were very good at producing and transporting food, feeding the urban poor was not their goal. Left to their own devices, they naturally sought to maximise profits, which meant targeting those who could afford to pay."
> (Steel, 2008:92-3)

Today, in advanced capitalist societies the food provision is mostly realised through capital intensive, chain stores that dominates greater parts of the national food markets. Supermarkets offer wide range of fresh products and unprocessed food at less expensive prices than convenience stores are important source of affordable and nutritious food (Smoyer-Tomic, 2006). And as the importance of food distribution in contemporary cities is recognised by many, the issue enters into the agenda of not only urban planning but also public administration, public health, retail geography and welfare geography.

In the literature, accessibility to supermarkets and their relative advantages are discussed on the basis of food deserts (mainly for the cases around UK) and food insecurity (for the cases from USA). Researchers identify those people having lower access to modern food retail providers and the reasons decreasing their ability of accessibility. Although there is a common ground about the reasons which are accumulated around combination or individual presence of financial, physical and mental barriers the question of food deserts is far from being concluded. It is believed that a research based on the political economy of capitalist system may contribute to our understanding. Considering that despite the diversity of cases and variety of geographical reflections the capitalist logic stays the same among cases and it can be seen as one of the major functions creating injustices through different spatial representations (about the North American experience see: Mayer and Scammon: 1993; Alwitt and Donley: 1997; Lewis et al.: 2005; Porter: 1995; Raja et al.:2008; Powell et al.: 2007; Smoyer-Tomic: 2006) about the UK experience see: Bowlby: 1979; Guy: 1984; Williams and Hubbard: 2001; Whelan et al.: 2002; Clarke et al.: 2002; Phillips and Williams: 1984; RTPI (Royal Town Planning Institute): 1988).

Although not dealing directly with the food insecurity and problems of accessibility to food retailers, I would like to separate David Harvey's work Social Justice and the City (1973) Harvey considers the real income, as an outcome of the production processes, as the central matter of justice as it enables the command over resources and thus becomes a function of locational accessibility and proximity (ibid:

69). From this point of view consumption is analysed as an outcome of productive forces, as a need-creating activity to ensure the necessary effective demand for products. Consequently, the idea of social justice becomes as a contingent matter produced out of the social processes operating in society as a whole. Regarding the scientific activities dealing with urban issues, Harvey concludes that the main objective has to be the elimination of the conditions giving way to the formation of those situations described in liberal formulations. The focus on descriptions can only inform us about the existence of problems but elimination of mechanisms generating these situations, and thus the theory. Furthermore this new emphasis will not only contribute to the transform of the results but also and leads to the formation of new, may be revolutionary theories helping to the production of just urban spaces.

3. Political economy of Turkey: Establishment of the neoliberal basis

Boratav (2010) divides the analysis of the Turkish economy into 5 parts and the last part starts with the implementation of new liberal and anti-labour economic policies backed with the military intervention. From that time on, the capitalist class were able to change the context for their benefit. As a reflection, the economic decisions (known as the Decisions of 24th January) started to be implemented at the beginning of 1980 and constructed the basis of neoliberal policies that have ruled Tukey's political economy since that day. According to Boratav, increased foreign dependency, deregulation of economic barriers and break of resistances were the three major characteristics of that era (ibid: 150).

Despite the general propaganda of neoliberalism which emphasises the distribution of wealth in much more egalitarian ways, the spread of prosperity and development to all sections of the society; unregulated capitalism mostly imposed by foreign institutions produced unprecedented inequalities. The state expenditure on structural programmes (like social security, education and health) had to be cut due to IMF and World Bank policies. The marginal sections of the society that could not participate in the economic system had to rely on unproductive money transfers from the State (or from EU funds but again through the intermediation of the State) which just contribute to their survival. This dependency relationship between poor sections of the society and the state not only became a strategic bargaining point during political elections but also led to the creation of religious organisations and charities. According to Boratav the present situation in Turkey is very similar to the condition in England two hundred years ago when "poor laws" were produced to contain unjust consequences of unregulated capitalism (Boratav: 175).

On the side of urban planning this new political economic approach produced a new planning paradigm for Turkey. According to Tekeli (2009: 134), the change represents the shift from viewing planning as a practice of technical rationality to an approach to planning as a democracy project. This transition is still happening with a lot of compromises. Previously implemented left wing "urban managerialism" movements underlined the use value of urban lands and considered cities as living spaces. The neoliberal governments of the 1980s underlined the exchange value of urban spaces and considered the development potential of cities as a source of

surplus production and profit acquisition (Şengül, 2009:143-4). In return, the social and economic polarisation in cities increased. According to Sönmez (1998) in 1990 the richest 20% of Istanbul's population was obtaining more than 57% of the city's income while the poorest 20% of its population could only obtain 4,6% of Istanbul's income.

The new economic restructuring, emphasising the dominance of capital in the urbanisation process, redefined the relationship between the primary and secondary circuit of capital. This redefinition emphasises a change in the established balances favouring the primary circuit of capital since the creation of the republic and a restructuring in favour of the secondary circuit of capital. As a result big cities become the target of most of the private and state investments. While infrastructure, transportation and housing investments change the urban landscapes, it is acknowledged that cities are no longer the space of small scale capitalists. Large capitalists first started to take part of state investments and then invest independently. During this period through the elimination of political resistance and legislative barriers, the capital becomes able to reach every corner of urban life and establish its hegemony over urbanity (Şengül, 2009:139). Urban entrepreneurialism that became the management strategy for urban areas also initiated at the beginning of 1980s. The local political strategy aiming the provision of services considering the urban poor and the idea of maintaining social services was completely abandoned and replaced with the idea of service provision through economic enterprises (ibid). Urban investments became the major instruments of the transfer of resources from central or local governments to private firms (Eraydın, 1988; Şengül, 1999). In return massive construction of shopping malls, five star hotels, convention and business centres dominated urban landscapes.

3.1. Examining the retail change: another reflection of neoliberal capitalism?

Positive economic indicators in relation to Turkish retailing sector can be linked to the modernisation of the retailing in return to diversified and expanded demand. In contrast to general belief, the retailing sector in Turkey is still dominated by large number of small, independent, and single-location retailers named as: *bakkal* (corner store), *manav* (grocer), *kasap* (butcher), *tuhafiyeci* (draper) and others. These small capital, technologically weak and less organised retail formats serve to their localities and brought commodities to people despite quality and variety deficiencies. Considering their locational choices, different from complicated site selection methods of organised retailers these small and independent formats "make their location decisions in the face of uncertainty, and essentially on the basis of intuitive judgement, experience, familiarity and coincidence. They only consider areas in which they themselves live, or with which they feel familiar. The spatial decisions can be understood simply in terms of size, type of business, or existing spatial structure. Once the decision is made, independent retailers become location-bound".

In the face of changing social political and economic dynamics Turkish retail structure started to change. Being the leading sub-sector of the retail economy, food

retailing is transforming rapidly. As identified by Kumcu and Kumcu (1987), before the 1990s, the Turkish retail structure was highly fragmented and was neither horizontally nor vertically integrated. Small-scale, capital-weak, independent, and family owned retailers dominated the trade (Samli, 1964, 1970; Kaynak, 1982, 1986). During the 1990s the transformation process speeded up and despite their dominance both in market share and number of stores, conventional food retailers started to lose their shares in favour of organised retail formats. Different sources provide different information about the contemporary condition of market shares and number of retail stores belonging to traditional and modern retail types. According to the information provided by AC Nielsen Market Reports, the number of food retailers larger than 30 square meters increased constantly in number from 1998 to 2008 (below left). From another source of AC Nielsen, reflecting the numbers between 1996 and 2003, it is observed that the number of hypermarkets and supermarkets is increasing while number of small corners shops (bakkal) is in steady decrease(below right). As a result the former group increased its number up to 60% whereas the later decreased in number to 20%.

(table 1)

Increasing number of modern retail types has implications on the market share statistics. The gaphics focusing on the sale of FMCG (fast moving consumption goods) between 2002 and 2006 illustrates the growth of supermarket's market share with comapre to other formats (figure below left). at the market share of supermarkets is increasing while the market share of medium size markets and groceries, Bazaars, Kiosks, and other retail types is decreasing. Another figure (below right) comapres the market share of retail chains, non chain formats and discounters. Non-chains having the largest market share concerning FMCG protect their position with increase while national and local chains keep going at the same market share, 8% and 4% respectiveley. Dıscount retailers on the other hand increase their share from 4% to 6% within the considered period of time.

Accessibility to healthy food products has always been considered to be a very important component of human life and it is unfortunately not possible to find any reference to this point when the reports about the food retail sector are considered. From Maslov pointing out the importance at the individual level to Malthus underlining the importance of food production for the continuation of human race, history of humanity provides great variety of researches identifying the relationship between food and man. Although the consumption habits of mankind changes to a considerable degree, the 'basic need' on food did not change as much. Furthermore, with the social division of labour man first became more dependent on food producers than to food providers to fulfil its need. Regarding the present situation, in most of the advanced capitalist countries organised food retailers dominate the food market and become responsible to meet physiological needs of societies. The market system which intensifies competition between retailers put unbreakable barriers between social needs and food providers. With the analysis of the supply side of Ankara's organised food retail system and through revealing its connection with the

socio economic status of neighbourhoods this research aims to prove this break, and if possible tries to provide alternative solutions.

3.2. The case of organised food retailers in Ankara:

Ankara can be considered as a city in transition. Despite the dominance of its traditional retail structure the development of shopping centres establish pressure over old retail styles. As a result of the shopping centre development for example, the brand quality of traditional city centres (Ulus and Kızılay) decreased and their retail and service composition change considerably. Considering the case of food retailing, still the traditional formats like corner shops (bakkal) and street bazaars (pazar) occupy important positions not only in terms of number but also in terms of market share. It is not possible to talk about a purely standardised capitalist form of retail provision as retailers (including organised food retailers) benefitting from provision of products regarding the needs of districts or neighbourhoods. Despite the power of the traditional retail structure it is hardly possible to defend the view that the retail structure in Ankara keeps protecting it homogeneity as before 1980s.

According to the retail activity reports prepared by private companies the modern retail types in Turkey general are increasing their importance to a considerable degree (see the tables below). Reports indicate that from mid 1990s to mid 2000s supermarkets and hypermarkets increased their numbers in the overall retail market first from 0,5%(1) to 2,4%(1) and than to 3,1%(2). Considering the market share the increase is much significant. The 12%(1) share of mid 1990s increased to 33%(2) in one decade. These changes are supported by the case of Ankara through a single available indicator which shows the retail centre supply and GLA per 1000 habitants. Ankara comes just after Istanbul considering the gross leasable area (GLA) but occupies the first position when city populations are included. According to Pamir & Soyluer (2008), Ankara has the largest GLA/1000 inhabitants in Turkey.

Considering the social and economic justice in Ankara, with the neoliberalisation of the economy the retail structure in big cities changed (details are discussed in previous chapters) and supply side diversifications happened with respect to socio economic characteristics of the demand side. This makes some consumers advantaged while some others fall into a position of relative disadvantage. In a direct way; to meet their basic needs disadvantaged consumers need to spend more of their material resources for a relatively limited variety of products. Different from advantaged areas where retail diversity create a kind of competitive environment for quality, variety and price of products disadvantaged areas have less of this competitive environment and are more dependent on what is existing. Furthermore the lack of competitive power of small retailers over big ones causes the closure or weakening of traditional retailers and this situation aggravates the disadvantage of such areas. Handicaps are not limited with direct consequences. Indirectly, to access more advantaged locations disadvantaged consumers need to spend more of their resources. Utilisation of more time and energy for grocery

shopping can be quantified when converted to fuel or money but social and cultural negativities such as alienation and exclusion are hard to concretise.

4. The Data:

Description: To prove the main hypothesis of the research (which is the consideration of urban retail production as a layer contributing to the development of urban inequalities) and also to provide an initial knowledge about Ankara's organised food retail geography this research is focused on 18 major organised food retailers having 516 stores functioning in metropolitan area of Ankara. These firms represent different retail capitals having different development stories, functioning at different spatial scales and having different spatial strategies. All these issues can be chosen as a special research topic but for the purpose of keeping the track on spatial injustices, author prefers to consider them equal entities whose presence in a neighbourhood satisfies the condition of standardised food accessibility. Shopping centres are excluded from the research as their purpose cannot be limited with food retailing but more importantly because their attraction range does not match with the scale of this research which is the neighbourhood scale. Lastly, it is important to remind that the research represents a picture in the history of capitalist development in Turkey which has a definite time (the year 2007) and a definite space (the city of Ankara). Considering the dynamic character of the retail environment at the time when the research is finishing the author recognise that the retail geography of Ankara has already been changed. Considering the year 20012, the question on inequalities is still persistent and can be the motivation of another research.

(Table 2)

Study area: Based on firms' web pages, addresses of the stores are found and their location is identified. Stores are then tagged on a GIS map covering metropolitan area of Ankara (green dots on the map). Because of the existence of some misinformation, sometimes due to technical impossibilities but mainly as a consequence of the geographical focus of the research (which is the metropolitan area of Ankara) thirty-eight stores had to be taken out of consideration. Despite these exclusions, the research covers 95% of considered organised food retailers. On the side of neighbourhoods, some of them need to be taken out of the consideration (orange coloured neighbourhoods) for two reasons. Firstly, some neighbourhoods, although appears within the boundaries of the metropolitan districts could not be considered as part of the metropolitan Ankara due to their rural character and poor connections with the city. Secondly some areas had to be removed as the major function they inherit is not housing. Military lands, Ataturk's Forest area and lands belonging to governmental institutions are examples of the second group of neighbourhoods which are excluded from the research.

(Image 1 and Image 2)

Socio Economic Indexes and retail / neighbourhood relationship: The research starts with the preparation of indexes. For the construction of indexes, socio economic indicators showing significant influence in the previous section and mentioned as important in the literature are taken into account. By doing this the importance of less significant indicators eliminated. After determining the most significant indicators, normalisation process starts1 with reference to group's minimum and maximum values. At the end, 11 indicators covering 65 information items are summarised in five indexes. DEMOG index is constructed with the combination of two significant indicators, the ratio of 1 person households and the ratio of households having more than six persons, are taken into consideration. For the formation of EDUC index three indicators are utilised. In addition to the ratio of high school graduates, the proportion of illiterate population and illiterate women ratio are brought together. ECON index is the most composite index among all. It includes information from position in the job market, status in the job, economic activity and occupation. The employed population ratio, the proportion of workers in the finance, insurance and real estate, the proportion of construction sector workers, the number of scientific and technical personnel over all occupation categories, the ratio of employees and ratio of employers over active population are utilised as key indicators for the construction of economic index. Good amount of information and indicator are eliminated before the construction of the building index BLD. At the end of different calculations considering all physical information, it is observed that the proportion of flats not having a kitchen, toilet, shower and flats having all these amenities outside the living unit is thought to be a good indicator that can be used to differentiate neighbourhoods. Finally the price index P is constructed on the basis of average land prices in the neighbourhoods.

(Table 3)

Formation of neighbourhood groups: In this step of the research descriptive statistics and box-plot analysis are presented for the initial exploration of the data. Similar to the construction of indexes, a simple data reduction method is utilised to group neighbourhoods. Neighbourhoods are grouped according to the organised food retailer number they include. First group is composed of 133 neighbourhoods having 0 organised food retailers within their borders. This group is assumed as the most deprived group of all. Second group is a group of 181 neighbourhoods having 1 to 5 food retailer inside. Neighbourhoods forming this second group are considered as 'normal' neighbourhoods having neither significantly less or significantly low number of food retailer. The third group represents the most advantageous neighbourhoods where the retail presence changes between 6 and 11. In this last group there exist 23 neighbourhoods. To be able to reach much more definite answers and a neat conclusion the research focuses on the first and third group of neighbourhoods representing 'extreme' sides of the organised food retailer presence.

[1] Normalisation formula (N): N(value X) = (value X – column minimum) / (column maximum – column minimum)

These two retail groups' statistics are analysed on the basis of socio economic indexes.

4.1. Data processing I: descriptive statistics and box plot analysis:

Considering the descriptive statistics, when one moves from first group to the third, mean values of the indexes increase without any exception. This can be seen as a sign of relative advantage of well of neighbourhoods as index numbers increase with the socio economic advantages. Different from other groups, in the first group index ranges vary considerably. For example, while for the BLD index the range is 0.81; the range of EDUC index is 0.91. This shows how neighbourhoods within this first group differentiate among each other. With a lot of outliers and extreme values, the one and only low range index is the price (P) index which indicates average land values. P ranges from 0 to 0.55 but has a mean of 0.06. This illustrates how similar the neighbourhoods of the first group in terms of average land prices.

The third group is characterised with lowest ranges among index values and illustrates significantly higher mean values for all indexes when compared with other groups. With relatively low number of outliers and no extreme values, this group is considered as more monolithic than others having much more outliers and extreme values. When general Ankara profile is considered, Education index EDUC which stays higher than other indexes reaches its peak in the third group with a mean of 0.78 and with a standard deviation of 0.14. Similar to other groups' profile, the price index P stays low with reference to other indexes (with mean: 0.18 and SD: 0.14). But different than others the range of P index varies between 0.03 and 0.53. furthermore the price index forms a much normally distributed quintile range. These specialities of the third group can be interpreted as the group is composed of neighbourhoods having various average land prices and the variation of prices is not skewed to any side and evenly distributed among neighbourhoods.

With the utilisation of socio economic indexes it becomes one more time possible to trace how the distribution of organised food retailers is dependent on socio economic profiles of the neighbourhoods. At one side, advantageous neighbourhoods in socio economic terms are one more time proved to be advantageous when retail distribution is considered. On the other side, socio-economically disadvantaged neighbourhoods experience another level of disadvantage with the uneven distribution of organised food retailers.

(Table 4, Table 5 and Table 6)

4.2. Data processing II: Correlation matrices and correlation coefficients

The third step towards GWR consists of statistical prove of the relationship between socio economic indexes and retail distribution. To this end correlation analysis is utilised. Correlation analysis is composed of two components: correlation

matrices and correlation coefficients. In statistics, correlation analysis gives information about the sign and degree of the relationship between two variables. This information is supported with an indicator of significance (R square).

Correlation analysis starts with the construction of scatter plots which graphically illustrates the relationships between variables. Then, with the correlation matrices relationships are analysed quantitatively. Regarding the scatter plot distribution of different socio economic indexes with reference to retail number it is observed that all the indexes have positive correlation with the retail number. In other words it is possible to say that there exists a general tendency that the retail number at neighbourhoods increases together with increases in those neighbourhoods' socio economic profiles. To be more concrete about the amount of increases and the relationship between retail number and socio economic characteristics, one needs to look at correlation coefficients[2]. For all the indexes the correlation analysis gives significant results. In the analysis it is seen that the coefficients change between 0.282 P (price) and 0.415 EDUC (education). According to correlation coefficients, the education index is seen to be the most influential index that contributes to any positive change in the retail number. On the other side of the index influence, the effect of P (average land price) in changes in the retail number stays very low. Among the most influential indexes, education is followed respectively by economic, demographic and building indexes.

(Table 7)

4.3. Data processing III: Regression analysis

Traditional regression technique is utilised to determine relationship between two numerical variables. Different from correlation analysis which is principally concerned with the determination of the relationship between variables, regression technique is utilised to predict values of one variable with the help of the values of the other variable. this relationship is expressed with a formula representing the relationship between variables. In graphical terms, the regression graph differ from correlation graph as the points forming the regression line do not produced from the variables forming X and Y pairs of a point. Instead, regression lines are produced so that the distance between every value and the regression line stays at the minimum when squared and summed. While the scatter plot of (x , y) pairs resumes the distribution, the best-fit line is viewed as a descriptive summary of an approximate relationship between x and y values in the data set (Devore and Pack, 1986:441). As a result the conventional regression equation becomes:

$$Y = a + b X$$

where X is the explanatory variable and Y is the dependent variable
(linear regression equation)

[2] Pearson Correlation Indexes and scatter plots are calculated with the help of SPSS 15 Statistical Software. During the calculations 7 outliers are identified and excluded from the analysis to protect and reflect the general trend.

With the utilisation of regression analysis it is intended that the relationships revealed trough percentages brought to a much more statistical and quantifiable level. With this, it becomes possible to distinguish variables according to their effect on the change in the retail geography. Furthermore, regression analysis enables the inclusion of all neighbourhoods without any classification. Through this, the analysis includes each and every individual case's socio economic information and retail specification. Another important implication of the regression analysis is that in multiple modes it becomes possible to reveal the relationship of different variables (dependent variables) over one variable (independent variable).

$$Y = a + b_1 X_1 + b_2 X_2 + b_3 X_3 + \ldots$$

where X_i is the explanatory variable and Y is the dependent variable
(multiple regression equation)

The regression model creating the relationship between socio economic indexes and retail number has a significantly low R^2 and R values. R^2 is the overall measure of the strength of the association between dependent (retail number) and independent variables (socio economic indexes). The R^2 score of 0.18 indicates that the global regression model including all indexes is not a very powerful model explaining changes in the retail number at neighbourhoods in Ankara. Additionally, the R value 0.425 which signifies the correlation between dependent and independent variables stays also quite low as underlined in the correlation analysis. Because the intention here is not to use the regression model for predictive purposes the R and R^2 can be considered acceptable to identify the influence of each index on the retail number.

When one moves beyond global model, the regression model confirms that retail number in the neighbourhoods positively related with the indexes reflecting socio economic status of the neighbourhoods. This means any positive increase in the indexes has an increasing effect on the retail number. Different from correlation coefficients the regression model explains the influence of each index in the number of food retailers. B coefficient of the model indicates that education (EDUC) has the highest influence on retail number while building characteristic (BLD) has the lowest influence. The EDUC coefficient 2.56 signifies that every unit increase in the EDUC index has a 2.57 increase in the number of retailers in any neighbourhood. For the case of BLD index, any single unit increase in BLD index causes 0.8 unit increase in retail number. The importance of education is followed by neighbourhoods' economic condition (ECON), average land prices (P) and demographic characteristics (DEMOG).

Although the OLS regression model reveals important relationships and helps to identify how much each index contributes to the changes in retail number, all indexes stay outside confidence intervals when their significance is considered. Together with low R and ^{R2} values, the low level of significance can be the result of some factors. First of all, despite normalisation the value range of organised food

retailers in any neighbourhood do only vary between 0 and 11 whereas indexes have much broader ranges depending on concerned populations living in neighbourhoods. As a result of the mismatch between the range of the dependent variable and independent variables the regression model may not be able accurately reflect the dependence between indexes and retail number. Secondly and may be more importantly the change in the retail number can better be explained with an omitted variable which is not concerned in this research. Because the research intents to reveal the influence of some specific factors, namely socio-economic characteristics, despite the low level of significance the results of the regression analysis can still be considered as valuable within the limits of the specific purpose of this study.

(Table 8)

5. Conclusions:

The political and economic crisis of 1980's shaped the coming social and economic policies. In this period of socio economic turmoil imposed neoliberal policies legitimised with few opposition and started to shape urban environments. The presented written material and many others from different cases can be seen as evidences confirming the validity of crises prone nature of capitalism and its dependency on space. Not only to understand the validity of the third assumption about unjust nature of capitalism but also to strengthen the link between first and second assumptions some basic statistical methods were implemented.

Statistical tools brought the verbal evidences into the field of quantifiable entities and illustrates that capitalist logic effecting organised food retailers (at a relatively unregulated planning environment) is highly sensitive to socio economic characteristics of the inhabitants. On the side of inequalities, this finding need to be understood as new retail formats are highly dependent on socio economic characteristics and socio-economic inequalities can be aggravated once more through the locational practices of food retailers. Another contribution of this research is the decomposition of the socio economic characteristics. With the help of this, it becomes possible to differentiate the interrelationship between different socio economic condition and locational preference of observed organised food retailers. Both the correlation analysis and the regression model underline that first the education (EDUC) and than the economic (ECON) variables are highly correlated with the retail presence considering the case of Ankara. Interestingly, average land prices (P) and the index of buildings' physical condition do not have significant influence on the presence of organised food retailers.

The findings and conclusions of this research can further be developed. globally proved relationship between the spatial character of the capitalist system and its influence on organised food retailers can be analysed in detail with different statistical methods decomposing the area of investigation into different much smaller fields (ie: neighbourhoods). By doing so it becomes not only possible to increase the statistical significance of the tests but also provide an understanding how different the effect of socio economic factors along the space. In other words, neighbourhoods

where education index has a more determinant role in the distribution of food retailers separate from the neighbourhoods where average land prices' influence is more. Apart from mere statistical practice, on the retail planning side, such differentiations would be beneficial to eliminate retail based inequalities once locally determinant socio economic factors are known.

THE ENERGY SELF-SUFFICIENT CITY

Ernst, Michael, Hörl, Bardo, Kalasek, Robert, Linzer, Helena, Mayerhofer, Rainer, Voigt, Andreas, Walchhofer, Hans Peter[1], Mintscheff, Ilian[2], Kainz, Ferdinand[3]

Abstract

The concept of an "energy self-sufficient city" involves a decentralised energy production system with energy extraction in neighbourhoods or villages which are interconnected in a "thermal smart grid". Regional renewable energy sources are to be given priority for energy production (electricity, heat, cooling). Current energy provision on the basis of fossil fuels in centralised thermal power plants involves a considerable negative impact on the environment. Traditional concepts require energy to travel large distances to reach the consumers. A solution to this problem is the conversion of a centralised energy supply system to an integrated network of local or regional energy suppliers. Such a decentralised energy system results in a regional "thermal smart grid" which operates on the basis of renewable, local energy sources (biomass, refuse-derived fuels, solar power, geothermal energy, etc.). The objective is to devise a regional energy supply system which integrates decentralised energy plants in various types of settlement. The energy supply concept is assessed and developed on the basis of model cases. The settlement types chosen for in-depth study are "city", "urban settlement", "rural settlement" and "neighbourhoods with a specific type of use" (light industrial district, heavy industrial district, mixed-use zone). The principle of a "thermal smart grid" is potentially feasible for each of the settlement types mentioned above. The methodology developed enables spatial planners to make quantitative and qualitative statements about the potential energy self-sufficiency in a defined settlement area and to develop concepts for an optimisation of settlement and spatial utilisation structures. Investigations into the achievable levels of self-sufficiency for the four model cases shows energy self-sufficiency is strongly dependent on the surface available for biomass cultivation.

1. Definition of the problem and approach to a solution

At present, the Austrian energy sector is largely dependent on non-renewable fossil raw materials imported from abroad. In addition to this dependence, the use of fossil fuels entails a considerable negative impact on the environment. To date,

[1] Vienna University of Technology, Department of Spatial Development, Infrastructure and Environmental Planning, voigt@ifoer.tuwien.ac.at, http://raum.tuwien.ac.at
[2] DESA-Umwelttechnik GmbH, Innsbruck
[3] Ingenieurbüro Kainz PlanungsgmbH

the energy required in settlements has usually been generated in a centralised system of thermal and other power plants, which are frequently located on the periphery of settlements. Traditional energy concepts require energy to travel large distances to reach the consumers. In this context it is accepted that up to 20% of the energy generated is currently lost again. In Austria, a more pronounced environmental awareness has taken shape in the course of the Kyoto Protocol process and in response to the strong fluctuations in the price of fossil energy sources. For many years now, Austria has been pursuing a forward-looking course aimed at using renewable sources of energy.

One approach to solving the problem outlined above is to convert the centralised energy supply into a network of local or regional energy suppliers. This would bring the energy producer into the immediate proximity of the consumers, which means that energy would be generated at the place where it is needed. This integrated network of decentralised energy systems creates a regional "thermal smart grid" (the main focus being on management of thermal energy) which operates on the basis of renewable local energy sources (biomass, refuse-derived fuels, solar power, geothermal energy, etc.). This grid should be capable of covering the heating and cooling needs of the entire catchment area. The energy supply concept outlined entails a change from the centralised energy production practised to date to a decentralised energy supply tailored to local conditions and based on renewable energy sources. Regional resources such as biomass, solar power, refuse-derived fuels, hydropower, etc. should be used to operate small-scale power plants.

2. Objectives and methodology

The technical feasibility study[4] on which this paper is based aimed to devise a detailed spatial energy supply concept which would establish the extent to which decentralised energy production facilities could be integrated into various types of settlement in different model regions in order to raise energy self-sufficiency to 95%. Within the framework of this feasibility study an intelligent thermal network, the "thermal smart grid", was to be developed on the basis of decentralised energy production plants using renewable energy sources, so-called energy hubs. The aim was to network the load graphs of the energy producers and consumers so as to amalgamate the daily, monthly and yearly load graphs. In addition, the study aimed to ascertain and evaluate options for achieving the highest possible level of self-sufficiency in the regional energy supply for each of the four defined settlement types. Possible regional and local energy sources for the production of heat and/or electricity are biomass (wood, maize silage, oilseed rape), solar power (solar thermal energy and photovoltaics), wind power, geothermal energy, small-scale hydropower plants and waste-to-energy plants. A further objective was to develop a combined energy and spatial utilisation concept

[4] „Neue Energien 2020“ ("New Energies 2020"), a project funded by the Österreichische Forschungsförderungsgesellschaft mbH (Austrian Research Promotion Agency, FFG)

based on sustainable spatial energy planning taking account of the daily, monthly and yearly load graphs.

The energy supply concept posited as an approach to solving the problem was verified on the basis of a model case for each of four settlement types and then developed further. The settlement types chosen for in-depth study were "city", "urban settlement", "rural settlement" and "neighbourhood with a specific type of use" (light industrial district, heavy industrial district and mixed-use zone).

As a further focus of the technical feasibility study, the energy consumption for mobility in the various model cases was investigated. The mobility of the population essentially depends on people's individual needs and the options available. The mobility cost results from the distances that have to be covered in order to satisfy these needs and depends on the starting location and destination as well as on the availability and accessibility of transport infrastructure (transport networks).

3. Key terms

An "*energy self-sufficient region*“ is a settlement structure – consisting of natural and open spaces, spatial infrastructure (incl. transport infrastructure) and settlement units ("energy self-sufficient cities") – which is capable of covering the energy requirement for heating, cooling and electricity, incl. mobility of the local inhabitants, for its area and population, based on the load graphs (daily, monthly and yearly) for the energy sources available within the boundaries of the spatio-functional system.

The "*thermal smart grid*“ is fed by several basically independent, decentralised energy hubs based on renewable resources (biomass, refuse-derived fuels, geothermal energy, solar power, etc.). These are operated all year round (8,000 operating hours per annum) at optimum capacity, or as close to it as possible. This networking of consumers and producers ensures that all energy generation plants are used as economically and eco-efficiently as possible. Economically means continuous operation, and thus shorter amortisation periods than with the duty cycle and intermittent partial load operation used before. Continuous operation results in a longer service life due to the reduced corrosion rate of the boilers. In terms of eco-efficiency, the non-intermittent operation of waste-to-energy plants results in lower emissions of harmful substances, the reason being that in waste-to-energy plants the highest concentrations of pollutants are emitted during the warm-up and cool-down phase.

4. Quality criteria for settlement areas

Humanity and the natural world as an integrated system should be the benchmark for technological and economic development, not the other way round. The way we live should be geared towards securing a high quality of life for the human population through long-term preservation of natural resources.

In all activities, the burden on people's health and on the environment should be minimised by using processes which largely avoid production of harmful substances and exploitation of the Earth's natural resources (raw materials and energy) by establishing closed cycles wherever possible.

The utmost goal of spatial and urban planning must consist in creating conditions that foster people's well-being. Giving due consideration to the social impact of all technical solutions is an essential prerequisite for this. The built environment should foster the development of a form of community which encourages communicative coexistence and guarantees the highest possible level of safety and security (prevention of accidents, protection against violence). The interplay of a large number of individual measures within the framework of an integrated ecological structure should restore the settlement areas' attractiveness as a living environment.

1) The principles of spatial organisation for an energy self-sufficient urban and settlement structure are based on the following considerations:

2) Maximum possible preservation and further development of viable natural spaces and countryside forms the basis for sustainable spatial development.

3) The infrastructural framework for forward-looking, sustainable settlement development is a smoothly functioning public transport system.

4) The twin foci of natural spaces and public transport allow a settlement concept based on key areas along the existing and planned public transport axes. These key areas are designed in accordance with the "city of short distances" model in the form of an "EcoCity".

The functional mix forms the basis for the spatial distribution of all everyday activities. The optimum organisational form at supra-local and local level is decentralised concentration.

The "city of short distances“ entails the creation of compact, space-efficient and hence energy-efficient settlement structures, a structurally balanced mix of compatible uses, and everyday amenities and recreational facilities that are within walking distance supplemented by less frequently used facilities that can be easily

reached by public transport. Careful, economical use of the non-renewable resource of land is the guiding principle.

In terms of population, the settlement units of the "EcoCity" are designed so that they allow the establishment of economically viable facilities for all essential functions (lower limit) on the one hand, while on the other hand guaranteeing that all these facilities are within walking distance (upper limit). The guiding principle of a "city of short distances" is thus the underlying spatial organisation principle of an "EcoCity".

The spatial quality criteria cited above, plus high energy efficiency and settlement units with low energy requirements together comprise an exemplary conceptual model of sustainable settlement development that can be referred to as a "smart city".

5. Model regions / cases

Two different patterns of settlement development can basically be distinguished, depending on topography and climate:

A) those in valley locations (in both Alpine and non-Alpine regions) and
B) those in lowland plains

The above giving rise to two different types of settlement development:

a) ribbon development in the valley locations, and
b) nucleated development in the lowland plains.

To allow an analysis of as many different permutations as possible, four model cases of settlement types in different model regions were selected for the present study:

+ the city in the lowland plain (Vienna Basin)
+ the urban settlement in an Alpine valley (Inn Valley)
+ the rural settlement in a non-Alpine valley (Pulkau Valley)
+ the neighbourhood with a specific type of use in the lowland plain (Vienna/Marchfeld)

The settlement types are based on Austrian parameters and comprise:

+ cities with a population of approx. 40,000 to 100,000,
+ urban settlements with a population of 1,000 to 5,000,
+ rural areas with fewer than 1,000 inhabitants per settlement, and
+ neighbourhoods with a specific type of use.

On account of the complexity of their structures and the low number of them in Austria, cities with populations of over 100,000 were not included in the study from the outset. The results for the settlement types "city" = medium-sized town or city and "urban settlement" should be transferable to small towns with populations of between 3,000 and 40,000 inhabitants, which make up the majority of urban settlements in Austria. Other energy supply concepts are – obviously - to be elaborated for isolated, entirely dispersed settlements.

6. Results and need for further research

The investigations into the achievable levels of energy self-sufficiency for the four model cases showed that energy self-sufficiency is strongly dependent on the surface available for biomass cultivation. Furthermore, the forms of an energy self-sufficient region in the various model cases investigated differ primarily in terms of topographical conditions, settlement structure and compactness and organisation of spatial functions and uses. In the present technical feasibility study, one of the criteria for defining regional energy self-sufficiency is a positive thermal and/or power balance for every month of the year. Calculating the thermal balance over the entire year does not appear useful for defining the concept of an energy self-sufficient region because there is only very limited potential for storing the surplus quantities of thermal energy obtained over several months in the summer.

Detailed analysis of a centralised energy supply concept permits the conclusion that it makes sense to keep any energy losses as low as possible. The energy loss of the thermal distribution network should not exceed a maximum of approx. 10%.

To summarise, a need for further research can be identified, particularly in the following areas:

A) "New" mixes of uses: definition of a concept for a balanced mix of uses for each type of region and settlement and a corresponding spatio-functional organisation of uses from the point of view of energy-conscious spatial planning;

B) Agriculture and forestry: elaboration of concepts for the reconciliation of competing needs (e.g. conservation of landscape ecology, food production, renewable energy sources) in the spatio-temporal use structure;

C) Inter-community and regional concept: inter-community and regional concept of energy supply as a spatio-functional partnership between predominantly urban and predominantly rural settlement areas;

D) Availability of geodata / spatial and usage data: comprehensive provision and availability of spatial geodata and data on usage behaviour to allow detailed

assessment of the status quo (volume of built-up area used for energy production and surface available for energy production) by urban area and elaboration of the necessary comprehensive energy concepts for specific regions or for Austria as a whole.

The research should focus on pilot plans for specific demo regions to explore the current findings in greater depth. In particular, the quantitative assumptions relating to settlement structures and structures of built-up areas should be reviewed, the energy and spatial utilisation concepts elaborated in more detail and the feasibility of implementing them tested by means of an appropriate study. Cooperation with planning practitioners (regional and local authorities, communities) and local and regional energy suppliers is a key prerequisite for this.

ASSESSMENT OF BROWNFIELDS REDEVELOPMENT PROJECTS IN PITTSBURGH, PA WITH THEIR ECONOMIC, SOCIAL AND INSTITUTIONAL DIMENSIONS

Assist. Prof. Dr. Gökçen KILINÇ
Erciyes University, Faculty of Architecture,
Department of City and Regional Planning
38039, Melikgazi, Kayseri-TURKEY
e-mail: gokcenkilinc@gmail.com

Brownfield redevelopment has been considered as one of the major environmental and social concern since 1980s all around the world. The revitalization of these sides includes diverse set of issues and understanding their complex dynamics requires theories, concepts and methods of different academic disciplines. There is no doubt that revitalization of brownfields not only brings improvements to the urban structure but also economic, social and environmental benefits. It is also acknowledged as an important tool to achieve development which is sustainable.

Brownfields can be found in almost every community in the U.S. and can impact communities in variety of ways. The environmental and public health threats, safety problems caused by brownfields. Their huge impact on the environment and communities triggered the governments to constitute new regulations which motivate the communities' participation and define the liability issues more clearly at federal, state and local levels.

There are numerous definitions about brownfields, but anybody who starts to work in brownfield arena generally find the USEPA's official definition: real property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutants, or contaminant".

In this context this study aims to take a picture of brownfields redevelopment in U.S. with particular focus on Pittsburgh, Pennsylvania. Pittsburgh has a strategic location at the southwestern Pennsylvania. During its history it has had greatly influenced by the three rivers and the regions' rich and plentiful natural resources. Both of these physical properties have had a significant role in the region's development. However, the structural changes in the regional economies due to the changes in manufacturing industries, to post-Fordist production and the rise in transportation technologies affected the Pittsburgh Region beginning from the late 1970s. The city of Pittsburgh represents a good example in transformation from a heavy manufacturing city to a magnet for education, health care, financial services and

advanced technology, the collaboration of different stakeholders and the support of governments beginning from federal level to local level.

The brownfield revitalization attempts in Pittsburg Region can be considered as one of the most remarkable institutional attempts all around the nation. There are three institutions which played important roles in Pittsburgh brownfield redevelopment: 1-Regional Industrial Development Corporation (RIDC), 2-Urban Redevelopment Authority (URA) and 3- Allegheny County Economic Development. These institutions play unique roles as initiators, catalysts, coordinators, planners funding agents, providers of technical assistance and land assemblies. Especially URA has been the key facilitator not only in funding but also in implementing the City's overall economic strategies.

This paper tries to examine the past and current brownfield redevelopment projects which have been achieved by these institutions according to their environmental, social/community, economic, legal and physical concerns through a comparative approach and addresses the question of what is essential in a successful brownfield redevelopment project. Furthermore, the barriers and assets of brownfields redevelopment in Pittsburgh, PA are determined with SWOT analysis.

Key words: Brownfields redevelopment, Pittsburgh/PA, sustainability, transformation.

1. Introduction

The structural changes in the regional economies due to the changes in manufacturing industries, to post-Fordist production and the rise in transportation technologies affected the Pittsburgh Region beginning from the late 1970s. Shifting from industrial economy to service sector based economy draws attention all around the country. (Deitrick, 1999:10)

During the industrial age, Pittsburgh became the seedbed of innovation and technological advances. However, these large industrial complexes along the riverfront ant rail lines that serviced them caused the isolation of the community from the waterways. (UP, 1998:7)

Since World War II, two developments have noticeably reshaped Pittsburgh's landscape. The first one, which took a series of redevelopment and known as Pittsburgh Renaissance, was the reformulation and involvement of public and private partnership (Muller and Tarr, 2005:35) Alterations under Renaissance programs involved the construction of new skyscrapers, downtown parks, automobile parkways along the rivers and clearing of structures and railroad tracks that damaged Pittsburgh's historic Point. (Muller and Tarr, 2005:35)

By the early 1980s, another tragedy struck Pittsburgh region again. Due to the lack of capital investments, increase in demands of unions, and fall in competitiveness in a world economy, the steel industry collapsed and many of the industrial complexes

closed. By the collapse of manufacturing in the early 1980s the region's employment fell 6.8% between 1980 and 1986, while the recovering national economy expanded by 11.4% (Deitrick, 1999a:16). Fortunately, Pittsburgh achieved to reverse the economic decline in manufacturing industry into a new development trend in service sector with a well-defined urban strategy in a short time.

Revitalization of the brownfields which were occurred as the result of economic decline was considered as advantages for reversing the city's bad situation with the sprawling office parks, retail shopping centers, and residential developments through urban periphery. Clearing of the brownfield sites began slowly during the latter part of the 1980s and the 1990s (Muller and Tarr, 2005) The Urban Redevelopment Authority (URA), private salvaging firms and regional nonprofit organization called Regional Industrial Development Corporation (RIDC) worked together under the direction of county government to undertake redevelopment of brownfields around the county. The primary goals were to attract new residents and provide new taxes and jobs.

2. The Institutional Structure of Brownfield Redevelopments in Pittsburgh

The brownfield revitalization attempts in Pittsburgh Region are the most remarkable institutional attempts all around the nation. There are three institutions which played an important role in Pittsburgh's brownfield redevelopment: 1- Regional Industrial Development Corporation (RIDC), 2-Urban Redevelopment Authority (URA), and 3- Allegheny County Economic Development

1)Regional Industrial Development Corporation (RIDC): The Regional Industrial Development Corporation of Southwestern Pennsylvania (RIDC) is a private, non-profit organization that focuses on a regional approach to economic development which was established in 1955 for fostering new employment opportunities and diversifying the regional economy of southwestern Pennsylvania (Muller and Tarr, 2003:37, RIDC. 2011). As a corporation, working under the direction of county government in Pittsburgh region, the RIDC undertook redevelopment of brownfields around the county (Muller and Tarr, 2003:37). However, its single-minded focus on economic development resulted in the sweeping demolition of the old industrial landscape and, except for a few isolated structures, almost a complete disregard for the history of the region (Muller and Tarr, 2003:37).

2)Urban Redevelopment Authority (URA):The URA, one of the first redevelopment authorities in Pennsylvania, was first incorporated in 1946 to take advantage of a new state law permitting municipalities to create redevelopment authorities for the purpose of acquiring and clearing blighted land through both negotiations and the use of well-known domain (Stewman and Tarr, 1982).

URA is still the major agency for the economic development of Pittsburgh city. Its goals are stated as creating jobs, increasing the city's tax base, and improving the vitality of businesses, neighborhoods, and the City's livability as a whole (URA, 2011, http://www.ura.org/about/about_us.php). Since the mid-1980s, The URA took on new responsibilities in addition to its traditional activities of land acquisition and clearance. As a joint developer with an economic stake in projects, its impact is varied through encouraging tourism, monitoring projects that could take advantage of the riverfronts for recreational use. By the early 1990s, URA had a role as a facilitator of major economic development initiatives, by 1996; it was involved to 31 major initiatives including riverfront development, industrial site reuse, downtown development, and neighborhood development (Stikkers and Tarr, 2000). URA's original purpose to eliminate slums and urban blight has been expanded over the years to encompass revitalization and expansion of Pittsburgh's economic base. This role led the URA into active revitalization of brownfields through land acquisition, clearance, planning, site preparation, marketing, financing and project management. (Stikkers and Tarr, 2000) Today it became an authority which is assisting low income clients to attain homeownership, recovering brownfields for new developments and helping communities reinvent themselves (URA, 2011)

3) Allegheny County Economic Development (ACED): Allegheny County Economic Development (ACED) determine its mission as managing economic and residential development for the County (ACED, 2007). ACED also serves a s the catalyst for public-private neighborhood partnerships. Federal government and the Commonwealth of Pennsylvania are their most important partners. In addition, in order to create Tax Increment Financing Districts, ACED partner with local governments and school board

3. Pittsburgh's Brownfield Projects

The brownfield projects realized by those institutions generally take place along the riverfront in Pittsburgh (Figure 3.1, Figure 3.2)

Figure 3. 1. Brownfields at Pittsburgh and its surrounding regions. (WPBC, available at http://www.cmu.edu/steinbrenner/brownfields/Case%20Studies/nav1a.html)

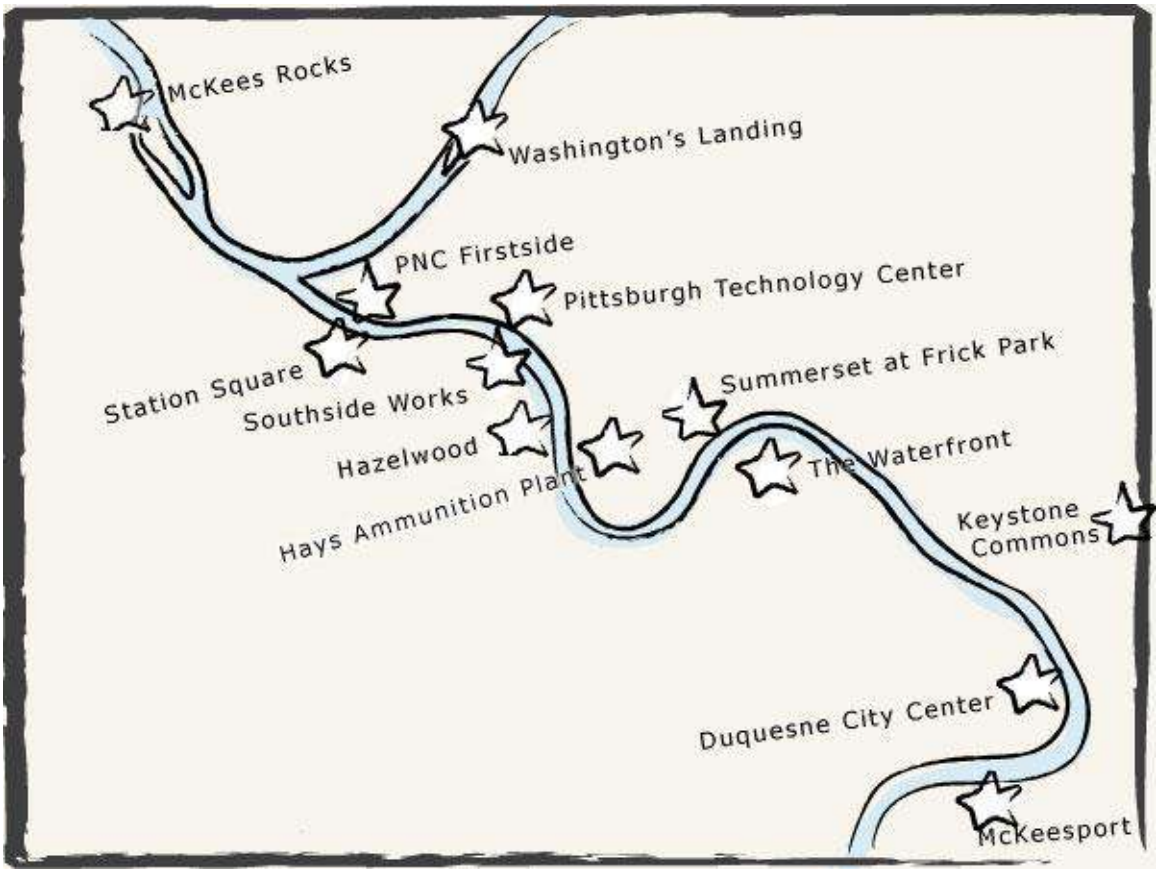

Figure 3.2. Some important Pittsburgh brownfield redevelopments (WPBC, available at http://www.cmu.edu/steinbrenner/brownfields/Case%20Studies/nav1a.html, August 6, 2011)

3.1. RIDC's Brownfield Projects

3.1.1. Industrial Center for Mckeesport

The Industrial Center of McKeesport was once home to several metal tube and pipe mill companies (Figure 3.1). In 1984, RIDC started working with the McKeesport Area Recovery Plan on a strategy for the distressed urban communities in the Mon Valley. (RIDC, 2010)

The Industrial Center of McKeesport offers land, water, and rail access. It is close to the turnpike and next to the river; although rail access competes with ground transportation (such as trucking) due to obstruction of passing trains (WPBC, 2007a).

RIDC undertook all the environmental threats since 1990s at the site. According to the Act 2 the developer of the site is responsible only for mediating immediate and direct threats to public health. Most of the contamination on the site was due to fuel oil and heavy metals. Starting in 1990, phased plans for environmental remediation, selective demolition and sale of miscellaneous scrap were undertaken.(RIDC, 2010)

The community's input is considered as the key factor for the success of the site. Particularly, the West-to-West Coalition was formed in order to serve as an economic developer for this and many sites. The Coalition represents 21 communities and has been selected to receive (WPBC, 2007a).

The RIDC used the Department of Community and Economic Development's (DCED) Industrial Sites Reuse Program funds for environmental assessments and for cleanup projects. Also, $8.0 million in loans and grants from the U.S. Department of Housing and Urban Development (HUD) were sent to redevelop the City Center of Duquesne and the Industrial Center of McKeesport. The Allegheny County Department of Economic Development worked with the Redevelopment Authority of Allegheny County (RAAC) and the Regional Industrial Development Corporation (RIDC) to take advantage of HUD's Section 108 Loan Guarantee Program, which enables public entities to leverage Community Development Block Grants into additional funding (WPBC, 2007a). Some images from the past and current use of the site can be found on Figure 3.1 and Figure 3.2.

Figure 3.1. Past and current uses of McKeesport Brownfield redevelopment site. Available at http://www.ridc.org/files/a_files/Case%20Study%20-%20McKeesport%20-%20red.pdf

Figure 3.2. Images from current use of McKeesport Brownfield redevelopment site.

3.1.2. The Almono Site (Hazelwood)

The 178-acre ALMONO brownfield site is a long, narrow strip of derelict riverfront land, geographically bound by the Monongahela River to the west and a steep hillside to the east. It was once home to two of the largest steel manufacturers in the Southwesten Pennsylvania region: Jones and Laughlin Steel Company (J&L) from 1884 to 1974 and Ling Temco Vought (LTV) Coke Works 1974 to 1998 (Gtech. 2011).

This land is the last large brownfield left within the Pittsburgh city limits, making it attractive to the hospitals and universities that reside in Oakland. Therefore, various site plans which aim to capture the interesting urban landscape of the site in a way to integrate the needs and current conditions of the nearby community have prepared (WPBC, 2007i). Because of its being the only brownfield owned by local foundations there are many opportunities that allow unique development. It is the first urban brownfield in the city in which is developed without the contribution of local government agencies and departments.

As the other brownfield sites which locate in the inner parts of the cities, Hazelwood also has a wealth of physical infrastructure that will be an asset for future developments. There are two rail lines that cross on either site of the site, one of

which connects to downtown and the other travels up Panther Hollow to Oakland. It has a working and licensed dock system that would allow for barge traffic and it is bounded by Second Avenue which is the main commercial corridor of the neighborhood. The size and flat structure of the site are the other features which enable many alternatives and opportunities for the future developments.

Due to contamination, the area needed to be de-commissioned of asbestos, petroleum, PCB removal, and other environmental hazards (Gtech, 2011).The site has currently cleared Act II remediation The entire site has been cleaned for commercial use and much of the site would need little or no remediation for future housing (WPBC, 2007i) (Figure 3.3.)

The community in Hazelwood is aware of the development of the site with a successful planning strategy and design criteria will bring the wealth and better living environment. The community involvement in the planning process has been organized through a Hazelwood Initiative, Inc (HI). The mission of HI is to act as a catalyst for the revitalization of the Greater Hazelwood Community in collaboration with the city, county and state representatives and serve as a vehicle to address resident concerns relating to various city services and to all community stakeholders (WPBC, 2007i).

Before starting the master plans, six stakeholder groups were engaged. These groups included transportation agencies; economic development agencies; private developers; river life and recreation interest groups; river commerce agencies and neighborhood residents from Hazelwood and adjacent communities (Vavro, 2003). In 2000, all these stakeholders developed their own vision of how to turn the site into a neighborhood in a sustainable way and how to make the site attractive for the residents. Their ideas, many of them similar to those that guide the Almono development today, include remediation of the site for commercial use, housing, recreation and regaining their access to the river (Fraser, 2004) (Figure 3.4.)

In the redevelopment process infrastructure costs will be significant. It is estimated that the redeveloping former steel mill sites due to the large building foundations that are often left after building teardowns will be difficult. The removal of the foundation take a considerable amount of money. The water and sewer lines, and other abandoned infrastructures on the site need a large investments to dig out, to refill, to repair, to replace or bury. (WPBC, 2007i)

Because of the land has not be developed yet it is not possible to estimate the possible economic benefits of redevelopment.

Figure 3.3. Current use of Almono Site (Hazelwood)

Figure 3.4. Almono site (Hazelwood Avenue- Courtesy of Urban Design Associates)

3.2. URA's Brownfield projects

3.2.1. Washington's Landing

Herr's island is located approximately 2 miles north of downtown along the Allegheny Rivers at a very famous point, where he Allegheny and Monongahela Rivers join to form Ohio River. The site's industrial history is extending over a hundred years to a variety of industrial uses (Deitrick and Farber, 2005) (Figure 3.5.)

In 1978 URA bought 0.5 acres from the Western Packing Company and, in 1979, 20 acres of the Buncher Company's land (Chute, 1979). The redevelopments began with the CDC, a private developer, and the city prepared a mixed-use projects comprised of commercial, light manufacturing, recreational and housing facilities. (Deitrick and Farber, 2005)

According to the environmental assessment of the central and northern part of the island, waste materials from rendering operations were found on the site. Besides, because of the placement of ash, sand, slag, cinders, and other granular materials in the fill, the groundwater did not meet drinking water standards (WPBC, 2007c).

During the planning and implementation of the brownfield redevelopment project, the developers tried to give much attention to the aesthetic viewpoint of the island in order to enhance the beauty of the island. The plantation of the streets and other public spaces, the materials used, building facade and roof slopes clearly defined. Eventually, in addition to upsacle townhouses, marina and tenis complex , many public spaces including public parks, tennis courts, biking trails, and hiking trails were formed in order to improve the accessibilty on the site (CMU, 1998a; WPBC, 2007c) (Figure 3.6.).

Figure 3.5. Image from past use of Washington's Landing

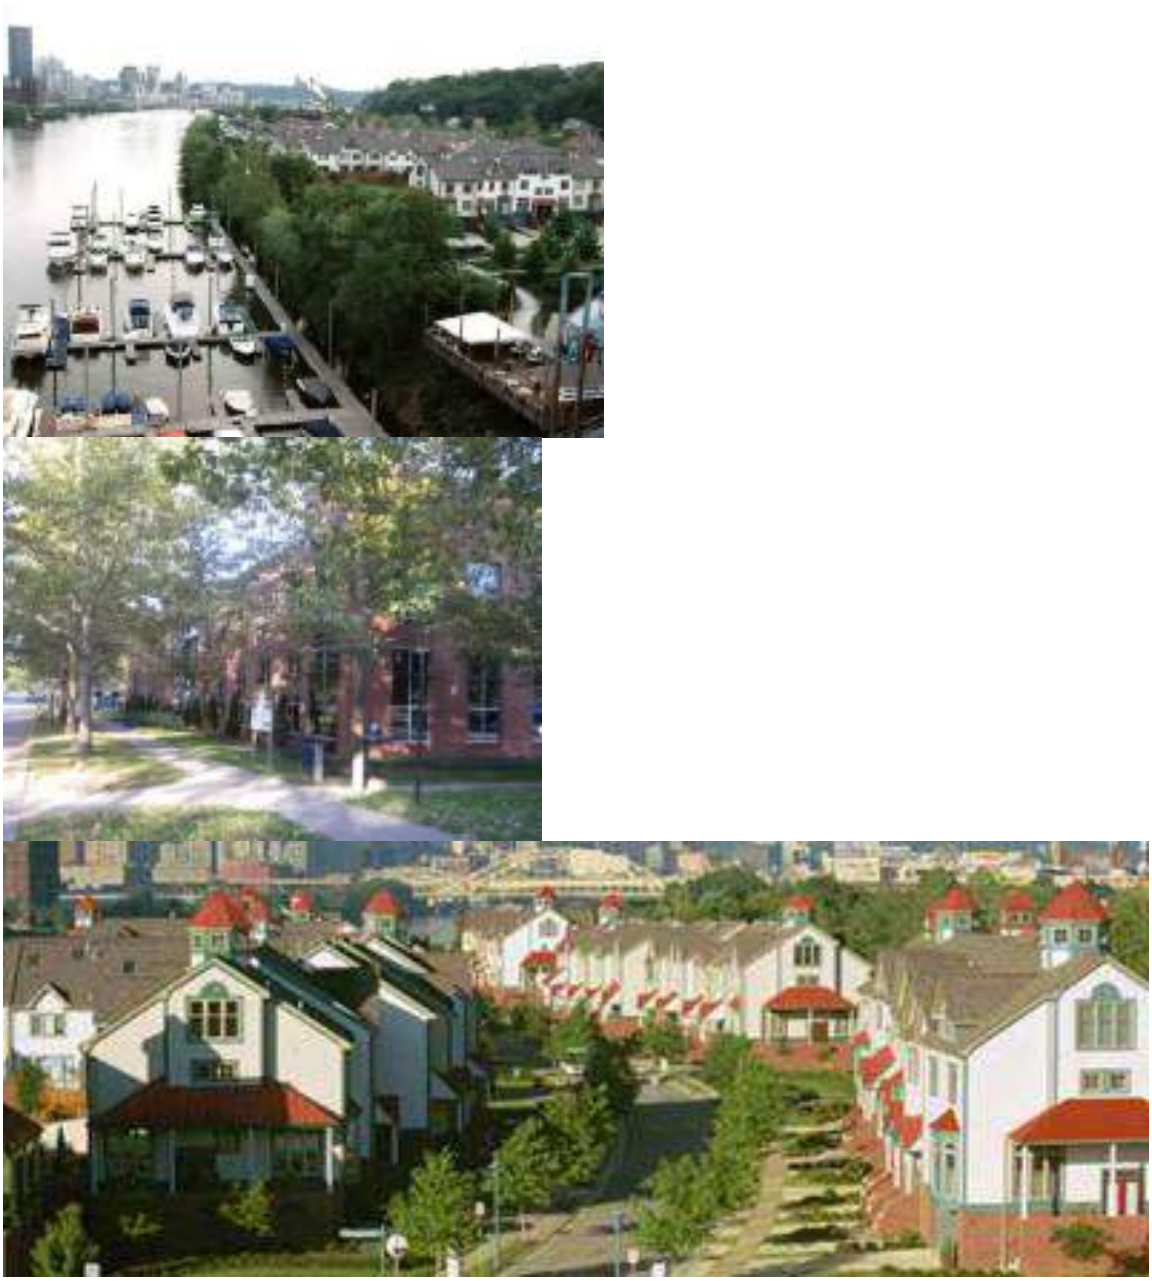

Figure 3.6. Images from current use of Washington's Landing

3.2.2. Pittsburgh Technology Center

Pittsburgh Technology Center sits on a portion of former Jones & Laughlin (LTV) integrated still mill located in Oakland across north side of the Monongahela Rivers

(Figure 3.7.). The site is less than two miles to Pittsburgh downtown and two major universities, the University of Pittsburgh and Carnegie Mellon. University.

There were numerous industrial uses during its history, including sawmills, iron and coke works, glass companies, manufactured gas, and steel production. URA purchased the land in 1983" (CMU, 1999a) Before construction on the site, all existing buildings except one, the former Soho Works galvanizing line and attached warehouse, were cleared off. Because of the wide variety and large number of industrial companies which occupies on the current PTC site, many environmental factors took into consideration (CMU, 1999a; WPBC, 2007d)

Although the URA wanted to increase access to the riverfront in this area, the active railway line on the bank of the river prohibits access. Existing infrastructure required renovations and some new infrastucture was required. None of the existing roads within the site were used. New sewer lines, electric lines, and a road system were constructed. The renovation of the Hot Metal Bridge was carried out in 2000. (WPBC, 2007d)

Today, there is an increasing demand for new office buidings in the area. The success and continious interest shown by private organizations induces URA to make more available land for office space and give more oppotunity to use more smart growth practices on the site (WPBC, 2007d) (Figure 3.8.).

This project is considered as an embodiment of Pittsburgh's evolution from town founded on heavy industry to a city on the cutting edge of innovative research and technology. (Lubove, 1996) Furthermore its sucess makes clear the contined prominence of the URA in shaping the Pittsburgh environment as well as the emergence of a broadened civic coaltion in the post-steel era (Lubove, 1996).

Figure 3.7. Images from past use of PTC

Figure 3.8. Images from current use of PTC

3.2.3. Southside Works

Southside Works is located on the south side of Monongahela River, directly across from what is now the Pittsburgh Technology Center. During the 19th century iron was produced and a big steel Company took place at the site for over a century (Santoro and Messenger, 1998) (Figure 3.9.)

After purchasing the land in 1993, URA made an effort for community consesus related to development of the site until 1996. Over the next few years URA tried to attract the developers while completing environmental, infrastructure, and traffic enhancement efforts and executing a Tax Increment Financing (TIF) package with the three taxing bodies The URA focused on improving the accecibility of the site and traffic. (WPBC, 2007e)

Today, the site contains approximately 330,000 square feet of specialty retail, restaurants, a hotel, residential urban living units, and up to 700,000 square feet of class A office space (WPBC, 2007e).

Southside Works considered as a first-class riverfront development utilizing a mix of office, medical, recreational, housng and retail uses. By this brownfield redevelopment Project, 5400 employmnet opportunities and approximately 1500 jobs were created (WPBC, 2007e) (Figure 3.10.)

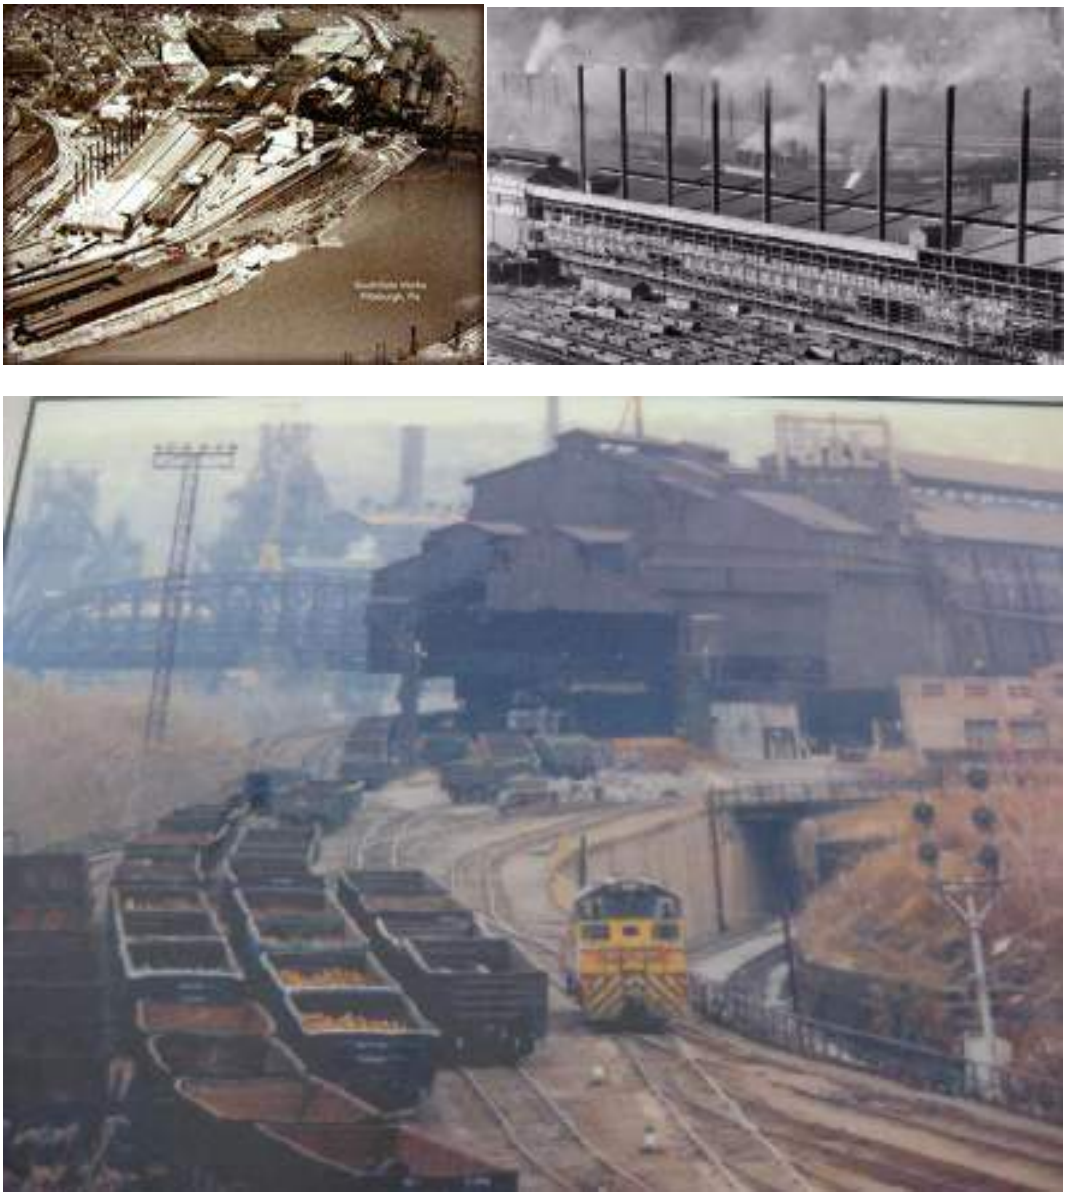

Figure 3.9. Images from the past use of SSW

Figure 3.10. Images from current use of SSW

3.2.4. Summerset at Frick Park/Nine Mile Run

In contrast to other Pittsburgh brownfields, any manufacturing facilities were constructed on Nine Mile Run and its valley during its history. It was served as a dumping ground over 17 million cubic yards of slag (Stikkers and Tarr, 2000) (Figure 3.11.). Nevertheless, its large size, close proximity to steel mills, river frontage and easy access to water and rail transportation made Nine Mile Run an ideal site for industrial development. (Stikkers and Tarr, 2000, CMU 1998b)

The URA purchased the property in 1995 and assembled a planning team to prepare plans for a housing development of up to 800 units (Deitrick and Farber, 2005:170)

Currently, Summerset at Frick Park projects is at its Phase II development. Phase I included 221 homes on 27 acres of land. Phases II will include 270 additional homes on 42 acres, and Phase III will include 213 homes on 40 acres. Phase I sales were a

success. (WPBC, 2007f) The developers constructed a main road throughout the housing areas. The projects is considered as a successful development in terms of economic concerns. There is a raise in the property taxes for the area and the project expected to generate over $2.9 million n annual revenue in the future (WPBC, 2007f) (Figure 3.12.)

Figure 3.11. Images from past use of Summerset at Frick Park and Nine Mile Run

Figure 3.12. Images from current use of Summerset at Frick Park

3.2.5. Hays Ammunition Plant (Galvtech)

The Hays site lies in the southeastern part of the city and is more properly culturally and geographically connected to the Monongahela Valley the location of many former steel mill properties (Deitrick and Farber, 2005) The site is not located along a riverside but at a very accessible point in the Monongahela River drainage basin. In 1942, the U.S. navy constructed the Hays ammunition plant to manufacture gun forgings near the southeastern border of Pittsburgh.

In 1993, the Army donated the site to the URA for $1 (Massey, 1995, Deitrick and Farber, 2005). In September of 1995, it was announced that the Hays site would be leased by GalvTech from the Pittsburgh Economic Industrial Development Corporation (PEIDC) which is part of the URA. (Belko, 1995)

Currently,there are plans for improvement in the rails to accommodate new rail traffic. Also, a new entrance constructed on SandCastle Recreational Park property may be created. The existing entrance will include the construction of new concrete pavement and the widening of the roadway intersections. Economically, GalvTech's activity has brought tens of new jobs into the area (WPBC, 2007g) (Figure 3.13.).

Figure 3.13. Images from current use of Galvtech

3.4. Allegheny County Economic Development's Projects

3.4.1. The Waterfront

The site is located on the Monongahela river directly across the city of Pittsburgh. It was occupied by a steel mill headed by the US Steel Industry (WPBC, 2007h) (Figure 3.14.). Despite some advantages of the topography of the land, there are some disadvantages in terms of accessibility. Even though the topography is flat and nearby other prime locations such as Squirrel Hill, the location of the site is not easily accessible to the communities within walking distance. Active railroad tracks separate the development from surrounding communities (WPBC, 2007h)

The developer had to undertake main streets because of the increasing traffic due to the new residential, commercial and retail uses. Many physical changes were made, however the historical character were destroyed during these efforts.

The lubricants used by the steel mill were stowed in underground storage tanks, which leaked and contaminated the soil. There was also asbestos contamination on the site. The asbestos cleanup and a storm runoff test was conducted before the development. (WPBC, 2007h)

What the people expected most from the redevelopment of the site was jobs for out off work steelworkers (Serrin, 1992). The former residents were conflicted over what the new Homestead should be, but many wanted industrial or retraining facilities so people could stay in place, prepare themselves for new jobs, and "have control over their lives (Serrin, 1992). The citizens formed a non-profit citizen's development corporation (CDC) and a Homestead Economic Corporation (HERC). The state formed the Enterprise Zone Program. HERC and Enterprise Zone were able to develop two master plans together, one for the mill site and one for the community. However, most of the residents disappointed with Waterfront development. Because retail jobs do not support families, neither do they provide the unemployed with the sense of control Homesteaders so urgently need (Pearce, 2006).

As a result of these projects a new landscape has emerged along the rivers (Figure 3.15.) Although paying more attention to the river, the private Waterfront development on the former Homestead Steel Works site on the Monongahela River is retail, entertainment, office, and light industrial complex seemingly designed without any consideration of the riverfront (Muller and Tarr, 2003:37) In other words, it can be said that he development of Waterfront based on the suburban model and the land would be better utilized if storied buildings as well as structured parking was also part of development plans.(WPBC, 2007h)

Figure 3.14. Image from past use of the Waterfront

Figure 3.15. Images from current uses of the Waterfront

3.4.2. City Center of Duquesne

The City Center of Duquesne is located on approximately 250 acre site along the Monongahela River, south east of Pittsburgh on the former Duquesne Steel Works (Figure 3.16.). The plant was in service until 1984. In 1984, RIDC started working with the McKeesport Area Recovery Plan on a revitalization strategy for the distressed urban communities in the Mon Valley. Allegheny County Economic Development took control of the site in 1987.(RIDC, 2010; WPBC, 2007b)

The site is at an accessible point via water and rail. RIDC welcomes the newly proposed funding for flyover ramps which would improve vehicular access over extremely active rail lines. The current access to the site creates significant traffic, pedestrian delays and safety risks. Therefore, transportation by ground, specially trucking access is considered as the key issue for the site (WPBC, 2007b)

RIDC did not pursue environmental insurance for the City Center of Duquesne. The primary contaminants on the site were heavy metals and PFCs. According to the environmental assessments, it is determined that the site would require at least 12 inches of fill spread over the entire site in order for approval as a light-industrial commercial property. On the other hand, demolished blast furnaces that are laden

with asbestos have presented a large obstacle to redevelopment of the sites southern end. (WPBC, 2007b)

The railroad tracks run between the community and the property causes the feeling of separation from the site. It is not possible to say that the communities' decisions have been taken into consideration during the redevelopment of the site. The West-to-West Coalition was formed in order to serve as an economic developer for this and many sites (WPBC, 2007b)

This site is large in an area with an economically disadvantaged population. The attack of Hurricane Ivan in 2004 decreased the market conditions on the site. Even though several public funds have been available for the site, the redevelopment process has not been completed yet. Some of these funds are:

To date, a total of $31 million has been committed to the Duquesne and McKeesport projects. The funding includes: $8.0 million in loans and grants from HUD; $4.5-million grant from the RACP; $1.0-million grant from the U.S. Environmental Protection Agency (EPA); and $17.5 million in earmarked federal transportation funding.(WPBC, 2007b)Until now, RIDC has renovated 5 existing buildings into multi-tenant facilities. In addition to them several facilities have been constructed filling up 60% of the site (Figure 3.17.)

Figure 3.16. Images from past and current uses of Duquesne City center Brownfield Redevelopmnet Site. Available at http://www.ridc.org/files/a_files/Case%20Study%20-%20Duquesne%20-%20red.pdf

4. Conclusions

With the redevelopment of brownfields through city's new economic vision and land-use strategies, Pittsburgh has achieved to reverse its decline into a a new development strategy. All the brownfield redevelopment projects In Pittsburgh analyzed here met the objectives of the following strategies

-Revitalizing the waterfront

-Increasing public access to waterfront

-Attracting the residents to the city

-Establishing high technology industry.

-Accelerating the urban developments through City's new development strategy

-Increasing the quality of life

-Reversing the city's economic decline

-Creating new jobs

There are some lessons which can be learned from the brownfields redevelopment projects of URA in Pittsburgh which can be applicable elsewhere. Stikkers and Tarr (2000) in their paper, try to clarify the important points for the redevelopment strategy in these projects: According to them all these projects facilitated the City's overall redevelopment goals of creating high technology jobs, encouraging people to move back into the city, increasing access to waterfront, and preventing the decrease in tax revenues. Public funding is the most important factor in achieving the city's redevelopment goals. It is nearly impossible to attract the developers' interest to abandoned lands in the cities where there is population decline. In many cases it was seen that the attempts to attract private developers and to develop the sites cannot be achieved unless the local governments took the lead. Most of the actors who play important roles during the redevelopment of these brownfields and in determining the City's new development strategy argue that without URA it was impossible to achieve these projects. It may be possible to find developers, but at that time the developments would have been not realized through mixed use planning strategy or through City's new development strategies.

In this context it is necessary to emphasize that to facilitate these strategies, significant amounts of public funds from local, state, and federal sources has been required. The city's efforts, combined with state government policies that favor brownfields redevelopment, have been able to provide the momentum necessary to transform and revitalize these properties.

URA has been the dominant body, as the primary source of funds, in the Pittsburgh's brownfields redevelopment process. As a developing agency, the URA was unique. As Lubove (1996) indicates, no other institution as URA combined so many functions: initiator, catalyst, coordinator, planner, funding agent, provider of technical assistance and land assembly. URA plays the key facilitative role not only in funding but also in implementing the City's overall economic strategies through acquiring brownfields and removing the barrier of environmental liability. By acquiring the land URA has the opportunity to control all the aspects of redevelopment. Implementing City's overall economic strategy may have been more difficult and slower had Pittsburgh sought to attract private developers to acquire and develop the land. Moreover, the success of removing the barrier of environmental remediation have only achieved by the lawsuits concerning environmental liability issues associated with the brownfield projects.

Infrastructure is another critical factor in the redevelopment of these sites. In most of these projects (except Hays Ammunition Plant and RIDC's projects), existing infrastructure was almost completely removed and the sites developed as it were vacant. This approach has some advantages in establishing connections to existing facilitates such as water and sewer system. A particularly important issue in this respect is transportation and how impacts to the community's existing street network will be addressed. Such a problem appeared at the Southside works by rehabilitating a historic bridge to serve as a new transportation gateway. In other cases, such a development cannot be achieved and the increased traffic with new developments has proven to be tough problem associated with development. An important issue

beyond the re-use of existing infrastructure, however, is the degree to which new development will connect to the fabric of surrounding community. In Pittsburgh cases, an important goal of redevelopment has been to transform the industrial sites at the waterfronts, to remove barriers associated with previous use of the rivers and to establish corridors that can connect the surrounding communities to the recreational public spaces at the waterfront.

In terms of transforming an abandoned site into a magnet for new jobs, the Pittsburgh Technology Center can be considered as successful project. However, the interconnection between the surrounding community and the riverfront was not achieved and an opportunity of enhancing public access to its prime waterfront location was missed. A rail road line along the site's southern edge adjacent to the Monongahela River was one of the barriers in the failure of this strategy. Because this line effectively blocks public access to the river and occupies land that might otherwise be used as a riverfront park. Critics also fault the development because of its overall design and use of space. Instead of establishing a connection between the river and surrounding neighborhoods, the site was designed as a typical suburban office campus.

Contrary to PTC, Washington's Landing can be described as successfully reconnecting the surrounding community with the Allegheny River. To achieve these goals and to improve public access, a historic bridge was refurbished with pedestrian and biking trails and these trails linked the island to an existing riverfront on the city's north side. These design features enabled Washington's Landing to achieve the goal of restoring access to the waterfront at a site that was previously reserved completely for industrial uses.

In the Southside and Nine Mile projects, similar design criteria tried to be accomplishing because of the success of the Washington's' Landing development. At Nine Mile Run, numerous collaborative meetings were organized between city officials, artists, engineers, landscape architects, and local residents for the viability of the project.

The preservation of historical industrial heritage can be considered as another failure in these projects. Each of these sites has deep historical roots and helped shaping Pittsburgh as the center of American industry during the nineteenth and twentieth centuries. Each site is also a symbol of the region's decline. Revitalization of these sites reflects Pittsburgh's determination to rebound from a devastating period of de-industrialization (Stikkers and Tarr, 2000). The design criteria should be developed with the approach to reveal the symbol of the sites.

In addition to these major redevelopment projects, the river landscape is changing in many smaller but no less profound ways. The former industrial riverfronts are not the only sites of renewal. Most dramatic developments of a regional shopping mall and an upscale housing complex were occurred on the massive slug dump. (Muller and Tarr, 2003:37) However it is still not possible to say Pittsburgh utterly eliminate the environmental pollution problems. Despite improving river conditions, the region

still struggles to meet clean air standards and the water quality is under the acceptable levels. (Muller and Tarr, 2003:38) Waterfront reclamation, is also considered as a key aspect in improving the marketability of these sites to both potential residents and businesses (UP, 1998)

Linking of the environmental, economic and legal efforts to a comprehensive community development strategy is very essential in brownfields redevelopment in Pittsburgh Region. Such a strategy requires that contiguous communities with shared interests but distinct political boundaries must begin to work with one another to both redevelop brownfields and revitalize their communities. Moreover, an effective redevelopment strategy with vigorously working groups in order to reduce the impact of the obstacles and liabilities can also strengthen and market the assets of the sites. (UP, 1998:57) Comprehensive approach should be evident, proper planning requires that several factors, including environmental factors, transportation, land use, community interests and long - range and regional focuses, should be included." (UP, 1998:57,58)

The Pittsburgh case study provides direction for other cities in a number of areas. As Roger S. Ahlbrant Jr. (1986) mentioned in his paper about the "public private partnership in the neighborhood renewal", city programs must be flexible enough to be tailored to the needs of individual neighborhoods. The Pittsburgh brownfield redevelopment experience also demonstrate that partnerships not only provide additional resources, enabling the city to leverage its public dollars, but also help to build the capacity outside of city government to respond to the needs of community. In addition, programs, include both technical assistance and funds for operating and project purposes, to build organizational capacity may be required (Ahlbrant Jr., 1986)

At this point, after analyzing and evaluating some of Pittsburgh' brownfield redevelopment experiences, it may be necessary to ask the question "At what point will the City's strategy stimulate the private market sufficiently enough to persuade investors to take on local brownfield projects without significant infusion of public funds? Must the URA continue to serve as the developer of brownfield sites by investing substantial amounts of public funds to return them to productive use?" Because the main goal in brownfields redevelopments in many communities is to attract private developers to assume the redevelopment of abandoned or underutilized properties.

Most of the actors, had important roles in the redevelopment process, argue that there is not a certain answer for this question. Actually, it is clear that URA should continue to serve until the country' and state' economy become better, stronger and stay stable. For example according to Stikkers and Tarr (2000) the answer of the questions may be evident in another regional brownfield just beyond the city limits.

Political support and leadership is the main driving force for the achievement of the purposed objectives. However, the political climate is not the same as in 1980s.

Therefore brownfield redevelopment in Pittsburgh, PA is more difficult today than 30 years ago.

Table 1. SWOT Analysis for Pittsburgh Brownfields Redevelopment Projects

	Strengths	**Weaknesses**	**Opportunities**	**Threats**
Environmental issues		-Soil and water contamination levels are still below the legal standards	-Legal arrangements related with contamination and preservation -Increasing public awareness in environmental related issues	-Urban sprawl
Spatial issues	-Existence of infrastructure -Accessibility -Waterfront	-Insufficient awareness in historical heritage preservation -Existence of railways as separators	-Existence inside the border of metropolitan city	-Greenfields
Political and institutional issues	-Central role of governments -Existence of RIDC and URA		-Strong political support at federal, state and local level	
Legal issues		Clouds on the determination of brownfields	-CERCLA, BRERA, Pennsylvania Land Recycling Act (Act 2)	

Economic issues	TIF	-Insufficient public funds -Limited market demand	
Plan/design based issues	-Well-defined development strategy for the city	-Lack of comprehensive planning -Insufficient design criteria for sustainable development	
Social and Communal issues	-Effective community development corporations (active participation)		-Collaboration between the stakeholders

It may be necessary to analyze the existing situation after looking back the brownfields, in the year of 2012. There are still some weak points and some threats which cause delays in some brownfield projects and some strengths and opportunities which still keep the brownfields redevelopment issues on the City's agenda.

It can be said that the economic problems are considered as the main obstacle in the redevelopment attempts for brownfields. It depend not only the global economic crisis all around the world but also the economic problems at the state level.

Urban Governance for Sustainable Development - The implementation strategy for a sustainable development plan at the administration of the City of Ludwigsburg

Prof. Dr. Detlef Kurth, Urban Planner
University of Applied Science Stuttgart, Germany
detlef.kurth@hft-stuttgart.de

Full paper for AESOP 2012 congress in Ankara

Keywords: Energy Efficient City, Climate Governance, Sustainable urban development plans

Climate change is the big challenge for sustainable urban development in the next decades. Especially in Germany after the exit of nuclear power, there are big programmes for energy saving and for new supply concepts of renewable energy. There are huge funding's for raising the standards of building insulation and improving the heating system. But beneath new technical solutions and individual projects it is necessary to focus more on spatial concepts for a comprehensive energy strategy.

EU Leipzig Charter for sustainable development

The goals of a sustainable urban development policy have been laid down by the European Union in the "Leipzig Charter on Sustainable European Cities" in 2007. This charter is being implemented within the framework of the German programme "National Urban Development Policy". Here, strategic guiding visions for urban development such as "the compact city", the "climate conscious city", "the City as a location for business" or "the socially balanced city" are formulated. It is a declared goal to prevent the European city from on-going urban sprawl and segregation and meet the challenges of demographic and climate change. Thus, the climate conscious and energy efficient city is part of a comprehensive integrated strategy for sustainability that - besides ecological themes - also accounts for social and economic aspects. (Bundesministerium fuer Verkehr, Bau und Stadtentwicklung 2007)

City-Climate-Plans

The Federal Government of Germany is supporting City-Climate-Plans, where the energy demand and the energy supply for the whole city is analysed and where on the basis of demand scenarios new projects are prepared. These Climate-Plans are connected with the individual funding of energy modernisation of buildings. Also there are new regulations that are forcing the landowners to a high standard of building insulation and new heating systems. These measures have crucial impact on the urban design, the composition of the façade and the planning system, and more and more they are dominating the other sectoral needs of a city.

In the point of view of urban planning, there is the question how to combine the City-Climate-Plans with the existing planning system. At the moment they are almost not integrated, sometimes the energy measures are against the current planning objectives. Individual energy projects could counteract to comprehensive supply strategies or objectives of city design. (Herrmann-Lobreyer; Kurth 2010)

Climate Development Planning

Sustainable development requires a renaissance of comprehensive urban development concepts. Germany has already a formalized planning system with the land-use-plan for the whole city (Flaechennutzungsplan) and the zoning plan for a new building project (Bebauungsplan), in between there can be established citywide or district development plans. To achieve the objectives of energy turn it will be necessary to make an “climate development plan” for every city with analysis about energy demand and supply and which will be integrated as a sectoral plan in the city development plan. These city-wide plans should be concretized on the level of districts and/or quarters, where the energy demand can be analysed much more detailed, and integrated in district development plans or zonings plans. If the energy plans are integrated in the planning system, conflicts of objectives could be solved preventive, and there will be a framework for individual energy modernisations. (Mitschang 2012, Oberste Baubehörde Bayern 2011)

Sustainable development plan of Ludwigsburg

The city of Ludwigsburg (90.000 inhabitants) in the Region of Stuttgart in Southwest Germany has created a continuing urban development process with an intensive participation to strengthen sustainable development. The approach is to create a urban development plan which combines different strategies of prevention, empowerment, social renewal, urban renewal and energy measures. This plan is combined with indicators of sustainability to identify energy efficiently urban structures. With thematic masterplans and district development plans the measures had been detailed. One masterplan was the city-wide “Energy-Concept” about supply and demand of energy and traffic. For the Citywide Energy Strategy, a multitude of activities in the areas of climate policy, climate change adaption, energy, transport, industry and land use have been compiled. These activities show that a special

priority is given to energy policy in this community. Furthermore, outstanding energy efficiency standards have been realized in building and conversion projects in Ludwigsburg. (City of Ludwigsburg 2011)

Municipal energy supply company

An important stakeholder for the energy concept is the municipal energy supply company (Stadtwerke) Ludwigsburg-Kornwestheim GmbH (SWLB), founded in 1858, delivers gas and water and since 2006 electricity. The company supports concepts for energy efficiency measures in buildings together with the local energy agency LEA by offering infrared thermography of buildings. In November 2009 SWLB opened the largest wood chip fired ORC cogeneration plant in Baden Wuerttemberg. With an electric power of 2.1 MW it produces 10.000 MWh electricity and 48.000 MWh heat. This covers 70% of the district heating energy and supplies 3000 households. By using 42.000 tons of regionally produced wood chips annually, the plant saves 18.000 Tons of CO_2.

Climate Governance

A unique feature of the City of Ludwigsburg is the strategy of the mayor and his administration to use the comprehensive administrative reform for establishing sustainable structures that advance the subjects of urban development, energy and climate protection. Many other cities promote climate protection in campaigns with doubtful success. In Ludwigsburg, the administration makes well-directed use of the instruments it already has at hand while trying to achieve a balanced municipal household that contributes to fairness among generations. The mayor established a new head office at the city administration called “Sustainable Urban Development” with special departments for energy and urban regeneration. This office is located directly at the mayor and can check every sectoral project from other divisions concerning the indicators for sustainable development. (Herrmann-Lobreyer; Kurth 2011)

Integrated sustainability management

As part of the climate governance and to secure continuous advancement of the urban development process, a distinct management system was developed for the administration. It safeguards the implementation and allows for modification of strategic objectives. It is a recurrent cycle that should be undergone every four years. The cycle comprises of five steps:

1. Assessment of the local situation: In the sense of an inventory, the present urban situation is reviewed by the help of neighbourhood walks, talks with citizens and experts or thematic workshops.
2. Further development of strategic goals: The existing goals are examined and, if necessary, redefined. Every three years there are future conferences.
3. Adoption of the guiding principles and objectives for the main themes. The

guiding principles and objectives are stipulated in a council resolution, so that the municipal action is politically legitimated.

4. Implementation via master plans: For each area of action, a master plan is drawn up that specifies the guiding principles and strategic objectives by assigning measures, time schedules and responsibilities. By linking the master plan to municipal budget and financial planning, a new and transparent steering tool is generated.
5. Reporting and evaluation (indicators): For each thematic field in the Urban Development Strategy, several indicators have been defined. In this way, the process can be checked against pre-set goals (evaluation). With these indicators, time series are generated that allow for early recognition of trends and comparison with other cities. (City of Ludwigsburg 2011)

Conclusion

With the sustainable Urban Development Strategy, the Citywide Energy Strategy and the consequent restructuring of administration, the City of Ludwigsburg chose an exceptionally comprehensive and integrated approach, especially when compared to other German medium-sized cities. The concept builds on experiences from municipal energy efficiency projects and national and international exchange programmes and takes them further in a consistent way. Participation in European research projects such as “Managing Urban Europe 25” (MUE) asserted wide influence on further conceptional development.

Energy efficient urban development already gained momentum during the 1990s, for example in Local Agenda 21 groups, urban regeneration (Social City) and housing development. This process has continuously been cultivated. It has particularly been stimulated by the introduction of the Urban Development Strategy in 2004 and the resulting Citywide Energy Strategy. In Ludwigsburg, the “concept of an energy efficient city” is part of an overall sustainability strategy. Aspects of settlement structure, infrastructure and traffic strongly influence the energy consumption of a community – be it in a direct or indirect way. A new integrated structure of administration and a comprehensive implementation strategy were developed in parallel. The effectiveness of measures is evaluated by a set of indicators in a regular management cycle.

Finally, energy efficiency and climate protection as parts of an integrated urban development approach contribute to safeguarding competitiveness and promoting economic development. In the long run, citizens and enterprises benefit from security of energy supply and low energy prices. The City of Ludwigsburg has realized that only energy efficient cities remain attractive for their citizens and can maintain their cultural and social offers and public services. In 2012 the city of Ludwigsburg won the prize of “climate neutral city” of the state of Baden-Wuerttemberg.

The approach of energy efficient city and sustainable governance was already evaluated by the University of Applied Sciences Stuttgart as a case study for the International Energy Agency: (http://www.ludwigsburg.de/servlet/PB/menu/1290113_l1/index.html). A similar research projects is on process about energy development plans for the city of Munich: http://www.nationale-stadtentwicklungspolitik.de/cln_032/nn_251538/Content/Projekte/energiegerechte__stadtentwicklung__muenchen.html

Overview of Romanian Planning Evolution

Author: Phd. Arch. Gabriel Pascariu

Institutional affiliation /address/e-mail: University of Architecture and Urbanism "Ion Mincu", Bucharest 1, Academiei str. 18-20.

Key words: planning history, planning instrument, critical approach.

The paper aims to present a brief overview of more than one century of urban planning development in Romania. Its historic evolution is split into four different stages, starting with the first roots that can be found at the end of the 18th century and in the first part of the 19th, when first urban plans and regulations were elaborated. The four stages refer to the predecessors (before 1900), the basics (the 1st half of the 20th century), the totalitarian age (the communist decades), and to the transition one (post 1990 decades). The analysis emphasises the main characteristics of each stage and the elements attesting continuities or discontinuities. The method of the author is chronological and comparative. The investigation is placing, whenever possible, the evolution of the Romanian planning within the European context. The planning knowledge and instruments have been inspired over the time by the Austrian-Hungarians or Russian Empire during the first stages, by the French or German schools later on, by the Soviet Union during the communism and most recently by the different trends that can be seen within the European Union, of which territorial cohesion becomes important. However, the paper mainly insists on the last 100 years, as being the most relevant interval, starting with the major theoretical gains of the inter-war period, going through the major transformations of settlements and territories during the authoritarian regime and ending with the decades of radical shift and reconstruction of a system under a liberal political and economic system. The significance and relevance of the paper stands in its comprehensiveness and synthetic perspective at the same time, providing information about a country with an important experience in the field, yet still looking for recognition and positioning at European and international level. The first comprehensive monographic studies of Ionescu de la Brad, in the 2nd half of the 19th century, the contribution of eng. Cincinat Sfintescu to development of spatial planning at macro-territorial levels in the early '30s, or the complex systematisation plans of the 6th and 7th decades leading to development of new towns, large touristic areas, or industrial zones (yet marked by functionalism and radicalism of the interventions), are some significant achievements. During the last decades, Romania has done several steps in order to catch up with the evolutions of planning education, instruments and methodologies, legal and institutional framework. A consistent and continuous process started after December 1989, leading to setting up a new planning system, a specific higher planning education and in defining the objectives and professional standards for the profession of urban planner in Romania. The approach is critical and based on various professional opinions as well as on own personal views. The paper is a follow-up of a recent issue on the same topic, of the planning magazine

"Urbanismul-new series", and can be used as a start for a planning course on recent urban planning history in Romania.

1. Introduction

Romania has a history which is specific for the Eastern part o f Europe. It is a rather hew state, which was born after the second world war in 1918. The setting up of the modern Romanian state, was the result of bringing together 4 different regions with 4 different administrative rules and models of organisation: the Romanian kingdom an independent state since the mid of 19th century, Transylvania an autonomous voivodship under the Hungarian and Austrian influence, Basarabia a region which was part of the Russian Empire and one small Northern region called Bucovina, part of the Austrian – Hungarian Empire at that time. It is obviously difficult to analyse the planning system evolution before 1918, as it was quite different in the 4 regions. In general all Romanian regions have suffered from different influences along previous centuries as they have been most of the time under the authority of the bigger powers, empires which were dominating the area: the Austrians to the West, the Ottomans to the South and the Russians to the East and North.

Figure 1. Romania in 1925. The 10 historic regions can be noticed. Muntenia, Oltenia and Moldova joined together in 1859 and formed the Romanian Kingdom. Dobrogea was added in 1878 (map by Ana Maria Petrescu, 2012)

Until the unification of the 20th century the history of planning is quite different in the West compared to the East and South and has specific features in the North or in the South-eastern parts between Danube and the Black Sea. Historic evolution left its traces if one looks at the structure, shape and development of human settlements, of towns and villages, traces that can still be noticed in spite of the last 100 years of attempts of a more homogenous development and also, mainly, in spite of the more than 4 decades of communism which tried to uniform and diminish the gaps and differences between regions, between rural and urban, or between towns.

However, it must be noticed that a solid tradition started to be created in the field beginning with the 2nd half of the 19th century. The modernisation of the so called Old Kingdom (Moldavia + Walachia) and the orientation towards the Western European models set up a path that will be further developed in the 20th century. Until the '50s, the new Romanian state set up new institutions and laws and developed a planning policy which was following very much the modern European and international trends of that time. The 2nd part of the century and specially the last decades meant a new fracture in relation to these trends and for a short period of time lead to isolation, stagnation and peculiar evolutions determined by an increasing authoritarian political regime.

The political shift occurred at the end of 1989, meant a new return to the Western European models and reconnection to the international trends and changes in general and in planning policies and approaches too. The last 2 decades are characterised by a continuous attempt to improve and adapt the legal and institutional framework, the planning instruments and procedures to the new political and social-economical context. A particular emphasis has to be mentioned in respect to the important steps done in the planning education system and in defining the profession of urban planner in accordance to the European principles promoted by organisations such as the Council of European Planners (CEU), but not only.

2. Analysis

The following lines will present the main characteristics of the 4 stages of evolution and development of the Romanian planning system. The first stage refers to the period before 1918, basically the 19th century, the 2nd one to the inter-war period ending with the change of political regime in 1947, when Romania became a republic, the 3rd interval represents the 4 decades of communism followed finally by the present period of transition which began in December 1989 with the fall of the totalitarian regime and the setting up of a new democratic society and a market economy.

2.1 The predecessors (before 1918)

The first territorial planning regulations can be found during the feudal period, since the XVI-th and XVII-th centuries. The use of lands owned by the landlords were subject to certain regulatory planning actions concerning the efficient use of the land resources such as forests, waters or agricultural land. The development of small rural settlements for the peasants who were living on the landlord property and worked the land were also sometime the result of a planned activity. As a public policy of a general interest first traces can be found in the Western part of the country, which was part of a process of modernisation of the territory initiated by the House of Habsburg, aiming to a better protection and administration (Gheorghiu, 2010, pp.17-23). The setting up of a more balanced settlements network, of a number of fortified

towns, were part of such a process, which was also accompanied by colonisation of people of various nations: Germans, Serbians, Bohemians, Slovakians, Hungarians.

The German and Austrian influence can be noticed in the specific design and volumetric developments of the "burgs" in the Western part of the country which become more urbanised and industrialised in the 19th century. The rest of the country remained mostly an agricultural one by the end of the century, when the Old Kingdom led by a German King (Carol the 1st), began a process of modernisation and capitalist development. The Ottoman influence remained however strong especially in the Southern part of the country along the Danube and in Dobrogea region. A certain indirect or direct French influence can be noticed after 1830 and the so called Organic Regulations. At that time, the Eastern and Southern part of the country were under Russian authority and were governed by these new rules of French influence. The Russian Governor or that time, general Pavel Dmitrievich Kiselyov (or Kiseleff) began a process of reconstruction of towns especially of strategic importance such as some Danubian harbours (Brăila, Giurgiu, Turnu Măgurele) (figures 2,3). The circular form, the radial street system and the peripheral boulevard were some common characteristics of such urban planning interventions. The general was also an initiator of some first works of urban modernisation of Bucharest by cutting some of the first large boulevards in its Northern part.

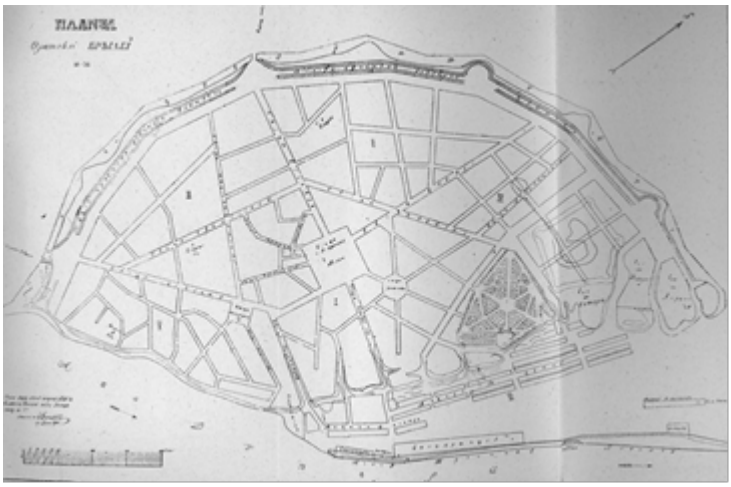

Figure 2. The Plan of Brăila in 1836

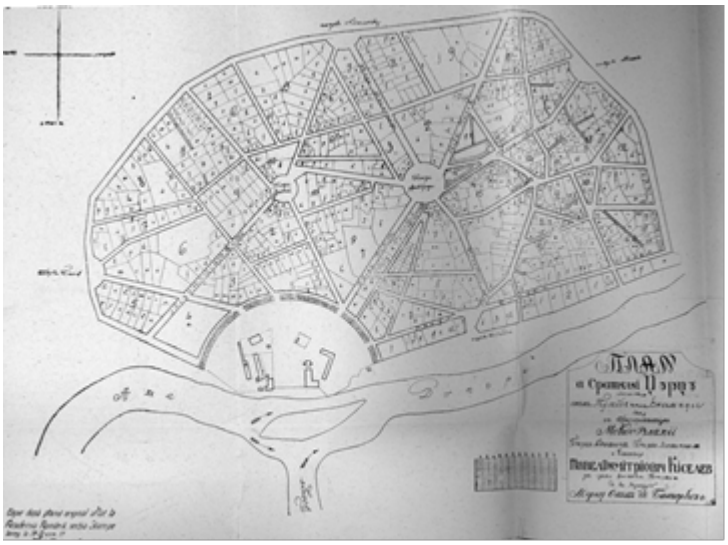

Figure 3. The Plan of Giurgiu around the mid of 19th century

The first traces of a modern planning system can be related to some legal initiatives of the beginning of the 19th century such as: the development of a cadastre, regulations for development of rural areas, first alignment plans and first accurate topographic maps for towns and cities. Bucharest gets its first complete topographic and cadastral map in 1847 (the Borroczyn plan). The 2nd part of the century is also characterised by a growing interest for urban infrastructure and embellishment works: public gardens and parks, larger and better urban streets and boulevards, social and cultural endowments are developed as well as water distribution and sewage systems. By the end of the 19th century, in 1894 the law for organising the urban communes was issued setting up rules for controlling the chaotic sprawl and creating conditions for a hygienic and secure development. The first development and regulatory plans for the capital city of Bucharest were elaborated around 1900.
At territorial scale there is a raising concern about the development of rural areas and of the large territorial infrastructure. During the 2nd part of the 19th century, the activity of Ion Ionescu de la Brad, specialised in agronomy, was significant. Besides the organization of the agricultural land use, he initiated some original research methods for better knowledge of rural life, which led to the elaboration of the first counties' monographic studies.

The unification of Moldavian and Walachian voivodships in 1859 was also the beginning of the construction of the modern state. The setting up of a ministry of public works was among the first measures taken by the new leadership. It was an important step for the development of the communication infrastructure at the level of the territory. The development of a railway network connecting the main cities and the Saligny's bridge over the Danube, followed by the development of the harbour cities on the Black Sea were important achievements of the time. One of the representative figures of the time is the engineer Elie Radu who had a major role in the development of engineering works from railways to aqueducts, bridges or water reservoirs.

It must be also mentioned the development during the last decades of the 19th century of education in the filed of architecture and civil engineering. This was another important step as by then the main public works and urban plans were done by foreign engineers, architects or landscape planners, or by few Romanians who graduated in Germany, France, England or elsewhere in Europe.

2.2. The inter-war period – 1919 - 1947

The 3 decades of the first half of the last century played an important part in the history of modern Romania. In spite of the troubled times of the last part of the interval, the social and economic progresses were remarkable. The role of spatial planning became important as modernisation of towns and cities and the further development of territorial infrastructure were major targets. The after war reconstruction, the land reform and the administrative reorganisation, the necessity to develop the capital city accordingly to is new status and in general the increasing role of the state were an impetus for a fast development of a spatial planning system.

Significant aspects can be mentioned such as: the setting up of the Town Planning Institute of the Union of Towns and Cities, the development of the education in the field and the development of an interdisciplinary approach to urban and regional planning, the issuing of a specialised publication – the magazine "Urbanismul" and of a collection "The Urban Planning Library", the master plan for Bucharest.

Figure 4-5. Covers of "Urbanismul" magazine from 1933 (5-6) and 1934 (3-4)

Relevant contributions to developing new approaches to study and research of the territory and human settlements were coming from fields like geography and sociology. The development of a Romanian "School of sociology", by Henri H. Stahl and Gustav Gusti and of the human geography one by Simion Mehedinţi and Vintilă

Mihăilescu led to an increased knowledge of the social and economic development of the country in general. The research of the rural areas continued the initiatives of the previous decades by elaborating detailed monographic descriptions. Architects, such as Florea Stănculescu, developed a kind of a rural planning and initiated at the Faculty of Architecture in Bucharest a course of "ruralism"

A critical overview of that period reveals significant evolutions such as: elaboration of general urban plans for a number of cities including the capital, urban plans for new resorts, and successful participations of Romanian architects in international urban competitions, cultural and editorial activities. Shortcomings are related mainly to precarious and incomplete legislation and weak quality of the administrative staff as well as a weak awareness of the general public for "systematization" (Marcu, 1930). The basis of higher education in urban planning is set up at the Faculty of Architecture and at the Polytechnique School (both in Bucharest) as well as in the Schools of Administrative Sciences (courses of urban legislation, civil engineering, urban hygiene or aesthetics).
The most important contributions to development of urban planning theory and practice belong to the engineer Cincinat Sfinţescu, who left a vast written work including volumes for "General Urbanism" and "Special Urbanism" (in original "urbanistica") or "The Superurbanism". His books and articles were based on the European knowledge of that time and touched most or the problems of spatial development from the details of urban design to the problems of organising the national territory. The concept of "superurbanism" was presented as an original contribution at the international urban planning congresses held in Rome (1929) and Berlin (1931) and speaks about the necessity to manage regional and national territories. Among the new concepts he speaks about urban agglomerations and their area of influence.

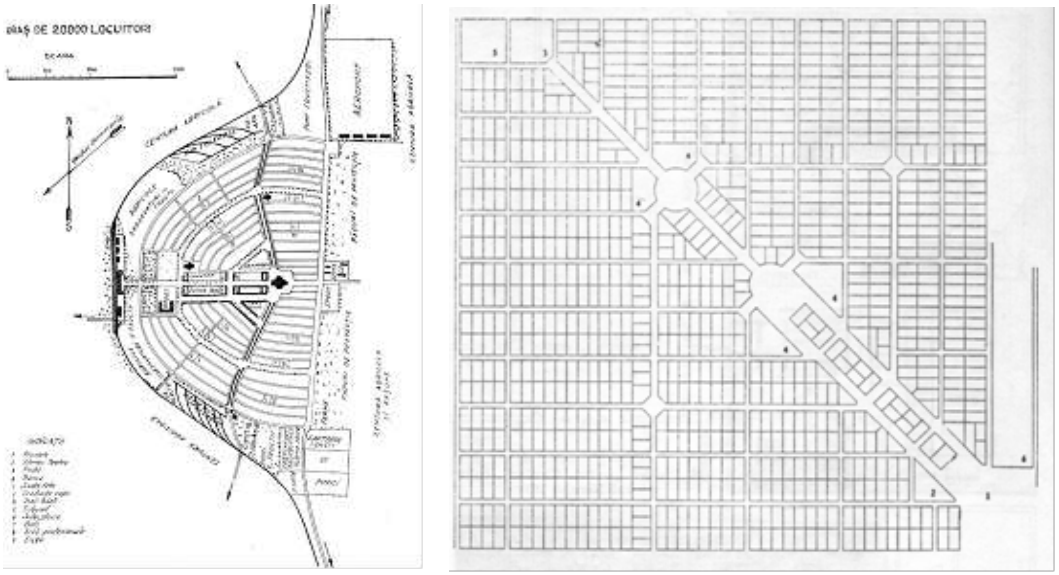

Figure 6-7. New town project by Sfinţescu (left) and project for a new village by Stănculescu (right)

One of the most important achievements of the period remains however the Directory Plan of Bucharest elaborated between 1934 – 1939, comprehensive master plan based on a long term strategy accompanied by a detailed urban regulatory framework. Due to the events that followed in the '40s it could not be put into practice effectively but remained a valuable source of inspiration for the next decades.

2.3 The communist period – 1948 – 1989

This interval is characterised by at least three different stages. A first one, which lasted until 1960, is related to a period of intensive reconstruction and major structural changes at all the levels of social, economic and cultural life. A second one lasted for another 15 years, by mid of the 8th decade and can be seen as period of consolidation of the new state and relationships. According to the official documents of that time it was a period of "achieving the economic basis for the socialist society". The third and last stage of the period is marked by an increased power of the Communist Party and its leader evolving to a totalitarian regime.

Spatial planning was much influenced by the political changes, but in general it was a good time for this domain as it became increasingly important for the regime, which used it as a political "tool" to module the society by transforming and reshaping the human settlements and the territory. During the first after-war decades, regional and large scale studies were developed and new master plans for towns and cities were elaborated. They were meant to prepare the ground and support the fast process of industrialisation and urbanisation which was a priority of the new political regime. Planning in general became important due to the fact that the whole society became centralised, coordinated and planned by a central authority. Most of the land became state property or was somehow managed by the state authorities.

The '60s were a time for complex studies of the settlements network, prognosis, developing the legislative and institutional framework. Spatial planning became an institutionalised activity, organised at national level within a network of public architectural design and territorial and urban planning institutes. These ones were quite large in size, counting tens and hundreds of professionals form various fields. They were pluri-disciplinary public companies were architects, engineers, geographers, economists, sociologists and others were working in inter-disciplinary teams. In the capital such institutes became really big, counting over 1000 employees. Spatial planning became a public policy of strategic importance, as it was a framework for most of the public investments. It cannot be denied the fact that during the first 2 decades there have been major achievements in developing public infrastructures, residential quarters, tourism and others (Lăzărescu, 1977). It may be mentioned:

- the regional plans done for areas reach in energetic resources (coal especially), followed by development of new towns and industrial areas,
- the studies and plans done for the touristic area of the Black Sea followed by the development of new resorts,

- the large scale regional and national studies for water management followed by the construction of numerous hydro-electric power plants and artificial accumulation lakes,
- the plans for large residential areas in big cities, characterised by high densities and collective housing,
- the development of new and large industrial zones especially in the Eastern and Southern parts of the country which were less developed before.

It has to be also mentioned the interest for some central areas of cities and some significant achievements regarding renovation and regeneration of some historic areas (Baia Mare, Brăila, Bistriţa etc.). However only in a few cases the interventions were paying consideration to the heritage. In general, renovation meant reconstruction and was aiming to develop new monumental and representative public spaces under the expression of "civic centres". In some cases (Giurgiu, Suceava, Piatra Neamţ etc.) the interventions were significantly changing the traditional pattern.

In 1974, in the second half of the interval a new planning law was issued "systematization law" which introduced a number of very restrictive provisions. The most important one was the so-called "built-up perimeter", which meant a very strict containment of the growth of rural and urban settlements. The new generation of urban plans were supposed to limit as much as possible the expansion of the localities and even reduce their size whenever possible. This approach was affecting mainly the rural areas were localities were traditionally quite spread along valleys and roads. The concept of "regrouping" of the inhabitants was used and in some cases localities were supposed to slowly vanishes and people relocated in a limited number of villages better placed geographically and better equipped.

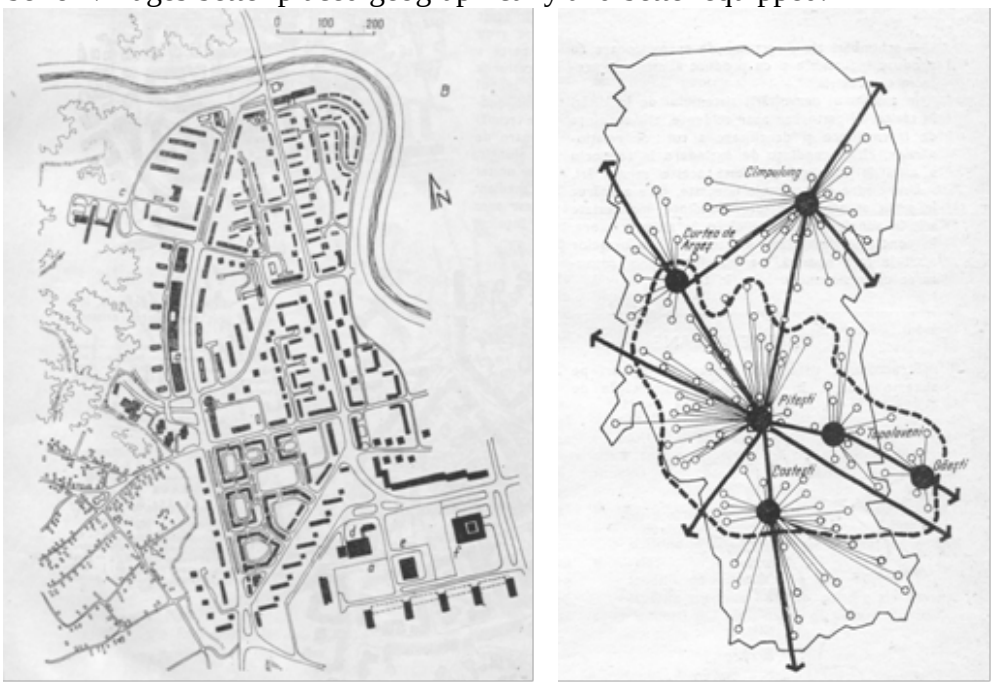

Figure 8-9. New town scheme (left) and development of a periurban area (right)

Another provision with significant consequences was related to the "liveable area". Minimal density indicators were set up by law, in relation to the average heights of a residential area. The law provided a minimum of 4,000 sqm for a 3 stories residential area up to 12, 000 sqm for areas going over 9 stories heights.

Figure 10. The new residential areas of collective housing

The last part of the period was characterised by studies at national scale aiming to a large restructuring of the human settlements network by rapid transformation of hundreds of rural settlements into urban ones (fig. 10). The terrible earth quake of 1977 opened the way to the radical restructuring of the central part of Bucharest and the construction of a new large boulevard of 3km long heading to the monumental House of People.

Figure 10. Large scale national planning concerning the development of the urban settlements network

2.4 The transition period – post 1989

2.4.1 A new legal framework

Systematization was perceived by the Romanian society but also by the Western ones as one of the most powerful symbols of the communist regime, responsible for the destruction of a large part of the built-up heritage of towns and villages and for the brutal reshaping of the urban environment. Important historians as Dinu Giurescu, describe systematization as being responsible for "the destruction of the traditional urban constructed area almost in its entirety and its replacement by tenement apartment buildings and the resettlement of the entire rural population" (Giurescu 1989:68). In December 1989 "Systematization Law" (58/1974) is abolished and systematization becomes overnight urbanism or territorial and town planning[i]. Its replacement and the reconstruction of the legal framework proved to be difficult and lasted longer than expected. Until 2001 the legal framework for spatial planning was rather fragile and regulations in the field were mostly coming from other areas: constructions, transports, environment and human health. The setting up of the legal system can be divided into three stages: the first decade of transition, the '90s, when some preliminary "bricks" were added, the first part of the 2nd decade, the 2000s', when a number of important laws were issued and the last few years, characterized by attempts to reforming and improving the system. During the first stage, after a short legal void, in 1991 the Law 50 for issuing of the building permit is approved. References to urban plans and to urban permit are made. Shortly after the law was issued, in November 1991, the 91st Ministerial Decree (MD) defines the new planning instruments at local and territorial levels and their content. Although during the first half of the decade a draft of a new Planning Act was prepared its discussion for approval by the Parliament was continuously postponed.

During this first interval, a General Urban Regulatory Framework is issued by Government Decree (GD), which defines some general rules for urban planning. Planning activity is also influenced by other laws concerning the land restitution (1991 Land Law), quality of constructions (1995), expropriation for public utility (1994), public property, cadastre and publicity (1996). It is characteristic for this period of time the associated status of spatial planning to the building sector. By the end of the decade the activities meant to set up a new and comprehensive framework for urban and territorial planning increase. Guiding documents for the elaboration of urban plans (general, zonal, detailed) are published and the concern for protected areas and heritage in general is also proved by legal documents: a Governmental Ordinance for the protection of historic monuments (GO 228 / 24.11.2000) setting up specific areas of protection and a law for approval of PATN Section III – Protected areas (law 5 /2000).

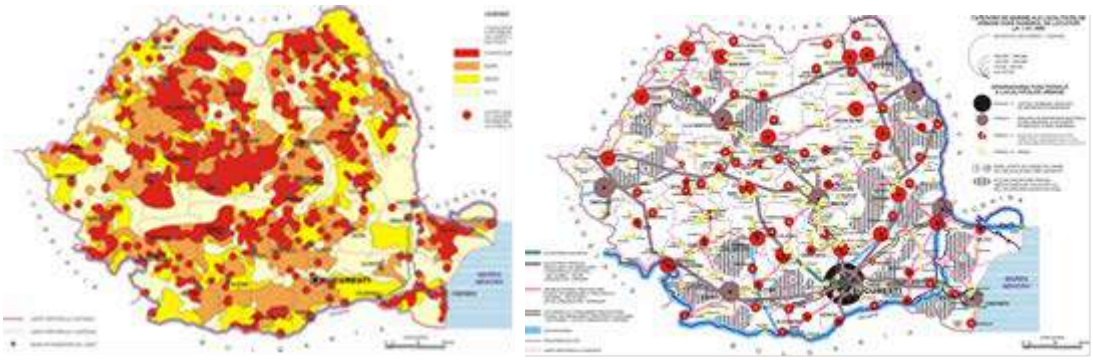

Figure 11. National Physical Development Plan. Sections III and IV concerning the built-up heritage and the human settlements network

The accumulations of the first decade of transition and the steps forward in view of European integration led to a better definition of the domain at the beginning of the new millennium. The new Territorial and Urban Planning Act issued in 2001 clarifies and enforces the planning instruments and public responsibilities. The new law provides an independent status for spatial planning which is no longer seen as subsequent to the construction sector. In the field of the heritage protection, also in 2001, the previous GO becomes a full law (Law 422 for the protection of the historic monuments), in 2002 the Parliament ratifies the European Landscape Convention (Law 451 / 2002) adopted in Florence in 2000 by the Council of Europe and in 2004 a complete list of historic monuments is published in the OJ (MD 2314 / 2004)[ii]. The legal framework is completed with a new and stricter environmental legislation, due to the European Union (EU) requirements, with a significant influence on spatial planning activities too. General urban plans, regional plans and sections of the national plan are elaborated and approved. In general the planning activity is very intensive and has a very dynamic rhythm.

Although the legal framework develops and becomes more complex it cannot keep up with the dynamism of the transformation of the Romanian society. Its shortcomings are becoming obvious during the second half of the decade and attempts are made for improving, correcting or reforming the system. Significant debates, relevant studies and even and audit of the legal system are done in view of elaborating a comprehensive Code of Urbanism. By 2008 revisions of the Planning Act are made, mainly aimed to raise its effectiveness and reduce the derogatory procedures. It also provides new planning instruments and specific responsibilities for the protected areas. The influence of the EU structural Funds for urban development becomes important too.

2.4.2 Institutional changes

The institutional framework for spatial planning can be followed at two levels: central and local as well as in two different social environments: public and private. It may be also discussed and analyzed in relation to decision-makers, professionals and communities. During the last two decades opposite processes can be observed: dissolution of the old structures and relations and construction and reconstruction of

new ones. Whereas the process of dissolution was much too faster due to the rapid and brutal changes of the social, economic and political environments, the construction and reconstruction proved to be more difficult and not necessarily continuous and ascendant.

At central and local level new institutional responsibilities were set up since 1991, based on the principles of local autonomy and decentralization. The importance of spatial planning as a public policy is recognized and clear attributions were set up by the laws for local administration[iii]. Urban and territorial development should be done according to plans that have to be approved by the local authorities and implemented accordingly. Within the Mayoralties at all territorial levels (county, town, and commune) special planning departments or offices were created, usually subordinated to a chief architect supported by advisory technical commissions. Full responsibilities for approval and implementation of planning schemes are given to local authorities (some particular areas of international, national or strategic importance being exempted). At central level, spatial planning remained an important sectorial policy and was part of specific in-line ministries.

As elaborators of the plans, professionals who were grouped until 1989 in big public institutes, as part of large multidisciplinary teams were forced to shift towards smaller private consultancy and design companies mainly mono-specialized, as the old structures were dismantled during privatization processes. The former multidisciplinary teams were slowly replaced by networks of small specialized firms. At central level one National Research Institute for spatial planning – Urbanproiect – was actively involved in the restructuring of the field especially during the first 10-15 years. Later on it was affected by a slow decay and become a part of one larger national research institute for constructions, architecture and planning[iv].

Although a great deal of effort was made to replace the old system and set up a new and functional one, the results were not satisfactory. The fragility of the institutional building is often seen as being one of the main problem of the whole planning system as "institutionalization is in fact the mean which ensure the control within the process of using and respecting the legislation" (Urbanismul 2010[v]). The weak involvement of state control in planning process, the low level of urban culture of the administrative staff, the lack of institutional cooperation, the overlapping of competencies are among the identified weaknesses of the responsible public institutions. At central level it can be noticed that along the two decades there has been a diminishing importance of the domain, which started in the '90s to be represented by a National Commission for Territorial and Urban Planning and then by a Ministry of Public Works and Territorial Planning. After being initially represented by a Commission of ministerial ranking, then by a Department within a ministry in the '2000s the domain was represented by an ever smaller Direction in Ministries whose major focus was Transport, Housing, Public Works, Constructions, Tourism or more recently Regional Development[vi]. As other fields developed and EU directives were also implemented, planning responsibilities were shared among

several central bodies such as Ministry of Transport, Ministry of Environment, Ministry of Agriculture and Rural Development.

The institutional system, which is seen as key element for the good functioning of spatial planning in general, is weaken by fragmentation of tasks, lack of cooperation, sub-financing and corruption: "Public bodies are eroded and infiltrated by <<ambassadors>> and <<mauls>> of the private sector and as a consequence is put to work for private interests. There is no culture of public interest…" (Urbanismul 2010[vii]). As most of the tasks concerning the elaboration of development plans at all levels are externalised, a big responsibility belongs to the professionals who are to be found within private firms but also in research units belonging mostly to universities. In this sector there is an uneven territorial distribution of professional competencies as well as among companies, which sometime deeply affects the quality of the planning documents. In order to provide a better control in this area, in 2005 the Register of Romanian Planners (RRP) was set up.

2.4.3 The Planning Instruments

The last but not the least important piece of the "puzzle" of the planning system is represented by the planning instruments. They are in fact the legal mean leading from conception to concrete development, via the planning and building permit issued on the basis of the plans. The new system was put into place in the early '90s and remained practically unchanged by now. It provides two main categories of plans strongly related to territorial levels. The so-called urban plans refer to local and sub-local levels whereas the territorial ones refer to upper administrative levels. Whereas territorial plans have a guiding / strategic character the urban plans are regulatory /operational and are accompanied by urban regulations, which once approved by the Local Councils can be enforced as a local planning law. Due to their operational character, the urban plans have a much stronger influence as the territorial ones in the reshaping of the built and unbuilt environment. However, territorial plans are also important as they set up and identify the main development objectives and the potential conflicts between development and protected areas. The basic principles of the system of planning instruments as it can be deducted from figure 12 is that provisions set up at upper levels are compulsory for the lower levels. Horizontal and sectorial correlations are also mandatory.

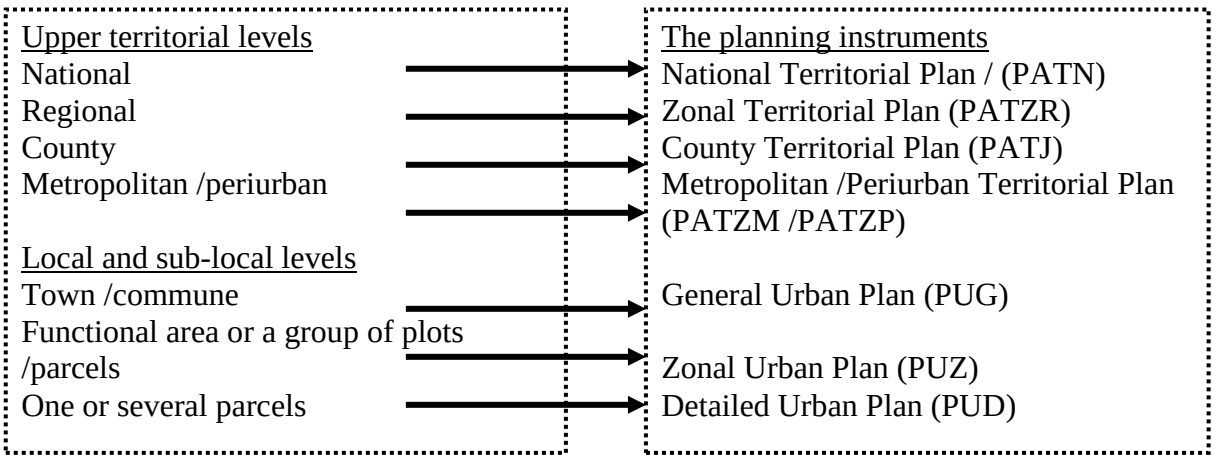

Figure 12. The planning instruments in relation to the different territorial levels

3. Conclusions

The short overview of the evolution of planning system in Romania shows a rather long tradition coming from the 19th century and before. Yet, the various changes of political regimes and at administrative level hampered a normal and sound continuity and effective use of the knowledge and experience accumulated in time. By the end of the first half of the last century, Romania was connected to the evolutions and trends at European level, but after the 2nd World War it has been disconnected and influenced by the new communist ideology and approach to spatial planning. The evaluation of the situation after more than 20 years of transition to democracy and market economy is not encouraging at all, indicating major weaknesses of the spatial development at local and regional levels. The reconstruction of the system, which began during the first years of the post-communist era, achieved to setting up a new legislative framework, specific instruments and procedures, yet was not able to generate an adequate institutional one and a sufficiently large and well qualified corpus of professionals in the field. The present state of general discontent against the aggressiveness of actions against the built-up and natural environment, in connection to the recent recommendations and actions of the EU to developing a sound and sustainable spatial policy, create the opportunity for a substantial reform in the field and a change of paradigm concerning the role of the spatial planner in the society (Pascariu, 2011). It can be concluded that Romanina planning system was much influenced over time by various other systems coming form abroad. Nowadays the most important influences come from the European Union and are based on general documents such as the 1983 European Chart of Spatial Planning up to most recent Green Paper on Territorial Cohesion.

REGIONAL LRT AS A BACKBONE FOR THE PERI-URBAN LANDSCAPE:
Research by design on an intermodal public transport network

Matthias Blondia[1], **Erik De Deyn**[2]
(two first authors)

Abstract

Public transport and the periphery have a troubled relation. In search for a more sustainable mobility, the idea of re-shaping the city is more appealing than the idea of re-shaping public transport. Public transport for the 'car-oriented' periphery is considered utopian, with a lack of density as the knockdown argument.

The Belgian region of Flanders certainly seems to prove this. An inefficient bus network covers almost the entire territory, but only 15% of its costs. Two types of public transport have remained somewhat successful: the train connections between cities and the bus lines within cities. The periphery, in which mobility is situated on an in-between scale remains dependant on the car. Is public transport for suburbia an impossible task? New concepts such as Light-Rail Transit (LRT) and Bus Rapid Transit (BRT) have emerged over the last decades. They blur the lines between classic PT concepts, and are able to adapt themselves to the structure of the contemporary city.

The region of Klein-Brabant is a typical peri-urban nebula, lacking a legible structure. The difficulty of defining this specific spatial condition, requires planners to propose a new spatial vocabulary for this type of territory. This research-by-design shows how the infrastructure of a regional public transport system (LRT) can become the backbone of Klein-Brabant after the sprawl.

From a theoretical point of view, intermodality has a great potential, as it increases the number of possible connections exponentially. In reality however, organizational issues prevent peripheral public transport networks from functioning as a real 'network'. The assumption of overcoming these issues allows to discover the spatial potential of intermodality. It stimulates the nodal function of a station in a network, expanding its role as a carrier of (sub)urban programs. In Flemish planning practices, many master plans for small-scale station areas are currently being developed by municipalities, trying to enlarge their capacity as an urban center by transforming their mobility nodes.

The relevance of a light rail network for Klein-Brabant is to a great extent related to the dispersed urbanity of the region. This kind of network functions through a large number of nodes at a small scale. These nodes ground the concept of mobility, making it tangible on a specific location, and within a network their role is increasingly important. Public transport thus gives way to nodal development, as a sustainable alternative to the ribbon development along secondary roads. The paper elaborates on a specific scenario for LRT implementation, namely heavy to light rail transformation, as part of a bigger research by design. Spatial morphologies are tested and proposed through this scenario.

This design proposal is part of an ongoing research project, called ORDERin'F[3] (*Organizing Rhizomic DEvelopment along a Regional pilot network in Flanders*).

1. Introduction: heavy to light rail transformation

On the former Zoetermeer Stad-line and the Hofplein-line, two heavy railtracks between Rotterdam, The Hague and Zoetermeer, the Randstadrail[4] combines an extension of the Rotterdam Metro network and the tram network of the Hague. Although major infrastructural works redirected the terminus of the Hofplein-line to Rotterdam Central Station, the rest of the trajectory follows the former train connection between these cities. The trains were replaced with faster and more frequent light rail vehicles. The main advantages of this transformation are a densification of stops and a better level of service. Existing stations were remodeled, with urban renewal occurring in their surroundings, while large scale new developments were simultaneously planned and are being executed around new stops. These stops offer extensive possibilities in terms of intermodality, connecting with bus lines and bicycle routes.

Similarly, the Atlanta Beltline[5] aims at a transformation of an abandoned railway corridor into a tangential tramway around the city of Atlanta, integrating it in a linear park structure called 'The Beltline Emerald Necklace'. Along the Beltline strategic interventions are planned, focusing on affordable housing, economic activities and public infrastructure.

A more modest use of regional rail connections as a catalyst for urban renewal can be found in the Swiss Canton of Zug[6]. Nine new stops were created along the two Stadtbahn-lines, creating a string of new public spaces. However, these stops are more than nodes of modal change; the stations often restore pedestrian and cyclist connections, giving the station a central position in local networks. Additionally, the architecture of the stations is consistent along the entire line, thus strengthening the regional identity of the Stadtbahn network. Although the project in itself is not

groundbreaking from an architectural point of view, the fact that this was realized in a Canton of only 113.000 inhabitants, with the main city as small as 26.000 inhabitants, is impressive. It shows that low densities can provide the critical mass required for regional railways to succeed.

In the Parisian public transport network as well, suburban tangential connections are made by tram. Both in the case of the T2 and the T4 tramways[7], former heavy railway infrastructure was transformed into light rail. On the former line between Puteaux and Issy-Plaine, which was in use for heavy rail between 1889 and 1993, operation of the T2 tramway started in 1997. For the T4 tramline as well, a heavy rail line was transformed into light rail, although in this case, a hybrid between tram and train was developed, making it the first Tram-Train in France (2006). The current trajectory runs on train tracks and at heavy rail voltage, while future expansions will be integrated in the regular tram network, taking over its technological characteristics. In 2010, the Tram-train concept was pushed even further in France, as the Tram-Train Mulhouse-Vallée de la Thur[8] opened. This line, which connects urbanizations in the Thur Valley with the city of Mulhouse, shares the railway track with regional heavy rail trains.

These projects show how the renaissance of the tram not only influences urban mobility, but also aims at establishing fast connections on a regional scale. In the examples mentioned above, this is realized through the transformation of abandoned or active heavy rail lines. Although this approach has only been put in practice systematically during the last decade, the major technological hurdles have been tackled since the 1960's, with the development of a regional public transport network around Karlsruhe (Cervero, 1998). The tram network of Karlsruhe makes use of four different systems, all of which integrate heavy rail infrastructure with light rail vehicles, through the technological adaptation of both.

When dealing with new infrastructures, a general ascertainment is the near impossibility to obtain public support, as their profound interference with the urban tissue automatically causes resistance. For public transport infrastructure this applies even more strongly, because trajectories deliberately seek out urban concentrations, as this provides the system with potential travelers. One possible way to avoid this issue, is by realizing a new system on existing infrastructures, without disturbing the tissue of the urbanized landscape. This possibility has been studied for the Flemish context in 2008, when an evaluation of 104 railway lines on their potential as candidates for light rail transformation, was published (Kauffmann, 2008). Based on this evaluation, three test cases were elaborated. The research focused on the condition of infrastructure and stations, travelers potential based on the existing spatial context, necessary adjustments to track configurations, traffic impact, travel time, exploitation costs and the commensal opportunities of planned developments. Although a wide array of characteristics was considered in the aforementioned study,

[7] For more information on this project: http://www.stif.info/

the potential impact such a transformation could have on spatial developments has not yet been explored. This paper intends to bridge this gap by approaching the topic of heavy-to-light rail transformation from a designerly point of view.

The next paragraph argues the relevance of this spatial potential through three arguments: one based on historical ascertainments, one by looking at current planning phenomena in Flanders, and one by learning from foreign reference projects. Subsequently, the topic of this paper and its methodology is framed within the research project from which it originates, after which the actual research is elaborated, first through an analysis of the region that serves as a test case, next by a design-based exploration of the transformed rail infrastructure and its context. Finally, some conclusions will be formulated.

2. Three perspectives on the issue: historical, current and foreign practice

To understand the distinct spatial patterns in the urbanization of Flanders, often referred to as the 'nebular city', one must look at the role that railway infrastructure played in the genesis of this landscape. Famous for its dense network of heavy and vicinal railways, the spatial impact of industrialization was quite different in Belgium in comparison to other countries. All across Europe, farmers were attracted by the job opportunities offered by city-bound industries, resulting in urban growth on the one hand and a rural exodus on the other hand. This was first documented in the late nineteenth century by Ravenstein (1885) and articulated into his 'Laws of Migration'. In Belgium however, the industrialization process had a different imprint on the landscape. As argued by De Block (2011), the dense network of railways allowed for agricultural laborers and farmers to transform into industrial workers without forcing them to leave their ancestral villages. Population growth occurred without considerable migrations, and urbanization was not a process of expanding cities, but of a balanced growth in communities of all sizes. Polasky (2004; 297) has framed this phenomenon within the objectives of Belgian politics. The fear for corruption of the working class when concentrated in the city, was tackled by an increase in mobility between the city and the territory.

Thus the Flemish territory – which today is among the most densely urbanized regions in the world, yet has only four cities larger than 100.000 inhabitants (including Brussels) – is a testimony of the structuring potential of railways. They have been a main instrument in steering nineteenth century urbanization, and has done so well into the twentieth century, until mobility and accessibility became even more ubiquitous thanks to the car and dense road network.

Although public transport in Flanders has reclined into a mostly intra- and interurban system, the spatial patterns still lead to diffuse mobility patterns, nowadays covered by car mobility. There is a little coherence between the spatial structure of Flanders and its public transport system, as regional trains and buses do not offer an adequate level of service to the suburbanized territory, resulting in a modal split that is not very favorable for public transport (Verthetsel, 2007). Furthermore, planning

documents do not predict a remediation in the near future. Against this background of a weak regional public transport system, it is remarkable how many municipalities are planning a redevelopment of their station surroundings (Blondia, 2012).

Since the end of the 1990's, many of the bigger cities in Flanders started struggling with capacity problems of their stations. Because of that, several expansions, renovations and infrastructural changes were planned. Sparked by a new focus within planning policy on the central cities, these projects became levers for the renewal of station quarters, resulting in master plans and development strategies, as is the case in Leuven, Antwerp, Ghent, Liege, … Urban design was introduced as a planning practice, and spatial planning gained a new dimension of a bottom-up project driven approach. Not only were these large scale station area operations influencing urban planning in Belgium, they also inspired smaller towns to invest in their stations.

The last years, a significant amount of master plans for small-scale stations was developed, and is currently under realization. They are very different from the bigger stations redevelopments, from concept to realization. The limited amount of program and resources and the lack of critical mass and density that encompass these projects, forces design proposals to tackle a maximal number of spatial complexities with a minimal number of interventions. They deal with the specificity of the nebular urban landscape in very different ways, but all of them highlight the role of public space in a peripheral context. With more and more of these projects emerging, spatial strategies are becoming recurrent. The knowledge and insights surfacing from these projects is currently being captured and shared by a number of towns in an Interreg-funded expertise network[9].

At the same time as these small towns are redeveloping their station quarters, the level of service of public transport is being diminished. In December of 2011, 170 train connections per day were dropped by the national railway company. By 2014, 23 other lines will be cancelled. Nearly all of these are regional connections[10], servicing many of the stations surroundings that are currently being planned. The bus network, which has nodes in all of these stations, is under pressure as well, as a 60 million euro budget cut (6% of the yearly budget) is being carried out in 2012 by the regional public transport authority. There is thus a strong discrepancy between the growing spatial ambitions for peripheral stations quarters and their shrinking importance as mobility nodes when the level of service is declining.

So, both from a historical point of view and looking at current spatial and mobility planning practice in Flanders, the development potential of regional public transport lines and the spatial structuring impact they have on their surroundings become apparent. A third confirmation of this potential can be found by looking outside of Flanders. Although the spatial and societal context is not always comparable to Belgium, the projects mentioned in the introduction – Randstadrail, the T2 and T4

trams in Paris, the Tram-train in Mulhouse, the Atlanta Beltline – show promising results of a qualitative upgrade of regional train lines into light rail, and the spatial impact it can have on the surrounding territory.

The concept of heavy rail transformation fits within a philosophy of optimizing the existing infrastructure networks, strengthening its ties with existing urbanization patterns, rather than adding new lines to a landscape already saturated with infrastructure. In the Netherlands, the potential of an optimization of existing mobility network infrastructures was studied in the BESTNET project (Rutten, 2011). All infrastructure networks were considered, yet a strategic advantage of public transport is explained through the 'Wegener Circle Concept':

> Good accessibility can lead to the development of new homes and businesses. The use of land then results in activities at that location, which then leads to even more mobility. This in turn has an impact on accessibility and so on. If this increased mobility involves cars, it can cause congestion, as a result of which the location and accessibility deteriorates, causing urban sprawl. In the case of public transport the opposite can occur: increased use of public transport can lead to higher frequencies and increased quality, creating a self-reinforcing system. (Rutten, 2011)

The aim of a research by design on heavy rail transformation, is to detect spatial opportunities on which such a dynamic could graft itself.

3. ORDERin'F: a scenario-based research by design

Heavy-to-light rail transformation benefits from existing infrastructures, and as such offers a feasible implementation of light rail. However, other strategies are also possible. Within the ORDERin'F research project (OSA, 2009), the structuring potential of three different concepts for light rail connections are tested on a specific sub-region of Flanders; Klein-Brabant, situated in between the main cities of Brussels, Antwerp and Ghent. In comparison to the usual discourse on Transit Oriented Development (Curtis, 2009; Dittmar, 2009), the emphasis is on a qualitative and design-oriented approach, rather than a quantitative exercise in densification.

On a basic level, a regional public transport network aims at significant economic, social and environmental benefits for the society at large. However, the ORDERin'F research also projects such a network as a lever to restructure the suburbanized spatial structure of Flanders in the long term. This ambition brings about a complexity in – sometimes contradictory – objectives that is also present in realized projects throughout Western Europe and elsewhere. The most interesting of these ambitions are positioned on the intersection between spatial planning and public transport planning. The main domains that the research by design is dealing with, are infrastructure planning, mobility planning and spatial planning. Corresponding to each of these, a design concept is determined that functions as a scenario, focusing

on the specific issues of this domain (Figure 1). These scenarios sharpen the consequences of design choices, and clarify the way in which decisions on a larger scale influence the small scale level.[11] The scenario of heavy to light rail transformation corresponds to the infrastructural component of the research by design, and is elaborated in the next sections.

Figure 1. Three inputs for scenario building: existing infrastructure (left), existing mobility patterns translated into the bus network (middle), guiding landscape structures (right).

4. The region of Klein-Brabant as a laboratory for regional public transport experiments

The region within which this scenario is tested is the broader area around Klein-Brabant (Figure 2.). It is situated at the heart of the Flemish Diamond. Although it is the center of a highly urbanized region, the density is remarkably lower than the surrounding cities, its landscape qualities and natural values however are much less defined than the Green Heart of the Randstad conurbation in the Netherlands. Instead, Klein-Brabant is characterized by a direct and diverse juxtaposition of unbuilt landscapes, different types of housing tissue and areas of economical activities, strung together in a network of towns connected by ribbon development. As such it is exemplary for the Flemish landscape (Figure 2.).

A major driving force behind the dispersed urbanization in Flanders has been the sequence of consecutive infrastructure networks projected on the territory, on which diffused urban growth grafted itself (Van Acker, 2011). Although this process has

[11] The overall methodology is elaborated extensively in: Blondia, M., De Deyn, E. (2012). Understanding the development potential of regional public transport in a peri-urban context through research by design: the case-study of Klein-Brabant (Belgium). BUFTOD 2012 - Building the urban future and Transit Oriented Development. Paris, 16-17 April 2012.
The third scenario has been elaborated earlier in the research. For more information: Blondia, M., De Deyn, E. (2012). Landscape-based design strategies as a sustainable backbone for regional public transport in a dispersed territory. Landscape as a guiding principle in the transit-oriented transformation of Flemish urbanization patterns. ECLAS 2012 Conference, Warsaw, 19-22 September 2012.

been a work of centuries, planning and urbanism discourse have only recently, since the 1990's, challenged the dichotomy between urban and rural, through concepts such as sprawl, rurbanization, ville territoire, edge city (Delbaere, 2007). As such, the Flemish hybrid landscape is being recognized as a continuous nebula of urbanization, strongly interwoven with the open spaces in between. Hence the name 'nebular city'.

Figure 2. Klein-Brabant and the surrounding region, with the intersecting train connections highlighted.

A closer look at Klein-Brabant shows that the 'nebular city' offers specific challenges for public transport. As it is the far-out corner of three separate provinces (Antwerp, West Flanders, Flemish Brabant) and five public transport regions (Antwerp, Brussels, Mechelen, Sint-Niklaas, Aalst), the spatial and mobility challenges of Klein-Brabant are seldom considered on the scale of the entire region, in particular with regard to public transport. Because Klein-Brabant is enclosed by

these bigger cities whose transport networks intrude and influence the region, public transport in Klein Brabant lacks a logic of its own; it is merely an overlap of these different city-based systems.

The starting point for a research by design on the transformation of heavy rail lines is obviously the existing network passing through the region of Klein-Brabant. Mechelen was originally conceived as the central node in the Belgian train network. Although nowadays Brussels is the main hub, there are still many lines intersecting in Mechelen, most of them among the oldest lines in Europe[12]. In the east part of the area lies the connection between Antwerp and Brussels, built in 1836. The line on the south edge of Klein-Brabant was opened just a year later in 1937. These two lines were part of the initial cross-shaped network projected on the Belgian territory. The other lines soon followed: in 1844 the connection between Ghent and Antwerp was opened, in 1856 a trajectory between Lokeren and Dendermonde was built, just west from the region of Klein Brabant. In 1870 a new diagonal intersected Klein-Brabant, connecting Mechelen to St-Niklaas. The last line to be realized was the line between Antwerp and Dendermonde, in 1880.

5. The dual concept of Belgian railways: a network of hybrid lines

All the lines intersecting Klein-Brabant were built in a period of merely forty years. As argued by De Block (2011), the Belgian railway network was realized as a comprehensive system covering the entire territory, conceived from the start as a carrier for national and transnational transport mobility, and at the same time as a tool for nation-building and territorial organization. These ambitions made the railway network into a hybrid scheme of engineering, spatial planning, politics and economy. This hybrid nature is also reflected in the trajectories of the train network. On the one hand, lines were planned as fast connections between the main cities or even between the neighboring countries. These lines were superimposed on the existing territory, their trajectories as straight as possible. On the other hand, the economical advantage that rail infrastructure brings to the context it cuts through, made a more subtle positioning of the trajectory desirable. Connections between cities deflected from a straight line to bring service to smaller towns in between, thus making the train a carrier for regional as well as inter-city mobility. On an even smaller scale, short branches of rail were often realized connecting individual plots of industry to the railway.

The function of rail infrastructure as a connector is thus of a dual nature: it connects the cities on both ends of the line with each other, while often also connecting the intersected territory to the national train network. These two different modes of ‘connecting’ are not mutually exclusive, nor are they perfectly complementary. As such, individual railway lines are not belonging to one of these two categories, but are always positioned somewhere in-between.

[12] Throughout this paragraph the building year refers to the date on which the part intersecting Klein-Brabant was realized, not the line in its entirety.

Since the conception and realization of the railway lines intersecting Klein-Brabant, the landscape has drastically transformed itself. Developments occurred around and because of the train network and its stations, while consecutive layers of infrastructures became attractors for activities in their own right. The interplay of the train network with the urbanizations and other infrastructures has lead to complex spatial configurations. Taking the railway as a starting point however, three concepts of spatial development configuration can be derived (Figure 3.). In reality most lines show a combination of two or more of them, and hardly ever are they a clear and certified example of one concept. The next paragraph gives an overview of these configurations, after which they will be applied to the different lines intersecting the region, thus offering a base for design choices.

Figure 3.Three concepts of spatial coonfigurations along regional railway lines: (1; left) train stations at a certain distance from town centers creating a dual centrality between both; (2; middle) parallel infrastructures attracting road-oriented development along the railway trajectory; (3; right) direct branches connecting individual plots to the train network.

(1) Depending on how strong the interrelation between the railway and the intersected territory is, communities have stations at a certain distance from their centers. As the train was the fastest mode of transport at the time of its conception, a shift in centrality occurred in the local fabric of small towns. The station attracted all kinds of functions and activities, creating a tension between the historical center and the new center of mobility, being the station. In most cases this materialized into an axis connecting both, usually named ‘Stationsstraat’ (Station Street). Since the railway network and its stations have been built, the urbanization of the Flemish landscape has grafted itself on other infrastructure networks as well. Primary and secondary roads have, since the democratization of mobility by car, been strong catalysts for urban sprawl within the finely grained settlement structure of Flanders. Consequently, in the current situation, the structuring role that once belonged to the station is not always equally distinguishable. In many cases, the expansion of settlements exceeded the distance between town center and railway, filling up the void between them. In many towns, the railway acted as a barrier, with only limited urbanization on the other side of the station, with the expansion of towns taking place in other directions, thus further

away of the station. There are however exceptions: in Puurs, for example, the Keulenhoek quarter is located on the backside of the station.

(2) The previous paragraph points out urbanization grafting itself on different infrastructure as a general concept, not specifically targeting the influence of one road in particular, but rather of the network as a whole. However, there are certain cases were a single infrastructure transformed the morphology of the urbanization, as the railway has done before. In particular, main roads and regional roads have attracted many developments. On the level of land use and morphology, these developments are confronted with the developments attached to or oriented towards the station. A fundamental difference between both, is the fact that train stations give way to nodal development, while road infrastructure stimulates linear development all along the trajectory. When projected on top of each other on the landscape, the resulting figure is a strip of linear road-oriented development, interrupted by nodal development around station locations. This occurs when segments of railway run parallel from main roads. The distance between the two infrastructure determines how strong the interplay between both is.

(3) A particular case of railway-oriented development occurs when the line originally was not only intended as a connection between cities and towns, but also for the shipment of goods from the industrial developments it passes along. For this purpose, short branches of railway were built, establishing connections between the line and the industrial parcel. This gave individual companies or clusters of companies organized on one site, the opportunity of a fast access to the national and international rail network. As road transportation gained ground during the twentieth century, the strategic benefit of a rail-bound location became of lesser importance for companies. Most of these branches have been abolished or even demolished, and many of the industrial sites have become brownfields waiting for reconversion.

These three types of configurations overlap and influence each other in different ways along the railway lines intersecting Klein-Brabant (Figure 4, Figure 5.). A line-by-line analysis that focuses on these configurations offers a solid base for design choices and future development. This is explored in the next section.

6. Line-by-line: concepts for a light rail-oriented development

6.1 Railway 59 connects Ghent and Antwerp with an almost straight line. Two major curves are made to enter the two cities at its end, and in-between only two minor direction changes occur. Obviously, the trajectory was not chosen in favor of proximity to smaller towns within the Ghent-Antwerp corridor. Initially, only a few stations were built, in Klein-Brabant these are the stations of Sint-Niklaas and Beveren. Smaller towns started having their own stations along the line only later. As the line was not initially conceived as a connection for these towns, the line often passes at a considerable distance of the center. The one exception to this rule is

Zwijndrecht, whose center happens to be located near the straight line between Beveren and Antwerp.

As the railway serves mostly as a connector for the bigger cities along its trajectory, it doesn't have a strong link with the urbanized landscape it cuts through. It is a supra-regional infrastructure, and although it has had some impact on the local tissue around specific stops, the distance between towns and stations has often been too large to encourage densification. Rather it stimulated a low-density expansion of the town towards the station. As a conclusion from the past development of this corridor, the interrelationship between the trajectory and the intersected territory appears not strong enough for a regional light rail to be added to the rail corridor.

Figure 4: Map showing all the trajectories intersecting Klein-Brabant with the stations that were initially conceived in the concept of the line (big red dots) and those that were added later (small red dots)

6.2 A similar logic applies to the lines between Dendermonde-Mechelen and Antwerp-Mechelen. As part of the initial cross-shaped network projected on Belgium, they were as well conceived as (inter)national connections. The line Antwerp-Mechelen still has its supra-regional function today, but as the central node of the Belgian railway network shifted from Mechelen to Brussels, the line Dendermonde-Mechelen was downscaled to a regional connection. Although its course is as well an almost straight line between the two cities, it passes more closely near several town centers (Buggenhout, Londerzeel, Kapelle-op-den-Bos, Hombeek). As these towns expanded over the decades, their station and "Stationstraat" (the connecting road) attracted developments and became an integral part of the town. The towns that have their stations more remotely located (Malderen, Baasrode) still show a pattern similar to the towns along the Ghent-Antwerp line.

Figure 5: Map showing all the trajectories intersecting Klein-Brabant with all the branches that were built to connect individual plots with the train network. Additionally, alterations to the original line, such as taluses and separated intersections, were mapped (red.

Looking at the relation between these three heavy rail trajectories and other infrastructures, shows that while the lines Ghent-Antwerp and Antwerp-Brussels each have a highway running parallel at distance of approximately 4km, the line between Dendermonde and Mechelen only has crossing infrastructures. In the case of those first two lines, the parallel infrastructure is of a supra-regional character, similar to the train connection. Thus, the same cities are being serviced. In the case of Dendermonde-Mechelen, where such a parallel infrastructure does not exist, the string of stops along the railway line does not function as a corridor. Spatial relations and consequent mobility patterns have developed much more criss-cross, into a pattern that is equally diffuse as the road network. Whether a transformation of this regional train connection into a high quality lightrail connection can provide enough leverage for a transformation of the existing spatial patterns is uncertain. Spatial development potential around the existing stops is limited, as most of them have already been absorbed into the expanded town center, which implies a scarcity of unbuilt plots. On the other hand, entirely new stops for new developments are not desirable, as the areas where this would be possible are part of big, albeit fragmented, open space structures. Furthermore, this would require new road infrastructure as well.

The best opportunities for new developments along this railway line, exist around the more remote stations. These are well connected by both road and rail infrastructure, and there is still development potential around them. Many of these stations have closed because of low ridership, and reopening them requires the creation of a travelers potential that previously was not there. This has to be done by a mutually reinforcing strategy of providing good public transport service and stimulating mobility from and towards the stations by providing development opportunities. Thus, the strategy for this line is to encourage the existing principle of small station redevelopment, combined with a higher level of service by public transport.

The previous lines were initially conceived as supra-regional connections, and although the line between Dendermonde and Mechelen became a regional line over time, they have the according characteristics of being straight lines that are not intentionally connected to the intersected territory. The two lines that cross Klein-Brabant diagonally were originally planned as regional connections, and this shows clearly in the morphology of the line and its interaction with the surrounding landscape and urbanizations. They are the connections from Antwerp to Dendermonde and from St-Niklaas to Mechelen.

6.3 When the connection between St-Niklaas and Mechelen was opened all the towns within the corridor were provided with a station. Later, more were added as suburbanizations started to grow. The typical duality in development between station and town center, as elaborated in previous sections, made the railway an important connector along the corridor. Developments occurred in and around the towns and smaller settlements, with the railway stations as important node in the tissue. In-between these towns, there were some connecting ribbon developments, but these

were limited to their linear shape, and as such, developments were not homogeneously spread over the corridor between St-Niklaas and Mechelen. This changed however when the N16 was built parallel to the railway. This primary road was conceived with the intention of stimulating economical activity in the region. Since it was built, a lot of industrial companies and offices have located themselves along the N16. As the areas around existing towns and stations were already developed, available space for these economic activities was primarily found in-between these towns. The resulting morphology is a strongly developed corridor around the N16 and the parallel railway, in which concentric towns with station-bound developments alternate with road-oriented industrial sites. Not all of the landscape has been consumed by urbanization though, as the hydrological structure of the region imposes linear unbuilt spaces along the intersecting water streams. Also, along most of the trajectory, the railway has served as a barrier for economic developments, thus protecting the landscape behind it from expanding industries.

The spatial development potential along this line (Figure 6.) mainly exists in a restructuring of the industrial tissue. Currently, it makes inefficient use of the available land and its layout is completely oriented towards the N16. An optimization could enhance the importance of public transport in this area as an important area of employment, while at the same time a more efficient organization of the industrial sites could further stimulate development, realizing a layout that is more favorable in terms of public space.

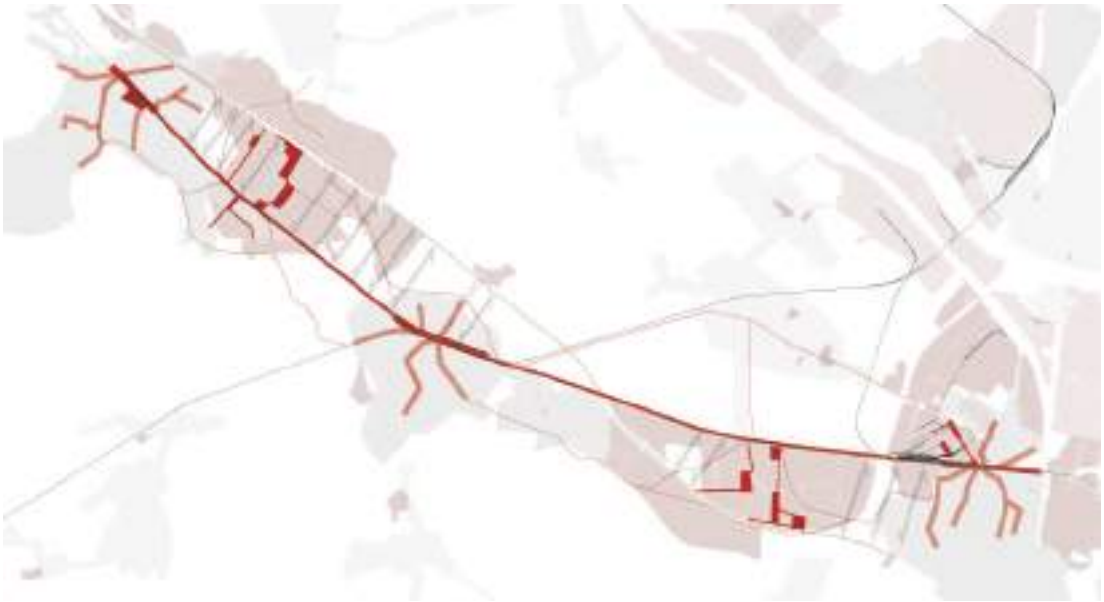

Figure 6. Development Scheme for the line between Sint-Niklaas and Mechelen (section: Bornem-Willebroek).

Within the town centers, main roads often connect in the vicinity of the station. Small-scale mixed-use redevelopment could occur on the long term along these axes. The railway bed in itself could also transform into such an axis, as a transformation of heavy into light rail softens the barrier of the infrastructure. Developments

currently have their backside oriented towards the railway, and the in-between space is strictly a residual strip that buffers the nuisances of trains. When light rail vehicles replace the traditional train cars, the rail trajectory can evolve into a public space, in which the infrastructure is integrated without imposing a strong barrier in the tissue. This new strip of public space could then become an attractor for redevelopment, changing the 'backside orientation' of flanking building blocks.

6.4 The line from Dendermonde to Antwerp has a regional character as well. There is a clear distinction between the sections Dendermonde-Boom and Boom-Antwerp. The first part of the line was built in a similar way as the line from Sint-Niklaas to Mechelen: with stations in or near existing towns with an intermediate distance up to a few kilometers. Between Dendermonde and Boom however, the railway trajectory never became an infrastructure bundle through the addition of a main road. This has resulted in very low spatial dynamics in this part of Klein-Brabant.

Figure 7. Development Scheme for the line between Dendermonde and Antwerp (section: Boom-Antwerp).

Most of the towns served by the railway have remained rather small and compact. In fact, as a consequence of its low dynamics, this section of the railway stopped its service in 1980. Currently it is exploited as a touristic steam train trail during the

summer months. Although a redevelopment of station areas could be possible along this section of the line, the desirability of a densification of this area is to be addressed with stakeholders, as this area has some distinct landscape qualities to preserve.

The section between Boom and Antwerp (Figure 7.) has more potential for a light rail transformation. It was also conceived as a regional railway with a strong connection to the intersected territory. Here there was already a particular water-based economic development at the moment the railway was conceived, thus creating a strong potential for this railway for the transport of goods. Big factory sites were connected directly to the railway by short private branches. These sites no longer have use of these branches, as most factories have either transformed into companies that don't produce goods, or have seized their activities resulting in brownfields waiting for redevelopment. In particular, near Boom, a number of clay excavation sites and old brick factories are a very specific type of brownfields. For most of these branches the railway infrastructure has disappeared, but the trajectory itself is still distinguishable in the landscape, as an unbuilt linear structure or as a boundary in the parcellation. All along the railway, redevelopment potential can be found in many of the plots at the end of old braches, either as redevelopment of existing businesses or as brownfield reconversions. The former branches can be reinstalled as pedestrian and bicycle paths, connecting a new development with a new station. This way, the development potential around the line not only exists in the immediate vicinity of existing and new stations, but also at the end of these connecting branches.

7. Conclusions

The research by design from which this paper originated has led to a number of conclusions. The main goal was to assess the spatial potential in the long term of a heavy to light rail transformation of existing railway infrastructures. First of all, not all railways are suitable for the installation of lightrail. The decisive factor behind this can often be traced back to the original nineteenth century conception of the railway. The extent in which it was conceived as either a supra-regional or a regional connector, largely defines its position in the current territory. The lines from Ghent to Antwerp and from Antwerp to Brussels show how straight connections were not meant to have a station in each town, which is exactly what a light rail would intend to do. The line Dendermonde-Mechelen was also conceived as a supra-regional connection. Coincidentally, many town centers happen to be in the vicinity of the straight line between the two connected cities. This is quite remarkable as there are not and never were any other parallel infrastructures stimulating a linear development between the two towns. The biggest potential for a light rail transformation however, can be identified for lines that were already conceived as regional connections in the nineteenth century. Their course was chosen as a balance between a fast – thus straight – connection and a line with proximity to existing settlements. These are the same characteristics that light rail seeks to exploit.

In terms of spatial elaboration of this development potential, the presence of parallel road infrastructures defines to a great extent the conditions with which the design has to deal. A primary or secondary road running parallel to the railway track is of great influence, as is the case between Sint-Niklaas and Mechelen, as well as between Boom and Antwerp. The corridor that is required for a well-developed light rail connection is already installed, but its morphology is not adapted to the nodal structure of transit-oriented development. Furthermore, the development potential along such a bundle is limited, as most terrains are already developed, due to the dynamics of the road infrastructure.

Where such a bundling with other infrastructures is not occurring, the desirability of new urbanizations filling up the landscape, as well as the feasibility of light rail in terms of mobility demands, are two main challenges. The mobility aspect will be calculated in the future steps of this research by design, through calculations with a newly developed traffic model[13]. The question of adding new developments in this landscape that are not well connected to the existing road system is a more complex matter, one that is much more subjective. As it is much more involved in the values and policy goals of various societal stakeholders, their opinions will be included in the elaboration of this topic. For this, the ORDERin'F project is developing socio-economic evaluation tools[14]. These are two important next steps in the research.

As the main goals of this paper was to emphasize the role of design in the ORDERin'F research, this track will also be further elaborated in the future. The options that were formulated at the meso-scale, will be explored and tested on a more detailed scale by the proposal of urban design schemes and development strategies on the local scale, highlighting the role of small scale stations as nodes of intermodality between regional and local mobility flows. As such, the role of design will be further explored in the matter of heavy to light rail transformation as a tool for urban development

'URBAN RESILIENCE' AS A NEW POLICY PARADIGM FOR ACHIEVING SUSTAINABILITY IN ISTANBUL[1]

Zeynep Deniz Yaman[*], PhD Candidate, yamanz@itu.edu.tr

[*]İstanbul Technical University, Faculty of Architecture, Urban and Regional Planning Department Taşkışla Street 34437 Taksim-Istanbul

Abstract

Because of the complexity of components and dynamics in settlements, planning practices and processes focus on diverse urban problems such as global environmental challenges, land and water degradation, biodiversity, habitat loss and fragmentation, natural hazards, climate change, inequitable distribution of resources and services, urban sprawl and fragmentation, traffic congestion, unsustainable way of urban form, social injustice, spatial segregation based on socio-economic differences of population and unemployment (Abukhater, 2009; Miller et.al. 2010). Consequently, it will be inevitable to have vulnerable and unsecure community and spatial form in urban areas. A city without resilient community will be extremely vulnerable (Godschalk, 2003). Based on this realization, throughout the past half century, there has been a growing and continuing demand towards developing more integrated approaches to spatial planning in a way to combat the disreputably complex and chronic urban problems (Abukhater, 2009). Therefore, the necessity to provide resilience in order to achieve sustainability for community development becomes more crucial. Since planning for a community may seem like a significant challenge, spatial planning should involve rational choices to get prepared for the future (Kelly and Becker, 2000). In this context, Wilkinson (2011) mentions a fundamental issue in planning theory that is "think planning again" in ways of admitting the emergency, unpredictability and inescapability of ecological processes.

This paper aims to discuss the integration of urban resilience theory into sustainable spatial planning process and to assess how urban resilience concept can be related with urban sustainability. Istanbul is chosen as a case study since having the largest metropolitan population and being the economic, cultural and international focal area of Turkey.

In the second half of the 20th Century, during fast industrialization and urbanization, Istanbul has been the destination of rural migrants in large scales that influenced illegal developments on public lands with low quality housing pattern lacking basic

[1] This paper is produced under the "Sustainable Urban Planning for Urban Resilience and Ecosystem Services" TUBITAK, Project, No.110K350.

infrastructure and technical guidance. Additionally, the majority of these illegal developments emerged on major water basins (Tezer, 2005; Tezer, et.al. 2011a; Tezer, et.al. 2011b). Consequently, the pattern of growth couldn't be sustained ecologically and socially. Due to the problems affected by social, economic and administrative characteristics, the community as well as the spatial form of the city became vulnerable. On this account, this paper will focus on the integration of social and ecological systems to develop better tools and policies for enhancing urban resilience in Istanbul. In this task, the key questions will be how spatial planning can be apprehended to provide urban resilience and how urban resilience can address vulnerabilities to achieve sustainable urban development in Istanbul.

Key Words: Sustainability, urban resilience, urban sustainability, spatial planning, Istanbul.

I. Introduction: Resilience Theory

The future can't be predicted, but it can be envisioned and brought lovingly into being… We can't surge forward with certainty into a world of no surprises, but we can expect surprises and learn from them and even profit from them. We can't impose our will upon a system. We can listen to what the system tells us and discover how its properties and our values can work together to bring forth something better than could be produced by our will alone. We can't control systems or figure them out. But we can dance with them! (Meadows, 2001)

The increasing complexity and rapid changes in world dynamics, brought to a growing interest in "resilience" as a concept for understanding, managing and governing complex social-ecological systems and managing the capacity to cope with, adapt to, and shape change (Figure 1) (Lang, 2011; Schultz, 2009). The attention this term receives is the response to a widespread sense of uncertainty and insecurity and a strain to find formulas for adaptation and survival (Müler, 2011). Resilience as a concept firstly appeared in the work of the ecologist C.S. Holling. According to Holling (1973), resilience is "a measure of the persistence of systems and of their ability to absorb change and disturbance and still maintain the same relationships between populations or state variables." In 1986, Holling (1986) refines this definition as "the ability of a system to maintain its structure and patterns of behavior in the face of disturbance." In the late 1980s, the ecological vision of resilience involved the interactions between people and the environment in order to measure the complexity of community-environment interactions, and the changes they bring (Maguire and Cartwright, 2008), then in the 1990s several scholars adopted this approach as an important tool to measure sustainability.

Now the general approach of resilience for urban development related sectors is quickly expanding and including the following: mitigation and adaptation to climate change (Satterthwaite et al. 2007; Dodman, Ayers and Huq, 2009; Deppisch and Hasibovic, 2011), disaster planning, management and recovery (Goldstein, 2009; Vale and Campanella, 2005; Godschalk, 2003; Berke and Smith, 2009; Normandin,

Therrien and Tanguay, 2009), energy and environmental security (Coaffee, 2008), urban design (Colding, 2007; Pickett et al. 2004), resilience as socio-ecological systems (Berkes, Folke and Colding, 1998; Adger, 2000; Folke, Colding and Berkes, 2003; Adger et al. 2005; Walker, Holling, Carpenter and Kinzing, 2004; Folke, 2006; Walker and Salt, 2006; Ernstson, 2008), urban resilience (Folke et. al. 2002; Alberti et al. 2003; Pickett, Cadenasso and Grove, 2004; Campanella, 2006; Gleeson, 2008; Maguire and Cartwright, 2008; Ernstson et al. 2009; Newman, Beatley, and Boyer, 2009; Deppisch and Schaerffer, 2010; Lin, 2006) and urban planning (Fleischhauer, 2008; Wilkinson, Porter and Colding, 2010; Scotti-Petrillo and Prosperi, 2011; Schrenk, Neuschmid and Patti, 2011; Wilkinson, 2011). The extended use of resilience allows the treatment of the issues raised by Holling (1986) about renewal, innovation and reorganization in system development and how they interact across scales (Gunderson and Holling, 2002; Folke et al. 2010).

Resilience means in the last two decades what sustainability meant in the 1980s and 1990s. Among the many authors discussing the relationship between resilience and sustainability (Table 1) the most remarkable are; Levin et al. (1998) claim that resilience is the preferred way to think about sustainability in social as well as natural systems, thus he suggests basically an equivalence of resilience and sustainable development. Holling and Walker (2003) showed how a resilient socio-ecological system is synonymous with a region that is ecologically, economically, and socially sustainable, while Gross (2008) quoted Holling promoting resilience as a better tool than sustainability.

Since sustainability policy has been adopted globally in the late 20th century, theorists are increasingly appreciating the interesting role that change, dynamics, and uncertainty play in sustainability, so that the Brundtland Report (1987) sets as the goal of sustainability, all the processes and abilities to deal with change in constructive ways. The Millennium Ecosystem Assessment (2003) also depicts sustainability as a process and suggests paying more attention to issues such as robustness, vulnerability, resilience, risk and uncertainty, which will determine the ability of a system to adapt to and take advantage from change. Put in these terms, resilience gives a new look to the perception of sustainability. Long-term sustainability will result in the ability of continuously adapting to changing conditions which growth and transformation are inevitable in urban systems. Paradoxically sustainability is grounded on the basic need for stability and security while facing and accepting the necessity of change (Novotny, Ahern and Brown, 2010; Schrenk, Neuschmid and Patti 2011).

However, the necessity of resilience in system's sustainability is still under criticism (Table 1), like Derissen, Quaas and Baumgärtner, (2009) explained these options such as: "*resilience of the system is both necessary and sufficient for sustainable development; resilience of the system is sufficient, but not necessary; resilience of the system is necessary, but not sufficient; and resilience of the system is neither necessary nor sufficient for sustainable development*".

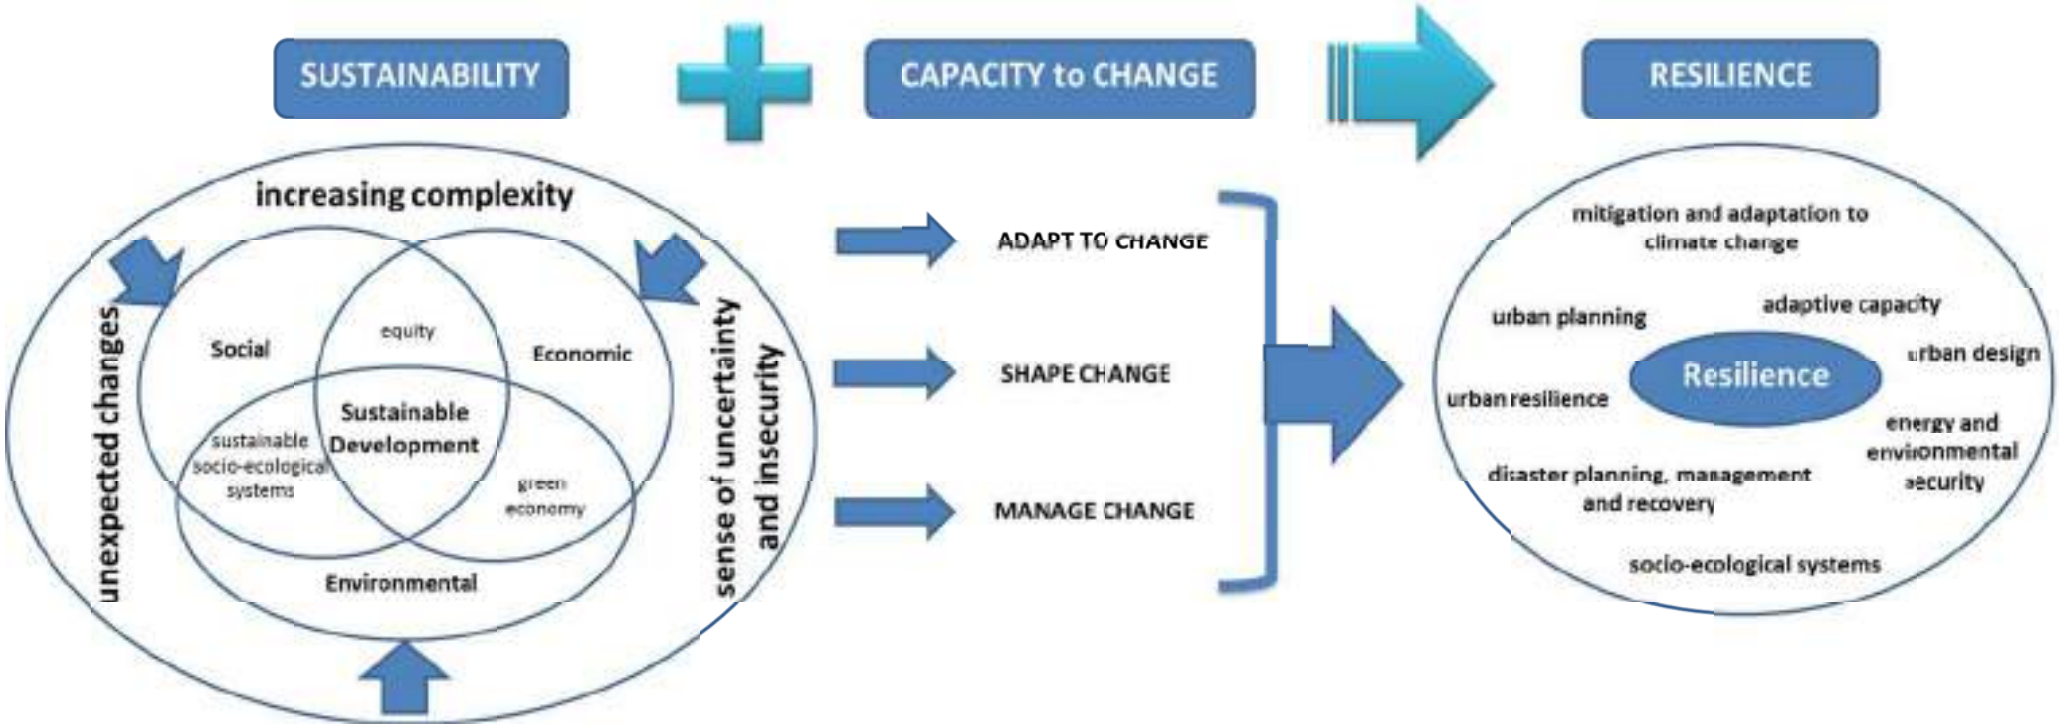

Figure 1. Resilience Theory

Clearly resilience proved to be effective, under its both social and ecological perspectives, as a crucial tool for the sustainability of urban development and resource utilization, not the least as a comprehensive strategy for urban sustainability, in sight of increasing working hypotheses about urban and regional systems, widening the interest to the whole aspects of human life.

II. Resiliency As A New Theory In Urban Scale and Sustainable Spatial Planning

Morphing in cities will always take place, carrying growth, change or the death of the city itself (Kowalik and Guaralda, 2011). Resilience in the urban systems risks to be lost (Folke et al. 2002), due to the growing complexity (Ernstson et al. 2010) and global integration of economic, social and physical processes putting in evidence the fragility of urban areas. Switching the perception of the city from economical to environmental, will guarantee better results allowing the city to prosper, grow and survive as long as these changes are not seen as negative but understood as yet another transformation being a natural part of the evolution of the metropolis. Recently there has been interest to apply the resilience concept to cities as complex adaptive systems (Newton and Bai, 2008; Alberti et al. 2003; Pickett et al. 2004; Newman, Beatley and Boyer 2009; Campanella, 2006; Gleeson, 2008; Maguire and Cartwright, 2008; Ernstson et al. 2009; Lin, 2006, Colding, 2007).

In order to be sustainable over significant periods of time, cities can't avoid being also resilient since, as it is natural, they will be affected by unexpected influences and disturbances (Novotny, Ahern and Brown, 2010). Newman, Beatley, and Boyer (2009) show cities' strain to endurance, to react to crises and adapt, and how they are compelled to re-shape and grow toward other directions; cities don't need only strong physical infrastructure and built environment, but also require their own inner strength and resolve. The novelty of this approach is a multi-level understanding of resilience of urban systems, recognizing the role of *metabolic flows* in sustaining urban functions, human well-being and quality of life; *governance networks* and the ability of society to learn, adapt and reorganize to meet urban challenges; and the *social dynamics* of people as citizens, members of communities, users of services, consumers of products, etc., and their relationship with the *built environment* which defines the physical patterns of urban form and their spatial relations and interconnections (Resilience Alliance, 2007). Urban resilience is created by the intersection of these areas.

Moreover, Gleeson (2008) suggests the ‘resilient urbanism’ via three principal branches: firstly, the acceptance of the inevitability of evolution and the necessity of adaptation. Urban planning's aim is to defeat disorder while navigating change flows, in search of urban resilience. The resilient city is the goal. Secondly, planning is an orchestration of activities (zoning, infrastructure, services, design, etc.), all of which converge in the best set of major improvements for urban well-being and efficiency. A good planning is a pre-condition for urban sustainability and resilience. The third branch of resilient urbanism is equity, meaning fairness not simple equality.

Table 1. Relationship between "Sustainability" and "Resilience"

Author	Relationship between "Sustainability" and "Resilience"	Which is more broader: "Sustainability" or "Resilience"
Hollings, 1973	A more laudable goal should be resilience rather than sustainability.	Resilience
Wildavsky, 1988	Resilience is the key to achieving long-term urban sustainability.	Resilience
Arrow et al. 1995	Economic activities are sustainable only if the life-support ecosystems upon which they depend are resilient.	Resilience
Lélé, 1998	Resilience is one of the contributing concepts of 'sustainability'.	Sustainability
Haris, 2000	For the ecologist, sustainability should be defined in terms of the maintenance of ecosystem resilience.	Resilience
Ahern, 2011	Resilience theory offers a new perspective, or possibly a solution to this paradox of sustainability.	Resilience
Carpenter et al. 2001	Resilience is often used to describe the characteristic features of a system that are related to sustainability.	Sustainability
Folke, et al. 2002	Management that builds resilience can sustain social-ecological systems in the face of surprise, unpredictability, and complexity therefore is closely related to concepts of sustainability and sustainability transition.	Resilience
López -Ridaura, Masera, and Astier, 2002	Resilience is one of the attributes of sustainable systems.	Sustainability
Bastianoni, Pulselli and Tiezzi, 2004	The role of resilience to achieve the goal of sustainable development is essential.	Resilience
Neuman, 2005	Sustainability draws from at least five intellectual traditions: capacity, fitness, resilience, diversity, and balance.	Sustainability
Fiksel, 2006	The sustainability of living systems-including humans-within the changing Earth system will depend on their resilience.	Resilience
Lebel et al. 2006	Strengthening the capacity of societies to manage resilience is critical to effectively pursuing sustainable development.	Resilience
Tainter, 2006	It is important to distinguish sustainability from resiliency. Sustainability is the capacity to continue a	Sustainability

	desired condition or process, social or ecological. Resiliency is the ability of a system to adjust its configuration and function under disturbance. The goal of human groups is more often sustainability or continuity than resilience. Most of us prefer the comfort of an accustomed life (sustainability) to the adventure of dramatic change (resiliency).	
Walker and Salt, 2006	Resilience is the key to the sustainability.	Resilience
Perrings, 2006	A development strategy is not sustainable if it is not resilient.	Resilience
Brand and Jax, 2007	Resilience is one of the most used concepts in sustainability.	Sustainability
Stirling, 2007	Stability, durability, resilience and robustness are each individually necessary and collectively sufficient for the quality of sustainability in social-ecological systems.	Sustainability
Callaghan and Colton, 2008	By shifting focus away from an ultimate end goal of sustainability, to an ongoing process of enhancing resilience it moves a community toward sustainability.	Resilience
Newman and Jennings, 2008	Sustainability cannot ensure survival, especially if disturbances are completely outside the realm of s system's experience.	Resilience
Stirling, 2008	Resilience as just one dynamic sub-property of sustainability	Sustainability
Derissen, Quaas, Baumgärtner, 2009	Resilience is the preferred way to think about sustainability.	Resilience
Du Plessis, 2009	Resilience, vulnerability and adaptability are seen as the conditions for sustainability of the city.	Sustainability
Hvid, 2010	A new systems approach is developing. It understands systems as incalculable complex entities in which change is discontinous, in which chaos and order exist at the same time. Sustainable systems are adaptive and have the capacity to change themselves in a world dominated by uncertainty.	Resilience
Novotny, Ahern and Brown, 2010	Understanding resilience is central to understanding sustainability. Resilience is a new way of thinking about sustainability, rather than a specific set of guidelines, instructions, or checklists.	Resilience
Thapa, Marshall and Stagl, 2010	Resilience is about adaptation, uncertainty and flexibility, which allow for continuous development for long-term sustainability.	Resilience
Pierce, Budd and Lovrich, 2011	Resilience is a major theoretical contribution to the understanding the likely sources of sustainability.	Resilience
Saporiti, 2011	The concept of resilience is not tied exclusively to the maintenance (for present and future) of natural resources, such as sustainability, but also to the transmission of these resources.	Resilience

Ernston et al (2009) defines ‘resilience in cities’, operating within the city and dealing with local-to-regional ecosystem services; while ‘resilience of cities’, operating at the scale of a ‘system of cities’ which is a concept borrowed from geography meaning a set of cities linked with each other through relations of exchange, trade, migration or other that sustain the flow of energy, matter and information between the cities. Resilient cities are constructed on solidity and flexibility criteria. According to sustainability, development is based on the creation and conservation of a prosperous social, economic, and ecological system, therefore the role of resilience becomes essential for a prosperous development of society (Folke et al. 2002). In order to become more resilient, cities and regions are supposed to adapt planning and design strategies versatile and able to foresee the economic, social, and physical stresses they will face (Müler, 2011). 'Adaptation' is surely the new keyword for planning: ‘ordering the use of land’ in a time of increasing urban disorder. Resilience wants to be the ordering logic and the potential of planning (Gleeson, 2011).

Planning theory conceptualizes change in many different ways, according to the philosophical starting point. Complexity theory and its conceptualization of the dynamics of change are concepts not new to planners. As Wilkinson (2011) expresses, the attempt to ‘defeat disorder’ inherent in traditional planning approaches is challenged and the ‘science of surprise’ is prioritized. Land-use disorders and the reduction of land-use conflicts (Fleischhauer, 2008) are becoming the core tasks of spatial planning, that contribute to all those principles of urban resilience dealing with the physical/environmental urban structure. Spatial planning is one of the fields which embed at its best the infrastructures that are necessary for resilient cities. Hence, one of the purposes of planning is to strengthen resilience of cities to be able to adapt to new trends, changes and impacts (Schrenk, Neuschmid and Patti 2011).

In recent literature, disaster management allowed resilience theory in urban planning to show up (e.g. see Godschalk, 2003) since recently natural disasters with distressing effects on human settlements have multiplied. Uncertainty of natural risks, gives resilience the possibility to provide a better guidance to produce effective hazard mitigation approaches in urban settlements. The disaster resilience concept, in terms of the adaptation capacity, provides not only built up infrastructures, but also non-built up environment such as community of life potentially exposed to natural hazards with a view to maintaining or restoring an acceptable level of functioning and structure (Alarslan, 2009).

According to Godschalk (2003; p.139) researchers who have studied the response of resilient systems to natural hazards find that they tend to be;

Redundant; with a number of functionally similar components so that the entire system does not fail when one component fails,
Diverse; with a number of functionally different components in order to protect the system against various threats,

Efficient; with a positive ratio of energy supplied to energy delivered by a dynamic system,
Autonomous; with the capability to operate independently of outside control,
Strong; with the power to resist attack or other outside force,
Interdependent; with system components connected so that they support each other,
Adaptable; with the capacity to learn from experience and the flexibility to change,
Collaborative; with multiple opportunities and incentives for broad stakeholder participation.

Both hazard mitigation and land use planning are noteworthy tools for reducing vulnerability and creating more disaster resilient communities that can front or absorb an impact, shape in order to overcome or recover from the backlash of a disastrous event and consequently adapt or learn from the experience. Disaster resilient communities are intrinsically more sustainable than those who do not undertake any action to reduce their exposure to natural hazards. A resilient community can actually return to prior conditions quickly, mainly because it has embodied hazard mitigation infrastructure and counter-measures into their community that reduce the spreading and the duration of the disorders due to disaster (Berke and Smith, 2009).

As Lebel et al. (2006) indicates a society's ability to manage resilience resides in actors, social networks, and institutions (Figure 2). The kinds of attributes such as participation, representation, deliberation, accountability, empowerment and social justice are considered to be part of good governance. Furthermore, to obtain urban resilience, governments should be self-organized and they should have the capacity to learn and adapt (Lebel et al. 2006) which means it is essential to provide hazard mitigation and urban planning indicators as well as the analysis of the risks (see Fleischhauer, 2008) and their possible impacts that cities may be exposed to.

Certainly, resilience theory can't be an approach only for disaster mitigation but also it has the tools in a larger scale in the sustainable urban planning. The goal is to pursue community resiliency striking an appropriate balance among economic, environmental, and equity values (Berke and Smith, 2009). As Wilkinson (2011) determines 'think planning again' in ways that acknowledge the emergency, unpredictability and inevitability of ecological processes, it is sure to define social-ecological resilience as of interest to the field of planning in several dimensions. In this sense, resilient urban planning approach should be accepted as a more comprehensive strategy for urban sustainability aiming to have low risk, low vulnerability, appropriate scale of planning, interdependent and independence of social networks (Tobin, 1999), a concrete, unified strategy for the overall urban development of a city which provides an overall vision for the future direction of urban maturity and which developments meet and enforce and the necessity to address current urban concerns – transportation, density requirements, urban facilities as well as having a clear direction in terms of sustainability goals and agenda (Kowalik and Guaralda, 2011). Therefore, resilient urban planning comprehends all the development plan elements and sustainability policies (Table 2).

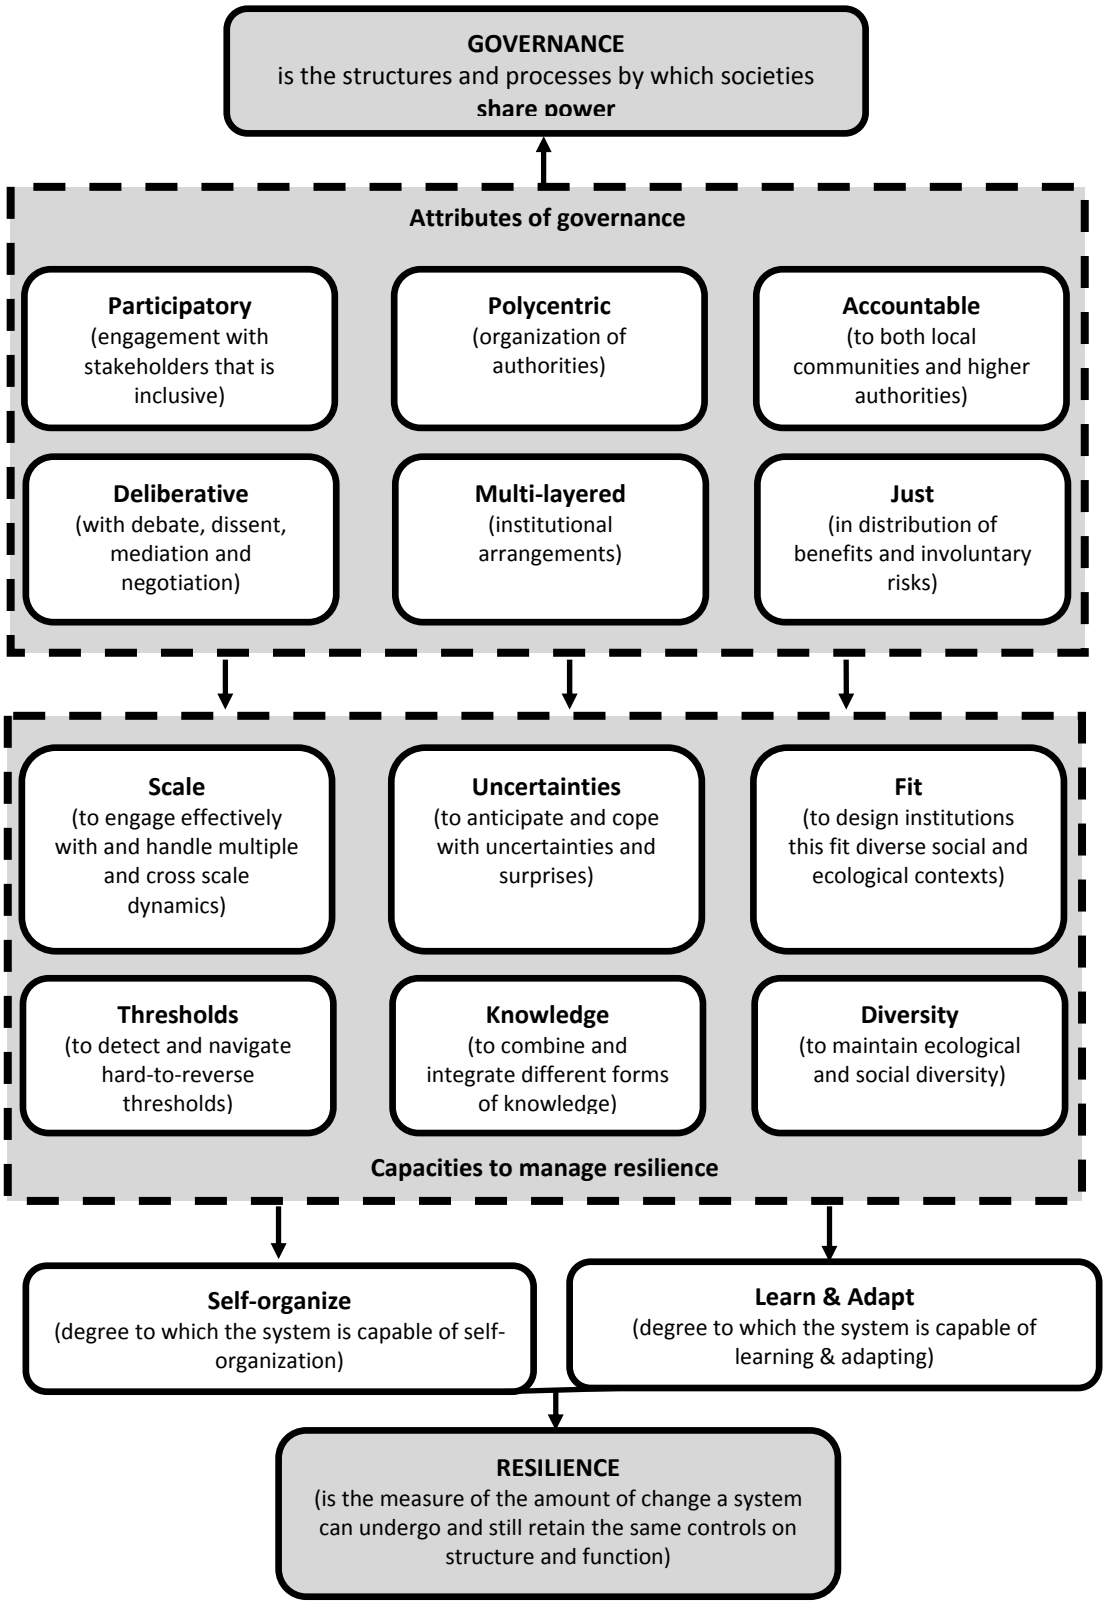

Figure 2. The Capacity to Manage Resilience (Lebel et al. 2006)

Table 2. Development/Master Plan Elements and Sustainability Policy (reproduced and adapted from Alshuwaikhat, 2006)

Urban Plan/Policy Development Components	Sustainability Policy
Physical Issues	**Land Use** Controlling urban area footprint Supporting mix land use and compact development Redevelopment of land and prevention of uncontrolled urban sprawl Balancing jobs and residential areas Managing sustainable housing policies Supporting smart growth **Transportation** Balancing travel density Balancing transit mode density Reducing car dependence Supporting pedestrianization and bicycle use **Infrastructure** Preventing ozone depletion Preventing excessive water consumption Providing available park space Managing wastes **Urban Design** Preservation of historic and archaeological sites and buildings Protecting open space
Environment and Energy Issues	**Environment** Protecting natural areas Protecting species and biodiversity Supporting agricultural land conversion Controlling Imperviousness Controlling water quantity Maintaining water quality Maintaining air quality Adapting climate change **Energy** Reducing excessive energy use
Economic Issues	Developing economic performance Increasing level of investment Increasing the ratio of employment
Social Issues	Enhancing human health Eradicating poverty Providing access to basic education Providing security Providing social inclusiveness

Resilience theory is at the frontier of contemporary urban planning and design, serving as a robust platform to shape and articulate the re-forming urban

development. Resilience is a new way of thinking about sustainability (Pickett et al. 2004), rather than a specific set of guidelines, instructions, or checklists. Resilience is strategic because, in order to be effective, resilience must be obviously based on, and informed by ecological, social, and economic drivers and dynamics of any particular place-called site specific, and it must be integrated across variety of linked scales.

III. Evaluation: Resilient and Sustainable Urban Planning in Istanbul

There is a commonsense that developing/less developed countries are exposed to more frequent and more severe natural hazard risks as a consequence of an increase in human settlements in vulnerable areas, rather than a rise in the number of geophysical events. The two main reasons for the exacerbation of the effects of natural hazards in developing/ less developed countries were rapid uncontrolled urbanization and unstable economic conditions (El-Masri and Tipple, 2002).

Cities are planned to last for long periods of time, therefore, continuation of functions ensures resilience in cities even in times of crises, unexpected changes or stressed spatial configurations (Surjan et al. 2011). The challenges for human dimensions research include those of measuring and addressing vulnerability, adaptation and resilience (Adger, 2006). Surely, resilience and vulnerability assessment is a necessary component of effective planning. Figure 3. shows vulnerable physical elements of urban settlements which are categorized in three scales in accordance with the scales in spatial planning.

Alarslan (2009) points out since urban settlements develop dynamics parallel with living organisms, the vulnerability of an urban settlement changes over time. Therefore, those elements in spatial plans at macro, meso, and micro scales should be updated to provide resilient urban policies. In this sense urban resilience theory is a relevant and noteworthy focus for contemporary urban development and enhancing urban resilience necessitates finding out how urban resilience can address vulnerabilities to achieve sustainable urban development. Table 4 is presenting a framework to explain how urban resilience relates with the key vulnerabilities and urban policy components. First of all, it is crucial to define the key vulnerabilities of different scales. Then, for realizing these vulnerabilities, it is necessary to emphasize what kind of urban development policies address them. Considering the role of resilience in providing and strengthening sustainability, third step is to define how to develop the resilience capacity. Enhancing resilience capacity is the overall concept of sustainable urban development with the scope of an increasing adaptability and manageability of the changing conditions.

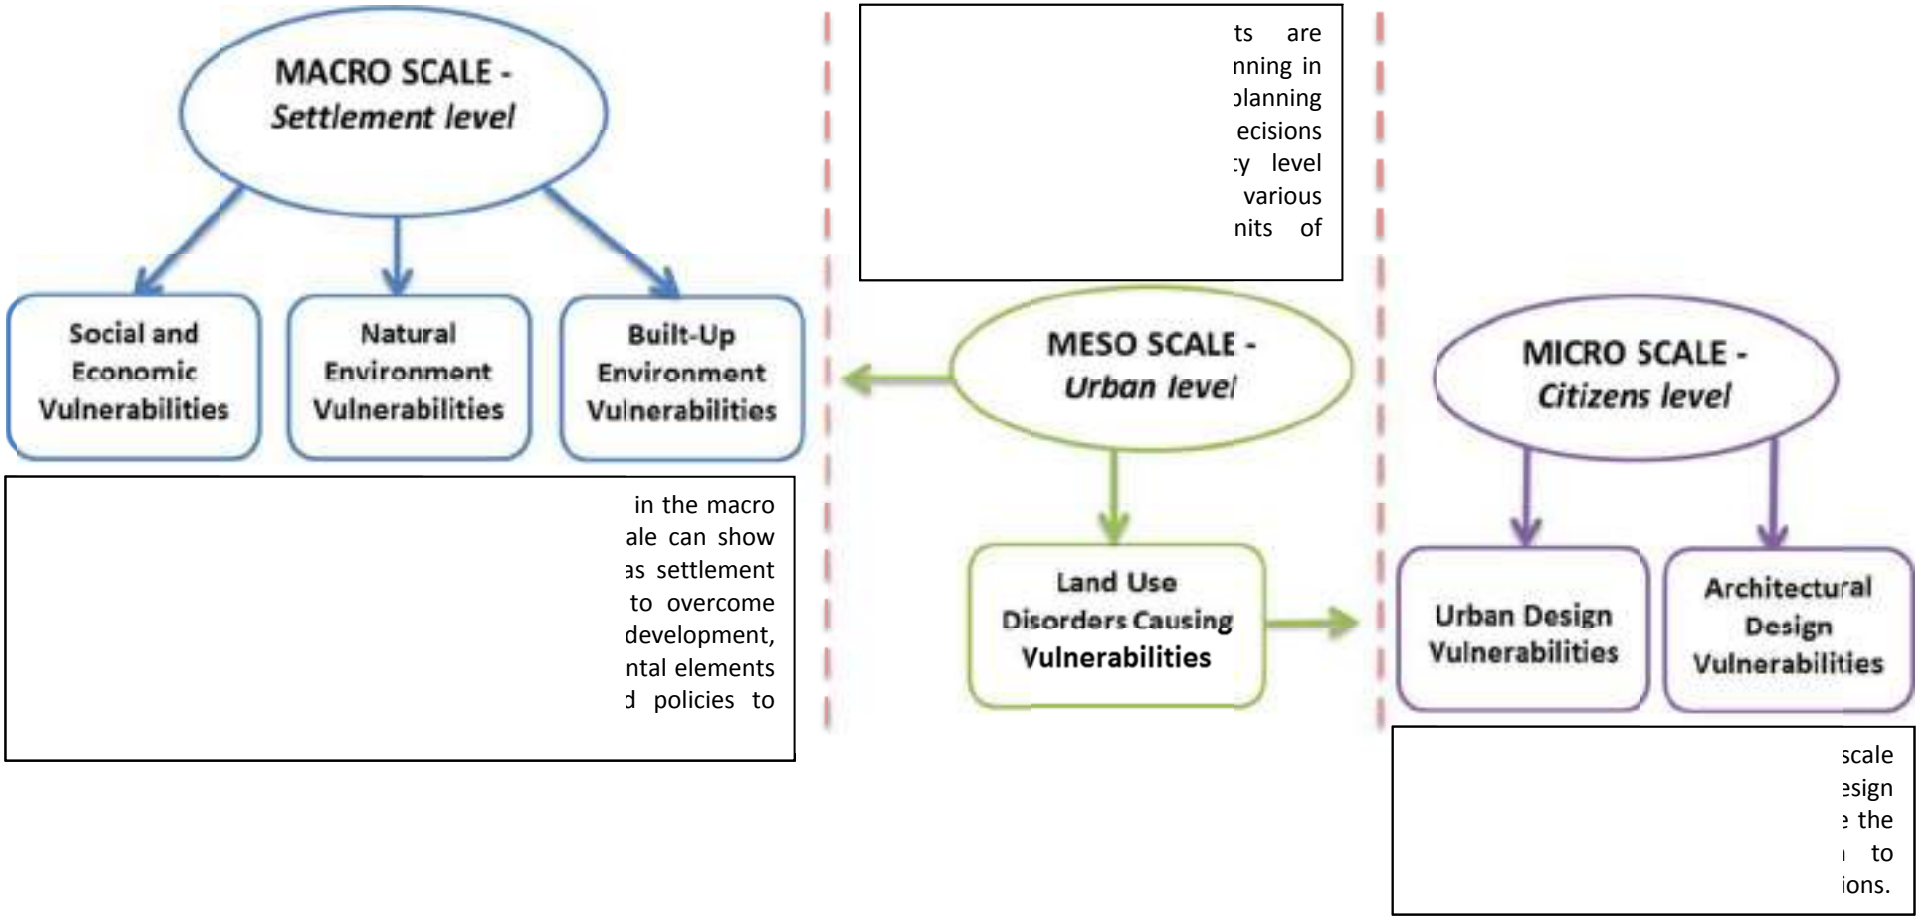

Figure 3. Vulnerable Elements of Urban Settlements (reproduced from Alarslan, 2009)

Turkey, like other developing countries, suffers from extensive pressures on natural resources due to rapid population increase and urbanization dynamics around metropolitan attraction nodes. The case of Istanbul sets a unique example with a population growth around 600% and a growth in built up areas 700% approximately since the 1950s. Today, Istanbul, with more than 12 million people, is still one of the most attractive internal migration nodes in Turkey. Diverse service facilities of governmental and private institutions, employment opportunities, cultural and historical background have been stimulating thousands of people from different rural parts of the country. As a result of the rapid growth in population and urban dispersion, there has been significant pressure on the ecological life support systems of the region (Tezer, 2005). The conditions, which are the origins of change processes creating vulnerability in megacities include high population density, high resource consumption, intensive land use (Deppisch and Schaerffer, 2010), a combination of economic and non-economic urban poverty, uncontrolled and unsustainable urbanization, unsustainable planning and development practices, and substandard urban management systems (Gencer, 2007), like in Istanbul. Istanbul shows high degree of complexity of dynamic ecological, social, economic, cultural and political interrelationships. Moreover, it is particularly vulnerable to changes and disorders.

In Istanbul, there has not been a plan covering the metropolitan area since 1995. There were many of local plans, which were not integrated to each other (Eyuboglu, 2004). While urban planning in Istanbul has been experiencing a rapid restructuring process intending to have an integrated and decentralized system, issues such as “environmental protection, risk management, transportation, urban renewal and regeneration” have increasingly been included into its urban planning discourse (Turan, 2011). In order to provide urban resilience through sustainable spatial planning process, first of all it is essential to address key vulnerabilities and define a framework to address those vulnerabilities with the resilient urban planning tools (Figure 4).

Although it is not the complete list of the assessments about the resilient urban planning in Istanbul, it may open up a discussion for further researches. Some of the indicators in the Figure 4 may be relevant for other crosschecks too. The aim of this evaluation is to represent the possible criteria of the resilient urban planning concept for policy development and spatial organization.

V. Conclusions

This paper examined the necessity to provide urban resilience in order to achieve sustainability for community development and emphasized the importance to consider planning in ways of admitting the emergency, unpredictability and inescapability of ecological processes. In order to face this new challenge, cities should cope with, adapt to and manage change and remains sustainable not only in terms of ecological perspective but also from the social and economic perspectives. It is important to note that, developing sustainable urban planning tools and creating

resilient and sustainable cities is fundamental for contemporary society. Planning is an ever-changing combination of activities such as zoning, infrastructure, services, design, etc., which meet the major improvements to urban welfare and competence. Effectiveness of the planning process is the first step for urban sustainability and urban resilience. Then, cities will be sustained over time depending on the ability to anticipate and adapt to new circumstances.

Surely, urban resilience will be the next objective of Istanbul to overcome the worsening social, economic and environmental problems. The evaluation in this paper shows that, there is still a long way to generate a concrete concept to clarify and explain urban resilience and resilient urban planning policies for Istanbul. Each scale (macro, meso, micro) in urban planning has its specific vulnerabilities and the resilience indicators addressing them. A macro perspective is instructive and might be the relevant starting one to evaluate both key vulnerabilities and urban resilience policies for urban sustainability.

Table 4. Evaluating Resilient Urban Planning[2]

	Key Urban Vulnerabilities	**Urban Plan/Policy Development Components**	**Attributes of Resilience Capacity**	**Attributes of Urban Resilience**
Macro Scale	Natural Environment	Protecting natural areas Protecting species and biodiversity Controlling imperviousness Controlling water quantity Adapting climate change Preventing ozone depletions	Scale Uncertainties Knowledge Thresholds	**Built Environment** Quality of Environment Quality of Housing Reduction of zones at risk Safety standards and codes Quality of transportation Urban planning **Metabolic Flows** Agriculture Business Economic development Education Energy Finance Health Insurance Sewers Telecommunication Water **Social Dynamics** Age
	Built-up Environment	Supporting agricultural land conversion Maintaining water quality Maintaining air quality Reducing excessive energy use Managing wastes Controlling urban area footprint		
	Social and Economic Vulnerabilities	Enhancing human health Eradicating poverty Providing access to basic education Providing security Providing social inclusiveness Developing economic performance Increasing level of investment Increasing the ratio of employment

Regional strategy, local dilemmas, and values. A study of values underlying a complex regional process and their role in solving local dilemmas.

L.M.C. van der Weide

1 Introduction

During the last 20 years, the nature of spatial development in the Netherlands has changed. Instead of being centrally governed, spatial development has become the responsibility of regional and local government. Furthermore, the influence of non-governmental organizations and civilians on spatial development decision-making has increased during this period: they no longer stand on the sidelines, but have become partners in drafting and implementing spatial development policy. An example of this type of collaborative planning in the Dutch province of Overijssel is a regional strategy for riverbed enlargement in the Vecht Valley region, called 'Ruimte voor de Vecht'[1].

Using the 'Ruimte voor de Vecht' regional strategy as a case study, this paper sets out to examine whether this new method of spatial planning is an improvement on current methods. Instead of using a more traditional interest-oriented approach, the case study is analysed from a value-oriented approach. The goal of this approach is to identify the values on which the various stakeholders base their basic choices. Basic choices are those choices in which different, sometimes conflicting, values are taken into consideration (Buunk, 2010a, pp11-13).

After describing the 'Ruimte voor de Vecht' case, this paper continues with a short description of the research method used to identify values involved in the complex process of collaborative planning. In addition to describing the method, an overview is given of the storylines, value sets, and values that form the process of the Vecht Valley regional strategy. Next, this paper identifies three possible dilemmas that are likely to occur. I will focus on one of these dilemmas, namely that of nature versus agriculture, by describing the basic choices that are involved in this dilemma and the values that may clash in making these choices. I will conclude by considering whether a complex process of collaborative planning, like that involved in the 'Ruimte voor de Vecht' regional strategy, should be adopted or avoided in the practice of spatial development.

1.1 The Vecht Valley region, The Vecht and 'Ruimte voor de Vecht'

The Vecht Valley region is located in the north east of the province of Overijssel and consists of four municipalities, including the province's capital Zwolle. Together the municipalities Zwolle, Dalfsen, Ommen, and Hardenberg are home to roughly 220,000 inhabitants, half of whom live in the city of Zwolle. The rest of the Vecht Valley region

[1] NB: Literally translated to 'Room for the river Vecht'

is mostly rural, with 1324 agricultural businesses, and consequently most of the region's GDP comes from agriculture. The riverbed is home to 20 agricultural businesses.

The economic importance of agriculture in this region is relatively new. Before the 20th century, the region's economy relied heavily on the river. In these earlier centuries, the river Vecht was a shipping route used to transport sandstone from Bentheim to the Zuyder Zee and beyond, to countries as the United States of America. However, in the 20th century, the river Vecht's main economic function and appearance changed, due to canalisation of the river. The river lost its characteristic meanders and gained multiple weirs to stop it from flowing too fast and, as a result, the river has become increasingly hidden in the landscape.

In addition to having become a hidden element within the landscape, the river Vecht also faces other challenges. For example, as recently as 1996 the Vecht Valley Region was confronted with high water levels and minor flooding. In 1997, responding to the flood, the regional water boards and Rijkswaterstaat[2] wrote a policy document on flood protection in the Vecht Valley region, which envisaged the river Vecht as a 'semi-natural' river. This semi-natural Vecht should freely meander through the landscape, with little riverbank protection, eroding the riverbed and creating its own path.

To achieve this goal, a number of projects were started in the Vecht Valley region, but ten years on little progress had been made. Therefore, the province of Overijssel took the lead and initiated a regional strategy called 'Ruimte voor de Vecht', in which developing a semi-natural river became the first goal. However, the province realised that the Vecht Valley region also faces other challenges that needed to be addressed and they therefore decided to combine these with the Vecht Valley regional strategy. These challenges include the ageing population and an economic decline in the region. Consequently, to tackle these issues, the second goal of the regional strategy is to give the region a socio-economic boost.

The third goal of the strategy is related to the natural environment of the Vecht Valley region. In 1992, European Union governments adopted legislation, called Natura 2000, designed to protect habitats and species across Europe. In line with the Natura 2000 legislation, the Dutch government drafted additional legislation, called the 'Ecologische Hoofdstructuur' (EHS)[3]. In accordance with the EHS legislation, the Vecht Valley region has to gain approximately 1100 hectares of new nature characteristic to the natural habitat of the region. Since the Vecht Valley region is mainly a wetland, new areas of nature should include vegetation such as marshes and grasslands.

As well as creating new nature, the EHS legislation also prescribes the creation of a so-called natural network in the Netherlands. Several natural areas and reserves in the

[2] The national institution responsible for water management
[3] NB Literally this term means 'Main ecological structure'

Netherlands are separated from each other, which causes problems for biodiversity. To increase the biodiversity in Dutch nature, it is necessary to create connections, known as *robuuste verbindingszones* (RVZs), between different natural areas and reserves. These connections are, for example, created by building ecological bridges over motorways so that animals can cross safely. Initially four RVZs came together in the Vecht Valley region, however, following recent political changes, these have been reduced to just one.

Although the regional strategy 'Ruimte voor de Vecht' has no formal responsibility concerning the implementation of EHS and Natura 2000 legislation, its stakeholders are committed to creating new nature in the Vecht Valley region. This commitment has partially caused the dilemma on which this paper focusses, namely that of nature versus agriculture in the Vecht Valley region, and will be discussed in more detail towards the end of this paper.

The three goals of 'Ruimte voor de Vecht' make it a very complex regional strategy. Furthermore, this strategy is based on the principles of good governance, which, among other things, promotes collaboration with non-governmental organizations and civilians. This collaboration has become a key element in drafting and implementing the 'Ruimte voor de Vecht' regional strategy. As a result, thirteen different governmental and non-governmental parties play a formal role in the process management, whom all consider the development of their region from different points of view, based on different values.

This method of planning, which combines different types of policy goals and is based on collaboration, is relatively new in the Netherlands. Although it is a new method, it seems to be successful and therefor interesting to evaluate.

2 A value-oriented research approach

This paper draws on research into the Vecht riverbed enlargement strategy and aims to evaluate this program by revealing the values on which stakeholders base their choices about the design, use and management of the area. This approach differs from a more traditional interest-oriented policy analysis that analyses the stakeholder's interest, assuming he/she behaves rationally and chooses a certain option because this option best fulfils his/her interests. While stakeholders tend to talk explicitly about their interests, they often keep values implicit in negotiations, although values do form a stakeholder's point of view. In this paper a value is defined as a wish, a goal or a motive that a person or organization aims to realize.

Although value-oriented policy analysis is new territory in spatial development research, it is a relevant approach to analysing regional strategies in which both governmental and non-governmental stakeholders cooperate. Since values, like interests, may determine the choice a person makes when facing different options (Haidt, 2007 , pp.103), it is likely that values will also play a role in a complex regional strategy in which

stakeholders have to choose between different options. However, the stakeholder's final choice may not necessarily be the one that is in his/her best interest, since choices based on values are not, by definition, rational. Therefore, if the underlying values are not made clear, choices based on values can be confusing. Such confusion can lead to a stalemate in a regional strategy, making it an unsuccessful planning instrument. As a result, it is important to take values into account when assessing a planning instrument.

Based on a value-oriented approach, this research uses discourse analysis to identify the values on which the stakeholders draw. Discourse analysis is a generic term for many different approaches. As described in (Buunk, 2010a, pp.46-47) and (Buunk, 2010b, pp.15), the approach used to analyse the regional strategy 'Ruimte voor de Vecht', focusses on storylines, value sets, and values. Based in part on Maarten Hajer's definition, a storyline can be defined as: "*(crisp) generative statements that bring together previously unrelated elements of reality. The main function of storylines is that these short narratives help people to fit their bit of knowledge, experience or expertise into the larger jigsaw of a policy debate.*" (104). In this study, the storylines were constructed using document analysis and interviews with stakeholders in the Vecht Valley region. From the storylines, values were extracted and categorized into a small number of value sets (Buunk, 2010b, pp.15-16).

3 The stories and values in the Vecht Valley region

In the process of the regional strategy 'Ruimte voor de Vecht' four storylines can be identified, namely:

- The semi-natural river
- Rediscovering the Vecht Valley identity
- The affluent river Vecht
- The connecting river Vecht

3.1 The semi-natural river

The semi-natural river is the most prominent and extensive storyline in the development of the Vecht Valley region. It focusses on the appearance of the river Vecht and its position within the Vecht Valley region. From the start of the development of the river Vecht in 1997 until now, the idea of a more natural-appearing river has been a guiding principle. All human interferences in the river's path have made it dull and hidden. By allowing the river to become more natural and by allowing the river more space in the landscape, it may be possible for the river Vecht to regain some of its former glory.

An important theme in this storyline concerns the technical problems due to climate change, and possible solutions. Climate change poses a problem for many rivers in the Netherlands, including the river Vecht, because it demands an increased runoff capacity

to prevent flooding. Furthermore, climate change increases the need for land for controlled flooding, which is particularly important for rainwater rivers like the river Vecht. Such rivers need more land for controlled flooding to be able drain off the distribution of water in the rainy season. To prevent flooding the Netherlands has directives on the runoff capacity a river has to meet and, in the case of the river Vecht, the runoff capacity must be increased. To many stakeholders, this is the key problem in the Vecht Valley regional strategy, and solving it, namely developing the most suitable river regime, is a vital task for them.

When stakeholders talk about the river Vecht as a semi-natural river, it becomes clear that this storyline is not only about the river's regime. The other themes in this storyline, namely flood safety and scenery, are concerned with the surrounding area of the river. To stakeholders, the scenery of the Vecht Valley region also plays a role in developing a semi-natural river, because this development not only requires adjustments to the river itself, but also to the natural environment of the riverbed. Throughout the process of developing the river Vecht, the province and its partners have consulted the University of Wageningen on the type of adjustments that can, and should, be made to the river and the surrounding riverbed. These studies have shown that, to create a successful semi-natural river, not only the

The theme of flood safety is closely related to the river's regime. Stakeholders believe flood protection of the surrounding riverbed can be improved by developing a semi-natural river with more meanders to increase the river's runoff capacity. On the other hand, a semi-natural river has more control over its own path, thereby decreasing human control over the river. Consequently, stakeholders, especially the water boards, believe that maintaining a controlled river regime is also important for flood protection. In short, when deciding on the development of the river Vecht, stakeholders have to consider different elements. They cannot simply decide on a number of technical adjustments that increase the river's meanders and runoff capacity, but they also have to consider the effect of these adjustments on the surroundings of the river. Furthermore, the stakeholders have different opinions about the extent to which the river's regime should be changed and which adjustments are most suitable to do so. Thus, while the first storyline may seem clear-cut on the surface, it is a storyline with many complexities and possible dilemmas.

3.1 Rediscovering the Vecht Valley identity

The second storyline 'rediscovering the Vecht Valley identity' also plays a vital role in the regional strategy. Stakeholders of the regional strategy consider the Vecht Valley to be a tightknit region, where inhabitants strongly identify with the region. However, the Vecht Valley region is a relatively new concept that came into existence at the end of the last century. In fact, just a small percentage of the inhabitants consider themselves as inhabitants of the region, rather than inhabitants of the town in which they live. However, the stakeholders of the regional strategy report that they wish to promote this

concept of the Vecht Valley region and that they aim to stimulate the inhabitants of the region to rediscover their collective regional identity.

The importance of the Vecht Valley identity is a new concept. Prior to the province becoming involved in 2007, rediscovering the region's identity was not an important issue. Before this time, the relevant water boards and Rijkswaterstaat were only concerned with the development of the river and the surrounding area, and had no interest in rediscovering or creating a collective identity for the region. In fact, stakeholders first discussed the need for a collective identity when the province took over in response to a suggestion by an independent research bureau. This agency advised the province that a collective Vecht Valley identity would contribute to accomplishing the multiple goals of the collaborative regional strategy. Furthermore, a collective identity might increase the connection inhabitants feel with their region, a feeling they can propagate, in turn increasing the popularity of the region in the rest of the Netherlands. The province and stakeholders acted on this advice and made it part of the regional strategy.

The collective Vecht Valley identity has become increasingly important in the regional strategy since drafting the master plan for the regional strategy 'Ruimte voor de Vecht'. It has become a regularly recurring subject in policy documents, minutes, and debates, but also in interviews conducted for this paper. When stakeholders talk about the Vecht Valley identity, it is clear they consider it to be an important issue in the Vecht Valley development, even though there is no exact definition of the Vecht Valley identity. For example, some stakeholders use words such as *peaceful* and *quiet* to describe the region's identity, while others think of the valley as a more *economic, agricultural region*. To discover the true Vecht Valley identity, the province initiated a cultural-historic study of the Vecht Valley region. This resulted in a book that describes and highlights the collective history of all the Vecht Valley inhabitants. Overall, the story of rediscovering the Vecht Valley identity seems to be a successful one, with recent studies showing that an increasing number of inhabitants of the Vecht Valley are aware of the concept and consider themselves to be inhabitants of the Vecht Valley.

3.2 The affluent river Vecht

The second storyline is called 'the affluent river Vecht' and is linked to the regional strategy's goal of boosting the Vecht Valley region's socio-economic situation. Although the river Vecht historically brought wealth to the Vecht Valley region, the main economic resources nowadays are tourism and agriculture, and both of these branches are currently declining. The tourism branch in the Vecht Valley region faces many challenges because of a lack of awareness of the region in the rest of the Netherlands and Germany. Another problem reported by stakeholders in the tourism branch is their inability to fully utilize the river´s business potential. Because of the many weirs in the river´s path, boating is not an attraction for visitors and tourists. However, for the most part the challenges in the tourism branch have been overcome

already. The tourism branch seems to be growing again in the Vecht Valley region, and apart from some issues on where boating should be allowed, the planning policy has succeeded.

The agricultural branch, on the other hand, faces tougher challenges and poses more difficulties for the regional development. Farmers in the region feel it is becoming increasingly difficult to compete in the national and global agricultural market and, consequently, many Vecht Valley farmers believe they have to expand their businesses to so-called factory farms to secure their future. These farms can, for example, house more than 120,000 laying hens and are highly debated in the Netherlands for ethical and environmental reasons. In contrast, the stakeholders involved in the 'Ruimte voor de Vecht' regional strategy believe that the future of agricultural businesses in the region does not lie in developing factory farms but in developing diversified farms. This type of farming is considered a wiser choice because animals are treated better, but also because it fits more closely with the third goal of the Vecht Valley regional strategy, namely to protect and develop nature in the Vecht Valley region.

The debate on farming defines the storyline. Most of the Vecht Valley farmers believe the government, especially the province of Overijssel, is interfering in their business management and making choices *for* them instead of *with* them. Therefore, the Vecht Valley farmers, represented by the Dutch farmer's organization LTO, had no interest in being part of the regional strategy for the first few years and did not join the regional strategy until 2009. After joining, the LTO drafted its own plan for the Vecht Valley development, together with the region's farmers. This plan was completed last year and will define/direct/guide their contribution to the regional strategy.

In the story of the affluent river Vecht, stakeholders and farmers do not always see eye to eye. The farmers believe the regional strategy may limit their choice on how they want to develop their agricultural business. The stakeholders in the regional strategy, on the other hand, believe there *is* no choice as diversified farming is the only stable future for farmers in the Vecht Valley region and is the only type of farming that fits with the vision of the regional strategy.

3.3 The connecting river Vecht

The final storyline is that of the connecting river Vecht, and revolves around collaboration. Collaboration is one of the distinguishing features of the regional strategy 'Ruimte voor de Vecht', and is not limited to collaboration with governmental organizations: non-governmental parties and even citizens are also stimulated to get involved. This need for extensive collaboration is what distinguishes 'Ruimte voor de Vecht' regional strategy from other regional strategies and spatial development plans, and makes 'Ruimte voor de Vecht' a complex collaborative planning process.

The number of collaborating stakeholders in the 'Ruimte voor de Vecht' regional strategy has increased since the start of the planning process. As with the 'rediscovering the Vecht Valley identity' storyline, the involvement of the province in the planning process changed the nature of the Vecht Valley development. In 1997, the development was aimed solely at the river and the riverbed, making it a plan in which relevant water boards were the only necessary partners. The involvement of the province not only broadened the goals of the development, but these policy goals also had a greater impact on the Vecht Valley region. For example, on the one hand, some of the goals implied a structural change in the appearance and the spatial function of the Vecht Valley region. On the other hand, developing a collective Vecht Valley identity meant that the inhabitants of the region also needed to change. Therefore, for the strategy to succeed, it was important to have a wide range of support, meaning the province and its initial partners needed to involve as many parties as possible. The number of collaborating stakeholders has now grown to thirteen, including a regional environmental group and the regional farmers interest group.

Initially the regional farmers interest group was reluctant to join the Vecht Valley regional strategy, because they were wary of the role they would play and the influence they would have on the decision-making. In the first meeting of the regional strategy they raised concerns about their lack of involvement in the early-stage fundamental decisions and thus decided to withdraw from the collaboration. Eventually the stakeholders already involved in the regional strategy successfully convinced the regional farmers interest group and the farmers joined the Vecht Valley regional strategy in 2010.

When interviewing the stakeholders of the regional strategy, it becomes clear that are not only bureaucratic reasons to invest time and effort into collaboration in the Vecht Valley development. What makes this storyline interesting is that stakeholders also find collaboration important on a non-bureaucratic level. They feel that the development of the Vecht Valley region should involve everyone in the region, so that the result is something everyone agrees on.

This feeling of collaboration is even symbolized in the use of a flower, namely a pink carnation, that can only be found in the Vecht Valley region. The story surrounding this carnation is that it cannot exist without collaboration between different elements in nature. As with the carnation, the Vecht Valley region can only flourish if everyone works together.

3.4 Values in the Vecht Valley region

After describing the storylines, the analysis of the collaborative regional planning strategy 'Ruimte voor de Vecht' continues with an account of the values identified in this process. Values are not normally the subject of research when evaluating the use of a planning method; instead, such research usually analyses interests. However, as argued

in this paper, values may play a vital role in the success of a planning method, especially one that relies heavily on collaboration, like the Vecht Valley regional strategy.

The values on which stakeholders draw in the Vecht Valley regional strategy can be divided into six different value sets, namely safety, nature, lively river, self-determination, landscape and cooperation. Within these value sets, sixteen distinct values have been identified. For example, a value in the landscape value set is 'self-consciousness', which means that stakeholders who draw on this value consider it important that inhabitants and communities in the Vecht Valley region become more conscious of their own regional identity. Another example is the value 'utilization' in the lively river value set, which has a more economic meaning. Stakeholders who draw on this value consider it important that the business potential of the river is utilized. The following table gives an overview of the value sets, the values and their meaning in the Vecht Valley regional strategy:

Table 1 Valuesets and values in the Vecht Valley regional strategy

Six sets of values	***Key values* and meaning in Vecht river management process**
Safety	*Prudence*. Adequate river regime is a necessity. *Guilt and penitence*. Climate change is man-made burden to which society needs to adapt.
	Fear of flooding limits possibilities of natural river regime *Sobriety* in the natural river regime is needed.
Nature	*Responsibility* for global biodiversity (in particular rare species and habitats).
	Love of local variety of nature and natural landscapes
Lively river	A lively river has high *aquatic diversity*
	The *beauty* of natural river dynamics needs to be visible in the landscape
	Harmony in natural beauty and recreational experience of the river
	Utilisation of business potential of the river
Self-determination	Economic *self-determination* for farmers who wish to seize investment opportunities with changes in allotment of their fields
	Justice in respecting property rights, not only decisive public interests in changing the river regime and surrounding grounds
Landscape	*Pride* in the singular scenery of Vecht valley region
	Self-consciousness of regional identity should grow with individual inhabitants and communities
	The agricultural, military, recreational and spiritual *history and traditions* of the Vecht valley region are worth rediscovering
Cooperation	Cooperation is *useful* for all

One conclusion that can be drawn from this overview is that there is a broad variety of values at stake in the Vecht Valley region. When making decisions about the

development of the region, stakeholders sometimes base their choices on different value sets, and thus different values. In other cases, stakeholders base their choices on different values from the same value set. This is especially the case when looking at the value set 'lively river', in which values like 'beauty of the natural river dynamics' and utilization of business potential' come together.

4 Dilemmas in the Vecht Valley region

The analysis of the storylines shows that, in a complex collaborative planning strategy like 'Ruimte voor de Vecht', stakeholders may draw on many different values when making choices. These values may complement each other, but they may also clash, leaving the planning process in an apparent stalemate. These clashes typically occur for dilemmas that are characteristic of the region and the regional strategy.

In terms of the 'Ruimte voor de Vecht' regional strategy, the storylines reveal a number of current dilemmas and possible future dilemmas. For example, one dilemma concerns the extent to which the river Vecht can, and should, become semi-natural. Although much has been written about the wish for a semi-natural river, it remains unclear what exactly a semi-natural river entails and how the river's path should be changed to achieve this semi-natural state. These questions form a dilemma because their answers require considering values concerning river safety, the natural environment and the economy. Another dilemma is that of boats on the river Vecht. One of the effects of a semi-natural river is that the depth of the river will decrease, leaving it less suitable for boating. Yet, in the Vecht Valley region, stakeholders from the recreational and tourism branch envisage the river Vecht as a river on which visitors and tourists can sail. In this dilemma, values concerning the natural environment and the economy have to be taken into consideration.

4.1 A dilemma of nature versus agriculture

This paper focusses on another dilemma in this strategy, which concerns a choice between the natural and agricultural function of the Vecht Valley region. Within the Vecht Valley region approximately 1100 hectares of new nature have to be developed to meet the criteria set by Dutch and European nature development legislation. Although the regional strategy 'Ruimte voor de Vecht' has no formal responsibility to meet these criteria, stakeholders have defined it as one of the three main goals, and thereby committed themselves to the Vecht Valley's natural environment. Furthermore, as was described in the storyline 'the semi-natural river', to create a semi-natural river it is also necessary to make certain adjustments to the riverbed. Among other things, these adjustments entail the cultivation of certain plants and vegetation that facilitate the river's runoff.

Due to the recent economic depression, the Dutch government was forced to implement a number of cutbacks in 2011, one of which concerned the EHS and Natura 2000

legislation. The Dutch central government decided to shift the implementation responsibility to the regional government level. In itself this was not a problem, because already the regional government was working on the implementation of both legislations, however the central government also decided that they no longer had the financial responsibility, meaning the regional governments also had to pay for all the adjustments required. Responding to these policy changes the province of Overijssel decided that they would no longer fully implement the EHS legislation, cutting back on the number of RVZ's and reconsidering the amount of grounds which would be used for the creation of new nature.

For the Vecht Valley regional strategy this contributed to an already existing tension between the natural and agricultural function of the Vecht Valley region. As described above, the Vecht Valley region is a mainly rural area, housing a high number of farms. Many of the farmers fear that the implementation of nature reservation legislation will limit their business possibilities in the region. One the one hand because grounds that could be used for agriculture are being used for nature reservation, and on the other hand the presence of nature reserves brings limitation to the magnitude of surrounding agricultural businesses. A larger farm will have more impact on its surrounding environment, so in order to protect the nature reserves, certain limits are set for surrounding agricultural businesses.

Furthermore, nature reservation is proving to be very expensive for regional governments, since they are not only responsible for creating new nature, but also for managing nature reserves. As a rule nature reserve management is outsourced to land managing organizations such as Staatsbosbeheer[4], who are considered to be experts on the field of nature reservation. However, land managing organizations rely on government funding, resulting in a costly management of nature reserves. In order to solve this budgetary problem, multiple provinces, including the province of Overijssel, have decided to explore the possibility of outsourcing nature reserve management to private parties such as farmers.

In the Vecht Valley regional strategy, creating nature and managing it is of importance for a number of reasons. First, in order to develop a semi-natural river, the surrounding riverbed needs to gain and maintain certain vegetation. Second, the extensive natural environment of the Vecht Valley region is a used as an attraction in the promotion of the region's tourist information offices and the region-wide tourism branch. When considering the value sets and values that are identified in this region, stakeholders that stress the importance of nature reserves and nature development draw from the value sets nature and lively river. In particular stakeholders seem to draw from the values *responsibility, love, beauty* and *harmony*.

[4] Staatsbosbeheer is a national organization commissioned a large part of the nature reserves in the Netherlands

The farmers, on the other hand, draw from another value set to substantiate their wishes for the region, namely the value set self-determination. The vision they have for the region has room for agricultural activities, and emphasizes the cultural landscape instead of the natural landscape. In this choice they draw from values like *self-determination* and *justice*, after all they consider the Vecht Valley region to be a rural area, *their* rural area.

5 Conclusion

This paper has given a short overview of an analysis into the Vecht Valley regional strategy, in order to consider if this new method of spatial planning should be avoided or adopted in the practice of spatial planning. The planning method has two interesting elements which are considered, namely the combining of different policy goals into a single spatial plan and the degree of collaboration with non-governmental parties and citizens. Furthermore, this paper presented a new method of analysing spatial planning projects, focussing on storylines and values, rather than on interests. Finally, to illustrate the importance of values in a planning process an example was given of how values play a role in causing and solving local planning dilemmas.

Combining different policy goals into a single spatial plan has occurred before in Dutch spatial planning practice, involving multiple non-governmental stakeholders and citizens in a planning process, however, is relatively new. The key advantage of combining multiple policy goals within the same region is that it increases the efficiency of the development in that region. Not only does this approach allow for cost reduction, it also slims down the bureaucratic process involved, since there is only one board of stakeholders involved. The downside of this approach to planning is that the project can become too large or even megalomaniac, which in turn destroys any efficiency.

An extensive collaborative process also has several advantages and disadvantages. First and foremost, the wish for collaboration is driven by a need for support from the society. Many spatial plans fail, because non-governmental organizations and citizens feel they have no influence on the choices governments make and consequently these organizations and citizens will try to prevent the a plan from being implemented. If non-governmental organizations and citizens are involved in a planning process, they have a better understanding of the decisions that are made. The second advantage is that involving non-governmental organizations and citizens gives them a feeling of responsibility in the planning process. Implementing the plan is no longer the government's job, it has become everyone's job.

The main advantage of this type of collaborative planning is also clear, namely that an increased number of stakeholders also means more opinions have to be taken into consideration. No longer can governments only take their own interests into consideration, they now have to negotiate with stakeholders that have different point of views on how a region should be developed.

The Vecht Valley regional strategy seems to be a good example of how a complex collaborative planning strategy can succeed. Since the initiating phase of the strategy, collaboration has increased, the strategy plan has almost fully been drafted and the implementation has already begun. Apart from that, the goal of boosting the region's economy has been met partly, now that the tourism branch in the Vecht Valley region is growing again. The combining of different policy goals in one strategy has not produced a megalomaniac plan.

In short, from the analysis of the Vecht Valley regional strategy can be concluded that a complex collaborative strategy, in which different policy goals are combined, is a planning method with many advantages. It is planning method which can increase the efficiency of spatial development, and thus should be adopted more often in the practice of spatial planning. However as this paper also showed, there are some dilemmas that the stakeholders of the Vecht Valley regional strategy need to solve, in order to fully succeed. These dilemmas revolve around basic choices, in which different values have to be taken into consideration. Spatial planning is not only a matter of considering different interests and technical data, it is also a matter of considering values. Policy makers need to take a full deliberation of values in consideration, in order to be able to continue the on-going collaborative planning process in the region.

The “bankruptcy” of the Greek Cities.
Neoliberalisation and the urban landscapes in the age of the crisis.

By: Andritsos Thanos, Iliopoulou Eirini, Patsopoulos Nikos, Poulios Dimitris, Triantafillopoulou Eleni, Tsadari Sofia

Introduction to the Sisyphean Myth

The Sisyphean myth is fittingly of Greek matter and essence. We will try to narrate the way that this mythological construction can be perfectly applied to our case study of Greek urban politics and agendas all the way from the early 90’s to the present time.

Issues such as corrupt local political and social behaviour, state inefficiency, low productivity but high wages and misuse of EU structural funds are among the causes that have been used repeatedly as explanations of the recent Greek debt crisis. Although there is good reasoning in these explanations, they tend to be either one-sided or very economistic in their assumptions (Hadjimichalis, 2011). Before focusing on the Greek case and in order to overcome shallow approaches we need to mention two parameters that are of major importance.

The first one is to underline the deep and systemic character of this crisis of over-accumulation and under-consumption. As Harvey assumes, it originated in the steps that were taken to resolve the crisis of stagflation and the political threat to capitalist class power in the 1970s in the core regions of capitalism - North America and Western Europe. These steps including among others the successful political assault upon organized labor and its political institutions, dismantling of capital controls over international movement, empowering money capital and bubbles in the asset market (Harvey, 2005; Harvey, 2010) formed neo-liberalism and dogmatic market fundamentalism that dominates until today in Eurozone and IMF policies. The second parameter is the relation between the particular way in which the international

crisis affected Greece and the socio-spatial structure of the European Union (Hadjimichalis, 2011). Considering the above as key factors, Greek deficiencies and particularities need to be taken under consideration in order to evaluate economic / urban policies and their incidence.

The debate around contemporary Greek cities has close links with the general process of economic integration with the European Community in the early 1990s and with the shift towards free market economies. The new urban trajectories were those of city competition, place marketing and urban boosterism. The support of an "entrepreneurial" vision and a way to compete in the European urban arena were monopolizing the discussion around urban problems (Swyngedouw et.al, 2002). More and more capital circulated – and still does - in the production of spectacular events with all sorts of consequences for consumerism as well as for urban life. But productions of this sort are invariably debt financed and, as the history of the Olympics clearly demonstrates, finding the money to pay off the debts afterward is often a problem. As we will explain furthermore it is no accident that Greece, which staged the Olympics in 2004, is now in a leading crisis role because of its sovereign debt (Harvey, 2011).

International Crisis and the Greek Epicentre

But let's start from the beginning. The primary epicentre of the national economic crisis was allocated in the United States. The crisis then quickly spread through the mortgage finance companies to the major financial institutions that still held an amount of what became "toxic" securitized mortgage debt. It then spread to other institutions that either held the debt, invested in the debt or insured the debt and other financial transactions. The parallel crash of Northern Rock in Britain indicated that there were problems in property markets elsewhere. The financial institutions located in New York and London then became the epicentre of the crisis. It largely fell to the U.S. and British governments, along with the U.S. Federal Reserve and the Bank of England, to stabilize the situation.

The crash of Lehman Brothers in September 2008 sent the contagion global. No matter where they were located, the holders of the toxic debt were in difficulty. But after the crash of Lehman Brothers, the whole global credit system froze, which formed the immediate primary blockage to the continuity of flows of capital. Perfectly good enterprises suddenly found themselves in difficulty because they could not roll over their debt. Many firms rescued themselves by laying off workers by the droves and intensifying wage repression. Debt-fueled consumerism and effective demand were halted, consumer confidence fell off a cliff, and unemployment surged although at radically different rates both within and between countries: compare, for example, Minnesota and Ohio in the United States or Spain (19 percent) and the Netherlands (4 percent) in Europe as of February 2010 (Saltmarsh, 2010).

The major export economies then took a hit as world trade contracted by one-third in early 2009 (Norris, 2009), sparking huge difficulties for businesses and emphatic surges in unemployment in East Asia as well as in Germany, Brazil, and elsewhere. What then followed depended crucially upon the imperatives, ability, and willingness of different governments to use their powers within the state-finance nexus to confront the crisis. Across the European Union Germany took the lead in turning the Eurozone to a monetary policy of deficit reduction through draconian reductions in public expenditures. The so-called PIGS (Portugal, Ireland, Greece, and Spain) found themselves in dire financial straights, in part through their own mismanagement but, even more significantly, because their economies were particularly vulnerable to the credit collapse and the sudden decline in property markets and tourism. Lacking the industrial base of countries like Germany, they could not respond adequately to the fiscal crisis that threatened them (Harvey, 2011).

Such issues are not new but they are structural in the way that the free market forces tried to reshape the Greek economy into a profit making machine. From the mid nineties, it had been made clear that the ultimate goal for the Greek capital forces would be to align the whole country to the new formation of the Eurozone. Obeying in the external and internal high pressure market commands led the primary sector of

production to be reshaped in order to fulfill not the need of the interior demand, but completely disconnect itself from the Greek market as a whole. In addition to that, since Greece never was an avid pole of secondary means of production, that left a one way street for the over growing of the tertiary sector. In reality if one traces down the extent of new antisocial rules that have been implemented in the past 11 years (after the admission of Greece in the EU), one would be surprised from the work achieved so far. The past two and a half years have only added speed to this process.

The introduction of the euro, along with other functions, was and is still being used as a mechanism through which global capitalist pressures are shifted to local labour markets in order to secure capital's profitability. European labour markets, however, owing to the weak geographical mobility of labour, remain a national / regional affair and are still regulated by national laws (Ioakimoglou, 2010).

When the unequally developed South East regions found themselves with the same hard currency in 2000, very few paid attention to their pre-existing highly unequal regional production systems and specializations, to their structurally different regional labour markets and to their unequal accessibility to markets (economically, institutionally and spatially) vis-à-vis the 'core' of the eurozone. And even fewer paid attention to differentiating the socio-spatial effects of putting an unevenly developed SE into a macroeconomic and fiscal framework designed purposely for north-central European economies.

The major problem in the very formation of the eurozone is the so-called 'national convergence criteria' (price stability, low interest rates, stable exchange rates and limits on the size of budget deficits and national debt) and the neglect of spatial or regional convergence. In the debate on the euro in the early 2000s and now on the debt crisis, very little attention was paid to geographical differences under the four important conditions for a successful monetary union. As Hadjimichalis (2011) underlines following Thirwall (2000), Magnifico (1973) and Martin (2000), (i) regional economic and social structures should have a degree of economic similarity – in the absence of such similarities, neoliberal restrictive monetary policies will

produce geographically uneven employment/unemployment; (ii) regional economic and social structures should have high rates of geographical mobility for capital and labour – if such mobility is weak, cyclical crisis may lead to persistent regional inequalities; (iii) regions should have similar propensities to inflation; and (iv) an automatic fiscal mechanism is required through a centrally organized tax/benefit system, that will compensate for different national and regional shock.

Nowadays the EU is being proved unable to handle the crisis owing to the above reasons and due to various dogmatic and inflexible neoliberal pacts that form its ideological and institutional mode of operation. The Lisbon Pact in particular prohibits any intervention to help national economies facing a crisis, such as that in Greece. When EU governments realized that the crisis was not restricted to Greece alone but could spread to the entire eurozone, a "solution" was found via a joint IMF/EU. The proposed package of cuts that would protect global investors placed a high burden on the working and middle classes. It included extensive privatization; percent increase in sales taxes; a 20–30 percent cut in salaries in the public sector; freezing and in some cases reducing pension payments; a 34 percent cut in public spending on education, health and public works; and, most importantly, major anti-labour institutional changes. These measures will complete a vicious economic circle of rising unemployment and inflation, shrinking tax revenues and profiteering market valuation of economic policies. They will sink the country from its current deep recession into an enduring depression with no obvious way out (Douzinas, 2010; Golemis, 2010; Krugman, 2010). In this context, the bail-outs for Greece in March 2010 can hardly be taken as a major solidarity step within the EU, or globally if the IMF is included.

The forced imposition by the EU/IMF - in collaboration with the Greek governments- of extreme neoliberal reforms in Greece was possible only because of the economic crisis. In Greece even until our days there are still strongholds of social control whoever small they might be. Demonstrations are still a major part of the civil life, unions and syndicates, however corrupt they might be, are still in existence. Since the majority of these orchestrations were established just after the military

junta, it has been proved really difficult for the provisional governments to take them away in a singular fashion.

Indeed, crises might be considered to be a primary engine of capitalist restructuring that internal and external elites and regional hegemonic blocs across Europe use, jockeying for better positions.

A very important factor in the success of the above politics was to maintain the constant practice of what we call “the carrot and the stick”. On the one hand to strengthen and reassure the Greek public that being part of the Union was not only necessary for their survival but also profitable for their life, using major projects directly connected to the media interpretation of civil life (like the Olympic Games, the new highways and other parts of infrastructure that was created just after joining the EU). On the other hand, when this policy was not deemed sustainable, the way of the “sword” had to be proven as the one with no alternates.
All these political dependencies drove us to what the free market forces want to call a crucial crossroad between the continuation of the policies that brought us here in the first place and what they let describe as the apocalyptic path that shouldn’t even be discussed (the exodus from the EU).

Neoliberal Policies and the Greek city

However, the question of how the recent austerity measures affect the urban development process needs to be answered. Despite the fact that the situation is ongoing and we may rush to conclusions, we support the view that there are major transformations towards ultra-neoliberal policies in every aspect regarding the urban landscape. There is a worsening of existing factors as well as the emergence of new phenomena that construct a “crisis setting” especially in the metropolitan areas.

Of course this phenomena was also a result of the particularities of the Greek urban development “heritage” of spontaneous urbanization, lack of planning and illegality

(Gospodini, 2002). The Structural deficiencies of strategic planning and significant transformations in development and function of the building sector are key factors in order to understand this genealogy (Mantouvalou, 2011).

The first Strategy Plan - for the city of Athens – that is still into force was written in 1985. In this plan's priorities *containment of Athens' expansion, re-orientation of the investments in order to be set outside Athens Metropolitan Area and population control* are included. In other words Athen's growth considered to be oversized. Thus, sweeping transformations during 1996-2006 were lead by Major Public Works -in the context of the Olympic Games and the inclusion of Greece in the EU- not placed among an integrated planning framework. Such choices, like repositioning of the city airport or defining the location of the Olympic developments, lead to urban sprawl, function diffusion and abandonment of whole areas. At the same time Inner City policy lead basic functions to be taken away. Relocating the Ministries outside the center was an emblematic example that dragged more movements. These factors made up favourable terms for crisis and its spatial imprints.

Supplementary, constructive sector changed during the 1990s. Construction is "traditionally" important sector for the Greek economy and the reproduction of social relations. Being grounded in small property and companies and having worked as a substitute of the welfare state for housing matters, its transformation brought the social relations at stake. Today the crisis in constructive sector is interwoven with employment and urban space crisis.

Despite these urban traditions we argue that the current crisis led to two changes:

Firstly it led to a radical reconciliation with the past of informal, illegal, spontaneous urbanization, which was now considered not a problem but a necessary characteristic of the future . The continuing expansion of illegal settlements in the fringes of Greek Cities was compared with the contemporary urban development of cities such as Boston or Atlanta (Aesopos, 2009). Notions like "overexposed city", "edge city", "generic city" were introduced to the vocabulary of architects and planners in order

to describe the new urban phenomenon. This was also combined with a promotion of the free market solutions in the design guidance and control system in Greece (Beriatos & Gospodini, 2009), both as a need for the economic elites but also as a side effect of the critique in the public funded projects. In short it was the promotion of New Urban Policies which would: (i) Revise the hierarchy of plans (regional, regulatory, city plan, architectural plan) in favor of more effective interventions (master-plans) which can be easily developed. (ii) Rethink and establish connections of network infrastructure and urban design in the cities. (iii) Promote the role of private initiative in the development process and the collaboration of public and private institutions (PPP-PFI). (iv) Form the new institutions that will implement these plans.

Secondly this theoretical debate was integrated in an "aggressive" neoliberal transformation of the planning system. In only two years the whole planning system was turned upside down, as we argue, in favor of private institutional forms and market speculation in particular:

- Changes in the Urban Governance system with the "Kallikrates" legislation (2010), which shifted many of the obligations of the State (planning, nurseries, schools etc.) to the Municipalities, but with no additional funding. The implementation of a 500millions austerity "package" to the local communities and peripheries. But most important the transition of a strategy of even peripheral development to a strategy of "competition" and economic antagonism.
- Changes in the Urban Development Policies with the establishment of the institution of "Fast-Track Projects". Projects that are basically private funded and can bypass state regulation (even environmental laws) in favor for economic sustainability. Also the formation of the Hellenic Republic Asset Development Fund (HRADF) in 2011 with the main goal the privatization of the Greek State's assets initiated a "sell-out" strategy of public spaces (like the former "Elliniko" airport, coastlines) but also major utilities services (energy, water, telecommunications, waste disposal).
- Changes in the Building Code (2012) in favor of "higher densities" and high rise buildings. In many areas especially in metropolitan districts the densities are

increased by 20-30% and also the legislation gives great power to the Minister enabling him to approve certain development projects, that are “in favor of economic development” but also cannot be approved by the existing system.

The “bankruptcy” of the Greek cities and communal resistance

These transformations in the planning system and strategies in combination with the austerity measures and the wider economic crisis have severe social impacts that are further noticeable in the central neighborhoods in the city of Athens, where one can clearly see the most tragic consequences of the Memoranda and the austerity policy: new poverty, high unemployment rates, rapid growth of homelessness as well as racial violence.

The city is the framework, where crisis appears in the most brutal and intense way: The rapidly increasing unemployment and poverty rates compose Athens’ new landscape, while the currently promoted urban policies intensify economic inequality, social exclusion and socio-spatial segregation. Quoting David Harvey ‘Violence is required to build the new urban world on the wreckage of the old and it is the poor, the underprivileged and those marginalized from political power that suffer first and foremost from the urban process of “creative destruction”’(Harvey, 2008). Social violence definitely marks the urban environment of a capital in bankruptcy, while on the same time forming new tendencies and political correlates within the social uprising and the emerging need for an overthrow.

However, as the urban process is based on the twin themes of accumulation and class struggle (Harvey, 1990), the city sharpens discriminations and contradictions, while on the other hand constitutes the arena where people's common needs, hopes and solutions can be perceived and organised. During the last four years, crucial political struggles and social movements developed in the city of Athens, starting with the revolt in December 2008, known as 'the first revolt of the crisis'. Less than two years after, the measures imposed by the IMF, EU and European Central Bank with the full

accord of the Greek government, have led to several general strikes, numerous regional strikes and other acts of resistance, which often paralyzed the country showing signs of rebellion against austerity. In the broader context according to the movement's timeline, the Arab spring, the indignados, the new social movements, the occupy movement underlined the possibility for a mass, global and local resistance against the current global economic catastrophe. Responding to the call for action within the <occupy movement>, the 'Syntagma Square movement' created new perspectives, especially when the labor movement got involved into the movement's progress. For more than two months the central square of Athens became a meeting point, where thousands of people gathered daily to discuss the next steps of the fight.

A year after the burst of the <occupy Syntagma Square> movement, one can observe what is left as a ‘legacy’: general assemblies and direct democratic procedures constitute a vital heritage for neighbourhood and grass-root movements were developed.

What is worth to bear in mind is that after December 2008 many urban movements arose, as people were more inspired to see and act beyond the closed horizons of the mainstream politics(Stavridis, 2009). Public places are being transformed, while many collective actions are invented. The collective reclaiming of urban space was connected with the demand for social justice reflecting in some cases an attempt to achieve a different social organisation, against the dominant ideology and the capital's laws. The new key-word is solidarity! As people in Greece keep on suffering from the brutal policies, the need for direct solutions and answers becomes more and more essential. The basic rights to housing, decent work, education and health are the emerging aspects of the “Right to the city”, while reclaiming urban space, public places and public buildings no longer in use remains an important precondition for solidarity social networks combined with anti-capitalist struggle.

Thus, the concept that enters the debate and affects both the spatial as well as the socio-political level is the 'demanding of urban life' transforming the city into a 'common place of demand'. The emerging action within the framework of urban

movements redefines urban space, while being a call for a radical restructuring of social, political, and economic relations, both in the city and beyond (Purcell, 2002) . Abandoning all former certainties regarding urban life, the rising 'right to the city' is like a cry and a demand (Lefebvre, 1996) that contests the dominance of state and capital in producing and reproducing, controlling and perceiving urban space.

According to the Lefebvrian thought, the 'right to the city' is interrelated with the right to participation and appropriation, while those aspects refer both to the radical transformation of urban space and social relations. The newborn social movements link the reclaiming of the city with the reclaiming of the socio-political scene. By occupying the central, crowded public square of Athens people not only demand their participation in decision-making processes regarding urban space but they also prioritise direct democracy and social justice fighting against the unbearable austerity measures and the corrupted undemocratic administration policies.

Urban space and its public places become contested places where dominance is a bet to win. Furthermore, urban space becomes a battlefield, where official public discourse, formal narratives together with police brutality and parastatal organisations construct 'moral panic' (Cohen, 1973) presenting urban movements as a threat for social order. On the other side, grass-root initiatives as well as platforms of the radical Left give voice to political subjectivities, who were in a large extend absent or silent during past periods of time and who elaborate on solutions to the on-going survival problems that the majority of the society faces. With the slogan “no one faces crisis alone” collective initiatives were set to motion focusing on: organising collective kitchen, ensuring that no house will be left without electricity due to the government's hikes, organising cultural events or offering free lessons to students in need.

Although the grass-roots movements and labor struggles are trying to reestablish the “right to the city” as Lefebvre reminds us “Capitalism has found itself able to attenuate (if not resolve) its internal contradictions for a century, and consequently in the hundred years since the writing of Capital, it has succeeded in achieving

‘growth’. We cannot calculate at what cost, but we do know the means: by occupying space, by producing a space.” (Lefebvre, 1976)

Who is going to prevail is something that the future will tell. However it is certain if we recall again our Sisyphean introduction that “the stone” is meant to come rolling down. Everyone is expecting it and certainly the neoliberal forces that implement those policies also depend on it.

Revitalization of a mid-sized city in Japan through public transit and land use policies: Case of Toyama

Noriko Kono[1]

Abstract

Beginning with the latter half of the 20th century, the excessive motorisation of cities has been one of the most controversial issues in urban planning. The impact of the automobile was far more wide-reaching compared to that of the earlier streetcar, which was more linear in movement and confined to discrete areas. The invention of the automobile allowed cities to spread in all different directions, and to sprawl into greenfields and undeveloped countryside. While it is true to say that motorisation raised the level of freedom and mobility for all, a high price has been paid in terms of both environment and minorities' lifestyles.

The City of Toyama, a mid-sized city in Japan, has succeeded to shift from a car dependent city into a transit-oriented, environment-friendly city. Presently the city, one of the 6 the Eco-Model Cities by the government, plays a leading role of the environmental conscious city planning. Innovative policies such as renewal of public transit into new model of Light Rail Transit (LRT), subsidy for development along public transit stations, and revitalization of CBD with introduction of new public transit/community rental cycle/construction of new facilities.

This study analyses the city's success in terms of modern urban planning paradigms such as Transit Oriented Development (TOD) and multi-core development. This paper first explains the outline of the City. Then it introduces policies of Toyama related to GHG emissions from the transport sector. Finally it calibrates environmental impact of the city's attempt by GHG emissions reduction and NOx reduction. For mid-sized cities, this case is one of the most successful examples of land use planning and development of public transit, which could avoid the degradation of CBD and environmental condition. In addition, the case potentially has a high relevance for developing countries.

1. Introduction

The capital of Toyama prefecture, Toyama city, has a population of about 420,000, making it a mid-sized city in Japan. The city is located on the coast of the Sea of Japan in the middle of Honshū island, about 200 km north of the city of Nagoya and 300 km northwest of Tokyo. The city was once prospered as the castle town by several feudal shoguns. The city's major industry is manufacturing using their ample water resources and medicine from the long tradition of medieval era.

For a few decades, the city has suffered from problematic aspects of the population structure that the cities remote from major megalopolis area of Japan could have. The population has been declining, and it is estimated that in 2045, 23% of population will be decreased compared to the 2010 level. Young population and labour population are to be decreased, while the old will increase up to 30 % of the total population in 2020.

Toyama prefecture also has its own problems which make the city to suffer from excessive sprawl. The prefecture is flatter than the other ones and has the 2nd most inhabitable areas among all prefectures. The prefecture's road preparation rate is the highest than the others. People in Toyama prefer to purchase their own houses (No.2 rate in housing owners in 2008) and one of the highest income per household in Japan (No.4 in net income in 2009). Also, the land prices in the suburb areas are much lower than in the city centre, so the prices of collective housing in the city centre are relatively expensive than single detached houses in the suburbs.

Presently the city has the lowest densities of all prefectural capitals (40.3 person/ha in 2011), second highest car ownership rate in Japan (1.72 cars/household in 2010). These has resulted in many administrative problems. First, citizens without cars were exposed to many inconveniences in mobility. Second, greenfield development in suburban areas and weakening of the Central Business District (CBD) reduced the attractiveness of the city as a whole. Third, sprawl due to motorisation increased the cost of infrastructure expansion and administrative services.

In the 2000s, the city tried to solve these issues through urban planning and transportation planning policies. The city’s attempts in these efforts are well-known among policymakers and researchers, but yet it does not have quantified their impact over global environmental challenges. This report reanalyses the city’s success in terms of modern urban planning paradigms such as Transit Oriented Development (TOD) and multi-core development and calibrates the actual effects in GHG emissions reduction.

2. Policies of Toyama

2.1 Tables and Figures

The city of Toyama has engaged in the following policies for urban renewal since the beginning of the 2000s:

1) Public transit promotion via introduction of LRT and subsidies for city buses;

2) Multi-core development with Transit-Oriented Development to accumulate residential and commercial businesses and cultural services in CBD area;

2.2 Public transit promotion by introducing LRT

This public transit planning was primarily intended for the short term. During mid-2000, when the city was involved with designing a new master plan, city officials realised that they needed to consider the declining population. One of the chief aims was to reconstruct the abandoned streetcar lines within the CBD and remodel poorly operated Japan Railway (JR) lines. These policies were soon realised in the late 2000s owing to the strong political will of the present City Mayor, Masashi Mori, who serves for the city since 2002.

The Toyama Lightrail, Portram is basically a renovation of the old JR Toyamako line originally opened in 1924. During and after WWII, this 8 km line ran from JR Toyama station to Toyama Port along the Tomiiwa Canal, a key transport route for cargo from the port. However, it had become ill-favoured due to its age, poorly-maintained cars, infrequent service, and lack of sufficient stops. In 2006, it was re-introduced as the nation's first modern Light Rail Transit System with fully air-conditioned, low-floor cars. It now serves 13 stations, four more stations than before, and cars run every 15 minutes from 5 am to 11 pm, an increase in the frequency and service hours of operation. These are the typical measures to increase ridership in fixed rail transit projects.

Table 1. Outline of the Toyama light rail (Portram)

Opening	2006.4.29
Length	7.6km
Stations	13 stations
Cars	7 cars
Duration	25 minutes

Figure 1 shows the stylish and futuristic cars of Toyama Portram. The system technique is imported from Germany Adtranz (ABB Daimler Benz Transportation, now merged to Bombardier Transportation) and it is the first fully

modern LRT system in Japan. The stations and cars are all equipped for handicapped people. Passengers need to purchase their own IC cards when boarding. The rail is earthquake proof and some tracks are planted with lawn. The LRT is full of new attempts that the present public transit systems can get.

Figure 1: Toyama Light Rail
Left - Modern, stylish design of the remodelled line, Middle - Lawn planted tracks, Right - Barrier-free floor, accessible for the aged and physically challenged. Note: Pictures taken by the author

Simultaneously, the city has tried the pilot study for transport on JR Takayama-Honsen. The study was held using a national subsidy for community planning (Machidukuri-kofukin) and attempted to work on transit oriented development in the areas of regional train, from 2006 to 2008, and, from 2008 to 2011, by increasing the frequency and making a new station to decrease the distance among stations. It also set "park and ride" policies and the city provided the free parking lots near these designated stations.

2.2 Multi-core development with TOD

Multi-core development with transit oriented development was to accumulate the residential commercial businesses and cultural services in CBD area. This policy is aimed to be achieved through theories on compact cities. Specifically, the theory employed was “dumplings-connected-by-skewers,” or connecting the cities (dumplings) with skewers (transport lines). Figure 2 shows a comparison of a conventional compact city and Toyama example to show the contrast in future development. Moreover, the compact city attempts also include the meaning of infill development in that it targeted to create a lively CBD area.

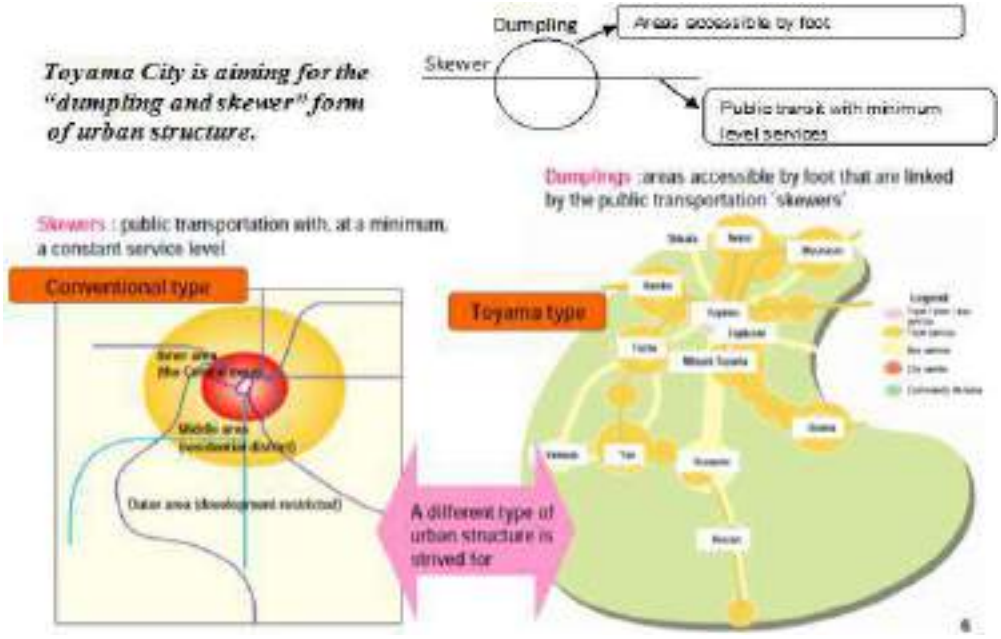

Figure 2: Toyama Multi-core Compact City Development Source: Made from Mori 2011.

3. Analysis

3.1 Changes made by the policies

The public transit renewal in Toyama has offered choice to its citizens in regard to mobility. The LRT conversion of the Toyamako-line has also shown an increase in ridership. It also tried the pilot study of the present JR lines, which represents a feasible option in terms of the total cost.

Table 1 illustrates the difference in number of users before and after the line remodelling. The city measured the ridership of LRT, both before and after the making of LRT line. Before the construction, the daily ridership of the LRT was about 2,200 in weekdays and 1,000 in holidays. After the LRT construction, each ridership became more than doubled and five times higher, around 5,000 for weekdays and 5,500 for holidays.

Table 2. LRT impact on ridership (Unit: persons)

	Before (2005 10)	After (2006 10)	Changes	Increase
Weekday daily average	2,226	4,988	224%	2,762
Holiday daily average	1,045	5,576	533%	4,531
Annual Weekdays (261 days)	580,986	1,301,868	--	720,882
Annual holidays (104 days)	108,680	579,904	--	471,224

Source: City of Toyama 2006

Figure 3 shows the LRT users previous modes measured from the questionnaire survey. Though half of the people are the former users of the same line before the renovation, the significant change can be seen that 11.5 % of people switch from driving their own cars.

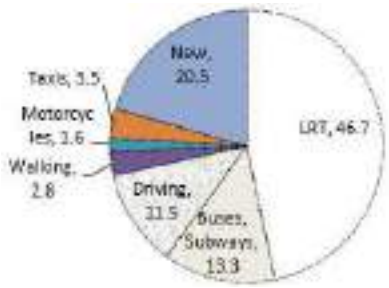

Figure 3. Modal shifts: Previous modes which transit users use (2006)

Note: Made from Mori 2011

Based on Figure 2, Table 3 calculates the estimated modal shifts of the riders in the year 2006. Though most of the users are former line users (556, 714 persons), 137,092 persons who drive, which are the most GHG emitting, switched to use LRT.

Table 3. Arrival of Toyama Portram and Mode Change of People (Unit: persons)

Switching from:	Percentage	Weekdays	Holidays	Total
Rail (former line)	46.7	336,652	220,062	556,714
Buses	13.3	95,877	62,673	158,550
Driving	11.5	82,901	54,191	137,092
Walking	2.8	20,185	13,194	33,379

Similarly, the city used a national subsidy for community planning (Machidukuri-kofukin) and attempted to work on transit oriented development in the areas of regional train in 2006 and 2008 by increasing the frequency by 42 % and making a new station to decrease the distance among stations. It also set "park and ride" policies in 5 stations, where the city provided the free parking lots near the designated stations.

Table 4. Outline of the Takayama Honsen (TH) line Pilot Project -City region

Opening	2008.3.15-2011.3.11
Length	36.6km (total 225.8 km)
Stations	10 stations
Cars	7 cars
Duration	51 minutes (Express: 36 minutes)

Source: City of Toyama 2006

Table 5 shows the change of the ridership in TH line before and after the pilot study. The increase of the ridership shows 113.5% increase, from 890,000 to 1,011,000. The increase is about 12 thousand.

Table 5. TH line impact on ridership (Unit: persons)

	Before LRT	After LRT	Changes	Increase
Daily average	2,440	2,770	113.5%	330
Annual average	890,475	1,011,000	113.5%	120,525

The city also experienced the changes of new housing development in the TOD area. The area where the transit stations exist had much higher new housing development during 2004-2009. Several studies show that neighborhoods in TOD clearly emit less GHGs from the transport sector (Winkelman 2000, Belzer and Autle 2002, Sotone et al 2007). Though the calculation for GHG emissions reductions needs more data, this certainly shows one aspects of the success of the land use policies in Toyama.

Table 7. New Housing Development in Toyama City

	2004	2009	Changes
TOD area	90	119	132%
Old City Area	2238	1455	65%

3.2 GHG Emissions Reduction

3.2.1 Toyama Portram

Previously the estimate of the people switched from cars to LRT was shown. Here the Person Trip Survey for the Toyama -Takaoka Regional Urban Area conducted in 1999 is used as the newest available person trip survey of this region. According to the survey, car users use cars average 22.4 minutes a day and average speed of car trips in this area (Hokuriku region) is calibrated as 33.5 km/h (2009). Using the calculation of MOE and MLIT, the emissions from a car per km are calibrated as 0.175kg-CO2/person-km. Also, GHG emissions from person who uses a fixed rail is calculated through GHG emissions per one car (0.574kg-CO2/car) divided by average number of passengers in one car. As there are 7 cars and 128 runs run in weekdays and 124 runs in holidays (Toyama Portram homepage 2012), weighted average passengers per car is:

Weighted average passengers per

$= 2{,}770 / (128 \times 5 + 124 \times 2)/7$ -- (1)

$= 5.80$ (person/ car)

Therefore GHG emissions per person who takes LRT is:

GHG emissions from people who take LRT

$= 0.574/ 5.80 = 0.0988$-CO2/person-km -- (2)

In this calibration, we estimate people do not share the ride and only pursue drive-alone. The calculation used the most recent population from notional census in 2005.

Annual CO_2 reduction by transport planning in Toyama city

= (0.175 -0.099) (kg-CO2/ km)×22.4/60 (hr) × 33.5 (km/hr) ×137,092(People) -- (3)

= 0.76 kg × 0.373 (hr) × 33.5 ×137,092

= 130,190.5 (kg-CO2/year)

= 130.2 (t-CO2/year)

According to Ministry of Environment, NOx emissions for a vehicle per km is 0.22 g/vehicle km. The LRT emits about 1/3 of the emissions and if its divided by the average number of passengers, it could be ignored as it is out of the range of significant figures.

Annual NOx reduction by transport planning in Toyama city

=(0.0022kg – 0) (kg-NOx/km) × 22.4 (hr)/ 60 × 33.5 km/hr ×137,092 --- (4)

= 3768.67 (kg-NOx/year)
= 3.77 (t- NOx /year)

3.2.2 Takayama Honsen

Previously the estimate of the people switched from cars to LRT was shown. The LRT is confined to the CBD area of Toyama, which occupies 43ha, about 0.3 % of the city. The study expands its scope to regional train. Car users use cars average 26.4 minutes a day and average speed of car trips in this area (Hokuriku region) is calibrated as 33.5 km/h (2009). Using the calculation of MOE and MLIT, the emissions from a car per km are calibrated as 0.175kg-CO2/person-km. Also, GHG emissions from person who uses a fixed rail is calculated through GHG emissions per one car (and the approximate number of people in one car (0.574kg-CO2/car). As there are 4 cars and 106 runs in weekdays and 49 runs in holidays (Toyama Portram homepage 2012). Weighted average passengers per car is:

Weighted average passengers per car

= (4988 × 5 + 5576 × 2) / (106× 5 × 4 + 49 × 2 × 4) --- (5)

= 21.83 (person/ car)

Therefore, GHG emissions from the people who take TH line is:

GHG emissions from the people who take TH line

= 0.574/ 21.83

= 0.026-CO2/person-km

In this calibration, we estimate people do not share the ride and only pursue drive-alone. The calculation used the most recent population from notional census in 2005.

Annual CO_2 reduction by LTR modal shift in Toyama city

= (0.175 -0.026) kg-CO2/ km× 22.4/60 (hr) × 33.5 (km/hr) ×116,271(People) -- (5)

= 0.149 kg × 0.373 (hr) × 33.5 ×116,271 (People)

= 216,476.78 (kg-CO2/year)

= 216.48 (t-CO2/year)

According to Ministry of Environment, NOx emissions for a vehicle per km is 0.22 g/vehicle km. The LRT emits about 1/3 of the emissions. 3×10^{-6} and this could be ignored as it is out of the range of significant figures.

Annual NOx reduction by transport planning in Toyama city
