Regional impacts vary and depend on the specificities of each country, the institutional and policy framework as well as the fiscal context (Davies, 2011, 1). As far as the individual EU regions are concerned, the situation differs from country to country in proportion to the extent that each country's overall system is exposed to the impact of the crisis. Even before the outbreak of the crisis, four key challenges were identified for European regions, namely globalization, demography, climate change, and energy, which determine the vulnerability of each region (CEC 2008). In the context of the preparation of the next programming period of cohesion policy, regional vulnerability to climate change has been given a key role, which is in accordance with the 'Europe 2020' strategy. This is expected to reinforce a shift towards resilience based regional development strategies in the Operational Programmes of the period 2014-2020 (Hjerp et al 2011).

The growing interest in climate change related measures in the context of cohesion policy and consequently on their territorial dimension has accentuated the role of regional spatial planning, which, however, is not in the competence of the EU. The reason is that regional spatial planning is closely related with territorial specificities of individual regions and henceforth to climate vulnerability of regions. The Directive on Strategic Environmental Assessment (SEA) (Official Journal 2001) was the first to influence regional spatial planning towards combating climate change, albeit with no direct reference to the latter.

4. Evidence from Greece

Evidence from spatial policies in Greece can serve to explore the potential of a resilient-based approach to spatial planning especially in metropolitan areas which are the most vulnerable to contemporary challenges. It is worth noting that both regional development policy and regional spatial planning in Greece are influenced by the EU policy and funding context, albeit to different degrees. Regional development policy has a relatively rigid character as it closely follows EU guidelines. Regional spatial planning, which is not in the competence of the EU, is influenced by developments in Europe and is likely to adopt up-to-date planning tools. When it comes to strategic planning for metropolitan areas this is the case with the 'Regulatory Plans' of the greater areas of Athens and Thessaloniki ('Rythmistiko Schedio' that is city-region plan) (EC 1997). As noted above, planning for resilience is of strategic character and is also closely related to the participatory process. Hence the potential of these two Plans towards a resilience-based approach can be roughly examined in terms of these two parameters. Evidence can also be drawn from the

way the issue of vulnerability is addressed in the relevant documents, which will be based on the case of Thessaloniki.

First, the strategic role of the two 'Regulatory Plans' had not been identified as such since their launch in 1985, as there was undoubtedly a desire for a regulatory role of spatial planning at that initial stage. Nevertheless, these Plans were the only then-existing strategic spatial planning instruments in the country (EC 1997). A renewed interest in strategic spatial planning emerged in the late 1990s that was associated with a similar tendency in Europe. From 2003 onwards the urgent necessity for an up-to-date strategic planning tool for the metropolitan areas found expression through the process of updating the two 'Regulatory Plans'. The relevant studies have been completed and put under public consultation and are expected to be given legal form. The strategic role of the new 'Regulatory Plans' of Athens and Thessaloniki is explicitly spelled out in the relevant texts and confirmed by their content, which includes a preliminary projection of strategic goals. Their strategic role is also evident in that they introduce new ideas and also in that they link process with outcome. More particularly, of the ideas they introduce the adoption of sustainable spatial development can be considered innovatory. As regards the linkage between process and outcome, this is evident in that the draft new Plans provide for an action plan.

Second, regarding the involvement in these two Plans of forms of participation that are considered a prerequisite of resilience-oriented planning, the importance of such an approach is acknowledged at several points in both planning documents. The draft new 'Regulatory Plan' of Athens cites "improvement of the system of spatial planning and governance" as its "number one priority axis", mentioning it along with ten selected thematic axes. In practice the elaboration of the Plans has proceeded in a rather formalistic manner with participation based mainly on public consultation and public debate with socio-economic partners and local and regional self-government. This has to do with the organization of the planning system in the country and especially its centralized character. In this respect it should be mentioned that a new balance between the newly-established institutions of local and regional self-government and the pre-existing central state mechanisms is currently under formation in the context of the 'Kallikratis' administrative reform.

Although not expressed as such, the notion of vulnerability of metropolitan areas in Greece is partly evident in strategic spatial planning, particularly with reference to: (a) civil protection and (b) environmental protection. The first one is addressed by a specific nationwide institutional framework which makes provision for competences of local and regional self-government and of metropolitan administrative structures (Dandoulaki 2011). The second one, namely environmental protection of the greater areas of Athens and Thessaloniki respectively, is evident primarily in that the official Plans which were ratified by Laws 1561 and 1515 of the year 1985 respectively have the title 'Regulatory Plan and the Environmental Protection Programme of the Greater Athens [Thessaloniki] Area'. Recently, the need to comply with the EU directive on SEA accentuated the environmental dimension of the draft new Plans.

Besides, according to the EU priorities, specific provision is made in these Plans for climate change-related measures, especially for mitigation purposes. The draft new 'Regulatory Plan' of Thessaloniki among others aims to "Contribute to climate change combating through reducing energy consumption … and preparing to address its impacts". It specifically provides for "Dealing with natural and technological hazards and disasters" by means of: (a) cooperation among agencies which have the responsibility of planning for civil protection and civil security, (b) planning and management of specialized studies and actions concerning civil protection and civil security and (c) utilizing environmental and spatial planning tools to promote additional mitigation and adaptation measures. Specific provision is made for measures aiming to prevent earthquakes, floods, industrial accidents and fires. In addition, in the 'Environmental Protection Programme', which is incorporated in the draft Plan, there is an entire subject area dedicated to climate change mitigation and adaptation measures with special reference to the relevant 'National Action Plan' (OR.TH. n.d.). However, despite the fact that the Plan's contribution to "sustainable and environmentally compatible development and reconstruction of the economy of the area" is identified as one of its key objectives, no reference is made to vulnerability pertaining to hazards of a socio-economic nature (OR.TH. n.d., Thoidou 2012).

It is evident from the above that the resilience-oriented approach to strategic planning of metropolitan areas in Greece focuses on the protection of the environment and the combat of climate change-related phenomena. This is more important if we consider that from 2008 onwards Greece has been under pressure from the economic crisis it is passing through, and the overall situation in the country's metropolitan areas has seriously changed. There has evidently been a contraction of the public sector's role in promoting metropolitan development through large-scale infrastructure projects. In addition, the competitive city/region strategy that prevailed in the 2000s should now be reconsidered, since it can be argued that "undermines any attempt at welfare planning" (Hadjimichalis 2011, 267-268). These proceed in tandem with the deepening of socio-spatial inequalities and tensions within metropolitan areas – Athens in particular – which in turn necessitates new ways of dealing with problems. Hence it seems reasonable that the whole endeavor of updating the Plans should take into account the new socio-spatial circumstances under the crisis conditions in Greek metropolitan areas.

5. Concluding remarks

As is the case with several concepts in the planning domain, regional resilience draws from an ecosystem approach and thus involves the risk of underestimating socio-economic parameters and complex processes that might cause regional vulnerability. However, its incorporation in the policy agendas of supranational organizations such as the UN and the EU and its further elaboration should not be ignored nor its expansion to regional and local levels, especially in the context of spatial planning. Planning for resilience is gradually being necessitated under current crisis conditions and gains ground as a tool capable of preventing areas from hazards

of various types. Furthermore, strategic spatial planning is considered to be a key parameter towards resilience building, through strengthening the institutional capacity of territorial systems in the sense of their ability to cope with contemporary challenges.

As in the scientific domain the issue of spatial planning in the crisis era seems to gain ground, it is worth considering whether it can be specified in practical terms through its incorporation in the planning documents and processes. The case of metropolitan areas in Greece reveals that the potential for such an approach depends on the characteristics of the plans and the related planning process. Arguably, under specific conditions, the strategic approach to spatial planning has the potential to secure both an adaptable structure of the plans and a genuinely participatory planning procedure that is suitable to serve as a tool of planning for regional/metropolitan resilience. Furthermore, the supranational context can be utilized as a reference basis for policy measures, planning tools and good practices which should be selectively adjusted to each particular territorial area. The sustainable development concept could serve so as to justify an approach to not only environmental but also socio-economic resilience. Above all, the effort towards building territorial resilience can highlight new ways of dealing with problems, new ways of utilizing policy instruments and more generally a rethinking of what has hitherto been taken for granted.

Age-based Neighbourhood Development – Challenges for Sustainable Cities

Heidi Sinning[1]

Abstract
In recent years modified demands on housing and community development have emerged because of different reasons. Especially aging and diversification of society due to the demographic change have become important issues for urban planning. The people in Germany who are 65 years and older are expected to increase from 20% in 2008 to 33% in 2050. Especially the very old people (80plus) will increase strongly. Similar situations exist in several European countries.

Elderly people are not a consistent group, but the group of seniors has very different lifestyles and demands. In order to be competitive in an aging market building companies as well as all other kinds of businesses and communities will have to adapt and react to changing demands. How can the aged population be systematized and classified? Which are the main specificities of the different groups?

In the context of the research project „WASta - Housing of Elderly People in the Context of Urban Development" results of surveys in the German cities of Leipzig and Gera and theoretical investigations have been used to find answers. One result is that the state of health and the financial situation of elderly people are basic factors for differentiation.

Based on these results, on preceding findings and a systematization of the aged population, requirements for housing companies as well as for communities are derived how sustainable cities can focus on the very specific demands of elderly people. A key answer is an integrated perspective on neighbourhood development. An age-based neighbourhood development needs to be oriented on the people's needs. It involves the planning and equipment of the dwellings, the buildings (incl. entrances, halls, stairs, corridors etc.), the environment of buildings (e.g. greens, gardens, footpaths, benches), open spaces, parks, social and technical infrastructures in a neighbourhood.

An assessment framework „Age-based neighbourhood development" has been worked out, which shall help to evaluate the current quality of a neighbourhood and to prioritize actions from the perspective of housing companies, urban development and elderly people. Examples illustrate the assessment framework and show how age-based neighbourhood development can be implemented.

Age-based neighbouhood development, demographical change, housing, community development

1. Introduction – current trends and challenges

Demographic and social changes result in modified demands on housing economy. With their rising share in the overall population elderly people become increasingly important enquirers on the rental market. In shrinking or stagnating city regions the rental market that used to focus on supply has been replaced by a demand market. Housing companies have to avoid enduring long-term vacancies of a bigger extent and respond to the needs of the elderly as an increasingly important target group in order to operate economically sustainable. Challenges for housing companies do not only exist in the overall increasing share of elderly people as enquirers but in their modified and diverse demands for their dwelling, its surrounding area and accompanying services. Housing in this sense refers to the flat, the building, the surrounding area, infrastructure, services and social networks.

However elderly people do not form a homogeneous target group. Therefore this article outlines the proceeding diversification of this group. In this context main questions are: What kind of approaches of systematization exist? Which aspects are especially interesting for the differentiation of elderly people? Which requirements have different groups of elderly people and which qualities do they expect? And last but not least, which strategic approaches for age-based development are of interest for cities and communities?

Looking at the significant trends the following aspects can be highlighted (see also illustrations 1-3; Statistisches Bundesamt 2009 und 2011):

- Increase of the elderly: The part of people in Germany being 65 years and older will increase from 20% in 2008 to 33% in 2050.
- Greatly increasing share of the generation 65plus and the oldest old (being over 80 or even over 85 years old): The share of people being over 65 years old will rise from 21% (2009) to 34% (2060). The share to the oldest old (85plus) will increase from 2% (2009) to 9% (2060) of the overall population in Germany.
- Parallel to a higher life expectancy more and more people experience a longer healthy life time. Health of elderly people is very differently pronounced. Studies have shown that a difficult health status and financial situation (increasing poverty among the elderly) lead to less outdoor activity and to a reduction of social networks.
- Especially elderly women often live alone. Between the age of 60 and 85 the share of women living alone rises significantly according to statistical data of 2009.
- The importance of social networks beyond family bonds increases whereas the significance of the classical family bonds decreases.
- Last but not least, elderly predominantly wish to live at their home place as long as possible.

Scientific Background

In the context of the research project „WASta – Housing of Elderly People in the Context of Urban Development“ trends and challenges outlined above were reassessed. The project has been funded by the German Federal Ministry of Education and Research (BMBF) and aims to describe the diversification of the target group generation 50plus, develop a classification to distinguish different demander groups among the elderly, and identify their specific housing needs. The project focuses on specifying the group 50plus with their differentiated housing aspirations and needs as a target group for housing companies. Furthermore recommendations are to be developed within the project to enable the application of the new aspects of classification and to meet concrete requirements on the implementation of an age-based neighbourhood (Gädker, Sinning, Thalheim 2012).

2. Systemizing the group of elderly people

For housing economy and urban development to adequately react to differentiated housing needs and demands of the target group of elderly people a small scale view and detailed knowledge of the target group are prerequisites. Against the background of theoretical approaches regarding aging, e.g. disengagement- and activities-theories, there are different approaches to systemize elderly people. Existing classification approaches are:

- chronologic age/calendrical age (e.g. „young old“ 50 to 65 years of age, seniors 65 to 80 years of age and „oldest old“ above 80 years of age);
- cohorts (by life experience, e.g. world economic crisis/ post-war period /economic miracle in Western Germany; see inter alia Kreuzer 2006);
- phases of life model (different approaches with two to eight phases; see inter alia Höpflinger 2008):
- life style approach (opinions, values, social position, educational status, financial means etc.; see inter alia. Schneider, Spellerberg 1999);
- Sinus-Milieus® approach (milieus are e.g. hedonists, performer, tradionals, konservatives; aspects of differenciation are spatial, cultural and social condition etc.; see inter alia.Sinus 2010);
- Social milieus (Federal association for Housing and Urban Development (vhw) together with Sinus-Sociovision): three types of elderly people, based on a “body & mind typology”: Best Ager, Old Ager und Old Kids (see amongst others Podding 2006, Borgstedt 2010).

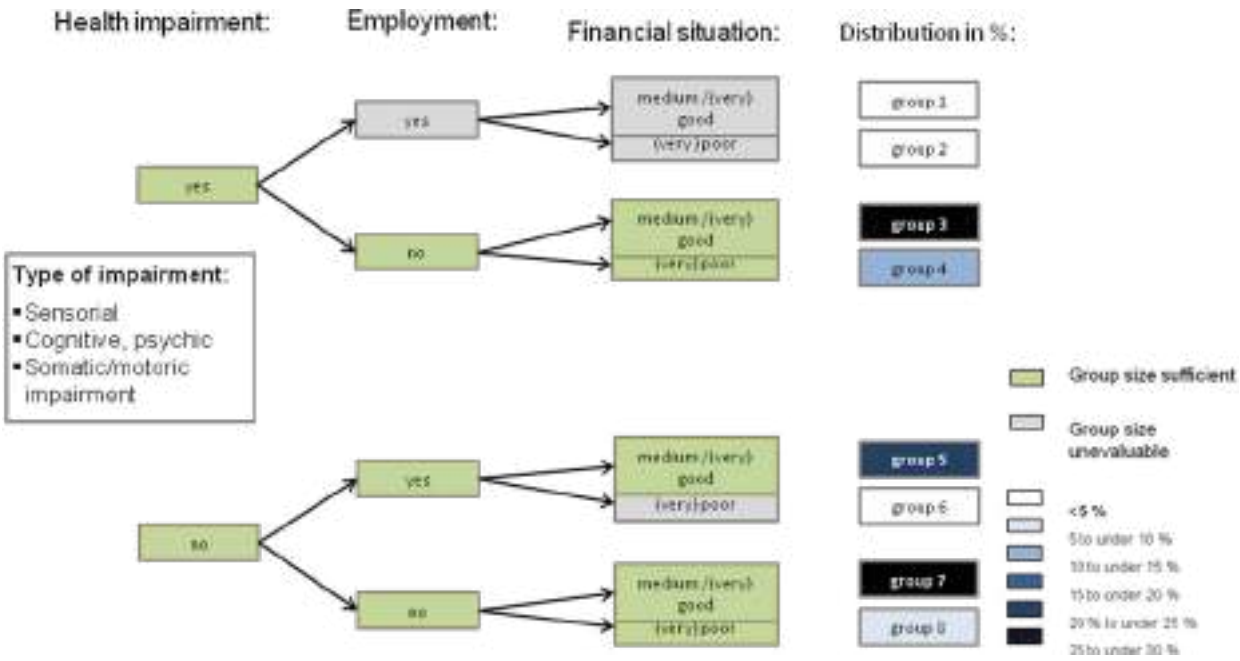
These approaches however rarely relate to housing. Due to insufficient data previous approaches are not easily applicable in the practice of housing economy or they are too general to allow specific conclusions regarding housing. Therefore, within the research project “WASta – Housing of elderly people in the context of urban development” the aim has been to work on an applicable classification of people being over 50 years of age.

For this classification of the elderly the heath status and the financial situation were taken as leading criteria next to recreational activities (life styles). So far these criteria have hardly ever been taken into account by housing economy and urban development. The classification approach is based on empirical findings from a written household survey of 3000 residents in the cities of Leipzig and Gera as well as from an expert workshop and literature research. In

the survey individual health impairments, e.g. in the fields of hearing, watching, walking, could not be included. But for deeper analysis it would be necessary to further differenciate.

As illustration 4 shows the groups 3 (group with health impairments, not employed, average to very good financial situation, about 25-30%), 5 (group without health impairments, employed, average to very good financial situation, about 15-20%) and 7 (group without health impairments, not employed, average to very good financial situation, about 25-30%) of elderly people in the cities of Leipzig and Gera are dominant. This means that in particular for group 3 there is a need for meeting their requirements on the housing market. Group 4 (group with health impairments, not employed, bad to very bad financial situation) is expected to increase in the future ("elderly poverty").

Illustration 4: Classification approach of elderly people by health status and financial situation (source: own scheme)



3. Requirements for neighbourhood development and housing economy

Against the background of the systematization approaches and health status and financial situation as main criteria of differentiation housing companies and urban development are challenged to develop and modify neighbourhoods and the housing stock according to the needs of their residents and in adequate quantity and quality. In this context the following challenges are important:

- Elderly people do not form a homogeneous but a more and more heterogeneous group. Accordingly a greater diversification becomes necessary oriented above all to health status, financial situation and recreational behaviour respectively life styles as distinguishing features.
- An age-based city and neighbourhood development, pursuing the goal of supporting the residents to as long as possible live their lives self-reliantly and self-determinedly, requires an integrated and neighbourhood-oriented approach of housing and urban development. Of particular importance is integration of housing stock, its surrounding area and neighbour-

hood infrastructure. Furthermore social networks and neighbourhoods ought to be taken into account.
- As the area surrounding the dwelling gains in importance with an increasing age a neighbourhood perspective is essential planning and developing concrete improvements to the quality of life.
- Quality of housing is a major „hard“ locational factor for cities and municipalities. For their residents the quality of housing has an important impact on their quality of life. Especially due to the great increase of the elderly and the share of old aged modifications to the quality of housing are promising activities for cities and municipalities to improve their position in a target group oriented competition for residents.

Assessment framework „Age-based Neighbourhood Development“

The differenciation of elderly people helps to understand their specific needs. A possibility to enhance the quality of life of elderly people is to measure this quality in detail. Therefore, an assessment on “Age-based Neighbourhood Development” has been developed aiming at the needs of local residents and at screening the quality of flats and buildings, the surrounding area, services and infrastructures in the neighbourhood.

The criteria “requirement-based/age-based” aim to improve the quality of life of different target groups. Age-based neighbourhood development includes constructional, social, financial and nursing aspects. Requirement-based expresses that adaptations to the neighbourhood are to be oriented on the actual requirements of different residential groups. This includes flexibility for adaptations to the dwellings for example or that services are oriented to actual requirements (pick-up and delivery services, care services etc.). The model of neighbourhood development is based on an understanding of the different needs of generations in a cross-generational neighbourhood. (cf. Kreuzer 2006: 156).

The assessment framework focuses on the demands of elderly people. Most items being of advantage to elderly people (no doorsteps, platforms etc.) are also of advantage to other population groups such as parents with prams, bicyclists etc.

The assessment supports screening the following aspects regarding their current condition and their contribution to the neighbourhood development:

- building / flat
  - entrance situation
  - front door
  - stairway / corridor
  - lift
  - door of flat
  - bell
  - floors
  - furniture
  - management utilities etc.
- area surrounding the flat
  - entrance area
  - parking sites
  - footpaths

  - street and traffic area
  - public transport
  - open space
  - infrastructure and services
  - recreational activities
  - supporting neighbourhood relationships
- planning and implementation process
  - participation
  - co-operation
  - communication
  - structural neighbourhood development

As the assessment of a neighbourhood is always subjective it ought to be applied by persons of different personal backgrounds. (e. g. stakeholders of housing economy, urban development, senior representatives, residents’ representatives with different health status). To apply the assessment it is recommended to develop a common interpretation of the assessment results as gathered by different persons. Besides others the following aspects ought to be assessed:

- Which aspects have not been put into practice / were regarded to have a negative impact?
- Which areas call for action?
- Which items of the assessment are assessed differently by different stakeholders?

From the results of the assessment of the current condition the need for action can be deduced regarding as well the community and the local development as well as the housing companies and their housing stock.

4. Conclusion

As the contribution shows it is of great importance to pursue an integrated strategy to meet the current adaptation requirements in urban planning and development in the course of an ageing population and a more significant generation of elderly people. Especially on the level of neighbourhood development stakeholders can contribute to the implementation of measures to meet the current and future requirements of age-based planning and equipment.

The challenge is not about developing "ghettos of elderly people" but to design mixed neighbourhoods for young and old inhabitants. All generations benefit from an age- and requirement-based equipment although the orientation towards health impairment and an increasing demand for local supply of social, transport, recreational infrastructure and services particularly corresponds in particular to the needs of elderly people.

There are specific demands and target group specific requirements of elderly people on housing and its surrounding area. To integrate health status and financial situation as distinguishing features in the classification of the elderly first of all necessitates the investigation of adequate data, e.g. in a local household survey. The availability of those data enables cities and housing companies to address specific housing requirements.

In order to design age- and requirement-based neighbourhoods, stakeholder groups, such as housing economy, city development, residents, representatives of residents like senior committees, will have to enter into a dialogue, commonly assess strengths and weaknesses of the neighbourhood development and deduce measures and priorities. Furthermore, age-based neighbourhood development requires interdisciplinary co-operation including different stakeholder and departments.

The assessment framework "Age-based Neighbourhood Development" has the potential to support this process. Existing assessments on age-based planning and design are often aligned only to singular topics, for example the flat or footpaths. The assessment framework which is described here is based on an integrated approach including all topics of importance for the quality of life of elderly people. Only a holistic view and co-action of several measures as well as the collaboration of different stakeholders in a neighbourhood can achieve a sustainable improvement of elderly residents' quality of life.

Finally it seems necessary to underline that a specific challenge for future urban development that ought to be taken into account at the implementation of an age-based neighbourhood development is poverty among the elderly and the related question how affordable housing and quality of life respectively housing can be maintained or newly achieved for low income households. This topic as well as the earlier explanations of this contribution show that age-based neighbourhood development will become an increasingly important challenge for the development of sustainable cities and especially for urban planning in the coming decades.

Landscape and urbanisation processes in Ave's Valley Region (Portugal): Inner-orders as expression of territorial resilience and new instruments of planning

Sara Sucena-Garcia[1]

Abstract:

The paper addresses the urbanisation processes in Ave's Valley Region, in the North of Portugal, over the last 60 years as a way to explain the look of a landscape that is hard to visually grasp or coherently describe. As in so many contemporary urban areas that withstood considerable expansion of its urbanisation over the last decades of the 20th century, especially the ones that grew in-between the traditional cities, the outcome is an almost chaotic (dis)organisation, visually marked by the difficult legibility of the logic between buildings and activities settlements, built and non-built spaces, scales of the built objects that stand side by side or the way they (do not) meet.

Traditionally, Ave is a region that is identified with the dispersed urbanisation within the countryside, but from the 1850s industrial era, the distinction between the countryside and the cities started to blur into a globally urbanised territory. Grounded in the rural parcelling system and served by pathways, and more recently also by roads, the diffused location of housing and industry within the territory derives from closely articulated economic processes and socio-cultural features. The textile industry is the head sector of this "industrial district" and the study of its evolution through time when adequately crossed with the urbanisation models is one of the prime instruments to understand the place we focus on.

The framework of analysis follows a dual-approach: the image of the landscape is analysed through its morphological components, as the comprehension of physical form constitutes the main trigger for this paper, but at the same time by a socio-economic perspective that reveals the importance of the facts that really provide an explanation for what we see. The mixing of housing, industry and agriculture inside the same private lot; the multi-activity setting of the inhabitants, or the empiric vs. academic knowledge of the industrial working force are some of the particular aspects that gave form to a very special landscape and that a focus based solely on the aspects of physical form fails to apprehend.

The sum up of the different urbanisation models – as expression of an identity deeply rooted in space – configures a palimpsest that is mainly the outcome of spontaneous processes. More recently, though, this has had to come to terms with an effective planning practice as well as with new economic inputs on territorial organisation. Global vs. local is the jargon that since the late eighties started to establish other «orders» in the territory and its effects added to the visual confusion and lack of legibility. Dealing with it, as we seek for «new» instruments of planning, meant

[1] Universidade Fernando Pessoa, Porto, Portugal – ssg@ufp.edu.pt

founding and revealing a possible inner-order that is hidden but is already there; and this may be a valid extendable principle to other critical aspects of territorial life.

Key words: urbanisation processes, resilience, planning instruments

1. Landscape and urbanisation processes in Ave's Valley Region (Portugal): Inner-orders as expression of territorial resilience and new instruments of planning.

The existence of urban areas that have grown beyond traditional city boundaries, holding these within and gathering them into relational systems – from which the continuous urbanisation is one of the most evident outcomes – is not definitely new in urban planning. Today it is globally consensual that the exception presented by P. Geddes in 1915, or J. Gottmann in the 1960's is now a common fact. However, the physical expressions through which they become real are quite different and their geographic place in the world and its background seems to be one of the explaining aspects of that difference (Dematteis, 1998; Gandelsonas, 1999).

This paper focus its study on the North of Portugal, on what some academics call the "diffuse city of the Portuguese NW" (CE-FAUP, 2002), an «object» that in so many ways mirrors an image one got used to recognise as characteristic of the Mediterranean countries of South Europe (Dematteis, 1998; Font, 2004). It is not, nonetheless, the whole *diffuse city* that it is going to be analysed here, as that city covers a maritime strip of about 120km length and 50km width in national ground, but which could extend until La Coruña, in the North of Spain (due to the features both territories share and that allow them to be understood as a bigger system, indifferent to national borders).

The study addresses one of the urban subsystems that constitute the "diffuse city of the Portuguese NW" – the Ave's Valley Region, distinguished for the specificity of its socio-economic and morphologic landscape and where the strength of the inner-orders that the analysis of its evolution through time brings to light as a resilient feature. It is this resilience that allows this case study to feed a part of the debate around which this track sustains itself, showing both the "*need to revisit the arguments regarding physical form and urban design*" and to question "*the applicability of compact city measures in existing urban areas*" that were not born as (part of) cities. To think about and intervene in this area (as in so many others of the Mediterranean contemporary urban systems) demands the compromising effort between the critical but distant analysis, (thus, more objective) and the understanding of local forces acting in place, such as the geographical, economic and socio-cultural ones.

The first approach to this understanding leans on comparative cartographic evolution since the 1950s until 2003[2] – the period when true spatial mutation happened –, observing the distribution of buildings and paths/roads within the territory, the changing of its density and the (il)logic patterns thus configured. However, if significant visual changes happen later in the landscape, the explaining arguments for this transformation date back to the second half of the 19th century (and even before), when Ave's Valley starts becoming the national leading textile industrial area. The presence of Ave's river and a dense network of water courses made it the ideal place for the delocalisation of

[2] In terms of population the reference period limit will be 2001, as it corresponds to the year of national population census.

industry from Porto (the main industrial northern hub), as well as for the settlement of brand new units; water was not, nonetheless, the only factor that weighted on the decision – the characteristics of the working force was also determinant to the spontaneous design of what much later would be called an "industrial district" (Domingues, 1999).

Ave[3] is an area located in the North of Portugal, NW from both Oporto city and the urban subsystem – the central subsystem of the "diffuse city" – for which that city constitutes the main reference. The *Non-Metropolitan Conurbation of Ave's Valley* – the second most important subsystem in terms of population had, in 2001 (one of the boundaries of the time period studied), 384,158 inhabitants and "*Occupies an area of 433 km2 and extends over 22km in the North/South direction and for about 30 km in the East/West*"[4] (CE-FAUP, 2002, pp.74). Geographically, the Ave's subsystem kind of settles within slopes, where population rarely colonizes the territory above the 350m height (Sá, 2009). Under this height, buildings and inhabitants disperse throughout the valley in a pattern that has long been recognized as one of its main and more distinguishable features. Some academics (Sá, 1986) mention it already for the late medieval period, though (being certainly different the meaning of «dispersion» back then and nowadays) what one should grasp are the characteristics that allowed and justified that organization: on one hand, the peaceful climate that did not force the agglomeration due to defensive reasons; on the other hand, the geographic features – the easy topography, the abundant water sources and the fertile soil, characteristics that favoured multi crops. Adding to these, the small dimension of the properties and a dense network of pathways designing their limits were two other aspects that also encouraged dispersion.

The conditions above provided the linen production that until the end of the 18th century made the farmers also artisans (Gonçalves, 1993, pp.3). Since then, this previously marginal task starts to organise into an «activity» and by the end of the 19th century the environment that turns out industry, namely the textile industry, the prime economic sector of Ave's Valley is settled[5]. However, this fact coexists with the preservation of a close interdependence with the farming fields, a relation that is somehow kept over the years, throughout the 20th century: "*Despite the strong industrialisation of the area one did not observe the abandoning of the fields (which is characteristic in identical situations of great industrialisation) in exchange for an employment in the industrial factory*" (Magalhães, 1984, pp.132).

Apart from the pre-industrial settling of population (that will not be considered here), the general evolution of *modern* Ave´s Valley allows the recognition of two development «models», which result from the interaction between the local economy development and the dominant socio-cultural paradigms, each one being characterised by specific settlement features/principles: (1) the *traditional settlement model*, to which correspond a first type of dispersion of the urbanisation; and (2) the *contemporary settlement model*, which is identified by two simultaneous movements – a second type of dispersion of the urbanisation and an interstitial concentration in specific parts of more dense agglomeration (Sucena-Garcia, 2011).

[3] According to the study previously referred: "The diffuse city of the Portuguese NW" (CE-FAUP, 2002).
[4] All quotations in the paper are a free translation from the author.
[5] Amaral (cit in Ferrão, 1987) places the pre-historical period of Portuguese industry between the 1st World War and 1940, just then starting the *modern age* of national industrialization.

Generally speaking, the *traditional settlement model* takes place from the mid 19th century until the 1980's, and has its «dispersion» grounded in a strong interrelation between industry, agriculture and housing, normally led by the former and driven by local features (geographical, economic, socio-cultural), which are endogenous to the physical outcome. The *contemporary settlement model*, though embracing the previous one, departs from the preceding model by some specific aspects that start to take place in the 1980's, and is still ongoing. In this sense, the kind of opposite dynamics of «dispersion» (different from the earlier one) and «concentration» that identify it are, in fact, «dispersion *plus* concentration», two sides of the same coin, that show the effects of globalisation and mobility – the new supra-local and supra-national key-words –, but also of planning; local territorial features still showing their strength, even if they have less interference with the recent settling preferences.

2. Socio-economic paradigms and urbanisation models

2.1. The *traditional settlement model*

The *traditional settlement model*, as mentioned above, grows from a close relation with the local productive system. A brief account of its evolution is noted here to better understand its development: when matching some of its stages with their «spatialisation», 4 main periods[6] stand out (Sucena-Garcia, 2011):

- A 1st period where the proto-industrial activity does not interfere with the organisation of urbanisation, which is primarily related to subsistence agriculture. Commercial concerns do not interfere as the linen production emerges from being a raw-material that is naturally available and is simply used to "*dress the body*" (Alves, 1999, pp.1). The dispersion of population and buildings is justified in agriculture practices and its «requirements», as well as in the size of the fields – a dominant micron-fragmentation of landscape – that is supported by the abundance of water and the easy topography.

- A 2nd period, between the mid 19th century until the late 1950s/early sixties, where the organisation of space – the space «order» – reflects the growing importance of industry, operating at two scales of buildings:

    - The setting of industry as an organised economic activity that develops in their own space generates new typologies, big buildings that settle in close dependence on the energy forces and the specific moments of the manufactured goods production and begin to spread within the territory. At first it is the space closer to the (main) water lines that starts to be colonised by those factories, but when other energetic resources became available – gas run motors, the steam, the electricity – they also start spreading throughout the "*inner farmlands*" (Alves, 2002, pp.375). By then, the concentration of population – and the potential amount of the labour force offer – is deemed as an important decision factor and industry moves into the boundary places between these small agglomerations and

[6] Sucena-Garcia (2011:132-145) synthesises various phases of the productive system according to the views of several authors; however, when one considers how they impact on space – their «territorialisation» – only 4 periods have significant meaning.

the countryside. Gradually, the national road network and the ease of access will be another decision factor (though far from the importance it will have later on); and industrial buildings spot along the road margins.

- Still characterising this period, at a smaller scale, the production of goods or the development of certain phases of that process happens inside micro-sized units, at home or in workshops. Though not exactly a new circumstance, it has became a more *institutionalised* dependence in relation to the big factory. As Marques (1988, pp.58) states, the move from the linen industry to the cotton industry (a much more interesting raw-material for large scale production) benefited from the specialised weaving know-how, and this was, as previously noted, a skill that was "*non-dissociable from the farmers' settlement'* (Alves, 1999, pp.2) being as such very spread out in the countryside. In this sense, the industrial production kept and somehow reinforced this original highly disseminated "*location pattern*" (Marques, 1988, pp.58).

- A 3rd period, between the early 1960's and 1974[7], that did not however display changes in territorial organisation, namely because the ones registered in terms of industrial production were not yet strong enough to cause it. Nevertheless, for the strength it will have in the following stage, it is important to highlight the emergence of the textile and *clothing industries*, side-by-side with the cotton industry, which will be more significant from the late 1960's onwards (Gonçalves, 1993, pp.7). This branch of the textile industry that is highly «mobile» in comparison with the more traditional one, both because of its raw material and its goods, is easily compatible with small sized spaces and thus quite indifferent to geographical constraints. During this period, the road network's attractiveness comes out reinforced as a settling reference to some industrial buildings.

- A 4th period, between 1974 until the early 90's, that is distinct from the previous ones not by an essentially new way of organising space, but by the reinforcement of dispersion in close association with the growth of the Textile and Clothing Industries (that reaches its peak during the 1980's).The post-1974 *status quo* gave birth to an exceptional dynamic in terms of the opening and closing of industrial companies (Mendes *et al*, 2001; Marques, 1988), but their small size and the possibility of sharing the same space with housing – inside the house or occupying a part of the lot –, or standing in its close neighbourhood, made it possible for this activity to spread throughout very extensive areas somehow «fading» into the countryside, substantiating a process that discloses a certain (and significant) marginality/informality of the activity and the lack of control over it, namely in visual terms. Anyway, the statement that in Ave's Valley "*what is already being designated as «diffuse industry» (...) starts to assume great expression elsewhere and not only within the textile industry*" (Portugal, 1988, pp.24) ascertains the recognition of its existence and importance as a *typical* phenomenon. In parallel to this settling logic, another one took place – a "*kind of «concentrated dispersion», mainly fed by relatively big scale companies of the textile sector*" (Quaternaire, 1992, pp.141).

[7] 1974 was the year of the revolution that changed the dictatorial regime (1933-1974) into a democracy (25th April 1974).

In short, one the most intrinsic aspects of the *traditional settlement model* in Ave's Valley is the "*subsistence triangle*" (Sá, 1986) – housing, agriculture and industry – which interdependence is fundamental for the survival of both the local productive economic system and the majority of the population – the families – that directly or indirectly depend on/from it. In fact, agriculture, albeit in a gradually weakened state, is the activity that essentially sustains the local economy as it grants the family a relative independence from job insecurity, freeing it from market swings and low salaries and guaranteeing a minimum stability that allows it to cope with moments of industrial crisis; on the other hand, it feeds the productive system that can increase or decrease resources if extra labour is needed or if there is a drop in production, granting it the flexibility that has allowed it to remain in play without having to take on permanent costs it would be unable to bear.

Regarding the physical aspects, the *traditional settlement model* in Ave's Valley match with the dispersion of population across the Valley, a «dispersion», however, that "*is not homogeneous*" in its territorial distribution, "*occurring with higher intensity in certain areas*" (Sá, 1986); neither is it random, finding its different causes over time in correspondence with the changes of the industrial productive system. In fact, the items above support that Ave's landscape show "*a proper logic in the location of activities, despite its noticeable «disorder»*" (Quaternaire, 1995, pp.38) being "*the industrial employment (...) what most directly relates to the image of dispersion*" (Portugal, 1988, pp.291).

2.2. The *contemporary settlement model*

The extensive and diffused model growth of urbanisation that is, traditionally, a characteristic of Ave's Valley shows itself less clearly nowadays. Especially during the 1990's new logics of urbanisation added to the former pattern – new logics for the distribution of activities in space, new logics for the organisation between built and non-built «pieces», new typologies – and whilst they blurred the clarity of the first model, they also made it part of another (and new) one. The *contemporary settlement model* is, thus, an expression that wants to signify the coexistence of different «rules» of territorial settling embedded by essentially distinct socio-economic features. It stands up for a sum of territorial events (more or less reconciled) that time has put side-by-side and which sometimes have in that physical presence the only tying link. It stands up, finally, for a new paradigm that keeps the evidence of the previous one – since it is hard to make *tabula rasa* for territorial facts – and brings both together as the emergence of a new model.

In the early 90's, the development model fed by the expansion of industrial units in space in which Ave's Valley economic production basically sustained – with particular focus during 1985-1992 – was exhausted and rupture was inevitable (Quaternaire, 1995). The effects of a more stable and consolidated democracy as well as the entrance of Portugal in the Economic European Community (EEC), in 1986, established the 80's as a kind of transitional decade where new socio-economic challenges started being designed, clearly affecting the changing of physical territory. In Ave's Valley, industry and agriculture – as tied together activities that sustained local economy and that for over a century had been complimentary, balancing and counterweighing in times of crisis (and resilience) – faced the need for restructuring: on the one hand, the

competitiveness of industry is challenged by qualitative demands that set to question the prior productive system, fundamentally based on quantitative and low-qualified criteria, leading it into a (one more) crisis' period and to the rise of unemployment; on the other hand, legal statistics account for agriculture losing farmers, namely the young ones (Marques, 2004); in both cases it is the growing tertiary sector of the economy that absorbs some of those out of work, offering them more diverse employment opportunities, namely in white-collar and commercial activities[8].

Still, as happened with the preceding *settlement model*, the economic aspects come as an important justification for the transformation of «spatialisation». In a very simplified description, the economy tertiary sector mentioned above reached unknown dynamics and levels of development due to new consumption habits as well as to new demand for facilities, both aspects supported not only by the general improvement of post-democracy standards of quality of life, but also by political self-imposed goals under a state-providence design. In terms of territorial changes, one of the immediate consequences was the reinforcement of agglomeration through public investment on community facilities – schools, hospitals and health care local units, administration and local government representation, etc. – mostly directed to central urban areas or to their immediate periphery. Retail, as well, tend to follow the same guidelines as they also depend on proximity relations with inhabitants, but it goes further and expands to secondary agglomerations as well or, depending on the goods it sells, establishes further afield following the human colonisation of the Valley[9].

This procedure, in fact, relates already with the reinforcement of the «opposite» settling dynamic – the dispersion pattern – that has in the trivialisation of the car ownership/use its main triggering aspect, soon followed by the ordinary use of telecommunication devices – mobile phones and the internet. In Portugal, the 80's witnessed the strength of the physical mobility with the increasing of private transportation ownership; the 90's saw it grow stronger as a consequence of the highway road network, favoured and largely supported by EEC funding in basic transport infrastructure, at the same time as it behold the emergence of virtual mobility, that became an ordinary fact during the 2000's. Dispersion as an urbanisation pattern kept, therefore, its presence in Ave's Valley, but its underlying motives were no longer the "*productive triangle of activities*" (Portas *et al*, 1990). New ways of perceiving and occupying territory are now driven by more globalised trends related to the seizing of new mobility conditions and corresponding socio-cultural patterns concerning the organisation of everyday life. Nonetheless, this pattern does not find any longer its main reasons in an intrinsic relation with territorial features: people choose to live in a specific place for a number of reasons, and though in certain cases there may still be some emotive ones behind/driving the choices, these are mostly the compromising effect between family needs (employment, school), financial arguments and opportunities.

Beyond «agglomeration» and «dispersion», these globalised aspects gave birth to a new territorial settlement typology, even if, again, it shapes like a kind of «concentrated

[8] Regarding the increase of employment in tertiary activities in this area, one has to be aware of the relative fragility of this statement as part of it was supported by low level qualifications' employees, who were the great majority of ex-farmers and industrial workers that got a job in it; nonetheless, this is also the economic sector that most benefits from the post-1974 investment on education (Mendes *et al*, 2001).

[9] Though this is not exactly an original aspect for this settling model, it comes out strengthened by the new circumstances.

dispersion» pattern, previously registered regarding the close settling of some medium/big scale textile industries. Nowadays, it preferentially occurs around highway nodes, sometimes extending to some of the main roads of the national road network, and joins together large scale commercial, industrial and/or logistic related buildings surrounded by large parking space areas. Large industrial areas and technological parks are also different topics for this «concentrated dispersion», for which easy access to the main highways is determinant, even if they do not always locate around those nodes (Portas *et al*, 2003; Portas *et al*, 2011).

Adding to the aforementioned present-day facts, one must have in mind that the contemporary settlement model of Ave's Valley keeps within the previous one, thus being the outcome of a cumulative process where the pre-existences from an obsolete past, the ones from a traditional but still dynamic past, and the emergent facts ruled by recent socio-economic paradigms share the same place; the result is the sum up of different and concurrent situations taking place side-by-side – of regression, stabilised situations, in mutation, embryonic situations –, a *palimpsest* that is not easily understood in terms of its physical effects, an apparently chaotic landscape that needs to reason within the arguments for its visual control and legibilility. Nonetheless, what seems to be clear at this point of the study is that Ave's Valley has grown into an urban system over time, mostly sustained by spontaneous processes, holding inside both *rural* and *urban* aspects, in truth the essence of its landscape. In this sense, rather than seeing them like a controversial and opposed duality – as traditionally they would be considered – one needs to face "*rural* and *urban*" as the basis of a «different» reality, the specific and «new» feature of Ave's Valley (and of so many other contemporary urban systems worldwide) to which Planning has to address and, find adequate responsive instruments.

3. Territory's inner-orders and Planning

Planning, as an instrument of territorial control, is recent in Portugal. The first master plans –*Municipal Master Plans* – came to light in the early 90's, packed with the uncertainties, good will and mistakes usual of the first and still inexperienced steps. Ave's Valley[10], even if within the same general framework, embraced however an exceptional procedure. A group of professionals, which included architects, engineers, geographers, some of them academics, who had dedicated part of their learning experience to the understanding of this specific territory as a «territorial unit», despite it being encroached into different municipal administrative limits, were set to lead some of the technical planning teams engaged in this initial planning process, that took place in the late 80's. This experience was in fact an opportunity to question some ordinary planning instruments in the light of the specificities of urbanisation patterns in the area, like zoning, dispersion vs. agglomeration, or the meaning of transferable planning models to the municipal border areas. However, what really made it special was the search for both an effective inter-municipal articulation (grounded on the *characterisation of* and the *reasoning about* that territory as a whole) and analogous development premises for the distinct (municipal) planning units.

Aside from the individual pathways and layouts of each municipal planning, the Ave's Valley vocation for both dispersion and the mix of activities were consensually

[10] At that time, in the early 90's, the three main municipalities of Ave's Valley: Vila Nova de Famalicão, Santo Tirso and Guimarães.

recognised as the two main idiosyncrasies of the area, which plans' regulations should have to address in specific ways: the first one – the dispersion pattern – was to be controlled under certain guidelines and some limits' definition; but the later – the mixing of activities – would be encouraged (if compatible), refusing the ordinary trend to mono-functional zoning, under the argument that it grounds a diversity that contributes to territorial balance. The evaluation of the results of that "*first generation of plans*" made by the municipal planning teams, that took place since the mid 2000's when those were set under their mandatory revision process, shows the general control of the urbanisation, as intended, and validates the consequences of the mixing of activities (CMST, 2008). However, master plans failed to restrain the general visual image of chaos that still embodies Ave's Valley and to imprint some ordering elements into the landscape, thus disclosing the inadequacy of the municipal level of planning to manage some important contents for the discipline of the urban territorial system. In fact, to deal with the various dimensions and the inherent complexity of the extensive and «continuous» urbanised areas, an operative intermediate level of decision-making is required, besides a wide understanding of the territorial interactions that goes way beyond the pre-established administrative borders.

In Portugal, however, «regions» have not a legal recognition and thus the lack of a valid jurisdictional entity capable of leading the supra-municipal processes, articulating them, whenever necessary, with the national, though sectorial, programmes of intervention, (regarding, for instance, decision about the main road network, hospitals, etc.) prevents a regional strategy being laid out for referential elements. Concerning Ave's Valley, the road network is precisely one of the most pertinent potential ordering aspects, as the area is characterised by an extremely dense set of roads, streets and pathways inter-playing, that despite their distinct physical features assume similar, and thus frequently inadequate, roles. The lack of clarity and discipline of potential structuring elements and their interrelation is, therefore, one of the main causes for the Ave's Valley chaotic image, one that demands different and simultaneous scales of intervention. Taking this item as an example for the reasoning about the "*need to revisit the arguments regarding physical form and urban design*" and "*the applicability of compact city measures in existing urban areas*" one could say that some of the general key-words and key-strategies commonly accepted to plan the traditional/compact city keep their meaning in this changing scenario, but its different scale demands a whole new set of operational instruments yet to be discovered.

Road network, for instance, would still need a certain level of hierarchy, eventually embodied with distinguishing and specific design principles, in order to guide the inhabitant within the actual dispersed and fragmented urban areas. The system, however, would have to reconcile macro and micro dimensions, being aware that the defining guidelines would have to take into account the new measuring units that build and operate the new urban areas. The car related distances replaced the pedestrian references and public space cannot be designed any longer under the previous guidelines as it does not support the former uses. Something as essential to the compact city public space design as the *sidewalk*, for example, is generally unnecessary for the urban areas that grew in-between those compact cities. In this sense, this understanding gives place to a paradox: on one hand, public space is one of the main landscape unifying elements, able to provide certain peacefulness for the uncontrollable post-modern diversity of the built environment; on the other hand, the arguments to qualify it are mostly unknown.

Reasoning was made about road network, but a similar one could be made about the hierarchy of «central places», another precious argument to the compact city planning: again in a very different scale, the need for a polycentric environment to be linked and organised inside hierarchical principles according to the distribution, for one side, of basic facilities, and for another, of more exceptional ones, would globally provide a desirable isometric territorial balance; but the "*interesting distances*" (Solà-Morales, 2009) between the constituent «pieces» of the various hierarchical levels, taking into account the recent mobility criteria, always more individual, is also yet to be found. In both cases, the knowledge about the real uses of local territory – of its *inner-orders*, the most persistent and intrinsic interactions between territorial facts and inhabitants – will provide the answers. As long as preconceived ideas, perceptions and theories are left aside and, instead, it emerges an opening attitude that starts by understanding *heritage* as an active and fruitful planning instrument – a matter for further research.

Aliens are citizens: the local dimension of inclusion policies

Nadia Nur

Abstract

This paper concerns essentially how local policies deal with inclusion of immigrants in Italian cities, with a focus on housing issue.

Despite the nation state is considered the main integration policy subject by European institutions, the once taken for granted correspondence between citizenship and nationality has been called into question as new forms of transnational and sub-national belonging are shaping up within the city due to global migration. This disjuncture between the conventional forms and spaces of citizenship and being a citizen in daily life has led to a political devolution of citizenship claims-making from national to urban space. Perhaps the crucial challenge in order to address the social and spatial inclusion for immigrants is to reimagine citizenship in the context of the globalisation and denationalization of urban space.

Since the transnational character of global migration flows and cultural networks have dramatically changed the narratives and practices of citizenship, “inhabitance” has become a status allowing participation in policy-making.

Immigration impacts mainly on social, spatial and political structures in cities, thus the response to such a global issue is mainly local. The steps of the policy making are now going from global to local. And this is self-evident especially in Italy where the State structure is turning into a federalist form.

Local activities on integrating migrants and setting up dialogue structure at the subnational level, and collaboration between various government levels and between local bodies and non-governmental organizations are essential to spread inclusion-driven policies.

Despite the numerous changes in the Italian institutional and legislative framework, the role of local administration in supporting immigrants integration and access to urban advantage, based on principles of freedom, equity, and social justice, remains crucial. An increasing number of Municipalities have recently set up immigrant consultative committees or special councillors representing foreigners, drawing special attention to political participation and migrants involvement into the policy-making process. Despite the great relevance of political participation, housing issues are even more crucial for an effective inclusion policy. While the gap between demand and supply for public housing is wider, the opportunities of private rental for moderate or low-income people are decreasing.

While some cities are taking forward inclusion-driven policies, some municipalities reject the multicultural idea denying basic rights to foreign citizens and seeking spatial segregation.

Both groups point out that national policies are no longer adequate to cope with migration issue.

1. Citizenship beyond nationality

The institutional configuration of citizenship based on nation state doesn't fit anymore to the reality of citizenship. This concept of nationality-based citizenship and the sovereignty of nation state are challenged by the migratory process and the claim of aliens inclusion. Boundaries traditionally separate the ones "inside" from the ones who are outside the territory of the state, who is to be considered a citizen from who is a non-citizen. Juridically, citizenship is a nation state matter, even if we consider supranational level (e.g. The European Union). However, if we take into account social citizenship, the matter turns immediately to a local level.

The idea of citizenship as a matter of belonging to a state has always been ambiguous. It assures inclusion and equality through the legislative system but at the same time it is an instrument of exclusion and closure.

The migration phenomenon is producing a radical change in the traditional concept of citizenship and is questioning a new definition of citizenship rights. Referring to the Italian case, the character assumed by local citizens is to be analysed through the lens of immigrants policies established by local governments. However we have to consider that the Italian territory is highly fragmented and heterogenic, both in cultural and political levels. Municipalities, regions and provinces show a significant differentiation in assuring rights access, both for aliens and national citizens.

Many regions have approved several provisions that promote the rights of participation to non-national citizens. Case study Regions could be Emilia Romagna, Tuscany and Campania, which are fostering the participation of non-national citizens and extending the right to vote to immigrants. The recognition of the right to political participation to non-national citizens is thus independent from nationality and it is based only on the residence in the Region. Those considered aliens or non-citizens by the national law system, thus acquire a sort of citizenship at local level, through the recognition of political rights. Aliens are citizens de facto. However, it is a long way to go to get the full recognition of equal rights of citizenship based not on nationality but on inhabitance.

2. Migration *vs* immigrant policies: from national to local level

At national level the first immigration laws – namely Law No. 943/1986 and Law No. 30/1990 – didn't mention any integration policy and didn't consider territorial

differentiation in access to citizenship rights and provision of services. Resources provided to the Regions were given only for first accommodation centres.

Only in 1998, with the Turco-Napolitano Law (40/1998), a comprehensive policy framework for immigrant integration began to be drawn and financial resources were established at regional level to implement integration programmes. With the establishment of the National Fund for migration policies (Article 45 of Law No. 40/1998) Regions have become a major player in the management of immigrant policies. However Regions had to sign agreements with Municipalities, which managed relations and cooperation with the third sector organisations such as charities, unions etc. for the provision of basic service at city level.

The main outcome of Law No. 40/98 is the recognition of the pivotal role played by local administration in providing assistance to unaccompanied minors, people under humanitarian protection and victims of trafficking.

In 2002, this law has been partially modified by the Law No. 189/2002 (Bossi-Fini) through a reform that made the relationship between work and residence permit more binding, reduced funding for integration policies, and made illegal immigration more difficult.

The Bossi-Fini Law increased the role of the Municipalities regarding asylum seekers issue. However, due to budget cuts, in 2003, the National Integration Fund became a more general part of the Social Fund given to the Regions for welfare interventions. In this way Regions alone are responsible for using this fund for general welfare services or even for immigrants inclusion policies.

At the moment in almost all Italian Regions there is a regional law for the integration of immigrants, rather than other regulatory measures. There is a Regional council (and sometimes even a Provincial one), a three-year program of interventions in different areas and an annual program in some regions, namely Piedmont, Veneto, Umbria, Marche, Puglia, Calabria, Sardinia. Monitoring migration, collecting and processing data in order to estimate the labour need is quite common praxis: now there are regional observatories on migration and a Register of Associations of migrants.

Despite the numerous changes in the Italian institutional and legislative framework, the role of the Municipalities in supporting immigrant integration and access to urban advantage, based on principles of freedom, equity, and social justice, remains crucial. An increasing number of Municipalities have recently set up immigrant consultative committees or special councillors representing non-national residents in the Municipal Councils (Fieri-Asgi, 2005).

The steps of the policy-making are now going from global to local. And this is self-evident especially in Italy where the State structure is turning into a federalist form.

3. State reform and new tasks for local governments

"Italy can be regarded as a case of a regionalised state structure in transition towards a quasi-federalist form" (Caponio, 2010, p166). In fact in the last twenty years a devolution process has undergone and local administrations acquired more authority.

The 2001 reform of Title V of the Italian Constitution changed dramatically the structure of the State, turning it into federalism and thus assigning more legislative power to the Regions, while Municipalities have administrative functions.

The reform provides that immigration issues remain yet under the exclusive jurisdiction of the state, while policies towards immigrants – including social services, health care, educational assistance, vocational training, and public housing – are under exclusive responsibility of the Regions (except for the protection of health care).

However amid this sort of incomplete federalism Regions cannot influence the legislation of the State since at national level there's not any chamber representing regions.

4. Local policies and aliens inclusion

"Social inclusion of international migrants depends largely on the positions they fill in the local economy, the socio-cultural conditions of the host city, the migrant own willingness to be "included" as well as the patterns of settlement and the uses they make of the public urban space. In fact, migrants are not a homogeneous group of people. To be effective, policies must acknowledge that different cultural, religious and educational backgrounds generate different perspectives on the notions of inclusion and citizenship" (Balbo, 2006, p.92)

In Italy the phenomenon of immigration is markedly urban. Thus it is in the urban context, or more generally at local level, that inclusion or exclusion is determined.

However, to understand the dynamics of inclusion urban, both social and spatial, it is important to take into account the territorial differences of the issue, both for the characteristics of the foreign presence and regarding the social context and local policies. Moreover, we have to consider the weakness of welfare policies and integration in Italy.

The Italian case is pretty unique as it is characterized by a fragmented model of integration and inclusion of migrants. Therefore is difficult to draw a clear framework of inclusion local policies: territorial differences and the different strategies adopted has to be added to cultural differences between immigrants communities. Policy differences have been related to the different context or to the different relations between public actors (Ponzo 2006) and between public and private players such as Ngo's, foundations, unions, associations etc.

Different citizenship models show that the "right to the city" for migrants depends essentially on the conditions offered at local level. In this context, policies for migrants inclusion are played on multiple levels of government (Zincone G., Caponio T., 2006). There are several interactions between the various levels of government and civil society organizations. Moreover, grassroots policies are growing as a new "informal" model.

Thus, local administration plays a more crucial role in supporting “right to the city” and providing services to alien citizens. Local activities to support integration, and set up dialogue structures at subnational level, and collaboration between various government levels and between local bodies and non-governmental organizations are essential to spread inclusion policies.

At municipal level, in Italy, early policies aimed at immigrant inclusion and integration have been carried out in the North of the country, in the late 80’s. Yet the third-sector already played an important role to assist first accommodation.

In the 90’s we assisted at a differentiation of inclusion models, which focused for example on housing (Milan), cultural integration, intercultural mediation and equal access to urban services (Bologna).

While in Northern Italy main actions were carried out mainly by municipalities, in the south of the country a crucial role has been played by non-profit organisations and the Catholic web (Zincone, G., Caponio, T., 2006).

“Inclusion has implications for any commitment to “urban citizenship” by both host and migrant communities. However, the emergence of an international migration with limited commitment to the host community, can lead to a decay in civic values. In this perspective, inclusion can be seen as a compact between migrants and host communities whereby they share certain civic values while other factors of diversity are kept untouched” (Balbo, 2006, p.92).

5. Housing Policies as a matter of inclusion

Housing is the most critical urban condition that involves inclusion of immigrants. Despite the great variety of conditions, generally speaking we can notice a massive situation of hardship and housing exclusion. Many immigrants, including the ones who are not to be considered poor, are badly housed. Poor immigrants, even if they are refugees, or under humanitarian protection, are often homeless because they are not provided with any housing right.

Within the real estate and rental market, accommodations offered to immigrants are basically worse or more expensive than those available to local people with same type of income (Makno-Ministero dell’Interno, 2007; Eurispes, 2007). Precarious conditions of inhabitance is a matter of concern also for regular immigrants with regular income.

The extent of discomfort and exclusion of immigrants call into question the issue of policies.

Social housing for immigrants is a recent and very dynamic phenomenon: most of the initiatives have been launched over the past ten years, and have increased rapidly over the past five years.

It should be emphasized that the local actions of social housing are generally influenced by the central government, which has established several funding for housing, but did never adopt a specific legislation aimed at the solution of this problem that is becoming more and more relevant even for the Italian middle class. A recent innovation, though it is part of a financial law and is not specifically oriented to housing r, is that of House Plan (L.133/2008).

Due to the lack of institutionalization of housing policies, social housing in Italy is typically constructed from the interaction between different players and using resources from different areas of policy. Moreover informal and self-managed grassroots solutions are to be taken into account.

Housing policies seem to be characterized by "different speed": the local level responds more quickly to the needs of new citizens, while the central government's response is slower (Ponzo, 2010) This trend follows in part the dynamics of the development of integration policy in Italy (Zincone, 2006; Caponio, 2006). But I argue that is strongly affected by changes in the composition and settlements of the migrant and immigrant population, and trends in the real estate market and the supply of housing, which impact first on local government before becoming sensitive at national level.

Probably what is happening is a kind of polarization (Crosta, P.L., Mariotto, A., Tosi, A., 2000) caused by the improvement in the conditions of immigrants already settled, and growing housing insecurity for those who are at the beginning of the migration experience.

Several factors have contributed to a transformation of housing demand: the stabilization of a large quota of foreign population, the growth of the number of families due to the reunification or the making up of new families, the different composition of new citizens. Regarding the housing offer, we are assisting at the worsening of the housing market, besides the lack of innovation in the institutional framework.

The settlement of families determines obviously an increase in demand for housing, in the sense of stable and adequate housing, not a first assistance shelter. And, the need for housing is basically a need for rental, which in most cases should be a cheap rental.

The gap between supply and demand for public housing is not filled by the increase of opportunities offered by the private housing market, which is no longer accessible to moderate or low-income people. This means that it becomes more difficult for immigrants to improve housing careers.

According to a recent research conducted by Fieri (Ponzo, 2010), which has surveyed the social housing projects for immigrants in Italy, 34% of the projects are carried out at the municipal level, 46% involve the supra-municipal level (province, district, district social-welfare, etc..) and only 18% is conducted on regional basis.

The highest number of housing projects is founded in Emilia Romagna and Tuscany, followed by Lombardy and Veneto. In Southern Italy the interventions are scarce and most of them concern first reception and information desks.

People involved in housing projects reflect the evolution of the foreign presence in Italy, characterized by a high proportion of families, increased as a result of family reunions and marriages.

Generally speaking, different players, public and private, are involved in the development of housing projects for immigrants. Public actors are getting more and more important both as promoters and partners of the project. However, at national level this data is not homogeneous: Fieri survey shows that two-thirds of the projects promoted by public actors are concentrated in Emilia Romagna and Tuscany. Real estate brokerage office and a social management of housing are the main actions that take place.

The role of foundations as promoters, partners and financiers, compensates the scarcity of public resources and lack of innovation. Conversely, the third sector and non-profit organizations play a marginal role.

Aiming to give just an overview on housing policies for immigrants in Italy, I attempt to highlight some positive experiences, where the objective of inclusion through the granting of housing right has been reached, but also negative experiences and innovative projects yet non implemented.

Veneto Region is an symbolic case of the bind between politics, local administration and attitudes towards inclusion or exclusion policies. The municipality of Padua has become famous when the local administration decided in 2006 to build a wall to separate “via Anelli”, the major immigrant settlement, from the rest of the town. Via Anelli was the typical example of an ethnically oriented neighborhood, that most of the times means that immigrants settle in a place after searching for housing in other neighborhoods and confronting with high rental rates, discrimination and often illegal behaviors of the owners. “However most migrants knew before they started their migratory journey that they were going to end up in Via Anelli as safe place where to receive the support of fellow citizens, in terms of working protection in situations of illegality” (Ostanel, 2010).

The community of via Anelli “can visibly use the city and its services but cannot exercise the same grade of citizenship as the natives. The term marginality, in this sense enquires various concepts such as access to housing, public space, services and security linking them to the notion of citizenship” (Ostanel, 2010). Immigrant population settled in Via Anelli can be defined “included with exceptions” ((Mezzadra cited in Ostanel, 2010).

In 2007, after the relocation of the nearly 560 regular inhabitants in public houses within the city and the province of Padua, housing became once again a hot issue for the immigrants that after having benefit of a location contract of 2 or 4 years, couldn’t find other affordable housing solutions.

The 2008/10 project “Oltre il ghetto” (Beyond the ghetto), sponsored by the municipality in cooperation with the Health and Welfare Ministry and other players, supported people (100% foreigners) that were living in Via Anelli in accessing the private housing market, helping them to pay the rent deposit, and facilitating cohabitation for singles. Moreover, the project aimed at the social inclusion of singles and at the mediation of ethnic conflicts. At the end of 2010, 230 people were still living in public houses due to the difficulty in accessing housing in the private sector. Moreover the financial crisis has strengthen the situation of marginality that migrants were living and most of them has become undocumented.

While the public administration looks at “Oltre il ghetto” project as a success, which allowed to recover a great number of public housing housing (Gamba, Ferrandino, Ruggero, 2011)the relocation policies “tried to solve the social and spatial constraints that Via Anelli were materializing, but they did not address the macro-social constraints that are forcing migrants to marginality. What is important to highlight is the relationship between local and national/transnational level of policy because it stresses the role of local government in managing migration: while local governments have a specific responsibility on the community they are governing, macro-social elements that are affecting migrants’ urban inclusion/exclusion are playing at different levels. Local policies become partial and national and transnational constraints are impossible to address” (Ostanel, 2010).

Another example, less emblematic and perhaps more ordinary, is the one of Cesena. The Foundation rental of Cesena, promoted by the Municipality of Cesena in connection with the "Cassa di Risparmio di Cesena" was created (along with religious players, unions and associations of owners of real estate industry) in 1993 to promote access to housing by households. The service was primarily aimed at families, but since 2005 groups of singles usually willing to share accommodation have been admitted. More generally the conditions for accessing the service are: a regular employment, a residence permit (in the case of foreigners) and an annual income of at least 8,000 euros. It is interesting to notice that to access the service is no longer necessary to have a permanent contract, but it is now sufficient to prove to have an income for several months.

At the beginning the foundation activity was addressed mainly to Italian families but today non-national citizens represent almost 70% of the target. The preponderance of immigrant users, however, has not been disputed by Italian ones.

On the contrary, "Vicini di casa", a cooperative-association founded in '93 as part of the parish of St. Dominic of Udine was initially targeting only the immigrant population until 2006. The extension to Italian citizens took place after being fund by Law No. 15/2005 which aimed to address people living in disadvantaged position, regardless nationality. Since then the association started promoting change in the legislation, urging the Immigration Sector to stress in the drafting of the Regional Immigration Law No. 5 of 2005 the issue of equal access to housing both for Italians and foreigners rather than on promoting interventions reserved for immigrants.

The percentage of foreigners users is still very high and varied depending on the service (from 65-70% in social real estate brokerage, to 75% in temporary residential facilities, 90% in real estate management).

The intervention is supported by the municipality and the social welfare sector. The main financial donors to “Vicini di Casa” are the Friuli Venezia Giulia Region and the Province of Udine.

While in Tuscany the “Abitare il mondo” project is financing actions aimed at promoting the inclusion of non-European immigrants through the construction and renovation of housing, in Lombardy the extension to 5 years of continuative residence as a condition to housing access makes this Region a sort of laboratory of exclusion. It is interesting to notice that in Milan, the number of non-Italians owners of houses has increased of 300% over the last ten years (22%). While this could be seen as a positive figure, often the choice of buying a house, in some cases shared between more than one family, reflects the difficulty to access to rental market or to social housing, due to the restrictive requirements or, in the case of private rental, to discriminatory attitudes.

5. Conclusions

The brief reconstruction of housing policies towards immigrants inclusion in several Italian cities highlights the importance of the third sector in supporting the public administration, which is highly fragmented. Different medium or long term migratory patterns, the influence of political attitude pro or anti-immigrants of the ruling political party, and the support of Ngo’s and associations paint an unclear picture of the local policies of inclusion of immigrants.

While public administration is the driver of inclusion policies, especially in the Northern Italy, the immigrant issue is completely undertaken by non-profit associations, charities, Ngo’s and Catholic networks. Local policies show a variety of strategies and conceptions, some oriented to integration, some to first assistance and some to security and control. In the north and sometimes in the center of the

country the attitude is to a sort of "subordinate inclusion" (Crosta, Mariotto, Tosi, 2000), recognizing the immigrants' right to be integrated in the productive sphere but not in the social and political one. In the Southern Italy the role of public administration is weaker and immigrants issue is a matter of concern mostly for the private actors.

As policy-making is played at so different layers it is difficult to underline a unique strategy. What is evident is the shrinking influence of the state and the national law system. Regionalization of housing policies in Italy puts local administrations in front of the concrete task of housing welfare for all citizens, immigrants included. Immigrants' inclusion is more and more a matter of local policy, despite the national legislation.

The ones considered aliens by the national laws, are inhabitants living in urban contest, thus they are de facto citizens, which means they should be provided all citizenship rights within the municipality they live in, especially housing rights.

Abstract

Youths in the U.S. experience health problems due to unhealthy eating behaviors. In terms of physical and social environmental factors, youths encounter problems with accessing healthy food. The purpose of this study was to determine the degree to which the built environment and socio-demographic factors affect teenagers' probability of visiting healthy or unhealthy food establishments.
Participants' frequencies of visiting healthy/unhealthy food establishments were obtained from the Teen Activities and Transportation Enterprise Project (TATE) survey. Food environments location data were collected from the Providence Plan and the Rhode Island Yellow Pages. Sociodemographic data were obtained using the TATE survey and statistics from the Providence Public School Department. Multinomial logistic regression models were used to explore the degree to which youths' frequency of visiting healthy/unhealthy food establishments were linked to availability and youths' socioeconomic status. The models reveal that the availability of healthy food establishments within walking distance from home, the frequency of visits, gender, employment status, and ethnicity significantly affect visitation to unhealthy food environments ($p < 0.05$). The availability of unhealthy food within walking distance, the number of members living in the household, the number of cars in household, birth-nation of the student and the student's father are not significant.

Introduction

A major public health crisis facing today's youth is the pandemic increase in overweight and obesity[1,2,3,4]. According to the 2007-2008 report, 18.1% of adolescents between the ages of 12-19 are considered obese. Ethnic/racial disparities exist and Black and Hispanic/Latino youth are more likely to be overweight and obese compared to white adolescents[1]. Given the detrimental physical, social, and mental consequences of obesity among youth[5], more research regarding the risk factors related to the development of overweight and obesity are warranted. An area of research which is still somewhat unexplored is the role of the built environment on adolescents' dietary and physical activity behaviors.

The built environment includes a range of physical and social elements that make up the structure of a community[6,7,8]. Examples of the physical food environment include access to eating establishments such as fast food restaurants, and access to grocery stores, convenience stores, etc. Examples of the social environment include the social norms surrounding eating[9]. The built food environment can affect dietary behaviors and obesity rates through creating a climate that can either promote or inhibit energy consumption[10]. A recent review of the built environment and obesity found that 84% of the included studies reported a statistically significant positive association between some aspect of the built environment and obesity[11]. In general, results of the studies found that lower prevalence of overweight and obesity were linked with increased access to supermarkets[12,13,14] and decreased access to fast food restaurants[15,16]. Greater BMI was also associated with higher area-level disadvantage scores of the census tract where participants shopped[17,18]. However, most of these studies were conducted with either adults or young children; none of the studies examining the built food environment were conducted with adolescents.

Although studies have found significant relationships between access to eating establishments and prevalence of overweight and obesity, the cost of food is also an important factor. For example, an increase in the prices of healthful food, i.e. fruits and vegetables, has been show to result in higher BMI for youths. In addition, a lower cost for higher fat foods such as meats also resulted in greater BMI levels[19,20,21].

Because adolescents are typically too young to drive and therefore are more likely to remain within their proximal environment, and they tend to have access to disposable income[22], it is important to examine the relationships between adolescents' access to food retailers and restaurants, specific spatial factors and demographic variables[23]. Thus, the purpose of this study was to determine the degree to which the built environment and socio-demographic factors affect teenagers' probability of frequenting healthy or unhealthy food establishments.

Methods

Study area

The study area is the City of Providence and the areas one kilometer beyond the border of Providence. As this study finds the availability of food establishments around

home and school within a walking distance of one kilometer for youths, areas in other cities adjunct to Providence within one kilometer were considered within the spatial area for analysis. However, buffered areas including natural barriers, such as the river were excluded from the study area. For instance, East Providence areas are adjacent to Providence, but between the cities, there is a river, making it impossible for youth to access a destination across the river.

Study sample

The study's sample consisted of one hundred and twenty-two inner-city, low-income, and primarily first-generation immigrants. Students were in the 9th to 12th grades, from an inner-city school in Providence, Rhode Island. Sixty-three percent were female and 37 percent were male. The largest ethnic group of students was Hispanic (59%), and approximately half reported Spanish as their primary language (54%). The second largest ethnic group was African-Americans (20%). Approximately 57 percent of the students were born in Rhode Island and 14 percent were born in the Dominican Republic. Students primarily described themselves as being a member of an immigrant family; eighty percent of parents were not born in the United States, with most coming from the Caribbean and Latin America. The majority of the students came from a two-headed, married household (49%) and 34 percent came from a household headed by a single female. Using the eligibility for free and reduced lunch statistics from the Providence School Department as a proxy for economic status, this population was mostly low-income, where 71.2 percent of the students received a free lunch and 13.6 percent received a reduced lunch rate.

Data sets

This study was designed to explore what teenagers do during a typical semester. Within a classroom setting, students were instructed to develop a list of at least 15 out-of-home regular or occasional activities, including the location and the mode used to access the activity. All food related activities provided the data for this paper. In this study three main datasets: students' socio-demographic data, their food activity lists, and the location data of local food businesses, were used to explore factors related to the frequency of visiting healthy and unhealthy food establishments.

Socioeconomic Background and Activity Lists

The dependent variable in our model represents the actual number of visits to food establishments of one hundred and twenty-two Feinstein High School students in Providence, RI. Independent variables used to predict eating behavior describe the individual and the individual's household. Socioeconomic and cultural data include ethnicity, gender, age, U.S. citizenship status, birthplace, and employment status. Since students were not directly asked about household income, several variables were used to describe the economic standing of the household including the number of cars in the household, the number of household members and employed members, head of

household type, and the birthplace of the mother and father. Students were also asked if they were employed part-time and if they were eligible for the free or reduced National School Lunch Program. These variables were included in the models to better understand how the individual, the household structure, and the social and cultural status of this student population affect eating patterns outside the home.

Students recorded a total of two thousand and nine activities, approximately 16.5 activities (2009 divided by 122) per student. The record field contains information about each activity pursued by the student, i.e. the students' ID numbers, names of places where students pursued activities, activity types, activity time duration, frequency of the activity, time of day the activity takes place, distance between activities and home locations, modal use, and individuals accompanying the students to the activity. The activity type field reveals that the majority of the activities were related to food visits (n=653, 33%) to fast-food establishments, dining, grocery stores, and convenience stores. All food related activity choices form the dependent variable, including the frequency of visits to specific food establishments, which are weighed against the eating pattern variables.

Food establishments Location Data

The food location dataset was treated as an independent variable. Location data of food establishments were collected from the Providence Plan (PP), a private nonprofit organization that has been working with the State Health Department to improve the health of Providence residents, and the Rhode Island Yellow Pages. The PP provided information on the location of 6,221 local food businesses. The dataset includes business names, addresses, license numbers, license types, and the number of chains. From the Rhode Island Yellow Pages, we captured data from 209 local businesses with names, addresses, and types of businesses based on the North American Industry Classification System (NAICS). The two datasets were combined, cleaned, and overlapping entries were eliminated.

In order to restrict our food environment dataset to businesses related to teenagers' eating behaviors, we used the NAICS code from the Yellow Pages to eliminate liquor stores, pubs, taverns, nightclubs, and cigarette stores, due to limitations on who can enter. In addition non-profit food stores or markets, hospitals, residential care facilities, elderly housing, and nursing homes were removed. Establishments serving food as a supplemental service were also eliminated, i.e. restaurants in hotels, inns, lodging places, and cafeterias in schools or civic clubs. Catering businesses carrying food or cooks to places requiring food services were also excluded. According to NAICS, a caterer is an industry comprising establishments primarily engaged in providing single-based food services, so that these businesses generally have equipment and vehicles to transport meals to events or prepare food onsite. Graduation parties, wedding parties, retirement parties, and trade shows are examples. However, caterers serving food in established places were considered general restaurants. If the business license type was "caterer or commissary" and the NAICS code was "caterer," the business was eliminated. On the

other hand, if the license type was "caterer or commissary" and the NAICS code was "full service restaurants" or "limited service restaurants," the business was included in the analysis. Finally, businesses having no address, business type or NAICS code were eliminated. After editing the dataset based on these criteria, 3,250 records entered our analysis.

Categories of food environments

Prior to categorizing food stores or restaurants as an healthy, intermediate healthy, or unhealthy food resource, it was important to develop an understanding of the types of food these places provide. Some food stores or markets deal with a single type of food, such as healthy food (e.g. fruits, vegetables, and other organic food) or unhealthy food (e.g. burgers, fried chicken, or pizza). These classifications are clear-cut. However, in the case of food stores providing both unhealthy and healthy food, such as general family restaurants, classification is more complex. The straightforward way to classify this type of food store or restaurant is to survey all items sold at the location. However, the time and cost of surveying all the food sold in a store would be great.

An easier way to classify food stores is to refer to government industry codes. Many governmental statistical bodies have tried to collect and summarize economic information in order to set economic policy, and this business information then functions as major indices of economic policies. In the U.S., there are two main industrial indexes, the Standard Industrial Classification (SIC) and the North American Industry Classification System (NAICS) established by the federal government. The industrial codes classify business establishments in terms of their types of healthy or services, size of establishment and types of services. Some scholars define food stores based on these industry code systems. Morland et al. (2002) defined types of food stores and food service places with 1997 NAICS codes. According to the codes, they classified food stores into supermarkets, grocery stores, convenience stores, convenience stores with gas stations, specialty food stores, full-service restaurants, fast-food restaurants, carryout specialty items, and bars and taverns[18].

Rundle et al (2009) defined food stores as three types of food environments: healthy, intermediate, and unhealthy[24]. Within these definitions, vegetable stores, supermarkets or grocery stores, and natural/health food stores are classified as healthy food stores. Other non-fast-food restaurants, medium-sized grocery stores, fish markets, and specialty food stores are categorized as intermediate food stores. Fast-food stores, pizza restaurants, convenience stores, bodegas, bakeries, candy and nut stores and meat markets are unhealthy food stores. Referring to Rundle's definition of the supermarket, NAICS codes regarding food stores are classified into the three types of food stores as shown in Table 1.

Distance to Food Establishments (Cumulative Approach)

The cumulative approach model was used to measure the availability of food establishments for each youth. Although the cumulative method is an old approach and has the disadvantage of tending to omit complex factors, the method is useful if researchers have limitations in getting detailed information, and the theory can simplify reality. For these reasons, many scholars still employ the method. The availability of food establishments was measured by counting the number of food establishments around students' homes and the school within a walking distance of one kilometer, using ArcGIS, a geographic information systems program[25,26]. After the buffer analysis, the "Intersect" tool in ArcCatalog was used to obtain the number of food establishments for each student. This number represents the availability of food establishments.

Analysis Methods

Multinomial logistic regression models determined the relationship between the probability of visiting healthy/unhealthy food establishments and the availability of healthy/unhealthy food establishments and socio-demographic factors. The multinomial logistic regression is "a form of regression which is used when the dependent variable is dichotomous and the independent variables are of any type."[27]. The food type information of visited food establishments can be healthy, intermediate, or unhealthy. However, the three categories were transformed into binary forms, such as healthy or not (intermediate or unhealthy) and unhealthy or not (healthy or intermediate) to estimate the models and interpret the information easily. Thus, two regression models were established—a model about the probability of visiting healthy food environments and a model about visiting unhealthy food. If a student visits one healthy, one intermediate, and one unhealthy food resource, then the model for estimating the probability of visiting healthy food environments becomes 1, 0, and 0, respectively. In the case of estimating the probability of visiting unhealthy food environments, the food types of these stores would be represented as 0, 0, and 1, respectively.

If the number of explanatory variables to affect the occurrence of an event, E, is n, the equation to explain the probability of the event occurring becomes

$$p(E) = \frac{1}{1 + \exp(-z)}$$
$$z = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_n x_n$$

, where p(E) indicates the probability of the event, E, occurring, and z is a linear combination of the explanatory variables, x. The parameter of each explanatory indicates β . Generally, we obtain the parameters by maximum likelihood methods. Logistic regression models are expressed by odds ratio (OR), so that OR can be

$$OR = \frac{P(E)}{1 - P(E)} = \exp(z)$$

Transforming the equation, using the logarithm form, the equation, explained by z, becomes a linear combination of independent variables.

$$\log\left(\frac{P(E)}{1-P(E)}\right) = z = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_n x_n$$

If a parameter, β_n of an independent variable, x_n, has a negative value, the odds ratio is less than 1, which means the probability of the event occurring decreases by an increase in the independent variable. Three models are used to explain the probability of accessing healthy food, unhealthy food, and intermediate food. This paper employs the logistic model to two cases, healthy and unhealthy food.

Results and Discussion

Cross table analysis

In terms of gender, female students tended to visit healthy food establishments more frequently than male students, and male students visited unhealthy food stores or restaurants more often than female students (Table 2). Twenty-one percent of food sources visited by females were healthy, while sixteen percent of food establishments visited by boys were healthy. Compared to other ethnic groups, Hispanic/Latino students visited more healthy food stores or restaurants (21%). Students who qualified for free or reduced lunch frequented unhealthy food establishments more often, compared to those who did not qualify.

Results from logistic regression models

The multinomial logistic model shows that the number of healthy food establishments within walking distance from home, frequency of visit to food establishments, gender, employment status, and ethnicity significantly affect visits to unhealthy food environments ($p < 0.05$) (Table 3). When the number of healthy food establishments increase, the probability to visiting unhealthy food environments significantly decreases ($p = 0.0469$). Students who live in areas with a significant number of unhealthy food establishments are slightly more likely to visit unhealthy food establishments ($OR = 1.05$). Males are two times more likely to visit unhealthy food environments ($OR = 2.10$). African Americans are three times more likely to visit unhealthy food stores or restaurants than other ethnicities ($p = 0.0144$, $OR = 2.89$). Students living with married parents visit fewer unhealthy food sources ($p = 0.0395$). Students not living with married parents are two times more likely to visit unhealthy food establishments than other students ($OR = 1.69$). Students who are not employed are two times more likely to visit unhealthy food environments than students who work ($p = 0.0187$, $OR = 2.01$).

There are fewer factors that affect visits to healthy food establishments (Table 4). Only two variables are significant; the availability of healthy food and gender. The more healthy food environments around the home location, significantly increase the frequency adolescents visit healthy food establishments ($p = 0.0393$). Students, who live in areas having more healthy food resources, are slightly more likely to visit healthy food establishments ($OR = 1.06$). Females are two times more likely to visit healthy food establishments than males ($p = 0.0267$, $OR = 1.90$). The model that predicts visits to healthy food is not sensitive to the number of unhealthy food locations within walking distance from the home location.

Conclusion

Eating is essential to sustaining our bodies and lives. Sustaining a human body heavily depends on which foods are eaten, as well as how frequently foods are consumed. Due to revolutionary changes in the food industry and the growth of wealth, most people in developed countries, especially the U.S., do not need to be concerned about the infrequency with which they are able to consume food. Unfortunately, these changes have not guaranteed that all people obtain high-quality food. Despite the fact that starvation is not a major threat in the U.S., many people suffer from diseases caused by consuming unhealthy food. Furthermore, food access differs by socioeconomic status. Many studies have proven that socially and economically disadvantaged groups are less likely to access healthy food for two main reasons: low accessibility due to incomes that are not sufficient to buy healthy food, and low accessibility to healthy food environments due to spatial segregation by race or income.

Findings

This paper is an empirical study investigating which factors influence youths' visits to food establishments and the extent of their influence. A main assumption is that the availability of food environments around youths' homes and their socioeconomic backgrounds affect their eating behaviors. In terms of the availability of food environments, more healthy food environments surrounding youths' homes encourage them to visit more healthy food establishments, whereas the existence of more unhealthy food around youths' homes encourages them to visit more unhealthy food establishments. Because children have fewer options in modal choice than adults, their eating places are often within walking distance of school and home. In terms of socioeconomic background, race, family status, income level, and cultural background, such as parents' origins, affect youths' choices of food establishments. Before testing these assumptions, the overall socioeconomic status of Providence, RI was reviewed, and the accessibility level of food sources by communities or neighborhoods in the city were calculated. After looking at the demographic and economic situations of the city, examining the accessibility levels of food environments in the city, and testing assumptions about youths' eating behaviors and several factors, this study made several important findings.

A multinomial logistic regression model was used to understand the probability of visiting unhealthy food environments. Independent factors included the availability of healthy food environments, gender, race, working status, and family status. The results revealed that the more unhealthy food stores around students' homes, increased the probability of visiting unhealthy food stores or restaurants for young people. Students, having a greater availability of unhealthy food establishments around the home location, are slightly more likely to access unhealthy food. Based on the results, the hypothesis about the availability of food environments was proven acceptable.

In addition, assumptions about the relationship between visiting food establishments and socioeconomic background can be accepted based on the results of the model. In terms of gender, male students are two times more likely to visit unhealthy food environments than female students ($OR = 2.10$, $p = 0.0031$). This suggests that females tend to be more concerned about the quality of food. In terms of race, if a student is African American, the student is three times more likely to be at risk of visiting unhealthy food establishments ($OR = 2.89$, $p = 0.0144$). The effects of being African American warrant further research. This may be linked to being socioeconomically disadvantaged compared to other races, or more likely to live with one parent families. Students living with unmarried or single parents are two times more likely to access unhealthy food environments than those who live with married parents ($OR = 1.69$, $p = 0.0395$). Students who do not work are two times more likely to access unhealthy food than those working ($OR = 2.01$, $p = 0.0187$). Employed students may be using their financial resources to support the family. Further research is needed.

Limitations

This paper contributes to defining the factors that affect youths' eating behaviors in terms of physical environment and socioeconomic factors. However, this paper has three limitations in addressing youths' eating behaviors, in terms of dataset and explanatory variables. This study did not collect data on purchasing or actual eating behaviors. The source of data came from a larger activity analysis where students were asked to provide information concerning places where they typical go during a semester; thirty-three percent of these activities were visiting food establishments. Food environments were categorized into healthy, intermediate, and unhealthy, based on NAICS and other business information in the Yellow Pages. Using NAICS is a convenient method of classifying food environments. However, the NAICS system tends to simplify the characteristics of an industry, so that the code system could lose some detailed food information. For instance, even though grocery stores or supermarkets are likely to sell more healthy food than convenience stores, they also provide unhealthy food. Moreover, relatively small grocery stores and supermarkets tend to offer more unhealthy food. It is not easy to capture more detailed nutrition information with NAICS. This challenge can exist in restaurants providing both healthy and unhealthy food, such as family restaurants. Even though the criteria used in previous studies that categorized food stores based on the nutrition compositions of the stores or restaurants was employed, the loss of detailed nutrition information was inevitable. If it is possible to get the number of food items by food type for each food store or restaurant, the proportion of healthy food in the stores can be used, instead of categorizing the food stores as healthy, unhealthy, and intermediate food environments.

In the statistical models used to explain youths' food establishment visitation patterns, this study tried to find socioeconomic factors affecting visits to unhealthy and healthy food establishments, which may be influenced by one's cultural background. The mother's and father's origins were used to represent cultural background. However, these variables had very low explanatory power when analyzing youths' food visitation patterns. This result may be due to the limitations of the collected data. It is difficult to quantify cultural background. In addition, the majority of the respondents were low-income. There is practically no variability in income status. In order to overcome this disadvantage, future studies need to conduct a qualitative survey to address the effects of cultural background on eating behaviors.

Planning for Countering Climate Change: Lessons from the Recent Plan of New York City - PlaNYC 2030

Introduction

In recent years, we have become increasingly aware of the environmental degradation and huge risks and uncertainties that climate change poses to our cities and communities (IPCC 2007, 719). Climate change is likely to affect the social, economic, ecological, and physical systems of any given city. It is supposed to bring higher temperatures, more intense rainstorms, droughts and heat waves, increased strains on materials and equipment, higher peak electricity loads and voltage fluctuations, transport disruptions, and increased need for emergency management. Ironically, cities themselves, through their economic production and modes of consumption, are major contributors to the environmental crisis. Apparently, cities and city planning have an important role to play in contending with the future impact of climate change, which, with its many complexities and uncertainties, poses new challenges for the planning profession. For this reason, generating a broad understanding of planning's role in fighting climate change is now emerging as a crucial task for planners, who are still in the preliminary stages of setting agendas and exploring possible directions (Kern and Alber 2008; Priemus and Rietveld 2009; van Leeuwen et al. 2009; Swart et al. 2009). Swart et al. (2009, 152) argue that although spatial planning is considered to be an essential lever of adaptation policy, "the references made to planning instruments widely remains very generic and vague" and "the specific potential of planning tools is, therefore, not yet addressed." Moreover, even though planners and planning have the "ability to think the big, long-term thoughts about the interrelatedness and interdependency" of complex issues such as hazard mitigation and climate change (Schwab 2010, 5), many cities around the world, including the most pioneering among them, still fail to utilize comprehensive and spatial planning in their fight against climate change (Kern and Alber 2008).

A review of recent urban plans aimed at countering climate change highlights three types of planning practices. The first, which has been used by a large number of cities, is the use of *mitigation* policies aimed at GHG emission reduction. The second has been used by a smaller number of cities, and involves the use of *adaptation* policies, in addition to *mitigation* policies, to contend with risks posed by climate change. The third, which has emerged more recently and has been used by only a handful of cities, promotes a more inclusive planning practice based on *mitigation* and *adaptation* policies, in addition to further integration of spatial, social, and economic policies. The ultimate outcome of this third type of practice is the construction of a new emerging approach to planning which I refer to here as *Planning for Countering Climate Change (PCCC).*

This paper explores and characterizes the emerging approach of PCCC and offers a thorough assessment of its advantages. More specifically, it examines the tools and procedures utilized by PCCC, as well as the role of *climate change* in shaping the planning process and its various components, beginning with problem formulation and culminating in its many outcomes.

New York City is one of the few cities in the United States and the world to employ such practices. This paper will analyze and gain new insight from the City's recent plan, *PlaNYC 2030*, which employs a PCCC approach to city planning.

Research Methods

This paper examines the role and influence of *climate change* through an analysis of the main components of the planning process, which include: formulation of the plan's problem statement, vision, and goals; its procedure and planning approach; its scope and the issues it considers; and its final outcomes. By considering questions related to the importance of climate change for each component, this paper provides us with a sound understanding of the role of climate change in city planning and the advantages of PCCC in the effort to counter climate change. The components analyzed and the questions asked are as follows:

1. *Problem Statement*: Overall, the goal of the problem statement is to justify the planning mission and present supporting evidence to convey a basic understanding of the nature and extent of the problems facing the city. What role does climate change play in the main problems addressed by the plan, and how is this role reflected in the problem statement?
2. *Visioning and Goal Setting*: What role does climate change play in the planning vision and goals of the plan?
3. *Procedure*: How was the plan generated? Who participated in the process? What was the nature of public participation?
4. *Approach*: What applied planning approaches (new urbanism, sustainable development, etc.) were utilized during the planning process?
5. *Scope of Issues*: What issues does the plan address? Does it focus only on environmental aspects and GHG emission reeducation, or does it also address relevant social and economic issues?
6. *Outcomes*: What is the nature and scope of the various final products of the planning process? Do these components focus primarily on mitigation and adaptation policies? Do they also incorporate social and economic policies and initiatives?

For the purpose of this study, we reviewed *PlaNYC: A Greener, Greater New York*, and several other related documents published by the city of New York, including: *PlaNYC: Progress Report 2009*; *Climate Change Report* (2009); *Energy Conservation Plan* (2008); *Greenhouse Gas Inventory* (2008); *Municipal Energy Conservation* (2008); *Think Locally, Act Globally: How Curbing Global Warming can Improve Local Public Health (2008)*; *PlaNYC: Inventory of New York City Greenhouse Gas Emission*. (2009); and *NPCC - New York City Panel on Climate Change*: *Climate Risk Information* (2009).

Problems Statement

Climate change played a major role in formulating the problems facing New York City and justifying the urgency of the new plan. A fundamental assumption of PlaNYC, which was launched on Earth Day 2007, is that "climate change poses real and significant risks to New York City" (*PlaNYC: Progress Report 2009*, 39). Both PlaNYC and the NYC Panel on Climate Change (NPCC 2009), a public body

proposed by PlaNYC and convened by the mayor of New York in 2008, portrays New York as a city at risk.

The NPCC holds that "climate change poses a range of hazards to New York City and its infrastructure" and that "these changes suggest a need for the City to rethink the way it operates and adapts to its evolving environment" (NPCC 2009, 3). Climate change is likely to bring warmer temperatures to New York City and the surrounding region, as the mean annual temperatures projected by global climate models are expected to increase by 1.5- 3 degrees (Fahrenheit) by the 2020s, 3-5 degrees by the 2050s, and 4-7.5 degrees by the 2080s (NPCC 2009). The city will also experience more intense rainstorms, while annual precipitation is likely to increase and droughts are likely to become more severe toward the end of 21st century. Heat waves are also expected to become more frequent, intense, and longer in duration, and sea levels are likely to rise, with increase of 2-5 inches by the 2020s, 7-12 inches by the 2050s, and 12-23 inches by the 2080s. In contrast to the period preceding the industrial revolution when sea levels rose at rates of 0.34 to 0.43 inches per decade, current rates of increase around New York City range from 0.86 and 1.5 inches per decade (NPCC 2009, 5-9; Gehrels, et al. 2005; Holgate and Woodworth 2004). As a result, general flooding and storm-related coastal flooding are likely to increase as well (NPCC 2009, 4). New York City has almost 578 miles of coastline and over half a million residents living within the current flood plain, and this poses a particularly dangerous risk to the city. At the current sea level, NPCC holds that New York City already faces the probability of a "hundred year flood" once every 80 years. This could increase to once every 43 years by the 2020s and to once every 19 years by the 2050s. According to one estimate, a Category 2 hurricane would inflict more damage on New York than on any other American city except Miami (NPCC 2009, 8).

As a result, climate change poses particular threats to New York's infrastructure, including: increased summertime strain on materials; higher peak electricity loads in summer and reductions in heating capacity in winter; voltage fluctuations, equipment damage and service interruptions; increased demands on HVAC systems; transportation service disruption; increased street, basement and sewer flooding; reduction of water quality; inundation of low-lying areas and wetlands; increased structural damage and impaired operations; and increased need for emergency management procedures (NPCC 2009, 4-30).

In addition to these threats, the already deteriorating physical condition of the City's infrastructure adds dramatically to the uncertainties surrounding climate change. According to PlaNYC (2007, 7), the City's infrastructure "is the oldest in America." Not only are the subway system and highway networks heavily-used, but about 3,000 miles of roads, bridges, and tunnels are in need of repair, as are many subway stations. To make matters worse, the water infrastructure has not been inspected in more than 70 years, and 52% of the city's tributaries that run adjacent to the shoreline and pass through neighborhoods are unsafe even for boating. Finally, about 7,600 acres throughout the boroughs remain contaminated, and the city suffers from one of the worst asthma rates in the country (PlaNYC, 7). Between the years 2000 and 2005, New York's greenhouse gas emissions increased by almost 5% (PlaNYC, 135), which is of particular significance because New York City emits

nearly 0.25% of the world's total greenhouse gases. As a coastal city, PlaNYC concludes, "we are vulnerable to the most dramatic effects of global warming: rising sea levels and intensifying storms" (PlaNYC, 133).

In this way, climate change and its effects play a decisive role in the manner in which PlaNYC describes the problems currently facing the city, which may lead to a dramatic deterioration of life in the city in the future.

Visioning and Goal Setting

Climate change is central to the visioning of New York City according to PlaNYC. PlaNYC begins by *diagnosing* the local and global climate change crisis as problematic and critical for NYC and the world as a whole. The plan portrays New York as the most sustainable and "one of the most environmentally efficient cities" in the United States (PlaNYC, 135), producing "less than a third of the CO2e generated by the average American." In this way, it explains, "Growing New York is, itself, a climate change strategy." According to the Plan, New York City is a globally responsible, pioneering, modern and innovative city – a city with an "unending sense of possibility" (PlaNYC, 130). Still, PlaNYC acknowledges, "in spite of our inherent efficiency, we can do better. And we must. Instead we are doing worse" (PlaNYC, 135). As one of the world's most spectacular cities, planners hold, New York should seize the opportunity and "define the role of cities in the 21st century and lead the fight against global warming" (PlaNYC, 130). The City "cannot afford to wait until others take the lead" on curbing climate change. "New York has always pioneered answers to some of the most pressing problems of the modern age," the planners argue, and "it is incumbent on us to do so again, and rise to the definitive challenge of the 21st century" (PlaNYC, 9).

PlaNYC's vision generates a sense of local and global *urgency*: "unless the public…appreciate[s] the urgency," it warns, "…we will not meet our goal" (PlaNYC, 110). "Meanwhile, we will face an increasingly precarious environment and the growing danger of climate change that imperils not just our city, but the planet. We have offered a different vision… It is a vision of New York as the first sustainable 21st century city— but it is more than that. It is a plan to get there" (PlaNYC, 141).

PlaNYC promises a *better future*: "The result, we believe, is the most sweeping plan to strengthen New York's urban environment in the city's modern history… we have developed a plan that can become a model for cities in the 21st century" (PlaNYC, 10).

> "It is a vision of providing New Yorkers with the cleanest air of any big city in the nation; of maintaining the purity of our drinking water;…; of producing more energy more cleanly and more reliably, and offering more choices on how to travel quickly and efficiently across our city. It is a vision where contaminated land is reclaimed and restored to communities; where every family lives near a park or playground; where housing is sustainable and available to New Yorkers from every background, reflecting the diversity that has defined our city for centuries" (PlaNYC, 141).

PlaNYC casts "climate change," or "sustainability," as a major concern and central theme of the plan. New York City Mayor Michael Bloomberg describes PlaNYC as "a long-term vision for a sustainable New York City" which "has been acknowledged around the world as one of the most ambitious – and most pragmatic – sustainability plans anywhere" (*PlaNYC: Progress Report 2009*, 4). He also maintains that each of the plan's 127 initiatives "will not only strengthen our economic foundation and improve our quality of life; collectively, they will also form a frontal assault on the biggest challenge of all: global climate change" (*PlaNYC: Progress Report 2009*, 2).

The vision advanced in PlaNYC includes solutions and planning strategies, calls for collective action, and promises that "We can do better. Together, we can create a greener, greater New York" (PlaNYC, 3). In the words of the mayor, "Truly, PlaNYC has become a citywide effort…we are creating a better and more sustainable city – one that will rise above the current economic turmoil and show the world how it is possible to come back stronger than ever… The City is committed to these goals, and together, I know we can build a greener, greater New York" (*PlaNYC: Progress Report 2009, 4).*

The vision of PlaNYC is ambitious: its practical aim is to reduce emissions by 30%, and its physical agenda is to develop NYC as a "greener, greater New York." The vision adequately addresses local and global climate change as a central concern of planning and future development. It aims to inspire and mobilize New Yorkers to collectively adhere to the planning initiatives and to build consensus and legitimacy for its implementation. For this reason, the word '*we*' appears 1,708 times in the 156 pages of PlaNYC, or about 11 times per page. At the same time, however, the vision overlooks the city's rich social and cultural agenda, which stems from its diversity. Strikingly, even though New York is "more diverse than ever; today nearly 60% of New Yorkers are either foreign-born or the children of immigrants" (PlaNYC, 4) - with 174 languages spoken by the city residents - the vision neglects the social and cultural issues that are relevant to this majority of the city's population.

PlaNYC classifies its main goals under six main themes, as shown in Table 1. All of the plan's main themes, and nine of its ten goals, are physically and environmentally oriented, while only one goal, which focuses on housing and affordability, can be considered social in nature. In this way, climate change clearly plays a key role in the vision of the City and maintains a strong implicit and explicit presence within the plan's goals.

Table 1. Goals of PlaNYC

Main Theme	Sub-Theme	Goals
Land	Housing	*"Create homes for almost a million more New Yorkers, while making housing more affordable and sustainable."*
	Open Space	*"Ensure that all New Yorkers live within a 10-minutes walk of a park."*
	Brownfields	*"Clean up all contaminated land in NYC."*
Water	Water Quality	*"Open 90% of our waterways to recreation by preserving natural areas and reducing pollution."*
	Water Network	*"Develop critical backup systems for our aging water network to ensure long-term reliability."*
Transportation	Congestion	*"Improve travel times by adding transit capacity for millions more residents, visitors, and workers."*
	State of Good Repair	*"Reach a full 'state of good repair' on NYC's roads, subways, and rails for the first time in history."*
Energy	Energy	*"Provide cleaner, more reliable power for every New Yorker by upgrading our energy infrastructure."*
Air	Air Quality	*"Achieve the cleanest air quality of any big U.S. city."*
Climate Change	Climate Change	*"Reduce global warming emission by 30%."*

Source: Based on information contained in *PlaNYC*, pp. 15, 51, 73, 99, 117, 131.

Procedure

Despite the significant planning it embodies and the crucial dilemmas it raises, PlaNYC the mechanism and procedures it proposes for facilitating citizen participation in the planning process are wholly inadequate. PlaNYC asks: "What kind of city should we become?" and asserts: "We posed that question to New York" (PlaNYC, 9). However, instead of a systematic procedure for public participation, the planners employed participation methods that were disorganized at best:

> "Over the past three months, we have received thousands of ideas sent by email through our website; we've heard from over a thousand citizens, community leaders and advocates who came to our meetings to express their opinions; we have met with over 100 advocates and community organizations, held 11 Town Hall meetings, and delivered presentations around the city. The input we received suggested new ideas for consideration, shaped our thinking, reordered our priorities" (PlaNYC, 9).

Notwithstanding this process, it is clear that public participation in the process was inadequate and insufficient for meeting the planning challenges stemming from climate change for one of the world's most socially and culturally

diverse cities. PlaNYC poses important urban dilemmas but does little to elicit real community participation. Instead, the planners appear to provide the answers themselves, in the name of New Yorkers: "By moving ahead, we will continue to ensure that the essential character of the city's communities remains intact as we seek out …opportunities for public rezonings" (PlaNYC, 21).

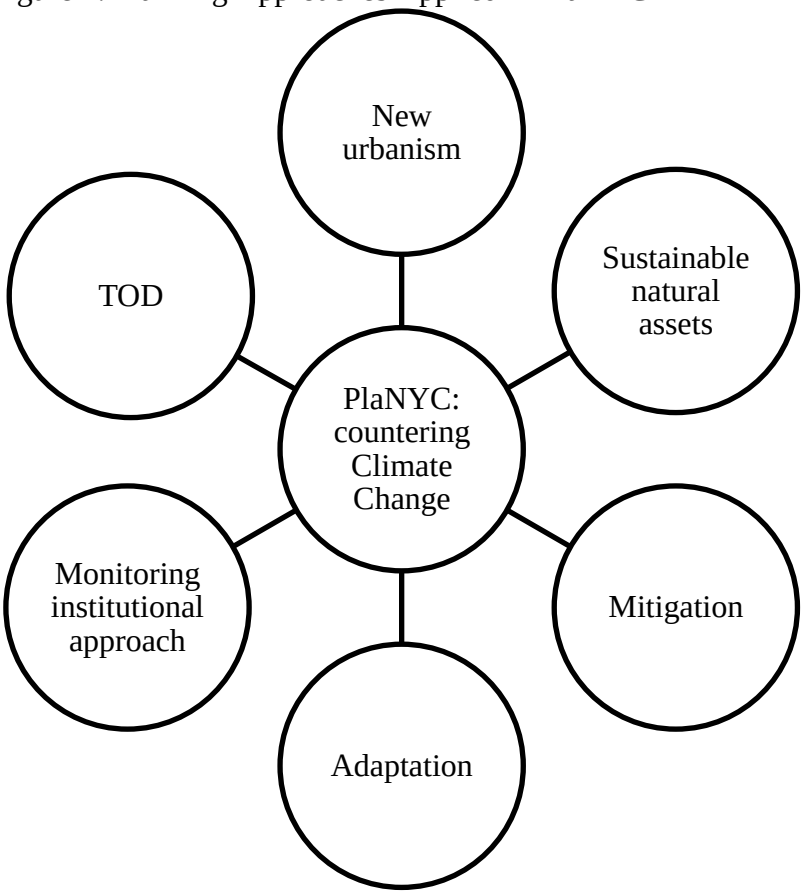
PlaNYC encourages community involvement in significant planning issues *in the future* and reflects little interest in community involvement during the preparation of the plan itself. In this spirit, it suggests *future engagement* in developing adaptation strategies, mainly by working "with vulnerable neighborhoods to develop site-specific strategies," and to "create a community planning process to engage all stakeholders in community-specific climate adaptation strategies" (PlaNYC, 138). PlaNYC also suggests working with communities while exploring potential sites for development in their communities (PlaNYC, 25), and in the rezoning of brownfields (PlaNYC: 44). Tom Angotti (2008) criticizes PlaNYC's community participation and suggests that instead of carrying out a single discussion with each of the 59 Community Boards the plan "could challenge each community to come up with its own priorities for long-term sustainability, affordable housing creation, open space, and transportation. Let the communities speak."

Planning Approach

PlaNYC is an inclusive plan for a big city. Its current population is approximately 8,363,700 (US Census Bureau 2009), and its target population for 2030 will surge past nine million (PlaNYC, 6). By the same year, the work force will grow by 750,000 jobs, there will be a need for 60 million square feet of additional commercial space (PlaNYC, 6), and the number of annual visitors to the city will reach 65 million. These additional jobs, tourists, and residents are expected to "generate an additional $13 billion annually" (PlaNYC, 6).

After careful analysis, this paper concludes that PlaNYC makes advantageous use of various planning approaches, particularly new urbanism, TOD (transit-oriented development), sustainable natural capital, mitigation policies, adaptation policies, and *institutional monitoring* approach. Together, these approaches contribute to current efforts to plan with an eye toward countering climate change in New York City. Their primary thrusts and the roles they played in the planning process can be understood as follows:

Figure 1. Planning Approaches Applied in PlaNYC



1. Sustainable Natural Assets: The concept of maintaining constant natural capital is an important criterion for sustainability. Natural capital should be kept constant over time in order to ensure that future generations will be able to generate wealth and well-being without harming the ecological system (Pearce and Turner 1990). PlaNYC focuses on three aspects of natural capital assets: air, water, and land. Its major strategy is asset restoration . To this end, PlaNYC takes the following measures:

(a) *Air:* The plan promotes initiatives to improve air quality and reduce emissions by 30% (PlaNYC, 116). If no action is taken, New York City's carbon emissions will grow to almost 74 million metric tons by 2030 (PlaNYC, 9).

(b) *Water*: The Plan calls for developing critical backup systems for the City's aging water network to ensure long-term reliability, and proposes ways of maximizing urban water absorption when planting trees (PlaNYC, 12, 59). It also proposes the creation of vegetated ditches (swales) along parkways to store direct rainfall and facilitate the natural cleansing of runoff (PlaNYC, 60).

(c) *Waterfronts and Waterways:* New York City has 578 miles of waterfront, which the Plan regards as "one of the city's greatest opportunities for residential development" and as an important site of other types of projects as well (PlaNYC, 22). PlaNYC also confronts the "legacy of the City's industrial past…" "…which treated New York's waterways as a delivery system" (PlaNYC, 51), and proposes the

opening of 90% of the City's waterways to recreation by preserving natural areas and reducing pollution (PlaNYC, 53).
(d) *Trees:* The plan suggests reforesting approximately 2,000 acres of parkland throughout the city by 2017 (PlaNYC, 128).
(e) *Land:* PlaNYC calls for more efficient use of the City's existing stock of land and for the reclamation of the vast majority of vacant, unutilized, and under-used land for development.
2. New Urbanism: PlaNYC actively promotes some of the main tools of new urbanism, including:
a) *Compactness*: The current overall population density in New York City is 25,383 persons per square mile, and the highest density in the city is 128,600 (New York City 2009). Today, less than 4% of the City's buildings account for roughly 50% of the city's built area (PlaNYC, 102). PlaNYC proposes a number of planning strategies to increase compactness within the City. It suggests *infill* "everywhere it is possible" and development of spaces that "are now lightly used," such as parking lots in public housing areas that were developed in the 1930s (PlaNYC, 23). It also calls for developing underutilized areas throughout the city that are well-served by public transportation and other infrastructure; for capturing the potential of transportation infrastructure investments; and for decking over rail yards, rail lines, and highways (PlaNYC, 19-25). Through *rezoning*, PlaNYC aims to continue directing growth toward areas with strong transit access; reclaiming underused or inaccessible areas of waterfront; and exploring opportunities to spur growth through the addition of mass transit (PlaNYC, 21). PlaNYC fosters rezoning and redevelopment of brownfields, which according to the Plan represent one of the City's greatest opportunities and cover some 7,600 acres throughout the five boroughs (PlaNYC, 41).
b) *Mixed Land Use*: PlaNYC encourages mixed land use in future development, mainly by mixing transportation use with residential areas and open spaces. It encourages co-location of the 43,000 acres of city-owned land with other uses. Most of this land is slated to be developed for government operations, "but significant opportunities exist for housing to co-exist with the current use—from libraries to schools to parking lots" (PlaNYC, 22).
c) *Renewal and Utilization*: PlaNYC proposes adapting unused schools, hospitals, and other outdated municipal sites for productive use as new housing (PlaNYC, 23). It also calls for cleaning and utilizing up to 7,600 acres of contaminated brownfields across the city and suggests strategies to "make existing brownfield programs faster and more efficient; to create remediation guidelines for New York City cleanups; and to establish a City office to promote brownfield planning and redevelopment" (PlaNYC, 41-44).
d) *Greening*: In NYC today, the average area of park area per thousand residents is 1.5 acres, and there is an average of one playground for every 1,250 children. Furthermore, in 97 out of the City's 188 neighbourhoods, the number of children per playground is even higher (PlaNYC, 30). In this context, PlaNYC adopts greening as a major strategy and proposes three primary ways to ensure that by 2030, nearly every New Yorker will live no more than a 10-minute walk from a park: 1) by upgrading land already designated as play space or parkland and making it available to new populations; 2) by expanding usable hours at current, high-quality sites; and

3) by re-conceptualizing streets and sidewalks as public spaces. The combined impact of these policies will be the creation of over 800 acres of upgraded parkland and open space across the city (PlaNYC, 31). PlaNYC also calls for beautifying the public realm and undertaking "an aggressive campaign to plant trees wherever possible, in order to fully capitalize on tree opportunities across the city" (PlaNYC, 38). In addition, it proposes the expansion of "Greenstreets" and the transformation of thousands of acres of unused road space into green space. It also suggests offering incentives for green roofs, which can reduce runoff volume and aid other natural process by absorbing and/or storing water (PlaNYC, 60). Since the launch of PlaNYC, 200,000 trees have been planted across the five boroughs (*PlaNYC: Progress Report 2009*, 3).

3. Transit-Oriented Development (TOD): PlaNYC pursues TOD and uses rezoning to direct growth toward areas with strong transit access (PlaNYC, 21). As a result of these policies, New Yorkers will experience more comfortable travel, reduced travel times, and greater reliability, thus achieving a new standard of mobility (PlaNYC, 97). Nonetheless, the city's transportation systems are currently in poor condition. More than half of the city's subway stations are in need of repairs, and the city is more than $15 billion short of what it would cost to get the transit and road networks back into good shape. Trains are crowded, half of the City's subway routes experience congestion, and a large number of New Yorkers have no access to mass transit (PlaNYC, 76). PlaNYC proposes a "sweeping transportation plan" to enable the city to meet its needs through 2030 and beyond. The plan suggests improvement and expansion of the transit network; improvement of bus service; expansion of the ferry system; completion of a master bike plan; reduction of the gridlock on the roads which has become an increasing problem, through better road management and congestion pricing.

4. Institutional Monitoring approach: PlaNYC addresses the future uncertainties of climate change on a general level and proposes primarily institutional measures - the establishment of the NPCC and the Climate Change Advisory Board – to address them. PlaNYC advances an ambitious agenda of measures to "create a sustainable New York City" that "will require tremendous effort: on the part of City officials and State legislators; by community leaders and our delegation in Washington; from the State government and from every New Yorker" (PlaNYC, 140). Nonetheless, planners acknowledge that "the existing organizations, programs, and processes are inadequate to implement these policies" and "no organization is currently empowered to develop a broad vision for energy planning in the city that considers supply and demand together as part of an integrated strategy" (PlaNYC, 104). On this basis, the plan concludes that "there is a clear need for a more comprehensive, coordinated, and aggressive planning effort, focused on the specific needs of New York City," and calls for the establishment of the New York City Energy Planning Board (PlaNYC, 105). It also calls for "changes at the City, State, and Federal levels - for transportation funding, for energy reform, for a national or state greenhouse gas policy" (PlaNYC, 11), and for "creating a new regional financing entity, the SMART Financing Authority, that will rely on three funding streams: the revenues from

congestion pricing and an unprecedented commitment from New York City that we will ask New York State to match" (PlaNYC, 13). In addition, it suggests establishing a City office to promote brownfield planning and redevelopment (PlaNYC, 45). In the ways mentioned above, PlaNYC promotes an integrative approach to the issue of climate change on the formal institutional level. Nevertheless, it fails to effectively integrate civil society and grassroots organizations, such as the 59 Community Districts and the Boards of New York City, into the effort.

5. Adaptation Policies: PlaNYC assumes that "there is no silver bullet to deal with climate change," and that "as a result, our strategy to help stem climate change is the sum of all the initiatives in this plan" (PlaNYC, 135). The Plan's main thrust for climate change adaptation appears to lie in the creation of "an intergovernmental Task Force to protect our city's vital infrastructure" and "to work with vulnerable neighborhoods to develop site-specific strategies" (PlaNYC, 136). In addition, PlaNYC proposes the establishment of a New York City Climate Change Advisory Board and a citywide strategic planning process "to determine the impacts of climate change to public health and other elements of the City and begin identifying viable adaptation strategies" (*PlaNYC: Progress Report 2009*, 39). Proposed adaptation policies also include measures to fortify the city's critical infrastructure, to be implemented through close cooperation among city, state, and federal agencies and authorities; updating the flood plain maps to better protect areas that are most vulnerable to flooding; and working with at-risk neighborhoods across the city to develop site specific plans. "In addition to these targeted initiatives," the Plan reads, "we must also embrace a broader perspective, tracking the emerging data on climate change and its potential impacts on our city" (PlaNYC, 136).

6. Mitigation of GHG Emission: PlaNYC promotes initiatives to improve air quality and reduce emission by 30% by 2030 (PlaNYC, 116). Moreover in order to maximize energy efficiency, PlaNYC calls for focusing this effort on buildings, the city's largest energy consumers (PlaNYC: 107). Over two thirds of the city's energy is consumed within buildings, compared to a national average of less than one third. According to the Plan, "the City has 5.2 billion square feet of space parceled into almost one million buildings" (PlaNYC, 107-108). By 2030, at least 85% of the city's energy will be used by buildings that already exist today. In this way, energy saving measures in existing buildings will result in a seven million ton reduction in global warming emissions. This is significant, for without the measures outlined in the Plan, emissions would rise to almost 80 million metric tons by 2030 (*PlaNYC: Progress Report 2009*, 39). In addition, the plan proposes an extensive education and training campaign in the realm of energy awareness (PlaNYC, 110). The most effective strategy, the Plan asserts, is to reduce the number of vehicles on the road and to simultaneously expand the city transit system and implement congestion pricing (PlaNYC, 136). According to planners, approximately 50% of reductions in CO2 emissions will come from increased energy efficiency in buildings, while 32% will result from improved power generation and 18% from changes in transportation. Planners explain their decision to not rely on "the widespread *use of solar energy in this* plan because its costs today are too high for general use" (PlaNYC, 136). PlaNYC suggests "greening" the Building Code of New York, and proposes focusing

on the reduction of the amount of cement used in concrete, as cement production is an energy-intensive process that releases one ton of C02 for every ton of cement produced (PlaNYC, 106-7).

Scope and Issues

Overall, PlaNYC focuses primarily on physical planning dimensions and less on socio-cultural issues. The vision, goals, strategies, and outcomes of PlaNYC are organized around six physical and environmental themes: land, water, transportation, energy, air, and climate change, none of which are socially or culturally oriented. Practically none of the major thrusts of the plan deal directly with issues of equity and justice, such as diversity, the future of communities and neighborhoods, the cultural diversity of the city and its immigrants, and poverty--a term which appears only once in the entire plan.

Energy in general and *ecological economy* in particular is a central theme of PlaNYC toward the achievement of its climate change objectives. According to the plan, improving the city's energy infrastructure and lowering demand will reduce energy costs by billions of dollars over the next decade; watershed protection will make multi-billion-dollar investments in new water filtration plants unnecessary; and improving public transportation and reducing congestion will reduce the economy's annual $13 billion loss due to traffic delays **(**PlaNYC, 133). By managing demand, increasing the energy supply, and saving energy in existing buildings, the city's overall power and heating bill will plunge by $2-4 billion, resulting in an estimated annual savings of approximately $230 for the average household by 2015. Congestion pricing is projected to generate net revenues of $380 million in the first year of operation, increasing to over $900 million by 2030 (PlaNYC, 96). To this end, PlaNYC proposes an amendment to the City Charter requiring that New York City invest an amount equal to 10% of its energy expenses in energy-saving measures each year. Planners also note that the measures required to execute these initiatives "will create thousands of well-paying jobs" **(**PlaNYC, 133), and that this will mean that the city will have "not only a healthier environment, but also a stronger economy" (PlaNYC, 13). In these ways, PlaNYC provides a number of economic engines to promote climate change objectives and a cleaner environment. Its well based conclusion is that "adapting to climate change and investing in mitigation not only ensures the city's long-term economic vitality, but it will encourage public and private investments in the city's infrastructure, support green jobs, and improve the quality of life and level of service enjoyed by New Yorkers today." (*PlaNYC: Progress Report 2009*, 38).

Affordable housing appears to be one of the only social themes that PlaNYC seeks to address. "The most pressing issue we face today is affordability," planners write. "Between 2002 and 2005 the number of apartments affordable to low-and moderate-income New Yorkers shrank by 205,000 units" (PlaNYC, 18). The Plan assumes that "if supply is not created as fast as people arrive, affordability could suffer further" (PlaNYC, 18). On this basis, it calls for expanding the housing "supply potential by 300,000 to 500,000 units to drive down the price of land" and for pairing "these actions with targeted affordability strategies like creative financing, expanding the use of inclusionary zoning, and developing homeownership

programs for low-income New Yorkers." This, planners hold, will "ensure that new housing production matches our vision of New York as a city of opportunity for all" (PlaNYC, 12). However, in practice, PlaNYC proposes the provision of 500,000 housing units without advancing effective policies for ensuring affordable housing and regaining the more than 200,000 units that have already been lost.

Although PlaNYC notes the existence of *environmental injustice* in the city, it fails to address the issue in a serious manner and takes no practical measures to mitigate the phenomenon. For example, planners acknowledge that most brownfields are concentrated in low-income communities, resulting in a case of severe environmental injustice (PlaNYC, 41). The owners of such land "often find that their financial interests dictate development plans that minimize cleanup requirements" and "may choose new uses for the land" that "do not reflect community needs or desires" (PlaNYC, 42-42). Moreover, "in some communities, the impacts of exposure to local air emissions have likely contributed to higher asthma rates and other diseases" (PlaNYC: 119). These clear cases of environmental injustices also go unaddressed by the plan.

Moreover, NYC is a diverse city with 5 boroughs, 59 community districts and hundreds of neighborhoods. PlaNYC acknowledges that shifting climate patterns will have a wide range of affects on these communities, taking lives and posing "major public health dangers," and impacting the property and livelihood of many (PlaNYC, 138). All five NYC boroughs "have vulnerable coastline." Moreover, the massive growth proposed by PlaNYC will certainly affect these communities, and may even "erase the character of communities across the city" (PlaNYC, 18). In considering the spatial impact of implementing the plan, planners raise a crucial dilemma for the future of New York City and its communities:

> "We cannot simply create as much capacity as possible; we must carefully consider the kind of city we want to become. We must ask which neighborhoods would suffer from the additional density and which ones would mature with an infusion of people, jobs, stores and transit. We must weigh the consequences of carbon emissions, air quality, and energy efficiency when we decide the patterns that will shape our city over the coming decades" (PlaNYC, 18).

Moreover, PlaNYC fails to address the climate change vulnerability, i.e., how climate change could affect each neighborhood, with an emphasis on the specific environmental risks that exist in each neighborhood and that each neighborhood is likely to face in the future.

On a practical level, PlaNYC neglects issues of *socioeconomic* and *cultural diversity*, including crucial socio-spatial issues such as segregation. It also fails to promote a wider variety of housing types. At the same time, however, PlaNYC recognizes that "the mixture of residents will determine, more than anything else, the kind of city we become," and that "by expanding supply possibilities to create healthier market conditions, we can continue ensuring that new housing production matches our vision of New York as a city of opportunity for all." "If New York loses its socioeconomic diversity," planners warn, "its greatest asset will be lost. We can—and must—do better" (PlaNYC, 27).

Outcome

The major planning outcomes are 127 new initiatives that aim, according to PlaNYC, to strengthen the economy, public health, and the quality of life in the city. Collectively, they will form the broadest attack on climate change ever undertaken by an American city. In addition, "most of *PlaNYC's* 127 separate initiatives contribute *directly to achieving the ci*ty's GHG reduction goals: to reduce citywide GHG emissions by 30 percent by 2030 and to reduce City government GHG emissions by 30 percent by 2017" (*PlaNYC: Inventory of New York City Greenhouse Gas Emission, 2009*). Each initiative is meant to achieve multiple goals and at the same time to contribute to the global fight against climate change. Their goals can be classified according to six themes: land, water, transportation, energy, air, and climate change (PlaNYC, 142-145).

In addition to these initiatives, the Plan proposes the establishment of new Planning and Monitoring Boards in order to achieve a more comprehensive, coordinated, and aggressive planning effort, focused on the specific needs of New York City (PlaNYC, 105). It also calls for "changes at the City, State, and Federal levels - for transportation funding, for energy reform, for a national or state greenhouse gas policy" (PlaNYC, 11), and for "creating a new regional financing entity, the SMART Financing Authority, that will rely on three funding streams: the revenues from congestion pricing and an unprecedented commitment from New York City that we will ask New York State to match" (PlaNYC, 13). In addition, it suggests establishing a City office to promote brownfield planning and redevelopment (PlaNYC, 45).

Lessons from *PlaNYC*

Characterizing PlaNYC:

1. PlaNYC is a comprehensive plan that aims to counter climate change.
2. The Plan integrates *climate change* into its planning components. Climate change played a central role in formulating the plan's problem, justification, and visioning and objective settings. The Plan's outcomes were also climate change directed.
3. PlaNYC is physically oriented. It promotes greater compactness and density, enhanced mixed land use, sustainable transportation, greening, and renewal and utilization.
4. PlaNYC applies an integrated planning approach, making use of the advantages of new urbanism, TOD, sustainable development, mitigation, adaptation, and monitoring institutional policies.
5. PlaNYC addresses future uncertainties related to climate change with institutional measures, and enhances the City's urban adaptive planning capacity. It recommends efficient ways of using the city's natural capital assets and pays special attention to strategies for providing New York with cleaner and more reliable power. It creates a number of mechanisms to promote its climate change goals and to create a cleaner environment for economic investment.

6. PlaNYC inadequately address social planning issues - such as social and environmental justice, diversity, poverty, economic development, and spatial segregation - that are crucial to NYC, the most diverse city in the world. It also fails to address the issues facing vulnerable communities due to climate change. New York City is "socially differentiated" in terms of the capacity of communities to meet climate change uncertainties, physical and economic impacts, and environmental hazards. PlaNYC calls for an integrative approach to climate change on the institutional level, but it fails to effectively integrate civil society, communities, and grassroots organizations into the process. The lack of a systematic procedure for public participation throughout the city's neighborhoods and among different social groupings and other stakeholders is a critical shortcoming, particularly during the current age of climate change uncertainty.
7. PlaNYC's focuses on GHG emissions reduction and lacks a proper adaptation strategy, or a strategy of preparing the city and its physical infrastructure for potential disasters caused by climate change shifting. PlaNYC did not make the desired shift toward planning for climate change and adaptation. It therefore seems clear that the planners of PlaNYC have not learned the lessons of Hurricane Katrina as well as they should have.

Advice to Planners for Planning to Counter Climate Change

1. *Planning to Counter Climate Change (PCCC)* is comprehensive and holistic in scope and in the issues it covers. It is integrative and multidisciplinary in its approach to the uncertainties and the complex and multidisciplinary phenomenon of climate change. PCCC integrates climate change into its major planning components. Climate change played a central role in formulating the problem, visioning and goal setting, and the outcomes.
2. *Planning to Counter Climate Change* integrates various planning approaches that aim to achieve its comprehensive objectives, and it is therefore able to utilize the advantages of new urbanism, TOD, sustainable development, mitigation, adaptation, evaluation, and monitoring policies.
3. *Planning to Counter Climate Change* must apply an inclusive, appropriate, and wide-scale approach to public participation.
4. *Planning to Counter Climate Change* must address the current and predicted needs of vulnerable communities. In addition to adaptation policies, hazard mitigation is a crucial aspect of this approach.
5. For their "ability to think the big, long-term thoughts about the interrelatedness and interdependency" (Schwab, 2010: 5) of climate change, planners are indispensible to efforts to counter climate change. They should therefore take on a leadership role and assume more control in fighting climate change on the city level.

Improving the integration between Rural Development Programs and spatial planning tools.

Agata Spaziante and Carlo Rega - DIST - Politecnico e Università di Torino

Introduction

Rural Development is one a major policy in the European Union aimed to promote competitiveness, sustainable management of natural resources, and a balanced development of rural areas (European Commission, 2010). It represents one of the two pillars of the Common Agricultural Policy (CAP), the other one being support to production. Currently, the CAP alone accounts for 34% of the total EU budget, with an annual expense of about 55 billion, of which 85% is allocated to the first pillar and 15% to the second one. Rural Development Programmes (RDP) are the instruments that Member States have to elaborate to target funding from the European Rural Development Fund to farmers.

RDP are structured into 4 main axis:

- Axis 1: Improving the competitiveness of the agricultural and forestry sectors
- Axis 2: Improving the environment and countryside
- Axis 3: Rural quality of life and diversification of the rural economy
- Axis 4: LEADER approach

Actions financed under Axis 1 are embrace a wide array of possibilities: purchasing of new machinery or substitution of old ones, building of new facilities, introduction and commercialization of new products or processes, education and training, support to young farmers, production of energy from biomasses or solar panels. Many of these actions have also a positive repercussion on the environment for example by reducing consumes of energy or water.

Axis 2 finances the so called Agri-environment schemes (AES): actions implemented voluntarily by farmers who receive financial support in return for adopting environmentally friendly farming practices and/or for delivering ecosystem services. Actions include: organic farming, integrated production, fertilisers reduction, pesticides reduction, crop rotation, maintenance of set-aside areas biodiversity conservation and enhancement actions, upkeep of the landscape including conservation of historical features on agricultural land.

Axis 3 promote the diversification of rural economies; financed actions include the establishment of touristic activities (agritourisms), support to the start up of new small enterprises, as well as development of services and facilities in marginal rural areas.

Axis 4 promote integrated actions by local communities through the elaboration of local development programs aimed at promoting and fostering the endogenous development of marginal rural areas. These programs are elaborated and managed by Local Actions Groups, partnerships made up of representatives from local authorities (municipalities), local companies and enterprises, other local agencies, farmers associations, and other relevant stakeholders representative of the local community.

This brief overview shows that rural development programs act on many different aspects with potential interferences or synergies with other planning and programming tools elaborated for other sectors, including spatial planning tools.

In this paper we draw from the case of the Rural Development Program of Piedmont Region (north-west Italy) to investigate its possible interaction with spatial planning tools, with the aim of fostering integration between these two dimensions of territorial governance. In section 2 we further elaborate on the integration issue, with a focus on the Italian context; in section 3 we present the results of an analysis of the content of two main spatial planning tools recently adopted by the Piedmont Regional government and by the Province of Turin, highlighting possible synergies with rural development policies. In section 4 we discuss the findings and point to some relevant emerging aspects for possible further researches.

2. Rural development policies and spatial planning: the need for integration

In the Italian context, the aspect of integration, coordination and harmonization of rural development policies and other territorial governance tools is particularly relevant at the regional level, as regional authorities have many government responsibilities on a number of issues including spatial planning, health, energy, the management of protected areas and transportation.

The RDP is therefore part of a variegated, complex and dynamic framework made up of many different laws, regulations and plans/programs. Furthermore, regions are in charge of elaborating and implementing the programs which are co-financed by the structural funds of the EU, such as the RDP itself and transnational cooperation programs (in the case of Piedmont, France and Switzerland).

Over the last decade, the regional system of territorial governance has undergone a significant shift from a hierarchical, command and control-based model toward a more cooperative one based on the principle of subsidiarity. The Piedmont regional government initiated a process of harmonization and integration of its plans and programs in order to overcome the traditional fragmentation and sectorialization of

the administrative action. To this end, the region elaborated the so-called Framework of Territorial Governance (FTG), gathering together the three main regional plans concerning spatial planning: the Regional Strategic Document, the Regional Territorial Plan and the Regional Landscape Plan, which all contain directives and guidelines for spatial planning, urban development and landscape/environment preservation for other sectors of the regional government (e.g., waste management, water or energy) and lower-tier institutions (provinces and municipalities).

in the Italian context, agricultural policies and spatial plans have traditionally been developed separately: agriculture related policies were designed considering mainly the economic aspects and only to a minor extent in relation to its territorial dimension. Furthermore, farmers' associations have traditionally been influential in steering the design and implementation of rural development policies and support to production.

However, also urban/spatial planning has traditionally paid relatively little attention to rural areas, which have been traditionally considered as "white areas", "not yet urbanized" underestimating their potential both as productive areas, or as biodiversity sinks and providers of ecosystem services. This separation in policies, plans and program-making has been amplified by an administrative separation within regional structures, whereby the rural department is separated both from the spatial planning department and from the environment department.

In pursuing greater integration between rural development policies and spatial planning, a number of key factors have to be considered: the RDP is a programmatic instrument which allocates economic resources among a plurality of stakeholders (mainly farmers), while spatial plans are regulatory instruments establishing rules and constraints for the transformation and/or preservation of the territory, and are not associated with a budget. This has important implications for how these instruments are elaborated and on their subsequent implementation: the allocation of economic resources and the establishment of regulations (which in the Italian context is the main difference between "programs" and "plans") may follow different rationales.

More recently, however, the need of a deeper integration between these two policy field has emerged also among policy-makers at the regional level: on the one hand, at the EU level the CAP increasingly emphasizes the multifunctional nature of agriculture and, therefore, the necessity of pursuing integration and synergies with other sectors; on the other hand, the newest generations of spatial plans are ever more recognizing the intrinsic value of agricultural areas and their importance from an ecological and socio-economic perspective.

In this frame, the Piedmont Region offers a particularly interesting field of research as new spatial plans have been recently elaborated and approved at the regional and

provincial level. In the next section we explore the interactions between rural development policies and spatial planning tools by examining three key planning documents, two of which were elaborated and adopted by the Regional Authority and one by the Province of Turin, namely:

- The Regional Territorial Plan;
- The Provincial Territorial Plan of the Province of Turin

3. Results

The new Regional Territorial Plan (RTP) entered into force in July 2011; it sets the main strategies and rules for spatial and territorial development at the regional level, pursuing the following main objectives:

1. Landscape preservation

2. Environmental sustainability and energy efficiency

3. Territorial integration of the infrastructures of mobility, transportation and logistic

4. research, innovation and productive transaction

5. Valorising human resources and institutional capacities

The RTP also establishes guidelines and rules for the elaboration of plans and programs at lower tiers of government, i.e. provincial and municipal. For the aim of this articles, the contents of the RTP relating to agriculture areas were scrutinized and relevant directives, guidelines or binding norms were identified and sorted out. The results of this exercise are summarized in the following table, in which the first column indicate the reference to the norms of the plans and specify the normative nature of the norm: (guideline/directive of binding prescription)

art. 20 - urban areas outside historic centre (Directive)	local plans shall preserve and valorize agriculture areas at the fringe of the urban fabric as important connection elements of the local ecological network; new developments should be primarily identified within the urban fabric and not in agricultural areas
art. 23 touristic network	Provincial plans should identify potential touristic sites near lakes and rivers and pursue synergies between agriculture and tourism (agritourism). in the territory of hills, traditional agriculture production shall be

	supported, and the stock of traditional rural buildings shall be preserved
art. 24: agriculture areas	Main objectives: to valorize the role of agriculture as a productive activity compatible with the preservation of biodiversity, habitats and the cultural historic assets
24.4 (directive)	Provincial plans shall identify within the rural territory the following areas: • Agriculture areas with particular environmental and landscape features • Highly productive agriculture areas • Peri-urban agriculture areas
art 25 Agriculture areas with particular environmental and landscape features (guidelines)	the main objective for these areas is preservation of their environmental/landscape features. To this end, provincial and municipal plans shall identify existing buildings with a negative visual impact and pursue the re-localization of existing activities in other areas. Allowed developments shall be realized with traditional materials and styles of the context; new facilities can be built only if strictly necessary and they cannot be used for other purposes than agriculture or related ones (agriturism, selling of agriculture products)
art. 26 Highly productive agriculture areas	These areas correspond to the ones classified in classes I or II of land use capabilities, according to the classification introduced y the USDA and based on soil characteristics and morphology. In these areas no limitations to agriculture production exists. In these areas the objectives are to support productions, integrate the income of agriculture and enhance productivity. To this end local plans shall avoid land take in these areas, support production, allow multifunctional uses (such as agriturisms) with the aim of creating new jobs
art. 27 peri-urban rural areas	in these areas located at the fringe of the urban fabric, provincial and local plans shall avoid further fragmentation and soil sealing and support multifunctional activities as source of integrating income for farmers. Plans shall also pursue improvements in the ecological equipments of these areas through tree plantations, installation of hedgerows and foster urban design aimed at demarcating more strongly rural areas from urban ones.
art. 28 Hilly areas	In Piedmont these areas have a strong tradition of vineyards cultivation and wine production. Provincial and local plans shall incentivize and preserve this production, while allowing for multifunctionality of farms oriented to the eno-gastronomic tourism
art. 29 Mountain	these areas the main objective is to contrast marginalization and

territories	abandonment of territories. To this end, their natural and landscape features shall be preserved, and form of income integration for farmers shall be pursued through eco-tourism and preservation of typical cultivations and pastures
art. 31: limitation of land take and soil sealing	Provincial plans shall establish specific rules to limit land take, soil sealing and urban sprawl, promoting the realization of new development in brownfield areas where possible. Municipalities cannot increase their urbanized areas more than 3% over a five year-period

The Provincial Territorial Plan (PTP) of the Province of Turin was elaborated in parallel with the RTP and approved in the same period. It is thus the first provincial plan approved after the entrance into force of the new RTP and shall implement its directives at the provincial scale.

Overall, the PTP pursues a strong policy of limitations of soil sealing and land take and requires that municipal plans subdivide their territory in three types of areas:

- *Dense urban areas* - where the urban fabric is consolidated and long established, and where the main urban services and facilities are located;
- *Transition Areas* - localized at the margins of dense urban areas and characterized by a less dense urban fabric;
- *Free Areas* - where agriculture or natural assets are the predominant land uses.

Following this classification, the PTP require that no new urban developments are planned in free areas: to meet the local demand of housing and other development, municipalities shall use the already existing stock of buildings or infill transition areas.

This undoubtedly represent a strong stand by the provincial government to counter current trends of land take and urbanization, which increased at an average annual rate of more that 2% in the provincial territory in the period 1990-2006. This policy is of course relevant also for rural areas, which, beyond natural and seminatural habitats, constitute the majority of the *free areas* as defined by the plan.

The PTP also introduces the concept of ecological compensation of new developments when they affect free areas or determine negative impacts on natural assets.

The PTP, following the directives of the RTP, also provides for specific policies and rules for agricultural areas, which are summarized in the following table.

art. 17, 21, 25, 27	I and II class soils according to their land use capabilities shall be preserved. No new developments (either residential or productive) are allowed on these areas unless strictly necessary and no other

	alternative are feasible. On these areas municipal plans shall encourage the permanence of agriculture activities and farms, and foster mutifunctionality of agriculture.
art. 26 agriforest sector	the PTP pursues the following objectives: • enhance the natural value and ecological functions of rural areas; • decrease the factor of environmental pressures determined by agriculture activity • increase the carbon sink capacity of agriculture areas new buildings in rural areas shall be realized according to traditional local architectural features and materials.
28 specialised cultivations	Specialised cultivations (DOC or IGP products) shall be preserved and no other land use a part agriculture is allowed on these areas, unless this is strongly motivated by external conditions.
31 peri urban areas	These are agricultural areas located at the fringe of urban areas, often fragmented, and at risk of being urbanized. In these territories local plans shall: incentivize the permanence of agriculture land use; enhance their ecological value by improving their vegetal equipment; improve their visual attractiveness by clearly demarcated the urban-rural edge, promote multifunctional uses according to the principles of the CAP and encouraging farmers to pursue synergies with the regional Rural Development Program

In addition to the directives outlined above, the PTP also designs the Provincial Ecological Network, which is articulated in the following types of areas:

- *Core areas*: comprise protected areas and natura 2000 sites
- *Main corridors:* comprise rivers and main creeks with a buffer
- *Buffer zones:* other areas with significant environmental and landscape features identified by the PTP; woods and wet areas if they are not comprised in core areas or corridors

In the following figure, the provincial ecological network as established by the PTP is depicted.

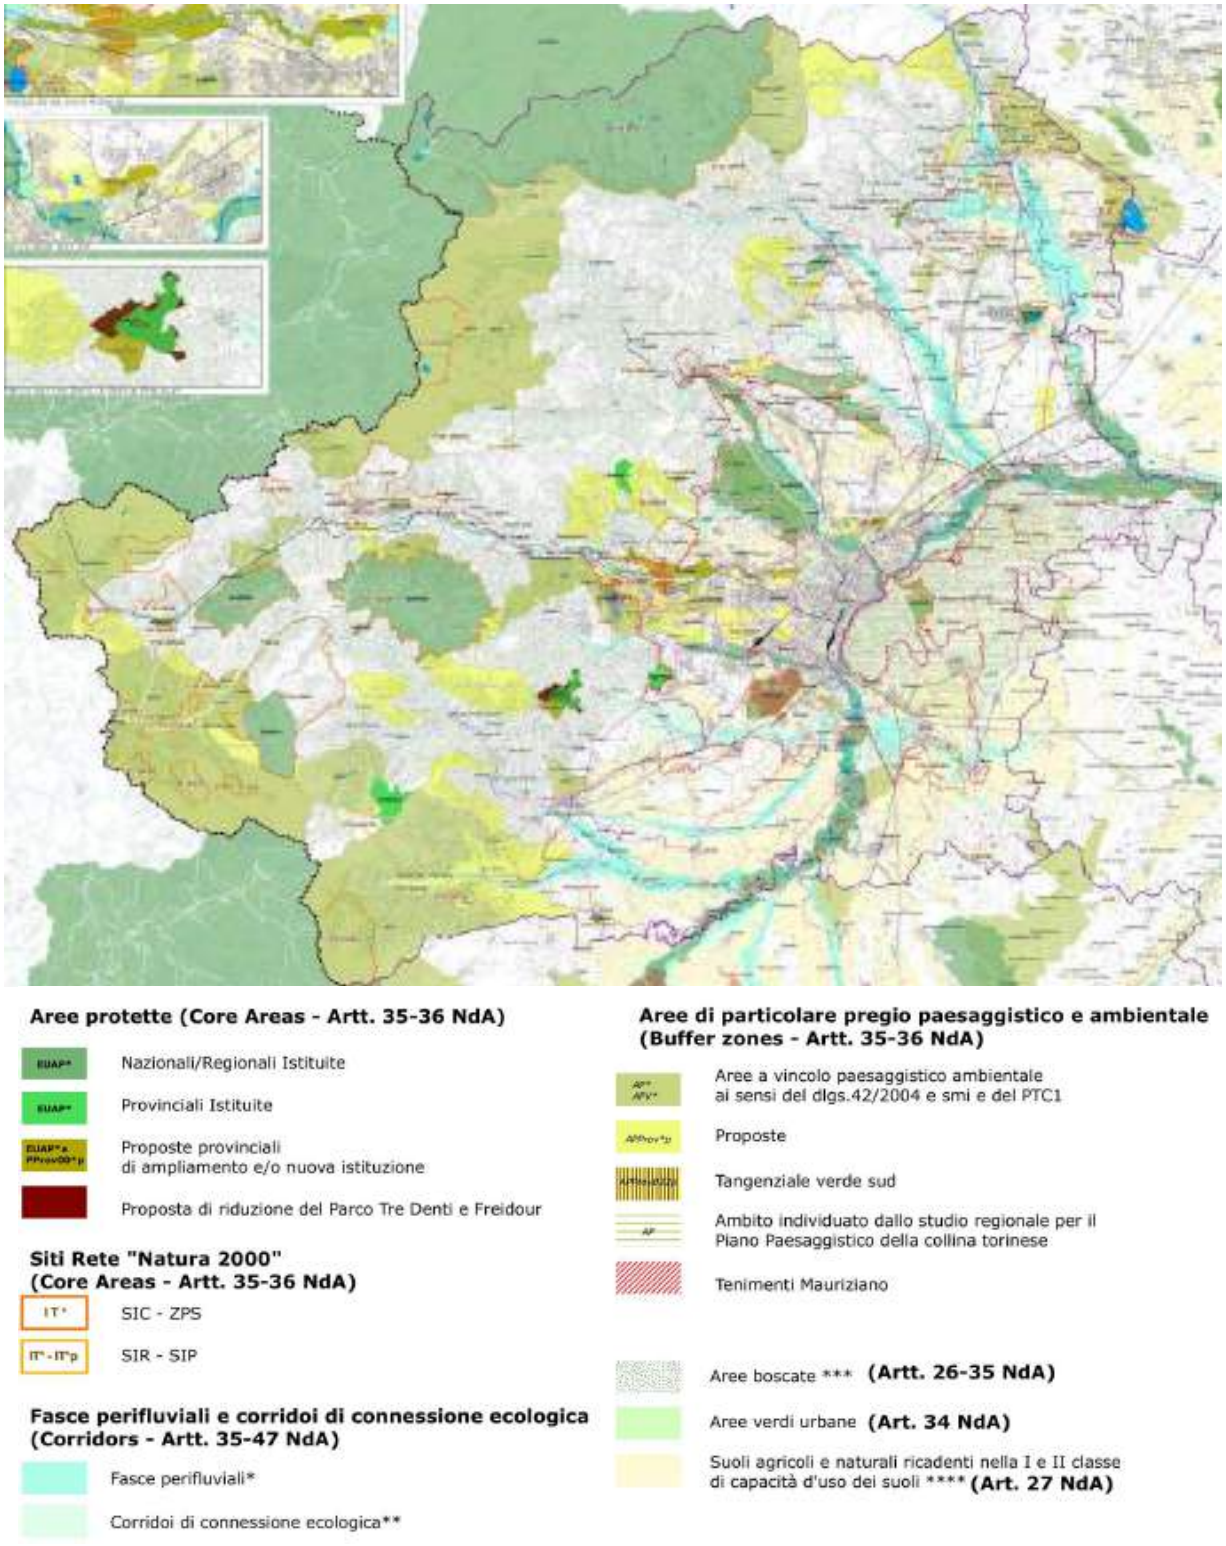

Figure 1: the ecological network of the Province of Turin

4. Discussion and concluding remarks

The analysis of two key planning tools carried out and reported in the previous section, has showed the deep interlinks between agriculture-related policies and spatial planning. It has also pointed to the fact that, at least from the spatial planning perspective, these interplays have now been fully recognized and recent plans now play much attention to the role and potential of rural areas.

As regards the PTP in particular, the relevance of its provisions concerning rural territories is twofold: on the one hand, as the previous table demonstrates, the PTP attaches great importance to agricultural areas not only in terms of spaces that shall be preserved by potential urbanization, but also in relation to their function as socio-economic drivers and providers of environmental assets and ecological services. This undoubtedly represents, in the Italian context, a significant innovation, especially considering that, although the provincial plan as a relatively weak prescription power, the majority of its norms being directive or guidelines, the province has a voice in the approval procedures of municipal plans, the only ones which can establish specific land uses and establish property rights. In particular the Province can impede the approval of the municipal plan if this is not compliant with the PTP.

In addition, the PTP explicitly refers to the CAP and the Rural development programs, and identifies in Agri-environment scheme a key tool to achieve its environmental objectives related to rural areas. Although the province has, overall, a limited role in the implementation of AES, this again represent a relevant step forward towards integration of planning policies and agriculture ones.

In this frame, the design of the ecological network is another key element, with potential strong interplays with rural development policies. In fact, as explained in the introduction section, poor spatial targeting represents one of the main weaknesses of current implementation of AESs in the regional territory. The identification of the different elements of the ecological network now provides a detailed reference to identify agriculture areas to which target AESs; the PTP itself identify the different elements of the ecological networks as the areas where compensation and enhancement measures shall be realized with priority and also states that the most suitable areas where to implement compensation measures are agriculture areas where the ecologic value can be significant increased. Whilst AESs as designed in the current RDP already provide for spatial priorities, the identification of the ecological network in the province of Turin represent a more detailed reference and would allow for a better spatial targeting of AESs.

The other side of the coin, that is the pursuing of stronger integration with spatial planning by agriculture-related policies and programs is instead less demonstrable. Previous analysis of the ongoing RDP of Piedmont Region aimed at assessing the coherence of the RDP with other regional plans and programs (Spaziante et al., 2012)

found that, although no incoherencies could be detected, deeper strategic integration between the different instruments were lacking in many cases. The design of the objectives and actions of the RDP is indeed based on a detailed analysis of the regional context, which covers not only agricultural aspects, but broader environmental and socio-economic ones as well. However, its implementation follows a sectoral rationale, meaning that its integration with other regional instruments has not been fully developed. Improvements in this sense shall thus be pursued for the next programming period (2014-2020). In 2013 the new RDP will be elaborated, and it is hoped that the lessons learnt from the current one will be taken into account.

We want to conclude by highlighting a further possible development along the lines outlined above, concerning the monitoring of both, spatial plans and RDP. Monitoring in fact represent a key activity in steering plan's implementation, and the new RTP and PTP attaches a great importance to this phase. As mentioned earlier, monitoring of RDP is regulated by the EU level, but the current Common Monitoring and Evaluation Framework is not adequate to assess environmental effects properly, nor to evaluate the level of integration with spatial planning tools. In this perspective, a further research development could be to analyse monitoring schemes of spatial plans, identify the indicators directly or indirectly related to agriculture and identify, as for the RDP, the actions that can produce changes in those indicators. A deeper harmonization of different monitoring systems would thus represent a very straightforward and concrete way of pursuing spatial planning/agriculture policy integration.

INSTITUTIONAL CAPACITY AS A KEY FACTOR IN TERRITORIAL DEVELOPMENT POLICIES: A CASE STUDY ANALYSIS IN THREE EU COUNTRIES

Carolina Pacchi[1]

Abstract

The aim of the paper is to present and discuss the results from a cross European empirical study aimed at exploring the relationship between capacity building policies, institutional capacity and territorial development policies, in the framework of territorial cohesion, and to reflect upon the relevance of capacity in this field.

In particular, the main focus of the SMART-IST project, funded under the ESPON programme and led by Politecnico di Milano[2], has been to investigate to which extent institutional capacity is a crucial variable in contributing to the design of effective territorial development policies, and which types of capacity building programmes and policies seem more appropriate, in the different contexts, to enhance, improve and strengthen institutional capacity.

From a methodological point of view, the project has analysed nine case studies in eight regions (Puglia, Sicilia and Toscana in Italy; Aquitaine, Alsace and Rhône Alpes in France and Dolnoslaskie and Lubelskie in Poland), focused on different types of territorial development policies across different policy areas (territorial integrated projects, decentralisation of competences in the management of Operational Programmes, integrated river and landscape management, waste and water policies) and in two different programming periods (2000-06; 2007-13).

In this paper we will focus in particular on institutional capacity, trying to understand how this relatively broad and fuzzy concept can be operationalized using empirical research, with the obvious limits of a very limited empirical basis, and which lessons can be learned in a policy perspective, looking at the design and implementation of the next EU funds programming period 2014-20.

Introduction

Connecting the effectiveness and the impacts of institutional capacity (and of related capacity building policies and programmes) with the quality of regional development policies, and with structural variables from the contexts is a question of direct interest for the definition, development and implementation of EU Cohesion Policy, in particular as far as the debate on the new programming period is concerned (university of Strathclyde, 2010). In fact, preparatory debates about the 2014-20 programming period highlighted the increasing importance of this dimension, seen as the ability of public administration to deliver sound and effective policy. In particular, the improvement of the capacity to design, implement and evaluate policies seems to be one relevant focus (European Union, 2010; European Union - ESF, 2011).

Moving from this background, the SMART-IST project framework proposed to investigate the connection between structural variables, capacity building policies and institutional capacity at regional level, with the aim to finally connect any intervention on these dimensions with the quality of policy design in the cohesion policy field, as illustrated in Figure 1.

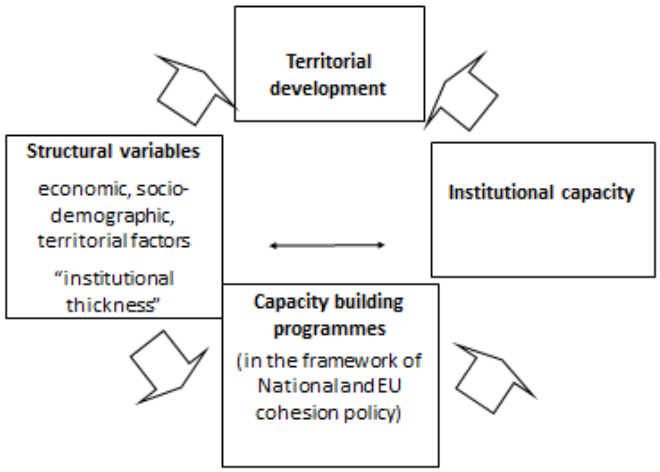

Figure 1. The SMART-IST Framework

As we will see, during the course of the project this interpretative scheme has been modified, according to the first results of the empirical work and extensive interpretative discussions.
In order to fully introduce this framework, the paper will propose in this section a brief presentation and discussion of each section of it, with a specific accent on the institutional capacity concept, which is the main focus of the paper.

In the first place, *structural variables* are those variables related to the socio-economic features of the different regional contexts, which are at the same time the starting point of regional development policies, but also the objective of policies themselves. Data bases at regional level are very detailed, both within and outside of the ESPON databases: the main objective of our research has been therefore not so much to improve such basic data, but try and find meaningful connections with the other variables in the interpretative framework.
It is important to note that the regions selected for the analysis are in quite different positions as far as development trajectories are concerned, which is confirmed by all the basic indicators: in particular, Alsace, Aquitaine, Rhône Alpes and Toscana are quite developed contexts, in which indicators as GDP are around or above the EU average, while Puglia, Sicilia, Lubelskie and Dolnoslaskie are in a very different situation, with GDPs which are well below the EU average (between 60 and 70% of the EU average, apart from the case of Lubelskie, which is around 40% of the EU average); in turn, the GDP in all regions (except Lubelskie) has been declining since 2005.
It is possible to detect a significant difference between the two Italian regions, which were part of the EU policies since many years, and the Polish Regions, which are part of a new accession country.

The second significant variable which was taken into account is capacity building policies: they refer to actions aimed at strengthening the capability of government officials to manage their programmes, to provide services to their constituents, or to manage their overall jurisdictional or inter-jurisdictional responsibilities. Capacity building refers, therefore, on the one hand to improving managerial practices (along New Public Management theories), such as management, strategic and operational planning, or evaluation; and on the other, to transforming power and institutional relations (in a governance perspective) and producing learning and innovative governing arrangements.

As far as *institutional capacity* (IC) itself is concerned, this has been the key variable in our study and its ability to contribute to the explanation of the quality of territorial development policies, in connection with capacity building policies and in the context of the structural features of different territories has been the main object of study. It is therefore worth considering it in detail. Since the concept of institutional capacity includes a broad variety of themes, we started our research summarising different approaches derived both from literature and from policy, able to propose convincing and workable definitions of IC, within the framework of EU policies and beyond, with the awareness that in the literature it developed first as a normative and operational concept rather than as an analytical notion (IMF 2002; UNDP 2011; for the analytical perspective Gualini and Salet, 2007).

If we focus our attention on the EU, the concept of capacity implies to pay attention to the development of strategies and competences to maximize the opportunities for

policy implementation, in particular as far as programming, selection and evaluation, implementation and monitoring are concerned.

Looking at the EU Cohesion Policy field, the role of institutional factors and capacity building has been considered since long as an important prerequisite in promoting territorial development. As the Barca Report puts it: "It is widely agreed that both formal and informal institutions are a prerequisite for a place to make full use of its potential". Starting from this assumption, in discussing the rationale for exogenous intervention in a place-based approach, the Report mentions institutional capacity among the most relevant concepts, that is "the capacity of public and private local institutions to govern and coordinate collective decision-making". As it happens with the agency of individuals, social capital, trust and democratic participation in decision making, the Report highlights that "all these institutional conditions tend to stimulate development by encouraging the involvement and cooperation of people, creating an incentive for them to pool knowledge and to develop collective projects" (Barca, 2009, p.22). In this definition there is the acknowledgement of the complex governance framework which is necessary to successfully design and implement regional development policies, which has also been at the basis of the SMART-IST analysis.

Analysis

In order to plausibly connect the different project variables, the project concentrated on nine case studies in eight EU regions.
Three cases were analysed in France:

- the decentralization of the management of the Operational Programme to the Regional Authority in Alsace;
- the policy interventions in the field of innovation and solutions for an effective cooperation between the Managing Authorities of the Operational Programme and the Regional Authority in this field in Aquitaine;
- the programming and implementation of a multi-regional programme, in particular in the field of management of river basins in Rhône Alpes).

Four cases in Italy:

- the setting up of the Regional Evaluation Unit in Puglia;
- policy interventions able to build up territorial integrated development programmes (TIPs) in Sicilia
- integrated development projects in particular in the field of urban development in Toscana;
- technical assistance measures employed by the Central government to support regional governments in the implementation of reform processes and sectoral planning in the field of water and waste management in Puglia.

Two cases concerned a CEE country, in this case Poland:

- the implementation of the Regional Development Strategy 2020 in the Dolnoslaskie region

- the decentralization of structural funds management in the period 2007-2013 in the Lubelskie region.

The researchers engaged in field research worked with a comprehensive template, aimed at describing at the same time the basic socio-economic structures in each region, together with more specific reconstruction of the policy course, explicitly aimed at capacity building (like the set-up of the Regional Evaluation Unit in one Puglia case) or in which the capacity building dimension has played a significant role.

Chapter 1: **Research problem**
description of the main research problem to be explored.
Chapter 2: **Context related features**
2.1 *Socio – economic development*
2.2 *Institutional and political characteristics*
general focus on structural variables and institutional thickness
analyze the departure point and changes in the main contextual factors – social, economic, and political- that shape institutional capacity in the analyzed regions over time (before, during and after the implementation of the interventions);
analyze the main challenges to social and economic territorial development in the region.
Chapter 3: **Outcomes of analyzed interventions**
analyzes the success of the intervention or its failure
Chapter 4: **Telling the story of the intervention**
retraces the story of the analyzed intervention with respect to the research problem.
Chapter 5: **Actors involved**
identifies the main actors involved in the analyzed intervention and their role in its programming, implementation, monitoring and evaluation.
Chapter 6: **Analyzing institutional capacity**
focuses on characterizing institutional capacity and its (eventual) evolution over time
Chapter 7: **Capacity building policies**
focuses on capacity building policies put into place and their effectiveness in increasing institutional capacity
Chapter 8: What works

focuses on the mechanisms explaining how institutional capacity brought about better interventions.

Table 1. Template for case study analysis

Results

As a first result of the analysis, the research identified three different declinations of the concept of institutional capacity, as emerging from the nine case studies. Our hypotheses are strictly linked with the policy area examined in the study and it would be necessary to test them in other policy areas and across a larger number of different regional contexts, in order to extend their analytical use. Nevertheless, they are probably worth mentioning and discussing as a first reference.

Even if they are partly overlapping at the empirical level, the three declinations can be distinguished from an analytical point of view, and can thus be very useful in a policy development perspective:

- the first one has to do with the *ability to come to terms with rules and procedures*, that is to say the complexity of the management dimension of EU funds, and the ability to combine them with the national and/or regional rules and procedures;
- the second one is the capacity to use EU funds and procedures to *bring forth and implement complex territorial projects and strategies*, which local actors already had in mind, or which they develop on purpose;
- finally, a third possible declination is the capacity to use the competences built through the use of EU funding in order to *improve the overall quality of administrative action*, i.e. the increase in quality of intervention due to the diffusion and mainstreaming of the partnership principle, the sustainability framework, the use of monitoring and evaluation, the emphasis on multilevel governance, etc.

As far as the first declination is concerned, we find evidence of such type one IC across all SMART-IST cases, even if in different modes and with different time dynamics, depending on the initial level of capacity present in the region, but also on the length of the period in which regions have been involved in EU funded policies: here, differences between regions managing European Structural Funds since long and newcomers can be significant.

In this sense, it seems that the Italian cases can be contrasted with the French and the Polish ones, but also that there are considerable differences between regions with a strong initial level of institutional capacity and weaker ones. If we look at the Italian regions, we can certainly say that the long experience in managing EU Structural Funds has meant an overall capacity to come to terms with such procedures, even if, since in most cases the administrative structures of the target regions were considerably weak and characterised by low levels of administrative and institutional capacity, the results have not been the expected ones. In such regions, quite

frequently technical assistance policies from the central government level have substituted local actors, without properly contributing to an overall increase in capacity. This has been for instance the case for the management of waste and water policies in the Puglia case.
On the other hand, in Sicilia, a Region with a long experience in managing Structural Funds, the huge amount of local development programmes promoted through Territorial Integrated Projects (TIPs) overloaded the regional bureaucracy and increased the level of conflict between centre and periphery, with a resulting low degree of effectiveness of the local development policy.
In the French cases, on the contrary, there is a widespread capacity of managing complex territorial development processes, and the only gap to be filled in is the one between the French national system of rules and procedures and the EU one. In this sense, the case of decentralization of competences in Alsace, for instance, shows that together with the transfer of specialised staff from the State administration, there has been a significant investment in human resources after the decentralization started. Similarly, the Aquitaine case shows a growing institutional capacity of this first type, and this brings forth the general acknowledgement that the Region is the right actor to deal with this process.
In the two Polish cases, introducing Cohesion Policy for the first time implied a significant effort in coming to terms and complying with new systems of rules and procedures, both at the national and local level: in this respect, the choice made by the National Government to proceed through a sort of 'delayed decentralisation' strategy, even if it overloaded regional actors with very complex procedures, proved effective to a certain extent. Probably the on-the-ground training implemented through pre-accession procedures and the 2004-06 programming period had not been able to build the institutional and administrative capacity which was in fact needed for the 2006-13 programmes. Thus, the complex institutional arrangements put in place between the Voivodship and the Marshal Office both in Dolnoslaskie and Lubelskie may be considered part of this institutional and administrative capacity building process.
In particular, despite its very recent institution, the Dolnoslaskievoivodship presented a good level of institutional capacity at the outset of the analyzed intervention, in terms of good quality, highly educated civil servants, organizational characteristics and interdepartmental relations, even if the high degree of personnel turnover has put some strain on the effectiveness of the administrative units involved. As for the Lubelskievoivodship, despite the overall structural socio-economic conditions, the analysis showed how the level of institutional capacity seems to have been growing throughout the time schedule of the observed phenomena (with a significant role played by the skills and competences of the administrative personnel, both those gained before entering the regional offices, and those gained afterwards).

The second declination is the capacity to use EU funds and procedures to bring forth and implement projects and strategies. While very frequently the availability of EU funding triggers opportunistic behaviour on the part of local or regional actors, in some cases actors have shown their ability to use funding in order to implement strategic and coherent projects or programmes which they already deemed necessary.

In other words, local actors show the capacity of implementing integrated policies, which means that they are able to integrate different sectorial policy issues by pooling different tools and different funding streams (public and private, regional, national, EU from different Structural Funds). This capacity to integrate thematic areas, implementation tools and devices and funding sources towards a strategic objective is to be found, within our cases, especially in the French cases and in Toscana, because this typology of institutional capacity does not specifically depend on the experience in managing EU rules and procedures, but is strictly linked with the initial maturity of administrative and institutional contexts, and it is possibly the least diffused of the three typologies.

We can find for instance this capacity in the Rhône-Alpes case, where a complex multi-regional regeneration programme used EU funding along with national and regional funding, through the reconfiguration of the original scope, from a quite sectoral to a more comprehensive and strategic one: the Plan Rhône is in fact interesting because it is representative of a habit of French actors involved in regional policies to expand the scope and resources of existing partnerships and inter-institutional cooperation devices through structural funds. From another point of view, in the Aquitaine case the ability to show competence both at content and at process level played in favour of the legitimation of the role of the Regional Government for the design and management of the programme on innovation. At the process level, the long acquaintance with experiences of contractualisation among actors, be they internal or external to the administrative structure, played a significant role, while from a content point of view, the experience in promoting, designing and managing policies towards innovation has significantly contributed to the overall capacity of this second type.
Probably the most interesting case in which such type two IC is found is the case of Toscana. Here Integrated Sustainable Urban Development Projects (ISUDP), the delivery mechanism of the policies defined in Axis 5 of the ROP 2007-2013, focuses on cities, as a fundamental part of a development strategy. ISUDP is a coordinated and systematic set of public and private actions aimed at enhancing sustainability and combining a better urban and environmental quality with a higher economic competitiveness, that has been implemented through a competitive mechanism and with a significant role played by the strengthening of partnerships at different levels. The opportunity of using Cohesion Policy funds on Axis 5 was matched with the emerging need of innovating the strategies and tools for urban regeneration at the local level. The regional structures showed here a significant capacity of matching the needs and attention towards urban regeneration with a more general policy perspective, which recognises urban contexts as significant hubs for territorial development in Toscana, and with the appropriate funding sources.

The third declination is the capacity to use the competences built through the use of EU funding in order to improve the overall quality of administrative action. In this declination, institutional capacity is a goal in itself and it can influence the final results in terms of territorial development, because its effects can improve the quality of administrative action beyond the Cohesion Policy interventions. More precisely,

the principles deriving from the diffusion of EU policies can be summarised in four main elements:

- the partnership principle, i.e. the ability to understand in which occasions it is appropriate or necessary to strengthen public/private or public/public cooperation and densify networks in a governance perspective;
- the ability to internalise the environmental sustainability dimension (through the introduction of tools such as SEA)
- the introduction of evaluation procedures in different phases of the policy cycle, along with the NPM framework and again in a governance perspective;
- the equal opportunities approach (in particular in the ESF funded policies and projects).

In the SMART-IST cases, we find evidence concerning mainly the diffusion of the partnership principle and of evaluation procedures, even if for instance in the Puglia waste, water and soil case, there is some evidence that the environmental competences built for the specific project may have had positive impacts on the regional structures more in general.

The Puglia Evaluation Unit case is very clear from this point of view: the Evaluation Unit has been a tool for the improvement of the capacity to plan, select and evaluate projects, especially but not only in the framework of the ROP: in terms of improving planning capacities, the Evaluation Unit had not a relevant impact in the 2000-2006 programming period as it was not involved in the programming phase, while its involvement in the elaboration of the 2007-2013 ROP contributed to the adoption of a different programming vision based on the use of specific methodologies, greater policy integration, the enhancement of participation. This means that the set-up of the Evaluation Unit, which can be considered to a certain extent a capacity building policy in itself, has promoted the mainstreaming and diffusion of evaluation across all the policy areas controlled by the Region, starting from the EU funded ones to encompass the others.

Toscana is another interesting case, because the implementation of the ISUDP policy enhanced networking and partnerships both along the vertical axis (multilevel governance) and along the horizontal one (different cases of inter-municipal cooperation). In this case, the increase in capacity has been one of the objectives of the regional actor, which enhanced its diffusion from the regional to the local level, in particular with the adoption of the competitive mechanism.

Also in the Aquitaine case, which focused on the process of establishment of an effective collaboration between the Managing authority of the Operational Program, the Préfet de Région, and the Regional Authority with particular attention to innovation, the analysis shows that collaboration is particularly relevant since it concerns the field of innovation and research, where the regional authority holds a strong leadership and technical capabilities. The new partnership sets real challenges both at regional and state level, with regard to two main aspects: the establishment of new patterns of collaboration and the integration of the new European guidelines and in particular of the innovation issue.

From the review so far, it seems that different types of capacity are present in different combinations: while in the French cases we find evidence of type two IC

and some elements of type three IC, while the first type is also intervening; Toscana offers a good example of type one and type three; in both Puglia cases again the emerging dimensions seem to be the first and the third one; in the Polish cases the first dimension appears paramount, and the same happens for very different reasons in Sicilia. As we noted at the beginning of this paragraph, a more comprehensive review of case studies across EU regions would be necessary to further test and refine this interpretative framework.

Conclusions and questions for further research

We can draw some preliminary conclusions from the SMART-IST research, as far as the institutional capacity dimension is concerned, knowing that in any case it is strictly linked with the other project variables, which cannot be discussed in detail in this paper.

Institutional capacity has been the object of increasing interest in the EU debate in the last years. Within the regulation document of the ESF, for instance, as we have seen in the Introduction, the concept of capacity is linked to the attention to be given to the development of strategies and competences to maximise the opportunities for policy implementation, a perspective within which the SMART-IST project moved from the beginning. In fact, regulations for both ESF and ERDF and prospective new regulation proposals for the 2014-20 programming period contain provisions for the strengthening of institutional and administrative capacity as a key element.

As far as the different typologies of IC are concerned, even if it is somewhat natural that in the European Commission (EC) policies particular attention is paid to the ability of the different Managing Authorities to efficiently manage Cohesion Policy, it would be a limitation to identify effectiveness only with financial management. In fact, the real test of effective implementation is the fact that the goals of the Lisbon strategy are attained and in order to do so the integration between European cohesion policy and domestic policies is actually working: type two IC is therefore very important and this has to do with the ability to avoid the risk of a strong separation between the public bodies in charge of the Structural Funds and the Cohesion Fund and the rest of Public Administration, as it sometimes can be seen in the case studies analysed.

Secondly, what emerges from the SMART-IST analysis is that in designing the strategy for enhancing IC the Member States and the EC should take into consideration a broader definition of administrative capacity than the simple ability to manage European funds. What seems necessary is therefore the ability to find some common indicators at the strategic planning level, in order to define not only the actions to be taken, but also the targets to attain in the different areas of IC.

THE SPATIAL TRENDS AND THE IMPORTANCE OF SPACE FOR FASHION DESIGN SECTOR IN ISTANBUL

Senem Kozaman [1]

Abstract

Researches that examined process of cultural production and creative sectors refer especially the importance of space. According to Scott, creative industries tend to agglomerate in areas where the easy access to specialized labor force, supply companies and support services are concentrated (Scott, 2000). Fashion design sector is also indicated the same trend as a sub sector in cultural industries. Furthermore with the structural change in global economy enhance the importance bestowed upon the sectors constituting the culture industries in the spatial, economical and physical development of cities. The sector of fashion design is amongst these sectors acquiring importance and generating economical gain through the creative capacity.

During these developments in the World, there are significant moves taking place in the field of fashion design in Istanbul. To put it in another way, Istanbul is among the prime cities with a potential for the development of this sector in Turkey. There is a vast accumulation of knowledge resulting from a history in production in the city with the biggest portion in exports in the clothing and textiles field in Turkey. On the other hand, due to its central position in commercial and economical activities and its global disposition Istanbul is also characterised as a centre of Turkish fashion where creative activities are located, various related fairs, activities and fashion shows take place, where the initial steps for organising the sector are taken and where institutions of education concentrate. The statements uttered by various actors of the sector in interviews, that there is no other city which contains so many key factors necessary for the development of fashion design prove that design is not considering to relocate.

Within this context, in the scope of the research the aim is determined as to reveal the importance of space over the development of design, spatial proximity and inter-relationship between production and design, and the geographic characteristics of fashion design in Istanbul as well as the contributions of interviews with fashion designers and some other stakeholders[2].

1. Introduction

In the literature, it is claimed that as a creative industry fashion design is a sector which tends to cluster and share a socio-economic environment. At the same time, in the sector many fashion companies in these places carries out cooperation with other local actors (Rantisi, 2004; Hauge, Malmberg & Power, 2009). Indeed, the trend in the world also proved the creative and production processes prefer places that provide appropriate necessary conditions. In fact, with the globalization, low-cost production in developing countries based on growth policies has led to a fragmented structure in the geographic distribution of fashion design, garment and textile sectors. Accordingly, the production takes place mostly in developing countries, design and marketing phase finds its place in global cities of developed countries (Bair & Gereffi, 2003:149; Hassler 2003:523).

However, it is emphasized that the importance of local conditions should be taken into account in questioning the relationship between fashion design and the space localization. There is a world-wide distribution of the value chain, but on the other hand in the creation of value the role of the local potentials are also important (Hauge, Malmberg & Power, 2009). In other words, the geographical location has an important role on the innovation and learning process. The innovation and learning ability can be produced conveniently where the resources, knowledge and other inputs and facilities aggloromated in the specific environments rather than a single individual attempts. The spatial agglomeration of firms within the same industry, related services, education, research and development activities that allows face to face relationships, share and facilitate the flow of information by creating scale economies (Asheim, 2007). Today, even though more recent developments in communication technologies created an incredibly long distances interaction, some of the knowledge and skills transfer takes place by means of face to face relationships (Malmberg & Maskell, 1999).

Beside, when the geographical features of fashion design industry analyzed, according to the global trends manufacturing and design activities are in different locations from each other, yet many fashion centers had a history of production. With this context when Istanbul is examined the presence of textile and clothing manufacturing has an important contribution to the development of the fashion design in Istanbul. Of course, this trend is not only shaped by the location selection of the industry but also the presence of an accumulation of the other creative industries, central structure of Istanbul in commercial and economic terms, fashion-related exhibitions, events and fashion shows take place in Istanbul and fashion design departments of universities and private institutions providing education in fashion design, even historic identity , considered to be important factors in the specification of Istanbul as the center of Turkish fashion.

Kozaman, S. , 2011. Fashion Design In Istanbul: Structural Features, Threats, Opportunities and Policy Implications. İstanbul 2010 European Capital of Culture Project, Inventory of Cultural Heritage and Cultural Economies in Istanbul.
<http://www.istanbulkulturenvanteri.gov.tr/files/yayinlar/ISTANBULDA_MODA_TASARIM.pdf >

Taking all of these developments into account the aim of the research is determined as to reveal the importance of space over the development of design, spatial proximity and inter-relationship between production and design, and the geographic characteristics of fashion design in Istanbul with the contributions of interviews with fashion designers and some other stakeholders.

2. Fashion Design Sector in Istanbul

Textile and apparel sectors, create important opportunities for economic development, especially in 19th century in England and in the 20th century in other countries the industrialization led to the development of exports by providing the accumulation of capital. Today, it's observed that due to the presence of cheap workforce in developing countries, especially in order to ensure the capital stock, the production of textile and apparel sectors take similar roles in economic development (Dal and Gülpınar,2010).

Indeed, the cheap cost of production-based growth policies in developing countries, along with the globalization, has led to the emergence of a fragmented structure in the geographic distribution of fashion design, garment and textile industries. Production takes place mostly in developing countries, design and marketing phase mostly located in developed countries and global cities. In other words, the geographical distribution of the production of apparel and the industry reveals widespread structure, yet the accumulation of value-creating activities such as branding, design and marketing in certain areas caused the flow of value into specific areas (Bair and Gereffi, 2003). In particular, Paris, Milan, New York, London must be considered as pioneers in global cities not only as the places of trend designators in fashion, but also stand out as the places of consuming fashion.

Textile and clothing sector in Turkey has a history based on Ottoman Period. To briefly summarize the status of sectors, during 1923-1970 government policies and development plans attributed to the importance of textile sector investments to increase production capacity in this direction. After 1980s, with the liberalization process in Turkey, foreign capital and goods started to enter with imports and also Turkey opened to foreign markets at the same rate. With the start of world brands taking place in local apparel retail market, the demand for consumption of fashion products has increased.

In 80's foreign trade relations based on textile and in 90's, apparel exports gained importance. During this period of structural change in the Turkish economy cheap workforce, minimum capital requirement and the existence of necessary raw materials in local industry (cotton etc.) has provided a rapid development in apparel and textile sectors. In addition, the number of large-scale enterprises in clothing sector has increased with the development of foreign trade relations.

Yet in 1990's the firms in Turkey and also in Istanbul had a market approach based on contract manufacturing. After the structural change in apparel and textile industries in the world this has turned into brand-building efforts. In order to manufacture products with high added value, companies tried to include design in the

production process. Especially in Istanbul after 2000s, a process was taken in the development of fashion design industry. In this context government and private initiatives has started to make significant investments in education, R&D operations. And also clothing, textile and fashion design professional associations were established. With the efforts of some actors in the sector and the public support major projects have been developed. In 2006 Fashion Designers Association were established and from August 2009 Istanbul Fashion Week was started with international participation. Although the latency of developments, these and similar steps contributed to the growth potential of the sector.

In Istanbul, due to the presence of capital in proportion of industrial location preferences textile and clothing sector has also started to concentrate in the city. When we examined the exports in garments and textile products, it's observed that most of the exports are carried out from Istanbul. In 2009, the share of Istanbul in Turkey is %78 in garment and %52 in textile products. From 2002 to 2009 export rates are increased from 3 to 5 billion $ in textile. In parallel to this improvement the export in garment products are also increased from 5 to 7.5 billion $.But from 2007 there is a decline trend in the export rates of sectors in Turkey and also in Istanbul (Turkish Statistical Institute, Foreign Trade Statistics,2002-2009).

According to 2009 data of Istanbul Chamber of Commerce (ICC), in the "personal or household goods such as textiles, clothing, shoes, jewelry, furniture and other interior decoration and other fashion goods related to fashion design activities" category there are 155 companies. This number is minor than the firms recorded under manufacturing or retailing classifications in garment and textile sectors.

Taking all these statistics into consideration, for fashion design, textile and clothing sectors Istanbul is the central location for trade and the large number of firms were concentrated in the city. Yet the number of fashion design companies registered to ICC is lower than the textile and clothing firms. In general, the results obtained from the review reports and data indicate that the export of Turkey in these sectors are in a declining trend. In parallel, the share in exports of İstanbul also shrinks.

It is clear that the approach that endorse cheap labor and production based manufacturing caused a redundant competition with Far East countries. In this aspect it's not rational to compete in cheap manufacturing category on a global scale. The sectoral acquisition will pursue to decline unless Turkey kept pace to the structural changes in the competitive environment. In this manner, the importance of innovative practices in design, branding developments has also been reported as dominant factors for the sectoral improvement in interviews with stakeholders.

> *"I've been working for an apparel firm as fashion design department director and also I have my own brand. In this geography, 10 years ago, there are no examples of designers who also work as a consultant for apparel firms. With this partnership the firm increases the rates of its turnover almost %50 in every season."*
>
> *Arzu Kaprol, Fashion Designer*

Today although fashion and manufacturing phases are prone to locate in different places according to global trends, many fashion centers of today had a history of manufacturing. Indeed, as mentioned previously, the presence of textile and apparel manufacturing in Istanbul made a valuable contribution to the development of fashion design in the city. Of course, this trend has been shaped not only within the framework of location preferences of the industry but also the presence of the accumulation of other creative industries, fashion-related exhibitions, events and fashion shows, fashion design education institutions even the historic identity of city effects the clustering potential in Istanbul as important factors. In addition, interviews with fashion designers mentioned that there is no other city in Turkey that has so much potential together for the development of the sector.

3. Location Choice of Fashion Design in Istanbul

With globalization as a result of competition to attract capital, urban areas which had become valuable for manufacturing have turned to be the preferable places for finance, commerce, creative and cultural sectors. In Istanbul this decentralization process is reinforced by strategic plans and policies. In this context, with the interviews, effects of decentralization process of textile and apparel manufacturing to fashion design sector are investigated. Interpretations of designers are differentiated from each other about the spatial relationship between production and design. There are some views emphasizing the importance and advantages of clustering or close spatial relationships between manufacturer and designers to ensure the existence of cooperation between them. Besides there are some opposing views that support the independency of design activities from mass production and possibility of cooperation without proximity and the development potential of textile and clothing industry (manufacturing) in other cities.

The current location preferences of the sector is also an evident for the consideration of the city as the most suitable geography for development of fashion design sector. The maximum agglomeration is seen in the Şişli District. %16.8 of total companies are located in this district. After Şişli, Beşiktaş (%8.4), Bakırköy (%7.1), Kadikoy (%6.5), Beyoglu, Kagithane and Umraniye (5.8% each one) are the locations that take over (Figure 1).

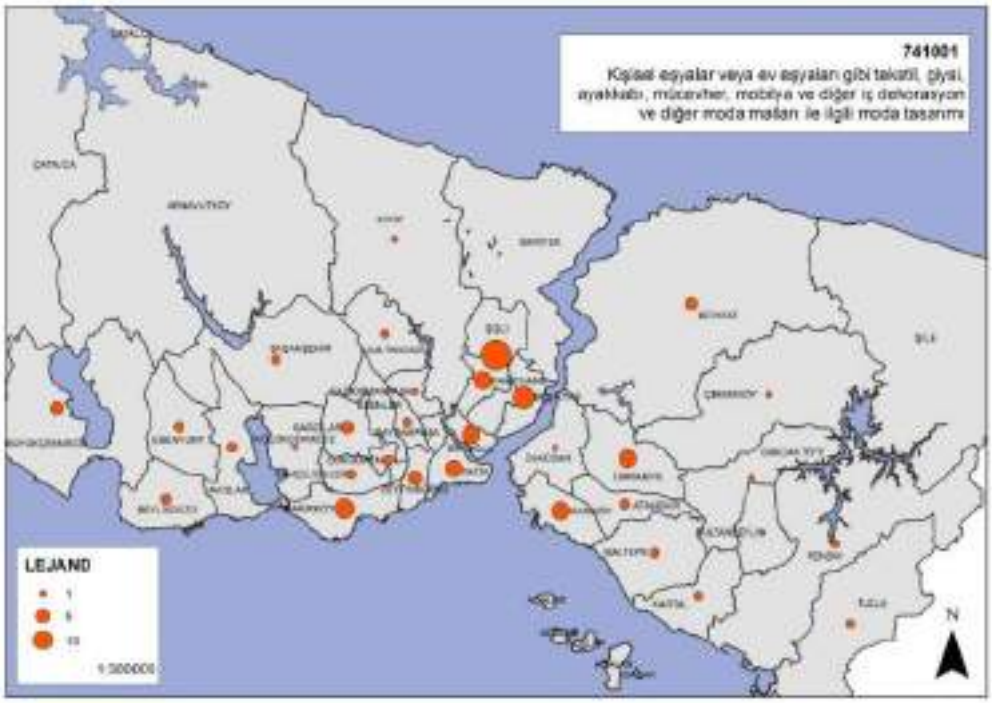

Figure 1. The distribution of fashion design firms according to districts (ICC member records)

In addition to this, there are 92 members registered to Fashion Designers Association. Members are classified as fashion designers, young fashion designers, fabric designers and future fashion designers (who are still students in universities). Two categories (fashion designers and young fashion designers) are considered to understand the location choices. The spatial distribution of 76 members in these categories show similar tendencies with the locations observed in ICC members. Sisli (%38), and Beyoğlu (%13) are districts with high agglomerations.

In summary, the fashion design activities have chosen to locate in the center of the city in places that has history and identity. Yet Şişli is a place not only with prestigious commercial streets but also from 1970's small garment workshops had located in the district. Fashion design sector tend to concentrate in space and this trend creates opportunities for market sharing and also can be considered in the context of a capacity to transform space. In Beyoğlu, Galata region is an evidence for this transformation.

> *"As my point of view, artists are the main leading stakeholders who can change and transform the space. Galata is one of the oldest and historical part of Istanbul. In its history, artists and radical people also lived in this old neighborhood. Strictly, there could be no other place for me better than Galata. I made an investment in here for my office and showroom. With this acceleration, creative people, like artists, designers, gallerists, architects began to come and rent shops, showrooms in here."*
>
> *Bahar Korçan, Fashion Designer*

4. Conclusion

As a result, clusters that have been shaped by the prestigious location preferences of the fashion design sector lead to create a network between space and fashion. And some places are associated with fashion directly like Nişantaşı which is a neighborhood of Şişli or as mentioned before Galata.

The interview below denotes an important clue about the location trend of a large-scale apparel company. However, in some interviews the importance and exigency for spatial proximity is mentioned between small-scale workshops and fashion designers as a result of contract manufacturing. When the production capacity is exceeded in a fashion designer firm, they prefer to work with small scale manufacturers in the city. And also some of the designers prefer to supply raw materials from the commercial units in these places.

> *"Our apparel company decided to carry manufacturing part to Çerkezköy in Tekirdağ Province. There are several reasons for this, but the main cause is based on some certain factors. The current place of the factory in Istanbul is closed to the transportation nodes like airport etc. So the area became much more valuable and in addition to this the labor force is much more expensive in Istanbul rather than other closed cities as a result of high income needs to maintain standards of living. Furthermore, the congestion and density in transportation effects the logistic operations badly. So it becomes a necessity to move to a place without these difficulties."*
>
> *General manager of Altınyıldız Apparel Factory*

There are several ascriptions that refer to the importance of cultural industries in policies for development of Istanbul. Some of views appraise Istanbul as "overvalued" for manufacturing activities in terms of labor and land prices. However, the proximity of designers and producers also seems to be an important issue. In this context, taking all these spatial relationships into account comprehensive studies have to be realized to provide and strengthen the development of cultural industries with spatial sectoral policies.

BUILDING RESILIENCE FOR SUSTAINABLE FRESH WATER USE IN THE NETHERLANDS

Johan Woltjer, Jannes Willems, Piet Pellenbarg[1]

-FIRST DRAFT-

Abstract

This paper makes a series of suggestions for strengthening our understanding of dealing, through spatial planning, with increasingly challenging fresh water capacities. Based on a literature review and a detailed case study on the Netherlands, the paper explores current capacities and the resilience of the users of fresh water resources at a national level.

More theoretical issues of adaptive capacity and resilience are central to framing the case. Accordingly, the paper offers a framework for planning practice featuring these issues as evaluative indicators. The suggestions are intended to reveal the resilience among fresh water users like industry, energy producers, drinking water suppliers, nature and agriculture, and contribute to the quality of spatial planning work in this field.

The paper reveals that, currently, these users suffer in varying degrees from lacking capacities for efficiency, productivity and substitution. There is also a need for a longer term commitment to innovation. Important emerging practices include efforts to strengthen accessibility and reliance at specific places, efforts to establish water as a factor of choice and certainty of location, and institution building for policy integration between water, urban and economic development.

It is suggested that vulnerability strategies express themselves through interventions at two notions of place. *On-site* vulnerability implies levels of capacity at current locations and contexts, typically featuring strategies like productivity innovation, efficiency and thrift. *Beyond-site* vulnerability implies the potential capacity for locational change and adjustment, typically involving integration and substitution.

1. Introduction

This paper discusses current issues on adaptive capacity among large users of fresh water in the Netherlands. The notion of 'large users' refers more specifically to

[1] Faculty of Spatial Sciences, Univerity of Groningen, Groningen, The Netherlands - j.woltjer@rug.nl

activities and choices in five prevailing sectors: industry, energy, water supply, agriculture and nature. These activities typically require relatively large amounts of fresh water for their existence and continuation. A leading question for the paper is to identify the major vulnerabilities these water users may face, given water availability issues from climate change, and to identify what capacities may be associated with these vulnerabilities.

Fresh water is an indispensable resource for many human activities. At the same time, it is distributed unevenly over space. It also suffers from inconsistent availability and variable accessibility. This is true on a global scale. Asia, for example, represents 60% of the world's population, but about 36% of global fresh water resources. Overall only 15% of the world's population lives in areas with abundant fresh water resources (United Nations, 2003, Revenga et al, 2000). But a similar uneven distribution occurs within continents, within individual countries, and at regional and local scale. One third of European citizens reside in countries with water stress, in particular around the vulnerable Mediterranean Sea (EEA, 2007). But also countries like Germany and Belgium deal with water stress.

For the Netherlands, vulnerabilities to water in general (like flooding), and fresh water shortages in particular, are on the increase. The European Water Exploitation Index (WEI) has been shown growing vulnerability (EEA, 2008). The Netherlands is also vulnerable due to its down-stream location for large European rivers like the Rhine, Meuse, Scheldt and Ems. Specifically, the country is vulnerable because of its high urban densities and the vast associated values on land, especially at places with serious potentials for water shortages and nuisance.

Overall, the problem here is one of changes in fresh water availability, specifically episodes of drought and intruding saline water from sea, due to climate change. The general situation is perceived as a situation with enough fresh water over the whole year, but, at the same time, increasing occurrences of insufficient quantities at the right place, insufficient quantities at the right time, and insufficient quantities of the right quality (Klijn et al, 2011; RWS, 2010).

Consequently, during the last decade there is growing uncertainty about locally continuous availability, and hence concerns about practices of securing adequate fresh water (e.g., RWS 2011). Climate changes in the Netherlands are producing higher sea levels, irregularities in rainfall intensity, limiting groundwater replenishment and unstable river flows, leading to land-use changes like 'space for water' and 'water sensitive' spatial planning in the Netherlands (e.g., Woltjer and Al, 2007). Climate change and resulting impact on water quality and availability have had important implications for the activities of water users. The vulnerability of their life and production is at stake (Nicholls et al, 2007). Vulnerability here refers to the degree to which an activity is sensitive to, and is able to anticipate the adverse effects of climate change, including variability and extremes in freshwater availability. The vulnerability of water users to climate change may be alleviated if their efforts and

the efforts of planners and policy makers seek resourceful ways to deal with water or establish substitution possibilities like alternative sources.

Clearly, therefore, the issue of fresh water usage is not only related to the availability of water itself, but specifically also the capacities among users to handle issues like water shortage and improve efficiency and substitution.

2. Analysis

The analysis here assumes the hydrological system of fresh water in the Netherlands and its related institutional arrangements to represent an adaptive system with abilities to change or adapt in response to stresses and strains. We see resilience as a dynamic attribute, as it changes over time (e.g., Holling, 1994; Pendall et. al (2010). We follow a definition on adaptive capacity from the IPCC: "the ability or potential of a system to respond successfully to climate variability and change, and includes adjustments in both behaviour and in resources and technologies" (IPCC, 2007). The paper focuses, therefore, on current capacities and strategies of dealing with fresh water and the changes in its availability in terms of location. Obviously, notions of adaptive water management are related to our thinking (e.g., Pahl-Wostl, 2007; Gleick, 2003), as are notions of water-sensitive spatial planning (e.g., White, 2010).

Location is a key aspect for water use. The international literature on freshwater consumption points to two types of location considerations (e.g., Gleick, 2003; Mitchell, 2005). First the analysis considers the potential capacity to anticipate a changing freshwater availability *on-site*, at current locations and contexts. Secondly, there is the potential capacity in the corresponding sector *beyond-site*, or for altered vulnerability, in other words, involving locational change and adjustment. The paper, therefore, considers a variety of contextual factors affecting potentially the adaptive capacities of a sector (such as transportation, proximity, quality and location). It will be clear, incidentally, that both types of location considerations are closely linked to planning and policy making.

Another key aspect from the literature is the policy or management strategy used for fresh water management. These strategies, as explained earlier, may involve a focus on:
- Efficiency (using as little water as possible for the same production) or
- Productivity (higher returns from the same amount of water);
- Thrift (to use less water per se);
- Substitution (the use of alternative sources or other qualities of fresh water).

The extent to which users are able to influence these aspects is reflected by their capacity to innovate, invest and adapt. An investment to adjust production processes for drinking water to switch from local ground water sources to local surface water sources, for example, would suggest adaptive capacities *on-site* related to a substitution strategy. A widespread emphasis in the international literature, but also

in national policies is on an efficient and sustainable use of land and resources. A central idea is that users are located at collectively the most effective place allowing for sustainable production. Within river basins, for instance, intensive users of water would be located downstream rather than upstream, thereby generating fewer effects on other users.

The paper will now focus on the capacities per sector for both possibilities at current places and opportunities elsewhere. Efficiency, productivity, economy, substitution and, overall, resilience are our central concepts. The paper attempts, theoretically, to refine the idea of resilience specifically to questions of place and strategy, and, empirically, to understand the capacities of fresh water users in the Netherlands.

3. Results

Dutch fresh water use involves both ground water extraction practices and surface water intake. Groundwater extraction is an activity common to the paper sector, the food and beverage industry, the chemical industry, and in agriculture and livestock, but above all in the drinking water sector (more than three quarters of the total). The general trend is that the extraction of groundwater by industry and water companies has decreased slightly in recent decades (PBL, 2011; Vewin, 2002, CBS, 2010).

Figure 1 shows that both industry and the drinking water sector nowadays obtain less groundwater than in the seventies, both in absolute terms and in terms of substitution with surface water. Considerations about drought and low groundwater levels are partly behind this (limited) shift. Extractions by water companies primarily involve tap water for households and industry (see Table 1). In the industrial sector, groundwater is used both as a raw material in manufacturing and as process water for cooling. For industry and energy companies, however, surface waters are an important source. It is striking that by far most surface water consumption (90%) involves use as a coolant (CBS, 2010). In particular, electricity companies are a bulk user (approximately 70% of the total), and represent risks in terms of quality of their effluent waters (e.g., oxygen balance). The largest plants are located around major rivers and the immediate coastal zone. There has been a slight downward trend in cooling water use.

Finally, it is striking that the total consumption has been relatively stable in recent decades (PBL, 2011): every year about 1 billion cubic meters of groundwater (found mainly in higher eastern and southern regions of the Netherlands) and around 13 billion cubic meters of surface water. In the same period, consumption and economic growth have been considerable.

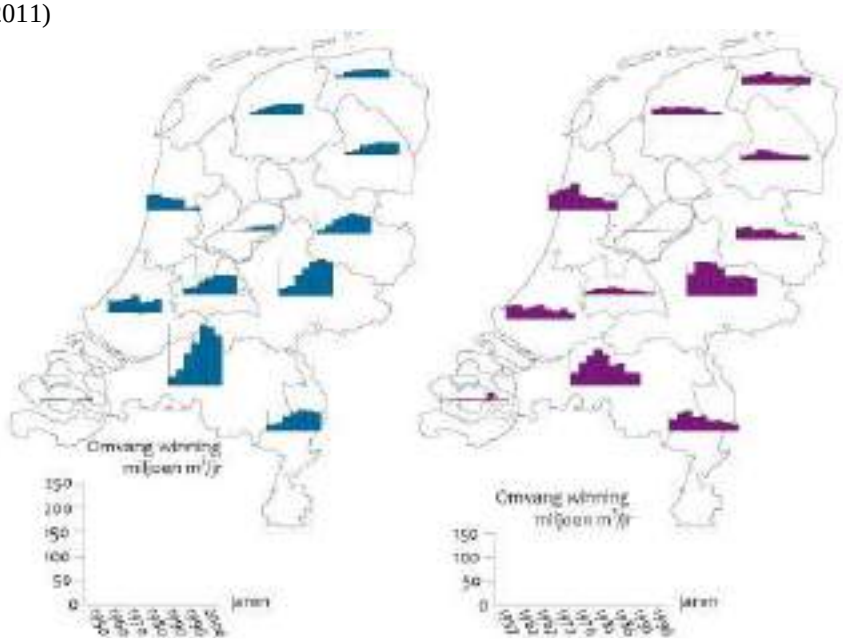
Table 1. Water extraction and use in the Netherlands per sector (2008, mln m^3/year)

	Total	**Ground water**	**Surface water**	**Piped water**
Extraction water supply agencies	1 252	762	490	-
Usage agriculture	119	47	24	47

Usage industry	3 643	155	3 308	181
Usage electricity plants	9 050	2	9 044	3
Usage other companies and households	1 329	1	431	905

Source: CBS, 2010.

Figure 1. Ground water extraction (in mln m^3/year) for water supply (left) and industry (right) (PBL, 2011)



3.1 Water use per sector

This section discusses consecutively possible capacities for 'water problems' in the sectors central to the paper: industry, energy companies, water companies, agriculture, industry and nature. The review here is based on recent (2000-2012) policy and strategy documents utilized by stakeholders from these sectors. In addition, the authors have held interviews with senior officials from organizations representing them, including the Association for Energy, Environment and Water (VEMW), Netherlands Energy Organisation (EN), the Netherlands Waterworks Association (Vewin), the Dutch Agricultural and Horticultural Organisation (LTO) and the Nature Society (VN).

Industry

Industrial products like steel, petroleum, chemicals and paper involve a number of heat-intensive processes. Typically, excess heat is transferred into cooling water, sometimes through large cooling towers. The industrial use of fresh water may also include the production of food or the generation of steam for temperature control or sterilization. Until recently, these industries have regarded fresh water as a relatively

ubiquitous and rather cheap good. This perception of abundance, however, is gradually changing. There is a trend to invest more in capacities aimed at:

- efficiency and reducing freshwater use;
- measuring and monitoring water consumption (in view of the cost);
- the deployment of technologies for further efficiency and adaptive capacity.

A strong point for the industrial sector involves the relatively large adaptability of some larger users. A more economical and efficient use of groundwater is apparent, although the use of sustainable technology and also possible substitutions with surface water have experienced a slow start. An emerging practice involves alternative management arrangements, featuring area-oriented options for clustering of industry and water companies. Shared infrastructure (e.g., pipelines) and the collaborative management of freshwater reservoirs are among recent initiatives. Companies have also advocated for improved, public-private management of water purification plants.

Overall, our findings for industrial water users suggest that they adjust gradually, for example through more sustainable production processes (efficiency). There are limited short-term vulnerabilities. The sector already anticipates towards more restricted future water availability. At the same time, the pace of anticipation is somewhat slow. There is some considerable attention to new regulatory arrangements for area-management and innovation.

Energy plants

Electricity plants generally use water in two ways. The first way entails cooling water, which is obtained from the sea, rivers, lakes or canals. This water can both be saline and fresh, depending on the installation. The second way involves internal water, or process water, which flows through closed circuits. Cooling water in particular is typically used in large quantities and is therefore of key interest. The amount of cooling water used has been fairly stable in recent years. Cooling capacity is one of the factors taken into account to find a suitable location for any energy plant. The current vulnerability of the sector is significant. These plants can usually absorb a few days of interruption in the availability of cooling water, but repeated interruption is clearly problematic.

Energy companies, therefore, experience significant vulnerabilities to freshwater availability (cooling water for large plants). On the other hand, adaptivity and substitution are also significant: energy companies now select profitable locations at sea, using salt water as a coolant. There is also a clear intention to invest in renewable energy, thereby reducing dependence on cooling conceivably further.

Overall, our findings indicate that the energy production sector is vulnerable but no major problems will be found, at this time and in the near future. The greater part of Dutch power in the future will increasingly be produced at the coast, where enough (saline) cooling water is available. Shares of renewable energy are growing, but lagging behind internationally. A final aspect is that energy producers tend to release

heat more efficiently at their plants, thereby increasing productivity.

Figure 2. Large-scale energy production units in 2011 (Energie-Nederland, 2011)

Water supply

Water supply agencies must ensure that they have sufficient supplies available to meet current and future demand. A resilient provision requires companies to develop the following capabilities (e.g., Wuijts et al, 2011; Gleick, 2003):

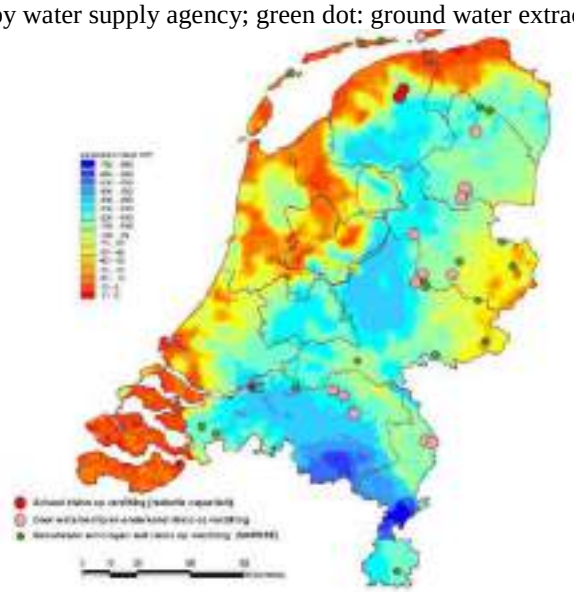
- Monitoring of local changes in rainfall and water supply and groundwater stocks, both short and long term;
- Possibility to store water or retain water volumes within their own areas;
- Programs aimed at reducing water consumption by large users (e.g., through price incentives, regulatory support and market mechanisms);
- Attention to diversify from different sources (surface and ground water, or from adjacent basins), and from available infrastructure;
- Promote water conservation through technological innovation and logistics.

Water companies get their water mainly from groundwater sources (approximately 55%) and surface waters (45% including 5% through dune infiltration). The extraction of groundwater occurs through some 220 extraction points, out of which 33 are vulnerable to salinization (Klijn et al 2011). There is a slight increase in the utilization of surface water (Geudens, 2010), which is consistent with policies to reduce groundwater depletion and diminish desiccation for agriculture and nature. Since groundwater in the western Netherlands is generally too brackish, these regions principally use surface water as a source for drinking water.

The dependency among water supply agencies from ground water represents an important bottleneck. Ground water volumes are gradually compromised by intruding brackish water. Salinity occurs along the coast or by ascending deep groundwater (Figure 3). This dependence is waning, however: the sector is seeking to build resilient through establishing a diversification of sources, particularly through substitution with surface water. On the other hand, this attention to alternative sources is also sparse. A similar finding applies to the utilisation of new techniques and innovations aimed at water conservation and efficiency. The sector, therefore, displays some considerable vulnerability to climate-induced changes in freshwater availability. Capacity-building may be required for safeguarding groundwater supplies, building surface water reservoirs and seeking possibilities for substitution.

A promising initiative among some water supply agencies has been to work together more strongly with industry, to produce industrial water. The focus is on establishing sustainable, integrated areas with coordinated infrastructure (i.e. water pipes), re-use of effluent waters, water reservoirs and differentiation for water quality demand.

Figure 3. Salinization risks for drinking water supply in the Netherlands (Klijn et al., 2011).
(red dot: current risk for salinization, reduction of capacity; pink dot: salinization risk acknowledged by water supply agency; green dot: ground water extraction with salinization risk)



Agriculture

The dependence of agricultural activities from fresh water is land-based. These activities depend on the existence of sufficient soil water, controlled ground water levels, and irrigation (LTO, 2010). The agricultural sector is prominent to the Netherlands as they are by far the largest land user in the Netherlands (about 60% of all available land). Irrigation is the main form of water use. The capacities needed to alleviate water dependency for agriculture focus, among other things, on:

- Efficient irrigation systems;

- Shift to crops that require less water in areas where groundwater levels fall, as precipitation decreases (higher sandy regions);
- Efforts to gradually concentrate, cluster or move (further) sensitive agriculture such as fruit and flower bulbs;
- Attention to potential economies of scale and technological innovation;
- Establishing robust management approaches to surface and ground water, focusing more on either extremely wet or dry episodes.

Our findings for agriculture reveal a diverse picture showing a varied dependency on groundwater and surface water, but also strong contextual dependencies related to socio-economic conditions. The vulnerability of the sector represents itself in two ways. First, there are quantitative difficulties, in terms of irregular water supply and episodes of drought. A second category of vulnerability is more qualitative: soil salinization. Both categories represent serious vulnerabilities. At the same time, however, we see substantial capacity-building efforts, particularly with regard to knowledge development on strengthening crop tolerance (against drought, salt), establishing new techniques, and increase productivity (Stuyt, 2006).

The Dutch agricultural sector is clearly not shying away from implications from climate change and hence water availability. The sector invests considerably in innovations (including pilot projects), thereby pursuing more efficient uses of water. There also is a focus on strengthening redundancies in terms of water sources and its infrastructure, and create the conditions for internationally high level of water certainty with the aim to improve European competitiveness to agricultural production.

Nature

For nature and ecological land uses, capacities to protect and regulate hydrological systems and understand consequences from climate change is essential. These capacity express themselves, for example, in:

- Attention both temperatures, the timing and volume of water flows in relation to ecosystem aspects like habitat, migration, survival, and food;
- Estimates of the adaptation of species to hydrological variability;
- The construction of water reservoirs and areas for buffers and natural variability;
- Anticipating natural, ecological and biodiversity change.

Nature protection and management is a sector working on complex interrelations between nature and the qualitative and quantitative characteristics of surface water and groundwater (Paulissen et. al, 2011). Issues such as habitat, reproduction, migration, survival, and food potentially pose high levels of vulnerability. Adaptation possibilities for animals and plant species to hydrological variability are essentially challenging. Our findings suggest ample adaptive capacity, however. At the regional level buffer zones offer good opportunities to battle drought and create more self-sufficient nature. There is also capacity to actively develop nature in a different,

adaptive direction, through adjustment of types of nature (more brackish habitats, with fresh-salt gradients).

3.2 Capacities per sector

Table 2 provides a general overview of all location factors, current capabilities and policy options broken down by sector. The overview shows relatively high capacities to deal with climate change impacts on fresh water at existing locations and places. Nevertheless, for three sectors a lack of situational capacities may require changes in location. At the short term relocation plays a role for energy production plants, who are increasingly taking coastal locations, near the sea, and thus would use less cooling water along major rivers and canals. In the longer term, locational change manifests itself as a reality to those water companies facing salinization, and for whom substitution possibilities with surface waters are limited. The proximity of infrastructure (pipelines) will be highly important to create redundancies towards water sources. It may also be possible that a gradual replacement of highly water-sensitive types of agriculture such as fruit and flower bulbs will be emerging. But these users also have many capacities on-site, including rich local regulatory arrangements and water management options like water buffers and reservoirs.

Table 2. Overview of place, capacity and strategies per sector

Sector	***Place***	***Capacity***	***Further strategies***
Industry	- proximity to surface waters key - specific activities rely on ground water - limited amount of large users do most consumption - smaller industries rely on drinking water	- substantial adaptive capacity, particularly for cooling water - recent efficient use of ground water - gradual application of sustainable technology (production, re-use) - limitations to innovation due to regulations and tax arrangements - capacities from attention to new 'water economy'	- technologies for efficiency, restraints and adaptive capacity - clustering of industry and water companies (e.g. separate water supply infra) - private of (semi-)public water management (e.g., for purification) - new fresh water reservoirs
Water supply	- proximity of clients and infrastructure essential - varying types and qualities of sources - by far largest user of ground water	- resilience through decreasing dependence on ground water (substitution with surface waters) - vulnerable due to uncertainties in demand, limited anticipation on increasing water demand - necessities and capacities for change of location (e.g., due to brackish water) - some, yet limited attention to alternative sources and technology	- attention to ground water supply and reservoirs - attention to curbing use through price incentives and innovation - attention to diversification towards sources (surface, ground, adjacent water sheds)
Energy pro-	- strongly linked to proximity of surface	- vulnerable due to need for consistent availability of cooling	- attention to risk management for

duction	waters - large users - mostly electricity companies (cooling water for large plants)	water - strongly decreasing vulnerability given viable locations at sea (saline cooling water) - growing (but varying) investment capacity in sustainable energy, decreasing dependence from cooling water	diminished water supply for plants - verification of optimism about sustainable energy, and the volumes of water use with new energy technologies
Agri-culture	- multiple dependence from ground- and surface waters - strong interrelation with socio-economic conditions - largest water user, heterogeneous composition	- vulnerable both in a quantitative (supply, drought) and qualitative sense (salinity) - changing fresh water patterns potentially cause serious changes in soil conditions - substantial attention to knowledge development and policy proposals - strong attention to adaptation strategies (e.g., tolerance of crops, new techniques, productivity enhancement)	- attention to efficient systems for irrigation - consequences of shift towards water-efficient crops - (further) concentrate, cluster of relocate highly water-sensitive agriculture like fruit and flower bulbs - more vigorous water management aimed at excessive wetness and drought
Nature	- complex coherencies between temperature, timing and volumes of water, and ecosystem characteristics like reproduction, migration, survival, and food	- focus on desiccation and 'natural' water level management - attention to buffer zones, self-sufficiency and nature as 'water supplier' - vulnerable from decreasing public funds - adaptive capacity from adjustment to 'target nature' (more brackish, saline-fresh)	- assessment of hydrological adaptability among species and plants - attention to anticipating ecological change

4. Conclusions

This paper has explored major capacity bottlenecks among major water users. The focus has been on location considerations, and also the capabilities and potential adjustments for five sectors, namely industrial companies, energy companies, water companies, agriculture and nature. Based on this study, a series of three general empirical conclusions may be drawn:

- The situation in which sectors, parts of sectors or individual companies are dependent singularly on locally available reserves or supply to such an extent that they will need to terminate production or relocate in the short term (next decade), is unlikely;
- There are no activities for which improvements in efficiency, economy, productivity, or substitution are all greatly reduced at the same time. Overall, there is sufficient capacity in all sectors *on-site*, to establish situationally specific adjustments and redundancies to commit to climate change.

- There is a varying awareness or recognition in the sectors of changes in future fresh water availability, and their own vulnerabilities. Further investment in innovation and capacity building in the longer term (more than ten years) will be necessary.

For spatial planning, the implications are to strengthen practices of building resilience at existing sites (including the establishment of integrations between water sources and infrastructure for water accessibility and delivery) and to strengthen efficiency through further integration of functions and more area-specific (water) management. But there are also other requirements for achieving more water-sensitive spatial planning. Various institutional designs should be examined, including those oriented towards accessibility and availability due to rules and regulations regarding ownership, rights, transport and access. It is also important to estimate the role of spatial planning in the short term (through the strengthening of site conditions) and to place and location in the long term (through other land use arrangements and geographies).

Industrial companies are mainly focused on spatial planning arrangements for renewal, and clustering, privatized water purification, and new freshwater reservoirs. Spatial planning for energy companies implies a focus on the use and conditions for sustainable technology. Spatial planning practices for water supply would concentrate on the protection of groundwater sources, preserving less salinity-sensitive ground water extraction sites, and making available more accessible alternative sources (through institutional arrangements and infrastructure). Area-oriented policies may be required to include buffers and reservoirs for nature and water sensitive agriculture like fruit and flower bulbs. For agriculture, and industries based on agricultural products, there is also the opportunity to play out, through spatial planning, the issue of internationally relatively secure fresh-water availability as an element of attractive economic location.

Overall, the paper has shown a need for further development of capacities against diminishing fresh water. Capacity represents an ability to adapt and innovate in the face of changing climate. Current initiatives in the Dutch case on fresh water have shown a prevailing practice in particular on vulnerabilities among large water users to on-site strategies. Important emerging practices include efforts to strengthen accessibility and reliance at specific places, efforts to establish water as a factor of choice and certainty of location, and institution building for policy integration between water, urban and economic development. The findings also suggest the need to further understand the resilience per sector, in particular related to episodes of reduced freshwater availability.

The notion of vulnerability for this case has also suggested a distinction between two notions of place. On-site vulnerability implies levels of capacity at current locations and contexts, typically featuring strategies like productivity innovation, efficiency and thrift. On-site planning practices seem to be particularly well-developed and rich, particularly for private actors and their activities (the focus is on establishing redundancies and efficiency). Public agencies tend to take a more facilitating role

(the focus is on area-oriented management and integration). Practices beyond-site are also emerging, but are considerably longer-term. Beyond-site (focusing on altered vulnerability) interventions imply capacities for locational change and adjustment, typically involving substitution between sources, and imply substantial public intervention.

For both levels of intervention (on-site or beyond) and in particular for the substitution strategy, establishing resilience turns out to be an issue of setting up alternative options of choice. Choosing between varying sources of water, between a variety of water networks, or between varying levels of production: more generic notions of vulnerability involve issues of available choice. Opportunity and capability theory, therefore, could potentially help to strengthen our theoretical understanding of these kinds of cases, and their overwhelming focus on on-site strategies, even further.

Power and politics in the planning system: a political economy approach using evidence from Ireland.

Linda Fox-Rogers[1]

Abstract

The urban planning system and property development sector have come under increased scrutiny in recent years as people begin to critically reflect on the conditions that contributed to a series of property crashes in countries such as the U.S, the U.K, Ireland and Spain. Much of the criticism has been levelled at the emergence of urban governance structures that foster close relationships between actors in the economic and political spheres. Mounting evidence and speculation surrounding the interactions of politicians, officials and property developers in the urban development process has cast doubt surrounding the democratic nature of the planning system as it seems that the interests of private capital increasingly preside over the common good. Although this phenomenon has been widely critiqued by academics, this paper argues that accommodating relations between the economic and political spheres is an intrinsic feature of the planning process and should in fact be expected when one considers the structural relations that govern the distribution of power in advanced capitalist societies. By adopting a theoretical framework that draws upon Marxist political economy approaches of the state and Chomskyan notions of power, this paper positions planning as an activity of the capitalist state and thereby seeks to demonstrate the inherent links that exist between the economic and political spheres in the planning system. The methodology consists of a series stakeholder interviews with urban planners operating within the Irish planning system. Empirical findings are offered to elucidate the manner in which power navigates the planning system by focusing on how power relations arise between competing stakeholders, the mechanisms by which power is exerted in the planning process, and the extent to which power relations become reflected as outcomes in the built environment. In doing so, the paper seeks to demonstrate how the realities of the planning system can be aligned to the theoretical framework employed.

Keywords: Urban planning, political economy, urban governance, Ireland.

1.0 Introduction

As commentators continue to critically reflect on the contributing factors to the global economic crisis, attention has turned to urban planning and its role in the creation of a series of property market crashes around the world (Lovering, 2010;

[1] PhD candidate at University College Dublin's School of Geography, Planning and Environmental Policy. Email: linda.fox-rogers@ucd.ie

Melia and Hogan, 2010; Kitchen et al., forthcoming). In particular, the extent to which the 'neoliberal turn' has been "reflected in, and in turn encouraged by, the reinvention of planning as a service to special interests, especially property owners and boosterist politicians" has been raised (Lovering, 2010: p. 227).

Although critically reflecting on the role of planning has a renewed significance in light of the current property crises being experienced, the emergence of increasingly entrepreneurial or neo-liberal approaches to urban planning have long been critiqued by a wide range of academics for their inherent focus on private-sector development activity and market forces[2] (see Brindley et al., 1989; Squires, 1996; Drudy & Punch, 2000; MacLaran and Williams, 2003; Kitchen et al., forthcoming). The emergence of neo-liberal planning policies has been broadly associated with the 'creeping enfeeblement' of local government (Peck and Tickell, 1994) and emergence of public private partnerships, appointed quangos, private sector alliances and entrepreneurial initiatives dominated by property-led regeneration (McGuirk and MacLaran, 2001).

Looking towards the Irish experience as a case in point, McGuirk (1995) elucidates the powerful position of developers within the Irish planning system and the significant barriers that hinder effective public participation, whilst recent changes to Irish planning legislation also appear to have exacerbated the privileged position of private capital over the common good (Fox-Rogers et al., 2010). Mounting criticism and speculation surrounding the interactions of politicians, officials and property developers in the urban development process has also been exacerbated by the recent publication of the final report emanating from a tribunal of enquiry[3] which was set up to investigate planning corruption in Ireland. The central findings of the tribunal (which lasted 917 days) broadly demonstrated the ability of development interests to exert power over politicians and the planning process in a manner that disproportionally serves their own vested interests at the expense of the population at large.

Central to all of these wide-ranging critiques is a concern with the extent to which urban planning deviates from its normative foundations which are rooted in the assumption that planning is an apolitical, value-free, technocratic process that serves the public interest. The reinvigoration of these debates in light of the current economic downturn have cast further doubts surrounding the democratic nature of the planning system as it seems that development interests increasingly win out over those of the general public. Although such concerns are indeed warranted, this paper argues that the facilitative nature of the planning process and the links that exist between the economic and political spheres are *inherent* and should therefore be *expected* if one situates urban planning as an activity of the capitalist state and critically reflects on the manner in which power operates in society.

[2] For an excellent and comprehensive review of planning related neo-liberal policies see Sager (2011).
[3] The Tribunal of Inquiry into Certain Planning Matters and Payments.

As part of a piece of on-going research that seeks to shed light on the manner in which power navigates the urban planning system, this paper offers some insights from the perspectives of Irish urban planners based on their own experiences[4]. The paper begins by setting out a theoretical framework based on Marxist political economy perceptions of planning and Chomskyan notions of power before outlining the methodological approach employed. Preliminary results are offered which seek to elucidate the manner in which power relations arise, are exerted and manifest themselves in the planning process and the extent to which such findings support the theoretical framework are explored in the concluding discussion.

2.0 Capitalism, power and politics in planning

As planning is an activity of the state, our understanding of the state is central to our perception of the role of urban planning. Marxist political economy perspectives of the state and urban planning differ significantly from more conventional pluralist perceptions as they are much more cognisant of the structural relations that govern how power is distributed in society.

While pluralist perceptions of the state and urban planning assume that individuals have equal power to assert their stake regardless of their resource levels, Marxist political economy perceptions question the ability of the state (and thus planning as a state activity) to act as a politically neutral institution given its historical origins. Rather than viewing the state as a neutral arbitrator between competing interests, the Marxist approach views the state as "…the instrument by which the organisation of society becomes the means of preserving intact the material interests of the dominant classes" (Paul, 1917: p. 95).

> "*Nominally it administers in the name of society, but in reality it only seeks to preserve the domination of the master class of any period."* (*Ibid*: p.95, emphasis original).

Central to this theoretical position from a planning perspective is that planning, as an activity of the capitalist state, is not an autonomous activity. Rather planning must be functional to capitalism and planners are thus seen as state agents that favour capital interests rather than the common good (MacLaran and McGuirk, 2003).

Although Marxist theory does not explicitly theorise about power per se, it implicitly elucidates the power relations which emerge between the capitalist and the worker under capitalism given the former's control over the means of production. Marx's (1976) concern with the threat posed to human liberty by the capitalist mode of production and its alienating effects can be aligned to classical liberal assumptions about the innate "human need for liberty, diversity and free association" (Chomsky, 2005: p. 123) unbound by external force or coercion. Given that the state serves the

[4] The full research project will involve interviewing three additional stakeholder groups namely, developers, councillors and community interest groups. As such, this paper relates to the first stage (of four) in the overall research project.

ruling class of any period, under capitalism its role is to preserve the basic power structure inherent in capitalist society by facilitating the continuation of the capitalist mode of production and assuaging class conflicts. From a Marxist perspective, the planning system is thus considered as one of the many state instruments that functions in a manner that reflects dominant interests in capitalist society.

It was not only Marx that was concerned with the power relations arising out of the ownership of private property. More recently, Noam Chomsky (2003) has argued that under capitalism real power lies in the private economy rather than the political system as political decisions made in the 'national interest' are "articulated by those who control the central economic and political institutions" (*Ibid*: p.147). Also drawing upon classical liberal ideas, the central tenant underpinning Chomsky's understanding of power is the assumption that any structure of domination is illegitimate unless it can be justified. The burden of proof rests with those in positions of authority to substantiate and legitimise their position; if cannot be justified, they should be challenged and ultimately dismantled[5].

However, both Marxist political economy perceptions of the state and Chomskyan notions of power recognise the self-preserving nature of power and the need for those in power to acquire the "consent of the majority of the governed" (Harvey, 2001: p.277) in order to survive. For Chomsky (2002: p.11), the standard way that such power relations are protected is to place a "cloak of mystery around power". This can be done in a variety of ways via a "complex system of filters" (*Ibid*: p.27) in the media and education, as well as the "terms of political discourse [which] are designed to prevent thought" (*Ibid:* p.41). Ideologically-laden terminologies such as the 'common good' and 'national interest' are examples Chomsky uses to demonstrate the manner in which language can be used as a means of 'containment'. Flyvbjerg's (1998: p.228) landmark study of power and planning in Aalborg similarly demonstrates that rationalisation (presented as rationality) is a "principle strategy in the exercise of power which can be difficult to identify and thus requires deconstruction". Marx and Engels (1970 as cited in Harvey, 2001) also identify similar strategies to gain the allegiances of the subordinate class. The first is to represent dominant interests as the 'illusory general interest' by universalising ruling class ideas as the only universally valid ones' (*Ibid*: p.71). The second is to give the appearance of neutrality in state operations by providing certain social goods such as social housing, education and transport. The fact that such goods are prerequisites to facilitate the continuation of the capitalist mode of production, but lie beyond the logic of individual capitalists to provide, is not made explicit (Sandercock, 1998: Harvey 2001; MacLaran and McGuirk, 2003). Strategies such as these are essentially employed to avoid class conflict and prevent challenges being brought to bear on the power structure governing capitalist society. As explained by Chomsky (2003: p.149) "power will work for its own purposes, whatever the rhetoric to disguise or legitimate it".

[5] See Anarchism 101 with Noam Chomsky. Accessed at: http://www.sciencestage.com/v/1038/anarchism -101-with-noam-chomsky.html. Last accessed 20th April 2011.

Analogous sentiments can be traced back to the work of Bertrand Russell (2004) in the 1930's, who similarly highlighted the importance of challenging structures of power and domination. Russell (2004) argued that to make 'naked' the 'traditional' and disguised form of power that is exerted by the capitalist state and the illegitimacy of the power relations it creates, a period of "free thought and vigorous criticism" is required (*Ibid*: p.75). He argues that "in every democracy, individuals and organisations which are intended to have certain well-defined executive functions are likely, if unchecked, to acquire a very desirable independent power" (*Ibid*: p.232). In order to overcome such issues there is a need "to bring swift criticism to bear upon officials, police, magistrates, and judges who exceed their powers" (*Ibid*: pp.231-232). Increased political awareness and public contestation is thus required in order to place more stringent check and balances on those with the power to administer decisions in the interests of the 'common good'.

Whilst it is acknowledged that placing checks and balances on those in power in advanced capitalist societies will do little to change the structural drivers of power that are inherent in the capitalist system, it is argued here that such challenges can assist in working towards a more equitable redistribution of economic and political power *within* that system, thus making tangible differences to those who are ill-placed and relatively powerless at present. To quote Chomsky:

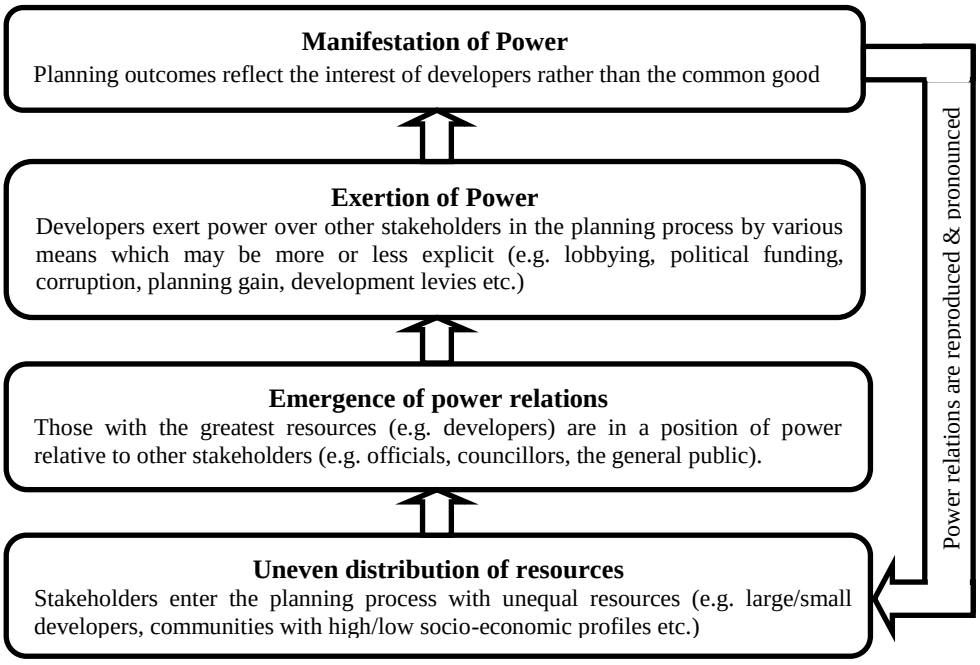
> *"I think it's completely realistic and rational to work within structures to which you are opposed, because by doing so you can help to move to a situation where then you can challenge those structures."*
>
> (Chomsky, 2002: p.345)

Based on the theoretical framework outlined above, it is assumed that power relations arise out of the ownership of private property or the means of production which confers power upon groups or individuals (see Figure 1). An unequal distribution of resources leads to leverage in the political sphere and political economic interactions work to serve the interests of the economically powerful by creating the conditions necessary for further capital accumulation and the consolidation of systems of private power. The outcomes arrived reflect the interests of private capital and thus serve to reproduce and reinforce existing imbalances of power in the system. However, checks and balances can be placed on those with decision making power to bring about somewhat more democratic outcomes than would otherwise occur.

By applying this theoretical lens to the sphere of urban planning, it is hypothesised that stakeholders enter the planning process with unequal resources and those with the most economic resources (e.g. property developers) are able to exert power in the political sphere and influence planning decisions in a manner that serves their own interests at the expense of other stakeholders (i.e. the general public). Given that planning is an activity of the capitalist state, public participation in planning and the politicisation of planning is needed to place greater checks and balances on those with decision-making power in order to generate more equitable planning outcomes.

The physical and social impacts experienced by receptive communities depends not only on the level of participation achieved, but also tends to reflect the socio-economic profile of the community as those with greater resources (e.g. education, money, skills) tend to be better placed to challenge the status quo.

Figure 1: Conceptualisation of the theoretical framework



3.0 Methodology

Qualitative semi-structured interviews were carried out to attain data from respondents from a selection of four local authorities within the Greater Dublin Area (GDA)[6]. The local authorities were selected on the basis that they together provide a wide range of planning contexts, development pressures, socioeconomic profiles and geographic locations[7].

Semi-structured interviews were used because many of the in-depth questions being asked did not lend themselves to quantitative approaches. Qualitative methods are also considered suited to the theory verification approach being employed, with

[6] The GDA was selected as the study area on the basis that is has experienced the highest levels of residential and commercial development pressure over the past decade nationally and also consists of a diverse mixture of urban, suburban and more rural local authorities. The GDA's economic dominance nationally, coupled with it being the centre of national decision-making and political power also makes it an ideal study area from which to analyse political economic interactions in the planning system.

[7] These criteria draw upon earlier bodies of research that link varying levels of active citizenship and participation in the planning sphere to an area's level of growth (Scott et al., 2011) or its socio-economic profile (Ellis, 2001; Lowndes et al., 2006).

Silverman (1993) outlining that pre-specified theories are increasingly being tested with qualitative data despite the traditional dominance of theory generation approaches in qualitative studies. An interview schedule was drawn up which focussed on core themes specifically relating to the objectives of the research. The questions were theoretically guided, exploring broad issues of power and politics in planning. Respondents were also invited to draw upon specific planning cases/controversies to help illustrate their responses and provide some specific contexts from which to understand these broader processes at work. A preliminary scoping exercise[8] of significant planning decisions and planning issues in each of the four local authorities over the past decade was thus carried out so that more detailed discussions could be facilitated where such cases arose during the course of the interviews. The interview guide was piloted successfully and no significant changes to the guide were considered necessary.

Respondents were selected on the basis of three core criteria: (1) their local authority; (2) their professional grade and (3) on the basis of whether they worked in development management or forward planning. In terms of (1), a quota of 5 planners was sought from each of the four local authorities, thus equating to 20 respondents in total. For (2), variations in the employment grade (i.e. assistant, executive, senior executive and senior) was sought to ensure that responses were not skewed in any particular direction on the basis of their level of experience or position. For (3), a mix between planners working within the development management (DM) and forward planning (FP) sections of their respective local authorities was also sought[9]. This was to ensure that appropriate information could be gathered from the various stages in the planning process. Table 1 provides a breakdown of the respondents based on the foregoing criteria.

Table 1. Breakdown of respondents by local authority, grade and expertise.

Local Authority 1	**Local Authority 2**	**Local Authority 3**	**Local Authority 4**
P1- Executive (DM & FP)	P6- Senior (DM)	P11- Senior (FP)	P16- Assistant Executive (FP)
P2- Senior (DM)	P7- Senior (FP & DM)	P12- Senior Executive (DM & FP)	P17- Executive (DM)
P3- Assistant Executive (FP)	P8- Executive (FP &DM)	P13- Assistant Executive (DM)	P18- Senior (FP)
P4- Senior (FP)	P9- Executive (DM)	P14- Executive (DM)	P19- Executive (FP)
P5- Executive (DM)	P10- Executive (FP & DM)	P15- Executive (FP)	P20- Senior (FP)

[8] The scoping exercise involved exploring some prominent planning cases, drawing upon an array of planning sources such as newspaper archives, individual planning authority's on-line planning systems, urban planning forums, An Bord Pleanála (appeals authority) inspector's reports etc.

[9] In some instances, planners had relatively equal levels of experience working within development management and forward planning.

Non-probability or 'snowball' sampling methods were adopted to generate respondents based on the criteria outlined above. The 'snowball' approach began by making initial contact with a small group of suitable respondents to establish further contacts with others. Many of the planners who agreed to participate did so upon initial contact, with some requiring follow-up e-mails and telephone calls. The interviews were anonymous to encourage the respondents to be as open and transparent about the realities of the planning system as possible and also to improve the participation rates of those contacted[10]. The interviews ranged from 48 to 73 minutes in duration, with the average interview taking 62 minutes to complete. All of the interviews were fully transcribed verbatim.

3.1 Analytical framework

In seeking to trace the manner in which power navigates the planning system, a series of hypothetical indicators of power were developed as a methodological tool to help identify instances where issues regarding the operation of power emerged from the data. These indicators were developed by applying the theoretical framework to the planning domain in order to postulate how one might expect power to operate in the urban planning system. Each of the interview transcripts were carefully analysed and instances where any of the 'indicators' emerged in the data were recorded and documented for each of the respondents. This facilitated the identification of the most commonly cited indicators and also illustrated the degree to which the realities of the planning system could be aligned to the hypothesised indicators and by extension, the theoretical framework. The following section outlines the most common indicators emerging from the interviews[11].

4.0 Results

4.1 The emergence of power relations

As outlined previously, it is hypothesised that stakeholders enter the planning process with unequal resources and those with the most economic resources are in a more powerful position to exert leverage in the political sphere and influence planning decisions. The two most common indictors relating to the emergence of power relations in the planning system are presented below.

4.1.2 Power emerging (1)

Having regard to the manner in which power relations arise in the planning system, the relative lack of local government resources and the subsequent reliance of local

[10] Out of the 30 planners contacted, 22 agreed to participate, 7 failed to reply and 1 declined to participate.

[11] Given the constraints on this paper, the results will be limited to the two most common 'indicators' in each category namely, power arising, power exerted and power manifested.

authorities on the private development sector to generate income streams[12] was the most commonly raised issue by the respondents. Indeed 80% of the 20 planners interviewed made reference to this issue highlighting that it places developers in a powerful position in the planning process. The level of consideration that is afforded to generating income streams from private development activity by planning officials was clearly outlined by an executive planner:

> *"…as a planner, we are not supposed to be considering the financial aspects of it* [an application] *but it's an impossibility not to and you have to realistically"* (P1: 11)

The relatively powerful position that this places developers in during the planning process was explained by the same respondent:

> *"…in a plan process, we also have to set it out or word it in such a manner that it will say 'yeah come, come here and it will be great. Yeah we do things better here. We'll give you another couple of floors on it or whatever it is. You know if you're going to build down town here, you're going to get- generally, not always, you're generally going to get a bigger development than if you're building in Sandyford industrial estate, but not always you know.'"* (P1: 11)

The current economic climate appears to have exacerbated the power of developers relative to the executive in this regard and was highlighted by an assistant planner reflecting on the ability of local authorities to provide public goods since the downturn:

> *"We're completely reliant on them* [developers] *now anyway- it's the only way anything is going to get built in the future."* (P13:14).

Another executive planner highlighted that the reliance on the private development sector to fund local government through building activity may be even greater in smaller local authorities that experience lower levels of central government funding:

> *"I suppose the smaller ones* [local authorities] *have a lot more to lose…because of a lack of budgets and a lack of resources, they won't get X amount of money into the county if they are not kind of seen to bend the rules you know?"* (P12: 12)

[12] The means by which local government in Ireland is structured has resulted in limited opportunities for local authorities to raise income independently of central government. Two of the principal means of raising income within the control of local authorities (and hence planning authorities) are commercial rates (payable to the local authority annually) and development contributions (payable to the planning authority as a condition to a grant of permission).

The forgoing suggests that the reliance of local authorities on income streams from development levies, commercial rates etc. to supplement central government funding places developers in a powerful position over the executive.

4.1.3 Power emerging (2)

Having regard to the democratic nature of the planning system and the power of communities to affectively engage in the process, the importance of resources appears to be of paramount importance. Of the 20 planners interviewed, 80% highlighted that the relative power of communities to assert their stake in the planning process was closely linked to their respective socio-economic profiles with stronger levels of opposition reported in more affluent neighbourhoods. As one senior planner outlines:

> *"There's a very poor relationship between the middle class people and the city council and Dublin in general, but by God do they come out when you see the likes of the Sean Dunne development* [a controversial high rise proposal] *then you have the 'A list' of barristers and the resources in Ballsbridge* [an affluent city centre neighbourhood]*..."* (P2:10)

The availability of resources appears to determine the power that communities have in planning process with those with higher socio-economic profiles being in a more powerful positions than those with lower resource levels. As explained by one executive planner:

> *"They* [a relatively affluent community] *just seem to have that real focus, a real drive, the know-how, the knowledge, able to get out there and get so and so's attention and interest in the project quicker. So I'm definitely thinking like the other group then* [a less privileged community]*, it's a newer area, there's been no investment out there in the last number of years because they didn't push for things. They* [a relatively affluent community] *seem to demand, they seem to know this is what we want, this is what we expect you know?"* (P10:10)

In a similar vein, the impact that this has on respective communities in terms of the planning outcomes arrived at is succinctly put by one senior planner:

> *"I suppose the evolution of the city would show that stuff gets put beside those who argue least…"* (P4:6)

The forgoing suggests that those communities with higher socio-economic profiles or resource levels are better placed to challenge dominant interests and prospective developments in their area, raising serious concerns for those communities who lack such resources.

4.2 The exertion of power

The following section outlines the most commonly cited mechanisms by which power is exerted in the planning process based on the experiences of the planners interviewed. Based on the theoretical framework employed it is assumed that those with the most economic resources (i.e. property developers) are best placed to exert power in the political sphere and influence planning decisions in a manner that serves their own interests at the expense of other stakeholders (i.e. the general public).

4.2.1 Power exerted (1)

Of the 20 planners interviewed, 85% highlighted that developers exert considerable leverage over councillors during the development plan making stage by lobbying them for favourable land zonings[13] in return for political funding. One planner succinctly explained the manner in which political funding plays a role in exerting power in the forward planning process:

> *"I'm* [a developer] *giving you* [a councillor] *a hefty donation knowing that the zoning is going to come up in two or three years' time. Now you know don't forget me."* (P6:6)

Another planner highlighted that political donations enable donors to exert influence over councillors in the development plan making stage or during the subsequent submission of a planning application:

> *"…now some people are quite happy I suppose to give money over* [to councillors] *because they are affiliated with such and such a party but some people have an agenda and there's no doubt about that. They're giving money knowing that they know they might need a hand down the road for whatever reason whether it's a planning permission coming in and they'll get the councillor to see can they you know, sway the decision a certain way…"* (P14:6)

The extent to which developers and councillors cooperate in the development plan making process was explained by a senior planner working in forward planning:

> *"...when I was in X* [local authority], *they* [developers] *were definitely lobbying and they were lobbying them* [councillors] *constantly. In fact the gallery was packed and they were texting each other* [developers and councillors] *up and down you know, I mean the scale of involvement. I mean it's no fun going into a council meeting and when they're actually having to*

[13] The Local Government Act 2001 provides the framework for reserved and executive functions that are carried out on behalf of a local authority. Reserved functions are performed by elected members (i.e. councillors) who essentially constitute the policy-making arm of local government. Executive functions are carried out by the local authority's manager or delegated officials (e.g. planners). Granting or refusing planning permission is an executive function, but the adoption of a development plan is a reserved function of the elected members.

elbow through all the developers, lobbyists, farmers and they're all trying to get stuff zoned, all standing in the lobby of the council meeting you know and it's packed…when they're making certain decisions." (P4:10)

The forgoing clearly illustrates the links between the political and economic spheres in the forward planning process and the manner in which the resources available to developers enables them to exert power in this regard.

4.2.2 Power exerted (2)

In contrast to councillors working on behalf of development interests, many planners highlighted that councillors can also be responsive and representative of community needs. The ability of certain communities to exert power over their elected representatives was raised by 75% of the planners interviewed. However, the extent to which councillors represent the interests of their electorate at large appears to depend on the extent to which the community places demands on them by making them accountable during the democratic process. As one senior planner explained:

"I mean they need to get re-elected so maybe if something was so widespread unpopular that they thought it might not stand to them at the next general election or if an opposing party was taking a strong argument against it then that might sway them." (P15:21-22)

An interesting distinction was made by many of the planners between the representativeness of councillors in the rural verses more urban local authorities. Various planners report that Dublin-based councillors rarely lobby on behalf of development interests and instead tend to lobby against developments on behalf of their constituents. This appears to contrast with non-Dublin based authorities when respondents reflected on their experiences of how councillors operate in more rural authorities. However, many planners simply attribute this distinction to the higher demands that are placed on Dublin-based councillors from their electorate rather than any moral obligation.

"Councillors in Dublin would be more sensitive about development and again it's not because they are virtuous, it's because they are responding to their constituents who are against development" (P2: 15).

Another planner reflecting on the differences between urban and rural local authorities in this regard outlines:

"It's to do with the voting public. The difference is, well one- there's the political difference. In Dublin you've a much stronger Labour vote. It's a much more organised population so the urban vote is more left-leaning naturally..." (P4: 15)

The forgoing suggests that communities who place greater checks and balances on their political representatives appear to have more accountable and representative councillors than they otherwise may have. Without these checks and balances being placed, it seems that councillors are more facilitative of private interests rather than their electorate at large. This may have significant implications in terms of planning outcomes arrived at as those elected representatives who are closely monitored by their electorate may be more likely to champion more socially just and equitable planning decisions. However, this raises serious concerns when one considers that many communities fail to engage with their elected representatives or politicise planning related issues.

4.3 The manifestation of power

Having regard to the manner in which the exertion of power becomes manifested in the planning process, it is hypothesised that planning outcomes reflect the interests of developers rather than the common good. The following highlights some of the most commonly cited effects that ensue from the exertion of power in the planning process.

4.3.1 Power manifested (1)

The most common manifestation of power in the planning process which was raised by 80% of respondents was that development plans (or material contraventions to the development plan) which are adopted by councillors tend to reflect the interests of developers rather than the principles of sustainable development or best planning practice. Some planners identified particularly 'crafty' ways that councillors ensure development interests are represented in the adopted plan. As explained by one senior planner working in the forward planning process:

> *"You go through numerous late evenings going on to midnight with the councillors going through the manager's report and then as I say, at the last minute they will submit motions from the floor and the motions are coming through completely left of field you know and you've had no time to prepare for them. They usually involved rezoning submissions or issues that really are not appropriate but they tend to be pushed through on the final night or the last couple of nights of the development plan process you know, which is a wee bit galling to be honest."* (P20:2)

The impact that this has on the quality of development plan was clearly outlined by the same planner:

> "*And usually the manager in the planning authority, to push the local area plan or the development plan over the line usually bargains away things that in the normal course of events they wouldn't."* (P20: 1)

4.3.2 Power manifested (2)

Another key issue emerging from the data with regards the manifestation of power is that the executive is hamstrung to facilitate development on the basis of rate generation and development levies. 75% of the respondents drew attention to this phenomenon during the course of the interviews. In terms of the manner in which authorities 'facilitate development', one planner explains that lower development contributions or less stringent assessments on planning applications may be used to attract development and help to stave off competition from other local authorities for the lucrative rates base.

> *"Yeah like a development contribution scheme, a lower development contribution scheme to reduce the cost of developing within a particular area- that's one way. Not sticking to principles in terms of land, develop wherever they* [developer] *manage to find the land, rather than within zoned land which might be more expensive."* (P 7:10)

The importance of attracting development and investment into counties was highlighted by another planner who outlined the lengths that a manager will go to in order to prevent the loss of prospective investment in the county:

> *"…it can get to the stage where for example a refusal is going out….he* [the manager] *can get on to the developer and suggest that he removes it from the system, that we sit down again and start negotiating about a revised development. I don't know whether from a political or whatever point of view it might appear bad for us to be say, refusing an employment generating proposal at the moment. So rather than it going out as a refusal, it might be withdrawn by the applicant and then they start negotiating to have to sort of a compromise."* (P6: 7)

The forgoing suggests that the needs of developers are catered for to a greater extent than the population at large given their inherent ability to exert power over officials and councillors. As a result, it appears that planning outcomes do not serve the common good but rather reflect the interests of developers given the power they exert in the planning system.

5.0 Conclusions

This paper has attempted to demystify the manner in which power operates in the planning system by clearly identifying some of the most commonly cited mechanisms by which power relations arise, are exerted and manifest themselves in the planning process. The results highlight the importance of resources (i.e. economic power) in the creation of power relationships between various stakeholders in the planning system. In particular, the importance of resources in determining: 1) the powerful position of developers relative to local authority officials; and 2) the ability to effectively engage in the planning system were the most commonly cited indicators. As these relations emerge, it becomes apparent that those in economically

powerful positions are best placed to exert power in the planning process. In this regard, the ability of the property interests to influence councillors to adopt development plans that reflect their vested interests emerged as the most commonly cited mechanism by which power is exerted. Conversely, the respondents also highlighted that certain community groups can exert leverage over their elected representatives through the democratic process to ensure they serve their own interests rather than the interests of property developers or big business. This observation in particular illustrates the importance of placing checks and balances on those in positions of power. In terms of the manifestation of power in the planning system, the most common indicators emerging were: 1) development plans being adopted that reflect the interests of developers; and 2) local authorities being overly facilitative development proposals. The potential impacts that these 'micro' level manifestations can have on a community become even more apparent when one considers the broader planning outcomes that emerge from these smaller manifestations that occur at various stages in the planning process. In this regard 80% of respondents made reference on some level to planning outcomes being arrived at that do not divert significantly from a non-planning scenario.

Although the results offered in this paper are preliminary findings and require further in-depth analysis and investigation, the foregoing indicates a strong degree of correlation between the hypothetical indicators of power developed from the theoretical framework and those emerging from the data. In doing so, these findings support a Marxist political economy approach which views planning as a state activity that facilitates the interests of private capital. By adopting such a position, critical reflections on the facilitative nature of urban planning in the lead up to a series of property crashes in countries such as Ireland, the US and Spain should come as no major surprise. As a result, it is argued here that any further reflections on the role of planning must be more cognisant of the structural relations that govern how power is distributed in society.

The Political Construction of Urban Development Projects: Comparative Case Studies From Turkish Cities

1. Introduction and Theoretical Framework to Investigate the Politics of Urban Development

The production of urban space is a politically constructed process to reproduce the dynamics of capitalism. In this political process, a hegemonic-ideological power has been constructed over the definition of urban political priorities. Urban development projects (UDPs), in this political process, could be investigated as politically-ideologically constructed hegemonic projects, providing dynamics for the reproduction of capitalist socio-spatial relations.

UDPs have become the dominant mode of producing urban space in capitalist countries over the last three decades. With the formation and implementation of UDPs, new central business districts, waterfront developments, tourism-oriented consumption complexes, gated and luxury residences and shopping malls… etc. have been produced to provide a "competitive" and "attractive" urban space for the sake of capital accumulation.

However, political-economic dynamics behind the formation of UDPs could not only be understood through analyzing the relations between the formation of UDPs and economic structure of capital accumulation. To reveal these dynamics, we should also critically investigate how governmental and non-governmental agents, in the capitalist system, form hegemonic block (a coalition of social forces in Gramscian terms) and organize political-ideological (superstructural) mechanisms with these UDPs to shape the policies of urban development. This paper focuses on such an empirical survey to reveal the political construction of UDPs in Turkish cities.

In the literature of urban development politics, there are different views on the politics of UDPs. Neo-pluralist and neo-Weberian theories including "urban regime" and "growth machine" approaches put emphasis on agent-based aspects, relations and organizations in the political construction of UDPs. Urban regime approach emphasizes formal and informal relations and networks between the agents of government and business (Stone, 1989). Growth machine approach underlines the central role of growth-oriented coalition formations and reveals how such coalitions have been formed by the involvement of land-based business elites, local media, universities and local non-governmental organization (Logan & Molotch, 1987).

These neo-pluralist and neo-Weberian approaches are critically reviewed by neo-Marxian regulation perspective and it is concluded that such agent-oriented approaches neglects to research the economic base of UDPs, they ignore the role of capital accumulation processes, class conflict and hegemony in the political construction of UDPs and fail to reveal how the capitalist state intervenes to this process (Macleod & Goodwin, 1999). These approaches develops an overtly emphasized agent-oriented focus at the expense of losing the structural capitalist

dynamics behind the formation of UDPs. Therefore they propose voluntarist explanations for the investigation of the political construction of UDPs.

On the other hand, there are Marxist geography approaches, focusing on the capitalist economic structure of urban development processes. As the leading Marxist Geographer, Harvey (1989a) argues that there is a structural relation between the production of space and capital accumulation. UDPs, within this approach, reflect entrepreneurial urban policy mechanisms, aiming to provide a good business climate for a better functioning of capitalist market forces under the dominance of coercive laws of inter-urban competition (Harvey, 1989b). Through following Harvey's framework of capitalist urbanization, Smith (2002) points out that UDPs have become global capitalist urban strategies to reduce the rent-gap between actually ground rent realized from the present and highest best use in terms of exchange value.

Marxist geography approaches are criticized since they overtly emphasized the role of structural dynamics and develop an economic determinist/reductionist approach in explaining the political-ideological dynamics behind the formation of UDPs. Marxist geography approaches do not provide a critical theoretical base to investigate the political-ideological superstructural dynamics of UDPs. What role the agents of state and capital play through which hegemonic-ideological discourses and activities in the political construction of UDPs? To answer these questions, neo-Marxian perspectives of urban politics should move beyond both the economic determinist explanations of Marxist geography approaches and voluntarist-agent oriented explanations of neo-Weberian and neo-Pluralist approaches. Paper argues at the theoretical level that this could be provided through adopting the dialectic relation between the structures and agents of capitalist urbanization and revealing how UDPs, as the policy-making mechanisms of urban entrepreneurialism, have been politically-ideologically constructed by a coalition of state and capital actors within the context of capitalist system.

Within this context, in order to formulate a neo-Marxian theoretical perspective to investigate the political-ideological construction of UDPs, Gramsci's (1971) idea of "hegemony" and Lefebvre's (1991) concept of "the production of space" and the relations between these conceptions are critically elaborated and discussed in this part of the paper. Gramsci (1971) defined hegemony as the "political and ideological activities, moral and intellectual leadership with which ruling class becomes capable to take active consent of those over whom it rules". Hegemony plays the central role in constructing a political-ideological power over the definition of political priorities in policy-making processes. However, hegemony is not the only basis through which the political-ideological power of capitalist ruling classes are produced and maintained. Force is also another key and important dimension of political power, therefore it is widely argued by Gramscian Marxist perspectives that hegemony (consent) and force (coercion) force are two underlying, interrelated and articulated dimensions of political power (Forgacs, 2000). In other words, political power of

capitalist ruling classes have been constructed by a differential articulation of hegemony and force.

Hegemony is constructed by the formation, operation and domination of "hegemonic projects". According to Joseph (2002) to reveal how hegemony is constructed it is needed to investigate "different hegemonic projects, the particular social groups and classes involved to these projects, the interest that they represent, the various values and world-views that they hold and the political blocks and alliances that are constructed in these projects".

Gramscian perspective of politics shows that the conditions for capital accumulation are not given but have to be socially secured through political and ideological mechanisms as well as economic ones (Gramsci, 1971; Forgacs, 2000). Hegemonic projects of capitalist ruling classes emerge from such a political-ideological superstructural context of capitalist system. Moreover, hegemonic projects are formed, organized and operationalized through utilizing organizing capacity of the state, which provides institutional frameworks for the implementation of these projects. Therefore, as Jessop (1997) argues, the state and its policy-making mechanisms could be viewed as strategic terrains upon which different social groups compete to implement their hegemonic and counter-hegemonic projects. This is how class struggle has occurred within the contexts of political-ideological superstructures of capitalist system.

With his neo-Gramscian regulation approach, Jessop (1997) also provides critical insights and perspectives to elaborate further the conceptions of hegemony and hegemonic project. According to Jessop (1997) hegemonic projects are very important mechanisms of political power, reflecting a unity of social forces (governmental and business actors, chambers and non-governmental organizations, universities and media institutions) and developed to secure the economic base of capital accumulation processes and relations.

Jessop's (1997, 1999) neo-Gramscian regulation approach has also provided new paths to investigate urban political economy within the context of hegemonic project concept. Since the accumulation of capital entails political, ideological, moral and intellectual leadership, hegemonic projects play a significant role in the formation of this leadership under the dominance of capitalist ruling classes. In other words, to investigate the relation between capital accumulation and hegemonic projects in a particular urban context, we need to investigate how hegemonic projects reflect a unity of diverse social forces and how they mobilize support behind a particular program of action that support long term interests of capitalist ruling classes. Hegemonic projects could be investigated, within this perspective, as the strategically selective sites of urban policy-making, reflecting how the interests of powerful capitalist ruling classes have been prioritized over the interests of powerless working classes.

Besides of the Gramscian perspectives discussed above, Lefebvre (1991) approached the conception of hegemony from a different perspective. As Kipfer (2002) unveiled, Lefebvre viewed hegemony "as a reformulation of the problematic of alienation and reification within the practices of everyday life". According to Lefebvre (1991) hegemony of capitalist system has been constructed through the relations of commodification, alienation and the contradictions of everyday life. Thus, Lefebvrian view of urban politics uncovers that everyday life practices and projects and activities to produce space within these everyday life practices could be investigated as a strategic terrain upon which hegemonic power of capitalist classes aim to acquire the active consent of the large segments of the society (Kipfer, 2002; 2008).

As Lefebvre (1976) revealed, state interventions and capital, the rise of new sectors including tourism and leisure, bureaucratically administrated consumption and rapid urbanization have all given rise to the deepening of capitalism in everyday life. Through observing and critically interpreting such alienating and commodifying socio-spatial relations, Lefebvre revealed that the serialized production of abstract space internalized in the everyday life through the moral principles and consent that provides a hegemonic-ideological power over the definition of political priorities. Thus, Lefebvre's conception of the production of space could be considered as an urbanized conception of hegemony, which gives rise to the commodification, alienation, homogenization and fragmentation of everyday life practices (Kipfer, 2008). From the perspective of Lefebvrian urban politics, it could be argued that Urban Development Projects play the key roles in urbanizing Gramsci's concept of hegemony, since these projects give rise to the alienating and commodifying socio-spatial relations in the contemporary capitalist city.

Through elaborating the concepts of "hegemony", "hegemonic project" and "the production of space", it is formulated a Lefebvrian-inspired neo-Gramscian approach to investigate the political construction of UDPs. Lefebvrian-inspired neo-Gramscian theoretical perspective show that UDPs could be investigated as a strategically selective mechanisms of urban policy-making, reflecting how the interests of powerful capitalist ruling classes have been prioritized over the interests of powerless working classes. The most important contribution of this approach to the field of urban politics is that UDPs could be investigated as politically constructed **"hegemonic projects of the production of space"**, serving not only to the construction of a moral, intellectual and ideological leadership in urban planning efforts but also to the strategy of capital accumulation in particular historical-geographical contexts of capitalism. Moreover, UDPs have also become a mechanism of entrepreneurial urban governance that reflects attempts to build a coalition of social forces at the urban socio-political context. UDPs are politically constructed attempts to acquire public support and consent behind a particular program of action that support long-term interests of capitalist classes.

As a result of this theoretical discussion, a Lefebvrian-inspired neo-Gramscian approach is formulated and within this theoretical perspective, paper puts forward

two initial arguments that give direction to the design of empirical research. These initial arguments are mentioned below.

▪ UDPs (Urban Development Projects) are attempts to form "hegemonic projects of the production of space", therefore UDPs have become the mechanisms of constructing hegemony over the definition of urban political priorities.

▪ UDPs have been politically constructed through the hegemonic arguments, discourses and narratives of key decision-makers and these discursive practices have been used to mobilize public support and consent of different social forces.

2. The Politics of Urban Development Projects in the World

The politics of UDPs are comparatively and critically analyzed through investigating six UDPs from different capitalist countries of the world, including Baltimore Inner Harbor Revitalization Project from US, London Docklands Regeneration Project and Olympic Games Urban Regeneration Project from UK, Potsdamer Platz Redevelopment Project from Germany, Abandoibarra Waterfront Regeneration Project from Spain and Lujiazui Central Finance District Development from Shanghai. The critical and comparative analysis of the politics of these six UDPs indicate that these UDPs have been politically-ideologically constructed by hegemonic discourses, arguments and narratives of key-decision makers from governmental and business actors. "Economic growth", "investment" and "employment" based such hegemonic discourses aim to mobilize public support and consent for the projects. As discursive practices to persuade different segments of civil society, such discourses show how capitalist forces behind the projects aim to redefine urban political priorities on the basis of "economic growth" oriented targets.

The critical analysis of the UDPs also show that not only discursive practices of hegemony construction, but also coercive-legislative mechanism of capitalist state play a very important role in the formation of UDPs. In this respect, through reorganizing urban planning powers and empowering new state institutions in the projects, coercive-legislative mechanisms of capitalist state have been utilized.

The utilization of hegemonic discourses and coercive-legislative mechanisms have differentiated according to different relations and articulations of state, capital and society. For instance, hegemonic discourses and activities to mobilize public support and consent may become very important in particular socio-political contexts of some countries where civil society is powerful. However, in socio-political contexts where state has a high repressive power over the society, there may be no or even less need to use hegemonic discourses and activities. Therefore, as a general interpretation, it could be argued that the role of hegemonic discourses or coercive-legislative mechanism have differentiated according to different contexts of state-civil society relations. In western capitalist countries (like US, UK, Germany and Spain), since the agents of civil society are powerful over the formation of the structure and policies of the state, hegemonic discourses and are frequently produced and disseminated through entrepreneurial urban governance institutions, local

business associations, media institutions, universities and chambers. However the political-ideological superstructure of UDPs have not only been constituted by these hegemonic discourses and activities of powerful capitalist forces. Coercive-legislative mechanism of the state is still important in these countries, since they provide exceptional power to reorganize urban planning authorities and to incorporate business-driven interests into the decision-making processes through the establishment of new entrepreneurial urban governance institutions.

3. The Political Construction of Urban Development Projects in Turkey

The political construction of urban development projects (UDPs) in Turkey are investigated through focusing on four UDPs from three major metropolitan Turkish cities. Haydarpaşa and Northern Ankara urban regeneration projects are critically and comparatively investigated to explore what roles hegemonic-ideological and coercive-legislative mechanisms of capitalist forces play in the political construction of UDPs in Turkey. A more detailed and comprehensive analysis of the political construction of New City Center (NCC) and İnciraltı Tourism Center (İTC) Development Projects from İzmir constitute the main empirical focus of the paper. The political-ideological dynamics, decision-making and opinion-buildings processes of these two projects from İzmir are elaborated and comparatively analyzed and they provided the empirical base to rethink the theories of urban development politics.

3.1 Haydarpaşa and Northern Ankara Urban Regeneration Projects from İstanbul and Ankara

The political dynamics of Haydarpaşa urban regeneration project could be discussed with reference to six main dimensions of the project. Firstly, in the first years of the 2000s, it was observed a struggle between local and central governments over the reproduction of urban space in Haydarpaşa. Both central and local governments intended to acquire the power and the authority of space production through initiating and leading an urban regeneration project in an urban location like Haydarpaşa which has a high level of rent-production potential (Urkun Bowe, 2008). There was a struggle to get the power of space production for an economically valuable urban space. However, towards the end of the 2000s, this struggle turned to a collaboration to implement a rent-oriented development. Central and local governments (Turkish State Railways, Privatization Administration and İstanbul Greater Municipality) have sustained and strengthened a pro-active rent-oriented development approach through agreeing upon the major land-use decisions and development strategies in the production of space in Haydarpaşa.

Secondly, the common point in the activities of local and central government was arranging an urban design competition. Turkish State Railways and İstanbul Greater Municipality intended to initiate urban regeneration process through arranging urban design competitions. In the early 2000s, urban design competitions was arranged before the preparation of development plan and thus, it was intended to gave a direction to the key decisions of the plan. However, in the late 2000s, it is declared that a new urban design competition will be organized after the approval of the new development plan. Preparation of development plans and arrangement of urban

design competitions have become successive events, defining a new organization in urbanism through prioritizing a project-led and profit-driven intervention logic over planning process. The third dimension in the political construction of the project points out the role of hegemonic discourses in mobilizing public support behind the formation of the projects. Central and local governments have proposed the same development logic (profit-driven and rent-oriented development) and they also proposed the same land use decisions including tourism and residential-based activities (like convention centers, shopping centers, luxury residents, culture centers, five star hotels and restaurants). Such a profit-oriented capitalist reproduction of urban space and its concomitant land-use decisions have only been realized through a common social legitimization ground which is provided by similar hegemonic discourses of key decision-makers. In this context, the key decision-makers developed a dominant rhetoric on the basis of "attracting investment and consumption", "providing new employment opportunities" and "national image improvement". Such hegemonic arguments are reflected in the media to mobilize public support behind the formation of the regeneration project. In other words, these hegemonic discourses play a very important role in constructing and sustaining political dynamics behind the regime of capital accumulation.

Fourthly, as Haydarpaşa case highlights, legislative interventions are very important in the political construction of UDPs. Legislative interventions provide exceptional power mechanisms through facilitating the implementation of the project and eliminating counter-decisions and actions (including the decisions of the Court and Regional Conservation Councils) against the formation of the project. Within the urban regeneration efforts in Haydarpaşa, new laws are introduced as a collection of changes in a number of laws and these new laws facilitate urban property transfer and privatization and they also give rise to the consolidation of urban planning powers through empowering central government institutions (like Turkish State Railways and Privatization Administration) and bypassing the decisions of oppositional actors (like Regional Conservation Councils, Districts Municipalities and some Court decisions). The fifth dimension in the political construction of the regeneration project emphasizes the role of the collaboration between the influential actors of the project. After the decisions of the Court and Conservation Council against the formation of the regeneration project, some governmental and non-governmental stakeholders (including Conservation Councils, İstanbul Greater Municipality, Kadıköy Municipality, Üsküdar Municipality, Chamber of Architects, Chamber of City Planners) were invited to the preparation process of conservation plan for Haydarpaşa (Urkun Bowe, 2008). Oppositional actors were invited to the process by neo-liberal central government to construct a common politico-ideological ground for the formation of the project. In other words, through using Gramscian terms, such a state-led collaboration effort could be interpreted as a search for a broader coalition of social forces in the production of urban space in Haydarpaşa. This was an obvious attempt to form a hegemonic block at the urban context through eliminating oppositional claims and contrary arguments of different social forces. However this attempt did not succeeded since the Chambers of Architects and City Planners did not involve to this process owing to their concern to

become a part of the support for the formation and implementation of a rent-oriented development. The sixth and the last political consideration highlights how oppositional groups act and define their criticism and counter-politics against the formation of the project. In fact, oppositional actors have mobilized their struggle on the basis of public interests. On behalf of public interest, such actors bring judiciary action for the cancel and nullity of the plans, laws and all sorts of regulatory frameworks related with the regeneration project. Some influential oppositional actors are Haydarpaşa Solidarity Group (consisting of 86 NGOs), Chambers of Architects and City Planners, and Union of Port Workers (Çavuşoğlu, 2010).

Policy-making efforts, new plans and laws, hegemonic discourses and arguments have not provided the political ground to overcome the opposition of different actors against the formation of the project. However, regeneration efforts never end. In 2011 a new development plan was prepared and approved by the collaboration of central government (Turkish State Railways) and local government (İstanbul Greater Municipality). In the following years, the implementation of this development plan is expected for the regeneration of Haydarpaşa.

There are four major conclusions that could be drawn from a political consideration of Northern Ankara Urban Regeneration Project. Firstly, to implement urban regeneration project, the first location-specific legislative intervention was made with the law no. 5104. This law shows how Greater Municipality of Ankara has been given exceptional power in terms of the preparation and approval of development plans, property transfer and carrying out construction works and infrastructure facilities. Urban regeneration areas, with this law, was released from current urban planning system and development legislation. Law no. 5140 show us again how legislative intervention is important in the political construction of rent-oriented UDPs. Secondly, there is a partnership of local and central government in this regeneration project. As a partnership of local and central governments, TOBAŞ has carried out key functions in managing and coordinating activities within the implementation of the project. Private sector involves to this partnership through the revenue-sharing scheme. Thirdly, although Greater Municipality of Ankara and Housing Development Administrations argued that the priority of this project is "enhancing the quality of life of the people living in the squatters", there was not such an increase in the quality of life of middle and low income groups, living previously in the project area. Contrary to such hegemonic arguments of the state (made to mobilize support behind the formation of the project), the majority of the people living in the project area have tended to move away from the newly constructed residences because they face a high cost of living in these residences. Under such conditions, most of the middle and low income groups (constituting the majority of the people living in the project area) have started to move to out of the regenerated north of the Ankara. For some of the scholars, this displacement of the low and middle income groups shows the first step of gentrification within the regeneration project (Özdemir-Sönmez and Yüksel, 2007; Uzun, 2006). Fourthly, this urban regeneration project unveils how a rent-oriented and project-based approach have become the mainstream urban (re)development policy since the 2000s

within the urban political context of Ankara. For instance, 2023 master plan of Ankara underlines the importance of urban (re)development projects for even a long term consideration of Ankara's urbanization (ABB, 2007). In this sense, it supports project-led initiatives and their roles in the production of attractive urban spaces in terms of attracting investment and employment opportunities and making the capital of Turkey a competitive city within the context of rising global competition between cities (ABB, 2007). Furthermore, the new urban regeneration areas are defined according to some new legislative interventions since the 2000s (like laws no. 5216 and 5140) and these regeneration areas have been subjected to rent-oriented development initiatives, increasing the level of property prices and the displacement of powerless low-income classes and enhancing socio-spatial polarization (TMMOB, 2007; Uzun, 2006). As a result, a critical consideration of Northern Ankara Urban Regeneration Project unveils that behind the political construction of UDPs there is a strong state intervention and this state-led urban regeneration initiatives have given rise to the dominance of a rent-oriented and project-based approach in the making of entrepreneurial urban policies, redefining the priorities of urban (re)development and intending to obscure the class conflict behind such urban processes.

To conclude, the comparative and critical investigation of the politics of UDPs from different capitalist countries of the world and Turkey give rise to the formulation of two further initial arguments. In addition of the two previously stated initial argument, that were formulated within the theoretical framework of thesis, these two initial arguments are mentioned below. These total four initial arguments constitute the starting point in investigating the political construction of New City Center and İnciraltı Tourism Center development Projects from İzmir.

- In the political construction of UDPS; not only discursive practices of hegemony construction, but also coercive-legislative mechanisms of capitalist state (new laws, change in the existing laws, decree laws …etc.) play a key role.
- UDPs have been politically constructed through the complementary relation and differential articulation of the discursive practices of hegemony construction and coercive-legislative mechanisms of the capitalist state

3.2 New City Center and İnciraltı Tourism Center Development Projects from İzmir

New City Center (NCC) and İnciraltı Tourism Center (İTC) development projects from İzmir are critically investigated through employing three methods of qualitative analysis with a complementary manner, which are (1) critical discourse analysis (of plan reports, related documents and media texts), (2) institution and neighborhood questionnaires and (3) semi-structured in-depth interviews. These different sources of empirical evidence are used complementarily to reveal different dynamics of decision-making and opinion-building in the political construction of NCC and İTC projects.

Paper intends to find out to what extend four initial arguments, that are mentioned in the previous parts, are capable to explain the political construction of NCC and İTC

projects. Different empirical research methods including critical discourse analysis, questionnaire and semi-structured in-depth interviews are combined and used together to test the validity of these arguments.

Critical discourses analysis of media texts and key documents reveal that governmental decision-maker and business actors in both of the projects use common economic development oriented words like "investment", "local economic development" and "employment". In addition to them, there are also different words specific to each project. For instance in the formation of NCC project; İGM, investors and local business associations use "urban regeneration" based words and themes extensively. Such actors, on the other hand, use "tourism" and "EXPO" based words and themes in the formation of İTC project. Moreover, there are coalition-based words like "cooperation" and "collaboration" of "different stakeholders". Such hegemonic discourses are ideologically constructed to mobilize and consolidate public support in the formation of the projects.

The findings of critical discourse analysis show that news, articles and advertisements in mass media tools play an important role in disseminating and dominating hegemonic discourses in the formation of both of the projects. It is observed that the declarations of governmental and business actors dominate the formation of news and articles in most the media sources. Hegemonic discourses stated in these declarations play a facilitative role in the dissemination of predominant view in the formation of the projects. However there are also oppositional discourses against the formation of the projects, therefore, discourses could be seen and studied as a political-ideological site of power, struggle and opposition of different social forces in the formation of the projects. Powerful state and capital actors (re)produce and disseminate hegemonic discourses to mobilize public support for the formation of the projects. However, on the other side, oppositional actors confront against these discourses through putting forward their counter/oppositional discourses. There is a struggle at the level of discursive practice in the formation of the projects. This struggle could be observed obviously in the formation of İTC project.

One of the main argument of thesis is that governmental and business actors aim to construct a **"capacity to produce consent" (CPC)** through the domination of hegemonic discourses and the collaboration with key agents of civil society like local business associations, chambers, universities, media institutions. The main target of CPC is to mobilize public support and consent for the project. This politically-ideologically constructed hegemonic capacity focuses on the mobilization of public support and consent in the formation of the projects and plays role in redefining the priorities of urban planning and policy. The construction of each capacities of producing consent (CsPC) for each project may vary according to different actors involved; but the common basis of each CsPC is that they are embodied by the hegemonic discourses of powerful capitalist actors in the formation of the projects.

Which hegemonic discourses have played role in mobilizing public support and consent for the projects? This major research question is answered by the findings of critical discourse analysis and urban field survey. The findings reveal that NCC project is defined and presented to public as "an opportunity attract investment" and "to provide employment". Such hegemonically constructed discourses are also supported with "urban regeneration" based discourses defining the problems of the project site as "urban decline". İTC project, on the other hand, has become a site of "tourism" and "EXPO" based discourses. Most of the governmental and business actors state that with İTC project "an economically unproductive" and "agriculturally declining" area will be transformed to "an attractive space of tourism development". In both of the projects, through (re)producing and dominating "economic growth", "investment" and "employment" based hegemonic discourses, a notion of "abstract space" (with reference to Lefebvre) is politically-ideologically constructed.

The findings of field survey show that the vast majority of the people and institutions, who support to the formation of the projects, adopt hegemonic discourses. Most of the people whatever their class positions state "investment", "economic growth" and "employment" based hegemonic discourses while they are expressing their support to the projects. This widespread tendency shows that hegemonic discourses have become common sense in the formation of the projects and therefore they play a political-ideological superstructural role in dominating and manipulating the formation of public opinion.

Through which mechanisms hegemonic discourses of the projects have been disseminated and dominated as common sense over the formation of public opinion? There are two common and influential mechanism in both of the projects namely (1) mass media tools and (2) the declarations of powerful governmental and business actors in these tools. Besides these common mechanisms, there are project-specific mechanisms. For instance, the advertisements of shopping malls, office towers and luxury residences have become influential in dominating hegemonic discourses, therefore they have played a constitutive role in constructing the CPC of NCC project. The other project specific influential mechanism of disseminating hegemonic discourses is EXPO. As field survey uncovered, the governmental decision-makers and local business leaders intend to mobilize public support for İTC project through forming the project with an EXPO-based strategy. To sum up, the CsPC of the projects have been constructed by the utilization of mass media tools. Particularly in the formation of İTC project, mass media tools have become the platform of political-ideological struggle between the predominant-supporter view (of governmental and business actors) and oppositional-counters view (of chambers affiliated to UCTEA and some other NGOs). However, it could be stated that predominant-supporter views have more advantages in manipulating the shaping of public opinion since they dominate and command most of the mass media institutions.

Although hegemonic discourses target to mobilize the consent of local public of İzmir as a whole, it could be identified particular targets. There are two particularly

targeted actors in the mobilization of consent which are "occupational professions" like city planning and "chambers affiliated to UCTEA". Governmental decision-maker actors intended to strengthen the CsPC of each project through "collaborating-cooperating" with such actors of civil society in the formation of the project. In the formation of NCC project, such efforts to collaborate with key actors of civil society have become successful since İGM, chambers and some academicians from universities have collaborated in the preparation of NCC development plan. However, since the opposition of chambers against İTC project has a political-ideological basis, they do not respond positively any consensus based discourse and reject cooperation-collaboration with the MCT in the preparation of İTC development plans. As a result, the CPC of İTC project has not become powerful owing to the failed attempts of MCT to collaborate with oppositional actors of civil society.

Thesis argues that under the guise of such "collaboration-cooperation" based relations, powerful governmental actors may exert dominance over the role and priorities of urban planning in the formation of the projects. Furthermore this "cooperation-collaboration" discourses and strategies could also be viewed as a hegemonically-constructed strategy to absorb and pacify the oppositional power of counter-oppositional actors. Governmental decision-makers fail to absorb and pacify the opposition of non-governmental social forces and therefore, the CPC of İTC project is restricted by the politically-ideologically motivated activities of chambers, environmentalist NGOs, some universities and political parties. Unlike the governmental actors of İTC project, the key decision-makers in İzmir Greater Municipality has "successfully" cooperated-collaborated with chambers in the formation of NCC project. This "strategically taken consensus based decision" enable them to strengthen the base of the CPC of NCC project, since they mobilize the support and active consent of the chambers with consensus-based relations. As a result, case study provide the empirical evidence to argue that the existence and the mobilization of counter-oppositional views and activities directly influence the construction of CsPC of each projects.

Since governmental decision-makers do not provide collaboration with oppositional non-governmental actors (like chambers, environmentalist NGOs) in the formation of İTC project, they tend to enact a project-based law to impose a coercive and legally legitimate base of power for the formation of İTC project. In other words, the CPC of İTC project is not strength because there is a powerful and ideologically-motivated opposition of chambers and some NGOs whose active consent could not be acquired by the governmental decision-makers. Thesis argues that owing to the weakness of CPC, powerful actors tend to dominate and impose a coercive and legally legitimate mechanism with a project-based law. However, such a project-based law still remain socially illegitimate since it is not a product of a consensus between different actors of İTC project.

Urban field survey also reveled that powerful governmental and investor-business institutions aim to acquire the consent of not only local residents and some non-

governmental organizations, but they also need to mobilize the active consent of their own members/officials/employees. Therefore, the capacity of producing consent (CPC) of the projects is constructed to dominate the views of these insider people who performs particular administrative or occupational duties. The level of intra-institutional consent is related directly and positively with the construction of CPC and high level of intra-institutional consent provided in a particular project means the more powerful CPC in the formation of this project. In other words, high level of intra-institutional consent facilitates the construction of hegemony over the definition of urban political priorities in the formation of the projects. The most important empirical evidence, in this respect, is that NCC project has a higher level of intra-institutional consent when compare with İTC project. Lastly, survey results indicate that the level of intra-institutional consent also changes according to the duties of the people and the political-ideological tendencies of these people in performing their particular occupations.

Institution questionnaire revealed that institutional categories such as "state institutions", "universities", "political parties", "chambers" and "media institutions" do not reflect one single coherent view; rather there are conflictual and contrasting views in these institutional categories concerning the formation of the projects. Such contrasting views are more observable for İTC project since there is a significant level of political-ideological opposition against this project. With reference to theoretical approach of thesis, such institutional categories could be identified as a site of political-ideological struggle upon which "a war of position" (in Gramscian terms) occur amongst the social forces of urban politics. As field survey results unfold, not NCC project but İTC project reflects such a site of political-ideological struggle.

As a general conclusion, it could be argued that governmental and investor-business actors have constructed a powerful CPC succeed to mobilize public support and consent in the formation of NCC project. However, the CPC of İTC project has not become powerful and failed to mobilize the consent of oppositional actors of civil society, therefore it could not have a hegemonic power over the definition of urban political priorities. The CsPC of the projects have also affected the implementation of the projects. Since NCC project is politically-ideologically constructed with a powerful CPC, it is started to be implemented. Unlike NCC project, İTC project is not implemented yet owing to the judiciary actions against İTC development plans, which also reflect the powerlessness of the CPC of İTC project.

4. Conclusion: Overall Summary of Empirical Evidence and Final Remarks on the Political Construction of Urban Development Projects

The critical and comparative analysis of rent-seeking UDPs from different capitalist countries of the world indicated that UDPs have become the mechanisms to secure the economic base of capital accumulation processes and relations. However, the political-economic dynamics behind the formation of UDPS could not be revealed only with reference to capital accumulation processes and relations, paper argues that UDPs are politically constructed "hegemonic projects of the production of space"

and that they reflect a unity of diverse social forces at the urban political context. With these profit-oriented and rent-seeking UDPs, public support and consent of large segments of civil society have been mobilized through producing, disseminating and dominating "economic growth", "investment" and "employment" based hegemonic discourses.

The main argument of the paper is that UDPs play the key roles in urbanizing Gramsci's concept of hegemony. However this hegemony is not something given or taken for granted, but rather it is constructed by consciousness collaborative-cooperative efforts of governmental and non-governmental actors including central and local governments, public-private partnerships, business associations, chambers, universities and media institutions …etc. The unity of these political and social forces, in the formation of the UDPs, could be defined with reference to Gramsci as the "political society + civil society". The key point to reveal is how the hegemonic power of UDPs have been constructed over the definition of urban political priorities through the hegemonic discourses of these governmental and non-governmental actors. UDPs from Turkish cities are critically and comparatively investigated to find out the answers of this question.

The empirical evidence of four UDPs from three Turkish metropolitan cities reveal that UDPs gain a hegemonic character if they are politically-ideologically constructed by the "growth", "regeneration", "investment" and "employment" based hegemonic discourses of powerful governmental and non-governmental actors. In addition to these hegemonic discourses, collaborative-cooperative relations amongst governmental and key non-governmental actors (including business associations, chambers, universities, media institutions …etc) in the formation of the projects also play crucial roles in constructing hegemonic power. Paper argues that hegemonic discourses and activities of these powerful actors aim to construct a "capacity to produce consent" (CPC), which aim to mobilize public support and consent for UDPs. However, it is also uncovered that not only this hegemonically constructed CPC, but also coercive-legislative mechanisms of capitalist state (including news laws, change in the existing laws, decree-laws and all sorts of legislative interventions) play important roles in the political construction of UDPs.

The utilization of hegemonic discourses, activities and coercive-legislative mechanisms have differentiated according to different relations and articulations of state, capital and society. For instance, hegemonic discourses and activities to mobilize public support and consent may become very important in particular socio-political contexts of some countries where the agents of civil society are powerful. However, in socio-political contexts where state has a high repressive power over the society, there may be no or even less need to use hegemonic discourses and activities.

Thus, within the light of the empirical evidence, paper argues that not only discursive practices of hegemony construction, but also coercive-legislative mechanisms of capitalist state (new laws, change in the existing laws, decree laws …etc.) play a key

role in the political construction of UDPs. UDPs have been politically constructed through the complementary relation and differential articulation of the discursive practices of hegemony construction and coercive-legislative mechanisms of the capitalist state, which means a differential articulation of hegemony and force in the political construction of UDPs.

RISK AND FAIRNESS AS PLANNING FACTORS: CONSOLIDATING THE SHARED AREA OF INVESTIGATION BETWEEN PLANNING THEORY, RISK THEORY AND ETHICAL INQUIRY

Claudia Basta [1]

Abstract

The matter of siting technological risks according to considerations of compatibility between hazards and urban areas has only recently been object of rigorous theoretical definitions in planning literature. This contribution is a further effort in this direction. Its aim is to delimit the shared area of investigation among risk theories, planning theories and ethical inquiry by building upon, particularly, Beck's discourse on risk (1996), the Rawlsian theory of distributive justice (1971) and its transposition into planning theory as done by Moroni (1994, 1997). By elaborating on these writings the contribution proposes that the equal distribution of technological risks in society through spatial planning instruments should be become an explicit aim of the planning practice. This is discussed by referring to a recent case of siting of a CO2 underground disposal in The Netherlands, here only narratively discussed at the end of highlighting some paradigmatic aspects of the relevant decisional process. Indications of the research trajectories to be followed for cementing this theoretical framework on the ground of empirical findings are mentioned in the conclusions.

Key-words: risks; fairness; siting of hazardous technologies; land use planning

1. Introduction

Although it is among the most prominent interdisciplinary themes to have emerged in the past two decades, the prevention of site-specific technological risks has only recently been object of rigorous theoretical definitions in spatial planning literature. The latter has given great attention to the ethical implications of the siting of risk-bearing installations, particularly regarding the legitimacy and fairness of decisional processes (Boholm 2004, Hayden-Lesbirel and Shaw 2005). This paper develops these reflections further. In particular it focuses on the role that considerations of "justice as fairness" may have in guiding planning decisions related to the siting of impacting and risky technologies meant to support the transition towards a non-fossil fuel era. An opportunity to reflect upon these emerging technologies is offered by the recent case of proposed siting of a CO2 underground disposal in The Netherlands, here only narratively discussed at the

[1] Wageningen University and RC, Wageningen, The Netherlands - claudia.basta@wur.nl

end of outlining the main elements of the relevant appraisal that support our arguments.

The contribution builds upon previous writings that started to explore, respectively, the challenge of distributing technological risks fairly through spatial planning instruments (Basta 2012) and the broader horizons of a planning theory based upon individuals' responsibility of supporting fair siting processes by means of active forms of collaboration (Basta 2012). In order to take these reflections further this paper develops, particularly, the discussion initiated in the former of these writings. At this scope the article starts with introducing Beck's discourse on risk (1982: 1996) and the theory of justice of Rawls (1971) as developed in planning theory by Moroni (1997). The main idea put forward is that of *safety as a primary spatial good*, that is, as a good to be equally distributed in society through spatial planning instruments. The following discussion revolves around the matter of its concrete application to the case of hazardous facilities, with special attention given to the emerging technologies meant to support the transition towards a non-fossil energy era. The focal point of the contribution (which, note, is primarily a theoretical contribution) is adding to the debate on the siting of these controversial installations by discussing the operationalization of the notion of *fairness* as a concrete planning factor. The example to which the paper will refer in order to support its arguments is the recent case of rejection of a CO2 underground disposal by the side of the population of Barendrecht, in The Netherlands. By highlighting some arguably paradigmatic aspects of the relevant controversy the paper highlights some distinctive elements of the increasingly relevant problem of balancing considerations of (global) benefits against considerations of (local) justice when selecting the appropriate site for intruding technologies. It is suggested that opting for the "right" site on the ground of costs / benefits considerations only, while exposing localities to immediate impacts and potential risks, may be not justified when considered under a light of both intra- and intergenerational fairness. The paper concentrates, particularly, on the former point and argues that the criterion of fairness in distributing impacting technologies at regional and national scales should inform the notion of "feasible" site together with all other technology-specific, site-specific and environmental-specific criteria. In the conclusions, some indications regarding the empirical research needed to support these preliminary considerations are given.

In the following sections the theoretical background of the contribution is introduced together with a short story-line of the example the article will refer to along its development.

2. Risk and fairness in (planning) theory: some preliminary notes

Rawls' *Theory of Justice* (1971) has been one of the most influential political philosophy theory of the past century. By its side , Beck's discourse on risk (1992) has been one of the most influential sociological theories of the last decades. The essentials of both theories and their relevance to our discussion are shortly recalled in the following.

As known the pillars of the Rawlsian theory are the conception of "primary good" and the two principles of justice. The former refers to the goods each individual would be entitled to following the contract that would regulate individuals' coexistence within a fair society. These goods would be identified by moral judges acting behind the "veil of ignorance"; that is, without knowing what their social, ethnic and religious statuses would be in a real setting. Arguably these moral judges would identify as "primary" the system of liberties and essential means each individual would need in order to develop the own self freely. Such liberties and means are those that can be equally assigned to anybody without violating others' liberties. Freedom of speech, of religious orientation and access to basic education are some examples. The two principles of justice relate to this conception of primary goods by, respectively, stating the obligation of their equal distribution in society (1st principle) and by legitimizing inequalities only when they do benefit the whole up to the most disadvantaged (2nd principle). The distinctive aspect of the Rawlsian conception of justice is therefore aiming, rather than to a restrictive form of social equality, to prime distributive mechanisms that would put all in the same initial condition. In more simple words, the fair society the philosopher had in mind is not a society in which everybody is equal in terms of status and belongings; but rather a society in which everybody has access to the essential means and rights needed to develop the own aspirations. Rather than a radical conception of equality as "leveling differences", the libertarian conception of justice put forward by Rawls is therefore "departing from the same set of essential means". This conception does therefore not exclude differences among social statuses; it does rather exclude the preclusion for some to climb up to higher conditions of education and wealth by guaranteeing to all a common "line of departure".

Beck's discourse on risk (1992) has interesting moments of affinity with this authoritative political philosophy theory. The German sociologist argued that one of the most distinctive developments that took place after World War II has been that of creating yet unknown forms of technological risks, unequally distributed in society next to the historical rooted unequal distribution of wealth. His work *Risk Society* (1992) is a collection of thoughts that revolve around the observation that the current economic development pattern, embraced in late modernity by Western society, is based on a massive introduction of hazardous technologies of unknown risky potentials. These technologies, among which we could cite nuclear, chemical and energy installations, create forms of inequality not only regarding the access to the produced benefits; but also in relation to the exposure to the relevant risks. In this vein Beck argues that current society is a "reflexive society", that is, a society that re-organizes its governing bodies and practices departing from a new awareness of the unwanted consequences that certain choices entail. In this view risks become the inevitable counterparts of the pursue of benefits; and as the former, they are distributed unequally. Note that according to Beck's early writing (1982:1996) the latter are no more tight to the place of origins, as their effects overcome spatial and temporal horizons; however, it is consistent to add that the site-specific among these risks create *de facto* situations of unequal exposure. Thinking of Rawls' idea of

justice, we can hence easily conclude that technological risks are therefore distributed *unfairly*.

The planning literature has been penetrated by both theories substantially, to the point that a thorough referencing of main contributions would constitute a work in its own. In the case of the Beckian discourse on risk the planning literature has given relevance to aspects of the theory other than specifically technological risks, particularly the notion of “reflexive modernity” and the consequent horizons of a reflexive planning discourse (Howe and Langdon 2002). Others instead concentrated on the “ideology of certainty” that kept permeating the planning system until “risky realities” started to be acknowledged as the only possible reality (particularly, Gunder 2008). Rawlsian lines of inquiry, by their side, penetrated the planning literature in, among others, the works of Harper and Stein (1992), Moroni (1997), Stein and Harper (2005) and Fainstein (2010). In light of the scope of this article I will elaborate on these latter lines of investigation more at length.

The planning theorist Moroni (1997) argued in details on the implications of the Rawlsian conception of “primary good” for the spatial planning theory. Replicating the line of reasoning of the moral judges acting behind the veil of ignorance, Moroni argues that decent housing, the access to green areas and to sufficient transport are the "primary" among the spatial goods. Such spatial goods constitute the basic “spatial” condition each individual should depart from in order to pursue the own objectives of self-realization and happiness. As such, they constitute the basic “spatial rights” that should be guaranteed to each member of society up to the most disadvantaged.
A sure point of interest of Moroni’s elaborations is his addition, to the list of primary spatial goods, of a "safe living environment". This entails that, in principle, all members of society are entitled to live in “spatially safe” conditions. Although Moroni doesn’t discuss this point at length, arguably this condition includes living protected from major hazards and being exposed to tolerable levels of risk.
This is in interesting point as it relates to the matter of siting hazardous and risky technologies and planning the surrounding urban areas accordingly. This matter is well known in planning literature, to the point of having given birth to a dedicated literature. Within it, two main lines of investigations can be identified. The first collects contributions revolving around epistemological and normative questions whose primary scope is advancing interpretational instruments for evaluating the implications of the siting of controversial technological installations from the policy and normative perspective (Boholm and Lofstedt 2004, Hayden-Lesbirel and Shaw 2005). Here, identifying the distinctive elements of Not In My Backyard (in the following: NIMBY) vs. non-NIMBY cases in such a way to enable the correct framing of siting controversies is a main point of interest (Boholm 2004, Owens 2004a). Note that several ethicists followed the same lines of investigation (for example Peterson and Hansson 2004; Hermansson 2007), contributing to form an “ethics of siting” literature of fundamental complementary value for the planning scholarly community.

A second mainstream of planning research focused on the more pragmatic problem of advancing analytical instruments that may support a safe allocation of land uses in relation to risks and hazards. Rather than to the debate on the epistemological and normative implications of siting processes, this second literature has rather contributed to establish an interdisciplinary corpus of notions and methods that may support the elaboration of land use plans compatibly with site-specific risks and hazards. Being this literature more focused on the practice than on the theory of siting, the relevant contributions are often based on the analysis of specific cases, hence types of installations together with their geographical implications (Basta et al. 2006; Basta et al. 2008; Schmidt-Thomé 2006, Schmidt-Thomé and Kallio 2006; Menoni and Margottini 2011). Because of its operational emphasis, extra-disciplinary contributions aligned with the scope of this literature are mostly provided by risk analysts (for example Bandini et al. 2006; Christou and Mattarelli 2000).

The scope of this paper is more aligned with the lines of the inquiry of the former literature described and builds, in particular, upon those contributions that investigated what makes a siting process a legitimate and "fair" process (Boholm 2004; Linneroth-Bayer 2005). Nevertheless inputs from the second stream of literature will be recalled when discussing the case-study in section 2.2.

Going back to the notion of primary spatial good as introduced in planning theory by Moroni (1994, 1997), the main theoretical implication is that aim of the planning practice should become distributing spatial safety in society equally up to its most "spatially disadvantaged" members. The main evaluative implication of this position is that there exist a "level" of spatial safety each individual is universally entitled to. Arguably this level has a concrete geographical dimension (for example "distance from", or "emergency routes towards") and its means of distribution are planning instruments: particularly, land use plans.

This is an apparently banal, yet important conclusion. Asserting that spatial safety is a primary good and that there is a level of it that should be equally guaranteed in society entails that safety, and fairness, become concrete planning factors: that is, they are a *dimension* and a *criterion* that should guide planning decisions in relation to risks and hazards. This is not banal especially when thinking that most of siting evaluations, in greatest part taking place under the supervision of institutional actors, are carried out by means of costs/ benefits analyses grounded upon a technical assessment of the risks at issue. Usually such appraisals consider a number of candidate sites and rank them accordingly to a rigorous technical consideration of the economic and social costs, against the benefits, of each alternative. The site chosen as the "appropriate site" is then usually promoted by risk information campaigns meant to enhance a perception of risk consistent with the "technicality" informing its appraisal. The supposed neutrality of the technical appraisal that informs such evaluative processes excludes considerations of subjectivity in risk perception together with distributive considerations, for example in relation to the installation of facilities in areas already exposed to industrial and infrastructural impacts.

This typical story-line replicates in most of documented cases of controversial siting practices referenced in this paper and, as discussed in past literature, stands at the

basis of the arguments that support the NIMBY rhetoric (Hermansson 2007). Here, narrow-minded locals motivated by selfish purposes are seen in contraposition with institutions acting in defense of the general interest. Owens identifies this as the "techno - rational" model of appraisal, consisting in "a process in which scientific advice, grounded in a positivist epistemology, translates straightforwardly into the substance of policy, and a `separation of powers' is deemed to exist between neutral, authoritative experts and the decisionmakers whom they advise" (Owens 2004b, p. 1945). In the specific case of siting of hazardous, risky and stigmatizing installations the advice of the neutral actor (usually a public research or environmental agency) becomes instrumental to the "implicit policy" motivating governmental decisions. Inevitably this creates a form of insolvable epistemological opposition in which two polarized parties have no possibility of dialoguing, being the only "truth" admitted in the arena the one expressed by the third, supposedly neutral, advising actor. Any dialogic solution of the controversy is therefore impossible.
But leaving aside the epistemological implications, this article wants to highlight how this predominant decisional model excludes any distributive consideration. When carried in this way, the inventory of candidate sites and the search for the "feasible" one restricts the assessment to their specific local features, without considering how each site would contribute to the distribution of technological risks at a higher scale; for example the regional or national scale. In other terms, localities already at-risk because of a concentration of industries but offering, precisely for this reason, a pre-existent infrastructure that would facilitate the installation of additional facilities are rarely discarded. Somehow, the possible violation of individuals' primary spatial rights and situations of risk exposure inequality in society keep being excluded from the aspects to be considered prior to legitimize siting decisions.
This will appear particularly evident in the case of CO2 underground disposal in Barendrecht (NL) discussed in the following. After its narrative illustration it will appear clear that whereas the notion of safety as primary spatial good does not solve the inevitable conflict of interests that will continue to animate the debate around controversial siting processes, it may provide those normative fences within which the relevant discussion could be framed. However before this discussion some words of caution that could guide the further reading are provided.

2.2 From theory to practice: some words of caution

In this section I will try to outline the practical implications of the conception of spatial safety as primary good more in details. However I would first clarify some possible deadlocks of my line of reasoning. Note that at the present stage of elaboration this paper does not offer empirically grounded arguments; it only addresses some preliminary considerations around one recent case of siting controversy that are considered paradigmatic in relation to the premises of my discourse. Indications for the further empirical research needed are given in the conclusions.

First of all, the main idea of this paper is that the unequal (technological) risk distribution identified by Beck as a distinctive element of late modernity has to be

approached, in both planning theory and practice, as a problem of inherent ethical nature. It is, in essence, a matter of inequality and of consequent unfairness; something that the planning practice ought to remove. However evidence suggests that this aim is confronted with a number of economic, social and obviously spatial constraints. As documented by Schmidt-Thomé (2006) the concentration of hazardous industries in certain European regions is inherited from the past and mirrors a corresponding concentration of industrial and services productive capacity. The European policy debate around the need to preserve these assets while ensuring a sustainable cohabitation between hazards and nearby population is an equally long-lasting debate. The latter gave birth to regulatory developments of due, yet complex implementation (Basta 2009). The balance between economic, spatial, legislative and ultimately cultural aspects of each national context called to regulate land-uses according to past, present and future risks is still a problematic, when not unsolvable problem (Basta 2011, Basta 2012).

However, underlining the normative deficiencies of the predominant techno-rational evaluative model is a due step forward for developing the relevant debate. This will become clear in the following section, wherein a paradigmatic case of an "unfair" planning practice in relation to a CO2 underground disposal is described.

2.3. The proposed siting of a CO2 underground disposal in a Dutch municipality: NIMBY or unfairness?

The case of the CO2 underground disposal proposed for siting in 2009 in the Dutch city of Barendrecht was discussed, under a different light, in a previous contribution (Basta 2012). The main elements of the story-line of this case will be here shortly recalled so to be discussed in relation with our theoretical premises, particularly in relation to the principle of fair distribution of technological risks through spatial planning instruments.

In the course of 2009 the municipality of Barendrecht, in the southern part of The Netherlands, engaged an open conflict with the Dutch government in relation to the proposed siting of a CO2 underground disposal. The local population opposed the pilot-project, which should have led to the installation of the disposal within the following few years, principally on the ground of its impacts on the local real estate market and the image of the town. Meaningfully, manifests claimed "we do not want to become the national CO2 dumping place" Following the first episodes of local opposition the debate on the technological option of CO2 underground disposals became of national resonance, leading several Dutch municipalities to reject, in advance, the possibility of being candidate sites for future disposals. Somehow, an initially "local" case of opposition to a specific installation became a sort of national movement against the very technology.

By its side, the Dutch government kept defending the project on the ground on the own policy objectives of climate change response. The promoter of the pilot-project was a known (inter)national oil corporation, acting in concert with the government at the end of promoting Carbon and Capture technology as a means for abating carbon dioxide emissions. This technology allows to capture emissions "at source" and

storing them underground into exploited gas fields. In order to assess what the best possible location for the disposal could have been the Dutch government delegated a feasibility study to the Applied Research Institute (in the following: TNO). 12 possible locations, precisely 7 off-shore and 5 inland locations, were considered in the relevant study (Breunese and Remmelts 2009). Among the 12 candidate sites the municipality of Barendrecht was the more densely populated. Nevertheless the geological characteristics of the gas field underneath its surface and some key technological constraints (among which the length of the pipelines connecting the points of emission, specifically the nearby refineries, to the storage), led the research agency to conclude that Barendrecht was the most suitable candidate site for proceeding with the pilot-project. The government defended this choice by recalling the main national interest, specifically alleging that "capture and storage of CO2 is a necessary transition technology to help cut carbon emissions" (Reuters, November 18, 2009).
The story-line of the Barendrecht case recalls the typical "techno-rational" model of appraisal mentioned above (Owens 2004b). The "owner" of the decision making process was the central government who, consistently with an explicit policy objective, delegated the inventory of possible sites to a supposedly neutral advisory body. The latter assessed a number of candidate sites on the basis of several criteria, among which the geological characteristics of available gas fields, the costs of each alternative and the technological requirements to be met (Breunese and Remmelts 2009). Among the candidate sites the area of Barendrecht was the most densely inhabited; nevertheless the main reason for its indication as suitable site seemed to be the criterion of cost-effectiveness, which explicitly related to the distance between CO2 sink and sources. The distance between the exploited gas field of Barendrecht and the source of CO2 emissions was estimated 20 km; all other sites were in the range of 75 up to 210 km. Here, "the fact that the Barendrecht field is located under a built area is not of a (geo)technical nature and therefore impossible to weigh against the other geotechnical factors considered" (Breunese and Remmelts 2009, p. 26).

By looking at the media that broadcasted the controversy the citizens of Barendrecht manifested against the pilot-project on the ground of their concerns regarding, particularly, the feared economic impacts of the installation on real estate market values and on the image of the locality, already "featured" by the massive presence of industries and refineries in the nearby area of Pernis, and the risks of release of CO2 from the underground with all possible environmental and health consequences. In both cases, the reasons for opposing the installation seemed to depict a NIMBY story-line: *not here, not now*.

But a different outlook on the opposition to the installation could be considering the already high concentration of industries in the area and its being inhabited in comparison to the other clear sites that were considered. The point of attention here is whether the fact that the site chosen was the only inhabited site, already dealing with the proximity of major industrial installations, was a factor to be considered prior to achieve the conclusion of its "feasibility" for the proposed project. When reading the technical report of TNO it emerges with clarity that the inventory of

candidate sites did not consider this aspect; being the evaluative criteria solely of geo-technical and economic nature, the study did rather allegedly neglect it. The chosen technical criteria did evidently exclude any other consideration regarding the impacts and risks distribution each site would have created at regional and national scale. In this perspective, more than something to consider in advance the population of Barendrecht seemed rather the problem to solve. When looking at the following rejection of the installation by the side of the local population, questions of ethical relevance do therefore inevitably arise. Is it fair not to consider the exposure of citizens to the impacts of installations among the criteria of appraisal of different candidate sites? Thinking in Rawlsian terms, is the individual right to spatial safety violated when not doing it? Should the facility at issue concretely benefit the whole, and hence social inequality being justified, shouldn't the most disadvantaged being compensated with other forms of primary benefits that could counterbalance their increased exposure to impacts and risks?

As anticipated at the present stage of elaboration the paper does not provide definitive replies to these questions; it only outlined a framework that allows to pose them with a certain rigor. Preliminarily, it is reasonable defending that when among the criteria used to review the 12 sites the criterion of "not exposing inhabitants to impacts and risks" or "not worsening pre-existent conditions of risk exposure" would have compared, the site of Barendrecht *could* have been discarded; or even not being considered at all. On a marginal note, it is important to notice that this could have steered the following national debate on Carbon Capture and Storage technology towards a different direction.

These hypotheses do not intend to promote a firm position regarding the specific case narrated here. However it is suggested that distributive considerations among the criteria to be accounted when evaluating the "right" site for an impacting installation may provide the normative solidity to the appraisal seemed to miss here. This is further discussed in the following, where suggestions for steering the (empirical) research in a direction capable of providing more definitive indications are given.

3. Towards a planning theory of fair risk distribution? Conclusions and ideas for discussion

This paper recalled some main political philosophy, sociological and planning theories at the scope of identifying some possible shared areas of investigation. In particular, the contribution intended to sign some trajectories of research that could provide valuable answers to the problem of justifying decisions related to the siting of hazardous site-specific installations by considering multiple perspectives, and particularly a perspective of fairness. Risks, fairness and siting of hazards are therefore the three key-words that best summarize the ideas that were here taken together.

These research trajectories are surely promising, as they do tackle the emerging problem of balancing global vs. local risks when siting energy facilities meant to support a transition towards a non-fossil energy era. Emerging technologies like CO2 underground disposals and renewable energy facilities are indeed serving the global objective of abating climate change; however they do also create impacts on localities of sometimes controversial pre-assessment. Here, distributive considerations regarding individuals' right to access an equal level of spatial safety may become the normative boundaries within which framing siting decisions, and thereby interpreting possible controversies.

The lack of such considerations in the predominant techno-rational model of appraisal described above was illustrated through the example of a recent case of opposed siting of a CO2 underground installation in a Dutch municipality. This case can be seen under different lenses when considering a more equal distribution of impacts and risks at regional or national scale as a neglected criterion of the evaluative process. Among 12 candidates the Dutch government opted for the only densely inhabited one, known for being already exposed to a massive presence of industries in the nearby area of Pernis. The latter area was indeed the main source of CO2 emissions. Considering the characteristics of the gas field underneath Barendrecht and its vicinity to the source, it resulted both economically and technologically sound to site the sink there. However, the criterion of fair risk distribution in society could have provided a normative perspective on this decision and possibly led to different results. But beyond this hypothesis, it would have at least provided a shared normative ground upon which basing the debate, whose only possible outcome under the present conditions could have been solving the polarization between the government and citizens with either a forced prosecution of works or the sinking of the project.

These are only suggestions that call, of course, for sound empirical research. In particular a needed research effort is keeping documenting the "specifics" of each risk-bearing technology and its set of technological and spatial implications in such a way to identify, with rigor, the consequent ethical implications. This is currently under development in the context of the Network Infrastructures & Mobility course at the Environmental Science Department of Wageningen University. The research conducted in the framework of this area of teaching approaches major infrastructural projects from a threefold perspective. This includes a dimensional, an impacts and risks and the ethical perspective. In the course of 2012 this threefold outlook will lead to elaborate guidelines for performing an integrated Spatial Ethical Technological Assessment (SETA) of infrastructural projects, ranging from individual installations like the one discussed in this article to major energy and transport networks.

The undergoing elaboration of SETA guidelines is obviously not meant to prevent the possible opposition of citizens confronted with the siting of intruding technologies; but only to provide a solid normative ground upon which basing the discussion among involved parties. This paper wished to sign some possible research trajectories that promise to lead to its establishment.

QUANTIFICATION OF PRIVATE RESPONSE TO PUBLIC RESIDENTIAL LAND DEVELOPMENT: A CASE STUDY OF EASTERN FRINGE, DHAKA CITY

Md. Manjur Morshed [1], Yasushi Asami [2]

Abstract

Dhaka is one of the most densely populated cities in the world. Accommodation of such number has been a great challenge waits to be met because of lack of buildable land. Different studies have suggested the solution in the private sector involvement in land and housing market. The necessary evil- the private sector is given rarely development permits based on the assumption, and also true, that they violate the rules. However, in Dhaka city, all development takes place in direct political influence under heavy corruption, and legality is a secondary issue to be present as an obstacle. Recently, as part of the intra-decentralization of housing, the government is creating a New Town in the Eastern fringe. Tempted by the availability of service facilities, many housing companies are agglomerated surrounding the New Town. None of these companies have legal permission to operate, and they are violating all the rules. The objective of this study is to quantify the private response to the government project in terms of the land conversion area, and to forecast the long-term implications of such development. Followed by an extensive literature review, an investigation is made among the available land developers. The major findings of the study are- i) private response is higher than government; ii) even though illegal, ultimately, the government cannot control such land conversion; iii) private residential land developments are taking place in the low-lying agricultural areas, and therefore, wide spread urban flood will be a common fact in future. Furthermore, due to illegality and complexity in land handling, security of land tenure is in question.

1. Introduction

Management of land and housing is one of the major problems faced in Dhaka city, Bangladesh. Being one of the most densely populated in the world, along with rural-to-urban migration, the city is struggling to cope with the demand for buildable land, and thereby, housing. According to Sivam (2002), land and housing market in developing countries are inseparable wherein the owner occupied housing is a predominant land market. One of the principle targets of land management is to ensure greater good for wider communities which often been breached under extreme competition due to

[1] The University of Tokyo, Japan - manjurmorshedkhan@ua.t.u-tokyo.ac.jp
[2] The University of Tokyo, Japan -asam@csis.u-tokyo.ac.jp

population increase, widespread speculation and above all, management failure to foresee the future.

It has been accepted that in most of the developing world, urban planning refers to government control (Mattingly, 1996, p. 115), Bangladesh is not an exception. In addition, land development has been a monopoly for the government institutions, mainly, by the planning authority of Dhaka city- Rajdhani Unnayan Katripakha (RAJUK). It has taken several land development initiatives to accommodate the growing demand for land and housing. Nevertheless, government projects have been biased since it prioritized government and semi-government employees. What so ever, these provisions proved to be scanty and unable to meet the public demand but attracts private residential development in the vicinity due to the service and transportation facilities. Based on the possibility of financial gain, private land and housing developers came in existence. Private land development and housing provision, which are often illegal, remained as the merely affordable but practical solution for the majority of the urban population. As proven to be more efficient, agile, and has the ability to bypass the legal requirements; private land and housing development has created a socially acceptable and swift mechanism. Solely profit orientation of this sector can be regarded as the main driver for urban expansion and local transition of land.

Against this background, this paper presents a case study of government New Town development in the Eastern fringe of Dhaka city, and tries to quantify the private land developers' response in the vicinity. The following section provides a short detail of land and housing demand, and government planning in the past. The subsequent section details the private response to government project. Provision of land and housing by the private sector thought to be the only market solution in current extreme demand. Even after the involvement of the private sector, how can it complicate the physical expansion is described in next following section. Finally, some concluding remarks to this problem are made.

2. Demand for Land and Planning in Dhaka City

Dhaka ranked 11th among the world megacities with an estimated population of 12.4 million in 2006 (UN, 2006), which turned out to be more than 16 million by 2010 according to the United Nations Population Division, and expected to grow up to 20 million by 2015 as projected by the same source. According to some unsupported sources, about 2,100 people migrate to Dhaka city every day, and if the influx continues, it would be the second largest mega city after Tokyo by 2015 (Chowdhury, 2010).

In accordance with the population growth, the increase in land price has also been unprecedented. Compared to the price of 70's, Dhanmondi, the most expensive residential area of the city, experience about 12,000 percent increase compared to 2010. In comparison, the commercial land price hike has been much lower, about 9900 percent

in Motijheel area (The Daily Star, 2010). Bangladesh Institute of Planners (BIP) estimates land price in some prime locations in Dhaka (value per square foot; 1 USD= 71.3 Tk.): Dhanmondi residential area is the most expensive, average roughly Tk. 3,500 or around $60; in Gulshan about Tk. 3,194 and in Baridhara about Tk. 3,000. Even in the least expensive residential areas, land price is about Tk. 1,600, around $27 per sqft which include peripheral areas like Uttara, Pallabi, and Shyamali (WB, 2007, p. 38). In comparison, land prices in most cities of the United States are much lower (in $/square foot): Boston $13.10; Chicago $14.5; Los Angeles $30.4; Miami $11.1; New York $32.3; San Diego $26; San Francisco $64 (Glaeser and Gyorko, 2003; see WB, 2007, p. 38). The escalation in land price restricts middle and low income group from accessing urban land pushing further to the peri-urban areas creating leap-frog, low density and discontinuous pattern of urban development.

The distinct characteristics (interplay of supply, affordability and price/speculation) of low and middle income land and housing market has resulted in private developers housing, sites and servicing as the most lucrative business in Dhaka city. In 1991, Real Estate and Housing Association of Bangladesh (REHAB) established with only 11 members. By 2007, the organization had 260 registered members which turned out to be 1004 by the year 2010. About 9,000-10,000 apartments and 5,000-6,000 plot units were delivered by the REHAB members in 2010. Considering the population growth, at least 50,000 dwelling units are required every year to meet the backlog and present housing demand in Dhaka city (REHAB, 2005, p.16). With the joint efforts from the private developers, individual initiative and government provisions; the current housing situation fall far behind the required, and is being aggravated over time. Government interventions in the land market have distinct effect over the market since it distorts the generic growth.

Apart from the population growth and failure in land management, there is several other factors effect land price. According to Brennan (1993), one of those is extreme level of land speculation in most of the developing countries which often depends on the national economy whether it is expanding and alternatives avenues exit for investment or characterized by stagnation and high inflation acting as a reliable investment against inelastic land for secure revenue generation. Bangladesh is one such example where people are working in foreign countries investing in land and housing market in Dhaka city creating artificial demand and speculation.

3. Multiplicity of the Problem

Government intervention in land and housing market adds complexity to the overall situation. Since government projects enjoys better transportation and service facilities like electricity, gas, garbage disposal etc., there is a tendency among private developers to be adjacent to the government ones. The attraction to the government projects by the

private ones has shaped different parts of the residential areas, and this technique has been applied in numerous cases e.g. Nikunja, Uttara, Gulshan.

Another problem associated to planning in Bangladesh is that government is the protector of the law, and also the violators. Usually, the violations from the government side have been legalized, but considered illegal for private sectors. Even though private sectors are able to bypass the laws, it is always a nagging and acts as continuous threat.

Dhaka Metropolitan Development Plan, 1995-2015 extended the formal boundary of the city to comprise 1528km^2 under the jurisdiction of the development control authority of Dhaka (RAJUK). The third stage of the DMDP, the Detailed Area Plans (DAPs) considered the development of a New Town in the eastern fringe of the boundary. The government land project- Purbachal New Town comprises an area of 6150 acres. From the Map-1, the Detailed Area Plan (DAP) of Dhaka city delineates the area of New Town and the peripheral land use. The plan is successful in producing a land use copied from ideal definition of New Town. The surrounding areas existing and proposed land uses are dominated by agricultural, flood flow zones and rural settlements. According to the Residential Land Development Act, 2004, no private residential land project can take place in agricultural and flood flow zones.

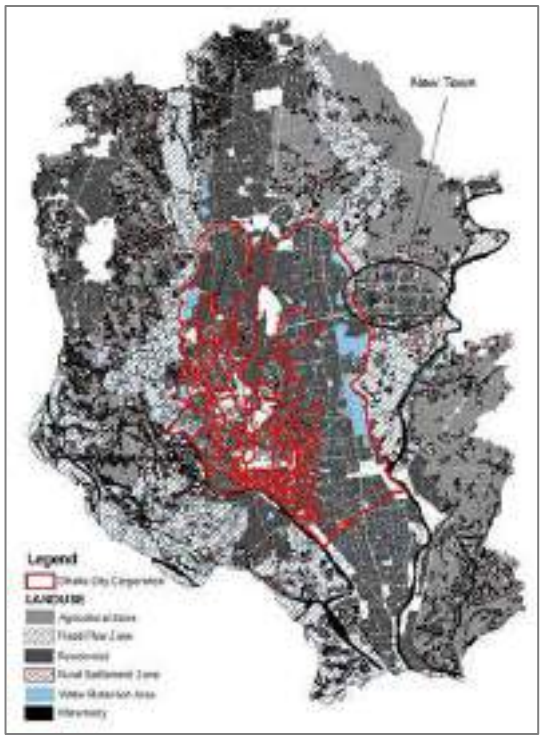

Figure 1: Detailed Area Plan of Dhaka City

The New Town will be connected with major commercial and residential centers of Dhaka city by roads, and major cities like Chittagonj and Sylhet by six lane highways. Furthermore, since it is a government project, crucial services like water, electricity, gas and waste disposal are ensured by the government.

4. Material and Methods

4.1 Study Area

Due to the extreme demand for land and housing, expectedly, urban area will expand horizontally and along the major highways. The proposed New Town is in the periphery of the Detailed Area Plan (DAP). Therefore, the actual impact of the New Town will be out-bound, and so, for the present study, the area considered for quantification of private

response extends towards mainly to the East, North and South. A total of 163.78 km^2 of the DAP area including the New Town has been selected as the study (figure 2). From the proposed land use of the DAP, there is, almost, no provision (0.01 km^2) for residential land development. Most of the areas are designated as agricultural, flood flow zones and rural villages. According to the Residential Land Development Regulation, 2004, land conversion for residential or other uses is prohibited. Recently, the planning agency has banned all private residential land development in the vicinity of the New Town. It must be noted that the New Town itself is a violation of the Residential Land Development Regulation, 2004 since it was developed filling out the low-lying agricultural and flood flow areas.

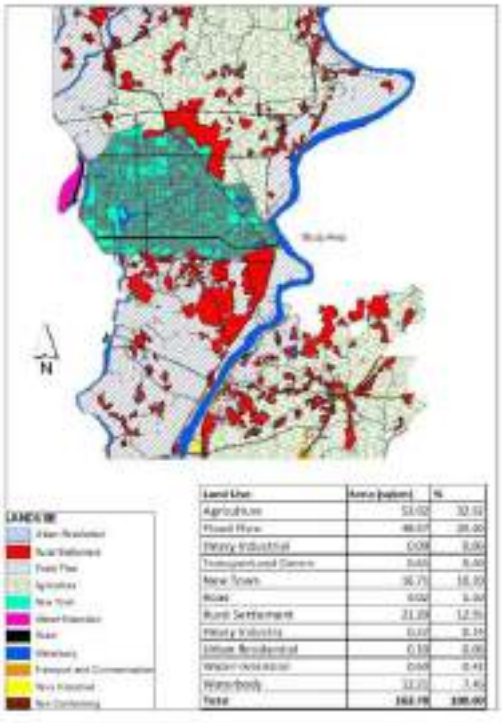

Figure 2: Study Area

4.2 Data Collection

The New Town has attracted many private residential land developers in the vicinity. The most recent newspaper reports indicate the existence of more than 100 companies. However, most of those are leapfrog, meaning, small and unrecognized companies subject to disappear under government pressure. However, more than 60 established companies are operating in the area. In total 30 established companies were randomly selected for the field investigation and data collection.

In depth interviews were conducted with the company representatives. Information was collection about: land area, price, possibility of investment in land and housing, government intervention in the future and distance from the major locational hubs.

Figure 3: Location of the Land Developers

Figure 3 shows the existing location of the 30 land developers. Most of these, if not all, overlap the proposed area. Presumably, this situation becomes worse if all of the companies are considered. Therefore, tenure security for land buyers is the biggest challenge in this informal and illegal land market.

5. Quantification of the Private Response

From the table (1), 12 recognized land developers are operating in surrounding the New Town inside DAP area comprising an area approximately 6269 acres. At the same time, 17 companies situated outside DAP area with about an area of 16312.59 acres. There are two important noticeable facts: first, land area covered by the private residential developers outside the DAP areas is much higher than within (comparison is shown by figure 4), and second, several companies overlap each other's area which is higher inside DAP area than outside (figure 3).

Table 1: Private Response Inside and Outside Detailed Area Plan (DAP)

Inside DAP			**Outside DAP**		
No.	Name	Area (acres)	No.	Name	Area (acres)
1	Lotus Valley	284	13	Purbachal Eastwood City	1523
2	Purbachal Pixel City	247	14	Purbachal HL City	423.9
3	Rose Land City	203	15	Platinum Purbachal City	991.3
4	Gold Man City	978	16	Ananda City	664
5	Purbachal City (Vision 21 Purbachal)	650	17	Purbachal American City	2072
6	Ashalaya	500	18	East American City	995
7	Dhaka Village	1020	19	Purbachal Nobodoy Housing	1283
8	Shikhder Royal City	380	20	Purbachal Bestway City	2991
9	Biswas Purbachal Hill City	257	21	Purbachal Regent RiverView	268.5
10	Purbachal Marine City	500	22	Purbachal Probashi Palli	366.2
11	Asian City- Shitol Saya	968	23	Purbachal Garden City	467.5
12	Vision 21-Park View City	282	24	Purbachal Park Town	427.5
Total		**6269**	25	Eastern Japan City	725
Overlapped Area Inside DAP= 27%			26	Eastern Park City	984.8
Overlapped Area Outside DAP= 6.89%			27	Purbachal Regent Town	1152
			28	Probashi Palli-2	627.7
			29	NRB Homes	350
			Total		**16312.6**

Source: Field Survey, 2010

Table 1 is the list of the selected housing companies in the study area. The overlapped areas among inside DAP (27%) shows scavenging of lands by the housing companies. This trend is less outside DAP (6.89%) due to availability of land. Furthermore, many landowners became self-motivated land developers who have very little idea about private residential land development criteria. Therefore, one conclusion is that most of

these housing companies cannot implement the proposed area, rather, have to compromise among different land owner, developers and rural settlements.

Figure 4 shows that the private response is about 3.67 times higher than the government project. However, this result shows the response from only 30 selected developers. If all the existing companies are considered, this is much higher than 3.67 times. The total area of these companies surpasses the actually available land in the study area referring to the problems of illegality and tenure security.

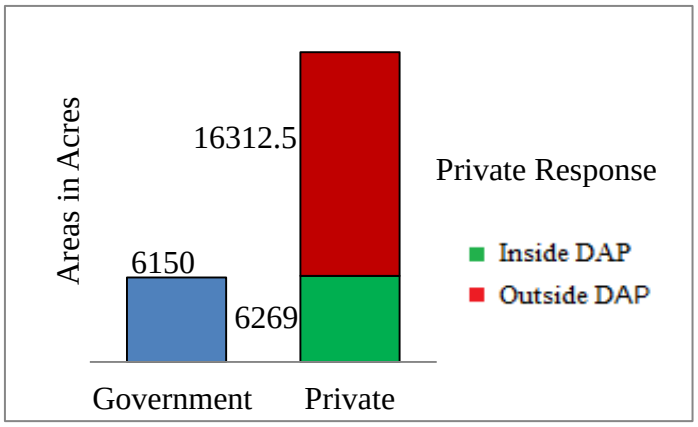

Figure 4: Private Response to Government Project

6. Implication of Present Land Conversion

Demand for land and housing in Dhaka city cannot be met from the government alone. Unless private sectors are enabled and allowed to participate in a strategic way, in foreseeable future it is going to aggravate. Even though the current private residential land development is associated with illegality, ultimately government cannot control the haphazard land conversion in the future. The past trend in the land market ensures the statement. The present trend will trend may leave irreversible impressions on the future of urbanization:

- The peripheral part of the city is characterized mainly by low-lying agricultural land, and acts as water retention area during rainy season. Unless natural drainage and water bodies are protected, which is just the opposite of residential land development; urban flood will be a common phenomenon in coming future. Figure 5 shows the existing land use of many proposed housing.

- Dhaka is one of the most densely populated cities in the world. Oversupply of urban land by private residential companies does not ensure the density rather it is a medium of land speculation. Ultimately, people who need land desperately will be deprived of land due to the price hike.

- As shown in the map 2, the area surrounding the New Town is completely taken over by the land developers. Dominant land use in this area is agricultural and low-lying one-

season agricultural land. Land conversion to residential plot will ultimately lead to destruction of valuable agricultural land.
- Figure 6 shows layout of the proposed housings. These are basically land subdivisions without provision of any urban social and utility facilities.

- The present land development will lead to low-density functional sprawl dominated by residential land use (this term first used by Ewing, 1997). Different studies, for example Camagni et al., 2002 suggest that functional sprawl increase travel distance, private car-ownership and environmental pollution.

Figure 5: Existing Situation

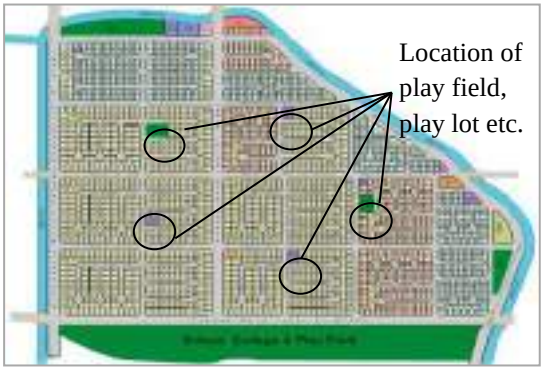

Figure 6: Proposed Layout

7. Findings and Conclusion

Private sectors respond to the government policy decision, and in this case, the private land developers came into existence because of the New Town. The response from the private sector is much higher than the government ones. Restricting the land developments is not a solution to the land and housing problem, and ensuring tenure security is the biggest challenge.

One of the targets of the New Town development was to trickle down urbanization in the surrounding area. However, the DAP land use does not allow any residential land development in the area. This is a double-standard policy of the government. To meet the land and housing demand for the vast majority of the population of Dhaka city, some agricultural area must be sacrificed. There should be a strict guideline for residential land developers to ensure density in this area rather than halting land conversion which would surely be a failure.

INSTRUCTIONS FOR PREPARATION OF FULL PAPERS

Luca Gaeta [1]

Abstract

The paper aims at tracking the main strategies to survive a world catastrophe in both science fiction novels and films. The underlying idea is that sci-fi mirrors the change of social attitudes, at different time thresholds, towards the threats affecting mankind. The imagined characters of survivors are observed in order to answer two questions: who is more likely to survive a world catastrophe, if any? What circumstances make survival more probable? The survey covers a set of narratives released from 1945 to present times in the US and UK, featuring three types of world catastrophe: nuclear, biologic and environmental. The survey shows how the authors' imagination about what is expedient to survive the world catastrophe has evolved towards individual instead of either governmental or collective patterns of action, and also towards the capacity of facing unexpected events rather than planning ahead.

Key words: science fiction, survival, catastrophe, nuclear, biological, environmental

1. Introduction

This paper lays at the crossroads of two discourses about the future of mankind. On the one hand, the discourse on Risk Society (Beck 1992; 1999) deals with the radical challenges to our Enlightenment-based modernity stemming from the expectation of human-made, technology-driven, world-scale catastrophes. On the other hand, the discourse of post-apocalyptic narratives, a sub-genre of science fiction, deals with the imaginative consequences of the actual outspread of Armageddon (Paik 2010). The sociology of risk presides over the antecedent side of world catastrophes, while post-apocalyptic science fiction covers the aftermath. However, both discourses address, more or less overtly, the issue of societal guidance under circumstances of ultimate emergency. The conditions of social life are taken to the limit where the last resort for salvation is revealed as the fundamental governing principle (Agamben 2005).

This theoretical and fictional thinking does not only conceive of present and future attitudes about government: it mirrors as well the changes occurred over time. The reflections upon preventing and surviving world catastrophes, in different historical periods, are used here to pattern the evolution of strategic attitudes to secure human life and civilization on earth. In order to outline a provisional genealogy of survival, the paper presents a survey of science fiction novels and movies featuring three typologies

[1] Politecnico di Milano, Dipartimento di Architettura e Pianificazione, luca.gaeta@polimi.it

of world catastrophes: nuclear, biologic and environmental. Two additional selection criteria were adopted:

(i) the responsibility borne by humans, particularly scientists and political leaders;
(ii) the release date subsequent to World War II, taken as the conventional beginning of the nuclear arms race and its fear. As a matter of fact, the bulk of the fiction covered was produced in the US and, to a lesser extent, the UK. That choice mainly depends on the greater ease of access to the sources, and by no means on ideological grounds. I gladly admit that a cross-cultural survey would be preferable.

Even though confined to a specific cultural milieu, the survey of science fiction narratives is supposed to test a broader hypothesis. That is that, since 1945, the social consciousness of what is appropriate to survive catastrophic events has evolved towards individual instead of collective (the less governmental) patterns of action. Of course the accounts are largely imaginative. No human has ever survived a world catastrophe hitherto. Such events neither can be tested nor allowed to happen but on imaginative stages. However, the keen social sensibility of sci-fi authors, combined with the talent of pushing hard scientific and technological innovation to its more extreme consequences, provides us with valuable hints to discern the past and present philosophy of survival. Through the looking-glass of science fiction literature we can figure out the relationship between imaginative escapes from the world catastrophe on the one hand, and current ideals of societal guidance on the other.

In the next three sections, the imagined characters of survivors are observed and compared in order to answer the following questions: who is more likely to survive in the event of a world catastrophe, if any? Under what circumstances can survival be achieved with favorable chances? To this end three topics are used to condense the subject-matter, namely the cause behind the catastrophe, its short and long-term consequences and, not least, the survival expedients. Nuclear catastrophes precede biological and environmental ones. Apparently they excited the fervid imagination of science fiction authors in that sequence, not without parallelisms with historically experienced threats.

2. Surviving the nuclear war

The threat can be traced back to the beginning of the nuclear arms race, since the day the Soviet Union conducted its first atomic test on 29 August 1949 (Weart 1988). The end of the United States nuclear monopoly was followed by early preparations to face the consequences of sudden attacks. The booklet *Survival under atomic attack*, released in 1951 by the National Security Resources Board, was complemented with a short homonymous documentary produced by Castle Films. “Let us face without panic the reality of our times: the fact that atom bombs may someday be dropped on our cities” says the speaker in the opening scene. Cities are presented as primary targets. To be prepared is the official survival strategy pursued in the series of short documentaries released by the Federal Civil Defense Administration, often about the testing of atomic bombs and their destructive potential (Jacobs 2010). The production of post-apocalyptic

narratives was intensified after 1949. Prior to WW2 the imagery of global disasters had been either cosmic or natural in origin (Broderick 1993). Then the consequences of the nuclear warfare became an endless source of inspiration. Significantly, narratives do not support the official strategy. With few exceptions, to be prepared is not supposed to increase survival chances. To survey such a multiform set of artworks the focus is put on survivors and their mutual relations. The resulting pattern can be articulated into three main attitudes towards survival, each covering a definite historical period, even though by no means exclusively. The first attitude is confident of the recovery of ordinary life conditions after the nuclear catastrophe. The second is suspicious of governmental and scientific loss of control over abstruse, top-secret defense systems. The third one is resigned to social collapse without redemption, if not to human annihilation.

2.1 Business as usual

Since 1950 until well into the 1960s the aftermaths of the atomic war are imagined as tragedies which nevertheless admit return to ordinary life conditions. *Shadow on the Earth* is the seminal novel published by Judith Merril. It was written in 1950 as a reaction to the arms race. In the same year the plot was adapted as the screenplay of a movie broadcasted in the Motorola TV show. Set in a suburb off New York in the aftermath of an atomic attack, the story depicts a wife with her two daughters facing the unpleasant intrusion of a neighbor serving as emergency squad man. The civil government is replaced by emergency authorities which carry on their own relief plans. The woman desperately tries to keep up appearances.

The partial preservation of the public authority is featured in novels as *The long loud silence* (1952) by Wilson Tucker, where the army sets up a sanitary cordon along the Mississippi river; in *Tomorrow!* (1954) by Philip Wylie; in *Alas, Babylon* (1959) by Pat Frank, where a small town in Florida is ruled by a former reserve officer until the government rescue teams land by helicopter. In *Damnation Alley* (1967), by Roger Zelazny, the United States is replaced by several police states. The movie version of 1977 features a colonel, survived in a military air base, leading a convoy towards the preserved community of Albany. *Malevil*, written by Robert Merle in 1972, tells how a small number of French villagers survive a nuclear blast in a cellar, and are rescued by the army after months.

Common to the latter narratives is the key idea that survival in the short run is not a matter of preparedness. Greater protection is expected from occasional shelters or favorable locations. Early examples of this attitude are found in *Five* (1951), directed by Arch Oboler, where three out of five survivors were casually under metal shelters during the fallout, and one more was on top of the Himalaya. Roger Corman's movie *Day the world ended* (1955) features an old man with his daughter surviving in a valley. The man says he has spent ten years getting ready for the day after. His house is far from large towns and surrounded by cliffs (a topic revived in *Z for Zachariah* (1973) by Robert O'Brien). In both cases no public authority has resisted the attack, as mankind was wiped out. However, the two narratives end up with hope in a new beginning, assigned to young couples in love. The possible recovery of civilization is set in a distant future.

2.2 Underground communities

Between the late 1950s and the mid-1960s a first change occurs in the imagination of nuclear disasters, to cite a seminal essay (Sontag 1967). Large scale preparations are being made by the superpowers up to the point when complexity and risks get out of control, thereby generating anxiety. The so-called mutual assured destruction through massive retaliation leaves little room for survival, at least on the earth's surface. Both the atmosphere and the topsoil would be irremediably contaminated. A number of narratives therefore set their survival scenarios underground.

The forerunner is *Unknown world* (1951), directed by Terry Morse. Dr. Morley is convinced that a nuclear conflict will inevitably occur. He conceives of "a plan to preserve human life on this planet" (min. 4). A team of scientists in an atomic vehicle descends in the bowels of the earth to find out a shelter. However, life underground proves to be impossible. Philip Dick wrote in 1953 his short story *The defenders*, later expanded in a novel. The superpowers survive deep underground while robots are supposed to fight on a devastated land with nuclear weapons. Instead, robots have ceased the war and restored the natural environment.

Early narratives show confidence in the scientific minded capacity, be it human or cybernetic, to redeem the wrongs of political leaders. But this is not how the series goes on. In the novel *Dark universe* (1961), by Daniel Galouye, two tribal groups of survivors live into dark underground galleries, handing down legends of luminous divinities and mortal radiations. The French movie *La jetée* (1962), by Chris Marker, stages a totalitarian government survived in the caves of Paris. Deadly experiments in time travel are made on prisoners to retrieve medical supplies, food and energy from the past. A stubborn policeman is the protagonist of *This is not a test* (1962), written and directed by Frederic Gadette. In the imminence of a nuclear attack he orders a group of civilians to take shelter in a truck container. In the final sequence they all die, whereas the survival of two fugitive young lovers in a nearby silver mine is predicted by the girl's grandfather.

The novel *Red alert* (1958), by Peter George, was satirically brought to the screen by Stanley Kubrick as *Dr. Strangelove, or: how I learned to stop worrying and love the bomb* (1964). This is the quintessential distrust of both governmental and scientific control of nuclear weapons. The US strategic air command is unable to recall the 843rd wing of intercontinental bombers. It was ordered to attack USSR by its insane base commander abusing the Plan R. This is a last resort measure to retaliate under a nuclear attack. If communications are disrupted and no central direction is left, then the Plan R empowers the isolated base commander to act on his own initiative. On the other hand, the Soviets have just activated their ultimate deterrent, a weapon automatically set to poison the atmosphere. The US President is advised to prepare plans for salvation in huge underground shelters.

Significantly, in 1959 Paul Baran joined the RAND corporation in Santa Monica to start his seminal research on a new communication system, a "distributed network that had no vulnerable central point and could rely on redundancy" (Ryan 2010, 14). Once combined

with the interactive computer technology developed by ARPA since 1965, Baran's concept laid down the foundations of the Internet.

2.3 Every man for himself

The novel *On the beach* (1957), written by Nevil Shute, sets the annihilation of life shortly after the nuclear war. A civil government is in charge in Australia only, not targeted by bombs. Its people pretend nothing happened. A submarine, the single remnant of US naval forces, is instructed to explore the northern hemisphere just to discover that lethal radiations are moving southward. By the time everyone becomes ill, blue pills are distributed to die painless. The submarine commander and his lover Moira, the book's main characters, choose to die separately. The man sinks the ship in international waters according to military rules, while she takes a blue pill staring at the scene on a cliff.

The topic of annihilation is paralleled with self-sufficiency. The movie *Panic in year zero!* (1962), directed and interpreted by Ray Milland, is about a family escaping the nuclear destruction of Los Angeles. The husband states his creed in a tense dialogue with his scared wife: "For the next few weeks survival is going to have to be on an individual basis" (min. 14). Later on the man puts it more plainly: "My family must survive!" (min. 25). Accordingly, he is ready to break the law to get what they need: food, gasoline, right of way, security, up until the social order is restored. On the other hand, the wife remains faithful to the traditional customs. The novel *Farnham's freehold* (1964), by Robert Heinlein, is a real cornerstone of survivalism, the radical movement popular in the US since the mid-1960s (Mitchell 2002). Hugh Farnham is a dictatorial person. His family survives in a private fallout shelter under the house. The shelter is transferred by the nuclear blast in a far future, where the environment is not damaged. The small group tries to adapt under Farnham's brutal leadership to the life conditions of pioneers.

The time travel expedient is also found in *Planet of the apes* (1968), directed by Franklin Schaffner. The movie differs from the original novel *La planète des singes* (1963), written by Pierre Boulle, inasmuch the extinction of human civilization on earth is due to nuclear warfare. This is the tragic find of the surviving character: a light-speed spaceship commander. His ship did not crash on a distant planet, but on earth in a distant future, where dumb human savages are hunted by civilized apes. *The Noah* (1975), written and directed by Daniel Bourla, features the sole survivor of a nuclear holocaust. To mitigate his loneliness he creates a whole series of imaginary companions.

In no other period than the 1980s is nuclear extinction so vividly imagined (Dowling 1987). *The day after* (1983), directed by Nicholas Meyer, tells the heroic efforts of a surgeon to keep his hospital operative, only to be overwhelmed by the flow of incurables in despair. No other civil or military authority is left. In *Testament* (1983), directed by Lynne Littman, people survive in a suburb where apparently no damage occurred. However, the radioactive fallout inexorably weakens the local community until the complete end. *Threads* (1984) is a TV movie directed by Mick Jackson. The scenario is about Britain getting involved in nuclear warfare. Careful preparations are made for civil

defense, but command and control links fail after the attack. No return is possible to pre-war conditions. Thirteen years after, survivors are regressed to pure subsistence. *When the wind blows* (1986) is a cartoon movie directed by Jimmy Murakami. An elderly couple in the countryside scrupulously complies with the rules of the official survival booklet. That protects them from the blast. Radioactivity affects the woman first. As the awaited assistance never materializes, the couple quietly succumbs in the sitting-room.

Even when extinction is escaped, no return is supposed to pre-war life conditions. *Doomsday plus twelve* (1984) is a novel written by James Forman. It depicts groups of survivors scattered through an environmentally damaged US twelve years after the war. The same topic is featured in the novels *Warday* (1984) by Whitley Strieber and James Kunetka, and *Children of the dust* (1985) by Louise Lawrence. Limited wars are imagined in the novels *Arc Light* (1994), by Eric Harry, and *Resurrection day* (1999) by Brendan DuBois. Temporary lack of pregnancy is experienced by women in *The last ship* (1988), written by William Brinkley. The crew of two USSR and US naval units wander the oceans in search of a safe place to live. *The postman* (1985), written by David Brin, tells the individual journey of a man delivering letters to small groups of Oregon survivors. Another lone hero travels a devastated country in *The book of Eli* (2010), directed by Albert and Allen Hughes. The man delivers the last Bible to survivors running a printworks and a library in the Alcatraz prison.

3. Surviving the pandemic

The biological threat differs from the nuclear one inasmuch it does not compromise the environment. Humans are infected, livestock may be, but the inanimate world looks the same. It usually keeps the resources to support human life. Therefore total annihilation is not envisaged. On the other hand, pandemics are even more socially disruptive than nuclear warfare. As people get infected, the social collapse is almost inevitable. Quarantine is the obvious governmental measure to halt the spread of the disease. This measure requires abundant confidence in the general interest of society, as the infected are sacrificed for the safety of the healthy population. However, in the set of narratives, survival is more often the result either of natural immunity or self-isolation. In both cases a pattern of distinction from the bulk of society prevails, no matter if it is occult or evident. The surviving individuals are protected by their own diversity.

The survey could be based on the dualism between pandemics contained by enclaves or aroused therein. The first case supports the enforcement of quarantine plans. Any violation of the rules means massive death. On the other hand, biological research undertaken within inaccessible compounds is the source of infection, as lethal viruses always find a way out. Then no containment is possible. Human agglomeration just favors the risk of infection. Indeed, this paper centres on man-made catastrophes (Davis 2002) to reveal the reliance on governmental planning. Therefore the selected narratives stage really often the scenario of pandemics spreading from institutional precincts. A first group of narratives puts some confidence in the remedial power of either scientific research or collective endeavours, while a second more recent group emphasizes survival as a private matter.

3.1 Science-based remedies

The novel *I am legend* (1954), by Richard Matheson, is worth considering here as it has originated three movies in different decades. The novel's protagonist is the sole human to survive a bacterial disease similar to vampirism. His life is devoted to burn corpses, destroy the living deads and find out a vaccine as a self-taught scientist. Meanwhile the infected are attempting to build their own society. The movie *The last man on earth* (1964), directed by Ubaldo Ragona and Sydney Salkow, features the man as a biologist owing his immunity to a bat bite. Lethal to vampires, daylight is the man's only outdoor protection. Day and night are the exclusive domains of each species. In *The omega man* (1971), directed by Boris Sagal, the epidemic is caused by bacteriological warfare. The infected hate the man, a US army scientist carrying a symbolic responsibility for their illness. In *I am legend* (2007), directed by Francis Lawrence, a genetically modified measles virus induces mutations instead of healing cancer. Flashbacks report failing military attempts to quarantine Manhattan. Even though the man is killed by the infected, the vaccine he has isolated is brought by a female character to other survivors in Vermont.

The series of engineered viruses is continued by *The last Canadian* (1974), written by William Heine. The main character takes his wife and sons to northern Québec to survive a deadly airborne epidemic spreading from Colorado. *Survivors* is the title of the television series devised by Terry Nation and broadcast by BBC from 1975 to 1977. Natural immunity preserves small numbers of human beings from the virus accidentally released in a Chinese laboratory. The UK collapses in a very short time. Survivors slowly gather in small rural communities, facing the harshness of a new beginning, and experiencing self-government arrangements. *Plague* (1978), directed by Edward Hunt, features a scientist working to find out a vaccine against the M3 deadly bacterium created in a Canadian laboratory. Another story of dispute between dangerous and beneficial scientific research is staged by *Virus* (1980), directed by Kinji Fukasaku. A biological weapon is developed in a US army laboratory without presidential authorization, then accidentally released. The scientific communities based in the Antarctic circle are preserved because the cold climate inactivate the virus. A peaceful federation is enacted to perpetuate mankind. However reluctantly, women accept to lie with more than one man.

3.2 The selection of the fittest

Increasingly since the late 1970s the reliability of science-based governmental plans deteriorates in science fiction literature. *The stand* (1978), written by Stephen King, is based on the accidental release of a virus in a US military camp. A soldier with his family breaks the quarantine rules to abandon the camp, ignoring they are already infected. Less than 1% of the world population is left alive. Social order is totally disrupted in spite of the martial law enforcement. Two opposing clans of survivors emerge that finally clash to the death.

Scientists gone insane are responsible for biologic catastrophes in the 1980s. In *The quiet earth* (1981), written by Craig Harrison, only a geneticist and a soldier survive in New Zealand a catastrophic event called The Effect. Survival is due to a rare gene. The rest of mankind is simply disappeared. After killing the companion, the scientist gradually recalls his sabotage of a sound-wave equipment for the manipulation of DNA. In *The white plague* (1982), written by Frank Herbert, a molecular biologist is driven insane when his beloved wife and son die under an IRA attack. In revenge he engineers a plague that kills women. The plague in then released in Ireland, England, and Libya. In *Blood music* (1985), written by Greg Bear, a bioengineer invents a computer based on blood cells. To remove the prototype from the laboratory, the man injects it in his own body. The blood cells start multiplying and mutating, until they can assimilate other humans to create a self-conscious meta-organism extended over North America. *12 monkeys* (1995), directed by Terry Gilliam, revives the time travels featured in *La jetée*. A man is sent back in time to investigate on the virus that has contaminated the earth's surface. He dies on the floor of Philadelphia airport while trying to prevent the bioterrorist from boarding with his lethal hand-luggage.

The last decade witnesses the purest individual philosophy of survival. *28 days later* (2002) is a horror movie directed by Danny Boyle. An animalist team steals by night in a laboratory to halt the vivisection of monkeys. The animals are carriers of a rage virus transmissible to humans. The infected are immediately turned into bloodthirsty zombies. 28 days later the protagonist awakes from coma in the hospital. Joining two survivors down the street he cannot figure out what is happened: "What about the government? What did they done? — There is no government — There is always a government. They are in a bunker or a plane" (min. 29). Any attempt to contain the virus failed. The army blockades were overrun. Later on the man is instructed that "plans are pointless" (min. 29) to stay alive. The sequel *28 weeks later* (2007) shows Canary Wharf compounded and recolonized by people from the continent. A woman is found alive whom is a sane carrier of the infection. She is spared because doctors hope to find out a vaccine. Her husband forces the sanitary cordon to visit the woman and gets infected. The virus is back. Trying to protect the sons of the sane carrier, a doctor persuades a helicopter commander to take the boys outside the quarantine zone. This violation spreads the infection across the channel. The moral is not merely that governmental plans have loopholes. It is implied that regards accorded to family ties threaten survival.

Doomsday (2008), directed by Neil Marshall, is exceptional here as the plague is not artificial. It tells the mission of a military squad beyond the wall separating England from Scotland, the source of infection. Survivors have been detected from satellites twenty years after the blockade. Abandoned by the government, they were supposed to be all dead. Perhaps there is a cure for the virus recently found in London. In the highlands a former biologist has become the feudal lord of a community. Questioned about the plague he admits there is no cure. The fittest survived natural selection. Quarantine failure is worsened in *Pandemia* (2006), written by Jonathan Rand and Christopher Knight. Modern transportation systems favour the spread of mutated bird flu from Asia to worldwide scale. The emergency causes the collapse of society.

In *The last man* (2008), a low-budget movie directed by James Arnett, a gang of marauders plunder a Soviet laboratory releasing a strain of small pox. About 98% of the world population is killed. Survivors are affected by various symptoms. Only one man is left immune to fight against cannibals. *Dog eat dog* (2010), written by David Rodger, takes place ten years after a global pandemic. A virus is released by accident in an air cargo crash. Over 70% of the world population is extinct. Apart from a few cities, mankind is preserved on space satellites. Two male characters try to get power and wealth in a world without law and order.

4. Surviving the climate change

The environmental catastrophe brings about either permanent or reversible changes of the natural process supporting human life. Alterations may affect land, water and the atmosphere, namely what humans take for granted. Nature under such conditions is no longer allied to mankind. The lost environmental equilibrium unleashes forces that civilization neither can resist nor control. When civilization bears responsibility for damaging the environment, then reckoning is particularly fierce in the settings of sci-fi literature (Lutz 2001). Unlike nuclear or biologic disasters, the environmental one is more the anonymous by-product of the two-thirds society then of its ruling élites, with the exception of multinational corporations.

The early tendency in the narratives is the already mentioned expectation that return to ordinary life conditions be possible somehow or somewhere. In *Mr Adam* (1946), written by Pat Frank, the world male population becomes sterile after the explosion of a nuclear fission plant in Mississippi. One year after a baby girl is delivered. When the explosion occurred her father — nicknamed Adam — was shielded by lead in the lowest level of a mine. In *The day of Triffids* (1951), written by John Wyndham, two events combine in a world catastrophe. The passage of a comet causes blindness to people staring at it. A species of engineered carnivorous plants, cultivated in order to extract oil, takes advantage of the situation to invade the world. A group of sighted survivors gathers on the Isle of Wight, determined to find a way to destroy the plants. In the 1962 movie version, directed by Steve Sekely and Howard Keel, sea water is lethal for the Triffids. In *The day the Earth caught fire* (1961), directed by Val Guest, simultaneous nuclear bomb tests drive the Earth out of orbit. The climate warming causes water to be severely rationed by governments. Scientists agree on a desperate plan. Several nuclear bombs are detonated in Siberia to bring the planet back to its orbit. In the end scene church bells ring propitiously under clear skies.

The awareness was progressively gained that climate change occurs as a by-product of our development pattern. No accident is required to alter the environment, but the endless consumption of resources (Buell 2003). In *The burning world* (1964), written by James Ballard, water is extremely scarce and valuable. The discharge of industrial waste within the sea resulted in a thin but resilient film formed from a complex of saturated long-chain polymers that prevents evaporation. In *Silent running* (1972), directed by Douglas Trumbull, no vegetable life is left on the earth. The very last specimens are preserved on a spaceship. The resident botanist refuses to obey the destruction order

given by the ship-owner. Having killed his crew mates, the man launches the spared greenhouse beyond the solar system with robots programmed to take care of it. The trade-off between human life and the natural environment is further amplified by extreme political regimes (Yanarella 2011, chapter 2). In *The sheep look up* (1972), written by John Brunner, a corporation-sponsored US government do not take actions to reduce environmental pollution. The urban population health is badly affected. Turmoil and unrest finally break down the social order. In *The bridge* (1973), by Keith Mano, civil war ends up with the coming to power of a radical environmentalist regime. All forms of life are given the same value, including microbes. The council then decrees the extinction of mankind whose breathing destroys innumerable microscopic creatures. In *The handmaid's tale* (1985), written by Margaret Atwood, pollution and chemical waste lead to declining female fertility. A totalitarian theocratic regime replaces the US government. Women are made subservient to men and only concerned with bearing children. In the ironic novel *Fallen angels* (1991), by Larry Niven, Jerry Pournelle and Michael Flynn, a coalition of environmentalist and religious groups takes control of the US, thereby enacting laws against technology to curb global warming. That eventually results in a catastrophic ice age. Another example of political coercion due to environmental reasons is found in *Clade* (2003), written by Mark Budz. When a so-called Ecocaust raises the sea level, civilization is preserved at the expense of freedom. Transnational political corporations rule the world. Humans are engineered at molecular level so as to survive in specific communities, and not elsewhere.

Industrial pollution is the often implicit backcloth of environmental catastrophes. The reduction of the ozone layer, observed since the late 1970s, is brought to its extreme consequences in *Mindwarp* (1992), directed by Steve Barnett. The earth is reduced to contaminated wasteland with the exception of Inworld, a protected biosphere where humans spend their lives being plunged in a virtual reality. In *Encrypt* (2003), the TV movie directed by Oscar Luis Costo, the earth's surface is ravaged by storms caused by the loss of the ozone layer. A storm catastrophe is imagined in *Mother of storms* (1994), written by John Barnes, after the release of clathrate compounds in a nuclear explosion. In *The day after tomorrow* (2004), directed by Roland Emmerich, global warming melts the polar ice caps then triggering huge hurricanes and a new ice age. The protagonist scientist first advises the President to evacuate the southern US, then faces the polar storm to rescue his son sheltering in a library. In *Category 6: day of destruction* (2004), directed by Dick Lowry, a storm hits Chicago which goes beyond any scale previously used. The population is not alerted because the electrical grid is sabotaged by a security manager to warn against the system vulnerability. Again, the male protagonist is first committed to reactivate the grid, then to save his family.

5. Surviving despite plans

The survey provides enough evidence to support a preliminary genealogy of survival, namely the derivation of current ideals of societal guidance. Of course the narrative mirror distorts and magnifies reality. On the other hand, sci-fi authors are "capable of achieving profound and probing insights into the principal dilemmas of political life" (Paik 2010, 1). The imagined last resort for salvation disguises the supreme guiding principle of society. Extreme emergencies are viewed as metaphors of governmental strategies. This is how the present survey was intended. Its results may not be valid outside the US and UK contexts.

So far as the nuclear catastrophe is concerned, doubts on the governmental protection accorded to citizens emerge right after WW2. Survival is not the outcome of defence plans implemented by public authorities. When partially preserved, authorities are slow to recover. Survivors are better protected either by occasional shelters or good locations. Accordingly all sorts of people escape. A miniature-society is preserved as the best promise that life conditions will get back to normal. Since the 1960s sci-fi authors figure out a different pattern. The nuclear war no longer is taken as a factual statement. Command and control systems of perverse complexity and the doctrines of mutual destruction do not reassure people's feelings of insecurity. This can be said to be a transition period towards another social attitude. Survivors are supposed to take underground shelter awaiting for the ecosystem to clean up, but the wait can last longer than expected. The point to be made is that not necessarily the anxiety about catastrophic events was the by-product of technological escalation. Whatever it may be, the emerging social attitude reflected in the narratives is based on the belief that human extinction is a real option. Since then a strategy of infinite diversification and self-sufficiency is supported as the best solution to maximise survival chances. The apparent resignation to social collapse on the day after is nothing but the inevitable, sudden transition to an alternative human ethology. Collapse is indeed adaptation to the nuclear aftermath.

The trend is apparent for biologic catastrophes as well. Early narratives are confident in the remedial power of either scientific or governmental endeavours. However, survival often depends on natural immunity and self-isolation. Survivors are shielded by diversity. By the end of 1970s the reliability of science-based governmental plans deteriorates. Plagues are spread from within top-secret compounds instead of being quarantined. The gap widens between dangerous and beneficial scientific research. In recent years survival ends up by reflecting the purest individualism. Even blood ties are sources of danger. Mutual help is based on extraneousness. That goes far beyond the painful alternative faced by Antigone, the Theban heroine imagined by Sophocles in the 5th century BC. She breaks the law of the city to bury her brother's body, but the defiance of the tyrant's edict to obey her fraternal piety is blessed in heaven. In the present mythology of survival no established social norm is sacred, be it natural or legal. Pandemics break the society into pieces, and that is the only condition of salvation left to the fittest (or luckiest) among humans.

The fictional environmental catastrophe reveals a rather different pattern, as it is the anonymous by-product of the market forces. Initially the origin of man-made natural disasters is the misuse of technology by governments. The return to ordinary life conditions is hoped somehow or somewhere. Sci-fi authors apparently suppose that no single government can alter the earth's climate permanently. Since the mid-1960s climate change occurs as the outcome of the endless consumption of resources. Consumers are to blame for that together with multinational corporations. No major accident is required but the daily waste disposal to alter the climate without remedy. A trade-off then arises in the narratives between human life on the one hand, and the environment on the other. Mankind is weighed against nature. No matter which is given priority, ultra-governmental powers take over control of life. Be it ecotopian or pro-consumption, civilization is preserved at the expense of freedom. This is another, even if paradoxical, way of feeling uneasy with planning as societal guidance. The perception of global risk shakes the foundations of planning as "the application of a scientific and technical intelligence to organized actions" (Friedmann 1973, 19).

The results of the analysis point out a discontinuity in the imaginative consciousness of world catastrophes. That may be dated between the mid-1960s and the late 1970s, according to different types of apocalypse. Sci-fi authors bend to think survival as an individualized and unorganized undertaking. Compliance with plans is no protection on the day after. The innate talent of facing unexpected events is more helpful than planning ahead. However, this is not to be confused with neo-liberalism. The basic rationale is not to favour the individual in itself, but the human race. The catastrophe takes millions of lives without distinction. Diversification does not reward according to individual merit.

The discontinuity in the imagination of survival can likely be derived from a keener perception of global risks. Science-based modernity is challenged from the inside, as many sci-fi authors are well trained in scientific disciplines. But why risk perception has increased so sharply? Beck suggests that, "in the modernization process, hazards and potential threats have been unleashed to an extent previously unknown" (Beck 1992, 19). A temporal correlation can be observed between alerts reported by media and sci-fi narratives. So do sci-fi authors merely perceive risks? In fact they do more, for post-catastrophic imagination disguises the dominant paradigm of government. Thus the increased risk perception is part and parcel with a paradigm according to which progress is risky. The alarming threats of modernity appear in the light of the individualizing society, namely when people are caught in a set of individualizing governmental technologies in the sense of Foucault.

STILT-HOUSE VILLAGES IN PORTUGAL: PLANNING THE UNPLANNED

Ana Lídia Virtudes[1]

Abstract

The promotion of urban heritage development by accepting, protecting and enhancing its special features as opposed to using a process of homogenization became a challenge in planning domain. The cultural and social diversities of the territories no longer constitute an obstacle to development and have become an opportunity for the promotion of local identity and site authenticity and a prerequisite for social development.

All over the world, several factors still justify the existence of settlements near the rivers. An urban morphology is often inherited from the fluvial landscape. The stilt-house built by the waterside is an ancient typology of vernacular architecture, whose origin and permanency are understood by a journey across the world and time. This legacy resulted in new forms of urban morphology and in new forms of fluvial settlements. Small rural villages by the riverside are characterized by the binomial river-ecological diversity /urban-cultural diversity. They have witnessed the long history of common geographies and the intersection of origins between rivers and urban settlements.

The attractiveness of large cities has tended to leave behind the small village such as the stilt-house villages in Portugal by the Tagus River. These territories with a particular architecture of wooden stilt-houses call for the establishment of planning strategies suited to situations of emergency. These natural spaces are useful and attractive precisely because of the difference that they mark from others. They are old and dysfunctional areas and are a precious legacy of a unique heritage that needs urgent preservation.

The original stilt-house settlements of Tagus River were built by the fishing community arriving from the Atlantic coast. Their urban morphology features are of either one or two parallel rows of houses with variations in terms of dimensions of the settlement and of localization by the river. Access to them is by one or more wooden pontoons which vary in size.

In terms of planning instruments, these stilt-house villages are unplanned places because of several factors:

- They are in flood area, and in a *non aedificandi* area;
- They are not included in urban perimeters, despite the Portuguese planning system which theoretically includes rural settlements;

[1] Department of Civil Engineering and Architecture, University of Beira Interior, Covilhã, Portugal

- They are in protected land area for agriculture and ecological purposes, where touristic activities, agriculture activities and infrastructures are allowed but not housing;
- The owners of the buildings are not the owners of the land where the buildings are, which technically means that all the buildings in terms of planning law are not legal.

In summary, the existent planning instruments for the stilt-house villages of the Tagus River currently regard these sites as unplanned places, despite their significance as the only urban settlement legacy of the vernacular architecture of fluvial landscape in Europe. This presents a great challenge and need for urgent rethinking. These stilt-house villages could be an endless resource of emotions and unforgettable experiences. In a word the great challenges of Portuguese stilt-house villages, is planning with the river in mind.

1. Introduction: The Origins of Portuguese Stilt Villages

Each territory has its own particular character and landmarks which create a sense of place and identity perceived as being positive perception by the citizens. This identity depends on the continuity between the memory of the past, contemporary enjoyment and future aspirations. It is the result of factors such as citizens' self-esteem, awareness of the distinction based on positive features of territory or the balance between the citizens' needs and capabilities of the territory to provide for this need. It is vital, in order to preserve territorial identity in the face of globalization, a multidisciplinary research to examine the complexity and diversity through partnerships between local, regional and national.

Several factors explain the existence of urban settlements near rivers, with an urban morphology marked by the fluvial landscape. The stilt over the water is one of the oldest types of vernacular architecture, whose origin and permanence is understood through a journey in time and over the world, by reflecting on the common building strategies, materials and methods of construction used.

The Tagus stilt villages in Portugal express a diversity (ecological, cultural and territorial), which results from a history of common geographies among urban settlements and the river, being the only European fluvial stilt heritage of vernacular architecture. These villages were erected by the fishing community of 'Avieiros' coming from the Atlantic coastline, in a migration process dates back to the mid-nineteenth century, part of the phenomenon of human reaction under adverse conditions of survival, demonstrating a strong spirit of perseverance by creating links with the river.

The Tagus is the largest navigable river in the Iberian Peninsula, with the 3rd largest European estuary. This stilt architecture was adapted from the dunes of the Atlantic shores to the Tagus, and proved itself to be an effective response to constant flooding. Gradually, the living conditions required a more stable,

comfortable and durable construction, using local materials which were sustainable and renewable (rods, branches and wood). The stilts are adapted to the daily improvisations of the fisheries that could be transported, if necessary, to another place. They are simply, irregular and small in size, supported by wooden stakes driven into the mud and painted in bright colours. The floor area, elevated over the soil, adapts to the site in an empirical way, responding to the inevitable risk of flooding. Access to the interior is effected by a wooden staircase on the outside, leading to the balcony. As a rule, the interior features four compartments (kitchen, living room and two rooms separated by wooden boards that do not touch the ceiling which is covered with wood thus creating an attic). The urban morphology of these villages consists of one or two parallel rows of houses, with variations in the size of each urban settlement, with a location facing the river and deployment of the building. Access to the village is by a wooden pontoon (one or more) with different sizes.
This article aims to provide information for future actions, legitimate strategies that consider the consolidation and expansion of Tagus stilt villages on the scale of urban design, together with regional measures, idiosyncrasies, complementarities and specificities of each village along the 'Avieiros' way.

2. The Tagus Stilt-Houses: One Case of Vernacular Architecture in Portugal

The stilt-house built by the waterside is one of the most ancient typologies of vernacular architecture connected with the rivers and it reflects a common building strategy, with common materials and methods perfectly matched with nature.
In Portugal, the stilt-houses emerged and became the most common type of housing in the sands of the western sea coast among Douro River and the Beach of Vieira de Leiria, between the end of the 18th century and the 19th century. These constructions, temporary houses of the fishermen during the fishing season, responded efficiently against the movement of the sands, particularly strong in that windy part of the cost (see Figure 1). The wood came from the forest planted in the dunes to prevent its movements.

Figure 1. Stilt-houses in the sand near the Atlantic shore in Portugal (1).

Nowadays, a large proportion of these houses in the sea coast, have disappeared or have been transformed by the emergent materials like concrete and brick. There are rare examples of stilt-houses in wood that have become the exception, isolated among the cluster of the dominant houses of hard materials (see Figure 2).

Figure 2. Stilt-houses in the Portuguese Atlantic shore (2).

However there are examples in Tagus River where these houses continue to be the domain type of house in villages where the population is still having a type of life in straight relation with the river. These examples can be found in the 'Avieiras' stilt-house villages.

The migration and fixation of the fishermen from Vieira de Leiria to the Tagus River led to the emergence of stilt-houses villages, which were implanted on the waterline edge of the river. 'Avieiros', as they were called, led one of the most important seasonal migration movements that happened in Portugal in the early twentieth century (see Figures 3 and 4).

Figure 3. Tagus stilt village family in the boat in the decade of 1950 (3).

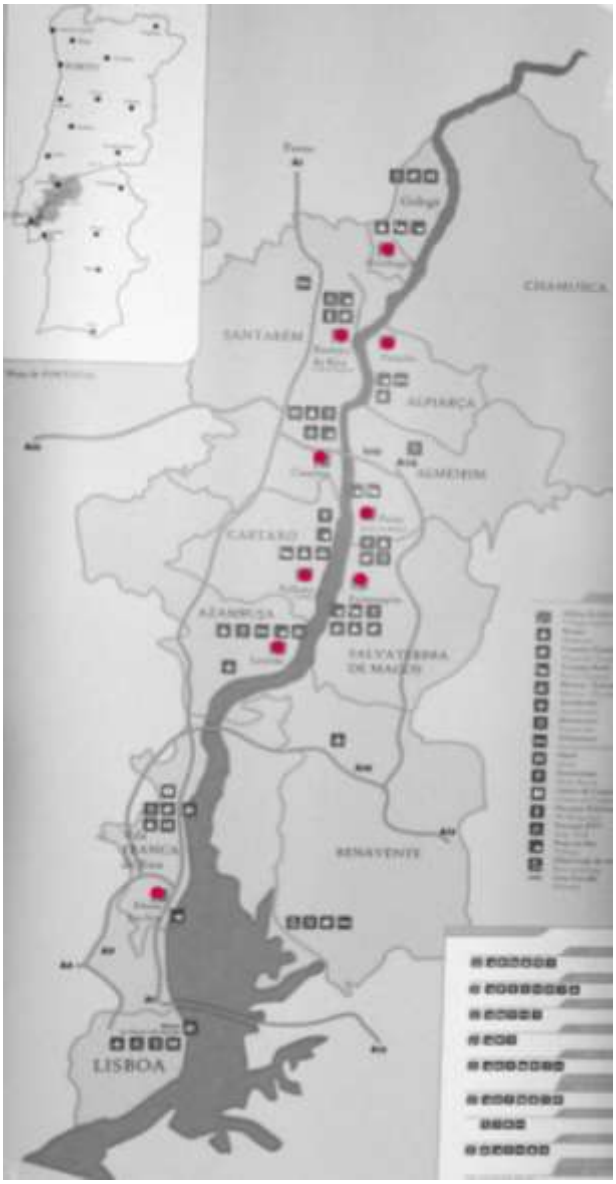

Figure 4. Map of Portugal and localization of stilt villages along the Tagus river (4).

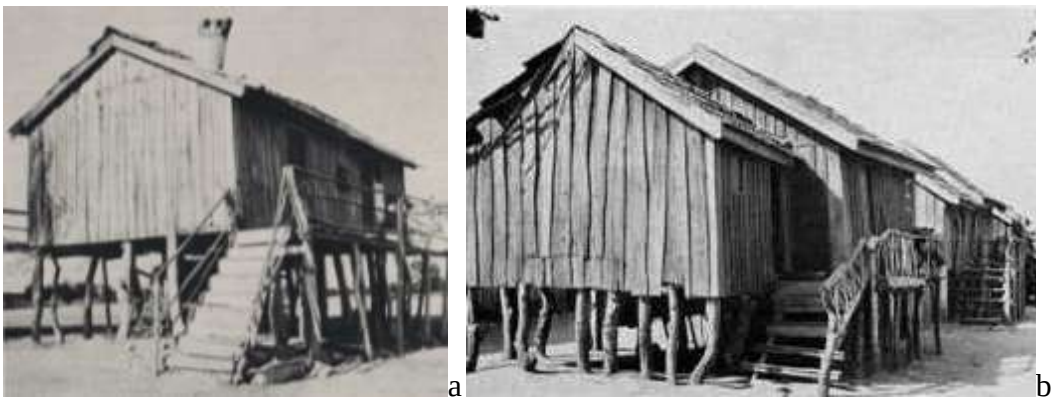
These stilt-houses represent one of the last testimonials of this type of occupation still existing in Western Europe. The essence of this vernacular architecture is in the fact that they were built by their occupants or members of the community in which they operate. These members – fishermen - arrived from Atlantic coast and brought a construction process deeply rooted in tradition. Also, these houses assume a direct correspondence with the natural and cultural environment in which they operate.
The identity of these villages is inseparable from the river. The fishing tradition which marks them out bears witness to their locality, construction methods, the material and the techniques used for the building, the architecture and urban morphology.
Among the uniqueness of these villages are their location in straight relation with Tagus River and the picturesque characteristics of their vernacular architecture which gives them a strong potential for tourism and leisure.

3. State of Conservation of Tagus Stilt-House Villages

Despite all variations from core to core and sometimes within the same urban area, it is possible to define a matrix in the original common architecture of these vernacular stilt-houses (see Figure 5):
- Firstly built on wooden piles or tree trunks lately substituted by concrete pillars;
- Exterior coating in wood boards arranged vertically and painted in bright colours with a predominance of green, red, blue and orange;
- External access balcony leading to the entrance door;
- Interior consisting of four divisions; kitchen, living room and two bedrooms; whose communications are blocked by curtains and the walls are painted or lined with paper coloured patterns;
- Rooms are symmetrical with a tiny window and different colour (blue for boys and pink for girls).



a b

Figure 5. The stilt-houses of Tagus villages in the decade of 1950. a. Tagus stilt village of Quinta do Alqueidão, b. Tagus stilt village of Caneiras (5).

Nowadays, these houses are in very different states of conservation according to the evolution of the Tagus stilt villages.
The inhabited villages are currently the objects of both constructive and destructive effects which demonstrate that identity develops in time and space and is a result of the constant dialogue between the inhabitants and the surrounding landscape.
The abandoned villages are in a very bad state of conservation, but these are the ones closer to the original characteristics of vernacular architecture of 'Avieiras' stilt-houses. In these villages, some houses are better preserved, such as the cases of Palhota and Escaroupim stilt villages (see Figures 6 and 7).

Figure 6. Aerial photo of Escaroupim stilt village of Tagus river (6).

Figure 7. Stilt-houses in Escaroupim Tagus village.

In Palhota stilt village (see Figures 8 and 9) the buildings are implanted along one street parallel to the river. In the Escaroupim and Caneiras stilt villages, the urban mesh has two main roads: one parallel to the river, where the oldest buildings are implanted in a street parallel to the river; and the other perpendicular to the Tagus river where the most recent examples of buildings are implanted, in an expansion area of the urban settlement.

Figure 8. Aerial photo of Palhota stilt village of Tagus river (7).

Figure 9. Stilt-houses in Palhota village.

These villages which lie abandoned and their stilt-houses are consequently in a very bad state of conservation, forgotten and in decline, such as the case of Patacão stilt village (see Figures 10 and 11).

Figure 10. Aerial photo of Patacão, an abandoned Tagus stilt village (8).

Figure 11. Stilt-houses in Patacão village, an abandoned Tagus river settlement.

4. Tagus Stilt Villages: The Experience of Planning the Unplanned

Although reports from the decade 1940 have identified 80 Tagus stilt villages, much of this heritage is unknown or has almost disappeared due to the following aspects:

1) Change of attitude of the inhabitants in their relationship with the river, due to declining fisheries and the progressive exodus to cities in search of work in industry and services;

2) Degradation of stilts due to the aggressive natural environment where they are localized;

3) Loss of architectural identity due to the replacement of traditional building materials (concrete and ceramic being applied as coating for walls and roofs in the search for durability and comfort), leading to the gradual replacement of wooden stakes by concrete or the complete replacement of the house.

In addition to the factors described above, there is another reason that hinders the preservation and development of these villages. This factor is the absence of measures and proposals in the content of the planning instruments in force, highlighting the urban morphology, architecture and landscape of the villages in their close relationship with the river. Some planning instruments are classifying them as being not suited to be built-up and urbanized, denying the existing reality. In this case it is appropriate to say that the planning instruments are dealing with the Tagus stilt villages as unplanned territories.

These factors have made the stilts less adaptable to the territory, further aggravating their weakness against the floods and the villages becoming more forgotten and unable to compete against the attraction for the cities. There is a need of promoting studies about the Tagus stilt villages applying principles and models of spatial organization in order to register this heritage of high landscape value and functional diversity on the multicultural European map.

The 'Avieiras' stilt-house villages express the ecological diversity and the urban culture of the Tagus River. They are the testimony of a long history of common geographies along the river and represent a unique inheritance of vernacular stilt-house architecture of the river in Europe.

This vernacular architecture and this unique territory require an urbanism of exception for special situations like these. Unique vernacular features originated the urban space of 'Avieiras' villages (see Figure 12).

Figure 12. Stilt-houses in Caneiras village.

In the urban space, invocative of the cultural diversity, memory and tradition are forces which, when considered by architects and planners in intervention and rehabilitation plans, enables them to change a place in line with the identity of the

community. The absence of these elements may contribute to the loss of the sense of belonging of its inhabitants. However, since the 'Avieiras' stilt-house villages grow not only in space but also in time, preserving the memory and tradition should not be a too conservative, static and closed principle. In that case, architects and planners run in the risk of nullifying the essence of the cultural forces and create obstacles to the deployment and dissemination of the culture of Tagus stilt-house villages. Instead, memory and tradition should be used as fundamental bases for innovation and create something reflective of local identity, at the same time both original and creative (Warren, Worthington & Taylor, 1998).

6. Conclusions

With regards to the buildings, the Tagus stilt villages meet the requirements inherent to physical inactivity, using local, sustainable and renewable materials. This aspect must be taken in account in the various proposals for rehabilitation that may be targeted. Often, the devaluation of vernacular architecture comes from its association with the past and underdevelopment. However, at present, it appears that we have much to gain from the study of vernacular architecture when we witness the construction of buildings called 'modern' but which are completely dysfunctional from the natural and cultural environment in which they operate. Rather, the vernacular architecture points out in many various ways how to build a passive technology, culturally acceptable and symbolically significant - a built-up environment compatible with the landscape. Therefore, finding ways to integrate the knowledge and experience accumulated in construction by the 'Avieiros' should be one of the main objectives of the stilt-houses of the Tagus village's rehabilitation.

In the river environment, invocative of the ecological diversity, intervention measures for the rehabilitation of 'Avieiras' stilt-house villages should aim to contribute to the achievement of an alive and functional ecosystem and to the adequate and efficient exploitation of the riches of the presence of water (see Figure 13). These measures should always consider the changes to the ways of life and their consequences on the territory.

Figure 13. The presence of water in Tagus stilt villages (Palhota and Lezirão).

Figure 13. The view of the Tagus river in Caneiras stilt village.

It is now necessary to find ways to qualify and quantify the desirable characteristics of each stilt village, which will help to mark each place and its identity on the cultural map of the territory. The marked identity of each urban settlement depends on its nature and the elements that create a striking sense of place and identity depending on the continuity between the past memory, the present and future aspirations. In the case of Tagus stilt villages, their identity is inseparable from the river. The sustainable future of the 'Avieiras' stilt villages lies in addressing both facets, ecological diversity (river environment) and the cultural diversity (urban space), which characterize and influence this community, by measures derived from an interdisciplinary, systematic and comprehensive study.

This is about giving back these pieces of history, the memory, identity and poetics to the contemporary society, alive which are the stilt-house villages of the Tagus water edge. Adding to that, there is the tourism potential associated with the idea that "there is usually attached to the rivers an important sense of the poetic to the identity of the sites and the psychological well-being of people seeking a peaceful state of mind" (COSTA LOBO, 2010) of a "unique value that matters to save and benefit from" (COSTA LOBO, 2010).

DISCIPLINING DISCOURSES – CONSTRUCTIONS OF THE CITY, THE URBAN AND THE PLANNER IN SWEDISH URBAN PLANNING EDUCATION[1]

Moa Tunström[2]

Abstract

This paper concerns discursive constructions regarding the city, the urban and planning within urban planning education in Sweden. It is the construction of norms that is the centre of attention, based on the hypothesis that education is one arena where this happens. Group interviews with students have been conducted, showing how students relate to urban history and current planning issues. The lack of visions and social perspectives on the urban is discussed. An important conclusion is the importance of a balance between social theory and design training in education, or between critical thinking and visions, or analysing and improving the city.

1. Introduction

> "My argument is that, however insistent this traffic, these buildings, and those inconsiderate bastards may be, my sense of this combination of information and affects as uniquely urban is mediated through a powerful set of political, sociological, and cultural associations. It is these connotations that are condensed in the symbolic space *the city*. You know what I mean about being in the city, not only because your lungs and ears have been assaulted like mine, but because you too operate with the city as a category of thought and experience." (Donald 1997, p.181)

The city as a category of thought, in line with Donald (1997), is a central starting point for the arguments in this paper. The purpose is to discuss ideals regarding the city, the urban and planning that are discursively constructed in Swedish planning education. The students both have to learn to understand and analyze spatial – as well as economic, cultural, social, environmental – situations and processes ("urban studies"), and in addition formulate proposals for change ("urban planning") (Tewdwr-Jones 2011). It is the construction of norms regarding this that is the centre

[1] Previously submitted abstract title: "Constructing the city and the planner. Urban discourses in planning education".

[2] Urban and Regional Studies, School of Architecture and the Built Environment, Royal Institute of Technology (KTH), Stockholm , Sweden (moa.tunstrom@abe.kth.se)

of attention here, based on the hypothesis that education is one arena (among others) where this happens, and that urban imaginaries are important in this process (Tewdwr-Jones 2011). The students' discourses and the students' ways of relating to, contributing to or being affected by, urban discourses is considered as an indicator of ongoing urban planning discourses, being open and interested, reacting to ongoing developments in their surroundings, stories in the news etc. as well as easily affected by education and the views and opinions of their teachers.

This paper first discusses the discursive approach in relation to urban and planning research, then how and by what factors "the planner" and "planning" as discipline are being shaped, and thereafter the results of an interview study with urban planning students from four different educational programs in Sweden is presented and discussed.

2. The city and the urban as discourse

> "… discourse theory turns our attention to the complex relations between discourse, power and knowledge." (Richardson 2002, p.353)

In analysing the stories and images of the city, the urban and planning this project uses a discourse oriented approach. Here it is considered as an *approach* more than a specific *method* (Howarth 2007; Torfing 1999). Firstly, language is of critical importance in affecting power structures and thereby also materiality, so considering statements as discursive means considering them as more than "just talk". Instead language and statements is intimately related to a practice and in this case to the shaping of the planner's ideals in the education context (Pinson 2004). Secondly, a discursive approach means looking at how actions are legitimized, naturalized and normalized – how conditions of existence for certain actions are created. This opens up for a discussion on how planning practice is, or could be, done. A discursive approach consequently epistemologically here has to do with how the interviews are considered as empirical material, how they are used and what importance they are given. Ontologically it means that categories such as "the city" or "the urban" are considered as ideological categories.

Urban planning is a discursive practice – policies and plans, as well as their implementations or realizations are discursive (Pløger 2001; Richardson 2002). We are all – students, academic staff, practitioners, citizens – part of this and affected by it. Images and stories of the city and the urban are constantly in the making and constantly changing (Çinar & Bender 2007; Donald 1997; Tewdwr-Jones 2011; Westwood & Williams 1997). In urban planning, imaginaries have high policy importance; they are a method, a tool – the creation of visions, plans, place marketing etc. It is not possible to dismiss them as "only ideas", or "only discourse" but necessary to consider them political, following a certain agenda. How should the city be developed or revitalised? What places should be preserved or altered, what places are safe or unsafe, postcard beautiful or shameful? Who belong in certain

places in the city and who do not? Urban discourses are a strong factor in the answers to these questions. Adding to this the often proposed communicative planning perspective puts more focus on the planner as a listener, mediator etc. and for the planner to invest his or her own personality in the work, instead of striving for the impossible neutral and rational model builder. This accentuates the norms and values of the planner, and raises ethical questions concerning the blurring of the personal with the professional/political.

Several authors have discussed planning and urban design as "potent speech acts", or storytelling (Donald 1997; Forsyth 1999; Throgmorton 1993, Tunström 2009; van Dijk 2011). This is to emphasize that it is not about a presentation of facts or aiming for the optimal solution, but to create stories about the present, past and future in the form of plans, designs or buildings, and that it is about sense-making, persuasion and even manipulation (Throgmorton 1993) – and that students in the field must be trained accordingly.

Van Dijk (2011) emphasises the power in the position as designer (or urban planner) and the power in their images, plans, sketches etc. – not from a perspective of politics but because of the political in planning and design activities and artefacts (a Foucauldian approach). Forsyth (1999) makes a similar point discussing the use of images of the US city Los Angeles in urban planning. Los Angeles is perhaps the most powerful contemporary urban image, often used as illustration for urban sprawl, car dependency and the unsustainable city. It is used to discuss such diverse phenomena as ethnicity in cities, the urban region and air pollution. Forsyth sees the use of images such as Los Angeles as an aspect of the rhetorical nature of planning, that also others have emphasized.

> "The images of urban places that show up in plans are influenced by theories and ideologies about cities and spaces. What urban space is understood to be, and how it is commonly represented, will shape how it is planned for." (Jones 2000, p.380)

According to Jones (2000) "the spatial discursivity" in the plan often neglected. In planning documents etc. an epistemology of space is embedded. Through categorizations such as "uptown" or "downtown", "inner city or "suburb" a spatial discourse is constructed. (See also Tunström 2009.)

3. The undisciplined planning discipline

Planning as a discipline has many guises. Pinson (2004) calls urban planning an undisciplined discipline due to the multidisciplinary character, both in education and practice. Gunder (2004) writes: "… the very nature of the illusiveness of a concise definition of "planning" makes it a prime candidate to be a master signifier and ideological hook or quilting point for its disciples." Planners are also considered "notorious for the difficulties they have in explaining to others – parents, friends,

university administrators – what they do." (Gunder 2004, p.302). It is physical and social, descriptive and normative, analytical and applied, theoretical and practical, multi-, trans-, and interdisciplinary (Pinson 2004).

> "Vital to planning is the illusion that the profession succeeds in providing the necessary solutions for harmony and certainty in our decision making as to what ought to be in the future." (Gunder 2004, p.301)

Planning borders architecture, geography and politics, and its consequences are visible in buildings as well as in the spaces and activities in-between the buildings. On this arena students and teachers, literature and education forms construct the city, the urban and the planner in the way they talk, write and in other ways relate to it. The students learn to talk the talk of planning and urban development, to use concepts and arguments. Gunder claims that:

> "Planners recognize themselves 'through the common use of some jargon-laden expressions whose meaning is not clear to anyone, be it' the public good, sustainability, globalization, smart growth or new urbanism." (Gunder 2004, p.302, quoting Slavoj Zizek)

These master signifiers are important for creating a common identity, an idea of who the planner is and what the task at hand is, and they change over time reflecting and contributing to a changed role of the planner (Gunder 2004). In planning education research there has been discussions regarding whether education prepares planners to "do the job", and whether education should be about producing planners (mainly practitioners) or educate students to become critical urbanists (mainly theorists) (Poxon 2001, p.539; Sandercock 1999). Poxon points to that the role of the planner is:

> "… so ill-defined now that it is difficult to claim that a planning course is providing training for a particular job. Instead, it should be exposing students to the complexity and intricacy of a planner's role, whether in public, private, or voluntary sectors, and equipping them with the knowledge, skills, and attitudes upon which further training can build." (Poxon 2001, p.573)

This opens up for further discussions regarding what issues this can be, more in detail. There is no fixed core to lean on, so this is partly created at the different universities. They tell certain stories of planning history or urban development, and they emphasize certain tools for planners etc. Poxon further states that:

> "Planning courses should […] encourage students to question what is happening in practice and provide them with tools to challenge, criticize, and respond creatively to these circumstances." (Poxon 2001, p.576)

Leonie Sandercock (1999) talks about necessary "literacies" and calls for a more elaborated analysis on contemporary urban development, for more discussion on ethics and for the students to take a stand, for planning to clearer relate to identity politics and also leave the ideal of rationality behind, in favor of empowerment and alternative ways of knowing and planning:

> "We need to replace the old core concepts of rationality, comprehensiveness, and the public interest, with new concepts of empowerment, alternative ways of knowing, and planning for multiple publics." (Sandercock 1999, p.540)

She considers that not only is a new conceptual language needed, but also a new practice. British planning researcher Patsy Healey (1999) is however hesitant to the literacies, stating that "[i]t takes time to become literate, each literacy having its particular bundle of concepts and skills" (Healey 1999, p.547).

In the following some empirical results will be presented and discussed, pointing to how Swedish planning students conceptualize their task and professional role, and touching on the issues of storytelling, multidisciplinarity and the conceptual language of planning that have been discussed so far.

4. Results

4.1 Planning stories are told and retold

In making the interviews the main focus was how the students relate to, contribute to or are affected by urban discourses. First it can be stated that it is clear that they do. They relate to stories, arguments and events in ongoing urban discussion. They have heard histories of planning and urban development that they structure their ideas around, and they express and negotiate their opinions in the debate. They seem to quickly be able to retell, and position themselves in, for example the story of modernist planning in Sweden, the reconstruction of Stockholm city centre in the 1960s or the story of the successful transformation of the city of Malmö from industrial to knowledge economy. The stories of planning of previous times are however often conceived of as stories of *mistakes and problems*. This resembles the so dominant welfare state critique in Swedish planning discourse (Tunström 2009).
They negotiate within and between themselves, constantly switching between own experiences, normative statements, current events, literature and lectures. Images and ideals are constructed through education, media, the discussions on coffee breaks between lectures and more:

> "… this together becomes a total, and you know what you are supposed to do."

The negotiations between own experiences, normative statements, current debate, literature etc. clearly develop over the years. In that sense the education is shaping them as practitioners and giving them a "language of planning" as one of their tools. They learn to relate to and position themselves in the urban development discussion. In the following long quote from one of the group interviews several aspects of storytelling in relation to planning education are illustrated:

> "– I was thinking about the heritage from previous planners, previous generations. This is something we maybe should problematise more. We hear a lot 'this is what they did before and this was bad and this was good'. We get quite fed with what went wrong, what was right, and quite controlled as regards what *we* should do. In some courses it has been like 'this is how it works, so do like this', and 'this is not good, but it is the standard so do the same'.
> – *Can you give an example?*
> – I was thinking about the course, 'Planning for work places', then we talked quite a lot about, or we have talked a lot about roads, that they take up a lot of space, there is very much road and hard surfaces and so, and I know that when we were planning work places we talked about doing it differently, to improve it. But then we had a lecturer that said 'yes, but this is the standard', and when you try to think differently, or someone did a different solution, it was 'yes, that is innovative, but it is better if you do it in the rational way', so I feel we should reflect more over what heritage we bring with us from previous planning, and what we have been taught to do, what is good. Every time has its norm, 'this is the right thing', and then after a few decades you see that it might not have been so good. Perhaps we need to be more aware of what we get from previous times. (…)
> – I feel sometimes that, like X said, that it is just repeated over and over what is good and bad and this becomes some kind of idealized image of what we do, as if that will not happen to us, but what we do will be right, and I am sure it will not. A lot will succeed but a lot will also fail, because we are strongly influenced, just like previous generations, by today.
> – Just look at our presentations and projects and how similar they are and what they need to contain in order to fill the expected demands at the moment. There is a very clear norm that we are influenced by and live in and are being taught.
> – *What do you mean similar projects, that you all do the same thing?*
> – Yes, it is a bit like as if you know that if you in a project presentation include certain aspects, you have not stepped outside of the frame and it will work out, sort of.
> – *What certain aspects?*
> – There is always talk about active ground floors and this is something that is always brought up – urban life and that. And no one really deviates from that since it is what we have been taught.

> – Something I appreciated last spring (…) we had a course called 'Planning theory' where we discussed the role of the planner over time, how a planner should be, from the 1940s and onwards. And that was quite rewarding, to see how they were thinking then, how we are thinking now and that you somehow are aware of that every point in time has …
> –Yes, and that parallel to that we actually went out to the million program areas (…) We have actually not visited that kind of areas until then, we went around in Stockholm, in Bredäng and Fittja et cetera. It is one thing to read about it because then it is always so biased, but to be there and see the qualities, because there are qualities, actually.
> – Yes, I think there is a lot of focus on that what was done in previous times was all bad, that we should be ashamed of the planning that took place in the 1950s, 60s and 70s (…).
> – *Is it like that in the course as well?*
> – A bit (…) We are given an example, for example here out in X, that is the million program area here, and there our job is to improve …
> – That is true, it was not renew, but improve …
> – Yes, and it feels like, OK, let's look at that kind of an area, with its surrounding structures, everything is 'what is wrong here', the focus was not on qualities, somehow (…) I don't know what you thought about that?
> – I can agree, in how that assignment was formulated, that we should 'change' or see if anything needs to be 'improved'. But it can also be more subtle, some comes from the school, some comes from television and some from a discussion over coffee, and somehow all this together results in that you know almost what you *should* do."

The same group of students thinks that a certain history is being told in their education through the planning ideals that they are being taught about – the garden city, the functional/international style, the building up of the welfare state and the post war mass housing schemes. These are not surprising historical categories, but they illustrate the need and use of categories in planning education, in rationalizing actions and constructing a line of development.

> "– It is very black and white sometimes. This is the way it was, it is not problematised very much.
> – You learn to appreciate that which has an explanation, I think. (…) You learn to understand, and suddenly it is something you like, because you can see something more than just how it looks."
> (…)
> – Even though I cannot say exactly what, I have a feeling of what is OK and not OK when I do a project. And the OK is then fully based on what the main teacher is communicating to us, and previous experiences with that teacher.
> (…)
> – X usually says 'this is nice, this is ugly'."

Another group states that they formulate their own problems, as part of their education. They get a site, but not a problem to solve:

> "You always look for a reason, something to support an idea. You are trained to look for reasons to do something."

So in different ways, a clear problem orientation can be seen, regardless of if it comes from the teachers or students. It is not about understanding or analyzing, but about *solving problems*.

A central problem to be solved that was mentioned often in the interviews was how to populate *public space*. Boredom, isolation, young people with nothing to do and a "dead" inner city was referred to. Another obvious node or problem is *sustainability*.

> "… sustainability, sustainable urban development, what have we more … compact city, the kind of words that are being used all the time, no one can really define what they actually mean, and we have seen that also from our discussion here. Everybody uses it but no one can really explain what it means."

In general the interviews show a strong disbelief and almost cynicism in relation to sustainability. They do not believe in the concept, there is no such thing as the sustainable city, and the concept in itself does not mean anything. Or, they might believe in striving for sustainable development, but not in "a sustainable city", or that sustainability strategies leads to a sustainable city:

> "… we know where to start, but no one is doing anything".

The *economic* storyline is another strong node. Consumption, an economic logic and economic development are conceived of as both a problem and a solution, paradoxically. The concept of *segregation*, concerning spatial segregation and physical barriers, densification and sprawl and the relation between city centre and suburb, is of central importance for some of the interviewees. Related to this is the discussion on *how to heal the suburb into becoming a city* (also discussed in Tunström 2009) – a physical and social problem at the same time. The role of the inner city – suburb division in Swedish urban discourse cannot be overstated. It appears and reappears constantly in different forms, also in the student interviews.

4.2 Envisioning the good city

> "I am not sure why but it feels like a very strong word. The entire program is built around visions. (…) It is really a profession of vision. I think the time perspective has a lot to do with it."

> "We talk about the future all the time (…) we want to make something better."

An important concept for many of the interviewees is *vision.* Many want to be visionary planners, involved early in the process, but also seeing it to the end. To be able to walk past a place and say that they made it happen. There are several aspects of the role of visions that are worth highlighting. First, to put it shortly – they like it, many miss it in their education, but at the same time they themselves are not very good at it. It was striking during the interviews that the students were unable, or at least had problems, putting their own vision into words and formulate clear urban ideals. For example, in the interviews they were asked to say something about inspirational images or places. Where do they for example find inspiration to their ideas of a "good city", or a "good place"? Many of the participants had trouble answering this and gave very vague answers. Whether this is because they are not trained in doing this, or too disciplined to allow themselves to dream and envision a "good future", or because this simply does not interest them, in line with a critical approach, is an issue up for discussion. But there are apparently also limits to visions. A student from a design oriented planning program referred to an incident when a fellow student in a project tried to argue for a radical and different kind of vision, but was met with so much questioning from the teachers that he gave up.

In general the interviews show that quite many lack training in social analysis and in conceptualizing the relation between the social and the material. Social aspects of planning, and the social in urban life interests many of the interviewees. It might even be there that their interest began, but the connections they make between the physical or material environment and "the social" are limited or not very reflected. Talking about urban theory, an interviewee tries to explain what she means by that:

> "– I mean, the way you see the city, from the outside … what to say, it is really difficult, not as a physical structure, but more as … the urban life.
> – More a social place than a physical …
> – Yes, exactly."

Several of the students however express that they miss urban theory, urban politics and social perspectives on the urban, at the same time as they in some statements consider this as outside of their own field.

> "There are many conflicts, with democracy and politicians … for example that they are building big external shopping centers that depend on traffic – or cars. This is nothing that we can influence very much, unless you work with planning in the municipality planning office."

Throughout the discussions "reality" and education, how it *is* and how it *is presented*, exist in parallel, in the way the students talk and are aware of the potential gap between the two. Or they express that they miss contact with "reality" – through guest lecturers, internships or similar. They constantly make this separation. There

are representations, images, marketing etc and then there is "the parking lot in Skövde" (representing what they think they actually will be working with, rather than the big visionary urban development projects) or "ending up in the municipality" when it comes to future employment. Also, references to the post war suburban areas as problematic places although they themselves do not – even as inhabitants in such areas – have experiences of the problems, similarly point to the gap between "reality" and images, stories or representations, and it contributes to constructing the rather gloomy image of planning practice as mentioned above. The city is discussed as a place for café and restaurant life, as a place where something always happens. At the same time several of the interviewees bring up the problematic approach in planning that something always has to happen and that it is hard to argue for no or very small projects.

> ".. it can be really good to think freely and big, no directions at all, but it can also be good to get the connections to how it works in reality, when someone actually has an idea of what should be there, to get the connection between reality and our project."

4.3 Critical thinking or cynicism?

The first conducted interview was with students in a quite social science oriented planning program, in the end of their first year of a bachelor. Critical thinking was a theme that came out very strong from their conversation, and this then occurred also in the following group interviews, in different guises and to an extent that was somewhat surprising. This first group appeared and expressed that they were strongly shaped by the stress on critical thinking from their lecturers. In their view their year so far was almost too focused on critique and what they referred to as discourse analysis. Paradoxically perhaps, they were also a group that expressed strong criticism of contemporary urban development and planning. What is possible to designate as *cynicism* characterized the conversation. It is necessary to reflect on the connection between critical thinking and cynicism, and perhaps especially in a planning program. Is a strong emphasis on critical thinking something that inhibits envisioning? They learn to critically analyze and criticize planning projects and urban development, but not to formulate their own visions?

In a design oriented program the students instead miss reflections and a critical discussion, here on their own working process. They feel that none or very little time is spent on discussing choices and alternative ways of working. They also express struggling with the balance between their own personal ideals and the ideals they are supposed to be working for, in line with what their education expresses as regards "the good city" or "good planning". Should I want the same as I think is good for the city, or would that be imposing my own ideals on the city as a whole? So there seems to be either an aesthetic steering or a critical analysis steering, and a need for more ethical discussion.

4.4 A neoliberal economic logic?

The cynicism and disbelief in good urban development among the interviewees is often expressed in economic terms. "The economy" is also recurrent as a major limitation in design projects. A group of design students say they do learn that every project is limited by economy, but they are not trained in estimating costs etc.

In the interviews there are recurrent references to the economy, the market and to different expressions of the privatized city – a growth focused planning, elite projects, commercialization or external shopping centers destroying small scale inner city shopping.

> "The only thing that is being built is identical condominiums that cost several millions."

Several of the interviewees frame this in quite a strong consumption critique. Together with the recurrent idea to reduce car use through planning this is actually where the few but more alternative urban ideals are expressed.

> "Consumption catches better what I am thinking about (…) irrespective of if it concerns things that we buy or if we buy homes – urban development is very consumption driven. How much money can we get out of this project, how much can we sell per square meter, what pays off – these are issues that we rarely discuss in our courses. We almost never hear about it, unless there is something wrong with the consumption patterns, we consume too much, but at the same time, everything is consumption driven. I think this is missing to a high degree, and that it is very interesting.
> – Especially the economics of it, that what you plan and design, it will be reduced by ten (…) And you can get quite depressed by knowing that all is decided upon by the market forces, the market and that all has to be profitable and not the best, that can make you lose faith in yourself a bit, what can I do in order to achieve good living environments and not only economically viable living environments."

In relation to this many voice, like the second statement in the quote above, disbelief in public planning and in their own future professional role. At the same time, the interviewees do in general express quite liberal ideals as regards urban life. People should be able to do what they want and to influence their environment and planning less is good. An organically growing and flexible city is a good city.

> "That there is possibility to do what you want in a city, that it is not limited to 'this is where you shop', 'this is where you skateboard', 'this is where you ride your bike' but that there is a mix and that people are allowed to do what they want in their city, basically, so that the city feels lively, and you do not have to go to different areas to do the different

things, but that the citizens create their own city. It is very important, according to me."

"That you are not limited, that you can do what you want without feeling any fear at all."

"Many big projects, such as many suburbs, have not at all resulted in what was planned. Perhaps we should build allowing for a lot of mistakes but that it is OK. A large framework, but it can develop as it wants. I don't know … just so we do not build anything completely static. What you build must be able to change as well."

4.5 The importance of the locality - the suburb, the small town and the town as planning project

In this section several aspects of *place* in relation to storytelling about the city will be brought up. The division between inner city and suburb plays a central role in Swedish urban discourse and the suburb is a contradictory both place and concept (Tunström 2009). This is clear from the student interviews as well. To refer to the division between inner city and suburb, and to do it in combination with a normative statement, is common. It is clear the students are aware of the suburb as a contested and almost emblematic place, and it engages them in different ways – in confirming or protesting against the image of the suburb as a problem. Also, there are those who live in places that locally are constructed as problematic, and to see for yourself can complicate and nuance the verdict. During the interviews places and concepts are negotiated between the interviewees – is the suburb in general a problematic place or not, is to be critical to be cynical, what are my own and your experiences and how do they match etc? But, the suburb as framed within a discussion on social, economical, environmental, design related and other problems is apparent.

"– An area you watch out for, that you have learned to stay away from, at least me who are from here (…) is X.
– Where all the students live.
– Yes, there are a lot of immigrants, drug addicts and students. (…) I don't know exactly how it is now since I am not usually there.
(…)
– I have only lived there for 2-3 weeks now and I have absolutely not seen everything, or I haven't experienced the crime there (…)
– … have only heard. I find it scary with the prejudice concerning these places. From people who have never been there and perhaps have heard, that is the most frightening, I think."

Secondly, the small town as an important concept for the students was surprisingly strong in many of the interviews – in the sense that they thought of it as an aspect that was lacking in their education. It appears also as the students learn a lot about the city in a period of development with high pressure and growth, but not so much

about a city in decline or stagnation. In relation the polarized discourse this emphasis on the small town among the students adds another dimension: the small town as absent, but also the small town as associated with lack of development.

> "It is like the precondition is always, if you plan a city, that it is growing. New people, new housing, parking spaces, it is always a precondition for all projects that we do. But this is not how it looks in Sweden today. What do you do in places where not much is being built? Don't they plan anything? Should everything just stand still there, and be boring, and nothing should happen?"

Finally**,** another aspect that puts emphasis on the importance of the locality is the location of the university. This of course influences examples, study visits, project areas etc. and a resource, but at the same time somewhat problematic in the sense that the local context heavily influences the stories being told. There is not much outlook to other towns or countries, according to the interviewees.

> "There are examples from here; this is where we look at the city. It is good to have something close by to go and look at, but sometimes it is a bit frustrating, that we do not broaden our horizons."

4.6 A spider in the web or a marionette?

In a discussion about "the good city" in an urban planning context the discussion often touches on planning as practice and the role of the planner. It is clear that many students go into planning because of an interest in architecture and design – the visual, aesthetic and material, and the final result of the planning process – but after a while shifting interest and orienting more towards the planning *process*.

> "– I think it has changed quite a lot. Or it is about what I thought before I came here, but also during the first and second year. Then it was a lot about learning to read a map, a drawing, all the time about creating, and you got the impression that 'yes, I will probably work with creating something that is good', and now it feels more like, OK, if I can manage something from an idea I should be satisfied. The creative has definitely been toned down, for me at least.
> – *And instead, what emerged?*
> – An understanding of the many perspectives there are on things, many priorities."

In spite of showing engagement and interest in urban development and planning, many of the students do have a rather "gloomy" view of planning. Working in a municipality is not the first priority in the beginning:

> "It seems unavoidable. Part of me wants to be in a municipality, but the thought of only doing that doesn't make me feel good, I want something more, somewhere else."

> "… in the beginning I thought 'I do not want to end up in a municipality, so boring and only coffee breaks and slow processes' but now I think it might be good since we do have a municipal planning monopoly, that is where you can see how this is practiced, that is where you learn the basics for that which you have to work with. (…) But at the same time there is some kind of a hierarchy, what is cool and what is boring, the municipality is seen as a bit boring and consultant is a bit cooler, perhaps."

The holistic perspective as central to what planning is, in the sense of multidisciplinarity and a comprehensive view on sustainability, reemerges constantly in the interviews. They are, in their own understanding, broad in their knowledge:

> "… you are a link between several professions, and you have to try to understand them. I think we know a little bit of everything."

But, the other side of the broad knowledge and holistic ambitions from the university is the confusion about what it is they really do know that some students feel, and what position planners have in society. One student refers to the common metaphor of the planner as the spider in the web:

> "– … it was something like that I had the programme described to me, that I should be like a spider in a web and collect all the different threads, but I do not feel that I am trained in leading in the way I think is necessary.
> (…)
> – What you said, about the spider in the web, I have heard that metaphor several times, but if it is true all things should start from the spider, but actually it is the politicians that take the decisions, so in that case we are only a tool of theirs, in a way. And seeing yourself as a tool is not as fancy as seeing yourself as the almighty, the one to put all the pieces of the puzzle together and create a nice final product.
> (…)
> – You didn't feel much like a spider, but more like a marionette doll. Redo and do it right.
> (...)
> – ... if we learn to listen, like we do very much, then we may turn into that [marionettes].
> (...)
> – If we start from that this is what I know, I have been trained, I am the expert, then we do not allow ourselves to be manipulated?
> (…)

> – I mean, if we come here and learn that 'your job is to listen', and then we go there and listen and try to mediate what other people are saying, then we are more or less steered by them."

The marionette/spider contradiction also has influence on the conceptualization of power. As the final statement in the quote indicates, there are expressions of ambivalence to power among the interviewees. They both long for it, fear it, and wonder why *they* should or would be the one having it. They both realize that they have to take responsibility, and fear it. They both think they are experts on something, and have a design idea to try to pull through, and that they are managers of a participatory process that might end up far away from the vision. On the one hand they look forward to making places or cities better, livelier or more beautiful, but they are also aware of the need for public participation and schooled into thinking planning as a participatory process rather than an expert dominated process. Their conception of the citizen is also related to power. The students in the beginning of their education still have a positive view of citizens, and identify with more them than with "the planner". They do not talk about NIMBY-ism and they downplay their own role as powerful actors. The more progressed students have a more problematic relation to their own knowledge and vision and citizen participation.

> "You have to listen to the people that live there, if you are changing an area, see what they want above all, I think (…) I do not think that it will be good if you say 'this is what is happening because I like it', you have to listen to the citizens, they have the last word."

To have the right knowledge, to make strong and convincing arguments as a basis for opinions is clearly important for the students. Knowledge and good arguments seems to be the bridge between the expert and the citizens, and between an opinion and a democratic decision, judging from the interviews.

5. Conclusions

The students' discourse can be characterized as paradoxical in several respects. Social aspects important – but they are not very good at that. Visions are stressed – but they have problems formulating them. They both reproduce a mainstream problem oriented history of the suburb, and question it. They are very ambivalent to power and discipline in planning. The radicalism or heterogeneity that I was hoping to see from the interviews is rather weak. Students in their first year of planning education are not knowledgeable enough to formulate a clear vision, and students in their final year of studies are schooled into conforming with both a critical position to a lot of contemporary urban development, but also into repeating established urban discourse through for example general statements about sustainability. The liberal attitude to the city and urban life – we should be able to do what we want – together with the "gloomy" view of public planning practice, the confusion about what their knowledge and skills actually are, the stressing of holism and the in some cases lack

of urban and social theory – I think points to the need for a deeper discussion regarding planning and power in education.

They are clearly shaped into thinking about the city and the urban as a problem to be solved, and planning as problem solving. This is apparent in how they talk about changing, improving, constructing problems, and learning to look for a reason to "do something". To not do anything seems unacceptable; instead places can always be improved. But there were also examples of not being allowed to be too visionary. This indicates steering, towards "doing something", but not anything. They are shaped by teachers, assignments, each other etc. Perhaps the focus on problems can be explained with the help of Tewdwr-Jones (2011):

> "The biggest challenge is to reconcile an historic desire for spatial fixedness on one hand, with recognition of space as a sphere of multiplicity and flows on the other. Spatial fixedness not only relates to viewing geography and location in a one-dimensional way; it also involves the planner's desire to legitimise and politicize intervention, which, by its very nature, requires space to be conceptualized and pinned down. Here then, is the paradox of planning and space – urban planners may recognise the city of emotion, of desire, of interconnections and of flows, but may not feel they can translate this awareness into a conceptualized and legitimate form without dismantling the very confines of conceptualized space they rely on to work within. Urban planners are caught between order and chaos, the natural desire for ordered spatial patterns, layouts and behavior against the space of movement, flows and interconnectedness." (Tewdwr-Jones 2011, p.25)

This illustrates a central issue that is addressed in different ways in this paper – the conflict or balance between social theory and design training in education, or between critical thinking and "envisioning", between analysing or improving, and perhaps even the different agendas in "urban studies" and planning. And, educating planners means both presenting planning as a private sector development oriented practice and as a practice in support of community development, environmental interests etc. This only emphasizes the balancing act. It is clear that a shift in the role of the planner both has been called for in Sweden and internationally since the 1980-1990s. This is connected to an emphasis on communicative planning that has increased the immediacy of issues of construction of knowledge, values and norms. This shift involves a more personalized, political, or politicized, planner. Planning education has yet to react to this, and also weigh between the procedural/process oriented, visual/design oriented and political/planning ethics. The research presented in this paper illustrates and underlines some of the central practice related dilemmas planning education faces – with some students lacking analytical capacity, and some where their analytical/critical perspective inhibits their ability to formulate urban visions.

Dealing with Urban Growth in Damascus, Syria: Challenges and Recommendations

Abstract

Damascus has experienced a rapid urbanization in the last decades, caused mostly by high population growth rates and migration. Uncontrolled urban growth has negatively affected the city's development. Increase in informal land development in and around the city, as well as the decline of green spaces as a result of urban sprawl, are the two major challenges, which the paper focuses on.

The paper analyzes aspects of urban governance in Damascus, Syria. It explores the legal and institutional framework, along with the planning system, and their role in exacerbating problems associated with urban growth in the city.

Finally, guidelines for dealing with urban growth on the national, regional and local levels are proposed.

1 Introduction

Damascus, Syria's capital city, has witnessed a haphazard metropolitan growth with a population reaching more than 4 million[1] in its metropolitan area, or about 35% of Syria's urban population (11.3 million according to official statistics (CBS, 2011)). Today, more than 50% of the population lives in urban areas in Syria; this proportion is expected to reach 75% by 2050 (Fernandes, 2008, p. 3; Lavinal, 2008).

The urban growth has led to unsustainable development features, such as informal land development and urban sprawl. These emerging urban phenomena have negatively affected the city's built environment and the quality of life in the city. For example, there has been a strong decline of open space in the city's historically famous surrounding green area Al-Ghouta[2].

Damascus has had problems in dealing with these challenges in the last decades: certain legal measures have exacerbated the problems, instead of solving them; the outdated planning system, ineffective institutions, lack of rule of law, and the absence of participation further hinder effective dealing with Damascus' urban development challenges.

Several national and international efforts have been made in recent years to solve these problems. For example a new master plan has been developed which deals with different growth problems, like informal settlements and transportation issues. The new master plan offers solutions to re-demarcate the borders of the metropolitan area and adapt it to the growth reality; however, the new master plan hasn't been implemented due to delays on the national level. Furthermore, the government has stipulated new laws or amendments of outdated laws to solve the problems of informal settlements in the city. Despite these efforts, the problems are still present and hindering a sustainable development of the city.

An effective legal and institutional framework for planning is a prerequisite to sustainable urban development and improving living conditions in the city. In order to create an environment that promotes a healthy urban life, it is important to make the local government more effective, reduce state control, and involve different actors and civil organizations.

In the first part, this paper describes the urban problems caused by the rapid urban growth of Damascus. After this, the legal and institutional framework is explored. The paper focuses on the current planning system and the role of the civil society and NGOs. In the final part, the paper proposes measures for improving the legal and institutional framework on national, regional and local level.

[1] Calculated based on estimates by (JICA, 2008, p. 11) for 2004 and the growth rates given in (CBS, 2011)
[2] Al-Ghouta is a traditional green area with farmland in the south and east of Damascus.

2 Challenges of Urban Growth in Damascus

The main factors underlying the process of rapid urban growth include natural population growth and regional migration and in-migration. It is worth to mention that over the past forty years Syria has been the destination for a large number of refugees from Palestine and Lebanon and in recent years from Iraq.

Up to 50 % of the urban population in the country's largest cities is living in informal settlements (Fernandes, 2008, p. 7 cited from Wakely, 2008). Informal expansion is an inevitable reality for Damascus.

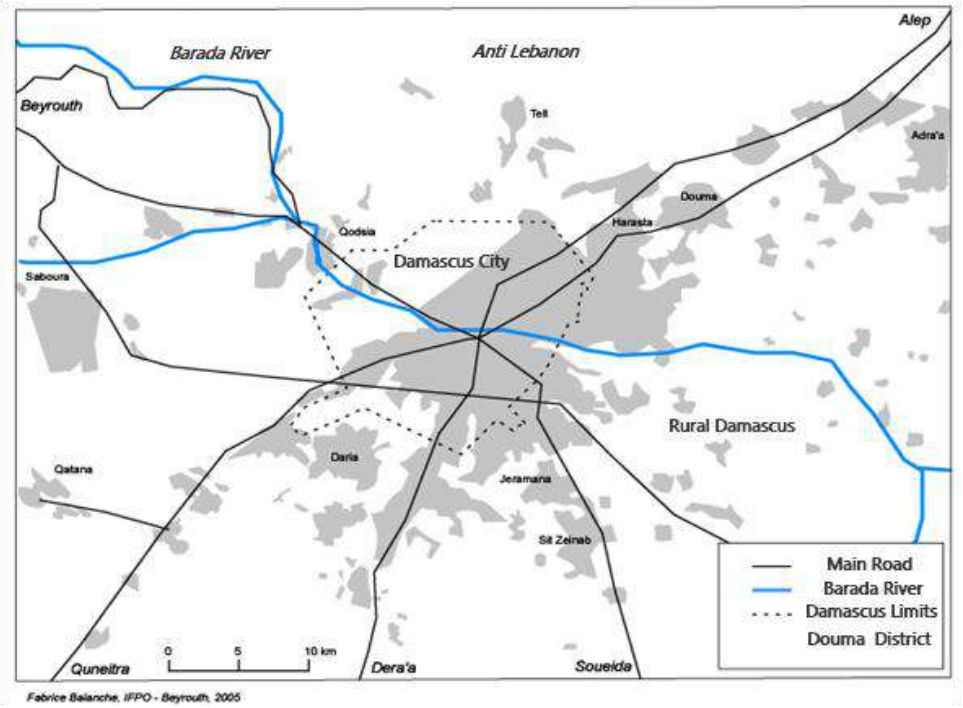

Figure 1. Damascus and Rural Damascus. (Fabrice Balanche, 2005)

According to the national statistics published in 2011, Damascus reached a population of around 3.6 million, with around 1.78 million people living in Damascus and around 1.88 million living in the governorate Rural Damascus ("Rif Dimashq") (CBS, 2011). However, the estimated numbers are around 2,836,000 for Rural Damascus (CBS, 2011).

Although Damascus and Rural Damascus are differentiated in administration and statistic, the plan for the metropolitan area considers the sphere of influence for Damascus City based on population growth within a 30 km radius from the city centre. It includes areas of Damascus City as well as of Rural Damascus, with a total area of approximately 4,700 km². The population of the Damascus metropolitan area (DMA) in 2004 was estimated to be 3.64 million, consisting of 1.55 million in Damascus Governorate and 2.09 million in the parts of Rural Damascus Governorate that are considered part of the DMA (JICA et al., 2008, p. 21).

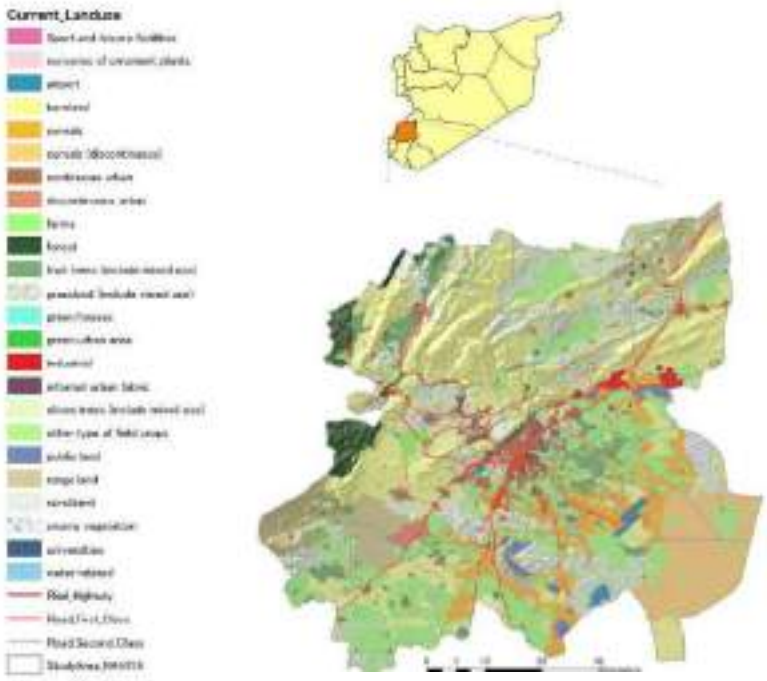

Figure 2. The Current Land Use Plan of DMA (JICA et al., 2008, p. 28)

Uncontrolled population increase and the absence of effective spatial and urban policies allow for informal urban development and encroachment of the green fields and vacant land on the fringe of the city.

In the next sections the informal land development and the effects of urban sprawl on the green spaces around the city will be explored and analyzed.

2.1 Informal Land Development

Migration from rural to urban areas started in the fifties of the last century, and reversed in the eighties onward through the counter migration from the city to peri-urban areas in the governorate "Rural Damascus". This can be seen in the increasing urban population in Rural Damascus and the decreasing growth rates in the city, as the following table illustrates.

Growth Rate in Thousand in Governorate	**1981 - 1994**	**1995 – 2000**	**2000 – 2010**
Damascus	18	14,7	13,3
Rural Damascus	45.9	37.6	34.1
Syria	33	27	24,5

Table 1. Annual Growth Rates (CBS, 2011)

The public sector failed to manage assimilating the increasing urban population by not supplying enough land for housing and eventually could not impede the urban sprawl into open space (SPC, 2006; GCES[3], 2008, pp. 96-99). However, most of these vacant open spaces and green areas were not intended for residential use, neither by the city master plan, nor by building regulations.

The rate of informal development in recent years has been estimated to be between 40% and 50% (Fernandez, 2008, p. 7). The number of people within Damascus' administrative boundaries, who live in informal settlements, is estimated to be 583,200 in 2004; which constitutes about 38% of Damascus' population (GCES, 2008, pp. 96-99). Because the informal settlements typically lack open space, parks or green areas, the population density is usually very high; according to estimates for 2004 between 380 and 800 people per hectare (JICA et al., 2008, p. 7-69) compared to 131.52 people per hectare in residential areas within the city (CBS, 2005).

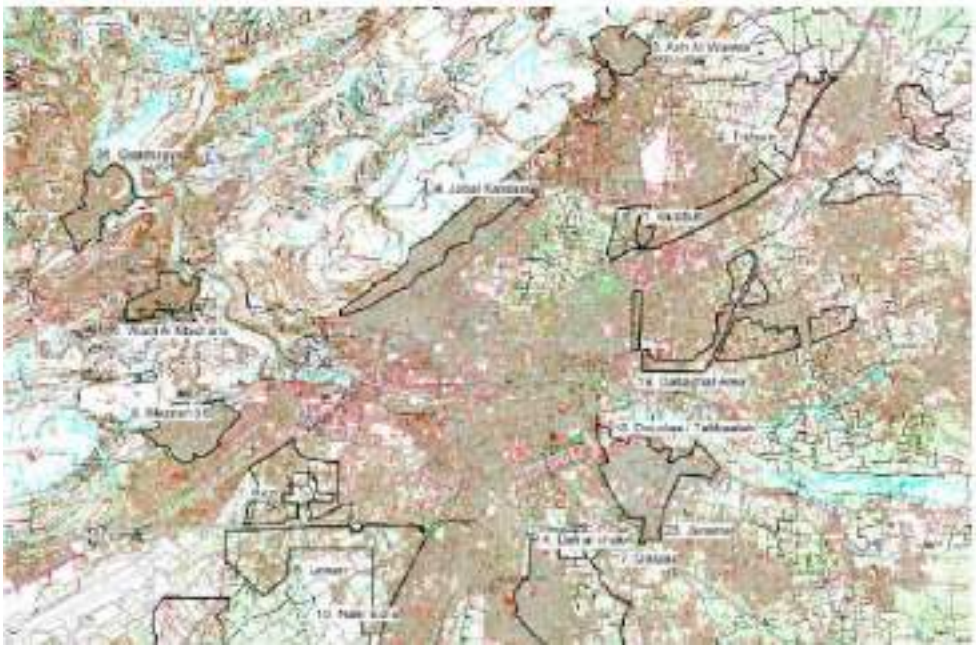

Figure 3. Informal Settlements on the City Fringe (JICA et al., 2007, pp. 1-3)

Legal Framework

With the urban expansion witnessed in the fifties of the last century, the amount of land for housing construction was getting less. That prompted the government to take several legislative measures. For Example:

- The Rent Act of 1952, which allowed rental contracts to be renewed automatically. This act led to the withdrawal of investments from the formal rental market.
- Law No. 3, "Prevention of Land Transaction", of 1976, which restricted the selling of unbuilt land, that is determined by any master plan as land "for building", to public or governmental institutions.

[3] Government-owned company that subcontracts with governmental bodies, mainly on the national level.

- The Urban Expansion Act No. 60 of 1979 which tried to freeze the urban expansion of the city. The law stipulates, that the government will appropriate all developed land outside of the city that is not included in the master plan and that anyone buying the land from the government may not sell it unbuilt. As a result, a lot of land was taken off the land market, leading to high land prices and the housing crisis in the eighties.

These legal measures escalated the problem and made it more difficult to own land or possess or rent a house formally (SPC, 2006; GCES, 2008, pp. 96-99).

With scarcity of formal land within the city boundaries, urban growth headed to the agricultural land surrounding the city. This land was normally of lower cost than the urban land and owned mostly by private owners, making transactions easier. As a result, since the eighties many informal settlements have been developed on the city fringe at the cost of agricultural land.

2.2 Urban Sprawl and Decline of Open Space around the City

The extensive urban sprawl has affected the open space in and around the city of Damascus. One result is the high decline of green and agricultural areas in the Ghouta fields. The Ghouta is known for its fertile land and urban agricultural villages, which surround the city. As mentioned in the previous section, in recent decades the open spaces and agricultural fields of Al-Ghouta have been illegally developed to informal residential areas to satisfy the high demand for land for housing.

The master plan of 1968 tries to direct urbanization toward north-northwest into the Anti-Lebanon Mountains, to protect the Ghouta fields in the east, and south-east. The goal was to maintain the ecological balance and to ameliorate the city's dry hot weather (Governorate of Damascus, 1972, p. 27). Most of the open spaces and green areas of Al-Ghouta are therefore categorized in the master plan of 1968 as open space zones (GCES, 2008, p. 96).

Buildings and industrial constructions encroached a vast area of the Orchards of Damascus, which used to cover over 3,000 hectares; today Al-Ghouta covers a few hundred hectares (MSEA, WB & UNDP, 2003, p. 42; MSEA & UNDP, 2002, p. 104). The arbitrary and unpredictable informal expansion is still continuing, and Al-Ghouta is expected to be completely urbanized by 2020 (Lavinal, 2008). The aerial photos below show the gradual decline of the green space because of the urban sprawl in recent decades.

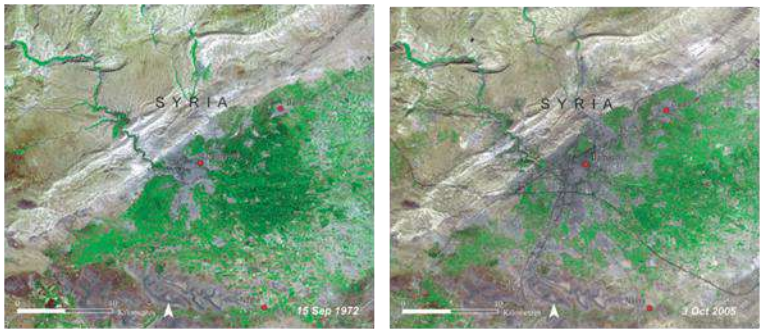

Figure 4. Aerial Photos of Damascus from 1972 (left) and 2005 (right) (UNEP, 2005)

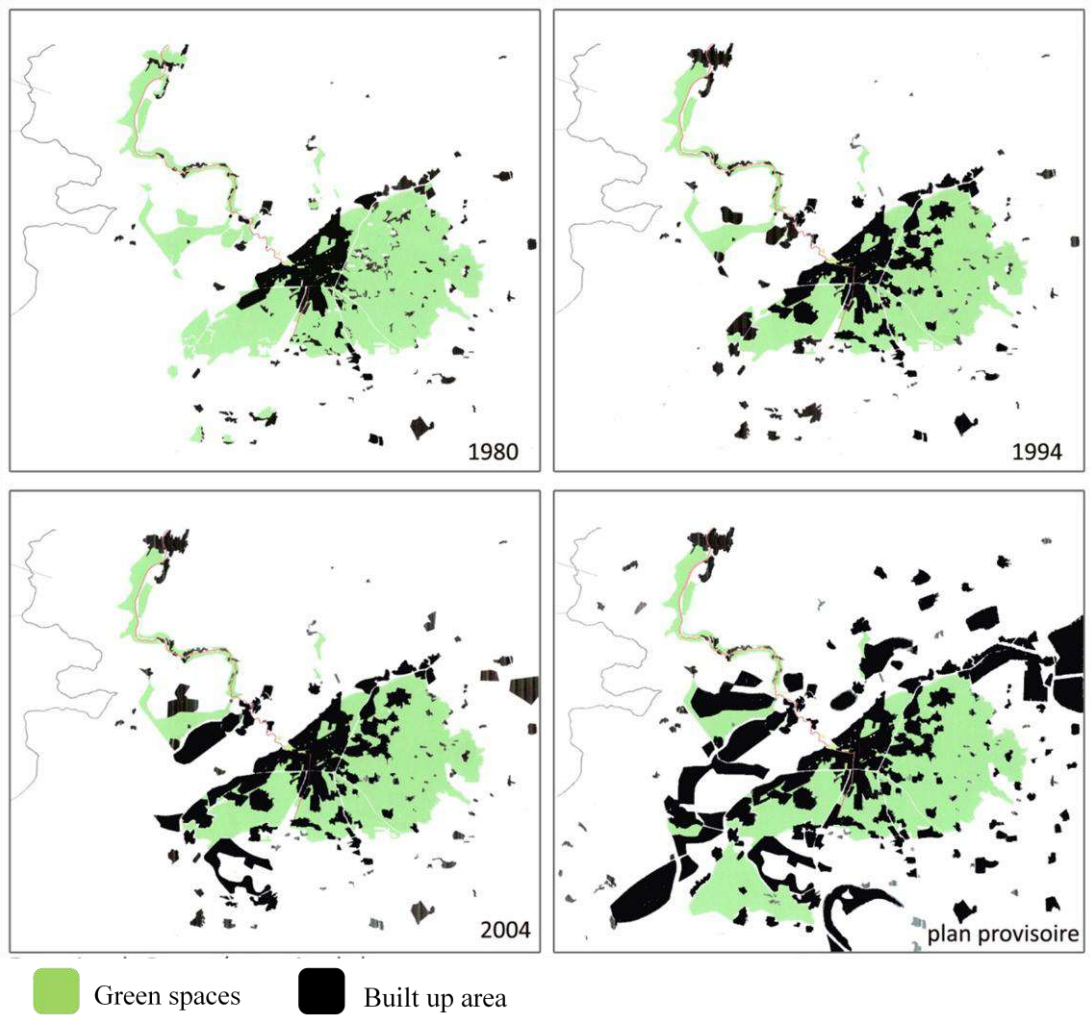

Figure 5. Urban Growth of Damascus 1980-2004 (Ali, 2008, p. 14, based on Balanche, 2006)

The loss of green space around Damascus till 2004 is mainly the result of informal housing which has claimed around 1070 ha. The table below shows a comparison between the planned expansion and the informal expansion.

Area of the master plan in hectares	10625 (within the administrative boundaries)
Area of planned expansion areas (suburbs) in hectares	1450 (suburb Qudsayya expropriated by the Public Housing Foundation) plus 450 (Artoz suburb)
Area of informal housing in Damascus City in hectares (including adjacent areas of Rural	about 1300

Table 2. Suburb and Illegal Housing Area from the Master Plan Area (MLAE, 2005, cited by the source: SPC, 2006, p. 590; JICA et al., 2008, pp. 7-69)

Despite the existence of a legal and planning framework for environmental protection, lack of effectiveness and rule of law led to the loss and degradation of the open space in Al-Ghouta. Some of these environmental measures in this context are: the National Action Plan to Combat Desertification in 2002, the Strategy and National Environmental Action Plan in

2003 to fulfil commitments to the Agenda 21 and sustainability, and the Environment Law No. 50 in 2002 to preserve natural resources and to prevent pollution.

3 Legal and Institutional Factors in the Planning Context

Most sustainable urban development challenges in Damascus result from failed urban governance. This includes: inadequate legal and regulatory frameworks for urban planning, improper enforcement of existing laws, lack of participation and absence of sound institutional structures and technical support; including shortage of qualified staff for urban planning and management (JICA et al., 2007).

The land administration system in Syria dates back to the French mandate times. It is based on the traditional land registry and cadastral maps in paper formats. On the one hand this helps to protect the land property rights from that time, but on the other hand, it is not reliable enough to meet the functional needs for today's development activities.

Another challenge in the legal and institutional system is the lack of coordination and the fragmentation of responsibilities between institutions, which makes land registration and transactions a long and elaborate process. In addition to that, the fragmentation and lack of coordination create an ideal environment for corruption; in the World Bank ranking for control of corruption Syria ranked 167th of 203 countries in 2011 (World Bank, 2011).

The lack of a reliable land management – land use and land administration system – contributes to problems, such as disputes on ownership and access to land, limited land transactions, restrained investments in land and low local economic development (GCES, 2008).

Another major challenge is the legal framework for land acquisition and compensation. The implemented laws regarding land ownership[4], for example, led to a situation where land stays undeveloped and abandoned for years in the city, especially where conflicts on land property rights exist and the legal framework could not provide proper solutions.

Appropriation of land for public interest as stated in Article No. 15 of the constitution always results in conflicts, because of the laws according to which the land is evaluated and the owners are compensated (e.g. the Legislative Decree No. 20 of 1983 for appropriation, along with other legislative measures[5]).

[4] The property rights section in the Syrian constitution (Chapter II economic principles, Article No. 14/3d) underlines the right to own land as a protected right according to the law. Nevertheless, in the same section, the article No. 15 stipulates: "Individual ownership may not be expropriated except for public interest and in return for a just compensation in accordance with the law" (The Syrian Constitution, 1973).

[5] Law No. 9 for cities urbanization/reconstruction from 1974 grants municipalities the authority of forced redistribution of land in order to implement urban projects.

• Act No. 60 of 1979, which froze the expansion of cities, the acquisition of unbuilt land, and distribution of these expropriated lands on the public-and Cooperative sectors at cost price, who showed later low capabilities fulfilling the housing demands in the city.

•Planning decree No. 5 dated 1982 states, that land must be included in the master plans.

3.1 The Planning system

The planning process has traditionally been guided by central planning authorities reinforcing hierarchical procedures for reporting and approval for projects, as indicated in the framework of the Local Administration Law No. 15 of 11/5/1971 (SPC, 2006).

The national government is guiding growth and organizing service delivery at a macro-scale with the Five Years Plan[6] (FYP). Therefore, municipalities are not allowed to decide on a wide range of functions, not to mention that most municipalities lack the capacity to fulfil some of their duties (ESCWA, 2001 cited by the source SPC, 2006). For that reason, any action or decision made by the local authorities or other actors concerning urban development cannot be legalized without the approval of the national government.

Regional planning in Syria has been in discourse on the national level in the past few years. Yet, this hadn't resulted in action plans towards legal and institutional framework for regional planning until 2008. In 2008 a regional planning law was presented to the Council of Ministers[7], followed by founding the regional planning commission, which is responsible for the regional plans on the national level (MAM, 2008). Although this is a first step towards decentralization, regional decisions still have to be legitimized by the central government.

Land use administration and planning in Syria are based on master plans created by a regional committee, in accordance to criteria set by the central government. Delays in creating these plans and failure to enforce existing regulations have led to the emergence of illegal housing, illegal industrial areas and decline of green spaces (MSEA, World Bank & UNDP, 2003; p. 29).

There is no comprehensive and efficient land use planning system implemented for the city of Damascus. But there is a zoning system based on the master plan of 1968.

Preparation of a master plan in Syria is a process that is going through many stages[8]. After the master plan has been approved on governorate and the subordinated levels, the master plan has to be approved on the national level by the Minister of Housing and Utilities. However, governorates play the key role in preparing and adopting plans for each individual municipality regardless of the administrative hierarchy[9]. A lack in technical knowledge, coordination mechanisms, shortage of comprehensive information systems and lack of public participation in all stages add more barriers to the implementation of an urban master plan (Asfour, 2007; SPC, 2006).

In the recent years two major studies have been conducted to develop a new master plan: one by the GCESC and one by JICA, the Japanese International Cooperation Agency.

---

[6] The National Five Years Plan (FYP) in Syria sets goals, policies, programs and projects for priority areas in development on social, economic and environmental levels. The current five years plan FYP is the 11th FYP (2011 - 2015).

[7] The council consists of the Higher Council for Regional Planning, the Chairman of the State Planning Commission and the Chairman of the Regional Planning Commission.

[8] Legislative Decree No. 5/1982, for the preparation of general master plans and urban regulations for governorates, is the main regulatory instrument that identifies the procedures of preparing such plans

[9] According to the decree No. 5/1982 the master plans are issued by the Minister of Housing and Utilities depending on the proposal of the Executive Bureau of the governorate's council (MELA, 2004)

The GCESC study, conducted in the nineties, considers the expected growth from 1994-2020. The study had problems dealing with land ownership and the constraints of the cadastral system. Furthermore, it didn't consider water supply and transportation, and the upgrading of informal areas

The second study has been conducted by the JICA (see JICA et al., 2007, 2008). JICA defines a vital surrounding area of 30 km radius from the city centre. This study considers the development until 2025. JICA's strategy is based on the analysis of water availability, the urbanization pattern and potentials for the spatial development of the Damascus Metropolitan Area (DMA).

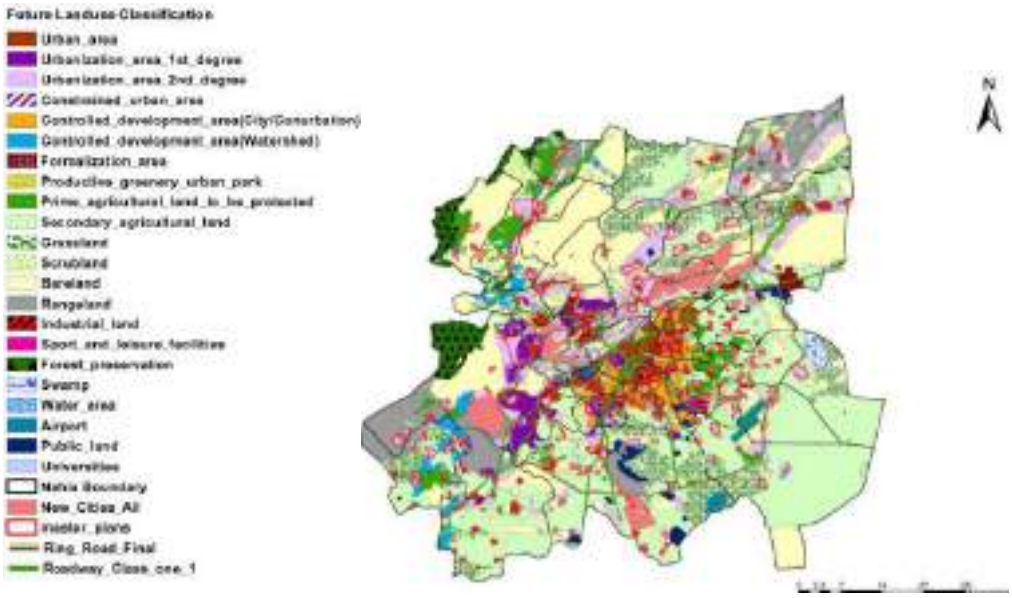

Figure. 6.Directional Land Use Plan for the DMA (JICA et al., 2008, p. 29)

Still, it is not clear when this plan, which is ready since 2008, is going to be implemented, because some legal and administrative issues have still to be discussed on the national level.

With the issuance of the 10th FYP (2006-2010) an improvement of the planning system and the urban governance has been initiated. For example, the following programs and projects have been launched by international development agencies:

- The Study on Urban Planning for Sustainable Development of Damascus Metropolitan Area by the Japan International Cooperation Agency (JICA) together with the government and the governorates of Damascus and Rural Damascus (2006-end of 2007) (see above).
- The MAM (Municipal Administration Modernisation) program by the EU (2007-2010 and 2010-2013): The program aims at developing regional planning and improving the effectiveness of local governance. In addition, pilot projects for urban development and management have been initiated which support the role of NGOs.

However, these projects didn't unfold tangible outcomes. This can be mainly attributed to the short term nature of these endeavours, the limited focus, as well as the lack of implementation of the resulting plans.

Such initiatives have the potential to achieve improvement in urban development but there are risks that institutions get dependent on such initiatives. Moreover, continuity is not assured due to lack of technical and financial support, and, above all, the lack of political support.

3.2 The Role of Civil Society and NGOs

The civil society and NGOs play an important role in creating a channel for communication between the local government and the people. One of the biggest challenges in Damascus is achieving cooperation between the local government and local communities. This is challenging because of the absence of public participation and the restrictions in the legal framework for civil society organizations. As a result initiatives and activities of local communities are not supported, and many people are not motivated to get involved in activities to improve their built environment.

However, the 10th Syrian FYP (2006-2010) states the need to involve the civil society (third sector) and the private sector in the development process. However, the FYP argues based on the definition and terms of a so called "Civil Society Organization". The terms of civil society organizations are defined by the law No. 93 of 1958.

However, Civil society organizations need approval by the General Security Service (article 6) and are subject to many restrictions (e.g., approval has to be requested for cooperation with international organizations (article 21)). Besides, the activities and funding of civil society associations require legal approval and supervision by the Ministry of Labor and Social Affairs (MOLSA, 2012).

Nevertheless, according to statistics of the Ministry of Labor and Social Affairs the number of associations in Syria was 4089 in 1994. This figure includes governmental as well as non-governmental associations; the number of NGOs in Syria was 625 in 1998. Depending on their purposes and activities, five types of NGOs can be differentiated, 240 charitable associations, 127 cultural associations, 26 Health associations, 29 cooperative associations, and 203 social unions (Abu Halawa, 2009).

In the field of sustainable urban development, there is, as of 2010, no organization registered, but there are about 30 registered organizations for environmental preservation and awareness raising (MOLSA, 2012). In addition, there's a number[10] of associations for human development aid registered (Abu Halawa, 2009).

Environmental organizations along with human development aorganizations can play a crucial role in approaching sustainable urban development and management in Damascus. Yet, this role is challenged by the lacking autonomy of these organizations from governmental supervision. In most cases, gaining the trust of the local communities has been difficult, particularly with the poor and marginalized groups, who distrust the local institutions and consider them obsolete and lacking in vision. Another challenge is the lack of technical and financial support due to the legal restrictions mentioned above.

[10] 18% of all organizations in Syria

4 Findings and Recommendations

Urban growth in Damascus led to an increasing number of informal settlements and an extensive decline of open space around the city. Important factors in this development are the lack of a solid legal and institutional framework for land development and environmental protection, and an inadequate planning system. Adequate laws are rendered ineffective because of the lack of enforcement of law.

The institutional framework is further weakened by high centralization with regard to decision making and a lack in capacity and modern technologies.

Other factors are outdated laws which show unfairness in terms of compensation according to the acquisition acts and lead to land use conflicts. In addition, urban governance issues like corruption, unaccountability and ineffectiveness escalate land use conflicts.

Finally, one major factor contributing to the problems dealing with urban growth is the absence of active civil society organizations that can take over responsibilities like the mediation between different stakeholders in urban planning and management processes.

Recommendations

In accordance with the national framework priorities of the 10th FYP, strategies need to be developed on national, regional and local levels to face urban development challenges. In the following, guidelines for these strategies are proposed:

On the national level:

- Ensure commitment of political actors and governmental authorities, especially, to decentralization and public participation.
- Get political support to realize a comprehensive planning system that ensures sustainable uses of scarce resources on the one hand, and economic and social development on the other hand.
- Emphasize implementing and monitoring of the national action plans like the action plan for combating desertification.
- Consider contributions of international organizations for technical assistance, especially with regard to modernization and strategic methodologies.

On the regional level:

- Empower regional institutions and implement regional plans to support rural development and to reduce the demographic pressure on limited resources like water and land of the city of Damascus.

On the local level:

- Build a coherent local institutional system, and ensure its autonomy.
- Improve urban local governance; eradicate corruption, increase accountability and capacity building of municipalities according to the good governance criteria.

- Ensure the implementation of land use plans as a tool for protecting the land function.
- Modernize the land administration system by providing new information systems, new plans and legal instruments instead of the old cadastre and registry system.
- Enhance coordination between different institutions. This action would provide a basis to resolve disputes on vacant land and lead to better use of neglected open spaces.
- Put the modernized master plan into action. The new master plan offers solutions mainly for housing problems and informal settlements.
- Involve local people in the urban management process, on different levels (e.g., city, district, neighbourhood, etc.).

5 Conclusion

The paper explored informal land development and urban sprawl as major challenges of urban growth in Damascus. The paper argued that the lack of a solid legal and institutional framework for land development and environmental protection, as well as the lack of a comprehensive planning system, are major causes of the problems in dealing with the urban growth in Damascus. Although these deficiencies are recognized and addressed (e.g. in the FYP and reform programs), the plans are yet to be implemented.

The next step is to explore ways to improve urban governance in Damascus, in particular by integrating participatory approaches in urban development and management processes.

Rightsizing Shrinking Cities: A new perspective on urban design for the U.S. city

Brent D. Ryan
Department of Urban Studies and Planning, MIT
bdr@mit.edu

Paper to be presented at 26th AESOP Congress, July 11-15, 2012, Ankara, Turkey

Abstract

Urban policymakers have begun to use 'rightsizing' as a term for the mismatch between shrinking city populations, physical plants, and budgets. Built for population often over twice as large as current exists, shrinking cities have increasingly found themselves with an unmanageable quantity of streets, utilities, and housing. 'Rightsizing' describes the yet-unproved process of bringing a city to a 'right' size proportionate to government's contemporary fiscal capacity. Detroit, the United States' largest shrinking city, has wrestled with rightsizing for several years (Economist 2010, Bloomberg 2012). Rightsizing is in reality a difficult proposition for shrinking cities, particularly in the United States where planning is decentralized and market-driven. Nor have scholars nor practitioners given enough thought to questions about rightsizing actually means, such as: What physical form and size should shrinking cities take? How do city officials decide who should live where, and whether relocation is necessary? Who will pay for rightsizing? Is there a long-term rightsizing vision, or will policymakers follow current imperatives? This paper argues that scholars and policymakers should consider urban design as an important part of any rightsizing vision for the shrinking city. Today's population and housing losses present designers and planners with an unparalleled opportunity better shape a built environment that also meets shrinking cities' economic and social needs. As the visual landscape of shrinking cities is, for many, their most disturbing feature (Vergara 2003, Moore and Levine 2010, Marchand and Meffre 2010), urban design seems an obvious means to reshape these cities not only for a post-decline existence, but to explore new neighborhood and even urban design ideals. This paper examines contemporary design ideals applied to the shrinking city, including New Urbanism, landscape urbanism, and everyday urbanism, before discussing a fourth urban design ideal, patchwork urbanism, derived in part from Lynch's (1960) idea of the polycentered net. I conclude by suggesting policy directions that might begin to implement patchwork urbanism in the shrinking city.

Introduction

Recently urban policymakers have made 'rightsizing' a watchword for the perceived mismatch between shrinking city populations, physical and infrastructural plants, and budgets. Built for a population in some cases over twice as large as that currently within the city limits, shrinking cities have found themselves, particularly since 2007's fiscal crisis, with an unmanageably large array of streets, utilities, public buildings, parks and housing. 'Rightsizing' has emerged as a word for the yet-unproved process of somehow bringing cities down to a 'right' size; in other words, to a size proportionate to city government's ability to pay for itself. Even Detroit, America's largest shrinking city, has been discussing rightsizing for several years (*Economist* 2010, *Detroit News* 2010).

On the surface, then, 'rightsizing' has been a difficult if not impossible proposition for shrinking cities in the United States, as citizens unsurprisingly resist compulsory relocation in cities like New Orleans (Campanella 2008, 344-350) and discussions over infrastructure shutdown in cities like Detroit are fraught with conflict as well (Bloomberg 2012). Nor have scholars or practitioners far given much thought as to what rightsizing actually means. What physical form and size should the city take after abandonment? Is there an ultimate vision of the city guiding rightsizing, or will policymakers guide rightsizing by following immediate imperatives?

This paper, part of a larger series of investigations of urban design in shrinking cities (Ryan 2012, Ryan 2013 forthcoming) proposes a dual argument; first, that urban design should be considered as a primary lens through which to view the physical future of the shrinking city. Given that many consider the visual landscape of shrinking cities to be their most striking and disturbing feature (Vergara 2003, Moore and Levine 2010, Marchand and Meffre 2010), urban design seems an obvious means by which planners and designers might reshape these cities for their lives after decline and by extension, explore new forms of the ideal urban neighborhood and, perhaps, the ideal city. Yet in the United States, physical visions for the shrinking city have been shaped as much by indirect strategies (e.g. demolition) as they have been by conscious

formal visions. The paper begins with a brief description of the nature of abandonment in shrinking cities, before discussing an agenda for urban design.

Second, this paper proposes that contemporary, widely circulated urban design ideals for the shrinking city are inadequate, as they fail to confront and accommodate the distinct and peculiar physical realities of these places, and that an additional urban design vision is therefore needed. The paper briefly reviews four contemporary urban design ideals: New Urbanism (e.g. Duany et. al, 2003), landscape urbanism (e.g. Waldheim 2006), and everyday urbanism (e.g. Chase et. al. 2008), before proposing a fourth, patchwork urbanism, derived in part from Lynch's (1960) theory of the polycentered net. The paper concludes with some projections of potential implementation mechanisms for this urban design ideal.

A brief description of abandonment

The built environment of shrinking cities is first and foremost characterized by abandonment. Therefore any urban design strategy for these places will have to contend with abandonment before all else[*]. Abandonment in shrinking cities is problematic at multiple scales. While planners often consider abandonment at the individual scale of a single building or parcel, abandonment also occurs at the scale of the city block, neighborhood, and city as a whole, causing different problems at different scales. This section will consider these different scales before reviewing contemporary city- and neighborhood-scale urban design strategies to resolve the problems of abandonment.

In a shrinking city, abandoned structures and lots are serious problems, and confronting the abandonment of individual structures often demands a substantial amount of policymaker attention directed to shrinking areas. Recent citywide demolition programs such as Philadelphia's Neighborhood Transformation Initiative (Stern 2012) and Buffalo's "5 in 5" program (five thousand units demolished in five years) (Ryan et. al. 2010a) act on a citywide

[*] In this paper, 'abandonment' is considered to mean permanently vacant buildings as well as the vacant land that results from the demolition of such structures.

basis to clear derelict structures but use only individual dwelling criteria (unit condition) as a means of action. American city officials have thus far made larger-scale assessments of abandonment only in a reactive context, such as when a proposal was imminent, or as part of a larger, citywide statistical analysis (e.g. The Reinvestment Fund, 2001).

Shrinking-city abandonment is just as challenging as the policy-directed neighborhood demolition of the 1950s excoriated by Jacobs (1961), Anderson (1964) and other critics of urban renewal. This is because abandonment in shrinking cities occurs more or less on an undirected, piecemeal basis as individuals decide whether or not to remain in their homes. Understanding the piecemeal nature of abandonment in shrinking cities is essential to understanding the nature of urban design problems these places face.

Because decline is episodic and scattered rather than neat and organized, when and if each individual property will become abandoned is difficult to predict. Since the status and condition of properties can shift, adjoining homes are vulnerable as well. On a block where owners are abandoning property piecemeal, block-scale stability is difficult, for as abandonment continues, the collective benefit of more concentrated housing is lost, and each resident's individual incentive to abandon their property would seem to increase. As abandonment progresses, individual parcels are vacated in a generally scattered fashion. Ideally, up to fifty percent of parcels might be vacated without any two adjoining parcels being vacant together. But real abandonment patterns are different; a quick aerial survey of a place such as Flint, Michigan indicates that remaining houses sometimes cluster and sometimes do not. At high (above seventy percent) vacancy rates, remaining houses become islands in a sea of green. This pattern is most apparent at a large scale in places such as Detroit's eastside or the northern half of St. Louis.

Scattered parcel abandonment with interspersed remaining houses persists even at high levels of vacancy. In Buffalo for example, except in blocks purposefully cleared by public action or through demolition of large, single-lot industrial buildings, some housing always persists. At the

block group scale, no cluster of blocks in Buffalo was ever more than 71 percent vacant (Ryan et. al. 2010a). Even in a ninety percent vacant area, one resident wishing to remain in her home will require officials to condemn the property if they wish to make an entire block available for redevelopment.

At the citywide scale, piecemeal, house-by-house abandonment leads to patchiness, where large areas of the city may have high vacancy while other areas have only minimal vacancies. Again, our analysis of Buffalo showed 50 percent of the city's census block groups at least 10 percent vacant, and that about 20 percent of those parcels (about 10 percent of Buffalo's census block groups/total), were over 50 percent vacant (Ryan et. al. 2010a). In Buffalo and doubtless in other shrinking cities as well, vacancy ebbed and flowed across space in a pattern that was never neat, always irregular, always shifting, and always interrupted by remaining structures on a more or less random basis. Over time these piecemeal patches of abandonment tended to grow, spreading from high-vacancy areas into some but not all adjoining lower-vacancy areas (Ryan et. al. 2010a). This patchwork abandonment can be seen in schematic form in Figures 1 and 2 and at a smaller scale in Figures 5 and 6.

An urban design social ideal: reconnecting design to social policy

Any move toward an urban design strategy for rightsizing shrinking cities will not be easy. A principal challenge is the need for such strategies to reconcile differences between socially-oriented planning and urban design that have existed for decades. While many theorists have argued that design must necessarily consider political, economic, and social function (Lynch 1981, Cuthbert 2006), integration has proven problematic. In planning, advocacy advocates like Davidoff (1965) signaled a theoretical shift toward values centered around social justice and economic efficiency. Ultimately, these shifts resulted in a profession divorced almost entirely from design (Dagenhart and Sawicki 1992). Similarly, architecture separated from social concerns (Tschumi 1975) as High Modernism wound down amidst skepticism of design. After

1975, urban redevelopment in the United States shifted from ambitious, modernist-inspired work promoted by the state to modest postmodern-styled projects (Ryan 2012, 8-16).

Yet one may also discern surviving links between innovative urban design and liberal social policies. Beginning in the 1970s community organizing generated the occasional innovative design such as Villa Victoria in Boston's South End that linked partially abstract Modernist architecture with social housing while respecting the urban design of its surroundings (Rowe 1993). In the 1990s Philadelphia's Office of Housing comprehensively redesigned Lower North Philadelphia with moderate-density, low-income housing (Kromer 2001, 2010, Ryan 2012, 147-161). Design was not a signal feature there, but Philadelphia's ambitious planning approach was reminiscent of such signal late Modern accomplishments such as the Yorktown houses constructed from 1960 to 1970 in Philadelphia (OHCD 1996) and the St. Lawrence development of Toronto from the 1970s (Gordon 1989, Klemek 2011).

The threads linking formally ambitious urban design to social action have become thin and frayed since the end of Modernism in the 1970s, but a renewed urban design agenda for rightsizing shrinking cities, if put into practice by committed policymakers, might begin to regenerate these threads. I propose that such an agenda be *interventionist*, *critical*, and *benevolent* in order to improve upon the modest and ineffective urban design strategies that shrinking cities are currently pursuing.

Interventionist urban design is committed to large-scale, comprehensive action across a wide area of space. Such large-scale action by and in the public interest characterized high-quality urban renewal efforts such as Yorktown in Philadelphia, but since the end of urban renewal interventionism in shrinking cities has been limited to occasional projects such as Philadelphia's Poplar Nehemiah. *Critical* urban design questions existing modes of practice, such as the nostalgic bent of neotraditional urbanism, and projects innovative formal and social strategies to address new or emerging social needs, as Boston's Villa Victoria (Rowe 1993) did so well. Critical urban design attempts to move beyond current-day conventional wisdoms to attain

different configurations of spaces, buildings, and activities. Lastly, *benevolent* urban design is committed to acting in the interest of disempowered or under-served city residents ranging from low-income renters to members of the middle class. Benevolent urban design recognizes the needs of the least powerful amidst more powerful urban residents while preventing the egregious stigmatization of the poor and "spatial pathology" of mid-20th century Modernist urban designs (Plunz 1990).

A renewed urban design agenda committed to critical and benevolent interventionism is more radical than it seems. Even Fainstein's (2000) call for a more "just" urban planning saw urban design as only a partial part of her agenda. But providing for society's less privileged should not be an invisible project, and the rebuilding of shrinking cities demands concern for the built environment. This condition therefore suggests that urban policymakers and designers use urban design to provide rebuilding with maximum public visibility. Innovative spatial solutions to these longstanding problems could occupy the foreground of American urbanism and restore the weakened connections between design and social policy.

Contemporary urban design ideals in the shrinking city

Designers will not find a rightsizing vision encapsulated in past ideals of city form such as neatly bounded garden or radiant cities, nor in contemporary ideals such as neotraditionalism, 'smart growth,' or landscape urbanism. These past and present urban ideals have little relationship to the novel and peculiar physical condition of shrinking cities. This section briefly discusses three contemporary ideals: New Urbanism, or neotraditionalism; landscape urbanism; and everyday urbanism, or bottom-up planning, and their relationship to the urban form of shrinking cities.

New Urbanism is perhaps the best known of contemporary urban design ideals in the United States, based as it is in a neohistoricist vision that views the ideal city of today as embodying the "best of" (Calthorpe 2009) historic urban features such as small-scale buildings, pedestrian-oriented urban environments, and familiar architectural features (at least in the US small town)

such as pitched roofs, brick or wooden construction, and small-scale windows "punched" into the building façade. The resulting environments are immediately familiar and have garnered substantial appeal both in suburbia, where endless automobile-oriented environments are both monotonous and uninteresting, and, more surprisingly, in national low-income housing policy, where New Urbanism has provided guiding design principles for the rebuilding of public housing. Yet despite this relationship, new urbanism's relationship to social justice is questionable. The U.S. Department of Housing and Urban Development's HOPE VI program of 1995 onward (Cisneros and Engdahl 2009), dramatically reduced the number of low-income housing units even as it rebuilt problematic complexes. HOPE VI's New Urbanist design did reduce the stigma associated with the highly distinctive High Modernist towers of public housing, but it did so by accepting a substantial reduction in the amount of units provided to house the very poor. At the same time, New Urbanism projects physical futures hardly compatible with the reality of shrinking cities. New Urbanism's favors street networks with relatively high-density housing, but in shrinking cities the restoration of the fabric is only possible in small quantities. The weak real-estate markets of shrinking cities prevent a full-scale reconstruction of the vanished fabric. Full-scale rebuilding along New Urbanist lines is also conceptually illogical as historic fabrics often lacked many contemporary amenities such as public space and diverse housing types.

Landscape urbanism, a recent design movement with very different ideals than New Urbanism (Waldheim 2006), is motivated by the somewhat paradoxical desire to combine natural ecologies, or landscapes, with precise, avant-garde design. This strategy generally operates best in large, discrete parcels of land with few structures. But the vacant areas of shrinking cities are rarely large and discrete; instead they are more often small and scattered, with many parcels, many owners, and many structures remaining. In time landscape urbanism may better confront the property conditions of shrinking cities; in the meantime, landscape urbanism is a very compelling strategy for large deindustrialized areas such as the "monumental wilderness" of abandoned grain elevators along the Buffalo River (Ryan et. al. 2010a) but not for the patchwork of vacant and settled areas that characterize partly abandoned areas. As a citywide

strategy, landscape urbanism has even less traction, for any large-scale open space strategy would doubtless face skepticism from political leaders interested in increasing economic development and fearful of alienating voters with threats of widespread condemnation for open space.

A third urban design ideal, perhaps best encapsulated by the term “everyday urbanism” (Chase et. al. 2008), finds its theoretical basis as well as justification, both in philosophical concepts of the meaning of everyday experience, particularly in cities, and in the libertarian approach to land use and political control of development that characterizes the American city. The combination of the two, in conjunction with the relative lack of design attention paid to most contemporary American urban environments, has given the appreciation of “everyday” activities like informal food and merchandise sales, or low-cost, locally motivated housing or commercial construction, a certain imprimatur of individual character and even cultural distinctiveness amidst the otherwise primarily homogenous American urban landscape. Most notable in sprawling, immigrant-heavy metropolises like Los Angeles where entrepreneurialism is rife and much ‘formal’ development particularly large-scale, auto-oriented, and often inhumane, everyday urbanism has come to stand for the urban, pedestrian, local character that most cities arguably historically possessed, but now lack. Critics deride the ideal for its “anti-design” character (Speaks 2005), but fail to acknowledge the previously mentioned qualities of individualism and informality that the movement appreciates. Everyday urbanism, in fact, can be seen as a reaction to the very forces of homogenization and “bigness” (Koolhaas 1995) that have made cities around the world more similar, less pleasant for the individual to walk in, and visually less interesting.

Toward patchwork urbanism

Photographs of historic industrial cities such as Detroit, Michigan or Buffalo, New York show a surprisingly uniform carpet of nearly identical houses stretching toward the horizon. With the onset of population loss and housing abandonment, the formerly homogenous development

pattern of shrinking cities has become a frayed and tattered urban fabric. Today, the cityscapes of shrinking cities, particularly those with very substantial amounts of abandonment like Detroit or St. Louis, MO might best be characterized as a *patchwork* of intact areas interspersed with declining areas with growing abandonment and with heavily abandoned areas. Current planning policies comprise a parallel patchwork of small-scale nonprofit-driven housing, market-rate housing in higher-income areas, and little or nothing at all in those areas with very high vacancy. In other words, shrinking cities lack a comprehensive urban design strategy to shape either their shrinkage or their growth. This problematic combination of individual building demolition, market avoidance of low-income areas, scattered nonprofit development, and lack of overall spatial planning in shrinking cities was recognized almost twenty years ago by Philadelphia's Office of Housing and Community Development (OHCD 1993).

The patchwork nature of decline with vacant areas of different sizes and housing in various states of habitation frustrates conventional urban design approaches such as new urbanism or landscape urbanism that require large cleared areas of land in which to operate. Such sites are rarely available even in highly deteriorated areas of shrinking cities. Shrinking cities therefore present urban designers and planners with a physical condition that current urban design ideals do not fully confront. Urban design has always projected visions of the city as a complete, idealized entity, from the symmetrical avenues of Baroque cities like Rome to Brasilia's bird-in-flight form (Evenson 1973) right through picturesque New Urbanist villages like Seaside, Florida or Kentlands, Maryland (Krieger and Lennertz 1991).

Precisely the opposite conditions, however, characterize shrinking cities. These places, due to their seemingly uncontrollable population loss and currently scattershot, ineffective rebuilding strategies, possess an incompleteness and imperfection that make the attainment of an ideal urban form a seeming impossibility. Urban designers tend to dislike imperfection and incompleteness, but any urban design theory and approach to the shrinking city ideal will, by necessity, have to value and incorporate these attributes.

Few urban designers have acknowledged and appreciated urban incompleteness as a formal ideal. Among them is Kevin Lynch (1960) who described an ideal metropolitan form that he called "the polycentered net." Such a net would possess both "intensive peaks" of density and "extensive regions of low density" within a "dispersed urban sheet" or urban grid. This grid would consist both of streets and of "belts and tongues of open land." This pattern would not be static, but would "specialize and grow, perhaps in a rhythmically pulsating fashion." Lynch's recommendation captured many of the characteristics that he felt were typical of the modern metropolis; generally low densities resulting from automobile use and a desire for pastoral settings; dynamism resulting in part from rapid technological and lifestyle advances; choice resulting from the increased desire of different types of people for different experiences at different times; and physical differentiation resulting from the presence of both historic and modern structures and urban patterns across any given area.

Lynch's polycentered net was a somewhat odd idea – he did not wholeheartedly explore it again nor has any other urban designer expanded upon it. It certainly has little resemblance to New Urbanism's "transect", which though derived from ecological sections of valley territories, as an urban strategy offers little more than a 1920s vision of a dense central city and low-density suburbs (Duany and Talen 2002). Fifty years later the polycentered net remains an apt ideal for the American city, accepting both suburban sprawl and urban centrality with neither nostalgia nor cynicism. This was precisely Lynch's intention: in a peculiar symmetry to his career, one of his last writings, *Good City Form* (1981, 293-317) described a "place utopia" which more or less realized in greater detail the same ideal of the polycentered net that he had proposed twenty years earlier.

At a smaller scale, the polycentered net is also a helpful spatial concept to apply to shrinking cities. Historically structured around speculative grids developed with a relatively homogenous pattern of housing and other buildings, shrinking cities have in their decline shifted toward a differentiated, if unorganized, pattern of lower and higher (i.e. historic) building densities. The differentiated grid of shrinking cities, with areas that are becoming denser and other, larger

areas with increasing abandonment, is analogous to the dynamic patterns of density and openness of Lynch's concept.

The fluidity and dynamism of Lynch's concepts constituted a sea change from the static urban design ideals of the past. In similar fashion, the shrinking city's housing loss within the historic street network is an inevitable change that any urban design approach in this environment should accommodate rather than reject. Stopping this shrinkage in the future is likely to be as fruitless as in the past, for individual abandonment and demolition of abandoned buildings motivated by safety concerns and neighborhood complaints will continue to generate piecemeal vacancies. Even if building loss in shrinking areas continues to be unplanned, decisions about growth or reconstruction of abandoned areas need not be; location should be as critical for state-driven redevelopment as it is for private developers building in shrinking cities.

We might call a future urban design approach for the shrinking city *patchwork urbanism*, reflecting both the existing patchwork of built and unbuilt areas that exist already, as well as the patchwork approach to design obliged by the shrinking-city condition, where the designer can operate only at intervals, with other areas either outside of control or undesirable for the same. Patchwork urbanism, in other words, both describes the existing shrinking cityscape and provides a framework for a new urban design approach to improve these environments. Another such episodic approach to design, in which architectural interventions collectively shape a form of urbanism, was described by architect Oswalt Ungers in his West Berlin study of the 1970s as an archipelago (Aureli 2011). Neither new urbanism's ideal restored cityscape of historicist homes, nor landscape urbanism's successional landscape of returned nature, nor even the informal and essentially uncontrolled environment of everyday urbanism, the shrinking city is instead a patchwork of differentiated areas containing settlements of different densities and form, interspersed with open areas of various size, program, and levels of use. This patchwork might be thought of as four interrelated scales: a large-scale pattern of interwoven growth and shrinkage, and its three components: areas with extensive shrinkage,

growth in isolation, and growth in connection. The following sections briefly describe each of these principles in detail, and I conclude by representing these principles in a hypothetical city and neighborhood.

At the largest scale, interwoven growth and shrinkage will continue to characterize shrinking cities as city officials demolish structures on a piecemeal basis year by year through demolition programs, and as areas with a stronger market experience episodic construction driven by the private sector. Shrinking, increasingly empty areas will intermingle with remaining, surviving areas of historic building stock and areas with building densities that may even be increasing. This pattern, currently affected on an area-wide level only by episodic, publicly financed demolition, might be shifted through purposeful, coordinated new construction as well. Even if overall shrinkage continues, urban design policy can reverse shrinkage in selected locations by constructing new large-scale, mostly residential neighborhoods that return certain low-density areas to a higher (if not historic) density level.

Government-driven redevelopment could construct these new neighborhoods even as private developers will continue to construct scattered, smaller-scale projects along major corridors in stronger market areas of the city. In other words, the overall city will continue to shrink, but certain areas of the city will grow within this declining fabric. Thus, today's pattern of patchwork shrinkage with concentrated growth in higher-income areas might shift to a more balanced pattern of shrinkage and growth across both high- and low-income areas of the city. This new growth pattern will stabilize parts of the shrinking city fabric, while allowing loss to continue elsewhere in the city. Interwoven growth and shrinkage acknowledges the overall inevitability of population and building stock loss while improving the quality of life in selected areas whose distributed geography offers opportunity for more citizens to benefit from new construction and activity there.

Almost all shrinking cities have areas of extensive vacant land or vacant buildings. The more buildings are demolished through demolition programs such as Philadelphia's Neighborhood

Transformation Initiative, active from 2001 to 2008 (Stern 2012), the more vacant land there will be. The fate of open, vacant areas in shrinking cities makes up much of the dialogue, both positive and problematic, about shrinkage. These open spaces both provoke those who wish for regenerated historic urban fabrics and provide promise to those who long for a fuller expression of nature in cities (Desimini 2012). Open spaces in shrinking cities are growing and evolving and will continue to do so, offering a rich palette for exploration and cultivation of diverse activities. Vacant areas are abundant, and they should be seen by urban policymakers and urban designers as 'open territory' for whatever gestures residents or outsiders wish to make there.

While the most practicable transformations are those such as the annexation of empty parcels by residents who have chosen to remain and who value these parcels as amenities for their own home, this 'strategy' may ultimately decrease as residents of scattered homes continue to leave the city. Ultimately the open areas of shrinking cities will themselves resemble a patchwork, with a mix of carefully maintained small 'blots' (Interboro 2008), larger areas cultivated as urban farms, and designated natural habitat areas, together with badly maintained city- or privately-owned parcels, and larger areas of land simply undesignated for any use whatsoever. New development will likely never occur in most open areas due to the lack of a strong development market. Still, scattered homes are likely to remain. Residents of mostly open areas who wish to remain there, surrounded by memories and a pastoral landscape, should do so. At the same time, minimal service provision standards need to be established to permit removal of city services to isolated, heavily vacant areas. Residents of isolated, sparsely populated open areas will need to come to grips with the reality that living in abandoned areas will require them to assume additional responsibilities. Detroit's recent proposal to extinguish streetlights in heavily abandoned areas (Bloomberg 2012) is only one of many service 'shutdowns' that will need to occur in vacant areas in the future

Given shrinking cities' extensive abandoned areas, some areas of the city can be considered 'isolated', in that they may be relatively far from strong-market, active areas of the city. In cities

like Detroit, abandonment has progressed to the point where some neighborhoods may be a mile or more away from areas with active retailing environments and market-rate housing. In Buffalo, for example, patchwork abandonment in the city's central declining area is almost two miles in diameter (Ryan et. al. 2010a). Isolated areas are poor prospects for conventional, privately-financed housing development. Many isolated areas, built in an era when cities were denser and pedestrian-oriented, are also remote from major arterials, making them inconvenient for automobile access. The result is that isolated areas receive little redevelopment except for the previously mentioned scattered nonprofit housing. For residents, physical isolation means disconnection from everyday amenities found in denser areas, much as "social isolation" (Wilson 1987, 57) isolates residents from socioeconomic role models. Large stretches of the inner cities pictured in Camilo Jose Vergara's photos (1997) feature nary a grocery store or restaurant in sight, a sign of physical isolation's cost. Abandonment in adjoining areas may also grow as abandonment in isolated areas increases and is not reversed. Our work in Buffalo has clearly showed this phenomenon (Ryan et. al. 2010a).

There is thus a strong case to be made for creating new neighborhoods in shrinking cities' most isolated areas. Perhaps the strongest argument in favor of new neighborhood development in such areas is based on equity; in a democracy, all citizens merit a decent living environment with equal access to public facilities, regardless of where they happen to live. The current-day lack of development in isolated areas diminishes rather than enhances equity for residents of these areas. Certain factors that influence private-sector development in shrinking cities, particularly visibility and access from major arterial roads, should also guide selection of new neighborhood sites within isolated areas. Any new neighborhood should adjoin at least a mid-sized arterial street to both enhance auto access, increase the probability of mass transit access, and offer a better market for retail development.

An isolated-area new neighborhood strategy would be a radical one for shrinking cities; recent development including Philadelphia's Poplar Nehemiah has been sited adjacent to active areas in the hope of incentivizing market development and buffering healthy areas from decline. This

strategy is legitimate (see below) but it ignored the arguably stronger equity motive for building in isolated areas. Urban design arguments for new neighborhoods in isolated areas are also strong, for there is little reason to replicate the long-gone pattern of speculative grids developed with monotonous, dense housing. Developers have often provided contemporary spatial amenities in inner cities, largely through the construction of suburban-style housing providing private parking, culs-de-sac, and closure from surrounding streets (Ryan 2012, 120-125), but urban designers have a responsibility to do more than merely imitate suburbs. Instead, they must supply housing that provides expected private amenities, but that also provides some of the activity, security, and visual and experiential interest of urban neighborhoods.

Constructing new neighborhoods will be costly and will demand significant time and capacity from city agencies. In Buffalo, however, reduced federal funding is not the limiting factor in constructing new neighborhoods. Rather, political commitment is lacking. With a ten-year time horizon, ample Federal and state funds were available to construct hundreds of new houses at densities of around 15 units per acre at a cost of up to $200,000 per housing unit (Ryan et. al. 2010c). The construction of new neighborhoods in abandoned areas of shrinking cities would seem feasible, at least on paper. Whether shrinking-city administrations are up to the task is another question.

Far from being composed solely of isolated, abandoned areas with little remaining inhabited housing, every shrinking city has healthy neighborhoods where middle-class residents choose to live and remain. However, abandoned neighborhoods often adjoin these healthy areas. In Buffalo, for example, the shrinking neighborhood of Masten Park, a low-income, African-American neighborhood with approximately 50 percent vacant land, directly adjoins the busy Main Street area (Ryan et. al. 2010b). Other shrinking cities possess many such “connected” shrinking neighborhoods, adjacent to prosperous areas but nevertheless badly deteriorated. New neighborhoods in connected areas offer different benefits both to residents and to the city as a whole. Since these locations are already adjacent to intact and higher-income residential

and retail areas, residents of new neighborhoods enjoy immediate access to these amenities. The success of healthy areas is also reinforced by adjacent new neighborhoods as additional residents are placed within walking or short driving distance of these places, which supports existing activities.

At a larger scale, construction of new neighborhoods at the frontier of decline can check abandonment's apparent spread across deteriorating neighborhoods. New neighborhoods on borderlands between healthy and vacant neighborhoods indicate that 'abandonment stops here'; risk to healthy neighborhoods is reduced, and formerly at-risk shrinking neighborhoods are revived. Constructing new neighborhoods in 'at-risk', connected areas promises to arrest or stabilize decline's spread and to reverse abandonment in areas where it has not yet fully taken hold, even if it offers little promise to areas elsewhere with deeper abandonment problems where a gradual leveraging of private-sector activity may take years or decades to spread. However, connected areas are generally less extensively abandoned than isolated areas, and latitude for major urban design intervention is correspondingly less. At vacancy rates of below 50 percent, street, block, and settlement reconfiguration is difficult barring extensive relocation of existing residents (Ryan et. al. 2010b). Urban design at moderate levels of abandonment is thus limited to small new clusters of homes, closure of occasional streets, and provision of new open spaces or community facilities on scattered sites.

Towards a new shrinking city, and a new perspective on urban design

This chapter has argued that a benevolent, interventionist, critical urban design approach can begin to project a future for shrinking cities that goes beyond the piecemeal abandonment and demolition that currently exists. Such an urban design approach might address each of the different landscapes of the shrinking city- areas with extensive shrinkage, new neighborhoods in isolated areas, and new neighborhoods in connected areas- with strategies that mix new construction in some areas with the acceptance of continued abandonment and decline in other areas. Ideally, the future shrinking city would be a 'patchwork city' of new, old, vanished,

and vanishing neighborhoods, intermingled within the bounds of the historic city. Such cities will not be perfectly preserved historic monuments, but neither will they be ruined wastelands. Ultimately, shrinking cities might become a lively combination of different types of environments, a central-city realization of Kevin Lynch's "polycentered net."

Current urban design ideals have dual shortcomings. Formally, they are ill equipped to confront the peculiar and distinct built environment condition of the shrinking city. New Urbanism is predicated upon restoration of the physical fabric, but such restoration is impossible given the housing loss that has afflicted most shrinking cities. Landscape urbanism, on the other hand, accommodates postindustrial sites ill-suited for habitation, but has little to offer semivacant residential neighborhoods except a sophisticated form of vacant-lot greening, leaving the problems of housing, commerce, and other urban functions unaddressed. Finally, everyday urbanism accentuates individual efforts but can make little allowance for the larger-scale formal issues like the loss of thousands of houses or businesses except to recommend bottom-up, incremental action. But the problems of shrinking cities are too small to leave to individual action alone.

At the same time, the realization of patchwork urbanism will require shifts, if not wholesale revisions, of the current incrementalist, demolition-focused political economy of most shrinking cities. is subject to the same challenges and opportunities as all other urban policies. Political leadership in shrinking cities is not necessarily strong; agencies have lost capacity over years of budget cuts. Federal and state funding is not generous, but it can achieve substantial aims if applied in large quantities to a single site. Constructing concentrated and innovative new neighborhoods, and deciding where those new neighborhoods should be amidst much larger landscapes of decline, will change urban development as usual and place new demands on nonprofit and public agencies accustomed to decentralized action. But the problem of shrinking cities is too large to be left to chance, to the market, or to scattered and ineffective actors. Rightsizing shrinking cities represents an opportunity to explore new frontiers in urban design even as it holds promise for addressing and improving the lives of shrinking-city residents.

WHEN KNOWLEDGE ECONOMY PLANS THE CITY: IMPROVING FUTURE OR INCREASING INEQUALITIES?

Divya Leducq[1], Helga Scarwell[2]

Abstract

Everyone can read, here and there, that metropolitan areas have to aim for excellence, considering global competition and expected trickle-down effects for the bigger ones. This new context blatantly modifies planning and management of cities. Within this framework, implementation of spatial policies, as for instance, the ones based on knowledge economy, are introduced as innovative ways of planning. Then, reshaping policies which affect urban space disclose social divisions, because the land-revaluing sometimes encourage gentrification of working-class areas (Van Criekingen, 2008). In the same time, in order to keep their unity, local councilors are forced to relate social issue to ecological issue. More and more often, architecture is perceived "as a second nature" able to restructure connections between these two stakes, on a theoretical mode as on an empirical mode, resorting to "a wide range of space appropriation models and to preferences in terms of neighborhood" (Lehman-Frisch, 2009 : 95). We can argue that it justify the subordination of "innovative" city to economic imperatives and its conversion into a tradable object of consumption. Benchmarking studies largely contribute to this phenomenon of "city branding". Their communication discourses use misapplications of notions and concepts, as for example "diversity" and "sociability", or extend new organic metaphor as "revitalization" and "renewal", which sound legitimate facing the rhetoric of "urban shrinkage". Indeed, looking for more spatial justice (Rawls, 1971) will lead to consider spatial inequalities, and more generally environmental inequalities. However, excellence investments bring technology and growth in a tricky issue, which creates recurring inequalities between human beings (Deléage, 2008). Those innovative cluster policies also express unequal nature of urban and facilities planning at the environmental level and regressive nature of environmental policies at the social level (Emelianoff, 2008). They convey the fact that urban space is "where strategies display and contradict each other" (Lefebvre, 1968) and put into light not only the role of knowledge economy in urban area's social organization but also public actor's strategies to plan this one. This paper aims to discuss spatial justice concept from the role of knowledge economy within socio-spatial organization of city. We will focus on how planning tools, land control instruments and finance mechanisms produce urban spaces. To sum up, we will

illustrate the debate networks/ territories thought a deep presentation of digital mega-projects in two different cities. The first field located within an ancient industrialized country, in the metropolitan area of Lille (Nord-Pas de Calais Region, France). The second field located in an emerging country's tier-two city named Pune (State of Maharashtra). The purpose is absolutely not to compare both, rather than highlight the common and different key issues within planning process of knowledge economy. In fact and maybe more than anywhere else, observed gaps and geographical disparities on environmental level within territories, prompt us to inquire some aspects of collective reality, even if it's strongly linked to resources issue. To what extent urban planning based on knowledge sufficiently consider gentrification phenomenon noticed in our cases studied?

1. Introduction

According to EU Lisbon Treaty (2000), innovation has fuelled post-Fordist economy, which itself is based on differentiation strategies of the territories as part of a globalized economy. These strategies aim to make urban spaces as heads of the networked knowledge economy and drive at the same time, more or less directly to the agglomeration of activities but also to metropolization of those spaces. From the perspective of spatial planning, this process is growing as urban projects for knowledge economy in fast growing business activities like education, research. The coming up of urban redevelopment, almost concurrently in different geographical contexts, and at the same time dedicated to the environment and to amenities in order to make the local economic territory more attractive, is not a coincidence. These speeches inspired by the success of US Silicon Valley's performances and benchmarking strategies for clusters, flooded the debates on competitive city of World Bank, International Monetary Fund, and regional cooperation associations such as European Union or South Asian Association. One can notice that the incentives lead by the public sector as well as the private sector to create "spaces of exception" (Halbert, 2010) within the city, carry new forms of spatial inequalities added to the existing ones, whether in formerly industrialized economies or in emerging markets.

Through the analytical description of selected sites in regional cities of Lille (France) and Pune (India), both chosen for being two metropolitan centers of excellence for multimedia industries and services, internationally oriented and maintaining somehow some technological links, we want to underline that sustainable development is the master piece of any discussion and any action on the territory. Indeed, studies of the Union (Lille, North of France) and Lavasa (Pune, Maharashtra, India), show that it represents the overall framework to register political, planning and economic decisions. So, results a strong "social engineering". However, those two instances also demonstrate the gap between the incantatory speeches on sustainable development and the practices of the city that fail to include the citizen participation in determining the directions and guidance

in land (use) management. The technological innovations expected by these new growth strategies seem to overtake the needs of social innovations.

This paper is organized around the two examples - French and Indian - that are developed to highlight three points of the urban planning for the knowledge economy. This method aims to highlight similar processes and similar strategies in spite of divergent contexts. Since the 80's, the Lille metropolitan area developed an ambitious project of "renewed city" on a wide range of intra-urban land, called "ZAC de l'Union" (73 ha) which became an urban brownfield following the triple crisis of coal, metallurgy and textiles. Later on, this site, scheduled to host the "CETI" and "La Plaine Images", also combined an eco-district, included in the Agenda 21 for Lille Métropole. In India, the take off of the city of Pune and its appearance in the rankings of biggest software cities starts in the mid-2000s, while Bangalore and Mumbai began to experience saturation phenomena. Since then, a number of urban projects, planned on the fringes of the Municipality tried to reconcile support for ICT growth and support to urban development. One of the latest case is "Lavasa Hill City Project", which is not only a private new town in the heart of the Western Ghats, but especially a project of New Urbanism design (NU) looking for a quick profit induced by a continuous and strengthening technopolitan effect, particularly around the Hinjewade InfoTech Park, and despite the economic downturn at the end of the last decade.

2. Case studied

2.1 L'Union, Lille Metropolitan Area, France

The history of the Union site is emblematic of "unsustainable development" and environmental inequalities (Roussel, Schmitt, 2009). The site lies at the crossroads of three cities: Roubaix, Tourcoing and Wattrelos and the characteristics of an industrial site under redevelopment. Historically, the life of this area is organized around factories and the Canal de Roubaix, built from 1827 to 1876, which allows the delivery of coal and raw materials for the wool industry, and provides water and rinse water for steam engines.

Farmland until the mid 19th century, the site was the scene of industrial booming during the 19th century with the building of plants in open fields, quickly surrounded by rows of workers houses. Urbanization develops spontaneously, an "oil spot", in an unplanned way and promotes the creation of a poor urban fringe. From 1970, the area suffered industrial decline, many factories were give up or relocated gradually. The last factory closed in 2004. The habitat, consisting of 50% of workers poor quality houses build before 1949, degraded and devoided of comfort. Many homes were demolished, but the "captive" poorest population is forced to stay in the area. By 1971, a major restructuring of the site was thought by the Chamber of Commerce and Industry (CCI LRT) around the location of a tertiary activities area, which resulted in the construction of the Tour Mercure

supposed to provide "an attractive element they were needed". The site was then left as a brownfiled and in 1992, the Urban Community of Lille (CUDL) identified through the project before the SDAU, the Union area among the five major metropolitan projects selected, but the EURALILLE project focused all energies and funding. The estimated 12,700 inhabitants of the area of the Union (1999) present singularities. It has the following characteristics: a significant proportion of young people and immigrants, low purchasing power, low mobility, low-skilled population, a high unemployment rate, a predominance of rental housing and the social accentuated difficulties. In 2000 this area is composed of many vacant plots resulting from the progressive destruction of homes and factories when it was originally scheduled to become a business district. That's when the site is again identified as a location priority in the new contract of agglomeration of the CUDL and in 2002 "metropolitan economic center of excellence". This is clearly to reassure the politicians of the North East slope by registering a project that balances the territory. While the first phase of the project Euralille ends, the time seems ripe for the Union. In 2004, the Union has been designated to host two clusters: one on the image and the second on textile innovation. At the same time, LMCU realizes that it must substantially increase its land supply to businesses and finding land to build housing. The land scarcity encourages brownfield redevelopment and gives, if necessary, the boost that facilitates implementation of an economic or habitat project.

Since the early 2000s, the Public Land Institution (EPF) has embarked on repurchase procedures for housing development in this regard. However, land management is difficult to acquire. In 2007, LMCU decides that the Union will host an "eco-district pilot" to be the "environmental showcase" of the metropolis since this space enjoys a unique cross-border, a quality service for transportation, including individual and a large area (80 ha), all assets which constitute a real opportunity to accommodate a development of national and European dimension. From there, the site originally scheduled to host a textile center and a multimedia cluster completed by 400 homes got suddenly 600 additional housing units.Thus, more than forty years elapsed between the time it was decided to locate on this declining site and the services center implemented in 2012 and where you can experiment the temporary facilities, including the not -woven test platform set up by one of the central player in the cluster, Up-Tex. But today, the environmental and social challenges associated with industrialization and de-industrialization in L'Union area are still numerous and make this site an interesting field of investigation to carry out a reflection on the co-construction of an urban project. Indeed, the process of inhabited areas reinvestment originally destined for demolition by people and associations including the island Stephenson is a privileged entry to understand what could be a sustainable city and to understand its meaning. A sustainable city is above all "a city where everyone can take ownership of surrounding, to co-construct, to make it a public good, to make his city a place of happiness to which he aspires" (Genin, 2010: 10). Now, it sometimes feels that sustainable development depends on environmental technologies and technical tools applied to urban buildings,

management of water, waste, transport, but as Michel Bonetti (2010) said "all those aspect can't be considered as sustainable urban design" (p. 250). Rather it is to develop both "the potential for social interaction, the landscape potential and the historical potential for identity" (p. 251) for an area. The purpose of this site rose to numerous studies on culture and sport projects, and/or a services center, then a "center of excellence" itself with a variable geometry content on a non-determinated space. This space deemed stricken and without amenity has been constantly thought to receive potential projects planned as part of plan contracts such as GPU, GPV and/or INTERREG II. All this dithering on the site's purpose were based, according to these projects actors, on the political target to change the image of a desolated area by its economic, social and urban transformation (Gaudefroy, Estienne, 2008). But elected politicians of L'Union, despite the fact they come from the same left party, don't share the same projects on what to do for this area. Thus, for the representatives of Tourcoing and Wattrelos, they must focus all for "economy" while Roubaix' representatives want a project focusing on city dwelling. What is surprising, according to us, it is ultimately a form of escheat in the definition of a consistent project for this area. This last argument is reflected by the market definition launched in 2004 by LMCU calling precisely for a site program. So, what we observed in this area is the lack of planning to serve a collective purpose and still the inconsistency and discontinuity of policies over a period of more 40 years. Finally, the "governance" system don't really know where it goes because the site of the Union's vocation may have been not to constraint the town centers affected by the crisis of the concerned and concurrent municipalities (Roubaix Tourcoing, Wattrelos), and not to overlap with the Euralille project that has absorbed much of the Metropolitan Area resources for the only benefit of Lille. Evidenced by the first porting task of the land project (1998) assigned to EPF Nord-Pas-de Calais by LMCU, following a perimeter definition of urban seizure right (DPU). Indeed, the EPF throw itself on a first campaign of buying homes and vacant premises (Vanhoutryve). A second multi-annual program of land intervention extends its action on the Union until 2006. During this period, the EPF has amicably acquired 22 acres under its mission to land recycling. However, it appears that homes purchased by the EPF are dilapidated, the windows are bricked up, the vegetation takes possession of the houses so that fungi make it unhealthy, factories are partially dismantled and empty spaces don't received any projects. It seems that the project justifying this land control was not clearly defined. Yet, legally, the delegation of pre-emption of LMCU to EPF must be substantiated. Worse, the pre-emption area has been redefined after residents (about sixty families) resisted selling their accommodations, formed a residents association ("Don't demolish my neighbourhood") and define an expression strategy for unoccupied spaces. Later on, a second association called "Collectif de l'Union" formed by former employees of companies also decided to invest in the economic future of their area because they perceived, at that time, the working return opportunities thanks to new business locations. Although the site is strongly marked by the demolitions and escheated urban environment, the project owners will have to take into account the fact that some inhabitants do not want to leave despite the pressures

(electric meter closed, maintaining insanitary conditions of the place and so on). February 14th, 2004, "La Voix du Nord" entitled “We won’t demolish their neighborhood!” and the houses will no longer be redeemed. LMCU is finally turning back. Also, what observations can we make? Firstly, if this project had been designed differently from the beginning by integrating the poor of this area, they wouldn’t have been concerned by the pre-emption area and would have take benefits from the amenity related to the new center of excellence. Then maybe, we would have avoided the equivocation on the final purpose of this space. Finally, behind all this, it is hard not to imagine that every actor has played only for himself.

In 2007, the urban development operation is delegated by the Mayors and LMCU to two companies (SEM Renewed City and SAEM Euralille). Actually, it covers a 80ha area dedicated to economic triptych Textile, Distribution and Image, included also the habitat with 80,000 m2 of housing and utilities with 63,000 m2 of facilities. In addition, the project evolved into the creation of an eco-friendly neighbourhood project where stakeholders have to meet the requirement of a participatory approach, register in LMCU Agenda 21. The action of various associations was beneficial because in 2008 a renovation program for the houses of the Stephenson block has been launched, fulfilling the consideration of requests from residents. The social dimension seems to be included to the commercial rehabilitation development of the area since on the 54 homes affected, 24 are still occupied or rented out by their owners (establishment of a self-rehabilitation plan) and 30 are in the renovation step. This mobilization prompted City Renewed SEM to devote homes renovation to Patrick Bouchain, a well-known architect who decided to undertake an innovative approach of "co-production of housing". In 2009, he settled on the site “The Electric Workshop”, a real common house for the site where residents involve for the rehabilitation of their future homes. However people do not show as much enthusiasm as they believe "We should be associated for a long time. Working together, this is not presenting us the forthcoming model". In April 2012, they challenge the traditional tile replacement by red, blue, pink or purple plates in the planned rehabilitation project of L’Union to an eco-friendly area. According to them “These sheets don’t fit the traditional architecture of the neighborhood. “It reminds me the roof of the chicken farm buildings during the sixties” says Lino Sferrazza. “In addition, the chimneys are found lower than the additional floors” notes Marguerite Parent, Chairman of the Association. If the objective was to choose bright colors to brighten up the Stephenson Street’s neighborhood, the fact remains that the dialogue is lacking. To justify the project, the site manager argues that "Architectural innovations improve the welfare of these old houses" since "the energy aspect has to be considered". Here we stress the limits of the technician’s answers. If the technological contribution is certainly significant, the “other factors” must not be overlooked or underestimated. Change cannot happen without “ownership” by the inhabitants, which comes close under the sociocultural register.

Through L'Union area, one can notice that models of economic and urban development must be embedded both in a sustainable development and smart growth contexts to instill sustainable, fair and environmental development of the territories.

2.2 Lavasa City Hill, Pune, India

In Maharashtra, 2nd exporter of software and computer services, urban development support in the knowledge economy has led to the vote of two InfoTech policies (2003 and 2009), and to the application of the Central decrees consolidating Special Economic Zones (2005) and the adoption of a law entitled Township Development Act (2006). This incentive regulatory framework encourages the private sector to invest together in the software activities and in the housing and urban development sectors. Pune is the fourth pillars of the Indian digital factory, in view of turnover now exceed those of Mumbai (Leducq, 2011). However, as its competitors, the city faces lots of problems such as intra-urban mobilities, pollutions, poor waste management, and water supply or electricity discontinuities. These negative externalities induced by an outdated Master Plan (CDP, 2006) and all management barriers induced by a lack of resources exacerbated by recurring corruption cases, tend however to decrease as far as we move away from the historic centre. Thus, if the ICT business and technological parks, such as the Rajiv Gandhi Infotech Park, located at the East of the metropolitan area, between the ward of Aundh and the Village of Hinjewade, are relatively protected, they indirectly suffer pollutions cited above. Meanwhile, a number of developers realized the growing demand for new housing from the more and more numerous "upper middle class", who work in riding high knowledge economy sector. Huge real estate projects mushroom. They are characterised by a poor development plan, embellished by little green spaces and don't take into account soft traffic patterns. Nonetheless, more recently, precepts of the NU, a contemporary architecture thought challenges the principles of zoning uses and urban sprawl (as addressed by the Charter of Athens, CIAM, 1954). The neo-traditional town planning, by creation of new towns (ex-nihilo), is therefore responding to the sustainable development imperatives putting emphasis on high liveable density and short distances between collocated urban services.

Therefore, economic, social and cultural regulatory conditions, were combined to allow Lavasa Corporation, an Indian private fund, to create an "eco-friendly city" meeting all the charters of the American Society of Landscape Architects in Ghats valley, along the Knowledge Corridor identified by Maharashtra as a strategic corridor for post-industrial growth between Mumbai and Pune (MIDC, 2002), thus ensuring profits within short and mid-terms. Conceived in 2003 and launched by 2009, this project was designed by HOK, an architectural and planning company from New York, with the support of biggest software names in GIS Master Plan and for benchmarking this pilot project as a flagship one. Lavasa, with a surface area of 100 sq. km, is built on seven hills around several lakes in one of the most important biodiversity area in India. It is expected to host 300,000

inhabitants by 2020. The first 1,500 apartments located in one of the seventeen districts of Lavasa were sold off-plan, before the excavation start. In addition to the 60,000 apartments for rent or purchase (apartments, villas and bungalows), six hotels, an international conference center, a hospital, schools and shopping centers will be built. Since Dasve area is already built “and furnished”, supplied with technical networks and inhabited, the world famous Indians succeed. They come from politics or entertainment “beau-monde” and, in fact, participate in advertising strategy of Lavasa, such as French hotels group Accor, Lausanne Hospitality Management School (leisure), Oxford University, Symbiosis International College (higher education) and Apollo Hospital Group (health and wellness).

Some would argue that perhaps the term of “palimpsest”, chosen in our sub-title is inappropriate or exaggerated, since no industrial or manufacturing plots were even installed in this location looking back to the loath to human settlement. Nevertheless, we will see later, that reality can’t be as simple as that in a state where population exceed 110 millions people, and while a number of villages were present and thwart the planned "new" town scope Lavasa, built without any consultation of the existing population. Firstly, if technical sustainability is partly met through the use of green technologies in the buildings construction or in their energy supply, one can mention that also there is no plan for wastes treatment either for the project itself either for the construction companies working in the valley. Moreover, from a purely architectural and cultural point of view Swiss village’s chalets or Italian brilliant colours might surprise visitors to Lavasa. The NU would be a ready-to-make kit model to export around the world, whatever are the specifics of vernacular architecture. Secondly, sustainable economic growth is also challenged by the life conditions of workers and employees who work for the proper functioning of the “new Ghats idyllic city”. Despite advertised social diversity announced as one of the sustainable development principles of NU, housing of the non qualified-workforce boils down to bad-ventilated dormitories or rooms for 4 to 6 people without air-conditioned, all-in-all leaving little space for family or personal development. In addition, BHK apartments to be rented to low-income people will be built in the 2nd phase of the project in the “Mugaon village”. Meanwhile, city managers say they want to accommodate computer-software companies or to comfort people to practice telecommuting, but for now the phenomena of firms’ relocation from Mumbai and Pune doesn’t exist except few cases, so software employees continue to go massively to Hinjewade. For now the city look like more to a ghost bedroom community during the day-time - outside the presence of curious and tourist buses who are potential investors - than to a city where integrated functions does not reproduce the failures of functional zoning. Environmental sustainability of Lavasa is also a growing source of questions, from the origin to the practical implementation of the project. Thus, the Ministry of Environment and Forests has first adopted denial behavior (2010) on the future issue of water supply of Pune city, confiscated by the implantation of Lavasa near a strategic dam, and for problems of landslides induced by the repeated explosions of the hill. It was

during the year 2011, which under the combined pressure of environmental NGOs, «looted» rural people and committed journalists associated in State prosecutor, a reversal was made by the Board of Pollution Control of Maharashtra and by the new Indian Minister of Environment, accusing A.G. (HCC) to cause significant environmental damages. In addition, Indian laws protect mountain landscapes located more than 1000 m above sea level by limited building regulations and planning standards. Lavasa, located at 1055 m altitude, but considered below the limit of 1000 m, was not bothered by those sections of the Town Planning Code of India. Finally and more generally, the governance of the project clearly calls into question the entire concept of sustainable urban planning in this project directly related to the information society flourishing in Pune. Upstream, there has been no consultation on the future of Adivasis peasant populations, or even honestly compensation system (employment and housing rather than cash) in return for the destruction of villages that dot the hills. An added complexity stems from the fact that 600 ha of land were subsidized by Maharashtra and therefore benefits, restoring some spatial justice, should have been tripartite: State - owner - operators. In addition, lucrative management of the place by a City Manager - American by the way - chosen by HCC Directorate Board questioned the relevance of this model advocated by national, regional and local officials as "the" solution to the rapid fragmented urbanization and economic growth. Indeed, how to reconcile and satisfy both rights and duties of citizenship and the demands of not more than customers? This management inevitably leads to phenomena of "entre-soi" reinforced by the presence of a security and monitoring service and putting emphasis on safety in Lavasa green city. Therefore, gentrification doesn't operate here by the transformation of an existing urban area, but by creating an "urban fabric" in predominantly rural areas, where new populations, with contradictory aspirations, replace the previous ones. Using example of Lavasa, the knowledge economy is both an origin point of gentrification and latter feeds the hopes of increasing shares of high value-added activities in the metropolitan area's GDP. The last limit to clear governance of this knowledge economic project, the suspicions of nepotism and corruption, like in another major project in multimedia economy in Pune (Amanora Film City, located in West of the city, ward of Hadaspar), revealing names of SP, former Prime Minister of Maharashtra and MP elected to Lok Sabha, his daughter and nephew. They were pursued for abuse of power for personal enrichment purposes in permits issued and active speculation on about 20 % of land sold by 2004 at Lavasa. Instead of strengthening the urban competitiveness and ICT economical bifurcation of Pune (software, images, Bio-InfoTech and Internet), it seems this project reveals additionally the growing contradiction between the project principles displayed by sustainable development and the accomplishment reality that comes at the expense of pre-existing populations, arguing that one's legitimacy overtakes another one.

November 2011's decision, taken by Indian State and State of Maharashtra, to stop construction of Lavasa Hill City Project, in order to make light on outlawed dealings that plague both politicians and businessmen, is less motivated by a new

conviction from the Government's officials that there is a need to regulate projects by real sustainable development principles and than by the political dissidents threat (from environmentalists to Naxalite guerrillas) might oppose all economic development projects (industrial ports, free zones...). However, this decision constitutes a turning point in the way of understanding the public-private partnerships, which until now sacrifice environment to economic growth. This decision is far-reaching for the implementation of post-industrial spaces.

3. Discussion and conclusions

Finally, we conclude with some remarks about the political decision that cannot be conceived as a discretionary act in its purest form. To bring out the sustainable city, the debate can't be reduced to "all for technology" because the city should not be only physically beautiful, but socially integrated. Also, major projects for the city must rely less on technological innovations and more on social mobilization, involving particularly the lower classes and the forces that constitute formal or informal associations. The concept of "governance" encourages any regulation to take place from the analysis of concrete system of agents or actors, from their "configuration", from their logic, from their respective powers, and from their relationships because the geographical and social space is a dynamic construction resulting from an interaction between the different players involving within the territory. Social innovation should combine the use of regulatory instruments as economic disincentives (taxes, fees) or incentives (grants, subsidies), and other instruments such as dialogue, persuasion, awareness, training, etc.

In Lavasa, up to present four main types of actors were involved in the knowledge economy urban projects: real estate developers and builders, the political authorities (regional and municipal) and public managers of technical networks, major ICT companies directly or through their investment subsidiaries, international investors (banks, pension funds, private institutions of higher education ...) that will always be kept under the local stakes. The Lavasa project claims to be representative of the NU, and therefore claims to work for sustainable urban development. Nevertheless, we find that a number of criteria are being challenged by practices that run up against the economic, social and environmental sustainability of the project. Expressing their disagreement with decisions taken in the absence of consultation, the 3,000 inhabitants of the 18 pre-existing villages invited themselves to the table of new urban models, by introducing directly the issues of environmental and social sustainability of knowledge economy urban projects. Lavasa was set up to be a replicable model 400 times in India, combining urban growth and knowledge activities, hosting a branch of the prestigious University of Oxford (UK). In view of the growing controversies on respect for human rights and for the environment, the project has lost confidence of academic UK investors and thereby, its initial target of becoming a new technopolitan area. A bundle of messages, along of a more

sustainable with less wealth ghettoization and spatial gentrification, has been sent to global, regional and local players in the economic planning in India.

In L'Union, the eviction of residents in the definition and initial development of a planning project results from a combination of factors that reflects:

- A negative representation of the history of an industrial site without regard for its inhabitants who could imagine a new project of their site. The inhabitants of the area are simply displaced and land reinvested in an excellence project;

- A classic vision of land use that does not sufficiently take into account the expectations and needs of resident populations and neglects citizen participation;

- A vision that reduces excellence as the first step of an economic project and in a second step, to an area of technological and technical performances;

- A vision of inaccessible and unfair city.

Abstract

The purpose of this paper is to update an on-going spatial study of US Department of Housing and Urban Development (HUD) Housing Choice Voucher (HCV) distribution in Hamilton County, Ohio, drawing from previous quantitative studies of 2000 (Wang & Varady, 2005) and 2005 (Varady et al., 2010) voucher holder location data that utilized GIS hot spot analysis to investigate the spatial distribution of HCV households throughout Hamilton County, Ohio in those two time periods. This involves repeating the previous studies' methodology in order to accurately gauge changes in voucher distribution and concentration. In addition to analyzing dispersal on the county level, this paper focuses in on suburban hot spots identified by Varady, et al's 2010 study in the Finnwytown school district and in a contiguous suburban area comprised of parts of the City of Forest Park, Springfield Township, and Colerain Township.

This study finds that voucher holders are generally moving away from fewer locations within Cincinnati to a greater number of locations around the county, but that voucher distribution is characterized for a large part by relatively few, fairly concentrated locations within and outside the city. This conclusion is drawn from density-based spatial analysis as well as comparing the appropriateness of US Census block groups versus tracts in quantifying dispersion.

Introduction

Since 1980, the US Department of Housing and Urban Development (HUD) has shifted its focus from subsidies to building owners to subsidies for tenant assistance, that is, the Housing Choice Voucher (HCV) program. One of the program's primary stated purposes is to provide low income renters with access to better quality housing, safer neighborhoods, and better neighborhood amenities. Academic discourse on the subject has focused in part on how well the HCV program succeeds at deconcentrating poverty and desegregating racial minorities, as well as the real and perceived impacts of voucher holders in local communities, especially suburbs.

The purpose of this study is to analyze the distribution of voucher holders within Hamilton County, Ohio, particularly the suburban community of Finneytown and a contiguous suburban area comprised of parts of the City of Forest Park, Springfield Township, and Colerain Township. For purposes of brevity we refer to the former as "The Finneytown Hot Spot" and the latter as "The Forest Park Hot Spot." These areas were chosen because a previous study (Varady et al, 2010) defined two voucher holder hot spots in those areas.

We seek to answer the following research questions:

1) What trends, if any, appear in the spatial distribution of voucher holders within Hamilton County between 2000 and 2011? In what ways are voucher holders concentrating or deconcentrating?
2) What trends, if any, appear in the spatial distribution of voucher holders within Finneytown, Ohio between 2000 and 2011?
3) What is the nature of the Finneytown and Forest Park hot spots including the style and condition of housing and the demographics of the population?

Voucher holder dispersal is analyzed on the county level and on the community level within two study areas as simple dot distribution as well as density. This GIS-based analysis is complemented by community profiles of both study areas and photographs taken during a windshield survey of both study areas.

The Cincinnati Metropolitan Housing Authority (CMHA) provided a Microsoft Excel spreadsheet of all voucher holder addresses within Hamilton County, which is up-to-date as of December 2011. Geocoding the 2011 dataset created a dot shapefile, of which 10,545 out of 10,630 addresses, or 99.2% of all addresses, were successfully matched or tied. We deleted from the dataset the eighty-nine unmatched addresses and manually matched the tied addresses. We plotted the shapefiles for all three time periods to analyze the spatial distribution of voucher holders as dots in all three time periods. The distribution of voucher holders as dots were quantified spatially using a variety of geographic boundaries, including municipal boundaries, census tracts, and census block groups.

We also analyzed voucher holder densities for all three time periods, repeating the methods outlined in Varady at al's 2010 study in order to preserve methodological consistency throughout the time series. We used the kernel density tool available through ESRI's Spatial Analyst extension for ArcMap 10 to convert the dot shapefiles for all three periods into raster density files. We used a cell size of 500 feet, search radii of

2640 feet (half mile), and an area unit (output) of square kilometers. To define hot spots within the density raster files, we considered any density that was equal to or greater than the highest density in 2000 to be a hot spot. We calculated this density to be 111.443 voucher holders per square kilometer.

In addition to analyzing the county as a whole, this research focuses on two study areas: Finneytown and a contiguous suburban area comprised of parts of the City of Forest Park, Springfield Township, and Colerain Township. Voucher locations were analyzed using dot distribution and voucher holder density in the three time periods. This research also explores the characteristics of various parts of both study areas and how vouchers are distributed within and between them.

The research included community profiles of the two study areas in order to better understand their dynamics and background within suburban Hamilton County. We studied the community's history, demographics, school system, land use patterns, governmental structure, transportation systems, economy, and housing stock.

Finally**,** the study included a windshield survey of both study areas on April 2, 2012. We visited areas in which the spatial analysis indicated clusters of voucher holders, few voucher holders, and no voucher holders. We paid particular attention to housing typology and property maintenance standards in each location. The photographs included in this paper represent the results of that survey.

Spatial analysis of voucher holder distribution: Hamilton County

Spatial analysis of voucher holder distribution throughout Hamilton County in 2000, 2005, and 2011 involved two primary methods: dot distribution and voucher density. We analyzed the distribution of voucher holders as individual locations in terms of city versus suburb locations, census tracts, and census block groups. The density analysis defined a number of hot spots throughout Hamilton County.

The first step in understanding the distribution of voucher holders throughout Hamilton County and how that distribution has changed over time was to plot voucher holder locations as simple dot distributions. For the 2000 and 2005 time periods, we used voucher holder location dot shapefiles produced for an earlier study (Varady et al. 2010). For the 2011 time period, we collected a table of voucher holder locations from CMHA in December of 2011, which we geocoded by address. Plotting voucher holder locations in these three time periods produced Figures 1, 2, and 3.

The most striking change between any of the three dot maps (Figures 1, 2, and 3) may be the increase in the number of vouchers between 2000 and 2005. The number in 2011 increased comparatively marginally. In 2000 there were 5,032 vouchers in Hamilton County, in 2005 there were 10,214, and in 2011 there were 10,545. Based on the dot distribution maps, the overall pattern of voucher distribution appears not to have changed substantially between the three time periods, though those areas where voucher holders lived in 2000 appeared to have densified in 2005 given the county-wide increase in vouchers.

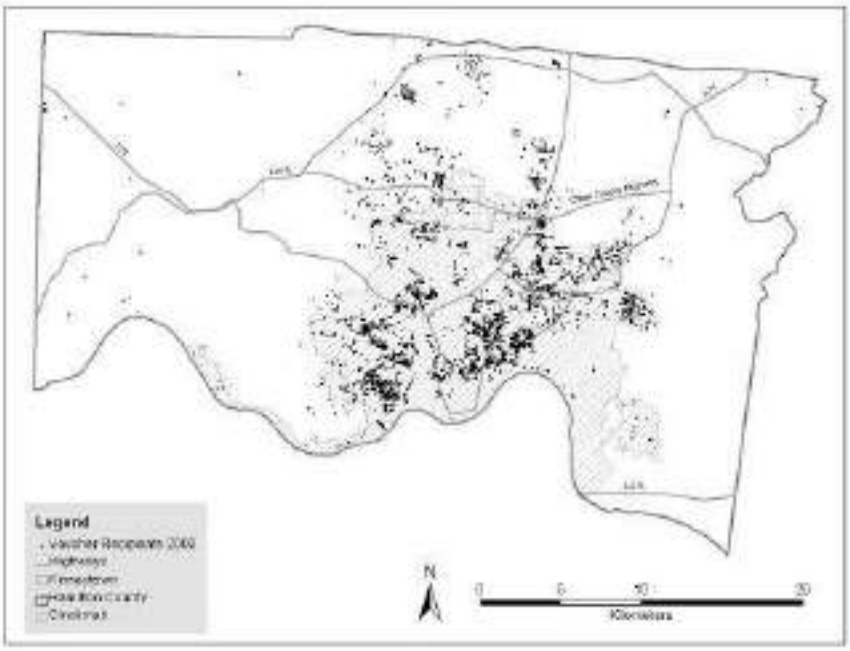

Figure 1. Dot map of 2000 voucher holders

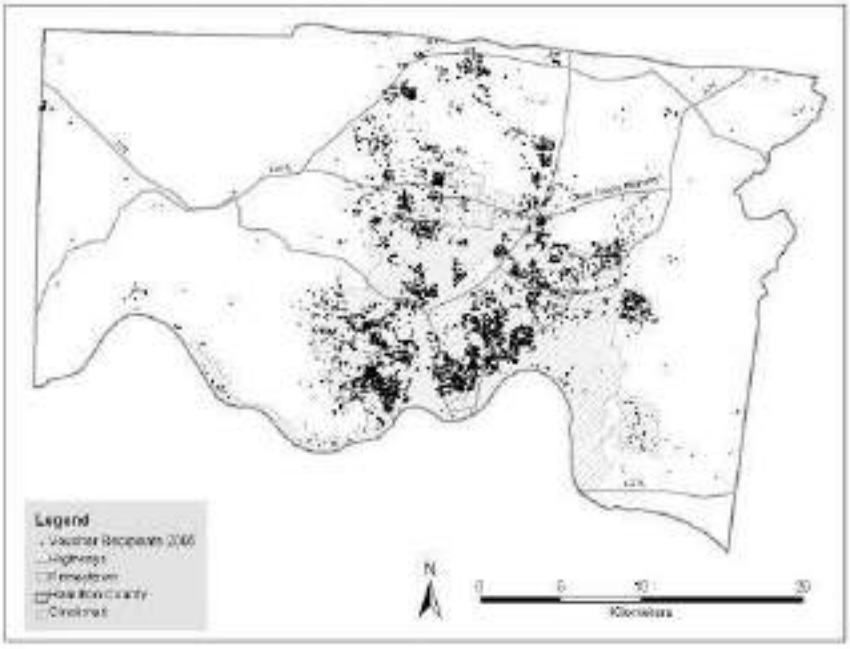

Figure 2. Dot map of 2005 voucher holders

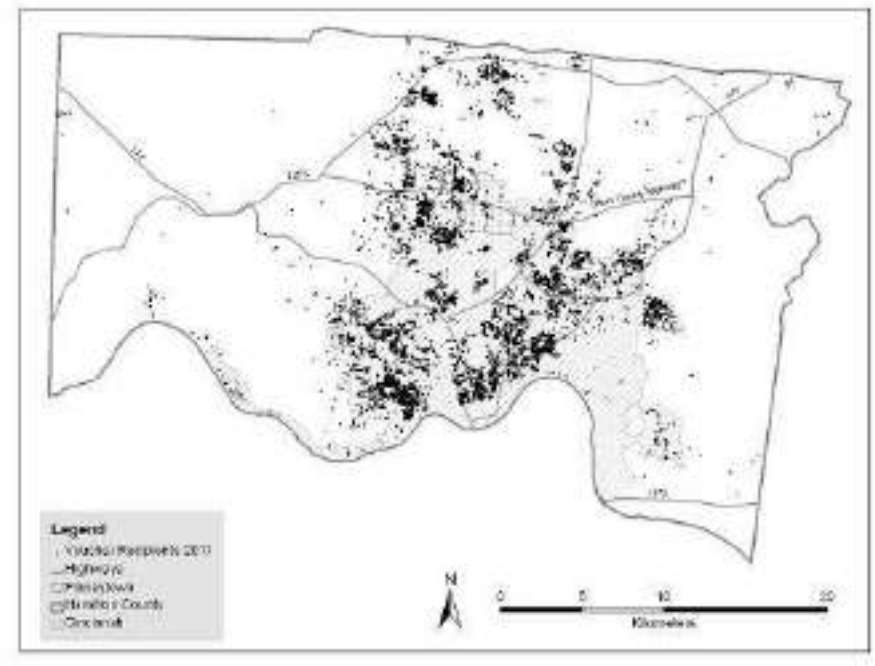

Figure 3. Dot map of 2011 voucher holders

One simple measure of voucher distribution is to compare those within the city and those within the suburbs. Given the complex nature of the Cincinnati metropolitan area, like others in the US, in terms of suburban neighborhoods that have been annexed to the city and urban neighborhoods that lie outside the city boundaries, myriad criteria exist for defining city and suburb. For the purpose of this analysis, we considered the Cincinnati city boundary to be the line between city and suburbs within Hamilton County.

Table 1. HCV distribution within/outside Cincinnati

	2000	2005	2011
Total vouchers in Hamilton County	5,032	10,214	10,545
Vouchers within Cincinnati city limits	3,738	7,303	6,915
% Vouchers within Cincinnati city limits	74%	71%	66%
Vouchers outside Cincinnati city limits	1,294	2,911	3,630
% Vouchers outside Cincinnati city limits	26%	29%	34%

Table 1 shows both the dramatic increase in vouchers between 2000 and 2005 that comparatively leveled off by 2011 as well as the steady movement of voucher holders from Cincinnati to other jurisdictions within Hamilton County over all three time periods.

Census tracts are a basic unit of spatial analysis when considering issues at the neighborhood, county, or metropolitan level. We calculated two measures of voucher dispersal within Hamilton County. The first measure is how many census tracts contained at least one voucher. The second measure is how many tracts contained half of all vouchers in the county.

The second measure was calculated by sorting in ascending order all Hamilton County census tracts according to how many vouchers each tract contains. Selecting from the top of that list and working down, this measure represents the number of census tracts required to surpass half the total number of vouchers in Hamilton County.

Table 2. HCV distribution by census tract*

	2000	2005	2011
Total tracts	230	230	222
Tracts that contain at least one voucher	172	208	198
% Tracts that contain at least one voucher	75%	90%	89%
50% of total vouchers in Hamilton County	2,516	5,107	5,273
Tracts that contain 50% of total vouchers**	26	59	72
Vouchers within the above tracts	2,550	5,128	5,295
% Tracts that contain 50% of total vouchers	11%	26%	32%

*2000 and 2005 figures represent calculations obtained using 2000 census tract boundaries; 2011 figures represent 2010 tract boundaries

**When tracts are sorted in ascending order according to how many vouchers they contain, this figure represents the minimum number of tracts that contain at least half of the total number of vouchers in the county in that time period

Table 2 shows that the increase in total vouchers between 2000 and 2005 also came with an increase of dispersal in terms of how many tracts contained at least one voucher. That measure of dispersal remained steady in 2011. The number of tracts that contain half of all vouchers indicates a steady increase in dispersal throughout Hamilton County between the three time periods. So it appears that while the number of census tracts containing vouchers did not increase between 2005 and 2011, a considerable number of voucher holders moved from tracts with more vouchers to tracts with fewer vouchers. If this trend continues, it seems reasonable to expect that half of the census tracts in Hamilton County will contain half the vouchers within the next decade.

Census block groups are a geographically smaller unit compared to census tracts and thus represent a finer approach to spatial analysis within metropolitan areas. We calculated the same two measures of voucher dispersal within Hamilton County for block groups as we did for tracts. The first measure is how many block groups contained at least one voucher. The second measure is how many block groups contained half of all vouchers in the county.

The second measure was calculated by sorting in ascending order all Hamilton County block groups according to how many vouchers each block group contains. Selecting from the top of that list and working down, this measure represents the number

of block groups required to surpass half the total number of vouchers in Hamilton County.

Table 3. HCV distribution by census block group*

	2000	2005	2011
Total block groups	736	736	697
Block groups that contain at least one voucher	417	528	506
% Block groups that contain at least one voucher	57%	72%	73%
50% of total vouchers in Hamilton County	2,516	5,107	5,273
Block groups that contain 50% of total vouchers**	48	71	74
Vouchers within the above block groups	2,531	5,116	5,304
% Block groups that contain 50% of total vouchers	7%	10%	11%

*2000 and 2005 figures represent calculations obtained using 2000 census block group boundaries; 2011 figures represent 2010 block group boundaries

**When block groups are sorted in ascending order according to how many vouchers they contain, this figure represents the minimum number of block groups that contain at least half of the total number of vouchers in the county in that time period

As was the case for census tracts, Table 3 shows that the increase in total vouchers between 2000 and 2005 also came with an increase of dispersal in terms of how many block groups contained at least one voucher. That measure of dispersal remained steady in 2011, as it did for tracts.

The percentage of block groups that contain half of all vouchers indicate a trend in voucher deconcentration between 2000 and 2011. By this measure, vouchers deconcentrated modestly between 2000 and 2005, when the number of vouchers in Hamilton County doubled. This trend continued marginally between 2005 and 2011.

Almost all measures of voucher dispersal in this section indicated deconcentration between the three time periods and those that showed reversal showed it modestly. Perhaps the most interesting difference comes with comparing tracts and block groups that contained half of all vouchers in each of the three time periods. Deconcentration appears more modest when analyzing block groups, both in terms of quantity and trend. It would appear that there are a number of census tracts in Hamilton County that contained no or few vouchers in 2000, but many more in 2005 and 2011. Within those tracts, it seems that vouchers tended to locate within a relatively limited number of block groups, thus accounting for the comparatively modest indication of dispersal of vouchers amongst block groups vis-à-vis tracts over the three time periods.

Because multiple voucher holders living in the same or neighboring buildings may overlap and cluster in ways difficult or impossible for the eye to perceive when viewing a dot distribution map, we continued analyzing voucher dispersal throughout Hamilton County by calculating voucher densities. Using the ESRI ArcGIS Spatial Analyst Kernel Density tool, we created raster layers that displayed the density of voucher locations using a cell size of 500 feet, search radii of 2640 feet (half mile), and area unit of square miles. These parameters were chosen to replicate those used in an

earlier study of voucher locations in 2000 and 2005 (Varady et al. 2010). The raster layers were symbolized in classified values in terms of vouchers per square kilometer.

In addition to displaying voucher density, we identified hot spots for all three time periods. Borrowing criteria from Varady et al.'s 2010 study, we defined hot spots as areas in which the density of vouchers was equal to or greater than 110 vouchers per square mile. This value is half the greatest density found in the analysis of voucher locations from 2000. Figures 4, 5, and 6 display the voucher densities plus hot spot locations throughout Hamilton County for the three time periods.

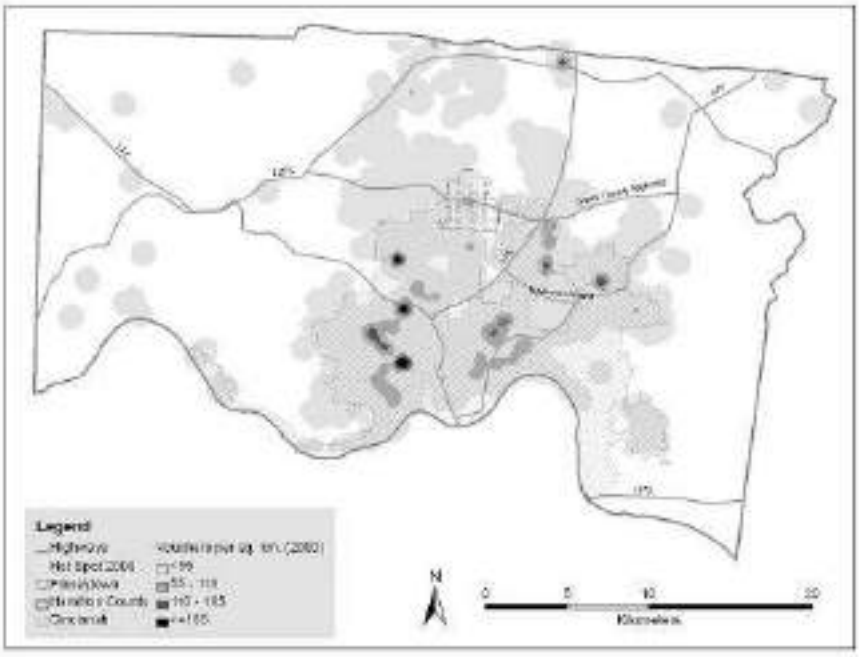

Figure 4. Raster density map of 2000 voucher holders

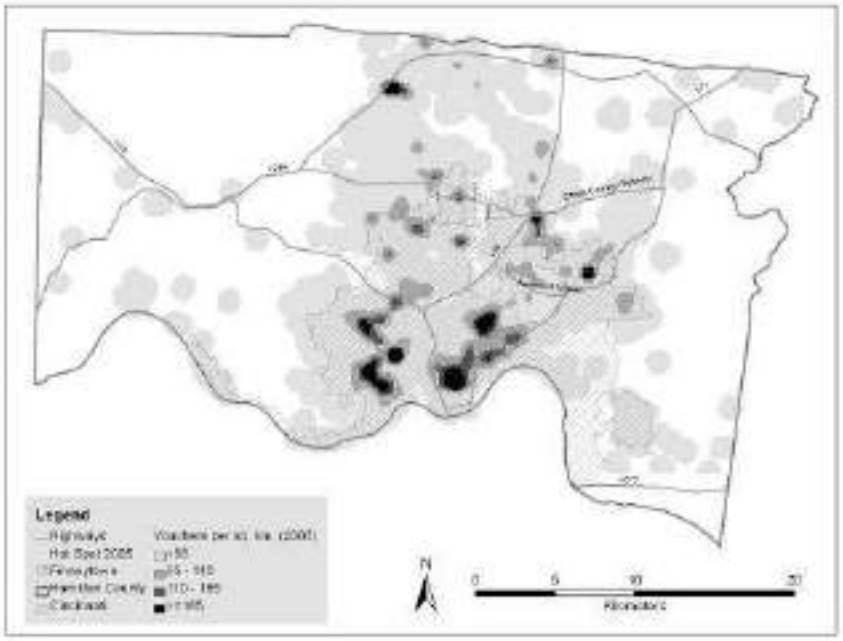

Figure 5. Raster density map of 2005 voucher holders

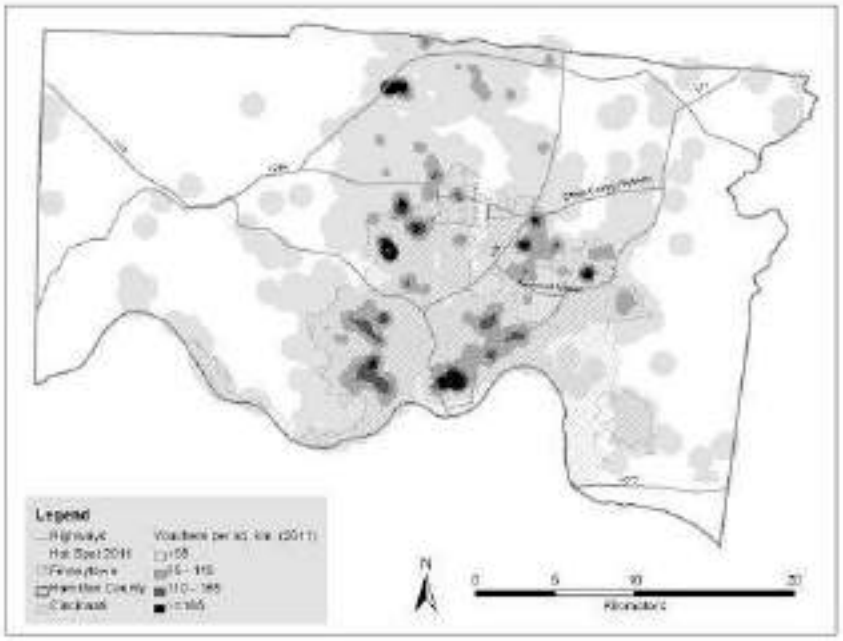

Figure 6. Raster density map of 2011 voucher holders

When the number of vouchers in Hamilton County doubled between 2000 and 2005, new voucher holders appeared to have located largely within the same sections of the county, but most notable increases in density included an area where Forest Park, Springfield Township, and Colerain Township intersect, neighborhoods on Cincinnati's West Side, and the central neighborhoods between Over-the-Rhine, Avondale, and Walnut Hills. In 2011, those hot spots on Cincinnati's West Side and central neighborhoods appear to have decreased some in size and density. At the same time, Cincinnati's northwestern neighborhoods and the intersection of Forest Park, Springfield Township, and Colerain Township all increased in voucher density.

Table 4. Hot spots*

	2000	2005	2011
Hot spots in Hamilton County	9	19	21
Hot spots within Cincinnati**	6	13	14
Hot spots outside Cincinnati	3	6	7
Total hot spot area (sq km)	3.56	19.29	16.60
Area of hot spots within Cincinnati	3.03	16.76	12.78
Area of hot spots outside Cincinnati	0.53	2.53	3.82
Max hot spot density***	223	380	407
Tracts that intersect with a hot spot	19	71	136
Block groups that intersect with a hot spot	29	142	126

*2000 and 2005 figures represent calculations obtained using 2000 census tract boundaries; 2011 figures represent 2010 tract boundaries

**Hot spots that have their centroid within Cincinnati city limits

***Vouchers per square kilometer

The figures in Table 4 suggest a complicated pattern in which voucher holders were dispersed throughout Hamilton County in the three time periods. The number of hot spots has risen, though most of that increase came with the twofold increase in the total number of vouchers between 2000 and 2005. And yet, the total area of hot spots dropped moderately between 2005 and 2011, at the same time that the number of hot spots, as well as the maximum density, was increasing. Hot spots inside and outside the city both increased by one, but the area occupied by city hot spots decreased considerably while the area occupied by hot spots outside the city increased moderately.

As part of this analysis, we counted the number of tracts and block groups that intersected with hot spots in the three time periods. We found that these numbers increased and decreased substantially based on inconsequential changes in the hot spot shapes relative to census boundary borders. As a result, we do not consider the measure of block groups and tracts that intersect with hot spots to be a meaningful calculation. The results are nevertheless included in Table 4.

Dot-based measures of voucher holder dispersal fairly consistently indicated a trend toward deconcentration within Hamilton County, though the comparison of tracts versus block groups that contain half of all vouchers raised an interesting question about

how dispersal was taking shape. The density-based measures offer a more complicated set of indications of both deconcentration as well as deconcentration. It seems reasonable to conclude, when comparing both, that voucher holders throughout the three time periods have tended to move away from fewer locations within Cincinnati to a greater number of locations around the county. However, vouchers holders are not spreading out evenly throughout the county, but rather locating within relatively few, fairly concentrated locations within and outside the city.

Finneytown, Ohio community profile

The purpose of this community profile analysis is to better understand the dynamics and background of Finneytown as a suburban community within Hamilton County. We studied the community's history, demographics, school system, land use patterns, governmental structure, transportation systems, economy, and housing stock.

Finneytown is a neighborhood within Springfield Township, most clearly defined by the Finneytown Local School District. The fact that the neighborhood is spatially defined by its school district reflects a suburban community traditionally characterized by young, middle class families with school-age children.

The US Census Bureau recognizes the Finneytown Census Designated Place, the boundaries of which are close to those of the school district. The census designated place is about four square miles in size.

Finneytown shares a border with the City of Cincinnati, but is about twelve miles from Cincinnati's Central Business District. Winton Road and Ronald Reagan Cross County Highway are the primary transportation facilities connecting the two.

Finneytown's built character reflects its period of primary growth between 1947 and the end of the 1970s. As an older post-war suburb, road and building configurations are auto-oriented, but more compact than newer, more far-flung Cincinnati suburbs such as West Chester in Butler County. The dominant land use is single family residential, with areas of retail along primary thoroughfares. Finneytown is traditionally regarded as a largely white, middle class suburb of primarily Proctor and Gamble and General Electric employees and their families, but recent demographic changes show a decreasing median income and growing proportion of Blacks.

Finneytown gets its name from Ebenezar Ward Finney, a Revolutionary War veteran and New York farmer who was the area's first permanent white settler and proprietor. The land area that became Finneytown was purchased from John Cleves Symmes by Finney's grandfather, from whom it was willed in 1795. Finney and his family moved to the area in 1798, building a farmstead near what would become the intersection of North Bend Road and Winton Road (Bean, N.D.).

What would become Winton Road was established by Native Americans and used by US soldiers traveling between Fort Washington (what would become Cincinnati) and Fort Hamilton (what would become the Hamilton) before Finney's arrival (Finneytown Local School District, 2004). The other early thoroughfare established around this time was North Bend Road. The intersection of these two roads formed the center of town in the early nineteenth century. Winton Road was not paved until 1926 (Bean, N.D.).

Finneytown's first school opened in 1800 in the basement of the New Light Church, but the first school building was not built until 1860. The school district was established in 1910. Shortly thereafter, the school district built the first brick school building, which later became Whitaker Elementary. The original 1915 structure exists, but is surrounded by multiple additions (Bean, N.D.).

The character of Finneytown changed dramatically after World War II from a small, independent town into a suburban community associated with major employers Proctor and Gamble and General Electric, as well as other firms in the Mill Creek Valley. In the first decade after WWII, student population in the school district increased 368%.

The school district responded by building a new high school, which opened in 1958 (Bean, N.D.).

Most of Finneytown's population growth occurred between the end of World War II and the end of the 1970s. Population growth stabilized in the 1980s. Finneytown's character began to change again at the turn of the twenty-first century as median income has begun to decrease and the proportion of black residents increase.

Table 5. Finneytown demographic profile

	2000	2009	Absolute Change	Percent Change
Total Population	13,492	13,687	195	1.4%
Median Age	38.5	38.9	0.4	---
% Enrolled K-12	23.5%	22.6%	---	-1.0%
% White	73.0%	65.4%	---	-7.6%
% Black	23.8%	31.5%	---	7.7%
% Asian	1.1%	1.7%	---	0.6%
% Hispanic	0.8%	0.8%	---	0.0%
Native Born	97.2%	97.0%	---	-0.2%

Sources: US Census Bureau, Census 2000 and American Community Survey, 2005-2009

According to the US Census Bureau, Finneytown's black population is growing and its white population decreasing, as a proportion of the total population, while total population is modestly increasing. Despite this modest increase in population, school enrollment is decreasing modestly.

Table 6. Demographic comparison

	Finneytown	Mason, OH	Hamilton County	United States
Total Population	13,687	29,354	851,867	301,461,533
Median Age	38.9	36.2	36.8	36.5
% Enrolled K-12	22.6%	24.4%	17.6%	17.8%
% White	65.4%	87.3%	71.3%	74.5%
% Black	31.5%	2.8%	24.2%	12.4%
% Asian	1.7%	6.6%	1.8%	4.4%
% Hispanic	0.8%	3.5%	1.9%	15.1%
% Native Born	97.0%	91.0%	96.0%	88.0%

Source: American Community Survey, 2005-2009

Comparing Finneytown's demographics to Mason, Hamilton County, and the US is helpful in understanding what is and is not different about Finneytown. Mason was chosen as a more recently developing middle class suburb to compare to Finneytown as an older suburb. As a suburb traditionally defined by young families and its school district, it is not surprising to see school enrollment is higher than the county and the

nation. Mason, the newer suburb, has higher enrollment, as a proportion of its population. Also indicative of its status as an older suburb, Finneytown's median age is a little older then the comparison areas.

Racial, ethnic, and native born statistics are all interestingly different among the different areas. While Finneytown is less white and more black than Hamilton County, it is considerably less white and vastly more black than Mason. However, Asian and Hispanic population in Mason is much higher, which may correspond with a much lower proportion of native born population.

The Finneytown local school district consists of three schools: Brent Elementary (K-2), Whitaker Elementary (3-6), and Secondary Campus (7-12). According to the representative from the Finneytown Civic Association we interviewed, a little less than half of the parents in Finneytown send their children to Catholic school, which include John Paul II Catholic School (K-8) and St. Xavier High School (9-12).

Single family residential is the most predominant land use and accounts for most of the residential land in Finneytown. Multifamily is largely limited to a few sections, namely Galbraith Pointe, Prince Frederick Townhomes, and a concentration of older apartment buildings on Cottonwood Drive. Suburban style commercial and office land uses are concentrated along Winton Road, most notably near the interchange with Ronald Reagan Cross County Highway and the intersection with North Bend Road. Brentwood Plaza, just north of the highway interchange, is the largest single commercial complex. St. Xavier High School and the Cincinnati College of Mortuary Science also occupy large tracts of land on North Bend Road east of Winton Road.

Finneytown is spatially defined by its school district, but for purposes of governmental administration, Finneytown is a neighborhood within Springfield Township. As a township, Springfield may not collect income taxes from its residents and must rely on property taxes to pay for public services. Since 2004, Springfield Township has administered its own zoning code. Before 2004, the township deferred to Hamilton County for this authority.

Finneytown's roadway pattern reflects the early post-war period in which it was developed. Roadways follow a hierarchical pattern, with semi-disconnected local residential streets leading to collector streets that connect to a limited number of thoroughfares. Ronald Reagan Cross County Highway connects Finneytown to Interstates 71 and 75. Winton Road is the primary north-south thoroughfare, connecting to secondary east-west thoroughfares of Galbraith Road and North Bend Road. Finneytown is also serviced by four bus lines operated by the Southwest Ohio Regional Transit Authority: 20, 41, 16, and 15X.

Table 7. Finneytown economic profile

	2000	2009	Percent Change
% With High School Diploma	24.0%	28.6%	4.6%
% With Bachelor's Degree	24.0%	24.8%	0.8%
% Unemployed	2.7%	4.8%	2.1%
% Families Below Poverty Line	4.3%	6.4%	2.1%
Median Household Income*	$64,416	$59,630	-7.4%

Sources: US Census Bureau, Census 2000 and American Community Survey, 2005-2009
*2000 Income Adjusted to 2009 Dollars

The proportion of Finneytown's population that has attained a high school diploma has increased in recent years, though the proportion of those holding a bachelor's degree has stayed largely the same. This may correlate with the increasing median age, as fewer school age children are living in Finneytown in recent years. Unemployment and families below the poverty line have increased comparatively dramatically, as median income has also decreased. These figures suggest socioeconomic decline in Finneytown.

Table 8. Economic comparison

	Finneytown	Mason, OH	Hamilton County	United States
% With High School Diploma	28.6%	22.1%	29.1%	29.3%
% With Bachelor's Degree	24.8%	31.4%	19.9%	17.4%
% Unemployed	4.8%	3.7%	7.3%	4.7%
% Families Below Poverty Line	6.4%	2.6%	10.4%	9.9%
Median Household Income	$59,630	$103,459	$65,081	$51,425

Source: American Community Survey, 2005-2009

Finneytown is above the county and US average for bachelor's degree attainment, but well below Mason. Finneytown's unemployment is higher, the proportion of its families living below the poverty line higher, and the median income much lower than Mason's. However, most of these statistics reflect better on Finneytown's socioeconomic status when comparing the Hamilton County and the US as a whole.

Nearly seventy-seven percent of Finneytown's housing stock was built between 1940 and 1969; about forty-five percent was built in the 1950s alone. These figures correspond to when Finneytown's population boomed the most. By comparison, less than five percent was built before 1940 and about nineteen percent was built after 1970.

Table 9. Housing stock comparison

	Finneytown	Mason, OH	Hamilton County	United States
% Vacant	4.1%	2.5%	13.1%	11.8%
% Single Family	88.0%	87.0%	62.0%	67.0%
% Multi-Family	12.0%	12.0%	37.0%	26.0%

% Renter-	19.5%	12.6%	37.8%	33.1%

Occupied				
Median Value	$138,100	$227,500	$146,100	$185,400
Median Rent	$873	$916	$632	$817

Source: American Community Survey, 2005-2009

The proportion of single family housing units in Finneytown is similar to Mason, but greater than Hamilton County and the US, reflecting these two communities' suburban character. The same can be said about Finneytown's and Mason's relatively low proportion of multifamily housing. Finneytown's proportion of rental housing is greater than Mason's, however, indicating that more of Finneytown's single family dwellings are renter-occupied. Nevertheless, Hamilton County and the US have higher proportions of rental housing, given Finneytown's and Mason's traditional suburban character.

Mason and Finneytown differ on the age of their housing stock, the majority of which in Mason was built since 1990, as compared to eleven percent in Finneytown. In this regard, Finneytown is similar to Hamilton County. Also notable is that Finneytown's median home value is the lowest of all four areas and Mason is the highest by far.

Finneytown presents itself as a suburban community like many others that were developed near mid sized and large cities in the early postwar period. That period is when population grew the most, the housing stock was largely built, and many of the roadways laid out. Perhaps coinciding with the growing age of its building stock and infrastructure, Finneytown's demographic characteristics are moving away from those traditionally associated with white, middle class suburbs and are becoming more like those of the city of Cincinnati. The characteristics that once defined Finneytown as a middle class suburb have been shifting to suburbs further from the core, such as Mason in Butler County.

Forest Park Area community profile

A significant suburban hot spot has formed and grown since 2000. It is located in north-central Hamilton County and traverses three different communities' boundaries - the City of Forest Park, Springfield Township and Colerain Township. Forest Park is a community with both single-family detached and multi-family attached housing. In its southwest corner Forest Park housing consists of two drives containing mid-rise apartment complexes. The nearby Ashley Woods Apartments is a multi-building apartment complex with a high percentage of voucher residents. Sevenhills, just to the east of Ashley Woods in Springfield Township, consists of single-family detached homes as well as some attached housing, and contains a high number of voucher residents. The three housing areas feed into Hamilton Avenue and Waycross Road and exist at the periphery of their respective municipalities. In fact, the entrance to the Ashley Woods complex is technically in Springfield Township. Note Figure 7 below which identifies Ashley Woods and Sevenhills in relation to Forest Park, Colerain Township and Springfield Township.

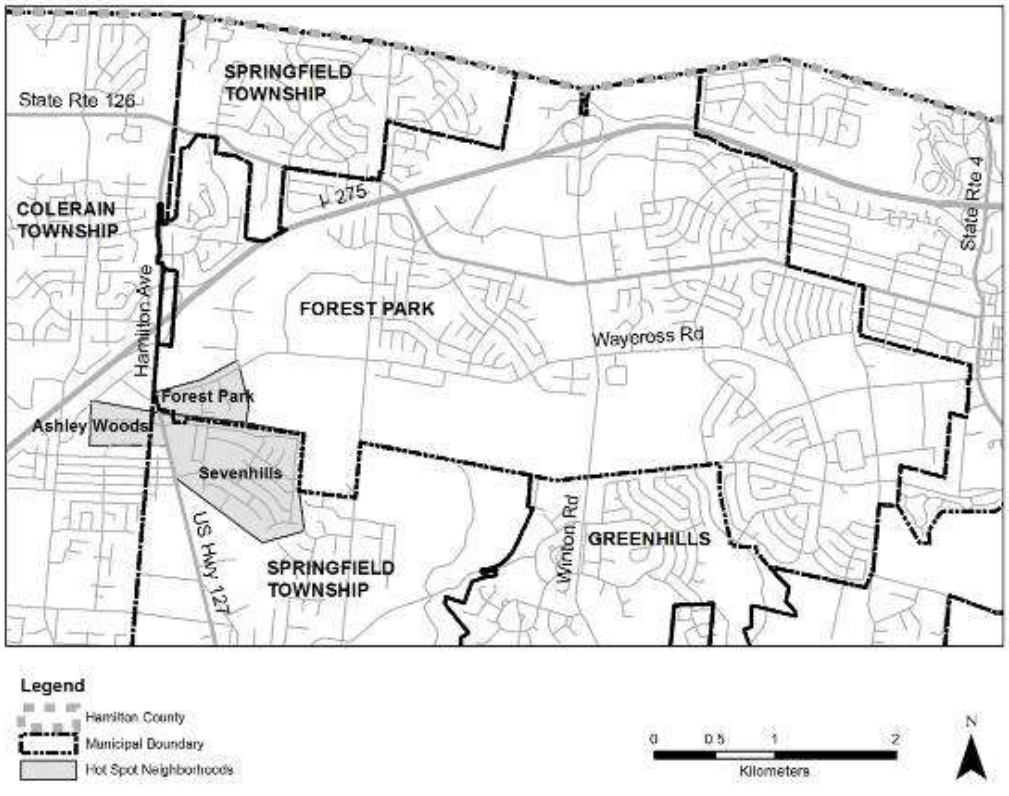

Figure 7. Map of the Forest Park area hot spot sub-neighborhoods

These three communities, and the portion of this hot spot contained within each, contain a variety of different housing types, but are experiencing some of the same demographic and population shifts. The following section first examines in more detail the historical and demographic backgrounds of these sub-communities, with an emphasis on Forest Park. It then continues with a quantitative analysis of Housing Choice Voucher distribution in the area, including changes in the number of voucher households within the hot spot, and a closer look at the progression of the hot spot since the year 2000. This hot spot exemplifies the fact that such clusters do not always respect municipal boundaries, but instead may grow around important commercial corridors or transportation nodes. The quantitative analysis will also go outside the hot spot boundary to examine voucher household numbers and density in the City of Forest Park overall. There are two reasons for an expansion of the study area to include Forest Park. First, it is a city that has experienced a significant increase in voucher households since 2005 on its eastern half, away from the hot spot location. Second, Forest Park offers an interesting history of post-World War II development into a diverse middle-class suburb. Finally, as a city Forest Park likely has greater capacity than either Colerain or Springfield Townships to respond to housing, social and economic issues. Photo images of housing in Forest Park and the area of the hot spot will also be provided throughout this chapter.

The City Forest Park is located about 14 miles north of downtown Cincinnati, connected to the greater metropolitan area by Interstate 275, which encircles Cincinnati. Today the city is governed by a city council and administered by a city manager. It has its own police and fire departments, and has a Community Development department which oversees planning and zoning, among other things. The city is divided between two local school districts - Winton Woods and Northwest (City of Forest Park, 2011).

The land which is now Forest Park was originally designed to be the greenbelt portion of a new Federally-funded greenbelt town, Greenhills, formed to the south on agricultural land (Miller, 1981). After congress passed legislation in 1949 authorizing the sale of Greenhills and other greenbelt towns around the US, the town was sold. Its greenbelt, now called North Greenhills, was bought in 1954 by developer Warner-Kanter. Zoning changes were approved to allow development and the name of the area was changed from North Greenhills to Forest Park (Miller, 1981).

Forest Park was planned by its developer from its inception to be a true community occupied by active residents involved in cohesive leisure and civic activities. The developer's target buyer was an upwardly mobile post-World War II middle class white collar worker. As a comprehensively planned community, Forest Park went through several design iterations in the 1950s and 1960s, navigating the dynamic of sometimes conflicting desires of the developer, the residents, and the civic associations and municipal government. Initially, the development was more concerned with the balance of residential, commercial and industrial than creating a socio-economic or racial balance. Additionally, despite being comprehensively planned, Forest Park was built by subdivision, and each subdivision was fairly homogenous in terms of housing price and age. Forest Park continued to grow and in 1961 was incorporated as a village. Soon after, in 1968, it reached city status (Miller, 1981).

While Forest Park began as a largely white community, between 1960 and 1970 the percentage of residents living in Forest Park who were black rose from 0.5% to 2.8%. In 1973, in response to claims of realtor's "steering" blacks to specific city

neighborhoods and whites to others, city council declared its commitment to fair housing practices. During the 1970s as the black population continued to increase in all Forest Park neighborhoods, issues of uneven integration and fears of blight became prevalent. By 1975 the black population had reached about 12% of total. Residents voiced opposition to multi-family housing and public housing, and support for larger lot sizes to accommodate more expensive homes. Public worries were expressed that blighted areas would lead to a concentrated influx of black residents and the formation of black ghettos. But during this time of change the community also recognized the right of any individual to choose to live where they pleased, and avoided setting quotas or seeking to implicitly segregate incoming populations (Miller, 1981). Figures 8 and 9 present photographs showing Forest Park residences. These are examples of typical single-family housing in central Forest Park.

Figure 8. Typical single family detached housing, along Waycross Road in Forest Park.

Figure 9. Typical single-family attached housing, Waycross Rd. in Forest Park

Forest Park is currently a city of 18,720 people. Prior to the 2010 decennial census, the city was the 3rd-largest city in Hamilton County (City of Forest Park, 2011). Forest Park's population, however, contracted by 3.8% between 2000 and 2010, shifting it from 3rd-largest city in Hamilton County down to 5th-largest. If county townships are included in the comparison, Forest Park is the 9th-largest city or township in Hamilton County, by population (US Census Bureau, 2011). Figures 10 and 11 show a multi-family apartment development in Forest Park, a development containing some voucher residents but not part of a hot spot. Figure 12 is an example of a street containing relatively large single family homes in Forest Park.

Figure 10. Low-rise multi-family apartment complex, Northland Village on Waycross Road

Figure 11. Private back patios and common yard at Northland Village on Waycross Road

Forest Park is a racially changing community. Census results suggest it has in fact become a predominately black community. In 2010 it was 24.9% white and 65% black. Between 2000 and 2010 the black population increased by 8.7%, while the white

population decreased by 11.8%. The Hispanic population increased between 2000 and 2010, from 1.5% of total population to 6.4% of total. Forest Park is also an aging community, with its median age increasing by from 33.9 to 35.8 between 2000 and 2010. Not surprisingly (considering the housing climate nationally and in Ohio) the number of vacant housing units in Forest Park increased by 5.1% between 2000 and 2010, even as the total number of housing units increased 1.4% (US Census Bureau, 2011).

Figure 12. Larger single family detached homes along a Forest Park street

Forest Park is characterized by residential districts, commercial corridors and a greenbelt, but is currently in a period of transition as new business opportunities and developments choose to locate in other places further out from Cincinnati. The community is almost completely built-out, and lacks prime developable land. The City's most recent redevelopment plan calls for a renewed focus on making vacant and underused sites more attractive for redevelopment, and the creation of individualized growth and improvement strategies for distinct districts (City of Forest Park, 2007).

The population changes that Forest Park is undergoing are mirrored in the Sevenhills neighborhood in adjoing Springfield Township. The statistics which follow incorporate not only the portion of Springfield Township within the I-275/Hamilton Avenue hot spot, but all of Springfield Township. It would have been difficult to isolate and analyze only the small portion within the hot spot, and allows for an "apples-to-apples" comparison of data from this jurisdiction with the city-wide Forest Park data already presented. The total population in Springfield Township in 2010 was 36,319, down 3.4% from 2000. The percentage white population also decreased by 11.4% between 2000 and 2010 to 55.7%, while the black population increased by 10% to 39.9%.

The Hispanic population doubled from 0.9% to 1.8%. The vacancy rate doubled as well, from 3.4% of total housing units to 6.9% (US Census Bureau, 2011).

Figure 13. Sevenhills neighborhood in Springfield Township, part of primary HCV hot spot

Springfield Township considers itself a collection of neighborhoods, and according to key informants its residents tend to identify themselves with these neighborhoods more strongly than with the township. Furthermore, Springfield Township is divided between four different school districts – Finneytown, Winton Woods, Mount Healthy and Princeton. Finneytown, an area on the southern edge of the township, is technically a school district. Yet when asked where they are from, its residents would likely claim Finneytown as their neighborhood or place of residence. It is in fact a US Census Designated Place. The Sevenhills neighborhood of Springfield Township is located in the Winton Woods Local School District in the northwest corner of the township, and the problems and issue occupying Sevenhills residents are likely not of concern to Finneytown residents (and vice versa).

The primary land use in Springfield Township is single family residential. Figure 13 shows small brick single family homes typical of the Sevenhills neighborhood. The housing stock in the Sevenhills neighborhood is predominately single family homes on small lots, and the area is seen by key informants as one in transition due to the age of the stock and a lack of investment, both factors leading to affordable housing prices attractive to moderate income families seeking to move from neighborhoods closer to the city center. Additionally, the commercial sector along Hamilton Avenue, marked by vacant and underutilized storefronts, fast food restaurants and small retailers is considered to be "in distress" (see Figure 14). The Township vision for the neighborhood includes revitalization of existing stores and homes, as well as the encouragement of light

industrial and office development in about half of the existing residential neighborhood (Springfield Township, 2011).

Figure 14. Hamilton Avenue Commercial District near Sevenhills neighborhood

Ashley Woods Apartments (Colerain Township)

Now we turn to the third sub-area, Ashley Woods Apartments in Colerain Township. The latter has a higher population than either Springfield Township or Forest Park. While its population declined between 2000 and 2010, the decrease was only 2.7%, less than in the other two communities. It has a higher proportion of white residents as well, although that is changing. Between 2000 and 2010 the proportion of whites in Colerain Township decreased by 8.9% to 78.9%, while the black population increased by 7.3% to 16.7% (US Census Bureau, 2011).

Figure 15: Ashley Woods Apartments

At the eastern edge of Colerain Township and where the southwestern corner of Forest Park meets the northwestern corner of Springfield Township is Ashley Woods Apartments (Figure 15). This gated, 352-unit complex, containing both townhomes and apartment units, provides amenities and is surrounded by woods and natural growth (Varady et al. 2010; Ashley Woods Apartments, 2011). Tthe gate remains open at all times, and there is no monitoring of who comes and goes. This development contains a high proportion of Housing Choice Voucher residents, making it a particularly interesting case of many voucher holders in a clustered area. Although Ashley Woods is under the jurisdiction of the Colerain Township Police Department, and within a primarily Colerain Township school district, its close physical proximity to both Forest Park and Springfield Township make this complex of interest to them.

Spatial analysis of voucher holder distribution: Finneytown area

Within Finneytown, we analyzed voucher holder distribution as dots and density, focusing on the following sub areas: Galbraith Pointe, Cottonwood Drive, North Hill Lane, and Glencoe. Spatial analysis of voucher holder locations within these sub areas is complemented by photographs from the April 2, 2012 windshield survey.

Figures 16, 17, and 18 display voucher holder dot distribution within the Finneytown school district in 2000, 2005, and 2011. For the 2000 and 2005 time periods, we used voucher holder location dot shapefiles produced for an earlier study (Varady et al. 2010). For the 2011 time period, we collected a table of voucher holder locations from CMHA in December of 2011, which we geocoded by address.

In 2000, seventy-seven voucher holders lived within Finneytown. In 2005, that number increased to 130, reflecting the overall increase throughout Hamilton County. In 2011, the number of vouchers increased comparatively modestly, to 153. Galbraith Pointe has accounted for a significant proportion of Finneytown's vouchers throughout all three periods. A considerable number of voucher holders also located in Glencoe, just outside the Finneytown boundary but within Springfield Township, between 2000 and 2005. Those voucher holders do not contribute to the Finneytown total.

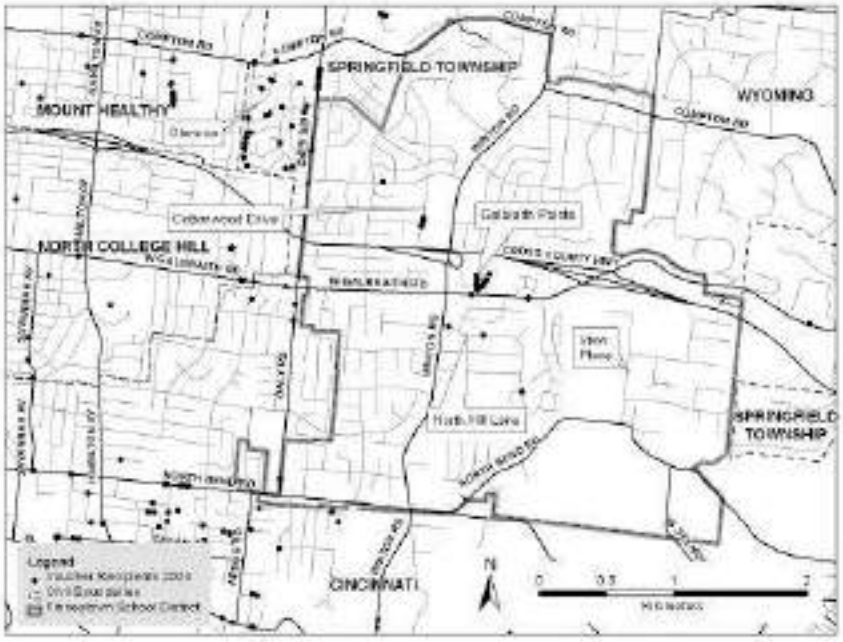

Figure 16. Dot map of 2000 voucher holders within Finneytown

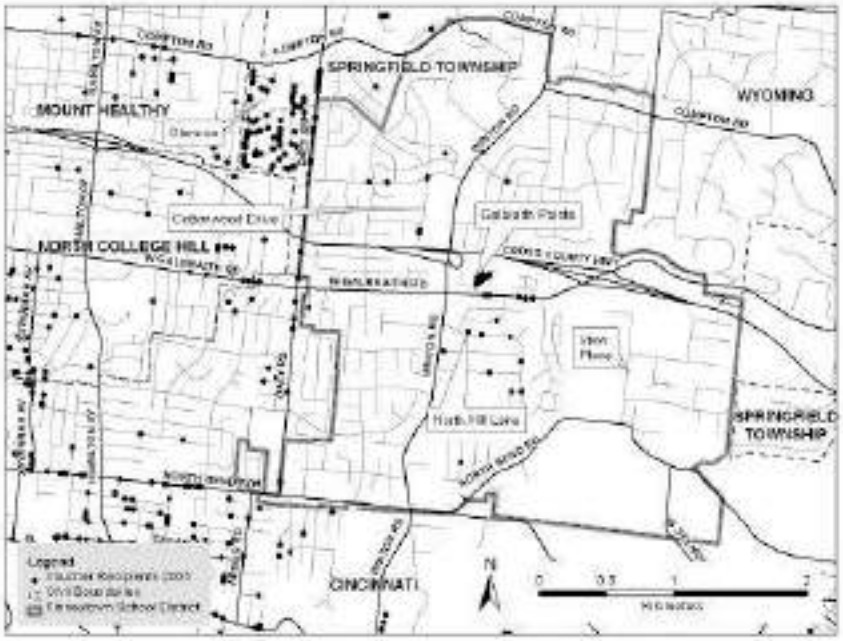

Figure 17. Dot map of 2005 voucher holders within Finneytown

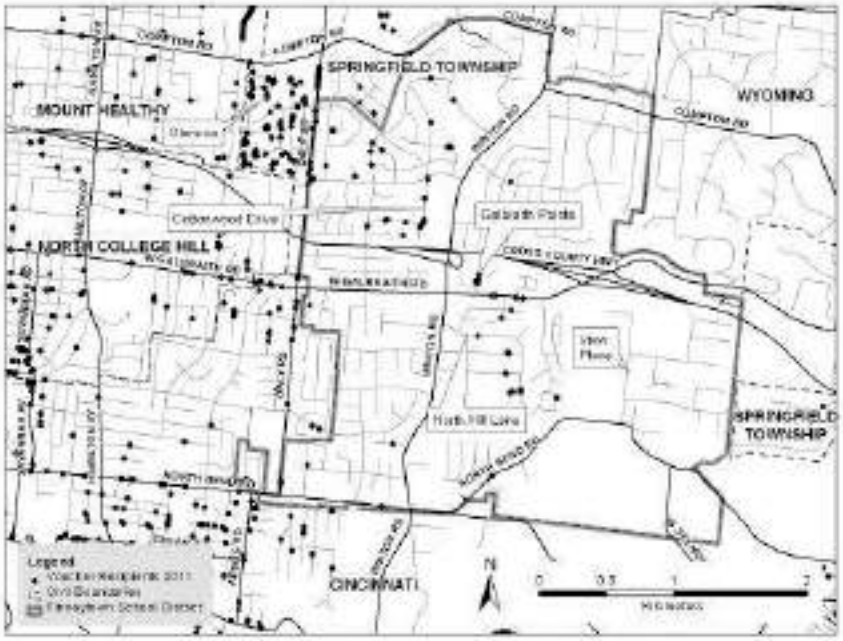

Figure 18. Dot map of 2011 voucher holders within Finneytown

After analyzing the dot distribution of vouchers throughout Finneytown, we displayed the voucher density raster layers created for all three time periods at the county-wide level. Figures 19, 20, and 21 show voucher density within Finneytown.

The voucher density analysis shows Galbraith Pointe at the center of the highest concentration of vouchers in Finneytown for all three time periods. Glencoe, just outside the Finneytown boundary, appeared as a voucher holder concentration in 2005 and 2011. The rest of Finneytown's voucher holders are dispersed enough to remain at the lowest density level.

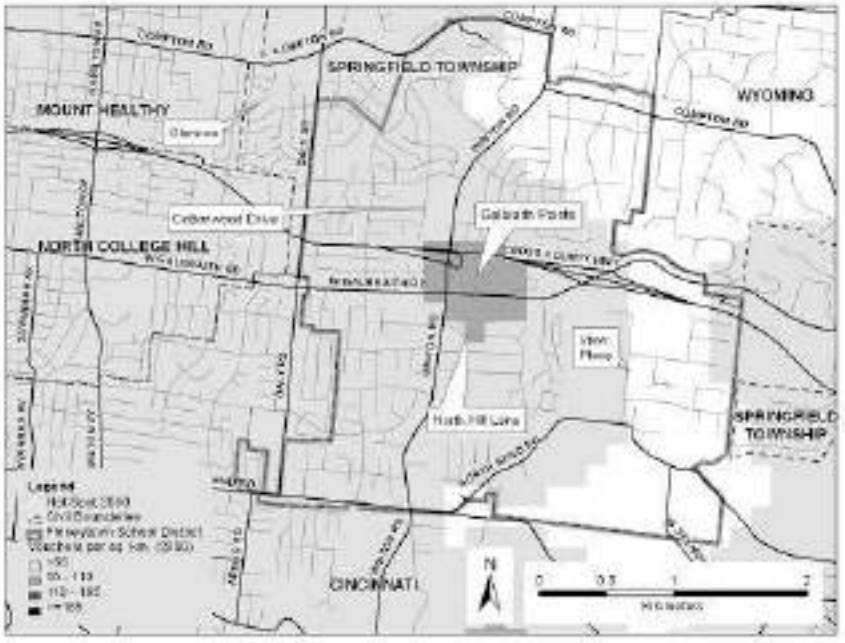

Figure 19. Raster density map of 2000 voucher holders within Finneytown

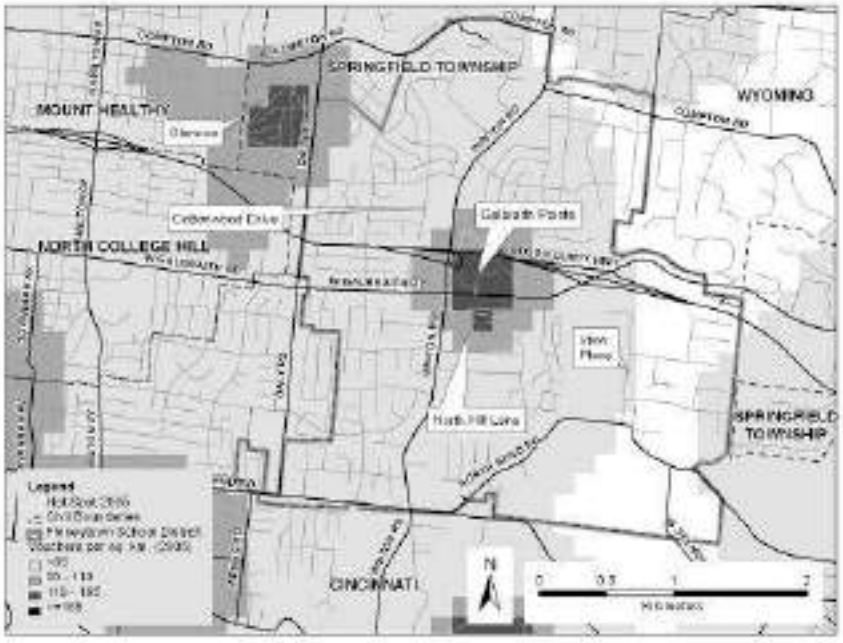

Figure 20. Raster density map of 2005 voucher holders within Finneytown

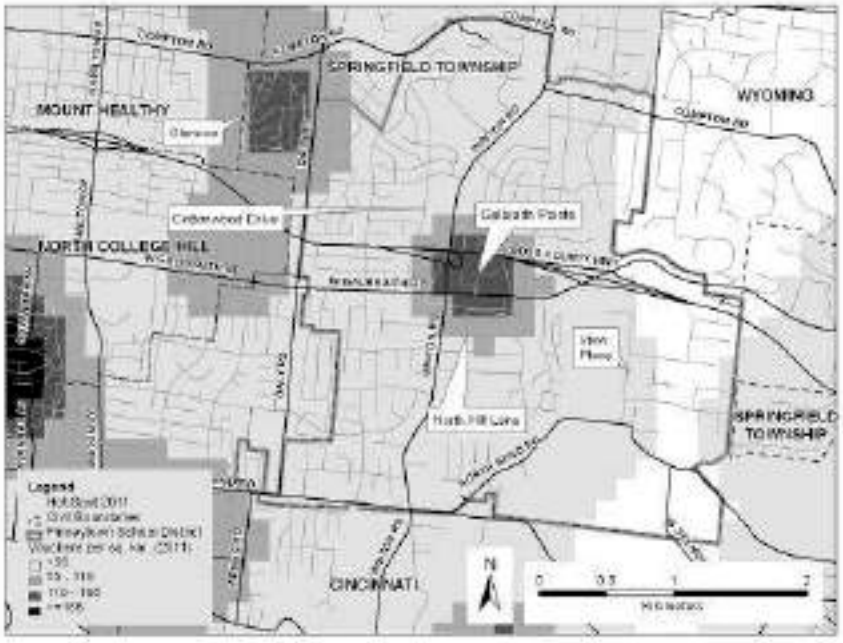

Figure 21. Raster density map of 2011 voucher holders within Finneytown

Galbraith Pointe is an apartment complex built in the mid-1990s and financed by the Low Income Housing Tax Credit. The number of voucher holders at Galbraith Pointe increased dramatically between 2000 and 2005, but decreased marginally between 2005 and 2011. In 2000 there were 55 vouchers; in 2005 there were 91; and in 2012 there were 88. Voucher holders account for the majority of this complex's residents.

In 2000, Galbraith Pointe's highest density was 86 vouchers per square kilometer; in 2005 it was 144, and in 2011, it was 139. In 2005 and 2011, Galbraith Pointe met the criteria of a hot spot.

Figure 22. Galbraith Pointe LIHTC apartment complex

Cottonwood Drive south of Hempstead Drive runs parallel to and exists behind the Brentwood Plaza Shopping Center, which faces Winton Road. The majority of the housing on this street is composed of apartment buildings, though there are a few single family houses. There are 29 apartment buildings and three single family houses that front this leg of Cottonwood Drive. In 2000, there were 8 vouchers; in 2005 there were 7; and in 2011 there were 10. At its highest proportion, in 2011, this accounted for an average of only one voucher for every three apartment buildings.

Vouchers are not evenly distributed along the street, however. In 2000, the vouchers were all located near the intersection with Thunderbird Ave. This pattern persisted in the two latter time periods, though vouchers appeared near the corner of Hempstead Drive in those two latter periods. Nevertheless, the relatively low number of

vouchers seems to belie the stereotype that the area has earned as a voucher neighborhood.

Figure 23. Apartment buildings along Cottonwood Drive near Thunderbird Ave

The North Hill Lane neighborhood stands out as one of a couple Finneytown neighborhoods with some voucher holder residents. This neighborhood includes Congresswood Lane, North Hill Lane, Denier Place, Finney Trail, and the smaller streets that stem from those streets. In 2000 there were 4 vouchers; in 2005 there were 9; and in 2011 there were 11. Locations within the North Hill Lane neighborhood appear to have changed in all three time periods and in no time period do they appear to be clustered within one section of the neighborhood.

Figure 24. Single family rental on North Hill Lane

The Glencoe neighborhood exists just beyond Finneytown's boundary, but within Springfield Township. It is roughly bound by Daly Road to the east, Compton Road to the north, and the Springfield Township boundary to the west and south. It is characterized by smaller single family homes in a suburban setting. In 2000 there were 28 voucher holders in Glencoe, in 2005 there were 82, and in 2011 there were 88. In all three time periods, vouchers were fairly evenly distributed within this neighborhood.

In 2000, Glencoe's highest density was 51 vouchers per square kilometer; in 2005 it was 130, and in 2011 it was 133. In 2005 and 2011, Glencoe met the criteria of a hot spot.

Figure 25. Single family homes in Glencoe

To summarize the results for the Finneytown area, Galbraith Pointe and Glencoe represent the highest concentrations of voucher holders within and directly adjacent to Finneytown; these concentrations increased substantially between 2000 and 2005, which is when the number of vouchers in Hamilton County doubled; and North Hill Lane and Cottonwood Drive represent comparatively low concentrations of voucher holders in all three time periods.

The Forest Park Area Hot Spot

The three dot maps below (Figures 26, 27 and 28) show Housing Choice Voucher household locations within the I-275/Hamilton Avenue hot spot and adjoining areas; that is, the entire City of Forest Park and parts of neighboring townships and municipalities. The maps represent data from the years 2000, 2005 and 2011. The dot maps indicate that the City of Forest Park experienced an overall increase in voucher families between 2000 and 2005. Additionally, a statistically significant hot spot appeared in part of Forest Park between 2000 and 2005 and thus was noted in the Varady *et al.* 2010 article. As previously mentioned, Forest Park forms only a portion of this hot spot, sharing it with the adjacent communities of Colerain Township and Springfield Township.

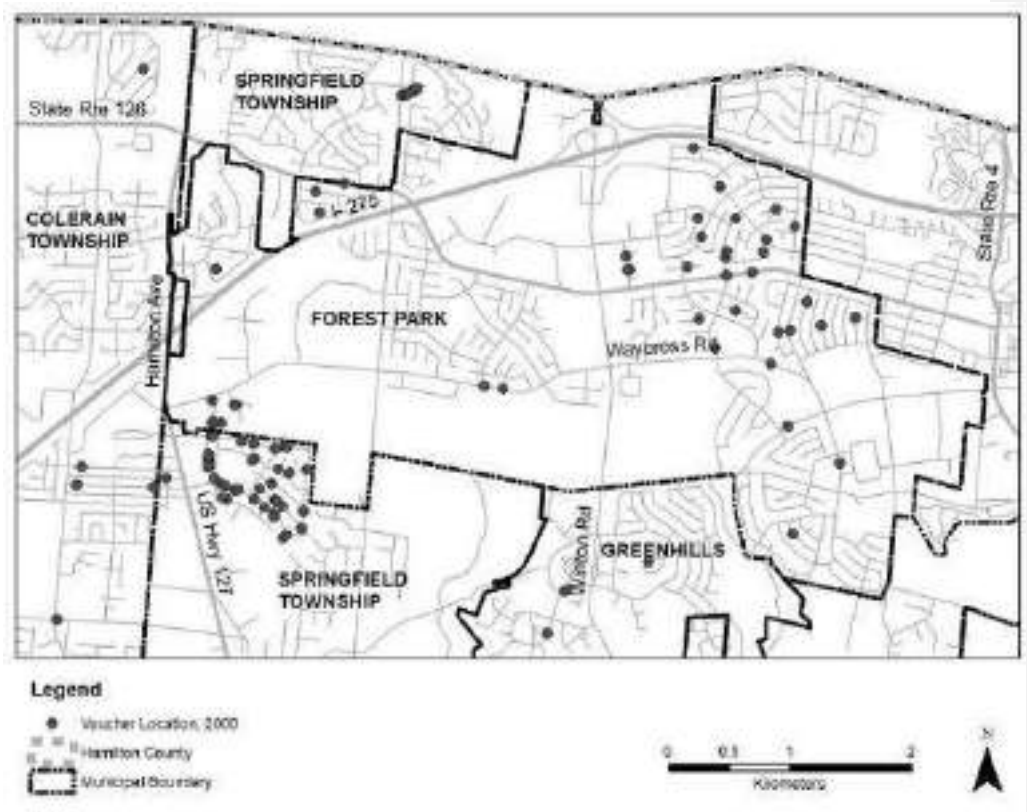

Figure 26. HCV Households in I-275/Hamilton Avenue hot spot and Forest Park, 2000

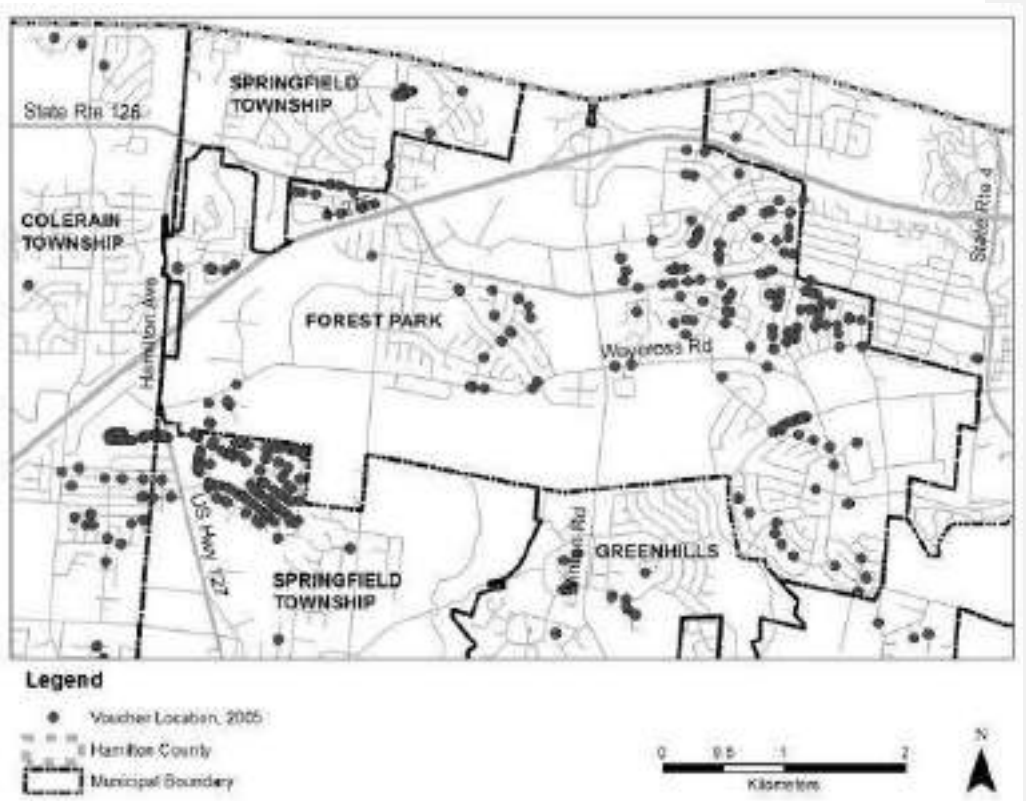

Figure 27. HCV Households in I-275/Hamilton Avenue hot spot and Forest Park, 2005

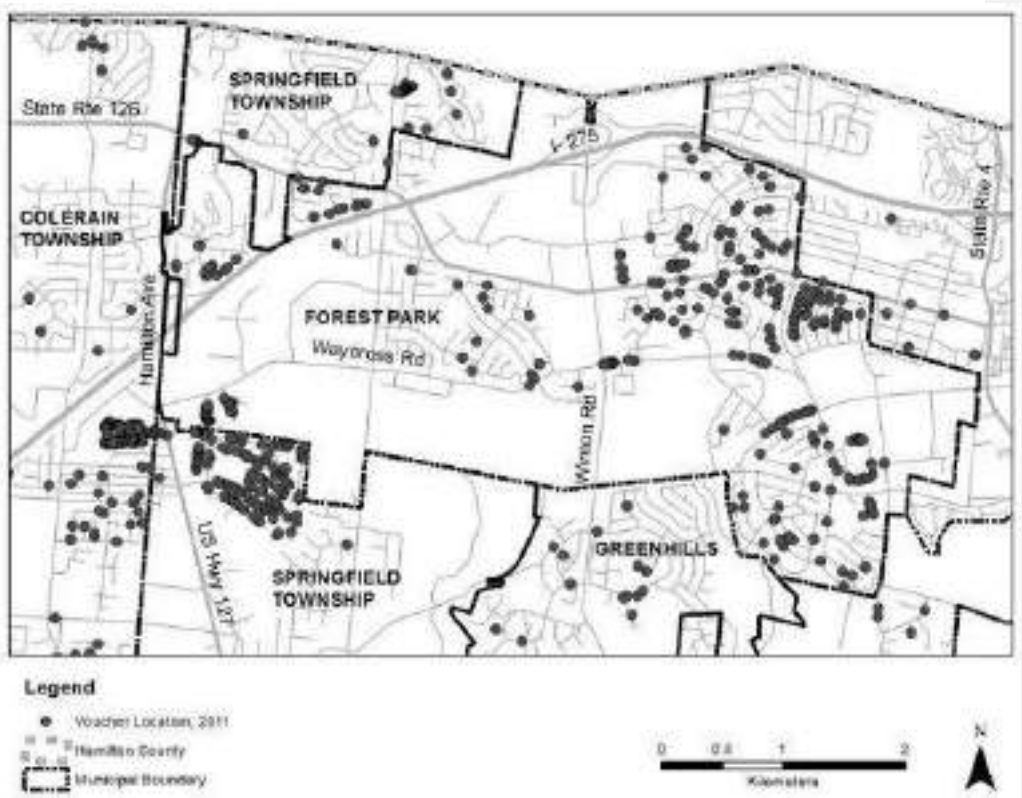

Figure 28: HCV Households in I-275/Hamilton Avenue hot spot and Forest Park, 2011

Figures 26, 27 and 28 show a steady increase in the number of HCV households in specific areas. First, the Ashley Woods development goes from no HCV households in 2000 to what appears to be a concentration of them in 2000 and perhaps an even denser concentration in 2011.

Table 10: Voucher households in study area

	2000	2005	2011	% Change, 2000 to 2005	%Change, 2005 to 2011
HCV Households					
Forest Park (Portion)	19	27	93	42%	244%
Ashley Woods	0	195	215	n/a	10%
Sevenhills	46	122	136	165%	11%
Total Within Hot Spot	65	344	444	429%	29%

Specifically, there were 195 HCV households in the development in 2005 and 215 HCV households in 2011. The Sevenhills neighborhood also shows what appears to be a steady increase between 2000 and 2011. In 2000 there were 46 HCV households, in 2005

there were 122, and in 2011 there were 136 HCV households in the Sevenhills neighborhood. In the southwest corner of Forest Park it is more difficult to see to what degree the number of vouchers has increased, but a count of vouchers in that area reveals a slight increase, from 19 to 27, between 2000 and 2005, followed by a large increase, to 93, between 2005 and 2011. Further study of the type of housing at these locations (single-family vs. multi-family), along with a hot spot analysis, will reveal the level of clustering here.

After a sharp increase in voucher households between 2000 and 2005, it appears that Sevenhills' HCV population has roughly stabilized. Ashley Woods saw a slight increase between 2005 and 2011 as well, and 61% of its units are now occupied with HCV households. Overall in Forest Park, it is apparent that the number of voucher households has increased, especially between 2000 and 2005, and especially in the eastern and south-eastern areas of the city. Between 2000 and 2011 the number of vouchers in total within Forest Park increased more than 600%. The total number of vouchers within the City of Forest Park rose from 57 to 253 between 2000 and 2005. The number rose again to 446 between 2005 and 2011. Forest Park overall saw a 76% increase in voucher households between 2005 and 2011, compared to a 48% increase within the I-275/Hamilton Avenue hot spot neighborhoods.

The previous section used numerical data to track the growth in voucher households of a suburban area of Hamilton County where a statistically significant hot spot was detected in a previous study. A density analysis of that area adds to this study by revealing whether and to what degree the hot spot has changed since 2005, and by showing additional areas in Forest Park that have seen densification. Figures 29, 30 and 31 show HCV household density and hot spot locations for the years 2000, 2005 and 2011. This density analysis was conducted using the same method and parameters as the previous county-wide analysis, and is in fact a result of that larger analysis, simply zoomed in to a larger scale.

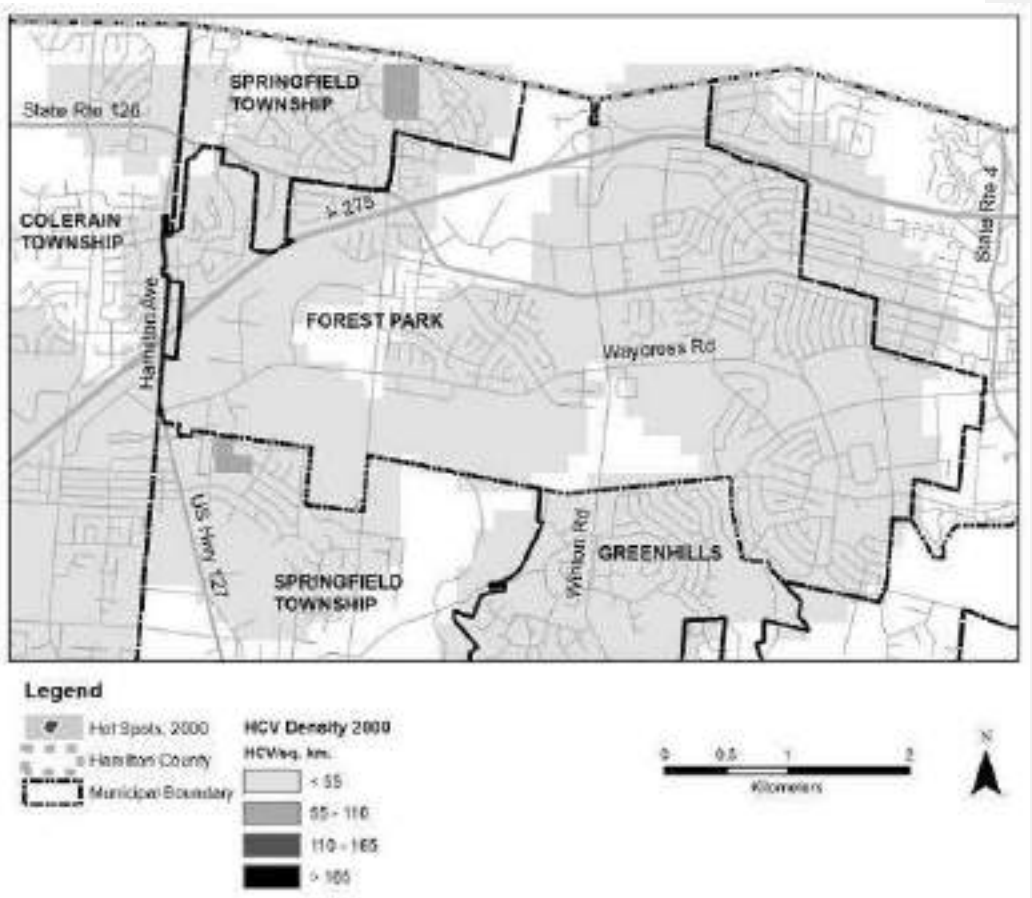

Figure 29. HCV Hot Spots in Forest Park Study Area, 2000

In 2000 much of Forest Park is at a density of less than 55 household units per sq. km. The area which will later become a hot spot shows only a small area with density higher, in the Sevenhills neighborhood. No hot spots are present in the area, but the precursor to a hot spot is visible.

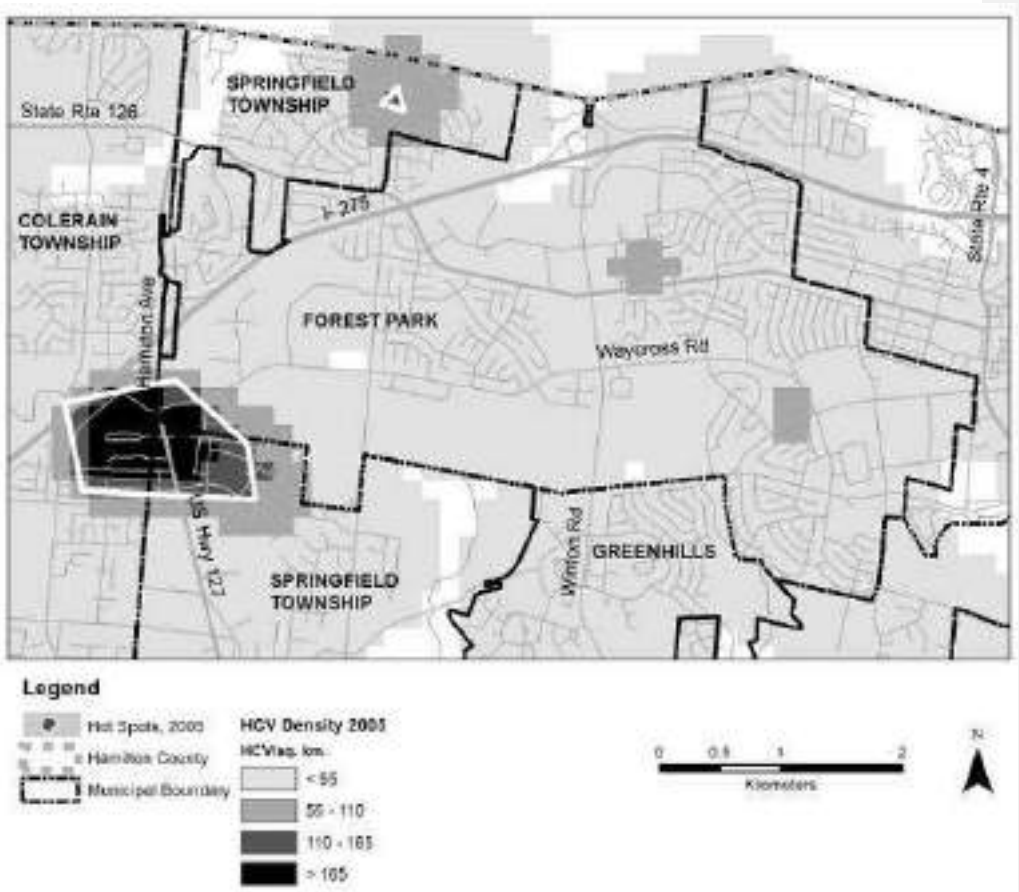

Figure 30. HCV Hot Spots in Forest Park Study Area, 2005

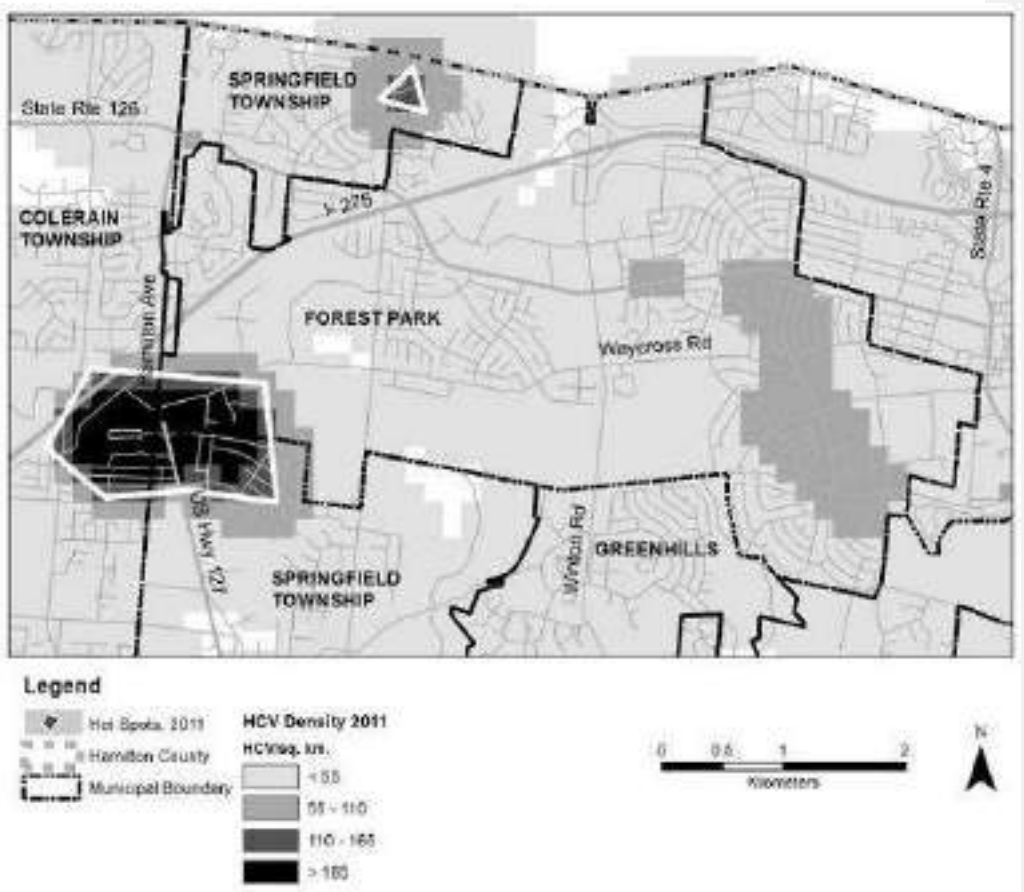

Figure 31. HCV Hot Spots in Forest Park Study Area, 2011

The change between 2000 and 2005 is dramatic. In 2005 there was a large area with a density of more than 165 HCV households per sq. km. This sharp increase came in large part from an increase in voucher households at Ashley Woods Apartments (Colerain Township). The Sevenhills neighborhood also experienced an increase in HCV density in 2005, in an area of the neighborhood of predominately single-family attached housing. An area north of Forest Park has also become a small hot spot zone. This small hot spot is in a small separated section of Springfield Township. It formed in 2005 and increased in size slightly between 2005 and 2011. In addition to a growing concentration in its southwest corner, Forest Park began to see some increasing HCV household density in two locations on its eastern side. Because of the distance between these areas and the hot spot, it is unlikely that the growth of the hot spot has induced the increase in voucher density in eastern Forest Park.

Between 2005 and 2011 the changes in HCV density throughout Forest Park, as well as within the I-275/Hamilton Avenue hot spot, were not as drastic as they were between 2000 and 2005. The hot spot has grown in area, now encompassing more of

Sevenhills, specifically areas of single-family detached housing. It also includes new areas of southwest Forest Park.

The Forest Park portion of the I-275/Hamilton Avenue hot spot consists of low- to mid-rise apartment buildings along two separate streets, shown in Figures 32 and 33 below. Two separate drives, Quailridge and Quailwood, lead off of Waycross Road and provide access to several separate apartment complexes, from one to three stories tall. Quailridge Drive is predominately brick three-story multi-family apartment buildings. At the end of a series of dead-end drives is a low-rise apartment complex with separate unit entrances. All of these structures and the yards surrounding them were in good condition during our windshield survey, reflecting responsible upkeep and maintenance. Quailwood Drive (Figure 33) was comprised of low-rise apartment buildings with common mailbox structures and private patios. The low-rise structures are unusual in the area, but due to time limitations I was unable to further investigate the development history of these complexes. Note in Figure 33 (right) the children's toys and games in the yard outside the private patio, signifying the presence of families here.

Figure32. Apartment buildings on Quailridge Dr. in Forest Park, part of HCV hot spot

Figure 33. Apartment buildings on Quailwood Dr. in Forest Park, part of HCV hot spot

Ashley Woods Apartments are of a similar form, but the complex also includes a centralized recreational and rental office facility. Figure 34 is a view of the gated entrance to Ashley Woods Apartments. There are security measures in place, such as a card scanner console and separate vehicle and pedestrian entrances, but the gate is no longer in operation.

Figure 34. Ashley Woods Apartments, “gated” main entrance

Figure 35. Ashley Woods Apartments, a gated complex and part of the HCV hot spot

Figure 35 shows the type of buildings within the Ashley Woods Apartments complex, part of the hot spot within Colerain Township. Housing types include both apartment-style (upper-right) and townhouse-style (upper-left). Also prevalent in the complex were posted signs governing acceptable behavior. The sign in Figure 35 (lower-left) reads in part "This property is protected and enforced by a curfew of 10:00pm daily for any persons under 18 years of age. This curfew is strictly enforced by law enforcement personnel." Ashley Woods Apartments overall is characterized by multi-family apartment buildings, limited access streets, fairly high quality construction, professional upkeep of the properties and rules in place to govern resident behavior[1]. A single Southwest Ohio Regional Transit Authority (SORTA) bus line, the #17, serves the Ashley Woods and Sevenhills neighborhoods. This route starts in downtown Cincinnati and terminates in a loop through Sevenhills. During weekdays the route runs every 30 to 80 minutes depending on time of day, until about 9pm, and during weekends runs even less frequently. Nevertheless, it is an important link to employment centers in Uptown and Downtown Cincinnati.

[1] It is unclear whether the curfew and rules signage was installed originally or as a response to problems. This is something we would have investigated if we had had additional time.

Figure 36. Sevenhills neighborhood in Springfield Township, part of HCV hot spot

In the Sevenhills neighborhood of Springfield Township, the hot spot encompasses an area of predominately detached single-family homes, along with some attached housing near the main thoroughfare of Hamilton Avenue. Figure 36 displays photos from the Sevenhills neighborhood. The picture at top left is of attached single-family housing in the part of the neighborhood closest to Hamilton Avenue. The other three homes shown in Figure 36, located in Sevenhills further east of Hamilton Avenue, are notable for several reasons. First, landscaping on these homes is minimal, with long grass and no flower beds. Second, these homes exemplifiy the generally small size of the homes in Sevenhills. Third, the driveway and yard of the home shown at top-right are cluttered with lawn chairs, a grill and an infant stroller. Complaints about upkeep conditions such as these were commonly heard during informant interviews. Despite landscaping and maintenance deficiencies, the homes themselves appear to be of solid and lasting masonry construction.

Other areas of Forest Park bear mentioning because, while not defined as hot spots, they do contain increasing concentrations of HCV households, particularly in eastern Forest Park. This area of densification has united two previously observed areas of increased density into a single density “corridor” along Waycross Rd. and Kenn Rd. This corridor is not part of the hot spot. It is possible in the future that this area will become a hot spot of its own.

Figure 37 is representative of housing in the southeast region of Forest Park where the voucher population has gradually densified over the last 10 years. Forest Park Apartments is a fairly well maintained project, with a portion of the land in the area developed and other areas still sitting vacant. Access to the complex is limited to three streets, none of which can be considered a thru-street or useful for non-residents. This apartment complex is similar to those seen on Quailridge Drive in terms of style of housing and limited access. In fact, Forest Park Apartments contained 25 voucher holders in 2011, compared to 68 along Quailridge Drive and 25 along Quailwood Drive. There are several factors which may be preventing Forest Park Apartments from becoming a hot spot, including the lack of dense HCV households surrounding the complex, better management, or higher average rents which allow for a more selective process for choosing tenants. Eastern Forest Park HCV households are generally fairly spread out.

Figure 37. Forest Park Apartments, low-rise complex containing voucher residents

Figure 38 shows the small detached housing in eastern Forest Park, an area that has experienced an increase in voucher residents since the year 2000. As in Sevenhills, all four homes shown are of partial or completely brick construction and of similar size, but two of them appear occupied and well-maintained, while the other two appear vacant and less well-maintained. Note the “For Sale” sign in the yard of the home shown top-left. Also note the open-air car port on the home at lower-right, typical of homes in Forest Park and Sevenhills. This layout is typical of homes built in the 1950s and 1960s that are considered ‘downmarket’ today. The home shown in the upper-right photo likely used to have a car port, but it was converted to living space. The generally good conditions show that neighborhoods from this time period (e.g. with “slab-on-grade” houses) do not necessarily deteriorate simply because the homes do not have the latest amenities.

Figure 38. Small single family detached homes along a Forest Park street with many vouchers

Figure 39. Small single family homes on Ramondi Pl. and Rangoon Ct. in north Forest Park

While the homes shown in Figure 39 may or may not be voucher households, this area in northwestern Forest Park, north of I-275, has experienced an overall increase in HCV residents since 2000, starting with one, then eight in 2005 and 14 in 2011. The neighborhood seems to be better maintained than neighborhoods in eastern Forest Park, even though the housing stock is similar in construction and size. There is no obvious reason why this is the case.

Figure 40. Street with no vouchers in Sevenhills neighborhood in Springfield Township

Figure 40 above shows two homes along a street on the eastern end of Sevenhills which has few vouchers, and these two homes are not occupied by voucher holders. The home on the left is well-maintained and landscaped, with a carport. The home on the right is similar, but note the for-sale sign in the yard. Because of the proximity of this street to other streets with more vouchers, homes along it are likely at higher risk of becoming voucher rental properties. The "for sale" sign signals that this home is undergoing a transition in occupancy, and if a buyer is not found or the buyer is an investor, this home may be converted to rental occupancy.

Conclusion

Forest Park and Springfield Township were once considered desirable and affordable locations for working- and middle-class families as they moved outward from Cincinnati toward more suburban locations. Today, these older suburbs have ceded their most-desirable status to cities and townships located even further north, such as Mason in Warren County and West Chester in Butler County. As upper-income residents move toward more peripheral suburbs or (if they have the means) to affluent and distinctive inner suburbs such as Indian Hill and Wyoming in Hamilton County, property values in the other inner-ring suburbs decrease, making these areas both attractive and attainable to lower-income and minority populations. The changes currently taking place, such as the evolution of Forest Park into a predominantly black, middle-class suburb but one with a growing voucher population, reflect these broader trends.

The number of voucher households in all of Hamilton County has largely leveled off. The increase in HCV residents from 2005 to 2011 was much smaller than that from 2000 to 2005. In Forest Park and the vicinity, however, the increase between 2005 and 2011 remained substantial, albeit not as substantial as the in-migration between 2000 and 2005. The I-275/Hamilton Avenue hot spot expanded further into Sevenhills and Forest Park, and increased in density in Ashley Woods. While no new hot spots formed elsewhere in Forest Park, an area of increasing density is apparent in eastern Forest Park. This area has the potential to continue to attract voucher residents.

The I-275/Hamilton Avenue hot spot represents several different housing types: a gated multi-family apartment complex, non-gated multi-family apartment complexes, and

a neighborhood containing mostly detached single-family homes. In the first type, Ashley Woods Apartments, we see a highly regulated and centrally-run apartment complex, with a single gated (although non-operable) entrance and a curfew for juveniles. The second type, in southwestern Forest Park, includes apartment complexes along one or more streets in a fairly quiet and secluded area. The buildings and property are generally well-maintained and offer several styles of housing, from one- to three-story. Finally, the Sevenhills neighborhood contrasts with both Ashley Woods and southwestern Forest Park in several ways. First, it is comprised of mostly small single-family homes that have been converted to rentals. Second, it exhibits areas of landscaping and structural neglect, varying by the street and individual home. Third, it was areas such as this that seemed to present the most problems for the key informants which we interviewed. Complaints on physical conditions were minimal or non-existent for the larger apartment complexes, but were fairly consistently addressed towards single-family rental home owners and their tenants. Assertions regarding single family rental properties and larger complexes will be elaborated on in the next chapter covering key informant interviews.

Three sets of policy implications may be derived from this study. First, HCV policymakers need to develop improved methods for guiding deconcentration planning efforts by local housing authorities, such as guaranteeing the use of up-to-date census data in defining areas of low poverty concentration. Second, the U.S. Department of the Treasury, which runs the Low Income Housing Tax Credit (LIHTC) program (not HUD) needs to change its regulations so as to encourage mixed income tenancy. Current regulations provide incentives to landlords using the tax incentive to attract as many housing voucher recipients as possible. Finally, the only long term solution to the problem of voucher clustering is to increase the dispersal of rental units throughout the metropolitan area. Achieving this goal will be difficult because of zoning regulations excluding rental housing.

The aim of this paper has been explore time series trends in voucher holder distribution in Hamilton County. A companion paper examines the views of politicians, developers, housing activists and civic leaders concerning negative neighborhood spillovers (e.g. crime, property values). Nevertheless, neither of our papers examines the extent to which housing voucher clustering causes negative spillover effects.(see Galster et al., 1999 for one such study). , it does not consider spatial correlation with presumed spillover effects such as lower property values, higher crime, and lower property maintenance standards. This study also leaves many opportunities for research questions regarding the issue of correlation versus causation between voucher holders and commonly attributed spillover effects. Many studies explore causation, which some extrapolate as causation. This research could also be extended by comparing voucher holder distribution with socio-economic census data throughout Hamilton County. An examination of trends between the 2000 census and 2010 census and how these correlate with voucher distribution trends would be useful.

The Real Estate crisis and the deregulation of Territorial Planning (Land Use). The Case of the Canary Islands.

By Eduardo Caceres, Prof. Emeritus
Las Palmas de Gran Canaria University.
Canary Islands. Spain.

This text is aimed at contrasting two different aspects of the same reality of crisis.

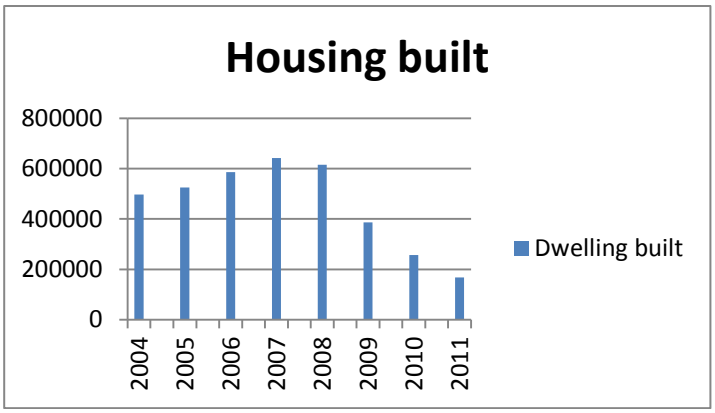
On the one hand, it examines the critical situation of the real estate sector in Spain and, correlatively, in the Canary Islands. Here, the intention is to draw out and underline the most significant indicators of the phenomenon.

On the other hand, we attempt to analyse the response offered by the public sector at the political level, through laws and urban planning regulations of a neo-liberal cut, designed, theoretically, to revitalise the building sector, in spite of the negative results given by the same in the last few years. In the Canary Islands, the justification is the rise in tourism (something which would appear to be purely circumstantial) given as the result of political instability in North Africa (the famous Arab Spring), above all in Tunisia and Egypt, the traditional competition for the Archipelago in tourism terms.

1. The crisis of the real estate sector

The bursting of the real estate bubble in 2008 hit Spain hardest (within the Euro-zone) and has been one of the major reasons for the tremendous impact of the economic crisis on the country.

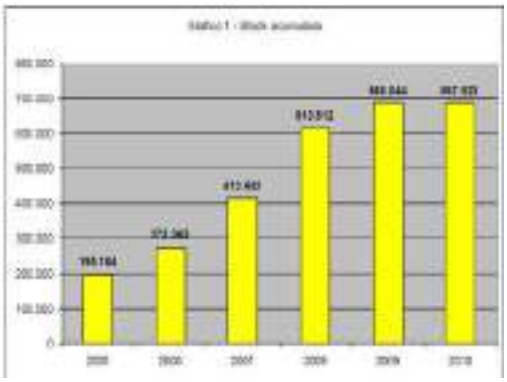
The enormous production of housing, with an annual average of approximately 500,000 units (moving from 496,000 in 2004 to 615,000 in 2008, see graph 1) has fallen off substantially since the crisis. In 2011, the housing production amounted to only 167,914, in other words, a reduction of some 70%.



Graph 1. Housing built by year.

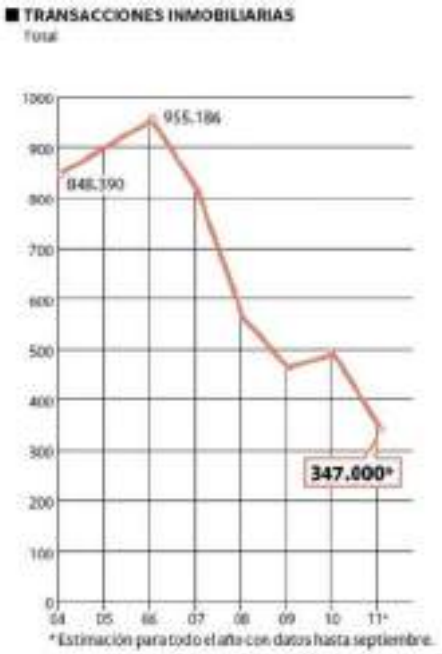
Similarly, and over the same period, unemployment in the building sector has risen from 6.06% in 2005 to 23.49% as it stood at the end of 2010.

As far as demand is concerned, the total lack of consumer potential on the part of the population has led to the economy contracting significantly. The falloff in GGDP has created a stagnated pool of some 720,000 unsold houses, above all in Catalonia, Valencia and Andalusia in percentages that range between 15% and 19% of the total stock of housing in the region. (See graph 2)



Graph 2. Housing pool by years

Logically, real estate transactions fell from 955,000 in 2006 to 347,000 in 2011 whereas land sales dropped from 23,566 in the first term of 2004 to 3,456 in the third term of 2011 (see graph 3).

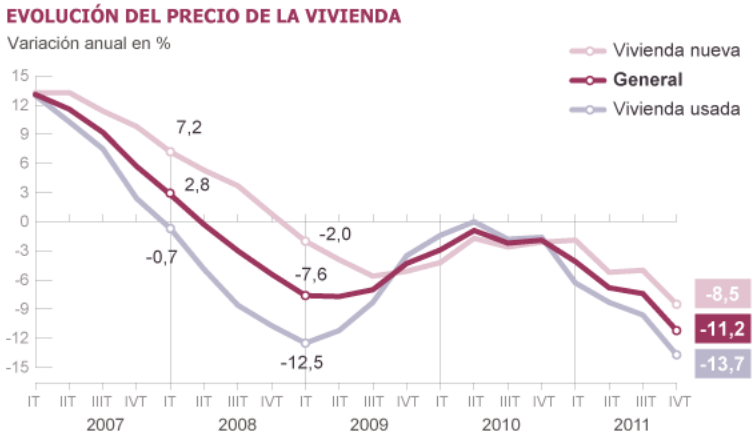


Graph 3. Real estate transactions

With respect to mortgages on houses, the market fell off from its peak of 1,342,171 operations in 2006 to a total sum of 188,339,112 Euros, to 409,337 operations en 2011 amounting to a total of 45,825,188 Euros even although the Euribor (the inter-banking loan

interests that directly impact mortgages and are passed on by the banks to the owners) moved from 5.393 %, in July 2008 to more normal levels, 2.004 % in December, 2011.

However, the price of new housing did not fall so dramatically. After a brief downward turn in 2007 and 2008, with an inter-annual variation of -6%, prices rose again from mid-2009 to the end of 2010. This has not meant, however, that the downward turn has been checked since in 2011, there was an inter-annual variation of - 8,5%. The average price per square metre has fallen from 2,905 Euros in 2007 to 2,376 Euros in 2011, in other words a decrease of 18%.



Graph 4. Evolution in house prices

This last trend is basically financial in nature and has to do with the de-capitalisation of the banking sector. The "Eurogroup" has imposed re-structuring and re-capitalisation of private banks on various States, imposing an iron hand to eliminate all trace of 'trash assets' while attempting, at the same time, to scaffold national deficits. However, these selfsame banks have been fiddling the books by including housing evicted as the result of unpaid mortgages as 'healthy assets'.[1] The banks have no interest in putting these properties on the market at their real market price because they would suffer as a result of the reduction of the value of their assets, making them eager, therefore, to keep prices as high as possible.

The outcome of this financial strategy is the stagnated pool of unsold houses because the prices remain much higher than the consumer power of the potential demand, without even giving further consideration to the part played by the rigorously stringent controls on credits given for house purchases.[2]

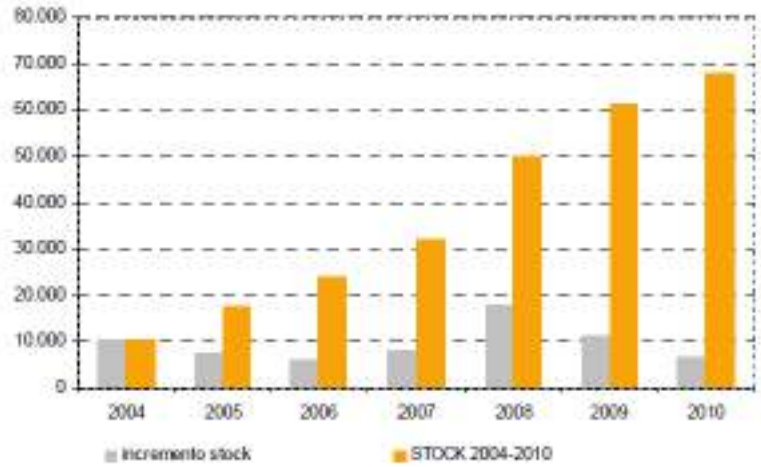
[1] Bear in mind that according to the data offered by the Consejo General del Poder Judicial (CGPJ or General Legal Jurisdiction) as published in 2011, the number of Spaniards implicated in some form of eviction due to failure to pay the mortgage amounted to a historical record 16,464 in the second term of the year, 21.2% more than for the same period the previous year.

[2] The family and company debt with financial entities in Spain went down by 0.3% and 0.2% respectively in November 2009 as compared to the same period in 2008, according to official data

2. The crisis in the Canary Islands

The situation in the Canary Islands is not significantly different from what is the picture at the national level, but rather more concentrated over certain aspects.

Between 2004 – 2010, the number of unsold houses rose progressively to 67,672 units, representing 4.9% of the national total.



Graph 5. Stock of houses in the Canary Islands

In the above graph 5, we can see how, in the period between 2004-2010, the number of finished houses has progressively grown more than the number of houses sold, giving rise, thus, to a large pool of unsold housing.

This is the result of two different trends. First, the purchase of new housing has fallen back more severely in the Canary Islands than in the rest of Spain as of 2006. And, second, the housing sector continued to build on a consolidated basis through to the maximum reached in 2008 in the Archipelago as opposed to 2006 in the rest of Spain.

In any case, and in both examples, the shift with respect to new housing can be seen with greatest clarity in 2009 and 2010.

The data with respect to 2011 confirm this trend. In the Canary Islands, at the end of the first term, there were 60.8% unoccupied houses, less than in the same period the year previous, and 46.9% less house sales.

However where the severity of the crisis was truly confirmed with respect to the economic crisis was the labour market. According to the data relating to the Survey of Active Population (EPA in Spanish) for three years back, the number of people employed in the building sector in the Canary Islands was 113,200 (data from the second term of 2008), a figure that fell in recent times to 48,600 (second term of 2011).

---

of the Bank of Spain. Spanish families' debt with the financial entities amounts to 908,272 million euros, situating it at values similar to the levels of June, 2009.

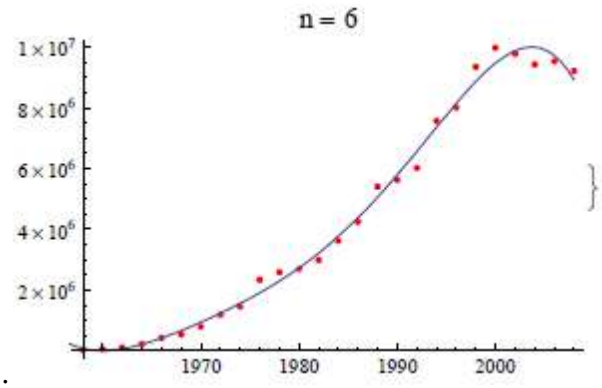
This loss of 64,600 jobs means that the workforce in the building sector has reduced 57% in the last three years, in other words, that three out of every four persons has lost their employment in the building sector.

It is also important, in this sense, to highlight the cutback in demand, also linked to the restriction on credit.

For the first time in many years, in 2010, the rhythm of advance credit given by the deposit entities in the Canary Islands was under the GDP (that is stagnant). And although this trend is barely to be noticed at a national level (with very few regional exceptions), in the Canary Islands, the Canary Islands is where the descent is most to be noted.

3. Conditions in the tourist sector.

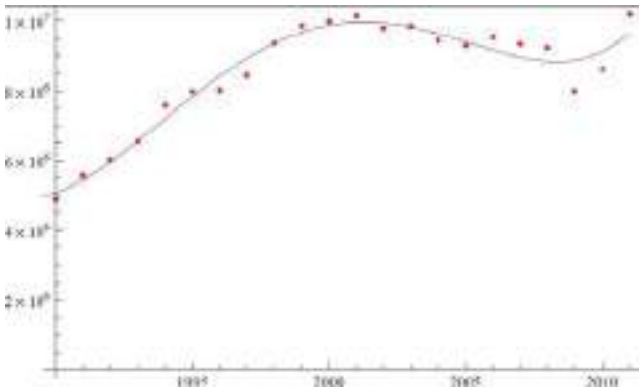
Tourist demand in the Canary Archipelago has undergone exponential growth as of the Sixties in the past century when Three 'S' tourism really took off only to fall significantly at the beginning of the century, partially due to increased consumer demands for personalisation together with changes in attitudes towards contracts (a reduction in package contracts, the impact of low-cost airlines, access to internet and changes in consumer control etc.,) besides a certain obsolescence of the product on offer



. **Graph 6. Evolution of the tourists in the Canary Islands between 1960-2010**

There is the generalised sensation that Butler's Life Cycle is being given in that, after a period of relative stagnation, there has been a notable fall-off. Numerically, the demand has fallen by 21% between 2000 and 2009. (In 2001, the numbers of tourists received were 10,137,202 whereas in 2009, the numbers amounted to 7,982,256)

However, and contrary to expectations, in other words, that there should be a direct correlation between the fall in tourism numbers and the economic crisis, something which began to be patent as of 2008, the last few years have produced an unforeseen renaissance of the tourist demand.

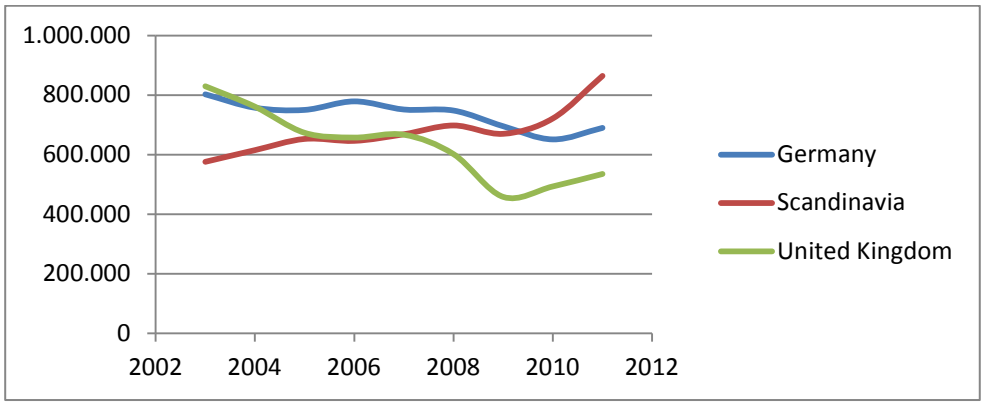


Graph 7. Evolution of tourists in Gran Canaria 1990-2011

Between 2009 and 2011, tourism increased by 27%, climbing back in the last year to a sum total of 10,182,997 tourists in the Canary Archipelago as a whole.

The question is how to analyse the direct causes of this phenomenon.

First and most evident is the re-routing of demand from North Africa (especially Tunisia and Egypt) to alternative destinations. Turkey, one of the main competitors, also received a significant increase in demand in 2011 with respect to 2010, around 9%. Egypt crashed catastrophically: in the first term of 2011, it lost 45% of its tourist numbers, dropping from 3,363,325 tourists to 1,894,044. The same occurred in Tunisia that lost 54% of its tourists in just one year.



Graph 8. Incoming tourists (Gran Canaria) by country

However, the question is much more complicated. If we look at the demand by outgoing tourists (country), we can observe, in the case of Gran Canaria, in particular, the following trends:

The fall in demand of British tourists, around 40.5% between 2003 and 2010, with the most sensitive point between 2008 and 2009 of around 23%, reversed if only slightly, picking up 8%.

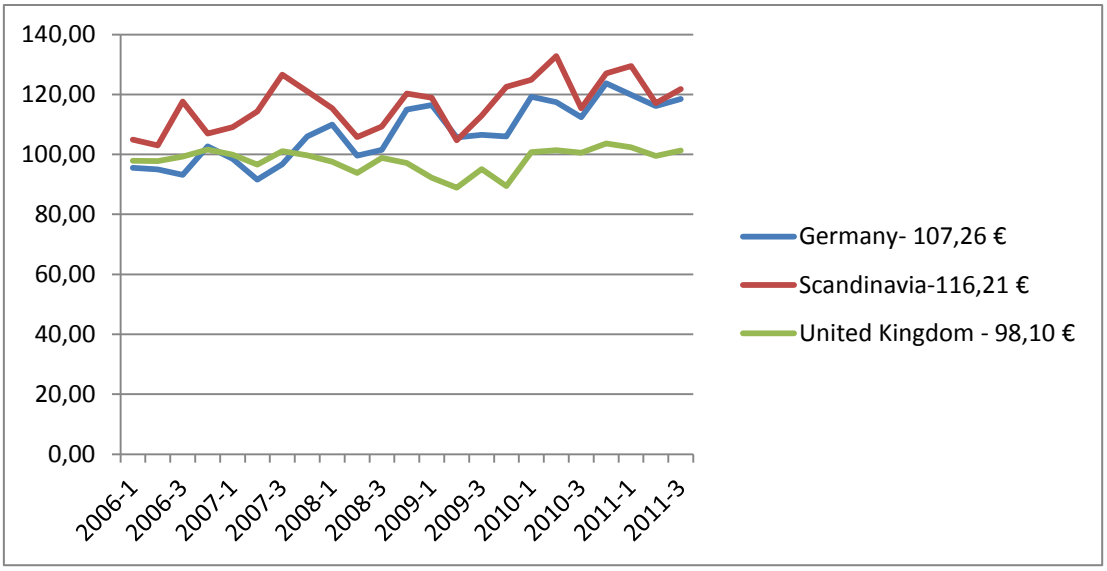
A similar trend occurred in the case of the German demand that first fell between 2003 and 2010 over 18% (five percentage points less than the British demand) only to pick up timidly, advancing 5%.

However, what was most spectacular was how the Scandinavian countries have behaved, increasing constantly to 288,440 from 2003 with over 20% of the increase between 2010 and 2011, outstripping easily the British and the German.

Year	Germany	Scandinavia	United Kingdom
2003	802,403	575,789	829,381
2004	757,347	614,999	760,897
2005	750,032	652,625	673,143
2006	778,681	646,120	657,221
2007	751,364	668,303	666,763
2008	747,869	697,811	601,529
2009	695,246	669,773	457,987
2010	651,021	721,425	493,150
2011	689,642	864,229	534,947

Table 1. Tourist arrivals at Gran Canaria by year and country

Likewise, the average outlay per consumer was highest among the Scandinavian tourists between 2006 and 2011, standing 8.3% ahead of the Germans and 18.4% more than the British.



Graph 9. Average outlay per tourist and country (term) 2006-2011

The last significant piece of data is that the number of foreign tourists who took their holidays in their own holiday homes, or with family and friends, rose between 2001 and 2007 from 9.48 million to 13 million. However, it began to fall in 2008 and, in 2010; there was an accumulated falloff of 4% according to Frontur, as a result of the economic crisis.

4. The legal response

In 2001, the Government of the Canary Islands passed a decree[3] whereby it was forbidden to give licences to build more tourist accommodation for, at least, three years except in specific cases of luxury hotel complexes and rural tourism. Later, in 2003, the **Directrices Generales de ordenación del territorio y del turismo (General Guidelines for Territorial Organisation and Tourism)**[4] were drawn up, designed, as outlined in the preamble to the law, to achieve a more sustainable and lasting model of development of tourism for the Islands, that would be more environmentally friendly and more apt to preserve natural resources, be they cultural or territorial, in search of greater social equity and greater distribution of economic wealth.

However, the pressure of the real estate sector never let up and, taking advantage of legal loopholes, they managed to build up a further 54% between 2000 and 2010, with an increase of 70,000 hotel beds although, as they themselves were frequently heard to say, "there is a bloody freeze on tourism building". This increased accommodation was built despite the fact that over these 10 years, tourism dropped off over 13.5% with average hotel stays down 12%.

[3] Decree 4/2001 (12th January), Autonomous Government of the Canary Islands on Suspension of Planning and Licences in Tourism planning,

[4] Law 19/2003, (14th April) whereby the Guidelines for General Land Planning and Yourism Planning in the Canary Islands were passed

Since the crisis set in with a vengeance in 2008, the government began to talk about the possibility of establishing 'emergency measures' to get round or dismantle the legal obstacles in favour of regulations designed to give "efficient" use to the available land.

These modifications were given weight in 2009 thanks to two laws (passed as emergency measures) that were to reform both the Law of Territorial Organisation ("Ley de medidas urgentes en materia de ordenación territorial para la dinamización sectorial y la ordenación del turismo" The Law of Emergency Measures in the field of Territorial Organisation designed to dynamise the sector and to order tourism- May 2009), together with the Law on Tourism ("Ley de Modificación de la ordenación del turismo en Canarias" The Law of Modification of Territorial Organisation for Tourism in the Canary Islands - April 2009).

The crisis had created, apparently, significant restrictions on real estate investment and, as a result, on employment, blamed by the promoters on the bureaucratic restrictions created by planning laws and regulations.

The surprise factor appeared in 2009 when tourist demand began to pick up notably as we have already said. The Government saw that there was a window for consolidating the reform measures and presented a draft bill for the **Armonización en la Ordenación Territorial y del Turismo (Harmonisation of Territorial Organisation and Tourism)** in 2012.[5]

Apparently, the Draft Bill was an attempt to respond to the extended idea that the complex regulations in the field of territorial organisation of the Islands translated through into grossly slow-moving red tape for the approval of planning documents, above all, urban planning, in the last few years, all of which, together with the difficulties involved in land promotion and investment by the economic agents, made it a requirement to dilapidate the present Law of Territorial Organisation[6].

Logically, the fact that the System of Land Planning in the Canary islands is a complex structure is significant in that it produces a convergence of five different levels of administrative authorities: European, State, Autonomous, Island and municipal, each of which contributes its different laws, norms and regulations to the sector, making it abnormally complicated to manoeuvre.

The hypothetical harmonisation now publicised by the present government is characterised by two main technical differences: some of the matters are regulated directly by the draft bill itself (territorial systems, buildings outside the norms, environmental assessment, biodiversity and organisational guidelines) whereas others were modified by the laws in force.

One of the most significant contradictions of the text of the law hinges on the fact that, despite the reiterated official declaration of the need to move towards socio-economic development without consume of land, therefore prohibiting any re-classification for tourist ends, the law establishes a procedure to do exactly the opposite. It allows for new plots to be classified for tourist activities or for re-classification of existing plots to the same end simply on request to the requisite town council or via an island report or, as a last resort, via a governmental release or parliamentary resolution, with no other caps than the load capacity established under the island plan.

The most important effect is on 'rustic' lands. In other words, all plots considered to be 'rustic' (plots not apt for building on, by it special condition of agricultural land) through "rural" land (likewise, not apt for building upon except by express modification). In the same way the potential rural plots for development (apt for support infrastructure) and plots under development in progress, until such time as the urban development determinant of its classification is completed, may be considered 'urban' (apt for development).

[5] Canary Official Gazette (BOCA) 2012 (16th Mars)

[6] Decree 1/2000 (8th May) of the Rewrite of the Text of the Laws for Territorial Organisation in the Canary Islands and the Natural Areas of the Canaries

Besides, all plots classified as 'consolidated urban plots' (with infrastructure) and 'unconsolidated urban plots' (without infrastructure) were likewise considered to be in a basic situation of development (apt to be built upon).

The general category of 'apt for development' was also extended to 'rustic land in rural settlements' (small villages and hamlets with agricultural land) that could be subject to development plans, in direct contradiction to the rural consideration afforded to all rural land in the preamble to the regulation.

Working along the same lines, the so-called 'territorial environmental systems' were created by way of rustic areas to be assimilated into general urban development systems. The substantial difference is that the owners of the general systems are expropriated and compensated for the loss of their property that then becomes public property to be devoted towards public uses. However, in this case, the owners of the territorial environmental systems maintain their property and only commit to upkeeping traditional systems of agricultural production and to respecting rules of usage and building.

Thus, and due to the land falling within the boundaries of a rural settlement or next to the same, the owners have the right to build 1 m^2 for every 50 to 100 m^2 plot when the land is inside the settlement and every 500 m^2 if outside the same.

This determination introduces a 'law' for building on rustic plots which does not fit inside any State or Autonomous legislation, where the law is limited to specific activities for the agricultural use of the land, in line with its classification and recommends legitimisation for any activity or work outside the same.

This is a concept diverse of the systems of property used in Spain, as in France, that cannot be partially transplanted by an autonomous ruling on territorial organisation that violates their logic and the state ruling on the matter.

However, independent of this attack on the preservation of 'rustic' plots, the government has prepared another law on 'renewing tourism' that eliminates the restrictions on five-star hotels on consolidated urban plots and modifies the incentives, by using the excuse of promoting rehabilitation of obsolete tourism accommodation on offer.

The incentives, moreover, offered by the Autonomous Government to promote rehabilitation of obsolete accommodation, were modified, presumably to move fast forward with the initiative begun in the last few months of 'Tourism energisation'. Among the incentives enumerated, there exists the possibility of increasing building potential while reducing the number of new beds built to substitute obsolete accommodation on offer. There is also an incentive with respect to density, that is, the square metres per bed required in a building to be renewed.

The Executive also covered all the suggestions made by the business sector within tourism such as the possibility of broadening the rural hotel potential and second home systems, in other words, of top quality villas and chalets on tourist plots.

First and foremost, the new law is directed at sustainability in time, without establishing limits to that time, thereby signifying that the Government assumes the responsibility for changing or suppressing the decree o incentives and criteria for building new tourism beds.

5. Conclusions

From all of the foregoing, we can conclude that the political movements are aimed, albeit subliminally, at dismantling progressively and legally all of the basic regulations with respect to organisation and preservation of territory. Beginning with the Guidelines that represent the

basic regulations to be referred to, and continuing with the Law of Territorial Organisation and Tourism Planning because the Canary economy is based on the service sector, predominantly on tourism.

In other words, it is not a matter of modifying the current laws either structurally or conceptually, after a period of serious reflection but rather we are contemplating partial modifications via orders and special clauses that end up perverting and emptying the present laws of all their content and meaning.

Should we admit that in a reduced and fragmented territory such as the Canary Islands, the preservation of rustic territory in general and agricultural land in particular should be one of the basic objectives of sustainable territorial planning, allowing for future generations to enjoy an essential natural resource capable of sustaining a quality lifestyle (an inherent quality to all distant islands such as are the Canary islands), then it becomes obvious that the question takes on a significantly critical profile.

However, the political powers that be continue to advance down the road of devastation of agricultural land, via Projects for Territorial Action that can only be put in place if they have an agricultural end.

The criteria of simplification and harmonisation presumably at the root of the Draft Bill to which we have made allusion are not sufficient to stem the total divorce with the limits on territorial use included in the principle of territorial sustainability and rolled out by the Organisational Guidelines.

The increased incentives for building in the tourism sector, moreover, with the excuse of necessary renovation of the tourist accommodation on offer is a mere cover for the real possibility of increasing building potential and land consumption that can only lead to surplus offer and, thus, obsolescence in the mid-term.

The euphoria produced as the result of the rise in demand produced over the last two years is nothing if not deceptive. This is purely circumstantial, as we have already made manifest. Therefore, support for liberal and unbounded building and occupancy of scarce territorial resources will only reproduce the results of the falloff in demand in 2000.

THE SOCIAL LIFE OF MOBILITY ENVIRONMENTS

Ileana Apostol [1]

Abstract

This is a position paper regarding the social dynamics of mobility environments associated with inner-city high-speed rail stations (HSR). This paper aims to complement the place dimensions in previous related studies that consider the stations as node and place, through spatial explorations of their social life. To this end I present briefly two analytical methods regarding people's use of the place and the everyday life rhythms, and propose to collect this type of information in a distributed, collaborative manner, which may include planning experimental courses. Including the provision for social life in decision-making processes for railway stations development is a measurable parameter of spatial quality that can indicate city's potential success in the global marketplace.

1. Introduction

The inner-city railway stations and their immediate proximity represent strategic locations, which typically concentrate development efforts on their attributes as transportation nodes, and as landmarks within the urban fabric. Historically the stations have been important urban "gates" opening to the broader region and leading toward foreign destinations. Recent redevelopment strategies of the areas at the railway station often address the aspirations of globally connected local economies and real estate markets. However, the railway stations need to receive more attention as socially constructed spaces, and because they mobilize large public budgets, among tangible public benefits should be also the improvement of their potential to accommodate public life. The necessity of social exploration becomes more critical for important locations like the surrounding areas of high-speed rail (HSR) stations, due to their national importance, increased accessibility, a particular space-time dimension including Castells' (2005, 2010) space of flows - space of places relation within the globalization process.

In this paper I propose to include the provision for social life in decision-making processes for railway stations development, as a parameter of spatial quality. The paper is part of a European research project (PORTA) that explores the social dynamics associated with inner-city railway stations in three cities along one of Europe's west-east axis stretching from the Atlantic to the Black Sea. Through this project I aim to formulate a synthetic view of the social life in the public spaces of

[1] ETH, Zurich, Switzerland - iapostol@ethz.ch

trains, and in and around the stations, which are called “mobility environments” (Bertolini and Dijst, 2003). The stations chosen for spatial exploration through field participant observation are the three Parisian stations that are currently destinations of international HSR (i.e. Gare du nord, Gare de l’est and Gare de Lyon), and the central station in Zurich (i.e. Hauptbahnhof) that receives HSR from France (TGV) and Germany (ICE). From the expertise with HSR networks development and stations urban integration in Paris and Zurich I derive lessons for future development of the central station, Gara de nord, in Bucharest.

At urban scale there is documentation of various planning initiatives to integrate railway transport and land use development at station area, either in urban regeneration and redevelopment projects in Europe (Bertolini and Spit 1998, Joseph 1999, Pol 2002, Bruinsma 2008), or in transit oriented developments (TODs) in the USA (Calthorpe 1993, Cervero 1998). In context Bertolini’s node-place model (1999) put forward an analytical framework that may be applied to urban regions, and also at specific stations’ location, in order to provide some insight in the urban dynamics between rail transport and adjacent urban activities and land uses. Along with the facilitation of the redevelopment process, an initial purpose of applying in practice the node-place model is “the realisation of the potential for human interaction at and around public transportation nodes” (Bertolini 1999, p.201).

Why is the spatial quality of rail station areas important? Or even why shall we consider rail stations as urban places at all? First, nowadays the vitality of the inner city is seen as a measure of the city’s potential success in the global marketplace (Castells 2005), and that can be influenced through the location and development of dynamic inter-modal transportation nodes. Second, such nodes like HSR stations are capable to represent the city as an interface between the global and the local scale. This is especially so, if one takes into account the transformations that fast train connections bring into the travel patterns, and into the present conception and future use of HSR stations and their surrounding areas, which is similar to that of the airport districts (e.g. *Gares et connexions*: Rol-Tanguy 2011, Duthilleul 2010, Amar 2010). In this case, the rail station and its adjacent developments may be the only local destination of foreign travelers. So having the potential to represent the city’s image projected to the world, the place qualities of these developments play an important role in shaping the city’s identity. Moreover, if the location is closer to the city core, often the space of the railway station becomes a city’s extension that creates unique opportunities for social exchanges, a place where locals can connect face-to-face with the larger regional and global context brought about by the commuting others (e.g. Zurich Hauptbahnhof).

Due to these symbolic transformations within the urban fabric, and in light of the stations’ importance also as transport nodes within the rail network, in this paper I propose to introduce in the analyses of railway stations as nodes and places, some urban design perspectives that complement their place dimension. In the following sections I present briefly a few possible methods toward such spatial explorations

that require, rather than removed observation and analyses, direct engagement in travel situations. The research findings may complement the node-place model, for instance, by means of participant observations of the spatial practice and associated temporalities. While the knowledge acquired from such analyses has the potential to inform in detail the development process, and also particularize it according to these findings, the main research challenges reside in the scientific formulation of the ambiguities, vulnerabilities, and the ephemera associated with such spatial explorations. Eventually, the PORTA project outcomes may add an important missing link between the spatial quality of railway stations, and infrastructure networks development and spatial planning.

This paper is organized in four parts. First I exemplify a spatial analysis method that helps to identify design choices for shaping "good places", which is based on people's use of space (Whyte 1980). Second, after structuring a place-based perspective, I make a concise overview of the nature of space and place, to advance a temporal perspective on the dynamic places like HSR railway stations. I present the concept of place in parallel with the node-place model (Bertolini 1999), in order to suggest some possible complementarities that stress on an urban design perspective of places. Third, I mention briefly a few characteristics of rhythm-analyses, as the method to be used in deciphering the temporalities of mobility environments. Fourth, I conclude with the perspectives of grass-roots deployment of these types of spatial explorations to generate collective images of the place, which may be further employed in the development processes.

2. The social life of mobility environments

Understanding thoroughly how people use and also would like to use the space of the mobility environments requires empirical research of human behavior in these urban settings. There are a few examples of such comprehensive and cross-disciplinary studies, for instance in the French language, the various related studies of authors in the edited volumes by Isaac Joseph (1996 and 1999). This body of work implied analytical frameworks from anthropology, sociology, political science, or geography, in addition to planning and urban design methods. In the planning processes grounded in the people's use of space, field research should be the starting point of future design and development, as advocated by scholars like Kevin Lynch and William Whyte.

In the classic work on the people's behavior in small urban places Whyte (1980) emphasized also the possibilities for action. Accordingly the social life observed by field participation became the basis for re-thinking the New York City zoning ordinance. By way of analogy, this study may be relevant to the case of mobility environments through evaluations of the main spatial elements observed in the field: 1) access and linkages, 2) uses and activities, 3) comfort and image, and 4) sociability, in the manner that the New York based *Project for Public Spaces*

developed Whyte's initial categories. The first two categories of variables are relatively similar to those considered in Bertolini's node-place model that aims to understand the nature of change between the mobility flows and urban activities. However, the last two categories of variables, which imply more affective, emotional and phenomenological aspects, are strongly related to the social construction of places. From this perspective the framework provided by Whyte's study brings to light some additional aspects that may explain the spatial quality of railway stations.

Besides its interest within the rail networks and at the urban scale, the railway station is for the community also a focal point in the neighborhood. So the place qualities of the station can be analyzed inside its premises as well as in its urban proximity. As a "place in the city" Bertolini and Spit (1998) defined the station as "All the built and open spaces, together with the activities they host, contained within the perimeter designed by a 'walkable radius' centred on the railway station building, as amended to take account of case-specific physical-psychological, functional-historical and development features" (p.13). In this study the authors take into consideration a 'walkable radius' of 700 meters from the main pedestrian entrance of the railway station. They propose four conventional manners to delimit the area around the station (i.e. the walkable radius, functional-historical elements, topographic, a development perimeter), but because none of them seems sufficiently flexible, Bertolini and Spit suggest as best solution the interplay between these four dimensions.

In a more bottom-up fashion and drawing on the experience of space, one may identify the limits of the railway station surrounding area as Lynch defines districts (1960) through the edges, landmarks and paths that have the potential to give hints regarding the spatial organization, and the structural framework that people refer to while navigating the space. After delimitation of the study area, let us return presently to the application of Whyte's analyses to railway stations, by means of four key qualities that make places successful.

2.1 Access and linkages

During this step the information may be gathered through empirical research, and completed from the related literature. Concerning the station accessibility I propose to structure the analyses according to two categories of variables. One category refers to the railway station premises and concerns elements like a) opening hours (e.g. the stations in Paris in Zurich close during the night between 1.00am/1.30am and 3.30am/4am, while the main station in Bucharest is open 24 hours/day), b) street entrances, c) fences (e.g. the opening of Zurich Hauptbahnhof toward the city versus the more enclosed spaces in Paris and Bucharest), d) inclusive access (functioning for everybody including people with special needs), e) signage and paths for navigating the station and f) inter-modality. The analysis of inter-modality in this case is similar to the node-content (or the accessibility of a node) in Bertolini's node-place model (1999, pp.201-203), which takes into account the intensity and diversity

of transport supply, and combines accessibility by various transport modes (i.e. train, bus, tram, underground, car, and bicycle). A special note regarding the Parisian pair stations Gare d'Austerlitz - Gare de Lyon is that the first inter-modal transport node materialized at Gare d'Austerlitz by building a stop of the metro line inside the station main hall (1906, see APUR 2006), and that at Gare de Lyon in December 2011 was inaugurated a station of the shared electric cars (autolib').

The second category of accessibility variables refers to the city and neighborhood linkages, as included in the area of study. Many inner-city historic railway stations benefit from the proximity of a planned neighborhood, which was conceived around the station as the main landmark (e.g. Zurich Hauptbahnhof, Gare de l'est and de Lyon in Paris). As a consequence nowadays the station premises receive a public function for the local community, whose access can be stimulated through other uses than those related to travel (see below the paragraphs on uses and activities). The construction of the railway station brought also the opportunity for opening a representative boulevard, allowing for convenient pedestrian access, in order to link the transportation gate with the inner-city (e.g. Bahnhofstrasse in Zurich, Boulevard de Strasbourg in Paris). But this is not always the case, and a famous example of lacking a representative connection with the city core is Gare du nord in Paris, due to the impossibility to execute the required land expropriations for a boulevard development during the Haussmannian reconstruction of Paris (refer to Bowie 1999, Sauget 2009).

2.2 Uses and activities

The uses and activities of the mobility environments may be recorded through participant observation, from the point of view of the occurring users of the place, and of the type of activities existing in the area of study. Regarding the users presence in the current phase of railway stations evolution, it may be, or not, related to rail travel. Hence a first question to be asked while observing the place is whether people use this public space besides passing through either a transportation node as travelers, or through this node within the urban fabric as passers-by. If there are additional uses to the mobility environments, it is interesting to look for signs of diversity (e.g. range of ages, individuals or group clusters, variety of purposes like walking, eating, relaxing, people watching, reading, playing etc), to identify the parts of the space used, and if there are some noticeable patterns. Note as a difference in comparison with traditional places, there is seldom outset design of stations as "nodes" in Lynch's term (1960) that means a gathering spot, rather the intention being to produce fast pace and optimally fluidized circulations. Hence the pace or tempo relative to people's use of the space is to be analyzed for each case also from a design point of view (i.e. entrances, paths, signage, announcements, noise, lighting, public space furniture etc). As an extreme efficiency example, the number of the train platform is published in the French stations only ten minutes before the train departure, which produces a "controlled" node in front of the traffic displays due to

constraints on traveling crowds' use of space.

The type of activities inside and in the station's proximity are to be listed and evaluated according to their use at different times of the day and week, if they are permanent or temporary events, their accessibility, scheduling, management presence, and the like. In addition to public transportation, currently commercial activities at the station are most common, including weekly or seasonal markets like farmer's or Christmas' markets. However, operators of contemporary railway stations made choices also for non-travel related activities. For example, the main hall of Zurich Hauptbahnhof is used as a city square for all sorts of events and activities that vary in scope and scale (e.g. celebrations, manifestations of political actions, sport events etc), and the forthcoming reconstruction of Gare d'Austerlitz in Paris will provide additional space for neighborhood activities such daycare etc. Moreover, there are unaccounted for activities at the station like people watching, which through the researcher's participant observation may reveal other dimensions of the spatial qualities, shaping the character of the place.

2.3 Comfort and image

To decipher the following two groups of place characteristics, the study may be divided between a) the place's conception by professionals, b) the one-time spatial experience (i.e. first-time visitors), and the lived experience of the place (i.e. the regular user of the railway station). During the observation of mobility environments, surveys and questionnaires need to be employed, as well as interviews with the actors involved in the process of spatial production. To the information gathered from field observation, archival research can add important information regarding the institutional setting: the planning culture, the initial policies, the conflicts and constraints within the development projects, and the like. The recorded findings may be evaluated in comparison, and presented in narrative form.

As for the place's comfort and image, the field survey may be structured according to qualities such as a) visibility / obstruction of the interior-exterior space and of the navigating details, b) ease of movement and legibility (e.g. do I always know where I am and where my destination is?), c) signage and spatial borders as leading or misleading (see Joseph 1996), d) use of lighting, materials, planting and green areas, retail frontage, seating and also if there is a choice of places to sit (e.g. Gare du nord versus Gare de Lyon in Paris) e) continuity and enclosure in terms of safety, and f) stimulated emotions like feeling of arrival, and impressions such as the first impression, observing if people are taking pictures of the place, or if there are people presenting the place to others etc.

2.4 Sociability

To what extent it is interesting to strengthen the place qualities of railway stations in terms of sociability? Shall a high-speed place be conceived more as a passing-by

transitory place, or shall it stimulate conviviality? Does a terminus station have higher potential for sociability than a through station? Is this a place where you would choose to meet your friends or where strangers make eye contact with each other? Are people smiling, and talking with each other?

Of course the answers to these questions about the interactivity, diversity and friendliness of a high-speed place depend on a multitude of factors. Yet the institutional aspects of planning and development processes, and the planning culture in general, play an important role in the achievement of the mobility environments as successful places in the city. As I mentioned in the introductory section of this paper, the railway station is a place of confluence between the others and the local community, and is capable to generally reflect the community at large. Within the railway station conception, there are design elements that can facilitate face-to-face interactions, and ad-hoc social networking, what Whyte called "triangulators". A simple example are the electric heaters placed in the main concourse of the Gare du nord or Gare de l'est in Paris, which create focal points that gather people around them, and also give the opportunity of strangers to face each other. A quality of place's sociability is to make users feel comfortable to interact with strangers.

The design elements related to rail travel like traffic displays, information points or retail kiosks are potential locations for Lynch's nodes, which are "the strategic spots into which the observer can enter, intensive foci, typically either junctions of paths, moments of shift from one structure to another, or concentrations of some characteristic" (1960, p.72). The place's sociability may be improved by developing such nodes and their corresponding amenities that can work toward triangulation.

The events and activities organized on the premises and in the proximity of the railway station create as well a multitude of opportunities for social interactions. Additionally, nowadays the French rail company SNCF develops various possibilities to create opportunities for social exchanges also in the high-speed trains, through designated spaces (IDTGV) and the use of information and communication technology (e.g. SNCF apps) that can transform the quality of the spaces associated with rail travel.

3. Place qualities of railway stations

From this brief overview of the qualitative aspects that participants can observe in the mobility environments, I return to theoretical studies, in order to build a thorough understanding of their spatial nature and as particular places. On the nature of space David Harvey (2006) proposes three views namely absolute, relative and relational space, which coexist and are not mutually exclusive. In his words, the absolute space is space being a "thing in itself" independent of the matter, where time does not play an explicit role in spatial formation (e.g. the spatial view of Descartes or of Newton). The relative space arises from relationships between objects, where the temporal dimension is being fixed like in the case of the modern time of clocks and watches.

While the relational space cannot be conceived in separation from time, it is "regarded in the manner of Leibniz, as being contained in objects in the sense that an object can be said to exist only insofar as it contains and represents within itself relationships to other objects" (Harvey 1973, cited in 2006, p.271). How does the concept of place fit within this spatial framework?

In a comprehensive study for the pedagogy of place, Arefi & Triantafillou (2005) propose as teaching models four ontological constructs of the place concept, which is "less coherent [than space], maybe borderless, and can come into existence for a short period of time by dressing the urban space with a new set of visual attributes (e.g., the new Times Square)" (p.77), and "is at times unpredictable and can be understood through engagement, not through detached observation" (p.76). These four place constructs embody a comprehensive understanding of the term, 1) as a set of visual attributes, which may be identified by exploring the complexity within spatial images and syntax (absolute space), 2) as product decoded from the analyses of spatial morphology, policy making and problem-solving (absolute and relative space), 3) as process, which requires a thorough understanding of the transformative forces over time (relative space), and 4) as meaning (relative and relational space). For deciphering the construct of place as meaning the analyses should imply phenomenological, intuitive, self-reflective takes, due to the ambiguity and complexity associated with the study of values, symbols, or human experiences such as perception, emotion, desire, volition, imagination etc. Note that in shaping the image of a place, these four constructs are kept in dialectical tension while thinking through the interplay among them.

Hence what places' characteristics are we talking about with respect to inner-city railway stations? Previous studies (e.g. Bertolini and Spit 1998, Pol 2002) take into consideration the first three components of the place concept (i.e. image, product and process), and the elements defining the place-content of its area are mainly the intensity and diversity of activities associated with the railway station being. For instance, in the node-place model, Bertolini accounts as variables of the place-index, besides the degree of functional mix, the number of residents in the area, and the number of workers per each of four economic clusters namely retail/hotel and catering, education/health/culture, administration and services, industry and distribution (1999, pp.202-203). Pol chooses spatial quality as a separate element of analysis, but defines it mostly as a physical space quality "of outdoor and indoor public spaces and their integration in the environment" (2002, p.111). While these views pertain to the understanding of place that could be approached from the perspective of absolute space, the inclusion in the analyses of the process (Bertolini and Spit 1998) or only of the actors involved in the redevelopment process (Pol 2002) pertain to the city shaped of space understood in a relative manner. According to a recent analysis (Peek and colleagues 2006), a next step toward improving the node-place model is the inclusion of the synergy between the actors engaged in the (re)development process into the set of variables: "In the end, synergy between node and place features at a station area is created by interactions between the land use and

transportation systems through different spatial markets, for instance the labour market, housing market and the market for mobility" (p. 457).

In understanding places, however, the absolute and relative understandings of space do not bring sufficient explanatory qualitative features in terms of its lived experience. As places are predominantly social constructions (e.g. Lefebvre 1991), inquiries may be pursued also from the perspective of the relational space, where it is "impossible to disentangle space from time" (Harvey 2006, p.273), and where processes define their own spatial frame. In a critique of functional theories Lynch (1981) mentioned the absence of time within, as it does not "deal successfully with continuous change, with incremental actions that lead in some progressive direction" (p.39). In the 1972 study on the evidence of time embodied in the physical world, Lynch suggested the possibility of "learning to enjoy the process of change in itself; the constant reformulation of action and aim, the delight of new revelations and new possibilities" (p.211).

Moreover, in the evolution of the railway stations French sociologist Isaac Joseph proposes three phases (1999), which interestingly could be a parallel to Harvey's classification of the spatial nature (2006). There is an initial view of the station as an artifact, referring to its functional role and characteristics as absolute space (e.g. the 19th century rail stations, for which the term in French is "gare"). In the 20th century, after the development of regional and urban rail networks in conjunction with the long distance and high-speed rail (e.g. during 1970s-1980s, APUR 2007), the railway station becomes an inter-modal node-place that in French is called "pole d'échange". As nowadays these exchange poles host also other city activities, their development corresponds mainly to a relative spatial point of view. As a third phase, Joseph introduces the term "place-movement", in French "lieux - mouvements dans la ville" (1999, p.5) that is investigated from the perspective of the relational nature of space. In these latter instances derived from relative and relational spatial understandings, social space is predominant, and time becomes relevant for the changes and exchanges within social networking.

To reflect these particular qualities of space, I will use henceforth the term "high-speed place" to refer to the spatial instantiation of the railway station that Joseph (1999) calls "place-movement". On the one hand this term describes the dynamic and transitory qualities of the current development of railway stations. The railway station and its surrounding area is a prospective lived place, through its capability to inspire meaning and eventually generate attachment through frequent reiterations and formation of emotional ties, but in a different manner than "slower" places such as a "place of birth" or a "place of residence". It is rather a more hasty place of passage, mobility, and relatively rapid change, hence the name "high-speed place". On the other hand, this denomination makes a parallel with the advanced technology of the HSR, reflecting also a fast pace of change, and the overlay of multiple life rhythms. Like I mentioned in the analysis of sociability, more than a transportation mode, HSRs become mobile work-and-play spaces with high potential for socialization and

ad-hoc networking. These emergent spatial uses shape a particular lifestyle with specific rhythms that get inserted in the local spatial practice of the destination place.

What are the similarities and differences in the quality evaluation between "slower" places and the "high-speed" places? In the case of classic places Lynch put into words: "A good place is one which, in some way appropriate to the person and her culture, makes her aware of her community, her past, the web of life, and the universe of time and space in which those are contained […] sensible, identifiable places are convenient pegs on which to hang personal memories, feelings, and values. Place identity is closely linked to personal identity. "I am here" supports "I am". Intense familiarity will create a sense of place" (1981, p.142 & 132).

Indeed the railway stations' qualities in terms of visual attributes --even only for a limited period of time through the use of public displays-- together with their meaning (Arefi & Triantafillou 2005) establish them as recognizable, memorable, and even prominent locations in the city. This is the case of all the central stations studied in the PORTA project. Then in the stations studied in Paris and in Zurich, more than half of the travelers are frequent commuters. The recurrent use of rail transport turns these environments into habitual locations, where attachment may be formed through actions' reiteration and representations of the everyday life. Hence my interest in a social and temporal perspective in the inquiry of place qualities translates into advancing a relational understanding of the spatial use of inner-city railway stations and their surrounding areas as high-speed places. In the next section I make a first step toward an analytical framework based on rhythm-analyses (Lefebvre 2004) of the everyday life in the mobility environments.

4. Railway stations as vehicles of time: the high-speed places

The temporal dimension is the most important potential and constraint of the people's use of high-speed places. Why would we analyze temporalities? Maybe because of the "struggle around time and the use of time. … There is no time to do everything but every 'doing' has its time". But also because time as a social product "divides and splits itself into use and use-value on the one hand, and exchange and exchange-value on the other. On the one hand it is sold and on the other it is lived" (Lefebvre 2004, p.74). Furthermore, analyses of the temporalities associated with the mobility environments show how the location, design and operation of railway stations are capable to impact the inner city vitality.

Hence comparative analyses should take into account railway stations' changes over time within historic overviews, as well as in ethnographic accounts of the everyday spatial experience of mobility environments. The constraints of practice may not allow the direct use of these narratives, as Bertolini notes in Bruinsma (2008), "The information should be sophisticated enough to be true to the complex reality, but plain enough to be understood by those involved in the strategy development process" (p.37). So while the knowledge derived from these methods of analysis may

not always be sufficiently plain to be used within the process of spatial production, I believe it is theoretically helpful, due to its potential to shape representational spaces that appeal the intuitive and poetic imagination, and through exemplifications may turn useful also in practice (e.g. Bates et al. 1998).

In a more and more globalized world, the railway stations especially the international HSR destinations embody spatial concentrations of the omnipresent overlapping flows: capital, information, technology, vehicles, people, goods etc. In the PORTA project I look at these flows historically in cities like Paris that appear to be focal nodes (Castells 2010), and then follow their distribution and their effects in more distant locations from these centers, for example in Bucharest. There is not a simple way to include the global flows in the analyses, although it is critical to capture their impact on the high-speed places.

As a starting point, because metaphors are a powerful way to represent the complexities of modernity, for mobility environments I suggest here the combination of two metaphorical comparisons inspired from the natural world. One metaphor comes from the ocean waves and tidal rhythms (e.g. Jones 2010), with the potential to describe the fluctuations in the spatial concentrations of flows embodied in a railway station. From this perspective, a station concourse, accesses and proximity may be paralleled with recent representative waterfront developments, as a "travel front" facing the incoming and outgoing variations of embodied flows. (Note that due to the modern rhythms of clocks, this happens mostly at the edge of conscious, as opposite to the ocean symbol of the unconscious). Then the juxtaposition of another metaphor --the heart-- is necessary to imagine the integration of this place within the urban systems. While acting as "urban hearts", currently some of the main stations "pump" daily the equivalent of the city's population. For instance, the same number of travelers as city core residents passes daily through Zurich HB (~380,000), and half of the number of Paris' inhabitants travels every day through the three stations Nord, Est, de Lyon (~1,000,000), and out of these travelers, half are frequent commuters that arrive at and depart daily from the station.

Moreover, due to its dual attributes as transport node and urban place, I note the overlapping qualities of the dynamics within a central railway station and its surrounding area (i.e. transport network, people traffic for various purposes). In other words, there is a certain rhythmic vibration associated with the high-speed places that seems to be part of their dual nature, and that cannot be reproduced in other places only by design. "The everyday is simultaneously the site of, and the theatre for, and what is at stake in a conflict between great indestructible rhythms and the processes imposed by the socio-economic organization of production, consumption, circulation and habitat" (Lefebvre 2004, p.73).

Within this framework, the rhythm-analyses translate spatial theory into design practice through their capability to restore the role of the human body in the spatial production, by reinstating the sensible in modern consciousness (refer to Apostol

2007). But what do we call the sensible? In Lefebvre's words, "It is neither the apparent, nor the phenomenal, but the present. The rhythmanalyst calls on all his senses. … without privileging any one of these sensations … he does not neglect smell, scents, the impressions that are strong in the child and other living beings, which society atrophies, neutralizes in order to arrive at the colorless, the odorless and the insensible" (Lefebvre 2004, p.21).

Rhythm-analyses refers to the understanding of spatial rhythms and their practical consequences, as rhythms could be defined as forms of repetition, or movements and differences within repetition, temporal measures that bring with them "a differentiated time, a qualified duration" (Lefebvre 2004, p.78). In the study of rhythms the relation between repetition and difference is critical. Difference is something new and unforeseen that introduces itself into the repetitive, which is usually what we perceive, for instance, from an announcement through the station speakers, to the renaming of the station public spaces (e.g Gare de Lyon in December 2011), from the construction of the suburban station building at Gare du nord (1990s), to the demolition of the Seine courtyard wing at Gare d'Austerlitz (February 2012), from the murmur of a water fountain, to the noises of the traffic flow interfering with the strolling flow. There are linear rhythms defined by the repetition of the same phenomena that mostly belong to the public realm such as routines, successions, predetermined encounters, a social and civil time (e.g. morning commuting, timetables, time at the café, work time, playtime, opening hours, scheduling, evening commuting). There are cyclical rhythms that have a determined frequency and new beginnings similarly to the cosmic rhythms (e.g. seasonal changes, seasonal markets in and at the station, the succession of day and night, rituals, alternating manifestations of social organization).

Rhythmanalysis was coined first by Gaston Bachelard in *The Psychoanalysis of Fire*, (1964 [1949]) although he borrowed the term from the Brazilian writer Lucio Alberto Pinheiro dos Santos (Lefebvre 2004, p.9), who wrote in Portuguese a work on rhythmanalysis published in 1931 that was lost subsequently. Bachelard used the term as "rhythmo-analysis" in *The Poetics of Space* (1994, p. xxxiv) and developed a chapter on "Rhythmanalysis" in *Dialectic of Duration* (2000 [1950]). Toward the end of his life, Henri Lefebvre made an attempt to develop a theory of rhythms that he exposed in *Writings on Cities* (1996) and *Rhythmanalysis* (2004), in which he aimed at expanding the theory of the spatial production into an applied method. Recent studies tried to advance the rhythm-analyses from the various perspectives of practice (e.g. Edensor 2010). However, research difficulties come from the fact that the rhythmanalyst "must simultaneously catch a rhythm and perceive it within the whole, in the same way as non-analysts, people, perceive it. He must arrive at the 'concrete' through experience" (Lefebvre 2004, p.21), because only the experience of rhythms could give the measure of what is concrete/present. Hence one perceives, analyses and records moods rather than images, picturing an atmosphere rather than reporting on the particular events.

5. Perspectives

Over the last one hundred and fifty years one may observe the transformation of the inner-city railway stations, from the 19th century monumental gates toward exotic worlds or connecting the city with the countryside, into strategic urban locations, concentrating within relatively small scales some of the city's identifiable features. The recent HSR railway stations embody qualities of transportation nodes and complex urban places, which I call here high-speed places.

To build the competency of drawing implications for steering future developments, planning research needs to comprehend the multidimensional spatial practice of these particular places. Empirical research is the only way to evaluate the spatial practice, which is revealed in the association of daily reality (everyday life) and urban reality (urban discourses and practices) within the social life of the mobility environments. The comparative analyses should take into account a "thick description" approach (Geertz 1973), which places the research data in context, and at the same time contextualizes the research findings in order to explain both discourse and practices.

To this end, in this paper I make brief overviews of two methods of analysis. One is Whyte's study of small urban places to evaluate the station's potential as a successful place (1980). The other is the relatively novel method of rhythm-analyses to build an understanding of the everyday life rhythms within the mobility environments. Usually in practice there are not available budgets (i.e. time, money) to perform these comprehensive studies through engagement in observing the people's use of space and its associated rhythms. Therefore, I suggest that only participatory and distributed collaborative processes can provide this data, pointing also at experiential planning course that draw wisdom from social sciences and use the mobility environments as the spatial laboratories.

China's urban planning legislation system in transition to a resource-saving and environment-friendly development

YING Yin

Abstract:
Recent years, China targets on transiting to a resource-saving and environment-friendly development, the realization of which is largely influenced by the performance of urban planning and building area. This paper proposes to identify the situation of urban planning legislations in terms of sustainable development, and to explore the potential for promoting environmental profile in urban planning legal system. The research methods here are based on literature review, document analysis and also the quantitative and qualitative study. In the beginning, this paper generally reviews the status and structure of current legislations and regulations on urban planning. Then, this paper adopts bottom-up strategy, to exam the legal system from detailed regulations to national laws, based on the principles and standards generated from *the main indicators of low-carbon eco-city development* [1] and *practical indicators of eco-city development*[2]. These generalized baselines are extracted into references for the examination of urban planning regulations in different level. The references include seven perspectives: urban function (land use), green transportation, green building, energy production and saving, ecological environment, waste management, water supply. Finally, it proposes some suggestions on how to strengthen the integration of environmental concerns into urban planning legislation system in China.
Key words: China, environment-friendly development, urban planning system, integration

1. Introduction

The concept of 'Construct an resource-saving and environmental-friendly society' was first specified as a basic national strategy in 'The 11th 5-year plan of the People's republic of China for economic and social development' (called 'the 11th 5-year plan' for short) in 2006, and then strengthened in 'The 12th 5-year plan' 2011. To construct environment-saving and environmental-friendly society is an inevitable choice of China for long-term development. China is a country which has a large number of population but short of main resources per capita, less than a half to one third of world average level. Meanwhile, with the fast increase of per capital income of residents, the transition of consumption level and structure will cause higher pressures on resources. (China's sustainable development strategy report, 2006) Considering these increased restriction of resource and environment, it is necessary to establish an idea of green and low carbon development, build up an resource-saving and environment-friendly pattern of production and consumption, and target for ecological modernization. (The 12th 5-year plan, 2011) The proportion of energy consumption separately in industry, building and transportation is 7:2:1 (China's research council of urban science, 2009), the transition of consumption level and structure will change this distribution in future. According to experience of developed countries, building and transportation will account for a large part of energy

[1] The main indicators of low-carbon eco-city development is developed in the 'China's low carbon eco-city development strategy' as an index of eco-city planning for 2020.
[2] Eco-city in China usually means an urban districts, in which residential area is the main function, is developed or redeveloped within a strong environmental-profile to achieve low-carbon emission and energy-saving targets.

consumption with GDP growth. Thus, to reduce the pollute emission and energy consumption in urban planning and building dimensions is crucial for a successful transition to an environment-friendly development.

Research problems

In last decade, a large number of researches and practices in urban planning were made to achieve sustainable development in China, but the progress goes very slowly partly because a lack of experience, knowledge and also a based foundation of legislation and regulation system. For instance, when implementing eco-cities, the absence of environmental profile in legislations or even contradict to become obstructions in the process. As the legislation and regulation system is considered as a crucial enforce for sustainable implementation in general, it is quite necessary to integrate environmental aspects into the systems. Although, until now, there are many specific studies on legislation and regulation systems in terms of either urban planning or environment protection area, but there is few researches focusing on combining them together. This paper is supposed to fill this gap by examining the integration of sustainable concern in urban planning legislation system.

Research goal and objectives

The goal of this paper is to explore potential possibilities to promote the legislation system of urban planning towards a resource-saving and environment-friendly development. Within the goal, two objectives are proposed: 1) Exam the integration of sustainable development into current legislation system of urban planning and points out its weakness; 2) Provide some suggestions on integrating environmental requirements into the structure and contents in the legislation system.

Research questions

To reach the research objectives, the paper develops a study by answering the following questions: 1) How does the regulation systems of urban planning work now? What is the relationship among different legislations and regulations? 2) What kinds of environmental aspects could be combined in the urban planning regulations? 3) How is the existence and absence of the environmental aspects in the current system? How to improve these combination?

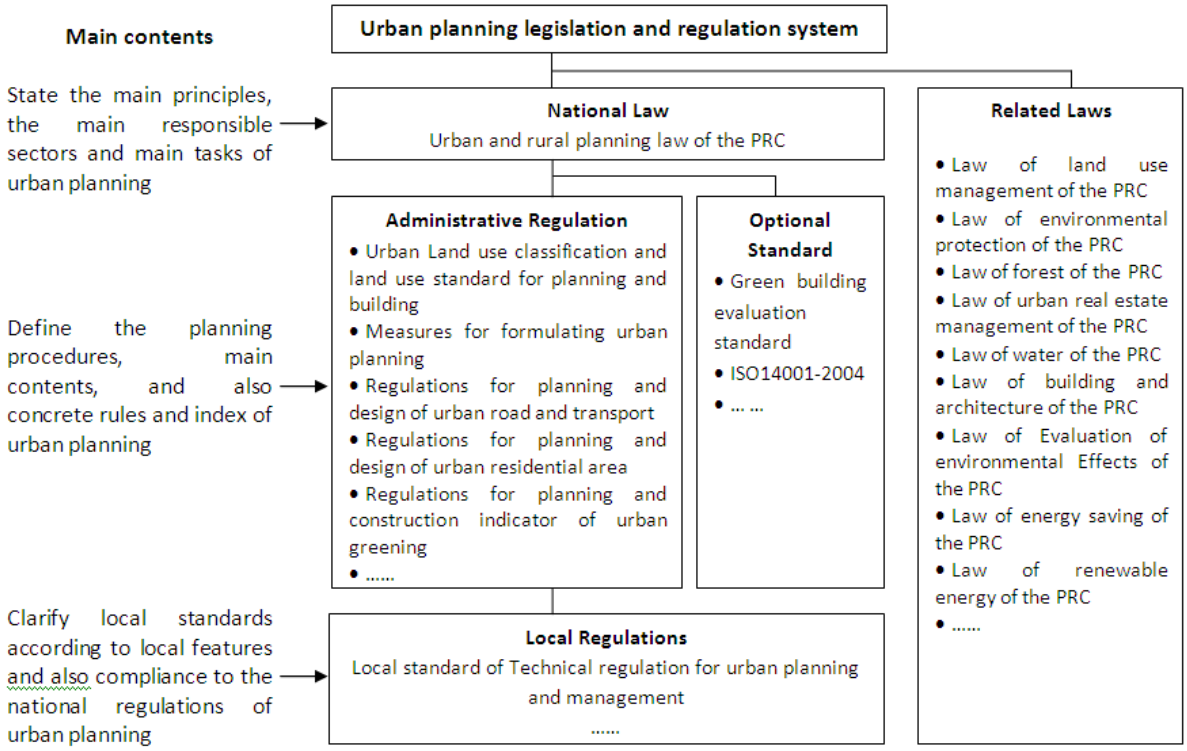
Research strategy and methods

According to two points, this paper uses bottom-up research strategy, which means exam the system from detailed regulations to the national laws according to the potential principles, standards and index, generated from *the main indicators of low-carbon eco-city development* and *practical indicators of eco-city development*. One point is that the regulation system of urban planning, including both vertical and horizontal sub-systems, is so abstract and wide-covered that it is difficult to manage the analysis from top-down. The other one is that the study should closely relate to planning practices to ensure the validity of the results. In recent years building eco-city has became a popular planning practice and important contributions to achieve resource-saving and environment-friendly development from local level. In this paper, the eco-indicator systems in two eco-cities is partly chosen as basic materials generated and extracted into references for the examination of urban planning legislations in different level. Another basic material is *the main indicators of low-carbon eco-city development* developed in the 'China's low carbon eco-city development strategy'. The references include seven perspectives: urban function (land use), green transportation, green building, energy production and saving, ecological environment, waste management, water supply. The research methods used in this paper are based on literature review, document analysis, and also the quantitative and qualitative study.

2. China's legislation and regulation system of urban planning

Urban planning system is usually divided into three parts: urban planning legislation and regulation, urban planning administration, and also the operational urban planning system. This study focuses on legislation and regulation because it works as a foundation for the administrational and operational system. In the vertical system of legislation and regulation, it contains three parts: national laws, administrative regulations and local regulations. （P_1） The main national law 'Urban and Rural Planning Law of the People's Republic of China (PRC)' was

enforced from 2008 in place of Urban Planning Law of the PRC' to state main principles, the main responsible sectors and tasks for urban planning formulation, implementation and management. The administrative regulations, for example, 'Measures for Formulating City Planning' and 'Detailed rules for Formulating City Planning', clarify the planning procedures, contents, and concrete rules and index, which direct the planning formulation, provides important basis for examining and approving urban planning results and implementation. There are also regulations in respective sector to be urban residential areas, transportation and urban green space, which provide concrete items for each dimension, such as 'Code of Urban Residential Areas Planning & Design'. At the bottom, the local regulations, such as 'Technical regulation of urban planning and management', are developed depending on different local conditions and could be stricter than national rules but looser.



Picture 1 The structure of urban planning legislation and regulation system in China

3. What could be integrate into urban planning regulations?

According to the new requirements from environment-friendly and resource-saving development, the following part analyzes what kinds of requests should be involved, how the current integration is, and how the future integration should be in regulation systems of urban planning.

3.1 Main indicators in 'China's Low-carbon eco-city development report'

The main indicators of low-carbon eco-city development were developed by China's urban science council to guide low carbon city development, from 6 perspectives, in which 4 of them are directly related with sustainable urban planning in physic sense and shown in Table 1. They are level of living standard, resource-saving, environment-friendly and environmental culture.

Table 1 Main indicators of low-carbon eco-city development

Types of indicators	Currnet	2020

Level of life standard	Green capacity rate [3]	>1.5	>1.8
	The radio of commute time which is less than an hour（%）	>85	>95
Level of resource saving	Storm water utilization（%）	>10	>30
	Reclaimed water Reuse rate（%）	>20	>50
	Domestic water consumption （L/day/person）	<150	<120
	The ratio of green travel（%）	>70	>90
	The ratio of green building（%）	>10	>30
Level of environmental-friendly	CO2 emission（t/year/person）	<1.8	<1.6
	The ratio of Cleaning energy in total energy(%）	>5	>20
	The ratio of urban domestic sewage treatment（%）	>70	100
	The ratio of in-noxious treatment for urban residential waste（%）	>90	100
	The coverage of urban area of noisy standard（%）	>75	>90
Level of environmental culture	The penetration rate of education and publicity of ecology and environment protection（%）	>80	100

3.2 Eco-indicators in eco-cities planning in China

Eco-indicators, which are the important carrier for implementing ecological strategy, and the crucial management mechanism and evaluating basis for eco-city construction reflect the practical requirements for fulfilling sustainable urban development according to general environmental principles and local conditions. This part chooses indicator systems of two eco-cities in China as part of basic resources for generating the checking references for the whole study. They are Sino-Singapore Eco-city in Tianjin, Sino-Swedish Low-Carbon Eco-City in Wuxi.

3.2.1 Sino-Swedish Low-Carbon Eco-City, Wuxi

Sino-Swedish Low-Carbon Eco-City (2.4 km^2) is located at Taihu new city (150 km^2) which also carries a strong environmental profile. But considering the demonstrative goal of Sino-Swedish Low-Carbon Eco-City, its construction standards are higher than other areas in Taihu new city, in which two sets of indicator systems and implementing guidelines are adopted. The implementation guidelines are supposed to decompose the indicators into details and provide some technical solutions for guiding managers and constructors in implementation.

Eco-indicator system in Taihu new city – a demonstrative district of national low-carbon eco-city （2010-2020）

This system includes 6 dimensions, urban function, green transportation, energy and resource, ecological environment, green building and social harmony，providing a comprehensive and concrete guideline and standards for eco-constructions in Taihu new city. (Table 2)

Table 2 Eco-indicators in Taihu new city

Indicator level	Indicators	Second-level indicators
Urban function	The compact and efficient layout	Comprehensive FAR of construction land
		The ratio of neighborhood with mixed functions
		Coupling of public activities center and public transport hub
		Combined degrees of underground space development and public center
	Public Facilities	The rates of free public facilities in 500m walking distance
	Public transport facilities	Density of bus route network
		Density of slow traffic road network

[3] Green capacity rate is developed for scientifically guiding and controlling green indicator in Master Planning, Regulatory planning, Detailed Planning, Green system planning, Special planning of green space system , urban design.

Green transportation		The proportion of bus stations in 500m walking distance
	Clean energy for public transport	The ratio of clean energy for public transport
	Green Travel	The ratio of green travel
	BRT system	The average speed of bus
Energy and resource	Energy	Energy saving rate of new residential and public building design
		Building energy consumption per unit area
		The proportion of renewable energy
		District cooling and heating coverage
	Water	Water consumption per capita/day
		Water pipeline leakage
		Coverage of water-saving appliances
		Coverage of water-saving irrigation
		Coverage of water sub-metering
		Utilization of non-traditional water sources
		Urban sewage treatment rate
		Compliance rate of industrial wastewater discharge
	Solid Waste	Waste emissions per capita/day
		Construction waste
		Classification rate of garbage collection
		Garbage recycling rate
		In-noxious treatment rate of garbage
Ecological environment	Natural Environment	The number of days of air quality ≥ standards II
		Environmental quality of surface water
		The coverage of urban area of noisy standard
		The ratio of wetlands and water
	Micro-climate	Wind speed in pedestrian area
		Compliance rate of settlements of sunshine standard
		Heat island intensity of outdoor settlements per day
	Landscape environment	Native vegetation index
		Plant species
		Green land rate of completion area
		Green coverage of completion area
		Forestation rate
		Public green space per capita
		Park area of each residential area (3-5 million)
		Shade rate of slow road
		The proportion of permeable ground
Green building	Green Building	The ratio of green building
	Building materials	The ratio of green material
		The ratio of local material
Social harmony	Low-carbon economy	Energy consumption per unit of GDP
		Water consumption per unit of GDP
		Solid waste emissions per unit of GDP
		Carbon emissions per unit of GDP
		The proportion of enterprises with ISO14001 certification
	Livable life	The ratio of green community
		The ratio of green schools (kindergarten, primary and secondary schools)
		Green hospitalx
		The rate of barrier-free facilities
	Social security	The ratio of replacement house
		The balance index of employment and housing
	Public satisfaction	The public satisfaction of environment and social service

The eco-indicator system in Sino-Swedish Low-Carbon Eco-City（2010-2020）

It contains seven perspectives，Urban function, Ecological environment, Energy utilization, Water and sewage, Waste management, Green transportation and Green buildings, with 47 items of indicators. (Table 3)

Table 3 Eco-indicators in Sino-Swedish Low-Carbon Eco-City

Indicator level	Indicators	Second-level indicators
Urban function	The compact and efficient layout	Comprehensive FAR of construction land
		Coupling of public activities center and public transport hub
	Public facilities	The coverage of municipal pipeline network
		The rates of free public facilities in certain walking distance
Ecological environment	Natural environment	Natural landscape
		The quality of surface water
	Green landscape	Average public green space
		Native vegetation index
		Species diversity
		Planting rate of green space
Energy utilization	Energy saving	Building energy consumption per unit area
	Renewable energy	The proportion of renewable energy
Water and sewage	Water resource saving	Water pipeline leakage
		Coverage of water-saving appliances
	Water health and hygiene	The coverage of drinking Water
	Water recycling and reutilization	Storm water utilization
		Urban sewage treatment rate
		The rate of grey water treatment and reclaimed water reuse
Waste management	Garbage collection and management	Classification rate of domestic garbage collection
		Vacuum waste transport system
	Garbage reutilization	The rate of garbage reutilization
Green transportation	Energy use of transportation	The proportion of renewable energy
	Facilities convenience of transportation	Density of bus route network
		Density of slow traffic road network
		The proportion of bus stations in 500m walking distance
Green buildings	Environmental friendly and energy-saving building	Natural environment design
		Energy-saving material utilization

3.2.2 Sino-Singapore Eco-city, Tianjin

In Sino-Singapore Tianjin Eco-city, related to physical planning, the indicator system regulates from national environmental and resources, living styles, municipal facilities and recycling economy. (Table 4)

Table 4 Eco-indicators in Sino-Singapore Eco-city, Tianjin

Indicator Level	2nd level of indicators	Vale and period
Natural and artificial environment	Surface water quality	Standard IV of GB3838 (from now)
	Tap water compliance rate (%)	100 (from now)
	The coverage of urban area of noisy standard（%）	100 (from now)
	CO_2 emission（t-c/ one million dollar）	150 (from now)
	Net lose rate of natural wetlands	0 (from now)
	Green building rate (%)	100 (from now)
	Local plant index	≥ 0.7 (from now)
	Public green space (m2/person)	≥12 (2013)
Life style	Domestic water consumption（L/day. person）	≤ 120 (2013)
	Average waste production (kg/day.person)	≤ 0.8 (2013)
	The ratio of green travel（%）	≥30 (2013); ≥70 (2020)
Municipal facilities	The ratio of urban residential waste reuse（%）	≥60 (2013)
	The rates of residential area within free public facilities in 500m walking distance （%）	100 (2013)
	The ratio of in-noxious treatment for urban residential waste（%）	100 (from now)
	The rate of barrier-free facilities （%）	100 (from now)
	The coverage of municipal facilities	100 (2013)
Recycling economy	The ratio of renewable energy in total energy (%）	≥20 (2020)

	The ratio of untraditional water utilization (%)	≥50 (2020)

4. Examine the integration of environmental improvement in urban planning legislation system

According to those indicator systems above, this paper sums up the crucial principles and indicators, which could be integrated into urban planning legislation system and checks their existence, absence and performance in the current system. According to the relevancy to physically sustainable development, the paper chooses several regulations as checked objects shown in Table 5. And the summarize of those indicators is also categorized as checking contents into three levels in terms of current legislation structure: A. Main seven principles, B. Sub-principles under main principles, C. Concrete standards and indicators. (Table 5) As regulations in different levels should be analyzed from different views, the checking process is made by considering the structured correlation between summarized data and selected regulations. (In following sections the corresponding numbers are used to represent checked objects (regulations as shown in Table 5).

Table 5 Checking box of structured correlation between summarized data and selected regulations

Levels	Selected regulations	Main tasks	Checking contents
National law	① Urban and rural planning law of PRC	State the main principles, the main responsible sectors and main tasks of urban planning	**A**. Seven main principles **B**. Sub-principles under each principle
National administrative regulations	② Measures and detailed rules for formulating city planning	Define the planning procedures, main contents	**A.** **B.**
	③ Code of urban residential areas planning & design ④Code of transport planning on urban road ⑤ Regulation for indicators of urban green planning and construction	Define concrete contents, rules, technical solutions and the value of controlling indexes	**B.** **C.** Concrete standards and indicators
Local regulations	⑥ Technical regulation of urban planning and management of Jiangsu Province	Clarify local standards according to local features and also compliance to the national regulations of urban planning	**B.** **C.**

4.1 Ecological Environment

Ecological environment protection and construction as one of main principles is largely concerned in China for many years, and it is also clearly stated in the urban planning regulations. In terms of the data collected above, the principle of ecological environment protection and construction within the urban planning area could be divided into three sub-principles: natural environment, green capacity, microclimate built. Green capacity as a new concept for improving green spaces has not been used in any regulations, neither of micro-climate built. The compulsory contents stated in the Measures and detailed rules for formulating city planning are mostly the planning of green landscape structure and green land use layout which is more concerning the morphology but from sustainable aspects. From the table, the most frequent concrete standards and indicators in the regulations is about average public green area per person, green land rate and green coverage of completion area. And for these indicators, the focus is more on the quantitative regulating but qualitative guiding, and also the content of indicators are simplex and uniformed for all the areas in China. A number of concrete indicators are absent, or although some indicators like *native vegetation*, *species diversities*, *species diversities* are already mentioned in the regulations, the way to be indicated is quite unclear, especially in 'Code

of urban residential areas planning & design', and 'Regulation for indicators of urban green planning and construction'. (Table 6)

Table 6 The including or excluding of indicators on Ecological Environment in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Protect and construct ecological environment	① ②	Natural environment protection	① ②	The air quality	--
				The quality of surface water	--
				The coverage of urban area of noisy standard	⑥ not clear
		Green capacity construction	--	Public green space per person	③ ⑤ ⑥
				Green land rate of completion area	② ⑤ ⑥
				Green coverage of completion area	⑤ ⑥
				Native vegetation	③ not clear
				Species diversities	⑤ not clear
				Species diversities	⑤ not clear
				Planting rate of green space	⑤ not clear
				The rate of natural wetlands	⑤ not clear
				Shade rate of slow road	--
				The proportion of permeable ground	--
		Micro-climate built	--	Wind speed in pedestrian area	--
				Heat island intensity of outdoor settlements per day	--

4.2 Urban function

Effective and compact urban function is clearly stated in national law and regulations. Following that, compact and efficient layout and effective public facility are also included in national law as sub-principles, but the concrete standards on how to approach these targets are lack in regulations. Although the requirements on *the Far of construction land, combination of underground space development and public center and the coverage of municipal pipeline network* are specified in some codes, more than half of the concrete standards are still absent, such as *the rate of neighborhood with mixed function, Coupling of public activities center and public transport etc.*. (Table 7) Mixed functions of land as an effective way to contribute to efficient land use, less vehicle travel of citizens and also an active neighborhood is still absent in the regulations. In the land use category, there is no category of mixed land use, and on the contrary, the main principle for land layout is clear function separation and centralization.

Table 7 The including or excluding of indicators on Urban Function in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Effective and compact Urban function	① ②	The compact and efficient layout	①	The comprehensive Far of construction land	② ③ ⑥
				The rate of neighborhood with mixed function	--
				Coupling of public activities center and public transport	--
				Combination of underground space development and	⑥

				public center	
		Effective public facility	①	The coverage of free public facilities of residential areas in appropriate walking distance	--
				The coverage of municipal pipeline network	③ ⑥
				The rate of barrier free facilities	--

4.3 Green Transportation

Green transportation includes three perspectives: improve public transport facilities, use clean and renewable energy for transportation, and transit to green travel model, in which only renewable energy is not contained. The public transport facilities is promoted by several standards in 'Code of transport planning on urban road', whereas there are some requests missing. The items indicating travel modes and commute time are existing in the regulations. And at the same time, a number of items target for encouraging private vehicles not restricting them, for example, in 'Code of urban residential areas planning & design', there is an item '8.0.6.1 parking rate of private cars for residents should not be less than 10%' , but no maximum limitation. And although the green travels mode of walking, bicycles and public transport are encouraged in some provisions, they are sometimes hindered unconsciously by other standards. For instance, in 'Code of urban residential areas planning & design' there is item '8.0.1.2 the crossing vehicles should be avoided in the residential neighborhood' which is to ensure the security and good living environment for residents. But as many neighborhoods are in large scale exclusion of the buses in the area and also public feasibilities out of walking distance increase demands of private vehicles which are not sustainable. (*Hai*, *Xiaopan*, *2009)* The absence of standards on density of slow traffic road network indicates that the travel space and facilities for non-motorized vehicle has not been well concerned as vehicle travel. (Table 8)

Table 8 The including or excluding of indicators on Green Transportation in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Green transportation	--	The convenience of public transport facilities	②⑤	Density of bus route network	④
				Density of slow traffic road network	--
				The proportion of bus station in appropriate walking distance	④⑥
				BRT system	④
		Clean and renewable energy use for public transport	--	The ratio of clean and renewable energy use	--
		The ratio of green travel	--	Distribution of travel modes	④
				The ratio of commute time which is less than an hour	④

4.4 **Green Building**

The principles of green building design and green material use are seldom mentioned in current regulations, especially in upper levels (Table 9). Only in 'Code of urban residential areas planning & design', there are several standards talking about utilize sunshine and natural wind to improve micro-climate, but the start point is not to maximize energy efficiency and reduce unit energy consumption of buildings. More controlling and guiding standards from resource-saving of green buildings are needed to be complement. But considering the main focus of urban planning legislation is on larger scale space rather than building design, the indicators on green building should not be too detailed.

Table 9 The including or excluding of indicators on Green Building in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Green building	--	**Green building design**	--	Natural environment/ Micro-climate design, e.g. utilize sunshine, wind etc.	②③⑥
		Green building material	--	The ratio of green material	--
				The ratio of local material	--

4.5 Energy production and saving

As the national strategy of environmental-friendly and resource saving, the target of the energy production and saving is clearly specified in the general principles of national law and regulations, but there are not any concrete items on energy saving and renewable energy utilization. (Table 10) Most items concerning on energy production and saving are quite general and has not integrated in urban planning system.

Table 10 The including or excluding of indicators on Energy production and saving in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Energy production and saving	①②	Energy saving	①	Building energy consumption per unit area	--
				Energy saving rate of new residential & public building design	--
				District cooling and heating coverage	--
		Renewable energy	--	The ratio of renewable energy in total building energy consumption	--

4.6 Water utilization

For the water utilization, there are four aspects related: utilization of non-traditional water resources, water resource saving, sewage treatment, water quality and health, in which non-traditional water resources is a new subject which hasn't been integrated in current regulations. (Table 11) And as the situation of energy production and saving, three sub-principles are stated in upper levels, while most of the standards and indicators are missing, such as the requests on using water-saving appliances, urban domestic sewage treatment.

Table 11 The including or excluding of indicators on Water Utilization in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Water	--	**Utilization of non-traditional**	--	Storm water utilization	--
				Reclaimed water reuse	--

utilization		**water resources**			
		Water resource saving	① ②	Water consumption per capita/day	②
				Water pipeline leakage	--
				Coverage of water-saving appliances	--
				Coverage of water-saving irrigation	--
				Coverage of water sub-metering	--
		Sewage treatment	① ② not clear	Urban domestic sewage treatment	--
				Compliance rate of industrial wastewater discharge	--
				Grey water treatment	--
		Water quality and health	① ②	The coverage of drinking water	-

4.7 Waste management

The principles and indicators on waste management, recently considered as important aspects for resource saving, is only unclearly mentioned in terms of waste collection. The domestic waste production, waste collection and treatment approaches are regulated as the compulsory content in the sector planning of environment and sanitary facilities in master planning, but there are no guidelines to formulation of these planning. As we see from the table, waste management is also a new area which are absent but need to be closely integrated in urban planning regulations. (Table 12)

Table 12 The including or excluding of indicators on Waste management in urban planning legislations

Main principle	Included	Sub-principle	Included	Concrete standards and indicators	Included
Waste treatment and reuse	--	**Reduce waste production**	--	Waste emission	②
				Construction waste production per km^2	--
		In-noxious treatment for urban residential waste		The rate of in-noxious treatment for urban residential waste	--
		Waste collection and reutilization	① ② not clear	Classification of domestic waste collection	②
				Vacuum waste transportation system ????	--
				The rate of domestic waste reuse	--

5. Discussion

Chart 1,2,3 show that more than half related indicators are not included in urban planning legislations, from main principles, sub-principles to concrete indicators and standards. This means the current legislation system is somehow out of date and inconsistent with practical sustainable urban planning requirements. Some strategic principles, like *environmental protection and construction, effective and compact land use, and resource and energy saving and utilization are pointed,* are clearly in the 'Urban and Rural Planning Law of the PRC' and Measures and detailed rules for formulating city planning. The principles on green transportation, green buildings, water utilization, waste treatment and reuse are poor stated in the upper levels. (Chart 1) As shown in Chart 4,5, the integration from perspectives of Green building and Energy production and saving is quite weak, while the concern from urban function principle is relatively strong comparing to other principles. The integration of renewable energy use into green building design, green transportation and waste recycling is an aspect to be promoted with large potentials.

As it has already been stated in section 4, the task of concrete standards and indicators is more on quantitative regulating but qualitative improving. And also the requirements of these indicators are so simplex and uniformed that they can not reach the environmental targets, and at the same

time meet different local requirements. Quantitative indicator is difficult to be a common value for the whole county, so effective standards on qualitative requirements and also the instructs on implementing these indicators are necessary. This problem also indicates a structural weakness of urban planning regulation system, the tasks of legislations and regulations on each level are mixed and ambiguous.

Another issue found in the analysis is the conflicts between sustainable indicators and items in current urban planning legislations, as stated in the checking on principles of Urban function and Green transportation. China is still in a certain condition of fast urbanization and transition, leading to rapid transportation dependent, and emphases on fast and centralized urban expansion, which contracts with the compact and efficient layout and green travel modes. These conflicts, which must result in obstacles when planning and implementing sustainable urban projects, should be figured out in good time in urban planning legislation system.

6. Concluding remark

To popularize sustainable urban planning in China, the revision of the regulation system is essential and imminent towards comprehensive content and clarified hierarchy structure. Based on above analysis and discussion, here there are three main problems need to be solved and improved. Firstly, in the urban planning legislation system, more than half of the principles, standards and indicators concerning on seven aspects stated in the paper are absent, because these regulations, developed in 1990's, are out of the date for the goal of resource-saving and environmental-friendly. The update of urban planning legislations is urgent. Another is there is a gap between national laws (general principles) and planning regulations (detail indicators), lack of operational guides. The structure and content of standards and indicators are quite mixed and ambiguous in the current system, this will lead the incoherence between principles and indicators, because the controls of concrete standards in middle level are absent. As the standards are supposed to be nexus between principles and indicators, this confusion and lack of the middle-level standards in regulations will lead the incoherence of principles which are unable to be implemented, and indicators which are given improper values. What's more, the principles in current urban planning system sometimes are apparently contradictory to some environmental goals, which should be given a balance and mediate during the future legislation formulations.

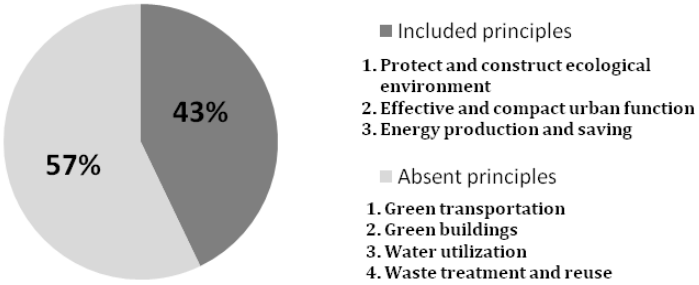


Chart 1 Coverage of main principles in the Regulation ①②

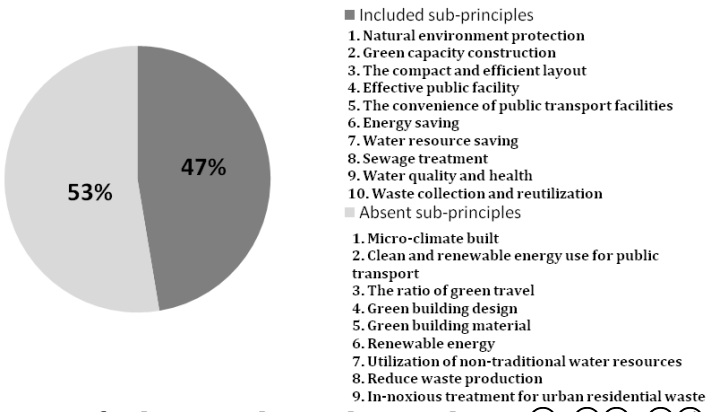

Chart 2 Coverage of sub-principles in the Regulation ① ②③ ④⑤ ⑥

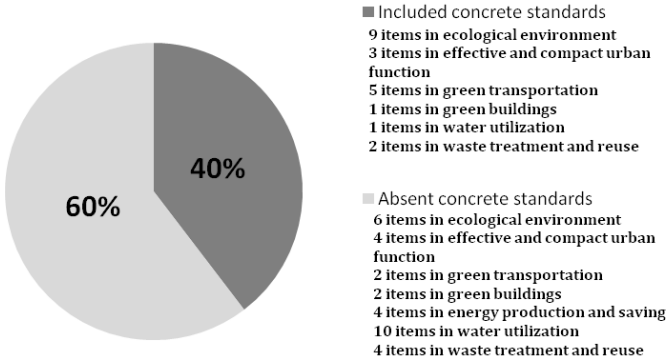

Chart 3 Coverage of concrete standards in the Regulation ③④⑤ ⑥

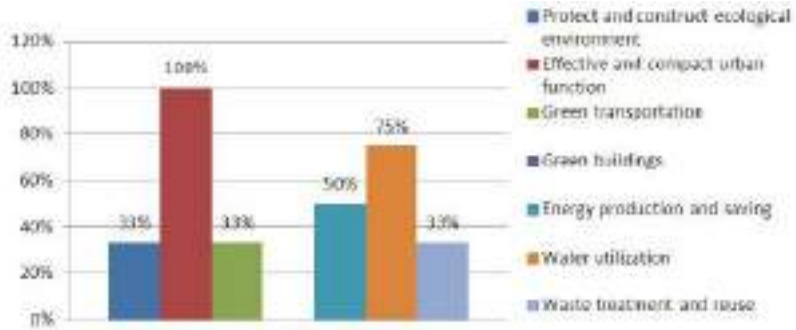

Chart 4 Ratio of included sub-rules of each category in the Regulation ① ②③ ④⑤ ⑥

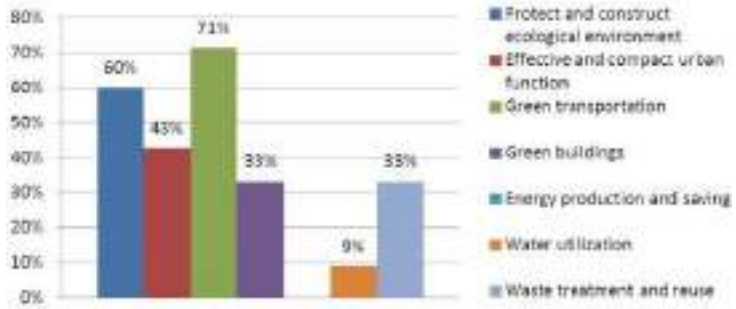

Chart 5 Ratio of included concrete standards of each category in the Regulation ③④ ⑤⑥

Tuna Batuhan[1]

Abstract

The political situation and institutional structure determines the policy approach that the host city prepares for mega-events. Although each host city uses fixed strategies to plan for the short term event, the outcome of these strategies mostly depends on the host city's political structure and its institutional culture. In other words, the impact of mega-events on host city's long term planning strategy varies on the choice to continue using these strategies in the long term and it is restricted by the host city's planning traditions. In this sense, this research intends to investigate whether the short term focused mega-event planning is expanded to reach long term goals of the host city and whether this short term focus affects the policy, structure, and culture of the transportation planning institutions of the host city.

Most past academic research has focused on the physical capacity of the mega-event host city and the investments made for the events. However, the impact of this temporary situation on host cities' policy making process for the long-term has been mostly neglected. By using 1996 Atlanta Olympic Games as a case, this paper focuses on the role of institutions, politics and power relations on Olympic transportation planning in order to gain a better understanding of the positive and negative impacts of the events on host cities. This research focuses on the policies used by planning institutions in the transportation planning process of 1996 Atlanta Olympic Games, and the change in transportation institutions' strategy and vision throughout the event planning process. Understanding the event organizational agendas and priorities in respect to transport and the decision-making process is important, and this research seeks to fill this gap by focusing more attention on the transportation planning and institutional side of mega-events.

1. Introduction

The Olympic Games are based on the spirit of competition between athletes. This spirit of competition is shared by rival candidate cities. In order to win their bids to host the

[1] The Florida State University, Florida, USA – tb10d@my.fsu.edu

Olympic Games, cities must put their best foot forward. Since 1984 Los Angeles Games, Olympics are growing in many aspects, mainly due to financial success of Los Angeles Games and increasing economic potential of the Games. Thus the event planning process becomes more comprehensive and more challenging. The Olympic Games require years of event planning, also pose one of the biggest global planning challenges. These forces combine to render urban planning an essential part of the Olympic Games.

Olympic Games generate demand not only for the event itself, but also for other related services including transportation. This study focuses on urban planning side of the Olympic Games; specifically transportation planning that can be derived through hosting this events. The transportation concept is one of the technical criteria to evaluate the candidate cities' capacity to host the Olympic Games and it is also one of the mega-events' main legacies. A typical mega-event transportation strategy is to increase the use of public transport during the event, thus quality public transportation is the backbone to passenger movement for all mega-events, and all game areas are designed to be accessible by public transportation.

Most past academic research has focused on the physical capacity of the mega-event host city and the investments made for the events. However, the impact of this temporary situation on host cities' policy making process for the long-term has been mostly neglected. This research focuses on the policies used by planning institutions in the transportation planning process of 1996 Atlanta Olympic Games, and the change in transportation institutions' strategy and vision throughout the event planning process. Understanding the event organizational agendas and priorities in respect to transport and the decision-making process is important, and this research seeks to fill this gap by focusing more attention on the transportation planning and institutional side of mega-events.

2. Transportation Planning for Olympic Games

The selection of the host city for the Olympics is a long process covering a seven-year period and starting with the National Olympic Committees (NOC) within each country. Any city interested in hosting the Olympics should express its interest to the NOC in the country. After the approval of its NOC, the city is considered as an applicant city and submits a candidacy file to the International Olympic Committee (IOC) to be evaluated by the IOC's Commission of Inquiry. This file is a technical document which gives detailed information about the city's condition in 23 categories including transportation and an important reference for the current situation and future implementations. The Commission evaluates each candidate city in terms of their technical, physical, financial, and organizational capacities, and makes an assessment on its potential to stage the Olympics successfully based on a set of technical criteria including legal issues, sports

venues, Olympic villages, environmental conditions and impact, safety and security, finance, and the transportation concept (IOC, 2009).
The transportation concept evaluation is about the main traffic planning objectives and the strategies on organization, ticketing, testing, and training. IOC identifies four different objectives for transportation: 1) *Offer* is about how to meet the demand for the Games by providing data about the current and future infrastructure on air transport, motorways, main roads and parking, main parking areas, and public transportation system; 2) *Demand* indicates the overall personnel and training needs and estimated spectator numbers; 3) *Concept* is about the strategy that will be used during the Games that shows the relationship between offer and demand for the particular candidate city; 4) *Planning and Management* determines the responsibilities of different authorities for different transport activities (IOC, 2006).

The transportation concept is one of the technical criteria to evaluate the candidate cities' capacity to host the Olympic Games and it is also one of the mega-events' main legacies. Quality public transportation is the backbone to passenger movement for all mega-events, and the Olympics provide an exceptional stage to seek long term approaches to transportation planning. All game areas are designed to be accessible by public transportation, and other modes of transportation are linked to public transportation, such as parks, automobile lanes, bike lanes, and sidewalks for pedestrians. The main components of the Olympic Transport Plan can be listed as follows (Bovy, 2003):

- Well-promotion and advertised 100 % public transport usage
- Free use of public transport with event tickets
- Spectator-parking ban in and around the venues along with limited private car accessibility
- Free park and ride spaces supported with shuttle services directly tied to the venues and transit stations

3. Literature Review

Most past academic research has focused on the physical capacity of the mega-event host city and the investments made for the events. Basically, the main focus was limited to the event staging period and how to manage this temporary demand for the events. However, the impact of this temporary situation on host cities' policy making process for the long-term has been mostly neglected.

Mega-events have the potential to be the catalyst for host cities to apply their planning strategies in a more focused environment, and they can result in remarkable changes in infrastructure, urban form, and city image (Essex and Chalkley, 1999; Essex and Chalkley, 2004). According to Essex and Chalkley (1998), the Olympic Games offer

"the justification for related developments to be 'fast-tracked' through accelerated planning, design and construction." (p. 201). Mega-events are "the best stage upon which a city can make the claim to global status" (Short, 2004, p.24). These forces combine to render urban planning, an essential part of the events planning process, and the event itself provides an exceptional stage to seek long-term approaches. The interest of cities for hosting mega-events has been growing mainly due to increasing economic potential of the events. The largest exceptional public events (ECMT, 2002) that are defined as 'mega' includes the Olympic Games, Expos, Soccer World Cups, and Commonwealth Games which attract large number of visitors and justify large-scale infrastructure development (Roche, 2002). Since mega-events have an impact on cities beyond sport, and these non-sport outcomes may be even more important than the sporting outcomes, the events can be analyzed from a policy perspective. The fact that the mega-events are not just about sports, but they give an opportunity to accomplish the plans on their policy agendas has also been realized by city leaders (Hiller, 2006).

Los Angeles Olympic Games in 1984 can be seen as a turning point for staging mega-events, mainly due to its economic success. It was the largest amount of temporary and portable facility implementation and utilization event at the time (Larson and Staley, 1998).After the 1984 Los Angeles Olympics, Atlanta organized the second privately funded Olympics with no direct public funding in 1996. "No new taxes" pledge was in the heart of the Olympic Organization to get and keep public support for the Games and it limited government involvement on major decisions (French and Disher, 1997). The lack of public involvement and public funding also meant that implementing comprehensive and integrated planning was limited. In order to hold the city harmless against in a financial liability, Atlanta took full advantage of existing facilities and adopted them to Olympic sports venues through necessary modification and/or installing temporary equipment and systems in order to avoid the under-use of venues (Larson and Staley, 1998; Smith, 2007).

The shift on the significance of mega-events increased the interest of researchers on the impact of mega-events. Mega-events have been studied from many different perspectives, such as its economic impacts, tourism impacts, or urban regeneration impacts. The early studies by Ritchie (1984), Hall (1992), and Roche (1992) provides the foundation that the Olympics can be seen as a tool for local economic development. For Preuss (2004), the Games globally increase the recognition of the host city and this positive climate attracts business investment to the host city. Olympics also create a positive tourism legacy by strengthening the host city's image as a brand. The involvement of government at different levels has also been investigated.

Most of the studies focus on the potential benefits and positive impacts of mega-events (Gold and Gold, 2007; Short, 2004; Hiller, 2006; Cashman, 2002), while there are few studies that investigate the negative impacts (Lenskyj, 2000). 1992 Barcelona Games left an indelible mark on Barcelona and cited as an exemplary Olympic Games. The Games

showed the positive effects of events on the city by strengthening its image, infrastructure, urban landscape, and culture to compete with global cities (Millet, 1995). "The Games served as a catalyst for urban and economic change in the city, positioning Barcelona internationally and communicating its constructed image to a global audience" (Kenneth and Moragas, 2006). On the other hand, Atlanta and Sydney Games are seen as the examples of negative social impacts of Games on host cities (Lenskyj, 2000).

For mega-events, the power relations between actors also determine the possible outcomes. In Atlanta case, downtown business coalition had the power and they made the critical decisions throughout the Olympic planning process. The three major categories of public policy – distribution, regulation, and redistribution – constitute real arenas of power, and the structure, political process, and relations are developed in each arena (Lowi, 1964). For Lowi (1964), distribute policies are defined as highly individualized decisions that only can be called a policy by accumulation; regulatory policies are also specific and individual and involve a direct choice as to who will be indulged and who deprived in the short run; and redistributive policies differ on impact which is much broader, approaching social classes. In terms of power, the distributive area is pluralistic and only organized interests are operating, the regulatory arena composed of a multiplicity of groups organized around tangential relations and the redistributive arena expresses different generalization.

Greenberg et al. (1977) states "public policy is almost never a single, discrete, unitary phenomenon. Indeed, the appeal of public policy studies as a focus of intellectual endeavor lies precisely in its richness" and illustrates the problems arising from the complexity of using policy as a unit of analysis by Lowi's work. Greenberg et al. (1977) discusses the difficulties they face in order to test public policy hypotheses. They briefly list the reasons why public policy is more complex as a focus of systematic comparative analysis: the policy process takes place over time and this leads to difficulty in explaining "the process" as a simple unit; since the policy proposal itself is complex and has several important aspects, it is very difficult to place it in any single category; the existence of many participants makes the policy making process complicated; and the public policy process cannot be described by simple additive models, because it is complex as a research focus. Greenberg et al. concludes that the researchers must make guesses and assumptions that cannot be just in order to operationalize the basic concepts of Lowi's theory, thus we may never be able to obtain hard knowledge of the policy process. In this sense, it is hard to systematically analyze the policy process for mega-event planning, since it is very complex and includes many participants.

For Olympic Game planning, institutional cultures, structures, and history determine constitutional choices, and constructional choice outcomes effect the operational and collective choice actions. In other words, institutions are path-dependent in one sense and they have limited capacity, power, and flexibility to make decisions than are

extremely different than their "path". The concept of path dependency suggests that future decisions are limited and embedded by the decisions made in the past, and the changed conditions are not always enough for a shift in policy decisions. Path dependency creates a policy situation where the organizations are weak and have limited options that they cannot create their own preferred policy agendas, and responding to changing public preferences becomes difficult when public policies are institutionally embedded (Low and Astle, 2009). The main barrier for this kind of policy change is "the inflexibility of mental models and the rigidity of institutions" (Low et al, 2005). The policy decisions of Olympic host cities are the result of the key policy actors' decisions, and these actors are oriented by "story lines" that present reasons for the taken actions as well as for the future policy directions (Low et al, 2005).

4. Case Study: 1996 Atlanta Summer Olympics

The City of Atlanta, a progressive city in the south, is in the center of the metropolitan region. Having no geographical boundaries allowed Atlanta to grow in a very low density pattern. Atlanta's population settles over a large area, and this lead to an automobile-oriented urban design feature. The Atlanta region's population has grown rapidly in the last few decades. Especially after the Olympics, the region has attracted millions of people and the economy has expanded. Class and racial separation are the two characteristics of the region. Historical class and racial separation became permanent with the edge-city suburban development, exclusionary suburban land-use regulations and weak fair-housing enforcement which created two separate cities: black south and white north (Keating, 2001). Local politics is controlled mostly by the city's downtown business leaders who influence elected officials. This political environment in Atlanta leads to the policy decisions that neglect public interests and undermine regional and social needs because of a narrowly defined private interest (Keating, 2001). Limited vision, class and race segregation along with the lack of attention to the fundamental issues created serious problems that are transferred to the future decision makers of the city.

4.1 Bidding for the Olympics

After President Reagan eliminated several federal aid programs geared toward urban policy in 1984, cities had to look for other funding sources and, for Atlanta, the Olympics provided the perfect economic impetus to focus on the revitalization of downtown area (Burbank et al. 2002). Atlanta's bid for hosting the Olympic Games can be understood as the product of an active growth coalition that already exists in Atlanta. For Atlanta, the vision and the central motivation among growth elites were to show that Atlanta is a "world-class" city that is capable of hosting Olympic Games. In order to justify local development, public policy strategies promoted tourism, and Olympic Games provided that promotional means to reach a broader population (Burbank et al.

2002). For Atlanta, the Olympic bid was not just about hosting a major sporting event, but to transform the city into a world stage player.
Atlanta competed with other cities – Athens, Toronto, Manchester, Melbourne, and Tokyo – for the nomination of 1996 Olympic Games. Since the 1996 Olympics was the centennial anniversary of the Olympiad, Athens was the favorite candidate city mostly because of sentimental reasons; however, IOC did not award Athens for hosting the 1996 Olympic Games, mainly because of the governmental instability at that time, and because of the fact that the city was not ready to be prepared effectively on time for this huge organization (Hutton, 2001). Some of these other candidate cities were engaged in bribes, attempted to buy the votes of IOC members, and acted unprofessionally during the election process. As a result, Atlanta – best of the rest – used technology, an image of enthusiasm along with the strong support from Atlantans, and the organization skills to be selected over Athens by a 51-35 vote to host the Games after five rounds of voting. Atlanta's bid was considered strong in terms of its concepts for transport – especially the air connection to the world with one of the leading airports in the world in terms of capacity and passenger –, existing sport facilities and accommodations, and communication systems; however these concepts created serious problems during the Games (Roche, 2000).

The business elites were the pushing power for Atlanta to bid for Olympics. Atlanta was able to host the 1996 Olympics through Billy Payne's (a real estate attorney and former baseball player) vision and determination along with the support of his friends known as the "Crazy Atlanta Nine" that will form the Atlanta Organizing Committee (AOC) later (Rutheiser, 1996). The members of the AOC preferred an organizational structure where decision making could be closely controlled and operations would be less subject to public oversight. To this end, they incorporated the Atlanta Committee for the Olympic Games (ACOG) as a nonprofit civic organization with a thirty-one-member governing board. The board included the mayor, delegates from the USOC and IOC, holdover members from AOC, and others drawn from Atlanta's civic and business elites (Burbank et al 2001:92).

The goal of the Olympic transportation plan in Atlanta was to confine activities to a constricted area to shorten travel time between venues. Thus, major venues and events were concentrated within the imaginary "Olympic Ring" circle - the 3.1 miles (5 km) in diameter of downtown Atlanta. The Olympic Transportation System (OTS) was created to coordinate all transportation systems to provide sufficient service. ACOG made a policy decision to assume responsibility for spectator transportation, even though IOC only requires Olympic Organization Committees to provide transportation for Olympic Family members. ACOG voluntarily took the responsibility for spectator transportation based on the assumption that Olympic families cannot be moved efficiently, if the public movement is not controlled.

Although transportation was one of the biggest challenges for an auto-oriented city like Atlanta, Atlanta's existing transportation plan, especially the rail system, was a vital part of their proposed transportation plan, which played an important role in Atlanta's winning bid for the Olympics. Atlanta Regional Transit System consists of MARTA, Cobb Community Transit (CCT), Gwinnett County Transit (GCT), Clayton Transit (C-Tran), and XPress Regional Commuter Service; but MARTA is the most-used public transportation system by far (more than 90%) in the region. For ACOG, Atlanta's transportation system prior to the Games was deficient for providing service to millions of people during the Olympics. Based on this argument, MARTA formulated a transport plan on using existing bus and rail systems with the support of a temporary bus system to operate during the Games which consisted of 1475 borrowed buses from more than 65 US transit agencies (ACOG, 1997; MARTA, 1996). Before the Olympics, the MARTA bus system consisted of 750 buses; whereas it utilized 1700 buses and 2000 drivers during the Games period. Including the borrowed buses, MARTA Olympic Bus System became one of the largest bus systems in the US. For the Olympics, three rail stations and 7 miles of additional route were added, and frequency of transit service was scheduled to increase and extended to 24 hours a day (ACOG, 1997). Available public transit services during the Games consisted of regular MARTA services with increased night services, shuttle services, park and ride lots in suburban locations, and special services for Olympic Family members. Overall, the public transit system met the expectations; MARTA system delivered about 14.4 million one-way trips, while the supplemental bus system delivered almost 4 million one-way trips during the Olympics (ACOG, 1997).

4.2 Olympic Legacy of Atlanta

Atlanta's Olympic effort primarily aimed to meet the IOC requirements in a most efficient way from Games organization to architecture with limited infrastructure investment. In other words, Atlanta, as a "pragmatic and bottom-line-oriented city", reflects the characteristic of 1990s – "a decade of stringency and moderated expectations" (Dixon, 1995, p. 52). An Olympic bid was a logical next step for Atlanta to grow and put the city in the world map. The goal of the Atlanta Games was to promote business growth, create a world city image, and attract international business to the city. After staging the Games, several companies relocated to Atlanta, and the Games was one of the important reasons for achieving this.

Although Atlanta put a priority to create a world class city image instead of creating permanent physical legacies, the city itself and its Universities – particularly Georgia Tech and Georgia State University – benefit form some of the physical facilities that are built for the Olympics. New dormitories that will be used by Georgia Tech and Georgia State University after the Games were constructed by $47 million ACOG contribution, a new $24 million natatorium was built on the Georgia Tech campus, and ACOG spend

$1.5 million to renovate Georgia Tech's Alexander Memorial Coliseum, the Olympic Boxing venue (Humphreys and Plummer, 1995). The Olympic Village was located at Georgia Tech and over $150 million in capital facilities had added to Georgia Tech which is the largest expansion in University's history. Among all, most notable legacies from the Games include the Centennial Olympic Park, Olympic Stadium, Georgia Tech Aquatic Center, twelve upgraded pedestrian corridors, and a new international concourse and a central atrium at the Hartsfield International Airport.

On one hand, the Games created opportunities for the construction of new sporting facilities as well as the improvement of the physical environment of the host city generated civic pride, provided an opportunity to generate world recognition and contributed to transforming the image of Atlanta (Malfas et al. 2004); on the other hand the 1996 Atlanta Olympic Games created negative social impacts on low-income residents, intensified social problems and deepen existing divides among residents. For example the Centennial Park construction dislocated many businesses without assistance for relocating. Additionally, the Olympics left a negative legacy among low-income neighborhoods where many people were relocated. The Olympic Stadium construction inflicted further damage on the low-income black neighborhoods in the area, and their limited role in Olympic Planning prevented local governments to take action and protect these people from damage (Keating, 2001). ACOG was a powerful coalition of business leaders and elected public officials who faced a legacy of distrust within the city's low-income African-American neighborhoods (Newman, 1999). This was the result of years of policies such as expressway construction and urban renewal which relocated thousands of low-income African-American families. Focusing and engaging on international business to create a world city image also resulted in losing local identity and neglecting local issues (Keating, 2001).

4.3 Politics and Power Relations

The trend for cities to increase their international connections in the global era and the increasing competition between cities to host Olympic Games has incorporated into economic strategies of cities. The rationale of image creation for a city has results in increase in tourism and business investments, and this change has an ultimate effect on local governance as local budgets become allocated along these lines. (Burbank et al 2001). Given the difficulties that city leader's face within the broader political and economic environment and the changes in federal policy and in the international economy forced American cities to play an entrepreneurial role, and the Olympic Games are seen as a way to achieve local economic goals (Burbank et al., 2001). Regime theory can explain the reasons behind the entrepreneurial growth approach. Regime theory argues that American political economy has two principles: government institutions are controlled by elected officials and the economy is directed by private actors (Burbank et al., 2001). Both government and business has interest in local politics and the urban regime provides an environment in order to make "the informal arrangements by which

public bodies and private interest function together in order to be able to make and carry out governing decisions" (Stone, 1989). The basic idea of regime theory is that the political leaders and businesses establish an "informal agreement" which consists of a network of well-established connections built on trust between business and political leaders (Burbank et al., 2001).

Urban regime theory expects that the business interests dominate the policy decision, although the structure of the regime varies from city to city, because of the different conditions in economics, dynamics, institutional settings, and history of the city. Most of the decisions are made through public-private partnerships. In this sense, for any city "an Olympic bid does not involve all the individuals who may be part of the informal governing structure of a city, but it does illustrate in a concrete fashion how business resources and governmental authority come together to undertake a policy initiative" (Burbank et al., 2001, p. 158). In contemporary American cities, staging the Olympic Games is not simply an international sporting event but a tool for implementing the vision of a world-class city. With their short duration, limited beneficiaries, and need for extensive planning, the process of bidding for and holding an Olympic games provide sufficient opportunity for growth (Burbank et al., 2000).

In Atlanta, the Olympic bid occurred because of the existence of an urban regime to provide a way to overcome the weaknesses of city government and benefit from businesses (Burbank et al., 2001). In the case of United States, the Olympic Organization Committees take the formal responsibilities of preparing and staging the Games. It does not mean that local and state governments are not involved or the Games were run by for-profit companies (Burbank et al., 2001). In Atlanta, the Olympic Committee (ACOG) had the main responsibilities. It was in control of every aspects of the game planning and it established an efficient redevelopment agenda for the city. The projects that met the desires of both public and private entities are undertaken and completed with a coalition (e.g. Olympic Stadium and Centennial Olympic Park).

In Atlanta Region, the relationship between the government entities and business helped to maintain the image of public-private enterprise. The idea of citizenship was replaced with consumers as the central point of urban public life and, the Olympics enabled Atlanta to make significant changes to the downtown infrastructure that were regard as dreams for many local business professionals and politicians for decades (Lowes, 2002). The main goal for business leaders was to create a commercial legacy by attracting private investment through encouraging companies to locate their regional and national headquarters and offices in Atlanta. The commercially orientated perspective of the Games planners resulted in a legacy that favored the redevelopment of commercial downtown districts rather than neighborhood renewals.

4.4 Institutional Cooperation

In the Atlanta region, individual political power bases create a situation where no suburban city, town or county want to combine its problems, its resources, and its effort with those of the city of Atlanta and any kind metro-wide cooperation is seen a threat to this status quo (Padgett and Oxendine, 1996). Additionally, largely divided community, and political and racial lines still exists in the metro area and these facts are other barriers for achieving metro-wide cooperation and coordination.

In order to achieve the most benefits out of Olympics, cooperation and coordination among several authorities is necessary from the beginning to the end of the Olympic planning process. Because of the tight deadlines of the Games, cities can do much work in a short time. Games are the excuse to guarantee to complete the infrastructure on time. Within its unique planning environment, the Olympics help to make the process faster with the positive affect of highest cooperation and coordination among different agencies and authorities. In Atlanta case, the collaboration among several authorities beginning from the bidding phase until the staging phase was the most notable accomplishment of the Olympics in Atlanta. (Padgett and Oxendine, 1996).

For transportation planning, especially for regional transportation planning, one of the biggest challenges is the difficulty of creating convincing harmony between different authorities. Organizational structure and management make the difference on the transportation accomplishment of the Games. Harpt (2002) states that one of the keys for creating a successful Olympic Transportation Plan is establishing coordination and cooperation among agencies. This harmony and cooperation is needed more and has the potential to create successful regional transportation plans. However, creating collaboration is challenging especially in the United States because of the political, cultural, historical, and social boundaries, and it is hard to expect the same motivation and concentration from each authority. Since the emergent problems caused by the Olympics are temporary, it becomes easier to agree on a "potentially controversial strategy" for each agency or authority; but once the games are over, disagreements can easily rise again (Giuliana et. al, 1987). Many of the changes in the way of thinking and operating do not retain after the Games.

The Atlanta Olympics showed that the Olympics may have a limited impact on renovating the host city. Even though the economic and physical benefits of the event were clear, institutional culture did not change significantly because of the lack of a comprehensive planning effort and funding. This experience reminds us that Olympics are not the "magic bullets" for solving cities' persistent problems (French and Disher, 1997). The city focused more on "Olympics-as-sport" side and the needs of communities are disregarded (Andranovich et. al, 2001). The motivation of Atlanta was to create a world-city image, prestige, reputation, and economic development through hosting the Olympic Games with a minimum investment on infrastructure. Atlanta's Olympic experience is an American way of making a justifiable government decision which is different from other countries (Dixon, 1995).

5. Conclusion

The Atlanta region is growing, and the region has attracted millions of people especially after the Olympics. Having no geographical boundaries, race and class segregation resulted in a growth pattern that settles over a large area with a very low density pattern and this lead to an automobile-oriented urban design feature. Local politics is controlled mostly by the city's downtown business leaders and this politic environment leads to a narrowly defined privately concerned policy decisions. The business elites supported the Olympic bid which was privately funded and included a feature of minimum public investment and a maximum private profit. The lack of public involvement and public funding also meant that implementing comprehensive and integrated planning was limited in Atlanta Olympic planning process.

After the 1984 Los Angeles Olympics, Atlanta organized the second privately funded Olympics with no direct public funding in 1996. The lack of public involvement and public funding also meant that implementing comprehensive and integrated planning was limited. In Atlanta, the local politics is controlled mostly by the city's downtown business leaders who influence elected officials, and this politic environment leads to a narrowly defined privately concerned policy decisions. This political environment leads to the policy decisions that neglect public interests and undermine regional and social needs because of a narrowly defined private interest. In Atlanta case, the business elites supported the Olympic bid which was privately funded and included a feature of minimum public investment and a maximum private profit. The lack of public involvement and public funding also meant that implementing comprehensive and integrated planning was limited in Atlanta. Downtown business coalition had the power and they made the critical decisions throughout the Olympic planning process. For mega-event planning, institutional cultures, history, and structures determines constitutional choices, and constructional choice outcomes effect the operational and collective choice actions. In other words, institutions are path-dependent in one sense and they have limited capacity, power, and flexibility to make decisions than are extremely different than their "path".

Atlanta's bid for hosting the Olympic Games can be understood as the product of an active growth coalition that already exists in Atlanta. For Atlanta, the vision and the central motivation among growth elites were to show that Atlanta is a "world-class" city that is capable of hosting Olympic Games. Regime theory can explain the reasons behind this entrepreneurial growth approach. In Atlanta, the Olympic bids occurred because of the existence of an urban regime to provide a way to overcome the weaknesses of city government and benefit from businesses. The main goal for business leaders was to create a commercial legacy by attracting private investment through

encouraging companies to locate their regional and national headquarters and offices in Atlanta. The Olympic bid was not just about hosting a major sporting event, but to transform the city into a world stage player. The Atlanta legacy is largely understood to have been committed to business and commercial aims – building the reputation of the city.

In the Atlanta region, largely divided community and political and racial lines are the barriers for achieving metro-wide cooperation and coordination. In Atlanta, the Olympics help to make the process faster with the positive affect of highest cooperation and coordination among different agencies and authorities, and the collaboration, beginning from the bidding phase until the staging phase, was the most notable accomplishment of the Olympics. This harmony and cooperation is needed more and has the potential to create successful regional transportation plans in the future. The Atlanta Olympics showed that Olympic Games may have a limited impact on renovating the host city. Even though the economic and physical benefits of the event were clear, institutional culture did not change significantly because of the lack of a comprehensive planning effort and funding.

Although Atlanta put a priority to create a world class city image instead of creating permanent physical legacies, the city itself and its Universities benefit from some of the physical facilities that are built for the Olympics. The 1996 Atlanta Olympic Games created permanent physical legacies e.g. the Centennial Olympic Park, Olympic Stadium, Georgia Tech Aquatic Center, 12 Upgraded pedestrian corridors, a new international concourse and a central atrium at Hartsfield International Airport, and the ITS System. The Olympic Games was a logical next step for Atlanta to grow and put the city in the world map and the city generated civic pride, provided an opportunity to generate world recognition and contributed to transforming the image of Atlanta. On the other hand, the 1996 Atlanta Olympic Games created negative social impacts on low-income residents, intensified social problems and deepen existing divides among residents.

The issue about the impact of Olympic Games on politics and power relations has largely remained understudied. This study represents an initial attempt to explore this phenomenon, and further research is needed to better understand this relationship. There are some limitations which must be considered in generalizing the findings of this study. First, this study focused on one type of mega-events; Summer Olympic Games and, investigated one single case, Atlanta. This study did not cover the Paralympics Games and did not examine Winter Olympics. Further, since this study only examines one case, the results may vary in other cities. Each Olympic host city's experience is unique, and this experience is not necessarily transferable for solving current policy problems of the city; however it provides some policy alternatives for the future. Each city is limited by its own conditions to benefit from the same Olympic strategies. Moreover, it might be argued that there has not been enough time to evaluate the real long-term impacts of the

Games in Atlanta, although 16 years have elapsed since the Olympic Games was staged. It might be still premature to totally evaluate the long-term effects which may extend to a few decades or more.

PLANNING, DEMOCRACY, AND UNIVERSITY ENGAGEMENT. A COMPARATIVE STUDY AND A CRITICAL REFLECTION

Laura Saija[1]

Abstract

Against an idea of University as Ivory Tower disconnected from the 'real' world and unable to deal with social problems, scholars around the world have implemented approaches to research and teaching that imply a direct engagement of faculty and students in real communities with concrete problems. Such approaches have had significant relevance in disciplines like planning whose paradigm is centered on the connection between knowledge, action, and social change. Often the declared aim of the scholarship of engagement is the facilitation of marginalized communities' involvement in public decision-making, within the general goal of furthering the achievement of the western democratic prospect in difficult contexts. Does reality match these expectations? The paper address this questions, in presenting the preliminary results of a comparative study of two long-term partnerships between two university planning research units with community organizations facing controversial issues:

- *the case of the* Graduate Division of City and Regional Planning *at the University of Memphis in partnership with the Vance Avenue Collaborative, in the Vance Avenue Neighborhood, in Memphis TN;*
- *the case of the* Laboratory for the Ecological and Environmental Design of the Territory, *University of Catania in partnership with the Coalition for the Sustainable development of the Simeto Valley, Eastern Sicily, Italy.*

Despite significant geographical and cultural distinctions to be made, the two partnerships share a commitment in addressing the most controversial socio-cultural challenges of their context of work. After discussing the practical and theoretical commonalities and differences of the two cases, the paper discusses structural challenges that might prevent Universities to play a transformative role within their own regional contours.

[1] Marie Curie Research Fellow, Department of Architecture, University of Catania, Italy; Visiting Faculty, Graduate Division in City and Regional Planning, University of Memphis, TN, USA – saija.laura@gmail.com.

> The university, if it is to be truly militant, must […] submit its doctrines to the test, and not only of reasoned criticism but of creative adventure in the practical world. It must put its faith in life, impassioned and purposive. The calm of the speculative life must needs find a place in the university militant; but as that of the seed, whose period of germination is followed in due season by leafage, flower and fruit. (Branford & Geddes, 1917. p. 215.)

1. Introduction

The debate on the role of higher education and research in the shaping of social and political organizations, promoting the Democratic prospect, is one of the oldest in human history, and has always been played in between two opposite images:

- The isolated Ivory Tower, place of production of objective and detached knowledge;
- The Engaged Institution that uses reality as field of laboratory, while helping humanity to solve concrete problems.

From an epistemological perspective, the deep and nonlinear linkage between human knowledge and action – discussed both by philosophers like Dewey and scientist like Piaget – is supposed to have an impact on the way Universities work: since both students and researchers, who are expected to "acquire knowledge" in specific disciplines, can acquire meaningful knowledge only through "thoughtful actions," excellence in both teaching and research can only be promoted by the integration in the official curricula of theoretical and practical activities.

From an ethical perspective, the active involvement of faculty, staff and students in highly controversial social, economic, and environmental issues is a way for Universities to play an active role in the accomplishment of the democratic prospect of their countries: students learn to be active citizens of the future, researcher get out of their "Ivory towers" while Universities have the opportunity to pay back communities that have been negatively impacted by their real estate choices.

Within this perspective, Universities and other research institutes have often been considered key actors in promoting socio-cultural and economic development in contexts where the advancement of the "Democratic prospect" appear to face substantial structural, organizational and socio-cultural obstacles. Whether or not Universities have matched a great deal of expectations in the field of international development, rural development, neighborhood revitalization, and community development – is a controversial terrain. How can Universities really play an active role in the accomplishment of the Democratic prospect in problematic contexts? Addressing the question might require further explorations on what concepts like *university engagement*, *democratic prospect* and *problematic context* can mean in concrete cases.

In the context of this paper, this is done through the comparison of work done by two engaged planning research units – the Laboratory for the Ecological and Environmental Design of the Territory (LabPEAT), at the University of Catania, Sicily, Italy, and the Graduate Division in City and Regional Planning (CRP), at the University of Memphis,

TN, USA[2]. The paper will share some critical reflections on the efficacy of University engagement in these two cases that, despite significant geographical and cultural differences, are similar for the way researchers conceive University engagement and the nature of the issues they face in their context of work.

2. Which democratic prospect in which problematic context?

The Italian South and the US Mid-South are very different contexts of work, in terms of Institutional traditions and planning framework, for planning researchers that try to deal with applied research.

Sicilian planning is strongly rooted in European political traditions attributing to public institutions to role of guarantee citizens' positive rights. Plans are required by national laws, as institutional tools for public administrations to promote the public interest through the provision of public collective services and urban spaces. On the contrary, Planning in the US Mid-South has to be understood within the frame of the US liberal democracy, in which public institutions are required to guarantee citizens' negative rights, mostly the largest possible degree of freedom in the use of private properties. Planning is not a legal requirement but is undertaken as a voluntary act mainly with the purpose of facilitating public-private partnerships and, ultimately, economic growth.

However, in both contexts the full realization of the democratic prospect, whatever ideal of social compact such prospect might be based upon, has been historically highly problematic. In both regions, modern institutional values and arrangements have been originated at the national level and then have been superimposed – not without significant friction – over a very different socio-cultural and economic structure. Before 1861 (the year of Sicilian annexation to the rest of Italy and the beginning of US Civil War), Sicily and the Mississippi Delta were characterized by highly hierarchical socio-economic structures, with small elites in control of resources (especially land) and, therefore, decision-making. In both cases, the system was based upon a significant social divide in the rural setting: *latifunda* owners vs sharecroppers in Sicily; plantation owners Vs African-American slaves in the Delta. This system was reflected in urban settlments whose economy was deeply linked to the commercialization of rural products (mostly cotton in the US and wheat in Sicily). Scholars have intensively discussed cultural and economic roots of underdevelopment both in Sicily (Banfield, 1958; Putnam, 1993) and the Delta (Hyland & Timberlake, 1993; Gnuschke, J. E. et alii, 2009; Rushing, 2009), and most of them recognize how problematic is the inability of these two "southern" societies to fully embracing the ideal of Democracy, i. e. a transparent political system in which "power" is hold by people, no matter what their income or their race is; they all agree in connecting the status of underdevelopment with the ability, at alternate periods,

[2] The paper presents partial results of a 3-years comparative research project titled "The Participatory Action Research Approach to the Test of Southern Inertia. Comparing experiences to broaden Boundaries of Action in the Environmental and Community Planning Field," carried out by the author through his active involvement in both of the presented cases. The project was supported by a *Marie Curie International Outgoing Fellowship* within the 7th European Community Framework Programme.

of ancient structures of power and socio-cultural organizations to dominate, conflict, desist, and then dominate again over "democratic" trends coming from the bottom-up and the bottom-sides. A sort of dialectic relationship between forces of different nature: on the one side there are the "dark forces," such as the Mafia phenomenon in Sicily and the racial segregation in the American South, both functional to the elitist way society is structured as a whole: the political patronage system in Sicily (Caciagli, 1977) or the overarching hegemony of private corporations on local decision making in the US (see, for instance, the role of mining companies in the Appalchian region; Gaventa 1980); on the other side, counteracting social, legal and cultural movements that manifest themselves in different ways in different moments in history, such as the Anti-Mafia Movement in Sicily (Santino, 2000) and the Civil Rights movement in the US (Couto, 1993; Green, 2007).

Today, any type of applied research that aims addressing the issue of promoting democracy in conflicted regions like Sicily or the Mississippi Delta has to face the same dilemma: what new form is taking the old never-ending conflict between formalized democratic institutions and long standing elitist socio-cultural structures? In the following paragraph two very different cases show a common approach to face such a dilemma.

3. What does university engagement mean?

CRP and LabPEAT are two small research and teaching units of two relatively large Public Urban Universities, The University of Memphis (UofM) in Memphis, TN, USA and the University of Catania (Unict) in Catania, Sicily, Italy.

The LabPEAT was established in 1995 as part of the Architecture and Urban Planning Department (DAU) by two faculties inspired by Agenda 21's principle that citizens' active participation was necessary for environmentally sustainable planning and design (Busacca & Gravagno, 2005). CRP, in its current form, was established in 1997 as part of the School of Urban Affairs and Public Policies (SUAPP) with a "focus on urban issues and link the teaching, research, service, and outreach efforts to the unique needs of the Mid-South" (SUAPP 10 years Anniversary Report 2010: 4). Despite many organizational differences, both units share a clear commitment to University engagement, that rejects what can be considered the most common model of planning applied research: the *professional expert model*, in which "the professional researcher is called in by a client organization – or talks his or her way in – to study a situation and a set of problems to determine what the facts are, and to recommend a course of action. In this type, the professional researcher is completely in control of the research progress except to the extent that the client organization limits some of the research options." (Whyte 1991, p. 8, 9) On the contrary, both CRP and LabPEAT are committed to what is called Participatory Action Research (PAR), an approach in which the researcher is an internal actor within a community, sharing control with others, in a process of collective change, in which knowledge and actions have a collaborative nature. There are of course different PAR approaches, in terms of goals and practical tools.

Ecological planning in the Simeto Valley

When it was first established, in 1995, LabPEAT's interest in applied researcher was originally inspired by the growing impact that complexity theory and ecology were having at that time on Italian planning and design theory (Bocchi and Ceruti, 1989). The initial focus of the group, when it was established, was to explore the consequences of those theories on planning paradigms and methods, without a clear understanding of the difference between the professional expert model and genuine PAR. The idea was to engage local institutions and, more rarely, community organizations, deal with Sicilian complex ecological systems. The expert model for applied research had been intensively used, before 1995, by other Unict planning researchers (various authors, 1990; Sanfilippo, 1991; Campo 2004). However, the LabPEAT had the awareness that the professional expert model needed to be modified, and that the only way of modifying it was to "try it out" and critically reflect upon it (Saija, 2007). Since 1995, LabPEAT researchers have progressively moved from the professional expert model to a PAR agenda, mostly inspired by Pizziolo's ecological planning and design theory according to which designers and planners are internal actors within a process of co-evolution of humans, other living species, and the environment (Pizziolo, 1995; Pizziolo & Micarelli, 2003). No matter how much they try, planners are not entirely able to control and plan the future of complex systems in constant evolution like cities and regions. As a consequence, the only thing left for them to do is to become purposeful and skilled agents for change, from the inside of a complex system, but letting things evolve toward directions that no one is entirely able to predict (Mugerauer 2005). Complexity theory, in the 90s, challenged planners' traditional technocratic perception of their social role, making them aware that every part of a complex system plays a role in the evolutionary process, for the good and for the bad. The question is: how can planners stimulate a process of evolution toward a "better" future? How does "better" mean? In Sicily, a process of evolution toward a better future has to deal with the most oppressing local issues such as the Mafia phenomenon.

While scholars were still debating on its very existence and on its real nature, the complexity of the Mafia, as symptom of a complex anti-democratic net of relationships between Sicilian culture, businesses and politics (Sanfilippo 2005), was addressed by the pioneering work of the *Centre for the Full Employment in Western Sicily*, established in 1952 by non-violent educator Danilo Dolci. In more than 13 years of work, the Centre demonstrated how is to pursue legal actions against Mafia's affiliates only within a much broader framework of action: a complex combination between community organizing and popular education aimed at collective cultural change that would help communities to liberate themselves, culturally and practically, from the Mafia's cultural and economic hegemony (Dolci, 1974; Barbera 2011). The same message was at the center of the large Anti-mafia mobilization that followed the violent years of 1992 and 1993: Sicilian organized crime is not an isolated disease to be eliminated with surgery (legal prosecutions) by anti-mafia experts (judiciary, policemen, etc.) or heroes (who then pay a high personal price); it is everybody's responsibility to deal with his/her own, more or less conscious, Mafia-genic cultural features and supportive actions.

LabPEAT researchers, during their work in partnership with community organizations in distressed neighborhoods of Catania, have developed an approach to PAR deeply inspired by Dolci's and contemporary Anti-mafia associations (Saija & Gravagno, 2009; Saija 2012). Such a development is based on the observation that there is strong parallel between a university scholar that understands the impossibility of being an "external" and "objective" researcher and an anti-mafia activist that understands his/her being part of a complex system of bi-directional relationships where it is very hard to trace a clear line between the good and the bad side. In both cases people are asked to undertake a process of collective learning and social change that would allow them to make sense together in the world (What is legal? Why?). The practicality of this general and abstract statement will be further discussed in the case of the work that LabPEAT researchers are doing in partnership with the *Coalition for the sustainable development of the Simeto Valley*.

The Simeto Valley Story[3]

The Simeto Valley, the central portion the 4000-square-km-large Simeto river watershed located South East of the Etna Volcano, in Eastern Sicily, comprises six municipalities with a population of approximately 140,000 permanent residents. The Valley includes the central stretch of the river, and small towns that are all but one built on the left bank, at the edge of the lowest lava shelf of the volcano and separated from the river itself by a fertile band of alluvial soil.

The Valley has historically played, due the richness of the soil and the abundance of natural water springs, the role of the food basket for the Catania metropolitan region, the second largest in Sicily with about 1 mln of inhabitants. However, since the 50s, public policies aimed at pursuing economic growth (i.e. mechanization of agriculture and promotion of industrial activities) have inflicted significant and irreversible damages to local man-made/natural ecosystems. In continuity with these policies, in 2002, the Regional Government decided to build a large incinerator a few km away from the river, as part of a new *Regional Waste Management Plan*. This decision was immediately opposed by community organizations, which in few months established the *Coalition for the Sustainable Development of the Simeto Valley* and started an anti-incinerator campaign. The rationale for the mobilization rational was twofold:

- The incinerator represented a great obstacle to the recent growth of economic activities related to ecotourism; and,
- There was enough evidence that the project of the incinerator was about to significantly favor local enterprises connected to the organized crime.

Thanks to a complex variety of legal, socio-cultural, and political strategies, the *Coalition* was able, at the local level, to temporary block the Cannizzola incinerator,

[3] A more detailed discussion on the Simeto case can be found in Saija (2011), and Saija (submitted on Jan 2012).

while joining a large campaign against the *Regional Waste Management Plan*, which eventually ended with a substantial victory of the anti-incinerators front[4].

However, despite the success of the anti-incinerator campaign, other ongoing institutional planning efforts planning processes, such as the *Strategic Development Plan for the Etna Region*, were at that time discussing controversial option of development of other portions of the Valley. To counteract present and future attacks to the Valley's natural and historic assets, the Coalition established a partnership with LabPEAT in 2008, and undertook a 6-month-long phase of collective training on possible bottom-up approach to community 'sustainable' development. The training was aimed at identifying "the stone able to catch multiple birds," increasing the ability of the Coalition to affect decision-making and the level of residents' and organizations' engagement, while promoting a new alliance between humans and nature.

The "stone" was named the *Simeto Community Mapping Initiative*. The Initiative lasted about 5 months and took place in 10 different locations within the Valley countryside and in 4 small towns along the river, involving 500 individuals and representatives of 22 community organizations, and city officials from 3 out of the 4 towns. All the community mapping activities were carried out by university and community members together.

The first event of the *Initiative* was conceived as an open house where participants were enabled to share their own knowledge and planning inputs through mental mapping, open-ended interviews and interaction with other participants in the location and description of places on a large wall-map of the entire valley (10mx3m). Later in the process, these activities were paired up with public presentations of intermediate results; special sessions of storytelling with seniors associations willing to share their memories and old legends about the valley; long public exposure of the wall-map; thematic mapping activities focusing on the water resource; an internet-based mapping tool; door-to-door recruitment of mappers; and in-depth interviews with local experts. The final event was conceived as a public workshop with experts and public officials to finalize the Initiative's outcomes. An official document was prepared and officially delivered to Regional, Provincial and Local Officials, containing a community map, a collection of stories and legends on the valley, and a more political section identifying:

- the material and non-material features characterizing the Simeto Landscape
- shared ideas on how to promote "sustainable development" in the valley (high quality food production, creation of jobs related to high quality food processing following traditional recipes, promotion of food-related and eco-tourism, support for local craftsmanship using local renewable materials, etc.);
- priority actions to be undertaken by different actors in different sectors (institutional, business, non-profit);
- concrete projects to be carried out even with scarce institutional involvement.

[4] After years-long legal procedures, Sicilian Governor Salvatore Cuffaro was condemned, on January 2011, for aiding and abetting Mafia and he is now convicted. The new President of the Region, Raffaele Lombardo, has officially abandoned the idea of building incinerators in Sicily (Regional Law n°9, 2010) and officially denounced mafia infiltrations in the incinerators' affair (for more details see Saija, submitted on Jan 2012).

The document was intended to affect the contents of the *Strategic Development Plan for the Etna Region* and other official institutional planning efforts. After the official ending of the *Initiative* two important outcomes were achieved:

- two community-led projects of transformation of two controversial areas with the purpose of addressing specific issues raised during the Initiative: two illegal dumping sites along the river are in the process of being transformed into a community riparian garden and an educational park (Raciti, 2012);
- the beginning of a process of institutionalization of a community-based resource management approach, called the *Simeto River Agreement*, following the model of the *Landscape Agreement* implemented for the Panaro river (www.parcopanaro.it, Pizziolo and Micarelli 2011). This process is proceeding, but not without difficulties, without a clear understanding whether or not all the key players will be sitting at the table (for more details see Pappalardo 2011).

Empowerment Planning in Vance

Unlike LabPEAT, whose interest in PAR is the outcome of a relatively slow transition process, CRP's approach to applied research, traditionally based upon the professional expert model, suddenly shifted toward a participatory model in 2008 when Kenneth M. Reardon – a planning scholar well know of his part experiences of University engagement in participatory processes aimed at community development across the US – was hired as new chair. Developed through decades of experience as Community organizer, first, and then University researcher partnering with grassroots organizations all across the US, Reardon's approach called Empowerment Planning integrates "the key principles and methods of participatory action research, direct action organizing, and popular education into a single organizational-capacity and community-building process, and enabled them to undertake increasingly challenging development initiatives" (Reardon, 2005: p. 86).

In particular, university faculty, staff, and students work together with community members and organizations to:

- frame the most oppressing local issues;
- lay-out strategies to address them;
- implement them; and,
- Cyclically re-evaluate priorities and strategies.

The approach is inspired by Alinsky's idea that the implementation of the projects that are in the best interest of the community (often in contrast with private corporations' interests) requires grassroots organizations to held enough power over local public and private decision-making (Alinsky 1971; Rathke in Saija 2011, pp. 14-18). As a consequence, planning aims at not only analyzing issues and setting up strategies, but also *increasing the level of organization* of powerless communities as a way for them to acquire more power. For this purpose, planning is enhanced by a variety of outreach efforts, aimed at increasing the number of engaged residents and enlarging the network of allies. Participatory techniques are then used to *identify urgent*

issues and priorities of action, while an *effective resources and control sharing* takes place between the University and the community partners. Such sharing might require the University to offer training not only to its students by also to the broader community. Inspired by the principle of libertarian pedagogy (Freire, 1968; Horton, 1997) and in particular by experience of Highlander Folk School in West Tennessee (Glen, 1996), the Empowerment approach allows community participants to develop new skills that enable them to carry on planning and action in the present and, eventually autonomously, in the future.

The Empowerment planning approach has been systematically implemented by CRP in strict collaboration with the Anthropology Department and in particular with prof. Katherine Lambert-Pennington, in two of Memphis' most troubled inner-city neighborhoods: the southern portion of South Memphis (Lambert-Pennington & Pfomm, 2010; Lambert-Pennington et alii 2011) and the Vance Ave Neighborhood, closer to downtown. In both cases, CRP has partnered with Andrew AME church and St Patrick Catholic Church respectively, pushing them to form a broader coalition of community organizations (Churches, non-profits, community groups, social services providers, etc.) aimed at promoting participatory community development. The Vance Avenue case will be discussed in more detailed in the following paragraph.

The Vance Avenue Neighborhood Case[5]

Memphis, the second most populated city in the state of Tennessee with its 647,000 residents, more than 60% African-American, has grow throughout the 19th and 20th centuries as commercial hub for King Cotton, thanks to its convenient location on a bluff on the Mississippi river (the old days major "US highway") half way in between New Orleans and St Louis. However, despite the glories of the past, over the past six decades all Memphis' inner city neighborhoods have experienced a significant decline. While urban sprawl and consequent downtowns' crises are very common phenomena among US Cities, in Memphis significant racial conflicts have made out-migration even more evident than in other parts of the country. Conflicts' peak was reached in 1968, when underpaid African-American sanitary workers initiated a long strike against racial discrimination, that then become one of the most tragic events in the American Civil Rights Movement history (Breyfuss, 1990; Honey, 2007): Martin Luther King, who came to the city to support the strikers, was assassinated on the balcony of the Lorraine Motel, few blocks east of the city's largest "negroes" public housing projects, Foote and Cleaborne Homes.

Since late 70s, several policies have been implemented by the City to face the decline. Public officials have mostly focused on Downtown Revitalization (through the establishment in 1977 of a Central Business District) and on the redevelopment of Public Housing Projects surrounding Downtown. Between 1994 and 2005, all but two Projects were redeveloped as "mixed-income" traditional neighborhoods – mostly through the

[5] For more details on the case see Reardon et alii (2011).

use of HOPE VI grants[6] –, and tenant-based Section 8 Vouchers were used to relocate former residents into privately owned units mostly located at a larger distance from Downtown. In 2008, the last two remaining Projects, Foote and Cleaborne Homes, the core of the Vance Ave neighborhood, became the target for redevelopment. In January 2009, the City officially announced that a new Development Plan was underway to tap federal money to develop an area called *Trinagle Noir* (20 city blocks just south-east of Downtown), envisioning an expanded entertainment district, new housing, a luxury hotel and as much as $1.1 billion in public and private investments. A structural element of the plan was the use of HOPE VI Grants to tear down Foote Homes and Cleaborne Homes.

Concerned about the impact that this plan would have had on local residents, local leaders from *St Patrick Roman Catholic Church*, one of the oldest institutions in the neighborhood, asked the University to establish a partnership with the purpose of carrying out a community planning process. The aim was to counteract *Triangle Noir* perceived as a strategy to create a gentrified "entertainment district," avoiding residents' displacement like in all the other Memphis' HOPE VI redevelopments, all of which had had a very low % of returning residents.

During the summer 2009, St Patrick and CRP formed a broader coalition, called the *Vance Avenue Collaborative* (VAC), of Community Organizations sharing their same concerns. The planning activities started in the Fall semester 2009, with a CRP studio class carrying out specific research activities – such as archival research, physical surveys, interviews with local leaders and residents – whose results were continuously presented at a monthly community meeting, and modified according to local residents' active feedback (usually collected through participatory techniques such as community mapping, visioning exercises, etc). For each community meeting students and faculty performed an intense outreach (phone calls, door-knocking, emails, mails, press release, pulpit announcements for parishes), also encouraging community members in actively participating in the research activities. During the spring break, VAC carried out door-to-door interviews with 170 residents, and then, at the end of March, held a neighborhood summit with the goal of:

- presenting the data and the main findings;
- Share a broad development goal for the neighborhood;
- Identify the developmental objectives through which the goal could be implemented;
- Generate, in small groups, as many action items as possible for each developmental objective;
- Prioritize the action items, based upon criteria of importance and/or feasibility.

Not surprisingly, community outcomes, summarized in June 2010 in a Document named *VAC Preliminary Planning Framework*, did not match the ones characterizing

[6] HOPE VI is a US Department of Housing and Urban Development Program established in 1992 after a political debated on how to address the physical and social decay associated with public housing projects all across the US. HOPE VI allows Public Housing Authorities to receive funds to replace "distressed" public housing projects with new development where usually only 1/3 of the units are for low-income residents (mixed-income developments). The replacement is mostly done through the establishment of public-private partnerships between public Agencies and private developers (Popkin et alii 2004).

Triangle Noir: residents did not perceive Housing as a priority in a neighborhood where the only service for citizens was actually housing. The priority was to provide additional neighborhood-based services and amenities (access to fresh food, neighborhood oriented retails, a well maintained park, health-care, a homeless-shelter, and after-school programs) as well as linking more explicitly large Downtown redevelopments, often employing a large amount of public money, to the creation of jobs for low-income residents.

Unfortunately, the very same month the community was presenting its Planning Document, the City was announcing the award of the 5th HOPE VI grant for the redevelopment of Cleaborne Homes. Cleaborne was demolished shortly after, and it is today in the process of being redeveloped.

The plan of redeveloping the very last Memphis Public Housing Project, Foote Homes, is currently under examination, but this time the Collaborative has the occasion to affect decision-making.

In an effort to address the strong criticisms moved against HOPE VI by experts and scholars (see Goez, 2003; Kleit & Manzo, 2006; Bennett et alii, 2006, among many others), HUD, with purpose of embracing an improved holistic approach to Public Housing "redevelopment," has recently lunched *Choice Neighborhood* (CN) Grants requiring applicants not just to deal with housing but also to expand supportive services and educational opportunities for residents. CN also require the minimization of residents' displacement, their direct involvement in the planning process and partnerships with neighborhood institutions. In the winter 2010-11 the City applied to a CN Planning Grant and, due to HUD requirements around community engagement, it asked CRP to be responsible for the participatory activities for the Grant. Other consultants were appointed to be responsible for planning around housing and social services.

Since July 2011, CRP has replicated, in the new role of *City planning consultant*, most of the activities carried out in the first phase, enlarging the number of engaged organizations and residents while enhancing data collection. A community organizer was hired, and several training opportunities on community organizing – one at the highlander Folks school – have been organized as part of the Planning Initiative.

The process is however proceeding with a significant level of internal conflict: the City and other consultants expect the process to lead to the submission of a CN Implementation Grant that would substantially replicate the HOPE VI approach, while participatory activities are expected to help building consensus among residents. CRP faculty and students are, on the contrary, collecting a great amount of data that reinforce the findings from the previous phase, including a strong preference for the rehabilitation instead of redevelopment of most of the Public Housing Units. How the conflict of positions is going to end is not clear yet, but the community values the fact that, at least, this time, VAC was invited at the table. In the meantime the collaborative is working at the implementation of one of the priority projects that were identified in 2010 within the *VAC Preliminary Planning Framework*: a mobile food marked, called *the Green Machine*, able to address the need of accessible and affordable fresh food in a neighborhood where most of the residents do not have access to private transportation.

4. What do they have in common?

Even from these synthetic descriptions, it is possible to identify many differences between the two cases, where PAR is used to deal with problems of a different nature. In Memphis, VAC is trying to affect decision-making for the benefit of the most disadvantaged, led by a social justice ideal, and deeply inspired by the US Civil Rights debate. In Sicily, the Simeto Coalition is working in favor of a new social organization able to establish a new alliance with Mother Nature, led by an environmental sustainability ideal, but also within the context of the local anti-mafia movement. However, even if inspired by different political and planning discourses and ideals, CRP and LabPEAT researchers share the idea that what really distinguishes PAR from other forms of applied research is the fact that it deals with power (see Hall 2005 for a good literature review on the topic).

In both cases researchers establish a partnership with more (*St Patrick Church*) or less (*the Simeto Coalition*) formalized organizations of people sharing concerns about the way planning and decision-making (the Sicilian Region Waste Management Plan, the Strategic Development Plan for the Etna Region, the Triangle Noir Plan, the Vance Choice Neighborhood Transformation Plan) are carried out in the place where they live. One of the main purposes of the partnership is to enhance the powerlessness status of the organizations affecting their ability to shape decision-making for the "better," being the way "better" is defined dependant, of course, on the situation.

In Memphis, the "better" means forcing city elites to reframe their way of dealing with poverty and public housing. VAC is reaction against a way of framing poverty as a plague rooted in the lack of individual skills of self-improvement which can be addressed through social and physical determinism: HOPE VI is based on the idea that self-esteem educational activities and replacement in a social and physical environment reflecting middle- and high- income social values is a good strategy to deal with poverty of public housing residents. On the contrary, Vance residents and leaders are asking public officials to address the structural causes of their scarce quality of life – the unfair distribution of resources and opportunities within the city – claiming the dignity of their being a community, whose painful history cannot be commercialized by private developers.

On the contrary, in Sicily "the better" means forcing local public institutions to make decisions based upon values of transparency and sustainability, abandoning the long-standing local custom of closing deals behind closed doors with Mafia-related businesses; in particular, the Simeto community is asking to face, in a structural way, the reality that the management of resources such as water, energy, waste, etc. is one of the largest source of profits for the organized crime (Legambiente 2007-2011).

In both cases, the Simeto and the Vance partnerships deal with what might be considered the main challenges for the full accomplishment of the democratic prospect in their contexts. They both embrace a controversial project that challenges decision-making (and the stable structures of power behind it), working on each own "giants shoulders," in the shadow of the most meaningful social movements that have historically challenged the status quo: the Anti-Mafia Movement in Sicily, and the Civil Rights movement in the American South. Very much in the shadow of the *Centre for the*

Full Employment in Western Sicily and *Highlander folks school* in Tennesse, CRP and LabPEAT use participatory planning techniques to advance participants' understanding of their status of powerlessness as a first step for social change. This is a very different use of participatory planning techniques, compared to the well-known *consensus-building approach*, inspired by Habermas's Discourse Ethics (Habermas 1983), in which the ultimate goal is the making of a decision that could be shared by groups with contrasting interests (Susskind & Field, 1996; Innes & Booher, 1999). Both Empowerment and Ecological planning go beyond the need of "mediating" between contrasting interests. Echoing Castoriadis' (1997) and Barcellona's (2005) critiques of Habermas' political theory, they operate on a different level: the creation of the collective subject that can eventually affect decision making. The aim is to shape transformative collective experiences that allow people to innovate "for the better" their collective identity, creating the space for "*arenas* where systems of meaning, ways of acting and ways of valuing are […] transformed" (Healey 1997: 58). In both cases, the arenas are places of painful conflict and/or joyful emotional attachment that touch not just rationality but also deep emotional dimensions of cognitive structures (Marris 1974, Pizziolo & Micarelli 2003).

In the Simeto and in the Vance case, the partnerships initiated a participatory planning process that, at first, did not have any institutional legitimacy; the legitimacy is gained along the way, with:

- Real effects on public decision making (the birth of the *River Agreement Initiative* in Sicily and VAC's involvement in the *Vance Choice Neighborhood Planning Initiative* in Memphis)
- The birth of community-led projects of concrete change on the ground (the community gardens in Sicily and *the Green Machine* in Memphis)

Both level of action, the impact on decision-making and the implementation of concrete projects, are crucial for the purpose of shaping a new collective political subject that is able to destabilize old structures of power with new political "instances." Without concrete projects, the never ending struggle at the decision-making level would be exhausting, and probably frustrating. Vice versa, concrete projects without the effort of affecting decision making would not be transformative enough.

5. Is it enough?

Despite the greatness of the inspiring ideals and acknowledging the good outcomes, it is crucial to ask whether or not the ambitious expectations of the type of community-university partnership presented in this paper are then matched by reality. In other words, to what extent CRP's and LabPEAT's work is promoting real social change? Are they producing a permanent modification of existing power structures, decision-making procedures? Are they permanently affecting the way humans interact with other living beings and natural resources?

It is difficult, for an author that has also been deeply involved in both experiences, to say something different then "I hope so." But for the purpose of the paper, It makes

more sense share some critical thoughts trying to go beyond hopes, wondering what kind of contingent or structural dilemmas are related to this type of work.

The Sicilian and the Delta cases, together with many other well-known cases in the literature, demonstrate that PAR is a very promising and fertile ground for planning researchers, whose disciplinary mandate is, intrinsically, action-oriented. If this is true, why do planning research seem to go toward a very different direction (Campbell, 2012)? While some scholars are still debating on PAR's epistemological validity, others stress the level of frustration that can be associated generated by practical and organizational obstacles in dealing with a research method characterized by a high level of uncertainty: PAR relies on the idea that you *modify your road while walking* (Bell et alii, 1990) in the face of rigid academic calendars and funding procedures. Is this the reason why PAR is not more diffused in the academic environment? I personally do not believe this is the real reason behind the scarce diffusion of PAR within the academic environment. I have seen many "traditional" researchers that, after a period of adaptation, have learned to deal with "uncertainty" through the use of flexible research approaches, enjoying the consequent increase of opportunities for innovative thinking.

With a more Foucauldian perspective, I do find myself closer to scholars suggesting that epistemological debates are deeply shaped by existing structures of powers: since the essence of PAR is the redistribution of power (to know, to decide, to act) in favor of the powerless, it is not surprising that such an approach is difficult to "digest" for large institutions whose financial existence rely on the existing power structures.

Both UofM and Unict, together with many other European and American Universities, are increasingly required to depend upon private financial supports. Are they really in a position to genuinely embrace the work of their "engaged" research units, supporting the idea of becoming involved in controversial issues oppressing their communities? Goldsmith suggests that this is not likely to happen, suggesting that instead "universities will continue, quite understandably, to be concerned with their own problems – tighter budgets, increased internal demands, and new pressures from government, alumni, and business" (Goldsmith 1998: 1246).

As a matter of fact, both CRP's and LabPEAT's commitment to PAR and social change does not reflect the broader mission of their Universities. Their work is carried out with a limited amount of resources, and the institutional support is very strong on words, but very limited in practice (money, staff support, etc.). It is legitimate to ask: how permanent are these community-university partnerships and their ability to produce positive outcomes?

The reality is that, in both cases, the work is carried out not by external and resourceful agencies (NGOs or similar) but stable local structures based upon a great deal of voluntary work (from the part of both researchers and community members) and the "creative use" of traditional Grants. Beside personal commitments of university and community individuals, there are not stable organizational and/or financial arrangements that can guarantee the continuity of the work that, despite the good outcomes, is still very much uncertain. After small successes within important conflicts, such as the anti-incinerator campaign, social change can be pursued only through long-term committed time and money both for community members and researchers. Dolci's Centre lasted 13

years, while Highlander, established in 1932, is still a working operation. Both institutions, though, were not part of large and powerful Universities. Was this the secret of their successes? I think this question, if addressed in a open and honest way, might help animate the international debate around the ability of planning research to address a genuine link between knowledge and action and, ultimately "to fortify the ideal of thus transforming Business and Politics -from a sordid struggle for survival into a civic and regional direction of energies to the maintenance and ennoblement of life." (Branford & Geddes, 1917: p. 215.)

LOCAL DEMOCRACY, PLANNING AND MANAGEMENT: SOME PERSPECTIVES FROM THE KARACHI METROPOLITAN REGION

By

Noman Ahmed, Ph.D

Abstract

In developing countries, urban planning and management has been administered through various institutional approaches. Centralized city government; location wise or functionally fragmented administration, elected municipalities with development authorities, combination of formal and informal institutions and geographically segregated jurisdictions are some of the alternatives that have been tried in different contexts. Karachi has experienced an uneven institutional transformation at the local government level during her post-independence history. As a consequence of experimentations and subsequent outcomes, many changes have evolved in the domains of urban planning and management of the city. This paper documents the changes and analyses the outcomes at respective stages to identify the impacts on the planning and management process till the present times. On the basis of the study, the paper also presents normative recommendations.

Key words: Local democracy, planning, management, Karachi

Urban Politics, Democracy, Governance and Participation

1. Information and Background

After the end of British colonial rule in 1947, Pakistan and India emerged as two major states in South Asia. Despite their large scale of territories and population sizes, each of them was pre-dominantly rural in demographic respect. The drastic political and administrative changes that emerged as a consequence of partition of Indo Pakistan Sub continent caused numerous transformations in the settlement pattern. A very large social dislocation from original places of habitation towards newly carved out states was a visible outcome. The port cities in India and Pakistan were the key recipients of refugees in a very large proportion. The administrative machinery of these cities was soon overwhelmed by almost the overnight increase in population. This transformation caused enormous problems in managing the cities.

The British had left behind a relatively stable mechanism of city administration. For management of towns and cities, municipalities of relevant legal and administrative composition were constituted. In order to deal with extraordinary issues in urban development and management, an exclusive institution with the nomenclature of

Improvement Trust was formulated. Thus Bombay (now Mumbai) City Improvement Trust was founded in 1898 after two years of a deadly plague epidemic. Delhi Improvement Trust was created in 1937, Calcutta (now Kolkata) Improvement Trust was founded in 1912 while Madras (now Chennai) Improvement Trust was constituted in 1945. The objectives behind each of these institutions was to deal with pressing problems of sanitation, road and street development, housing management and other related subjects. It may be noted that all of these cities had a reasonable size and complexity which required the concerted input of an additional institutional and technocratic arm. In contrast, Karachi was a small town of 435,000 inhabitants when Pakistan came into being in 1947 (KMC, 2012).

Before partition, Karachi was a well managed city comprising Hindus, Muslims, Christians, Jews and Zoroastrians, peoples. However the influx of refugees from India changed the composition, population status and urban profile (see Figures 1 – 5). The city rose to the size of 1,050,000 people in 1951. Due to inadequate provision of housing and other amenities, the refugees occupied significant part of the hinterland territories and squatted haphazardly all around the developed areas. While the city had a municipal corporation, it was unable to deal with the grave issues that emerged as a consequence of high in-migration. Learning from the experiences elsewhere in Indian cities, the central government of that time constituted Karachi Improvement Trust (KIT) to deal with planning, development and management issues in the city. Karachi continued to experience a high growth rate ever since and posed new challenges to the various forms and formats of administration.

2. Karachi in National Context

In 1947, Pakistan comprised both West and East Pakistan (now Bangladesh). The city of Karachi was chosen as the national capital due to the fact that it possessed basic urban facilities and was relatively accessible by sea route for the people of East Pakistan. It soon emerged as the primate city of the country and continues to enjoy this status till today. The city accounts for about 7 percent of total national population and 22 percent of total urban population. It contributes 15 percent of GDP and 25 percent of the national revenue. The city holds 50 percent of the bank deposits while accounts for 72 percent of the total issued capital. The two major sea ports and busiest national airport is also situated in the city (CDGK, 2006). The city is also a major hub of industrial, commercial, banking and cultural activities.

3. Local Democracy, Planning and Management in Karachi: A Review

3.1 Local Democracy

It is important to note that for most of the time period during post independence times, the city has been governed by a combination of technocratic – bureaucratic nexus with very short lived phases of local democracy.

As observed in most of the young post colonial nation states that acquired independence in the twentieth century, Pakistani administration followed a centralist tradition of decision making and governance. Important decisions were taken by the head of the state and implemented by an efficient framework of bureaucracy. Thus key matters related to city planning and development was also settled by the federal government. An example of this fact is the creation of Karachi Development Authority in 1957 through a Presidential Order. The same order stayed valid as a law for the next half a century. The local government institutions, mainly the municipal corporation, were perceived as an urban management agency. It was assigned to deal with rudimentary matters such as maintenance of streets, retail water supply, sanitation, monitoring of public open spaces, maintenance of hygienic conditions in market places, management of abattoirs / slaughter houses and dairy farms, quality control of food and beverage items, preventive sprays on stagnant pools of water etc. as the country soon plunged into a political turmoil leading to military rule in 1950s, the necessary awareness to address policy making for local matters and connected avenues could not be explored. When the local elections were held by military regimes, the councilors and mayors gradually developed political maturity to deal with the pressing issues of the city and beyond. Many of these councilors became politicians of substantial acumen and status and led the various affairs of the country.

It is worth mentioning to note that while the decision making and implementation mechanism was largely centralized during 1950s and 60s, the visible sincerity of purpose of the bureaucracy and technical competence of senior officers in the municipality became the reason for better management and governance of the city. Some matters, which evolved to become grave issues in the future, included the rise in squatter settlements, pressure on water supply and sanitation, exponentially high population growth rate due to in migration, uncontrolled urban sprawl and slow but steady commodification of urban land.

The absence of a powerful and capable metropolitan government during the later part of the institutional history caused many grave consequences. Small and medium scale land management agencies multiplied. Such developments stretched city infrastructure in multiple directions and generated their own dynamics that gravely impacted respective neighbourhoods and the surrounding territories. A concise retrospect of the evolution and status of local democracy in Karachi during the post independence period is illustrated in Figure 06.

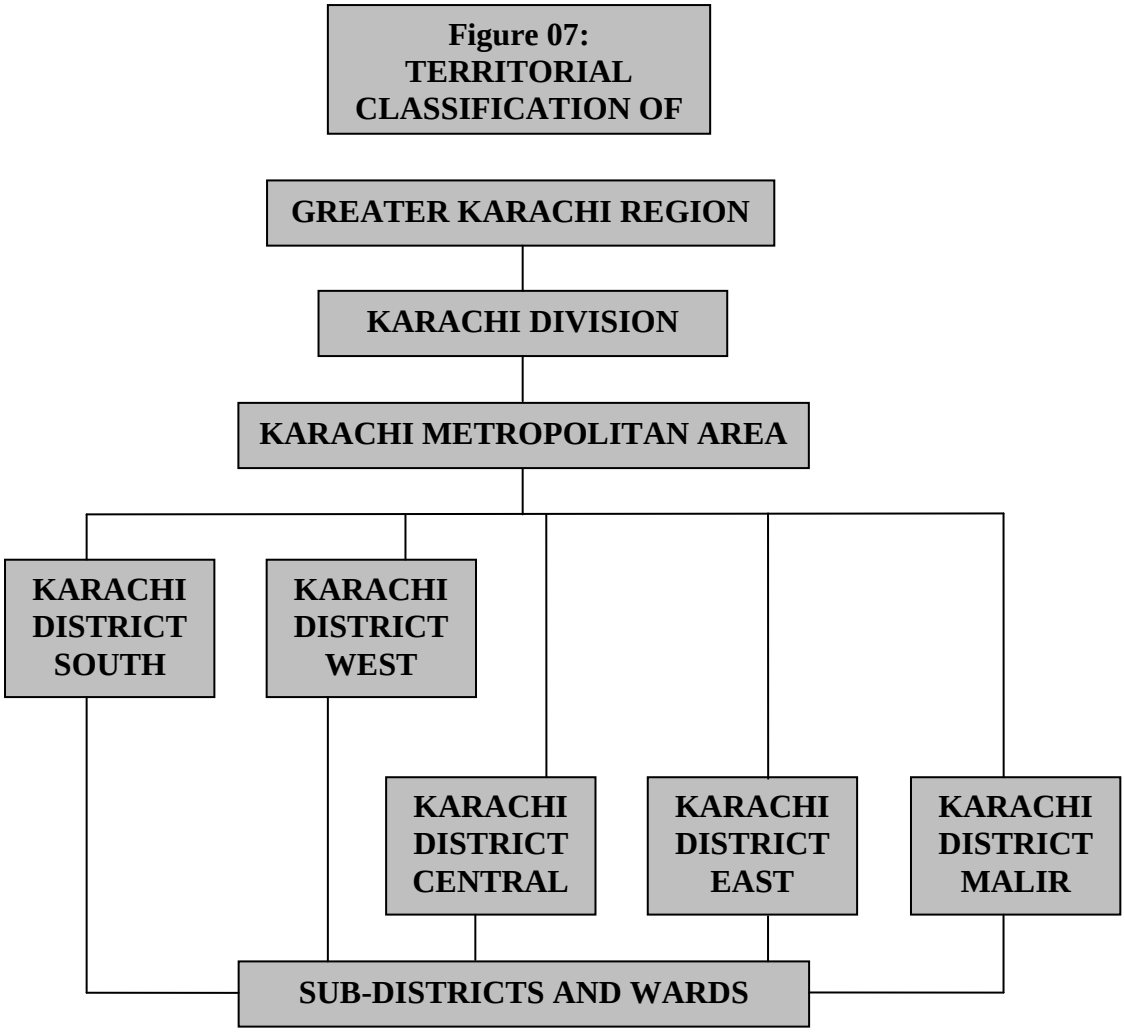
Figure 06: EVOLUTION AND STATUS OF LOCAL DEMOCRACY IN KARACHI SINCE 1947

PHASE	STATUS OF LOCAL GOVERNMENT	REMARKS
Initial developments (1947 – 58)	• Karachi Municipal Corporation functioned as local institution under bureaucratic leadership. • Commissioner of Karachi held most of local administrative powers. • Karachi Development Authority founded in 1957 to focus on and facilitate bulk water supply, sewage and roads / highways development. It also instituted physical planning.	• Negligible participation of citizens in municipal affairs. • City remained in a drastic stage of transition and change. • Being the national capital, Karachi was the centre stage of national political activities. • Infrastructure and housing shortage made the core reason for launching KDA. New housing schemes were developed.
Basic democracies (First and second military regimes) (1958 – 69 and 1969 – 71)	• Military regime introduced Basic Democracy (BD) System in 1959. • Elected municipal councilors in local government.	• BD system introduced to accord legitimacy to military regime. • Very limited autonomy was enjoyed by local government – privilege of decision making and administration remained with Commissioner's office.
Democratic government at provincial and federal level (1972 – 77)	• Elected government at provincial and federal level. • KMC and KDA continued to function as bureaucratic organs – KMC upgraded as Karachi Metropolitan Corporation.	• Despite democracy in upper tiers, elected municipal institutions could not be revived. Potential political impediments from elected local government were found as the core reason.
Third military regime (1977 – 88)	• Elected local government in Karachi and elsewhere in the country revived in 1979 KMC had elected councilors and mayors.	• Though elections were held, KMC had limited powers and privileges – provincial bureaucracy and upper tiers of government controlled majority of affairs.

Democratic interregnum (1988 – 99)	• Elected local governments replaced by appointed administrators.	• Perhaps due to quick changes in federal and provincial governments, the elected local governments could not be revived.
Fourth military regime (1999 – 2008)	• Local government in Karachi and elsewhere revived. • Significant powers and resources were devolved to local government in a completely re-vamped format.	• Wide ranging reforms introduced. • KDA, KMC and DMCs merged to form City District Government Karachi. • Many provincial functions were devolved to the local government.
Current regime (2008 to date)	• Local government's reforms repealed. • Present working of local government partially reverted to the status of 1979.	• Absence of political consensus between political stakeholders led to stagnation of local government affairs.

Source: Author's interpretation of various government records and archives, 2012.

The present status of Karachi is similar to its administrative organization that was prevalent till 1999. The city is spread on a larger region termed as the Greater Karachi Region. However this physical space is valid for planning considerations only. The other details of territorial organization of the city are shown in Figure 07.



Source: KMC Archives, 2012

At present, the status of local government in Karachi and the Sindh province is passing through a stage of transition. The existing structure of institutional framework is presented in Figure 08. The political parties that have representation in the provincial assembly have to devise a new law to evolve a consensus for the future functioning of local government and elsewhere in the province.

* Karachi Electric Supply Company is now a private entity. It functions under the regulatory framework laid down by National Electric Power Regulatory Authority (NEPRA).

3.2 Urban and Regional Planning

Despite the burgeoning problems that the city faced during the earlier phases after independence in 1947, Karachi received many planning inputs on a continuous basis. Different institutional arrangements were manifested to channelize these attempts which are concisely illustrated in Figure 09. Whereas none of the plans and planning recommendations was implemented in full, many changes and impacts were caused by them during the entire time frame.

Greater Karachi Plan stabilized the direction of growth of the city towards north east and eastern stretches of the urban peripheries. The plan had also provided an elaborate scheme of a capital complex and allied facilities in the anticipation that the city will continue to function as the national capital. However due to an administrative decision of the government, the capital was eventually located into the newly planned city of Islamabad.

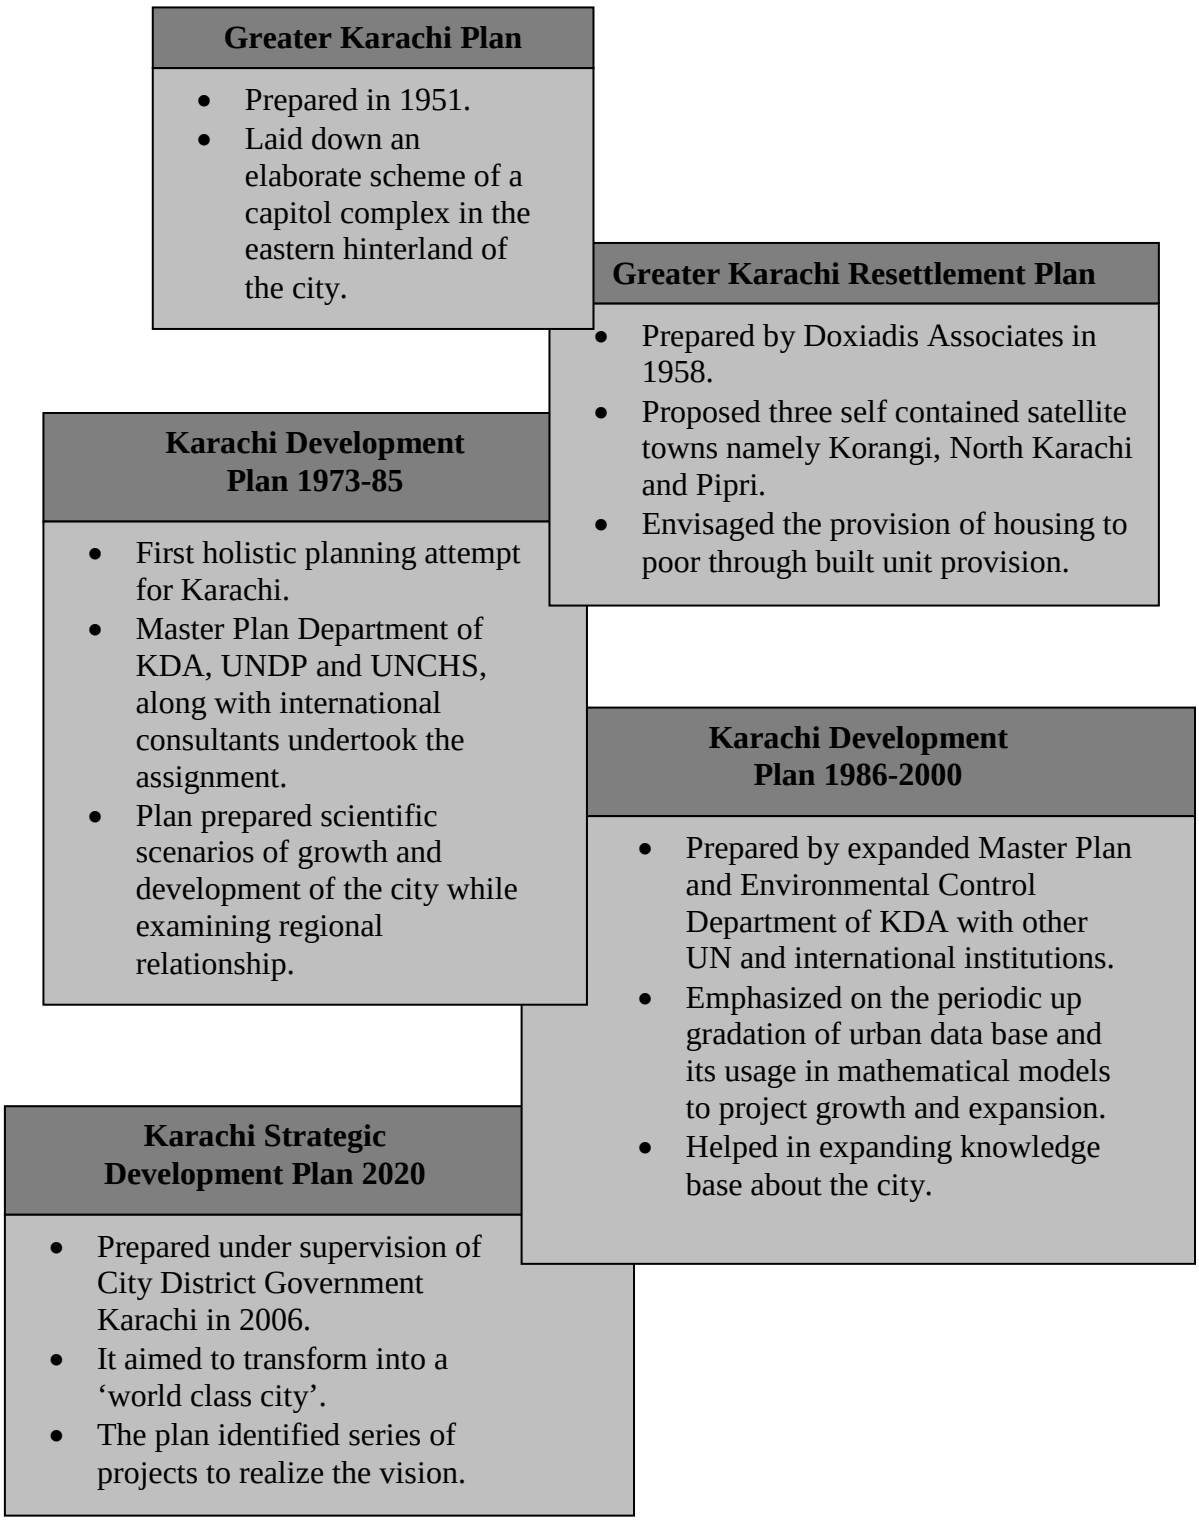
Well known planner C.A Doxiadis was commissioned to plan and develop organized satellite towns at a reasonable distance from the city centre. Articulated schemes were prepared for Korangi and North Karachi areas. The schemes were to ensure self contained and independent sub-urbanization. However due to concentrated location of manufacturing, government offices, small scale enterprises and other magnets of employment towards the south and west of the city, enormous demand for commuting eventually intensified. Many critics were of the view that the poor and low income households moved out from the vicinity of city centre and located at far away distance. After bearing high commuting costs for prolonged period of time, these people continued to struggle to escape from the spiral of poverty. Political factionalization and rise of ethnic politics eventually evolved as a consequence.

A well formulated planning attempt was begun in late 1960s. An exclusive planning unit namely Master Plan Department (MPD) was created. The MPD was an integral part of KDA and undertook extensive surveys, preparation of useful maps and profiles. It also launched sectoral studies to document and analyse the respective situation in a scientific manner. The planners in the team deliberated at length to evolve worthwhile proposals for instant action, medium and long term basis. The Karachi Development Plan of 1973 – 85 proposed a viable framework of growth facilitation and management that guided the city administrators and stakeholders to a reasonable extent. Through the same institutional setup, the Karachi Development Plan 1986 – 2000 was prepared. It aimed at growth management and use of accurate data to project management scenarios through mathematical modeling.

The Karachi Strategic Development Plan 2020 combined the experiences gained during the past exercises. Prepared by a consultant, the plan aimed to support capitalist practices and devised pro-market approaches for real estate development. Some of its prescriptions, such as sub urban developments for consolidated land allocations for education, textile manufacturing and media facilities are being outlined for implementation.

A summary of planning exercises is presented in Figure 09.

Figure 09: PROFILE OF IMPORTANT PLANNING EXERCISES IN KARACHI SINCE

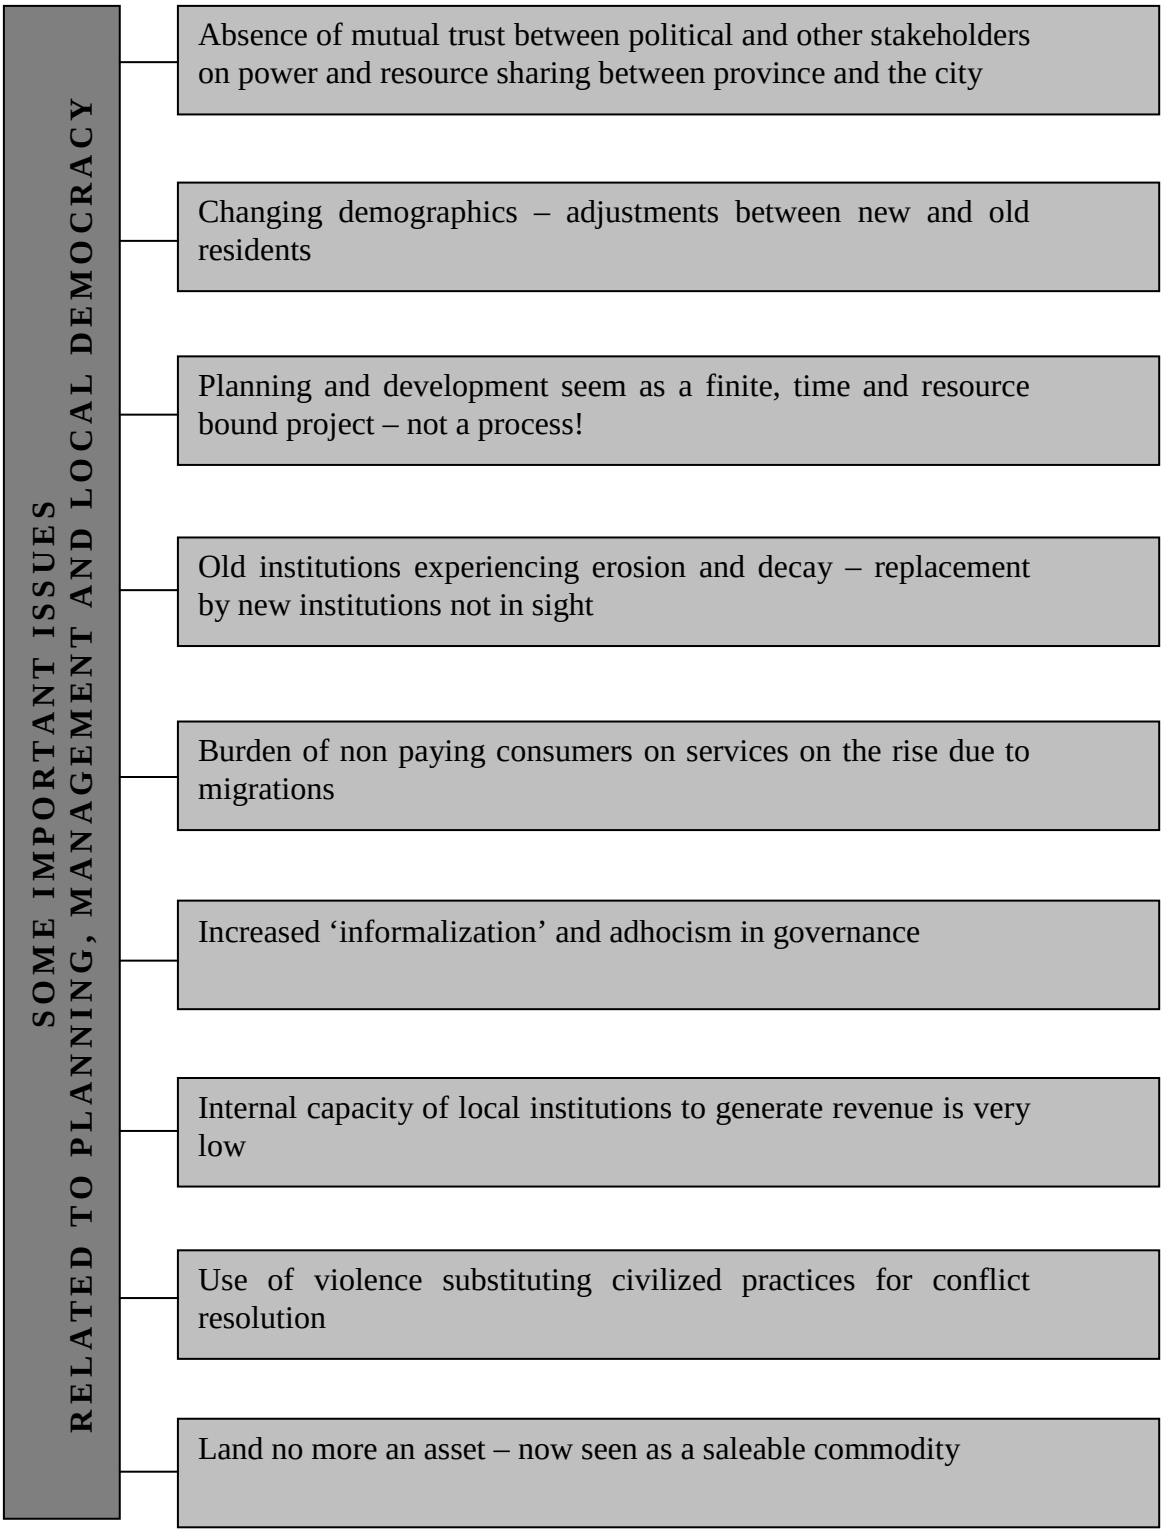


Source: Author's interpretation based on KDA (1974), KDA (1990) and CDGK (2006).

4. Issues

The above account refers to several core issues in respect to local democracy, planning and management that are outlined below in Figure 10. As the city evolved through cyclic migrations and other drastic socio political changes in the region, a political discord and mistrust evolved which was aggravated due to absence of a sustained system of local democracy. The changing stakeholders began competing politically rather than fostering collaboration for mutual benefit and progress. In a turbulent milieu, the process and institution of planning could provide partial relief around long standing developmental problems. With continuous change in the composition of local and even service delivery institutions, the capacity to respond to escalating needs in society became eroded. Socially and internally displaced people utilized urban services and infrastructure without any revenue contribution. In order to address common problems related to governance, informal sector bridged the gap which was created due to decline in administrative ability of local and autonomous institutions. Violence and use of form has now become the means to resolve disputes between factions and groups. Such a non-civilized practice has rendered the law and order machinery helpless. A key reason of dispute is the urge to control land which is perceived and transacted as a commodity. It is no more viewed and managed as a social asset.

Figure 10: LOCAL DEMOCRACY PLANNING AND MANAGEMENT IN KARACHI: A SUMMARY OF SOME OF THE VISIBLE ISSUES



5. Conclusions

This study offers several important conclusions and lessons. Political consensus at the local level is vital to be promoted around the form and format of local democracy. Such a consensus can help transform procedures and practices to manage the city affairs. An institutional system is needed to deal with social and political disputes and help prevent conflicts and violence. The process of planning must attempt to analyse the specific needs, aspirations and requirements of communities and stakeholders while determining the planning outcomes.

INTRODUCING SOUNDSCAPE

Östen Axelsson [1]

Abstract

Soundscape – the acoustic equivalent of *Landscape* – is a relatively new area to many. It concerns the acoustic environment as perceived, experienced or understood by people, in context. Current development in soundscape research is directed towards urban planning and design in promotion of sustainable development, health, well-being, and quality of life. Above all, soundscape is about what sounds are appropriate to, or belonging to, a place. There is no one ideal soundscape. To determine which soundscapes are good, we must consider which activities the soundscape may enable at a place. Furthermore, soundscape creates a sense of place, and it is an important aspect of our cultural heritage. For instance, what soundscapes will our generation transfer to the next, and how will this affect sustainability and quality of life in the future? To incorporate soundscape into urban planning and design, we must understand the relationship between sound and human activities in the urban environment. What sounds and human activities are compatible, and which are not? For example, what sounds are compatible with urban street-life, or with a young children's playground? What sounds promote or impede social interaction in urban open spaces, or what sounds promote or impede tranquillity? In order to advance soundscape research, a coordinated, cooperative and interdisciplinary effort is needed.

1. Introduction

The present paper is a brief introduction to current soundscape research in Europe, relevant to urban planning and design. It is not exhaustive, but provides an overview of some central research activities and their results.

2. Soundscape

Soundscape is best understood as the acoustic equivalent to *Landscape*. Probably, it was first defined in *Handbook for Acoustic Ecology* (Truax, 1978, 1999):

Soundscape – "An environment of sound (or sonic environment) with emphasis on the way it is perceived and understood by the individual, or by a society."

Since then, many new definitions have occurred, and as of yet there is no consensus on how the term should be defined. Nevertheless, most soundscape researchers seem to agree that *Soundscape* denotes the acoustic environment as perceived, distin-

[1] Stockholm University, Stockholm, Sweden – oan@psychology.su.se

guished from the acoustic environment itself. Presently the working group ISO/TC 43/SC 1/WG 54 *Perceptual assessment of soundscape quality* of the *International Organization for Standardization* (ISO) is working on the first part of the first International Standard on soundscape, ISO 12913-1 *Acoustics — Soundscape — Definition and conceptual framework* (Axelsson, 2011a, 2012). The working group aims at international consensus among soundscape researchers and practitioners on a definition. At present (May 2012) the proposed definition reads:

Soundscape – "Acoustic environment as perceived and experienced and understood by people, in context."

This definition was inspired by the European Landscape Convention (Council of Europe, 2000) that defines *Landscape* as "an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors".

3. Some European soundscape research

The Canadian composer Murray Schafer is widely recognised for having made the term *Soundscape* popular through the *World Soundscape Project* in the 1970s (Schafer, 1994). In 1998, Schafer visited Stockholm in Sweden to present his ideas about acoustic ecology at the conference *Stockholm, Hey Listen!* (Karlsson, 1998). The conference inspired some noise-and-health researchers, like Professor Birgitta Berglund from Stockholm University, to adopt the term *Soundscape*. Together with Professor Tor Kihlman at Chalmers University of Technology, Professor Berglund took the initiative and developed the first European soundscape research programme *Soundscape support to health*, 1999–2007 (Gidlöf Gunnarsson, 2008). A similarly large and interdisciplinary research programme, named the *Positive Soundscape Project*, was conducted in United Kingdom 2006–2009 (Davies *et al*., 2009).

Both programmes found that soundscapes may be described by a two-dimensional model of emotional responses: *Pleasantness–Eventfulness* (Axelsson, Nilsson & Berglund, 2010), or *Calmness–Vibrancy* (Cain, 2009). The latter model represents a 45° rotation of the *Pleasantness–Eventfulness* space (Figure 1). Moreover, there is a meaningful relationship between emotional responses and perceived sound sources. Technological sounds (e.g., road traffic) are typically judged unpleasant, natural sounds (e.g., singing birds) pleasant, whereas human sounds (e.g., voices) are eventful, regardless of the sound-pressure levels (Axelsson, Nilsson & Berglund, 2010). This is important to urban planning and design, because it provides us an idea of how to actively design soundscapes. To create a calm soundscape it seems necessary to abate both technological and human sounds, and to promote natural sounds, whereas to create a vibrant soundscape it seems necessary to promote human sounds and to abate technological sounds.

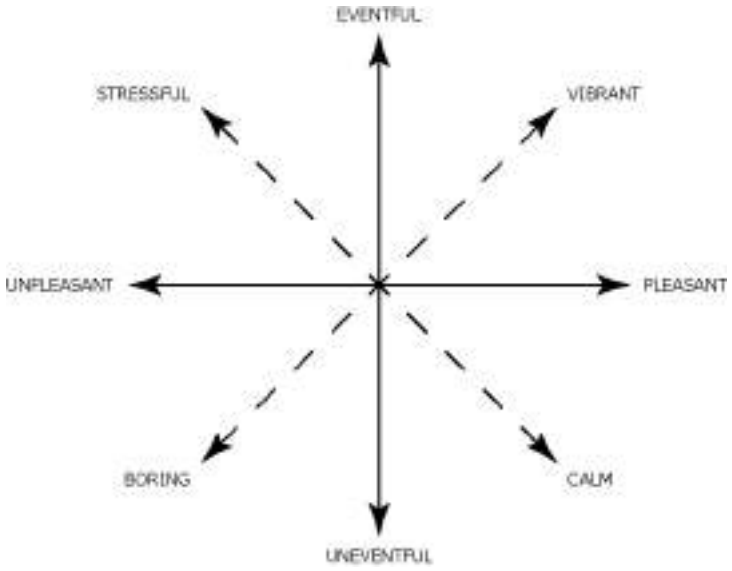

Figure 1. Conceptual model of emotional responses to soundscapes

3.1 Soundscape and water

The environmental planner, Professor Lex Brown, Griffith University in Brisbane, Australia, has proposed a 4-step model for acoustic design of outdoor space (Brown, 2011; Brown & Muhar, 2004), according to which wanted sounds may be used to mask unwanted sounds. In particular Professor Brown has proposed to use water sounds to mask road-traffic noise (Brown & Rutherford, 1994). Inspired by this notion, soundscape researchers have begun to investigate this empirically.

There are several different qualities of water sounds. For example, a purling stream is superior to splashing and hissing sounds from a fountain (e.g., Jang & Kook, 2005; Jeon, Lee, You & Kang, 2010; Rådsten-Ekman, Axelsson & Nilsson, 2012). Unfortunately, it seems that it is easier to use road-traffic noise to mask water sounds than the other way around (Nilsson, Alvarsson, Rådsten-Ekman & Bolin, 2010). In addition, there is a risk that water sounds do not only mask the unwanted sounds, but also wanted sounds, like singing birds (Axelsson, Nilsson, Hellström, & Lundén, 2012). Therefore, it is important to think carefully before erecting a fountain in the urban environment. More research is needed, to find out how fountains must be designed in terms of sound.

3.2 Soundscape auralisation

Another research area that is relevant to urban planning and design is soundscape auralisation (i.e., the rendering of digital virtual reality soundscapes) (e.g., Forssén *et al*., 2009; Maffei *et al*., 2010). It aims at creating tools for architects and urban planners for simulating future soundscapes for design purposes.

3.3 Soundscape mapping

A new, emerging area in soundscape research is soundscape mapping. This means to use Geographic Information Systems (GIS), or similar, for analysing and describing current soundscapes, and to plan future soundscapes (e.g., Hällgren, 2011). However, as of yet, no applicable methods or tools have been presented.

4. ISO and soundscape

The Swedish research programme *Soundscape Support to Health* resulted, among other things, in a method for measuring soundscape quality, known as the *Swedish Soundscape-Quality Protocol* (Axelsson, Nilsson & Berglund, 2009, 2010; see also Berglund & Nilsson, 2006; Nilsson & Berglund, 2006; Axelsson, Berglund & Nilsson, 2010). When the research programme ended in 2008, the research team approached ISO, through the *Swedish Standards Institute* (SIS), to propose a Preliminary Work Item to develop the first International Standard on soundscape.

The scope of the Preliminary Work Item Proposal was to provide specifications for questionnaire studies, as well as minimum reporting requirements in soundscape research. The proposed International Standard was intended for researchers or public users who are interested in measuring soundscape quality. Examples of intended applications are questionnaire studies in residential areas, or among visitors in urban open spaces. Based on the *Swedish Soundscape-Quality Protocol*, the International Standard was proposed to cover questions on sound source identification, overall soundscape quality, and attribute profiling. The latter would be used to measure affective qualities of soundscapes by attributes scales like ‘pleasant’, ‘exciting’, ‘eventful’, and ‘calm’ (cf. Figure 1).

The proposal was well received, and a new working group, ISO/TC 43/SC 1/WG 54 *Perceptual assessment of soundscape quality*, was formed (Axelsson, 2011a, 2012). As mentioned above, the working group is presently developing the first part of the first International Standard on soundscape, ISO 12913-1. Within 2012, the working group intends to begin to develop a second part on the minimum requirements for reporting the results of soundscape studies. The working group consists of 32 experts from 16 countries distributed across four continents: Asia, Australia, Europe, and North America.

5. The COST Action TD0804 on soundscape

The same year as the ISO working group was formed, European soundscape researchers and practitioners joined to form the COST Action TD0804 *Soundscape of European Cities and Landscapes*. It will operate until June 2013, and is funded by the COST programme (European Cooperation in Science and Technology), which is supported by the EU RTD Framework Programme. Out of the 36 COST countries, 24 participate in this Action.

The Action is motivated, because reducing sound levels – the focus of EU environmental noise policy (EC, 2002) – does not necessarily lead to improved quality of life. A new multidisciplinary approach is essential. Soundscape research represents this paradigm shift as it involves not only physical measurements but also the cooperation of human/social sciences (e.g., psychology, sociology, architecture, anthropology, medicine) to account for the diversity of soundscapes across countries and cultures. The soundscape approach considers environmental sounds as a 'resource' rather than a 'waste'.

The main aim of the Action is to provide the underpinning science for soundscape research and make the field go significantly beyond the current state-of-the-art, through coordinated international and interdisciplinary efforts. The Action will promote soundscape into current legislations, policies and practice, aiming at improving/preserving our acoustic environment. The Action does this by workshops, seminars, conferences, short term scientific missions, and summer schools.

6. Soundscape and cultural heritage

Soundscape is also an important, but neglected aspect of cultural heritage. The COST Action drew attention to this at its think tank *Soundscape as a part of Culture Heritage* on Capri, Italy, in October 2011. On the on hand, soundscape is important to cultural heritage sites, as well as to cultural festivals and ceremonies. On the other hand, soundscape is an intangible aspect of the cultural landscape, and an expression of human presence and activity. It is transferred from generation to generation, while society is constantly reshaping the soundscape as a reaction to the contemporary environment. Because the soundscape contributes to our well-being and is central to sustainable development, a central question is: what soundscapes would our generation transfer to the next?

7. Designing Soundscape for Sustainable Urban Development

In September 2010, the year Stockholm was the first European Green Capital, the COST Action organised the international conference *Designing Soundscape for Sustainable Urban Development*, on soundscape and urban planning, in Stockholm. It was organised in cooperation with the City of Stockholm, EUROCITIES' working group on noise policy, Swedish Association of Architects, and the Swedish Society for Town and Country Planning. The purpose of the conference was to assemble practitioners and researchers in architecture, urban planning, acoustics, noise, and related disciplines, to discuss how the soundscape approach may be implemented in urban planning and design in Europe (Axelsson, 2011b).

In the presentations at the conference a number of central themes emerged. The soundscape is an environmental resource that must be creatively planed and designed, not considered in retrospect. It concerns the meaning of sounds, which is fundamental in establishing a sense of place. Soundscape is not a question of how loud sounds are, but what sounds are appropriate to a place. It is an important aspect

of quality of life and may promote or impede psychological restoration, as well as daily activities, like speech, sleep, and recreation. At the same time there is no one ideal soundscape. In order to decide which soundscapes are good, we must consider which activities the soundscape may enable at a place.

The conference highlighted that there is a need for case-study research, where soundscape design measures are evaluated from acoustical, architectural, perceptual, and health points of view. The hitherto low number of large-scale case studies was cited as one reason why soundscape design has not yet reached the urban planners. Architects and urban planners continue to request more concrete cases that inspire and provide a basis for new approaches. Thus far, case studies have been limited to individual residential and recreation areas, as illustrated by the presentations in the conference.

The main conclusion of the conference was that soundscape planning should not be implemented through legislation and directives. Rather, the path to implementation is via applied research in urban planning, in close cooperation with municipalities and other stakeholders, and with the support of basic research and other scientific disciplines such as acoustics, human geography, psychology, and sociology. The strategy is further international and interdisciplinary research collaboration, and exchange of experiences at conferences in urban planning and architecture. Progress will be based on learning from each other by continuing to develop, present and discuss concrete and successful cases of soundscape planning. The special session on soundscape in AESOP 2012 is organised to continue this discussion, and to promote further development.

WHAT DEFINES SUCCESS OF A VISION?

Terry van Dijk [1], Gerd Weitkamp [2]

Abstract

Visions can be valuable tools for guiding and uniting land use interests in a region with fragmented administration. What determines the strength of a vision and how can it effectively play its role? We tested and summarized hypotheses on the success factors of visions. We chose New Orleans, a city in a rebuilding process because that represents a most intensive and pressing vision process.
We interviewed local policymakers, designers, researchers, and journalists to find out what they would spontaneously cite as a vision's most crucial factors. We also reviewed the subsequent New Orleans recovery plans and compared our findings with hypotheses from visioning literature.
The interviewees' spontaneous answers largely confirmed the key hypotheses about success from the visioning literature. But the most frequently mentioned factors were not in the literature: a vision needs to be propagated by a powerful authority, a favorable larger political climate, and the funds to sustain the implementation process. For a vision to make a difference, it needs to be substantively persuasive but also have a favorable institutional climate to help it along.

This paper is considered for publication by the Journal of the American Planning Association. Pre-presented at AESOP with permission of the editor.

1. Introduction

What does a vision need to be effective? What factors enable people to devise a central idea about future urban form that sets the agenda for future development? Ambitions are cherished, promoted, and pursued by individuals, groups of people, or city councils who all hope that they are able to make a difference. Visions can coordinate the interdependent decisions that result from these ambitions. We chose New Orleans' post-Katrina rebuilding challenge as a specifically telling example of vision-making. This example was used to test and supplement hypotheses about the strength of visions from literature on the success of visions. This article reports our findings on vision performance, based on interviews in New Orleans.

[1] Assoc.Prof. at University of Groningen, the Netherlands; t.van.dijk@rug.nl
[2] Ass.Prof at University of Groningen, the Netherlands; s.g.weitkamp@rug.nl

Our visioning perspective distinguishes our study from other work written about New Orleans and similar post-disaster rebuilding challenges, which typically take the perspective of recovery theory (Olshansky et al., 2008; Olshansky, 2006; Kates et al., 2006; Nelson et al., 2007). Recovery theorists analyze the total recovery process, often with an institutional focus and little emphasis on the contents of the recovery plans. In contrast, we specifically wanted to learn about the catalyzing power of ideas about future urban form. How does the content of a plan guide actions and succeed or fail in uniting stakeholders?

It is complicated to establish the causal link between the dynamics of societal reality (i.e., urban form, social relations, political processes) and the mental constructs (i.e., ambitions for future spatial situations) that partly explain them. First, it is difficult because the mental constructs address various parts of reality, they vary in the degrees to which they are made explicit and the degree of agreement by the wider community. But, foremost, the causal link is difficult to establish because society and vision cannot be separated – they are one, instead of separate entities. They transform simultaneously; it is impossible to divide them and point out a causal link with certainty. There is too much interdependence and too much interference from other factors.

Yet, in their pretense to guide paths of development with appealing ideas, groups in society (i.e., planners, politicians, NGOs) do seek ways to make a difference. We use the word "vision" to address the larger ideas of a city about its future development, such as strategic plans (Healey 2007). Such visions are typically in constant transformation; they are largely implicit but may be made explicit in planning documents. And although planning documents (e.g., zoning plans) will in practice have a more narrow scope than visions because they are partial operational steps designed to contribute to a broader vision, they are the only manifestations of visions that last. The rest of the mental images for the future have evaporated and cannot be reconstructed.

Post-Katrina New Orleans represents a situation where a disaster damaged the city, forcing a city that was not used to making plans to make drastic choices about how to rebuild for the future. After the devastation of 2005, the city suddenly found itself forced to choose what it wanted to look like in the future. People asked for plans that would guide the recovery and reduce uncertainty for them as individual actors. Just like Port-au-Prince, Haiti, Christchurch, New Zealand, and Asian coastal zones damaged by tsunamis (Diefendorf, 2009 even compares the New Orleans situation with war-damaged German cities), New Orleans had to choose in what form it would rise from its ashes.

Our study tests and supplements the critical factors for vision performance. Section 2 reviews the visioning literature with the purpose to extract

hypotheses on success. We describe the challenge of rebuilding New Orleans in Section 3, presenting its geographical structure and the cause and nature of the 2005 devastation. Section 4 presents our research design, aimed at unraveling the competitive struggle among visions and documenting which strengths and weaknesses key players in that process now attribute to the various visions. The results are presented in Section 5. The paper concludes with a discussion of the outcomes.

2 Hypotheses from vision performance literature

Our New Orleans case study is meant to test and supplement theoretical assumptions about vision performance. In the aftermath of Hurricane Katrina in 2005, opportunities for the city's future had to be explored. Given the multitude of interests, perceptions, and opinions, this case provides a unique example of upcoming and conflicting visions.

We reviewed hypotheses about successful visions described in literature – as explained in the introduction, we exclude post-disaster recovery literature because we chose to concentrate on the substantive side of visions. Although, largely speaking, planning literature is extensive, literature that specifically addresses how to devise and implement powerful city or regional visions is limited and fragmented. This may be because it is easier to study incremental steps of improvement, such as plans, than to study processes that address radical, innovative, large-scale, long-term transitions. Nonetheless, several attempts have been made to analyze visioning processes.

Robert Shipley's writing is most explicitly concerned with visioning. He concentrates on cities that pursue radical views to guide land use, and other policies. Many cities in Europe and the U.S. have engaged in visioning processes with varying impacts. From Shipley, we obtained a number of hypotheses about how to design the visioning process in such a way that the eventual performance of the outcome is maximized.

Storytelling literature would also be applicable to implementation of a vision. Because a vision is a compelling reflection of a possible future, the seductive force central to storytelling is of great importance in successfully using the vision to lead the way. Some books about strategic planning also hint at the phenomenon of the vision, but without choosing clear concepts and hypotheses (for instance Healey, 2007).

Hypotheses on critical factors in visioning literature

Visioning literature presents a number of recommendations for factors that are critical to successfully devising visions. The factors we derived in our review of this literature are typical to collaborative processes in general. This is logical,

considering that visioning, like collaborative planning, refers to "processes through which parties who see different aspects of the problem can constructively explore their differences and search for solutions that go beyond their own limited vision of what is possible" (Gray, 1989, p.5). This appears to imply that a powerful vision is, by definition, an image of the future that has support from all the important actors, and that support begins when stakeholders interact while jointly drafting the vision. A powerful vision needs broad representation from stakeholders, active participation, and clarity about the terms of engagement; everybody has to contribute ideas and everybody has to eventually profit from the results.

Shipley's attempts to develop visioning theory provide a number of clues about performance variables. Foremost, a vision has to be specific and challenging (Shipley, 2002, p.13), as "specific and challenging goals lead to better performance than 'do your best' goals." Setting high goals will result in high performance. At the same time, the vision has to include specific goals with specific tasks that are explicitly assigned to actors. This is important because the vision needs to overcome the collective irresponsibility in the region that necessitated the visioning in the first place. The vision has to assign actors to take specific actions (idem, p.15) and tasks articulate the "how question" of visioning (Shipley, 2006) that is both activating and relevant in helping the community judge whether to support the vision. Support for the vision depends on the projected result but also the way it is proposed that leads up to that result.

Furthermore, people should be asked to contribute early in the process before any solution is proposed (Shipley, 2004, p.208). Preconceived solutions smother creativity but genuine participation allows participants to think freely and to later recognize their ideas in the result. Note the difference: not just participation, but participation sufficiently early in the process to affect the result.

Papers presenting case studies on selected visioning processes implicitly confirm these hypotheses to varying degrees. Helling, for instance, stresses the importance of several principles of proper collaborative planning and emphasizes that it is vital to produce sufficiently concrete targets to guide the shorter-term decisions (Helling, 1998, p.344).

Complementary to Shipley's recommendations, Helling's (1998) analysis of the Atlanta VISION 2020 process found the role of experts to be vital, as they can add missing information (idem, p.346) when the process is trapped in discussion about facts. Too much expert-driven process, however, can be a pitfall when attempting to build consensus and wide support among stakeholders. Helling, therefore, suggests that expert views have to be subservient to the people's perceptions and preferences. Otherwise,

stakeholders may experience the process as merely symbolic, believing the experts have no genuine interest in what the people say but only have interest in their preconceived solutions.

Helling also mentions the danger of devising utopias instead of strategies for action, which is also the main message of Peel and Lloyd (2005). This is in line with the specific tasks Shipley (2002) mentions, but she warns against his suggestion to set "challenging goals." Goals must not be set too high.
Helling furthermore considers it crucial for a vision to appeal to a shared sense of urgency (idem, p.345). It is dangerous to treat the collaborative process as a goal in itself, because that will deplete energy. The goal must be to produce a compelling image of the future that effectively guides action.
Margerum's (2005) analysis on visioning in Denver also largely confirms the need to respect the principles of collaborative planning in terms of actively involving population, striving for consensus and joint learning, and managing interdependent interests. Interestingly, he believes that it would work best on the street or neighborhood level because regionally-concerted action is too hard for people to identify with and thus they would not support the result.

Hypotheses on critical factors in vision application

What subsequently defines the performative power of the vision in the phase after its interactive, expert-informed drafting? Visioning literature emphasizes that a vision has to be well-rooted in the region's stakeholder agendas. The storytelling literature talks about how to disseminate the results for maximum effect. Throgmorton (1996), Sandercock (2003), and Myers and Katsuse (2000) stress the rhetorical quality of the story. Is the story consistent, elegant, and clearly positioned in time with a specified direction? Importantly, does it convey a morally compelling message?

Myers and Katsuse (2000) think a story can be successful when the reader (i.e., a stakeholder you want to persuade and activate) recognizes his position, opportunities, and responsibility. This means that stories have to be addressed to target groups to be effective. This concurs with Shipley's emphasis on assigning specific tasks to actors.

However, it would be insufficient to just address stakeholders separately. Connecting multiple interests and separate implicit visions is the power of a good vision, according to Throgmorton (2003). A planner has to accept the stories present in the region while leaving room for newly emerging microstories, but add to that a metastory that connects multiple interests and, thus, joins multiple energies. This shared nature of visions is also the cornerstone of collaborative planning (also see Peel and Lloyd, 2005). That shared nature can emerge either from the vision-making process or from very good analysis by the storyteller.

Conclusion

Critical factors for vision success are not just about content. The literature talks little about what information a vision should contain, but more about whose agendas it must be useful to and how, where and when to present the message. Success for a vision is about the psychological significance of its content. Does it spark stakeholders to act? For that, it has to connect to the stakeholders' perceptions. As Van Dijk (2011) describes it, every new story finds itself in a context of already present stories, leading to either rejection or adoption, but it is always transformed before being used.

Our case study tests the validity and completeness of the literature's success factors. The publications reviewed here explicitly label the following sucess factors: (1) setting high goals that are appealing and consistent; (2) creating a roadmap with steps and assigned tasks to reach those goals and break them down into concrete, realistic projects; (3) building on early participation; (4) including the right amount of expert knowledge; (5) maintaining a sense of urgency; and (6) connecting multiple mutually benefiting interests.

3 Case description

New Orleans is a mid-sized city in the state of Louisiana, sitting between the mouth of the Mississippi River, where it meets the Gulf of Mexico, and Lake Ponchartrain, which forms the northern boundary of the city. The city is located on the Gulf Coast, which is frequently hit by hurricanes that emerge above the gulf and move north. They tend to reach the U.S. mainland somewhere between Houston and Florida, where they usually lose strength rapidly.

The Gulf Coast around New Orleans consists of extensive wetlands through which the farthest downstream section of the Mississippi River has had multiple branches. Some branches disappeared due to natural reroutings of the river; other branches have lost their function because of regulation of the river that was done mostly for navigation purposes. Throughout the delta, numerous towns lie in a complicated pattern of marshes, natural levees, and tidal canals. The city of New Orleans was founded in 1718 on one of the natural levees formed by the river. The levees were the sites with firmer ground, where the Mississippi had deposited coarser sand. Their natural properties made these sites safe to live on (Ford, 2010; Campanella, 2008); floodwaters did not, and still do not, reach the houses built on the natural levees. The high, old part of the city is still the historical tourist district. From the properties at the fringe of the old town, plantations extended into the lower and wetter areas behind the city that were harder to make habitable.

This original pattern of habitation on the natural levees, from which extended a fan of plantations into the marshes north of town (Campanella, 2008, p. 131), stayed in place for 200 years. Then, as Ford (2010, p.17) notes in her account of New Orleans' development, "city leaders, however, longed to make something more of the swamps – to drain them, to recover the land and put it to a more profitable use: sell it, collect taxes. […] in the early 1800s the city of New Orleans sponsored construction of canals meant to drain the swamps […] using Wood's pumps […]. […] after World War II, the previously drained swamplands were finally – and quickly – developed all along the old drainage canals, where man-made levees shored up resident's confidence that the land they were living on was safe […] flooding seemed 'impossible'." (Ford, 2010, p.20) As Campanella (2008, p. 158) writes: "progressive municipal activism and new technology radically rewrote the 'rules' that drove the geography of New Orleans' urban growth."

Ultimately, most of the city's houses lay well below the level that the water in the Mississippi River and Lake Pontchartrain reached on a regular basis (Kates et al, 2006). The houses lie protected by floodwalls, manmade levees, and pumping stations, on soil that subsides because there is no longer any sedimentation and the soft soils have consolidated.

Hurricane Katrina hit the city on August 29, 2005, causing major failure of the protection system at seven or more separate locations. Dams and walls broke and vast neighborhoods were flooded in several hours by up to 3.5 meters of water, killing almost 2,000 people. None of the pre-1900 streets flooded; only the more recent, typically poorer, suburbs. The disaster proved the weakness of the protection system. The apparently insufficient standards applied by the Army Corps of Engineers, who do the civic engineering for flood protection, were criticized for causing massive failure.

After the storm, people wanted to rebuild their homes and lives. For that, they needed clarity about the recovery process. What could they expect from the future? When would services be restored in their streets? Would their streets be allowed to be rebuilt at all? Tens of thousands of city residents had fled to other parts of Louisiana and other U.S. states because their houses were uninhabitable and there was, temporarily, no employment for them. They needed certainty before making the leap back. In addition, they had become aware of the dangers of the neighborhoods they were living in. Ideas emerged about how to rebuild in a more sustainable way.

Much research has been done into the rebuilding process, but mostly from a social geographical point of view, describing developments in community resilience, social capital, place attachment, psychological health, crime rates, migration, and local economy. Initially, interest in the city's planning process was high (notably, Nelson et al., 2007; Burby, 2006; Kates et al., 2006;

Olshansky et al., 2008), however it now seems to have faded away. Our research extends the time span of the reconstruction of the planning process and uses the reconstruction as a case study to help develop theory about successful visions.

4 Research design

The authors visited New Orleans to collect data in early 2011. The objective was to reconstruct New Orleans' process of finding a vision for rebuilding the city, with the purpose to test and supplement hypotheses from literature. Which visions can be pointed out throughout the process? How long did they last? And, most importantly, what explains their decay or persistence?

Because visions do not have a fixed form that allows objective direct observation, we proceeded to make this reconstruction in the following way. We took the overview provided by Ford (2010) as our first point of reference at the start of the field research. She gives a personal and partial account of the New Orleans visioning process.

We then interviewed a broad variety of people that were involved in some or all of the post-Katrina vision-development process, and who are known to have a good overview of the total post-Katrina planning process. We took their names from planning documents that listed their involvement in the process and, upon asking for an appointment, asked them who else we should talk to. We did not tell them exactly beforehand what our questions would be, because we wanted them to directly retrieve the requested information from their personal memories.

We eventually interviewed three influential designers; three researchers from Tulane University; an important civil engineering contractor; four journalists from local news networks and newspapers; and two policymakers. After each day of field research, the researchers from our team exchanged findings and, accordingly, enhanced their foreknowledge for the next interviews. This made the team increasingly more informed about the post-Katrina plans, allowing for better interpretation of answers by interviewees. When interviewees gave permission, digital recordings of the interviews were used for the final analyses when our own notes were unclear.

In all interviews, we asked the interviewees: (1) to give an overview of all subsequent or parallel post-Katrina visions; (2) to indicate in what documents these visions were articulated; (3) to approximate the time of emergence and abolition of visions; and, most importantly, (4) to explain each vision's disappearance or persistence. The answers would enable a final reconstruction of the array of visions and the reasons for their alteration. In practice, however, interviewees did not always allow the conversation to follow the predesigned structure. We also asked the interviewees what, in general, a vision needs in

order to make a difference. We wanted to know what they spontaneously think are the essential factors in creating effective visions.

So we did not project the theory on this case, but rather awaited the factors interviewees would mention spontaneously and compared them to the insights that emerged from literature afterward. This systematic and semi-quantitative way of hypothesis testing distinguishes this study from seemingly similar studies into New Orleans' rebuilding efforts.

We primarily limited our discussion to the visions about the city as a whole. There have also been several visions and plans on the level of the neighborhood or parish (a governmental layer comparable to a county in other U.S. states), as well as visions for the Mississippi delta enveloping New Orleans. The repair and reinforcement of the existing structure of levees and floodwalls around the city by the Army Corps of Engineers is, in a way, based on a vision too. Although these levels of scale are, or at least should be, interrelated (as Nelson et al., 2007, p. 24, emphasize), information about such visions was not included in our study because of their different scale in comparison to that in most of the visioning literature, and the fact that they do not touch on improving urban form.

The remarks of the interviewees, which obviously were worded in all kinds of ways, had to be aggregated into one-liners that represent a variety of exact statements. Because of the potentially distorting effect of this aggregation, it was done as soon as possible after the actual interview by the researchers that held the interview, possibly in interaction with the lead author.

Aside from conducting interviews, we also screened the archives of one of the city's main newspapers, "The Louisiana Weekly." We analyzed articles about visions for the recovery of New Orleans for indications of flaws and strengths of visions. We compared these with the outcomes of the interviews to see if additional factors were mentioned. Information from websites was treated with caution, as their information could be colored by contemporary interpretations of the actual process. We used newspaper archives and websites only for orientation but not for primary data collection.

5 Results

Before presenting the precise data we sought to collect, some unusual features of the New Orleans case must be explained. Every case that is selected to explore the questions we asked would be unique. The interviewees mentioned three important aspects that make New Orleans an uncommon site for visioning: lack of previous planning culture, displaced people ultimately not returning, and the role of the trauma from the hurricane.

Several interviewees indicated that New Orleans did not have an actual planning culture prior to the Katrina disaster. City government and residents were not used to engaging in thinking about the city's future (also see Olshansky, 2008, p. 278). This caused the first plans to encounter an audience that was not used to, or even hostile to, the idea of governmental interference in urban form. This may mean that the first plans had no real chance of succeeding. Timing, therefore, turns out to be an important issue. Plans, in terms of content, form, and level of ambition, are not good or bad, but rather either appropriate or not for the situation at that point in time.

Visioning is further complicated because an estimated 125,000 people still had not returned to the city by 2011. These people fled the city because of their damaged properties or the lack of opportunities to generate an income. It is hard to rebuild a city when these displaced people cannot join the process; this means you have to make decisions about properties whose owners are absent and sometimes cannot even be contacted. It also means the city does not receive their taxes to pay for public services.

And then there is the trauma of the hurricane. The sudden massive devastation, displacement, and the subsequent despair are likely to make people less inclined to think in terms of the bright new futures of a better city. Even though the disaster showed the dangers of the post-Katrina urban form, traumatized people tend to crave a return to "how it used to be" (Kates et al., 2006, p.14656). Visions in that case meet a conservative attitude, which was also said to be the New Orleans culture before Katrina. That does not necessarily mean that no vision is accepted, but rather that visions need to make an explicit connection to local identity and heritage in an effort to further reinforce what is cherished locally, while simultaneously solving important problems.
The answers given in the interviews are summarized in Table 1. The plans were the most practical points of reference during the interviews and it was hard to make the interviewees discern between vision (i.e., the philosophy behind choices) and plans (i.e., the operational translation of visions) that did not necessarily coincide. That caused all interviewees to structure their account of the vision process around the most important plans. However, we concentrated on the content of the ideas.

The table lists the plans in chronological order with the success factors the interviewees indicated. The information we received from the policymakers and the contractor was not systematic enough to include in the results. Although, given the research questions, we did not intend to be quantitative, the table does give numbers for how many interviewees mentioned that factor. It is an indication of the perception of that factor's importance. It also shows which groups of interviewees mentioned a factor and which did not. The last column shows whether that factor is already mentioned in the literature.

Table 1. Overview of the results. These factors were mentioned by the interviewees as vital to success. Some were linked to specific plans and some were general. Although this is not intended to be a quantitative study, we indicate in superscripts the number of interviewees that mentioned this factor, given respectively in number from: the researchers (out of 3) | designers (out of 3) | journalists (out of 4). A dash (-) means that the plan was not discussed in sufficient detail by that group.

The Bring New Orleans Back Plan (BNOB) was the first plan to be presented after the havoc wrought by the hurricane. A commission of expert consultants installed by Mayor Ray Nagin drafted the plan. It included ideas from a plan by the Urban Land Institute. The vision of the BNOB plan was to make the city more compact on its higher parts and make lower parts suitable for controlled flooding in case of emergencies. Shrinking the footprint of New Orleans would make the city less vulnerable, less costly to provide services to, and more realistic given the projected population decline.

The public response to BNOB was very negative (also see Ford, 2010, p. 30-33 and 52, and Campanella, 2008, p. 68, 344-350). Our interviewees were, however, unanimous that the plan's vision was not a bad one at all. And it did try to fulfill the prerequisites for collaborative planning with interactive websites, public meetings, and a grand presentation to the public in March 2006.

The plan's main flaw, as indicated by our interviewees, was the bad connection to the needs of the city's people at that moment. Timing was described as a very important factor here. Only six months after the storm, the people were presented an image of a city they did not recognize, and they were not ready to cope with the idea that some of their streets would not be rebuilt at all. The communication about the plan did not address citizens' short-term needs, making them more insecure than they already were. What would this vision mean for them in the short term? When and how would they be rebuilding their lives when their original street was wiped off the map? The plan lacked a vision for getting from the present to the projected future state. In addition to this, two interviewees (in contrast with Ford's [2010] much more intensive criticism) lamented the lack of leadership by the mayor for this plan specifically. That person stated that the mayor did not seem to be on top of it or even care about people's personal futures.

After that, according to Ford (2010, pp. 33-36) and Campanella (2008, p. 353), there was a short period where the mayor pushed a non-vision, meaning that recovery of the city would be left to market forces. This laissez faire vision was not officially documented and most of our interviewees do not recall this as a distinct phase in the process. It did, however, spark neighborhood-level planning attempts.

In late 2006, work started on the Unified New Orleans Plan (UNOP). It was infused by ideas from the community-based Lambert Plans on recovering flooded areas (compiled throughout 2006) and implemented via the Blakely Plans in 2008. The initial idea was to cover the entire city and interactively develop out-of-the-box ideas with citizens, both those still living in the city and those displaced to other cities. This, obviously, was a reaction to the BNOB's failure. The UNOP's vision was not so much to create a specific new urban form but, foremost, to create a set of pragmatic objectives that would be acceptable to citizens and that would attract recovery funds from the federal government. It was successful in generating government funds in early 2007.

The plan evolved into a list of conservative objectives and projects centering around 17 key investment areas with a focus on acquiring funds from governments, developers, and businesses that would be needed for neighborhood recovery. The plan is clearly tuned to restoring the pre-Katrina situation, using words like "repair," "improve," and "revise" in relation to flood walls, infrastructure, and housing. There are no maps and only minor hints at an adapted urban form: for instance, "help encourage and facilitate the redevelopment of higher elevation areas of the City that were underutilized prior to Katrina" (City of New Orleans, 2007, p.74).

The plan's main flaw, as indicated by our interviewees, was its lack of appeal. It was called an uninspiring list of projects that nobody could disagree on, but that did not spark enthusiasm either. It had no story to it at all. Though the plan indicated some priorities, its massive set of goals (Appendix B's table alone covered 78 pages) may have reduced action.

The current Master Plan (officially titled "Plan for the 21st Century: New Orleans 2030"; see www.nolamasterplan.org) was positively assessed by all interviewees. This comprehensive plan is hundreds of pages long and filled with numerous artistic impressions and analytical and visionary maps. It also includes extensive accounts of citizen involvement and has been well received by the citizens. The plan explicitly and convincingly presents a vision for the future that includes livability (mainly history, green space, and health), opportunity (climate for entrepreneurship), and sustainability (resilience, energy, and drinking water). Each objective is elaborated in image, text, maps indicating impacts on urban form, and lists of recommended projects. It mainly reinforces existing qualities rather than proposing radically new structures.

Though we perceive its substantial appeal as stemming from its elegant images of the future, the interviewees mainly attributed its success to the force of law, its flexibility, and the moderate change it proposes. They noted that the low level of intrusiveness would make it more acceptable to the people and they gave it the force of law because the wards can choose to reconsider aspects of the plan when they have difficulties implementing them. Together with the moderate changes it proposes, people tend to accept its authority because the plans accept their autonomy.

When we asked the interviewees for the most important success factors regardless of specific New Orleans visions, several strongly-felt ideas were expressed, most of which were not mentioned when talking about the plans in particular. Authority, political will, and a realistic budget scored very high. That appears to have been a lesson for those involved in the New Orleans visioning experience.

6 Discussion

New Orleans represents an unusual situation, whereby a city was hit by a natural disaster and forced to make radical choices for its future urban form. Extensive flooding caused massive damage to properties but also to faith in the ability of water management technology to counter the risks of living below sea level. It caused a flurry of planning efforts that were hard to research; we found partly contradictory information on dates, objectives, and content.

We sought to supplement existing hypotheses in literature about vision performance. Comparison of the literature with the case interviews shows that five out of six factors derived from the literature in Section 2 were actively mentioned by the interviewees. They are once again validated. Factor 1, setting high goals that are appealing and consistent, was frequently mentioned by all groups of interviewees as a general success factor. The need for a realistic roadmap with steps and assigned tasks to reach those goals (Factor 2) was mentioned as one of the reasons the BNOB plan failed, and mentioned by many interviewees as a crucial factor in general. Factor 3, building on early participation, was mentioned in relation to the BNOB and the Master Plan and was considered to be a crucial factor by almost all interviewees.
Factor 5, the sense of urgency, was mentioned as a general factor, but it also could be related to answers about timing. Because sense of urgency is constantly changing in intensity and focus (for instance, first to extending services to damaged neighborhoods and later to protection against new hurricanes), sense of urgency conflates to the frequently mentioned issue of timing. Sense of urgency, then, is something you need to make use of by proposing the right ideas at the right moment. Factor 6, connecting multiple mutually benefitting interests, was mentioned as a general factor. The one

factor from literature that was not heard in the answers of the interviewees was Factor 4, applying the proper amount of expert knowledge.

New factors the interviewees mentioned that we did not come across in our reviewed literature are: (7) an actor with authority that appropriates and embodies the vision; (8) a supportive political climate for the central idea; and (9) money to fund at least the first steps in realizing the vision. In our New Orleans study, these factors scored very highly in terms of the number of people that mentioned them (respectively, 7 out of 10, 6 out of 10, and 6 out of 10) – also all much higher than all the factors found in the literature. Only the importance of genuinely connecting to people ranked equally high (7 out of 10). This supplementary set of factors helps us to better understand the power of visioning processes.

Shortly after Katrina, the first visions were launched under the supervision of a mayor who was criticized for being too little involved. The appointment of Mayor Landrieu is considered to have been a big help for effective planning and the success of the Master Plan, not least because of his sister, a U.S. senator. This, together with the advent of the Obama administration in Washington, created a very different political climate for rebuilding New Orleans. Interviewees saw this as a vital prerequisite for vision performance. The availability of funds that make a vision viable, to an important extent a result of authority and politics, was also considered essential for effective visioning.

Interestingly, these three interrelated factors are central in the post-disaster recovery literature (summarized in Olshansky, 2008, p. 274) that we chose not to concentrate on because it focuses on process and institutions. In the case of New Orleans, it is obvious that lessons about successful visions should be informed by insights from recovery processes. But we feel that our results are relevant to wider spheres than just post-disaster planning. Leadership, funds, and political climate boost the performance of any vision. We agree with Olshansky (idem, p.279) when he says “post-disaster planning is just a more intense version of normal planning.” We therefore propose to combine the insights from these two fields of literature. Whereas recovery literature may profit from becoming stronger on plan content, visioning literature may improve by including process more strongly. No idea is effective without a good process, and vice versa.

Surprisingly, several factors that were indicated as crucial to plan performance were mentioned as a negative and a positive factor at the same time. For instance, flexibility, in terms of being able to reconsider decisions in case of future changes in insight, was mentioned as an advantage for the Master Plan. It was also mentioned as a danger, as the plan could eventually cease to make a real difference. Integrating multiple interests in the plan was also mentioned as being both an advantage for aligning several sources of power and a

disadvantage for inadvertently excluding some groups from benefitting. This suggests that it is not about having that factor, but about having the right amount of that factor.

So it is partly a matter of degree: a vision needs the proper amount of many factors. And is a matter of combination: several factors are simultaneously indispensible. It is about subtle differences: timing, influence of government and strength of vision. A high score on one does not compensate for a low score on another. In the case of the UNOP, all the community involvement in the world could not make up for its lack of inspiration. It was replaced by the Master Plan, but it did succeed in convincing authorities to extend hundreds of millions of dollars for recovery funding, illustrating a chain reaction between subsequent plans as well.

One thing that emerges from these findings is that the less vision a plan has, the better it will be accepted. This was most explicitly discussed in the interviews with the designers. The first plan for rebuilding New Orleans was very visionary with relevant ideas for how to build a more resilient city. Interviewees say it lacked proper timing, but even were it presented today, we question whether it would be accepted by the residents of New Orleans. Its vision was to make a better city, but the people seem to want the same city. The UNOP and the Master Plan seem less visionary and more in line with the people's urge to turn back time. Therefore, they are accepted and considered more successful. Here, the tension between Shipley's high goal setting and Helling's realism becomes evident.

The question therefore remains how to define "success." A vision may be accepted, adopted, adored, generating action, and granted the force of law; a success in short-term performance in terms of output of the democratic and formal process. Despite that success, its content may fail to address the deeper, long-term issues that were the real cause of the city's problems. A vision with high performance power could be poor or average in terms of its capacity to solve the underlying problems, or vice versa. One interviewee from the group of designers put it this way: "[Many] plans stop where they should start. They were made to please everyone."

This brings us back to the question we started out with. How can an idea make a difference? As it turns out, effective visionary planning is a balancing act: you have to go with the flow, because when you try to stop it you will be ignored. But to what extent can planning bend the trends? Our study shows that the most important factors for bending the trends are connecting to people, authority, a supportive political climate, and sufficient financial resources. A bit of coincidence is needed for all these factors to come together, but a plan that is sufficiently relevant, elegant, and persuasive to help create a favorable

environment for itself. A favorable environment will at least partly be the merit of a persuasive vision too.

Acknowledgement
We are very grateful for the time and effort contributed by all the students that helped do the data collection and the interviewees. Gratitude is also extended to our University's Honours College for supplying travel funds to collect field data.

THE POLITICS OF PERI-URBAN PLACE MAKING

Terry van Dijk [1]

Abstract

The paper explores the linkages between planning and place making. These processes are interrelated but that is hardly acknowledged. Land use planning is about intervening in all kinds of land development, obviously with an important political component of combining an array of claims. This is about action and future. Place making is about the personal and community perceptions of what the world around people really encompasses. That is about perception and the present.

The paper provides European examples of how planning can reframe perceptions of place – mostly as an unintended consequence, but always with an unpredictable impact. We argue that when the dynamic but unpredictable nature of place making were acknowledged, cultural geographers and planners would jointly understand more of the social side of geographic change than in isolation.

Then planners and their products may intentionally be employed as co-framers of place, and of action. With geographers monitoring and explaining changes in frames. Not as a top-down tool, but as an attitude for authentic dialogue and social learning about places in the framework of the society of tomorrow. In particular communities in peri-urban areas, that tend to suffer from lack of sense of place, need help to learn what their place is. We review relevant theories to precise and conceptualize this political process of place making.

1. Introduction

Land use planning is about intervening in all kinds of land development. We want to change the world - improve it. This is not an easy task because each site and each objective is surrounded by an array of claims. This is about action and future. Although we are aware that these claims have to be solved in a political way, obviously with an important political component of deliberation and decision-making, perceptions and intentions of people tend to be seen as static. The political decision, then, is an amalgamation of the positions it seeks to integrate. But with these individual positions unchanged, there will always be a misfit for everybody involved.

[1] Assoc.Prof. at University of Groningen, the Netherlands; t.van.dijk@rug.nl

In my article "Imaging Future Places" (Van Dijk, 2011a) I contend that people's interests and perceptions are fluid. They change during a decision-making process. In fact, outcomes of planning processes, once shared with the public, immediately change how people see the world around them. Because plans point out problems and propose solutions, the limitations and possibilities are exposed. The result is a changed place.

Place making is mainly a geographical term, about the personal and community perceptions of what the world around people really encompasses. That is about perception and the present, while planning is about action and the future. But place making would be worthwhile to be seen as a planning result, as well as a planning objective.

In this paper, I present some examples to illustrate this point (section 2), showing the unpredictable yet inevitable social effects of plans. I then point out that peri-urban areas, by nature, particularly would benefit from planning as a way to help construct a joint image from a region (section 3). In section 4, relevant theories are reviewed.

2. Examples of plans that primarily changed place-perception

This sections seeks to empirically demonstrate the subtle frame changes that plans bring to bear. And the indirect changes on land use that are the consequence.

2.1 Harbour plans that sparked landscape appreciation [2]

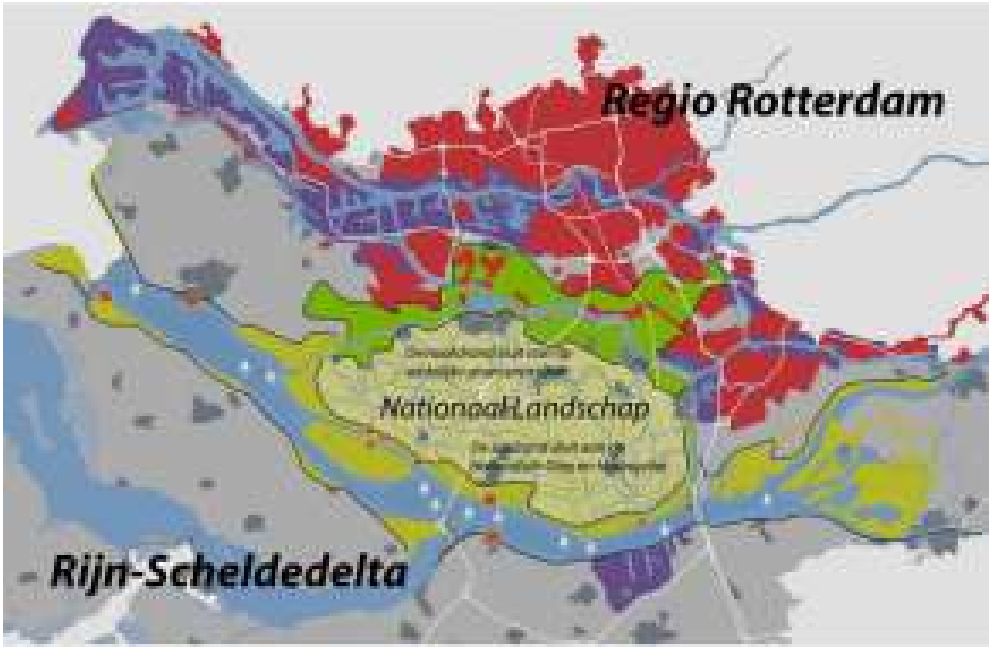
Just south of Rotterdam lies an island surrounded by several river branches just up the river mouths. Given the deficit of space for harbour expansion directly around Rotterdam, this island, called the 'Hoekse Waard' is a good location for building new harbour terminals that complement Rotterdam seaport. Politicians from Rotterdam and the relevant province start preparing plans and a political lobby to put pressure on the 'Hoekse Waard' city councils.

The population on the island does not like the idea. Although the six local governments on the island initially promised to cooperate in designating a preferred harbour site, this joint agreement was challenged by wealthy people living close to its projected site. They started the protest, enabled by dominating the municipal elections at that part of the island.

They try to stop the plan. Initially by using the conventional hearings and appeal procedures, but their efforts are in vain. The threat of the harbours make them

[2] For more details, see:
Van Dijk, Aarts and De Wit (2009) and Van Dijk, Aarts and De Wit (2011)

aware of the landscape on their island. They see the value, because they are about to loose it.



Then they discover that the national government is preparing to designate to several sites the status of National Landscape. This coincidental opportunity locally prompts further study into the cultural-historical values of the site and the locals successfully demonstrate that Hoekse Waard is well worth preserving.

So, the plan for harbour expansion reframed the perception of the area – but in an unexpected opposite way. First among the locals, that successfully change the place perception among the national politicians. The Hoekse Waard island actually becomes a National Landscape and that means the harbour is off.

As the area receives this official designation, also the larger public start to perceive the area differently. The representations of the area, in cycling guides, tourist communications and magazines, give it a new significance.

So, although the harbour was not made, the plan did change the meaning of the area. It even was given a legal status, meaning that certain land use changes are not permitted any longer. The plan has changed the phyical world- in an indirect way.

2.2 Strategic land purchases because of expected gains

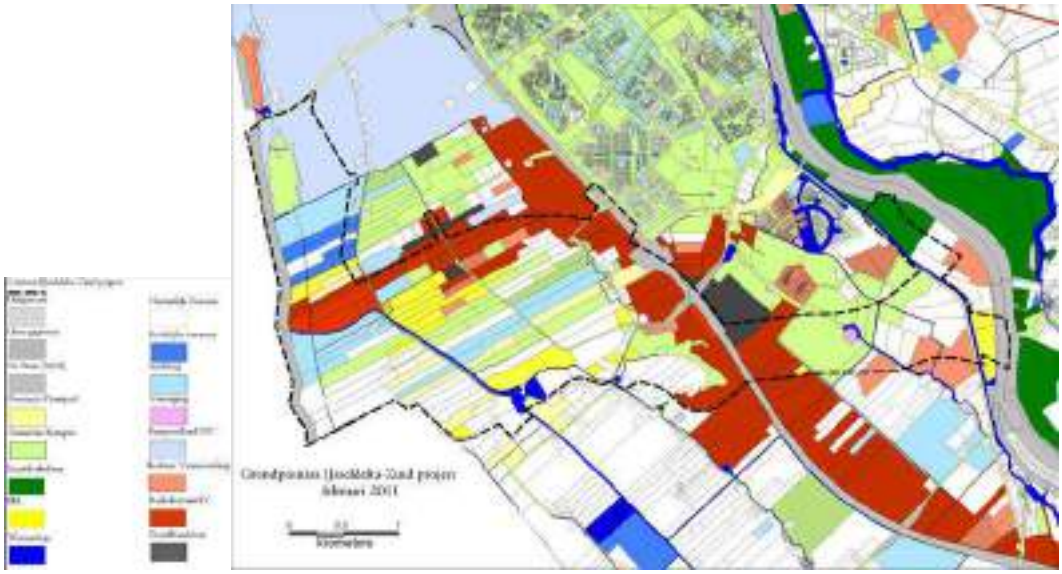
Reframing places may spark anticipatory behaviour in the form of land acquisition. Plans feed expectations of where new land development will occur.

The Portland Urban Growth Boundary (UGB) for example steers land hoarding by developers to go to other sites than in an unregulated situation; it channels expectations. Plans to expand the UGB induce speculation long before the changes come into effect.

And so may plans for a new highway exit, for instance, prompt land purchases by developers. The anticipatory behaviour, by its subsequent land ownership situation, will influence the eventual nature of the land development.

Below is a picture from a major regional project close to the Dutch city of Kampen. It proposes a new river branch and high-end housing sites. During the decision-making, the area was given new meaning. Not the landscape qualities became highlighted as in the first example, but it became a place of possible real estate gains. Land purchases started to occur.

The dreams, rumours and discussions that lead up to formal plans generate anticipatory behaviour. So, the context for plans, that will obviously change compared to the time of drafting the plan, changes partly self-induced. It is a feed forward loop that changes project conditions – either in favour (self-fulfilling) or complicating (self-falsifying; Portugali, 2008).



3. Peri-urban areas in need of alignment of frames[3]

The inherently transformative nature of peri-urban areas, together with their typically fragmented institutional landscape (Mattingly, 1999; Simon, 2008), imply a particularly complex setting for conventional planning efforts. We argue that dealing with transformative zones such as the peri-urban area may require planners to develop a more inspirational role. Planners that are aware of the reframing processes may be valuable for peri-urban planning in particular, as it potentially can mediate stand-offs between actors by uncovering shared values and interests.

If planning actually has to be designed to encourage imagination, spatial visioning goes beyond conventional consensus planning, that Innes and Booher (1999) lament for lacking creativity, instead offering comprehensive concrete and credible images of the future that reframe problems and opportunities (Van Dijk, 2011).
Of vital significance but little discussed in the literature is that the peri-urban characteristics mentioned above (dynamic, diverse, fragmented) have a social impact which complicates peri-urban planning: they cause regional identities to be weak, with much contestation or many conflicts of identity. We believe this to be an inherent property of the peri-urban area. Daniels (1999) also provides an elaborate characterization of the peri-urban area as a zone of collision, emphasizing that the transitional zone between city and country tends to be a place where controversies over land use are most visible and bitter.

Peri-urban residents share one space but live in different places (e.g. Kunstler, 1994). This mental division is the most challenging aspect for planners, causing difficulties for planning, since sustainable spatial developments often rely on common goals and collaborative planning efforts. Such goals are difficult to determine in fragmented and diverse peri-urban areas, where many conceptions of the identity of the space co-exist.

The lack of a common cultural identity, which lies behind peri-urban conflicts over land use, is a direct consequence of peri-urban dynamics, diversity and fragmentation. Because peri-urban areas are located in-between urban and the rural regions, they are home to an array of sub-communities with particular niche interests. For example, some farmers might attempt to continue farming, while others anticipate selling off their land for urban development. Then there are those who are neither farmers nor urbanites, who prefer to live in open

[3] This section draws on parts of an article accepted for publication by Environment and Planning B, with the title 'A design-approach to forge visions that amplify paths of peri-urban development.'

spaces, perhaps keeping horses and enjoying a certain freedom. Moreover, there are the entrepreneurs and the manufacturers, expanding their business districts and office parks into the peri-urban area along the easily accessible regional road network. Furthermore, there are the more wealthy urbanites, who desire new low-density housing and recreation facilities. In sum, a diversity of interests can be found in peri-urban areas.

Deeply distinct perceptions of and demands on land trouble planning in peri-urban areas. This diversity hinders the emergence of a consistent and shared peri-urban identity, making it difficult to make sensible, concerted and sustainable choices about future land use. Due to the fragmentation of peri-urban identities, the political basis for deciding over future land use is also fragmented. For spatial policies to be successful, they need to connect to what the population considers wise, acceptable or desirable. Any normative assessment by the public of any government policy on land use draws on a normative framework – whether a person supports a policy depends on their general world-view as well as their view of the peri-urban area in particular. Do we want new factories, roads and houses here, or would that be harmful to our region as we know it? Identities are such frameworks for the normative assessment of optional policies.

Facing a fragmented pattern of meanings in peri-urban areas, planners have to deal with the diversity of frames that makes it difficult to determine which future developments are acceptable. Planners can help to overcome this complication, uncovering shared values by sharing and discussing images of the future, thereby contributing to a fusion of horizons (Dierkes et al., 1996).

4. Concepts for seeing planners as reframers

Hoch (2007) and Throgmorton (1996) have emphasized the significance of rhetoric in planning (considered in the constructive, storytelling sense), and in my article I pointed out three important implications of the rhetorical perspective which had not been adequately explored, but which are vital for further understanding of planning performance in regional design processes.

My first contribution to existing rhetorical planning thought was the idea that design deserves to be understood as a particularly powerful form of storytelling because it is central to the devising and sharing of credible and appealing stories about regional futures. Indeed, these stories have to be forged. Designers that analyse spatial configurations and propose changes to them, are in essence forgers of such stories.

Secondly, I expanded on the effect of designs in regional communities by drawing on theories of framing and place-making which logically follow from the notion of rhetorical planning, but which are nonetheless still remarkably absent from the discussion. Because designs change people's perceptions, they

are reframers. If we would exploit that capability, change induced by plans would be understood, measured and appreciated in a different way. It is a way out of the post-modern relativity of planning that dismisses rational and instrumental perspectives without offering a constructive alternative.

Thirdly, given the reframing effect of designs, I argued that the relationship between governments and regional communities should be understood as symbiotic and therefore in constant interaction. In this sense, the relationship can be considered as much more diffuse and co-constitutive than is commonly acknowledged by planners and policy scientists. This suggests that regional society itself is the source of regional change, rather than change being the result of regional policy that is exogenously administered to a society by a government. Nevertheless, with respect to planning issues, the values held by the regional population are also fluid and partly influenced by communicative planning processes.

Together, these three claims help us to understand regional planning in a more strategic relational way, where stories constructed within and told through design, play a central role in spatial developments. In this perspective, the formal and governmental are just single aspects of an overall regional web of interrelationships.

Acknowledging the mental side of making and communicating plans prompts an image of two interrelated cycles of change. One is about the mental world, where ideas, dreams, expectations, stories are conceived, shared and transformed. This is a social process, hard to measure, more cultural geographical than planning. The second cycle is the action that people take,

based on people's place construction. As shown in section 2 of this paper, this action ranges from highly spontaneous and individual (on the property market or establishing a business) to formal and collective (giving an area a protected status).

Whatever the nature, as visualised in the diagram, people stand between ideas and physical reality. People are part of dynamics of place construction. And they are part, in all kinds of ways, in the actions that change physical reality. People translate ideas into spaces. And spaces are one source of information for place construction.

An interesting additional theory for the left half of the diagram is visioning. Shipley and Michela argue that it can be defined as "the process of arriving at a consensual vision" (2006, p. 224). It is based on dynamic worldview as its premises is that the best way to plan for the future in a world of constant change is to trace back from a imagined future, build on inventiveness, intuition and reflexivity, instead of extending the present (Gaffinkin and Sterrett, 2006). Moreover, visioning is seen as a collaborative process (Helling, 1998), since the assumption of most proponents of visioning is that 'plans that resonate with citizen's deepest aspirations and values have the best change of being implemented' (Klein et al, 1993, p.10).

Related to this assumption visioning is a process of persuasion. Visioning processes are undertaken with the aim to elicit a contribution of the stakeholders to the development path drawn up with help of visioning (Shipley & Michela 2006). In contrast to designing spatial plans, aimed to decrease perceived contemporary problems, visioning processes are conducted with the explicit purpose to create shared and multidisciplinary ideas of the future and as such offer a common ground for guiding spatial developments.

The left cycle is known to have several effects. According to Hajer and Poorter (2005) they have an orientating, coordinating and motivating function. Considering the first aspect, visioning may provide an overview of principles that are considered desirable for guiding planning activities (Zonneveld, 2005). Subsequently, visioning produces a framework, an leitbild, for process of change that enlights the general, pursued, direction of development and strengthen the capacity to coordinate decisions on future investments (Rotmans et al., 2001; Peel and Loyd, 2005). Finally, visioning is considered to have a motivational effect on stakeholders to invest in line with the end's defined during the visioning process (Ames, 1997).

5. Conclusion

Plans co-constitute what is - they make what people see around them. When the dynamic but unpredictable nature of place making were acknowledged, cultural geographers and planners would jointly understand more of the social side of

geographic change than in isolation. Peri-urban areas, with their fragmented identity being areas of troublesome decision-making, could benefit particularly from planning as place-making. It could unite the disjointed places that the people sharing those spaces live in.

Then planners and their products may intentionally be employed as co-framers of place, and of action. With geographers monitoring and explaining changes in frames. Not as a top-down tool, but as an attitude for authentic dialogue and social learning about places in the framework of the society of tomorrow. In particular communities in peri-urban areas, that tend to suffer from lack of sense of place, need help to learn what their place is.

Different Approaches to Disaster Resilience of Urban Settlements of Developing and Developed Countries: A Comparative Case Study on Yalova vs Cologne

E. Alarslan[1]

Abstract

This paper outlines a disaster resilience model for urban settlements with a comparative analysis of two cities: Yalova/TURKEY vs Cologne/GERMANY. After examining different disaster characteristics of various countries, both developing and developed, some common features and local specifics relevant to disaster mitigation are identified. Such common features and local specifics provide a starting point for designing a model for disaster resilient urban settlements. This model sets out guidelines for disaster mitigation, including standards, criteria, and building codes for disaster-prone settlements. On the basis of such guidelines, proposals are formulated for short-, medium-, and long-term strategies and policies.

The model focuses on the physical resilience of urban settlements rather than on social, political, administrative, etc. structures. Nevertheless, such structures must be taken into account since multi-dimensional functions interact in an urban settlement. The model distinguishes between risk factors of an urban settlement and elements of resilience. The model offers a checklist of possible actions rather than a detailed and comprehensive guidebook. Though based on a standard checklist, the model proposes different approaches for developing and developed countries, respectively. It is designed in a hierarchical structure from macro policies to implementing measures. The variables used in the model and the checklist can conveniently be updated to changing conditions of urban settlements over time. Multi-dimensional features and prospective methods of the discipline of city planning are reflected in the model.

The application of the model is discussed with a view to Yalova and Cologne, respectively. This comparison suggests different priorities for strengthening disaster resilience in developing and developed countries, respectively. Although Turkey is not a developing country, it presents typical features of developing countries due to its rapidly increasing population. Germany is a typical developed country with a shrinking population. Thus, Cologne typically represents the relevant features of developed country settlements while Yalova reflects those of developing country settlement.

[1] The Turkish Ministry of Environment & Urbanization/General Directorate of Geographical Information Systems, Ankara, Turkey- ebrua@csb.gov.tr

Key words: Disaster resilience, Cologne, Yalova

1. Introduction

Recently, natural disasters with devastating effects on human settlements have proliferated. In light of this fact, this paper will present a disaster resilience model for urban settlements. Since urban settlements are densely populated and constructed habitats of men, they a priori represent high natural disaster risks. Unless new planning strategies integrated with disaster mitigation approaches are applied to the urbanization process, natural disaster risks remain unacceptably high in urban settlements. In the model main principles, policies, strategies, and standards are set out to guide disaster prone urban settlements in the disaster mitigation process. As another notable point, this model sets out two different approaches to lessen the hazardous effects of natural disasters on urban settlements.

2. A Model on Disaster Resilience of Urban Settlements

This model is aimed at maintaining physical resilience of urban settlements rather than strengthening social, political, administrative, etc. structures. However, since an urban settlement is a space in which multi-dimensional functions interact, other relevant issues such as political, administrative, economic, and social are also taken into consideration to support the physical resilience of urban settlements. The disaster resilience model is structured with a view to correlations between disaster mitigation stages and the procedure of spatial planning in various scales.

The model has two main parts, namely risk factors of an urban settlement and elements of resilience. Risk variables are classified as natural disaster variables and urban settlement variables are taken into consideration in drawing the risk profile of an urban settlement. Total disaster response capacity, coping capacity, policies, and instruments of disaster resilience of an urban settlement are assessed in the part of “Elements of Resilience” (see also fig. 1). As “Figure 1” shows, the parts of the model interacts each other to adapt to the dynamic features of the urban settlement concerned or those of the natural disaster threatened the urban settlement.

The model is designed as a checklist of actions rather than as a detailed and comprehensive guidebook. This checklist of actions and recommendations can be easily modified to urban settlements of both developing and developed countries in light of the relevant set of priorities. The model is designed in a hierarchical structure from macro policies to implementation details through the headings set out below:

A-Risk Factors (of a Settlement)

A-1 Potential Impacts

For a certain urban settlement, the characters/features, magnitude and range of the natural disasters as well as the frequency, the occurrence time, the duration of disasters, and the type of disasters should be determined by considering recorded

historical data. Depending on historical damage reports of natural disasters, future potential hazard estimations should be calculated. Natural hazards are parts of potential impacts of natural disasters. Although the proposed model aims at maintaining the physical resilience for urban settlements prone to natural disasters, in this study, the theme of the model is earthquakes. In the case of earthquakes, ground shaking, surface faulting, liquefaction, landslides, tectonic deformation are all features of natural hazards (Melching & Pilon, Eds.2006). In addition to these hazards, the potential impact of earthquakes cover environmental, technological, social, political, and infrastructure risks as well as economic risks (Munich Re Group, 2004). A risk assessment study for an urban settlement prone to earthquakes should be prepared by considering each feature of potential earthquake impacts. Furthermore, such a risk assessment study can be enriched by long-, medium-, and short-term impact analyses. Following a detailed risk assessment study, efficient solutions can be produced for earthquake resilience.

A-2.Vulnerabilities

In light of the aforementioned potential impacts, a vulnerability analysis should be prepared with respect to each feature of an urban settlement namely, the site of the settlement, the ground survey of the settlement, the planning standards and criteria of the settlement, land-use, population density, the population profile and public awareness for disasters, the construction density and quality of the settlement, the quality in urban infrastructure & services, economic profile of the settlement. In order to facilitate a vulnerability analysis for an urban settlement, the vulnerable physical elements of urban settlements are grouped at three scales (macro, meso, micro) in accordance with the scales in spatial planning. At each level, useful questions are recommended to relevant authorities and other responsible bodies for assessing physical vulnerability.

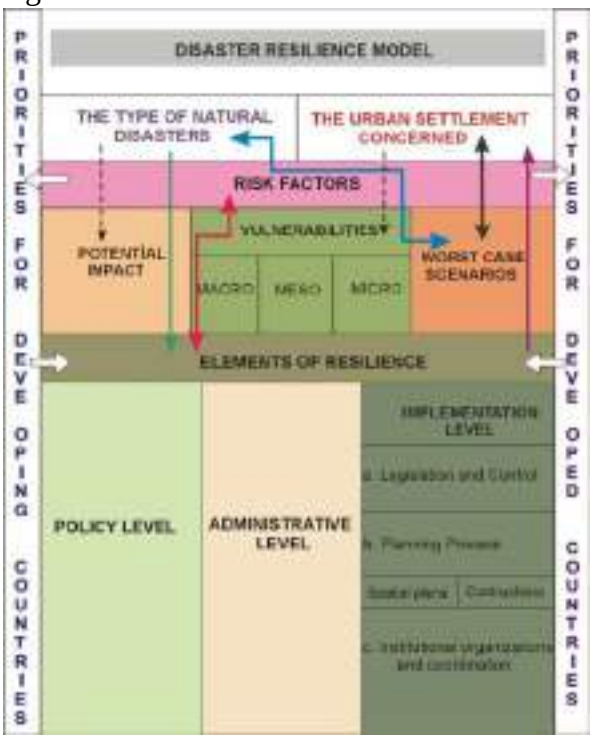
A-3. Worst Case Scenarios

In order to be prepared for the future natural disasters, the administrative body or disaster management authorities of the urban settlement should prepare various alternative disaster management plans and programs based on possible destructive natural disaster scenarios. These scenarios should be designed by the participation of disaster experienced executives, technical experts, academics and members of other scientific institutions, representatives of search and rescue teams and relief organizations, NGOs, other public interest groups, the Media. The worst case scenarios should lead participants (such as disaster experienced executives, technical experts, academics and members of other scientific institutions, representatives of search and rescue teams and relief organizations, NGOs, other public interest groups, the Media) to answer the following questions in the case of materialization of the scenario:

- What are major lessons learned?
- What are priority topics?
- What are challenges in terms of institutional, financial, organizational, administrative, and political capacities and capabilities?

- If possible, what are the results of SWOT Analysis in terms of local coping capacity?
- What short-, medium-, and long-term solutions can be generated?

Figure 1. A Disaster Resilience Model for an Urban Settlement



Source: Own source.

<u>B-Elements of Resilience</u>

<u>B-1.Policy Level</u>

At the policy level, urban policy-makers and governors, mayors, and relevant local administrative officers as well as agents of the central governments who are in charge of local development policies should design an effective disaster mitigation approach with a view to disaster resilience. As already mentioned, unless new planning strategies together with disaster mitigation approaches are applied to the urbanization process, urban settlements will remain exposed to high and probably increasing natural disaster risks. Some main principles, policies, and strategies are proposed to guide disaster prone urban settlements on disaster resilience. The elements of the disaster resilience policies should be analyzed with a view to the question of ***"What makes the urban settlement disaster resilient?"*** The policy instruments available for designing a disaster resilience process should be determined by the guidance of the following questions:

- What particular features of the urban settlement imply risks and challenges for a disaster resilience policy?
- Which elements of the coping capacity of the urban settlement are supportive of a disaster resilience policy?

- What long-, medium- and short-term approaches can be envisaged towards improving disaster resilience of the urban settlement?
- What processes and instruments are available in implementing disaster resilience policies?
- What (potential) side-effects of disaster resilience policies and measures must be taken into account?

However, development trends and policies of countries may create further undesired results on and vulnerabilities of urban settlements. While this model serves to both developing and developed countries, it is useful to emphasize that developing countries should pay more attention on generating policies to reduce environmental degradation. In this context, the vulnerability of urban settlements in developing countries should be evaluated on the basis of interactive relationships of intensity of disasters, environmental degradation, and side-effects of disaster resilience policies & activities. On the other hand, in developed countries, various approaches and methods are available with a view to protect the environment such as policy instruments for sustainable urban settlements and EU Strategic Environmental Impact Assessment Directive (SEA, 2001/42/EC; European Parliament & European Council, 2001). Hence, developed countries should integrate these instruments into disaster resilience programs of urban settlements.

In general, policy designers and decision makers of the urban settlement should pay attention on negative effects of disaster response and mitigation activities as well as general development policies and settlement strategies on urban environment and space. In this respect, the following questions will provide guidance to policy designers and decision makers of the urban settlement:

- What are the possible sources of environmental contamination and damages in the urban settlement during the disaster response activities?
- What types of disaster response activities can give damage to the urban space in terms of disorder and distortion?
- What are the possible sources of environmental contamination and damages in the urban settlement as a result of disaster mitigation activities?
- What types of disaster mitigation activities can give damage to the urban space in terms of disorder and distortion?
- What are the possible sources of environmental contamination and damages in the urban settlement as a result of general development policies and settlement strategies?
- What types of general development policies and settlement strategies can give damage to the urban space in terms of disorder and distortion?

In the light of the above questions, the preparations of some key documents are strongly recommended to build effective disaster resilience policies. These are the macro scale disaster mitigation map, macro scale spatial policy document which outlines national-wide policies and approaches towards mitigating the disasters, local scale disaster mitigation map and spatial policy document including relevant local details should be prepared. An efficient resilient policy should be constituted with the

participation and sharing knowledge of central governmental institutions, local authorities, NGOs and community-based organizations as well as private sector representatives, academic and research institutions, search and rescue teams, disaster assistance organizations, and media (ISDR, 2003).

B-2.Administrative Level

One of the pre-requisites of an effective disaster management is a well-organized administrative structure as well as institutional organization and coordination. In case of problems and inefficiencies in the administrative structure and institutional organization the following questions would be helpful to designate problem areas and to find effective solutions out:

- Is there any conflict or gap among the responsibilities of various institutions in terms of disaster mitigation, preparedness and response? If yes, the following criteria will provide guidance to the reorganization of tasks and responsibilities among institutions:
  - ✓ Historical background of an institution (age and experience)
  - ✓ Field of experience in terms of disaster mitigation (response, preparedness, recovery, mitigation)
  - ✓ Financial and technical capacity and capability
  - ✓ Institutional performance in case of disasters (overall assessment of institutional capacity as well as capability of intercommunication and coordination of relevant institutions and organizations)
- Are responsibilities efficiently shared by relevant institutions? Is there any overloaded or below capacity worked institution? Is there any institution which misfit to its field of work?

B-3. Implementation Level

Implementation level can be divided under three subtitles namely, legislation and control, planning process, and institutional organization & coordination.

B-3.1. Legislation and Control

To sustain disaster resilient urban settlements, relevant spatial planning instruments should be supported by effective legislation, controlling mechanisms and processes as well as dynamics of institutional and public awareness. In terms of effective legislation the following principles are recommended. Unless the existing legislation satisfies the following principles, the new legislation should be design with respect to these principles:

- ✓ A macro scale disaster frame law should be prepared.
- ✓ All disaster related-legislations of the country should be brought in line with this macro scale disaster framework law.
- ✓ Controlling mechanism and processes should be described and clarified through execution of the legislation.
- ✓ Controlling processes and measures towards increasing institutional and public awareness play integral roles in implementing a disaster resilience policy.

- ✓ Public and institutional awareness facilitates to build disaster resilience policies which implement relevant spatial planning standards and methods and foresee adequate disaster preparedness measures.

B-3.2. Planning Process

Spatial plans are important to prepare a base for a disaster resilient urban settlement. For the disaster resilience, using multi-dimensional planning instruments and integrated process of spatial planning into disaster mitigation will be beneficial. Disaster mitigation techniques should be included in the preparation process of a spatial plan; more specifically, the process should include the i) preparation of analysis maps, ii) preparation of a synthesis map by inserting data of analysis maps, iii) preparation of a spatial plan based on a synthesis map. It is possible to insert disaster/earthquake mitigation techniques and approaches into these steps of spatial plan preparation process as follows:

- ✓ Preparation of a land-use map
- ✓ Preparation of various layers of analysis maps
- ✓ Preparation of vulnerability analysis maps of different land-uses with respect to the records of previous disasters/earthquakes
- ✓ Preparation of disaster/earthquakes risks maps (hazard map + analysis map of spatial distribution of vulnerable physical elements)
- ✓ Preparation of spatial plans of the urban settlement in various scales.
- ✓ Preparation of a micro zoning map denoting i.e. safe zones, zones where buildings are permitted subject to adherence to special technical standards, and building prohibited zones.
- ✓ Preparation of a risk mitigation plan including an evacuation plan and an urban transformation action plan in the case of emergency.

As integral parts of spatial planning process, building plans and construction process should also serve to earthquake resilience. The recommended strategies and instruments serving to earthquake resilience of buildings are stipulated as follows:

- ✓ Preparation of existing building stock analysis in terms of quantifying the amount and likelihood of losses that buildings may suffer in future earthquakes.
- ✓ The recommended analysis should be prepared according to different indicators, such as function of the building, construction style and materials of the building, other relevant technical construction details of the building, height of the building, age of the building, soil ground analysis of the building (Meskouris, Kuhlmann, Mistler, 2003). This analysis should also be prepared for other types of construction elements such as storage areas, terminals, bridges, dams, viaducts, etc.
- ✓ Preparation of feasibility analyses of various alternative programs aimed at reducing the possible loss in future earthquakes (FEMA, 2004)
- ✓ Designing earthquake resilience action programs in cooperation with building insurance and building permit authorities and their procedures.

B-3.3. Institutional Organization & Coordination

The effective institutional organization and coordination is a significant issue in terms of implementation of disaster resilience on the urban settlement. All disaster mitigation plans and programs need to be prepared in the pre-disaster period, and they need to be coordinated under one single authority. In this context, the following key questions should be answered to find an effective coordinator institution:

- Is there an institution in charge of coordinating all disaster mitigation activities and programs in the urban settlement?
- If yes, does this institution work effectively?
- If not, what are the shortcomings of the existing coordinating institution?
- Is the existing institution able to overcome such shortcomings or is a new coordinating institution required?

After clarifying the position of coordinating institution, the dynamics of the institutional structure in terms of coordination and organization should be determined. In this study, the main elements of institutional coping capacity are determined as (i) risk perception, (ii) institutional awareness, and (iii) organizational administrative, technical, financial structures and equipments.

As already mentioned, though based on a standard checklist, the model will include the different approaches for developing countries and developed countries, respectively. In this part, these different approaches are clarified in terms of different priorities of developing and developed countries. The following topics are stipulated to provide guidance to developing countries with respect to their priorities in terms of disaster resilience:

- ✓ Survival of citizens
- ✓ Provision of shelter, security, and some basic goods and services for survival of citizens
- ✓ Organizing public campaigns and well-attended public training programs to teach citizens how to apply self-survival techniques
- ✓ Considering the limit of financial resources, strengthening of super- and infrastructure starting from centers of provision of essential services
- ✓ Prevention of environmental degradation and protection of natural resources

For developed countries, the following issues are recommended as priorities:

- ✓ Strengthening of super- and infrastructure
- ✓ Building effective disaster/earthquake insurance system for both buildings and infrastructure
- ✓ Designing the new program and process to provide earthquake/disaster resilience in provision of main services and utilities, such as electricity, telecommunication, energy and drinking water pipelines as well as emergency service units
- ✓ Building and developing the capacity of airway transportation modes and vehicles for disaster response
- ✓ Enhancing civil initiatives and community based organizations with a view to increase public awareness on disasters

The priorities above should always be taken into consideration while each part of model is applied on the concerned urban settlement. However, these priorities will provide more guidance in the part of "Element of Resilience" rather than "Risk Factors" due to the structure of check list in terms of potential impacts and vulnerabilities. In the part of "Element of Resilience", the way of applying policies and other relevant instruments is much more important than types of policies and instruments applied on the urban settlement. In this respect, above priorities will provide guidance to the relevant authorities to reach efficient results.

3. A Comparative Case Study of Yalova/TURKEY and Cologne/GERMANY with Reference to Different Approaches towards Disaster Resilience

3.1. Yalova and Cologne as Typical Examples of Different Priorities

This model sets out two different approaches to lessen the hazardous effects of natural disasters on urban settlements. From the perspective of a city planner, it is possible to distinguish between urbanization processes and urban settlements in developing countries and/or population increasing countries on the one hand and developed countries on the other hand. Such distinction will lead to two different approaches in the disaster mitigation process in different urban settlements. Even the main concerns of these two approaches are different. Thus, the proposed model offers two different sets of priorities with respect to developed and developing countries, respectively, while the main body of the model remains intact. The model should be applied in accordance with the relevant priorities of the concerned urban settlement.

Although Turkey is not a developing country, it has some crucial features similar to those developing countries, such as a rapidly increasing population, agglomerations around urban settlements, and economic difficulties. On the other hand, Turkey has similar features with developed countries in terms of know-how on disaster mitigation. It is very interesting that Turkey has advantages over Germany in terms of more comprehensive disaster legislation, a compulsory earthquake insurance system, and more integration of disaster mitigation issues into the spatial plans. Yet Germany performs well in running relevant processes, such as compliance with spatial planning standards and building codes. Hence, Turkey can build on her success in process planning in terms of disaster resilience as well as planning and construction activities to support disaster mitigation.

In this frame, a comparative case study has been carried out with a focus on Yalova and Cologne. Yalova is one of the cities affected by the 1999 earthquakes in Turkey. Cologne is a city in Germany which has significant earthquake risks due to its seismic background and existing settlement conditions. Since Yalova experienced high intensity earthquakes in 1999[2], the proposed model is updated and detailed in

[2] These particular earthquakes are internationally known as the *1999 Izmit and Duzce, Turkey earthquakes.*

light of local experiences in Yalova. Both cities were analyzed with reference to their seismic backgrounds, existing spatial planning and disaster mitigation activities as well as institutional coping capacity and problems. Subsequent to the analyses of these two cities, the earthquake risk assessments of the cities were performed. It should be noted from the outset that the risk assessment of Yalova will be quite different from that of Cologne in view of the significant experience of the 1999 earthquakes in Turkey. However, this difference creates an opportunity to test the proposed model enriched by the local experiences of Yalova on Cologne which has not yet experienced a devastating earthquake despite of its high seismic risk. Another opportunity through the testing process is to denote different priorities of the aforementioned cities as representatives of developing and developed countries.

3.2. Principle Findings of the Case Studies

Since the proposed model itself focus on the physical resilience of an urban settlement, the whole test results denote physical strengths and weaknesses. These results may pave the way to develop earthquake resilience in Cologne and Yalova.

The model building part mainly relies on lessons learned from the 1999 earthquakes in Turkey while the details are enriched by the case study of Yalova. In light of the model testing as well as personal experience of the author[3], the overall assessment was performed by using the SWOT analysis method (Alarslan, 2009). The 1999 earthquakes gave rise to reviewing the entire disaster mitigation system in Turkey in light of the lessons learned. Many initiatives and ongoing studies on legislation, institution-building, insurance, and quality control look promising for disaster resilient settlements. On the other hand, there are some threats regarding these initiatives due to instable institutional structure, budgetary constraints, lack of public awareness as well as inadequate organization and coordination (The Turkish Ministry of Public Works & Settlement, 2004). With reference to the different approaches set out in the proposed model, it is suggested that Turkey should follow the priorities of developing countries. Although Turkey is not a developing country, it has some crucial features similar to those developing countries, such as a rapidly increasing population, agglomerations around urban settlements, and economic difficulties.

As a result of the model testing, the key findings are formulated to provide guidance building disaster resilience of Yalova. The risk in the settlement of Yalova can be reduced by building awareness of hazards as well as designing and building of all infrastructure and superstructure with a view to decreasing vulnerability (BECT, 2000). For an earthquake, many authorities and citizens are already aware of the hazard of a certain magnitude. However disaster awareness and improvement processes are still complicated in such a country with an increasing population like

[3] The author of this paper worked in Yalova as well as other cities affected from 1999 earthquakes in the disaster mitigation projects of the Turkish Ministry of Public Works & Settlement. She is stil an advisor of the Municipality of Yalova in the UN Campaign of “Resilient Cities”.

Turkey. Because of the multitude of institutional responsibilities for relevant public services such as planning and infrastructure works, the awareness of disasters is not always sufficient to prevent the next disaster hazard. With this shortcoming in mind, measures towards lessening vulnerability can be grouped under three headings, namely “Site and Location of Buildings”, “Construction Quality and Design”, and “Control and Monitoring”.

Figure 2. The City of Yalova

Source: http://www.yalova.gov.tr/yalova_resimler/ana.htm

In sum, Turkey still needs to develop effective institutional organizations and coordination structures, well planned processes of construction control, application of relevant spatial planning standards, a more comprehensive disaster insurance system as well as public awareness. In the light of the relevant priorities recommended by the aforementioned model, Yalova will have an opportunity to be resilient in the next shake of an earthquake.

As a result of testing the model on Cologne, the strengths, weaknesses, opportunities and threats (SWOT) were outlined in terms of risk factors and elements of resilience with a view to priorities of developed countries. The model facilitated to generate useful and effective approaches, methods, and instruments for further earthquake resilience activities. In this respect, the proposed model is an instrument providing guidance to the local authorities as well as to policy- and decision-makers of Cologne by asking them some key questions and proposing some studies in response to their

answers. However, due to time constraints on the study, the confidential nature of some data, and the hesitation of some authorities to give genuine answers to questions on earthquake risks, the proposed model could not be entirely completed on the basis of information received from authorities. Rather, the model was supplemented according to data collected via interviews and questionnaires in Cologne (Alarslan, 2009, pp.334-475).

Figure 3. The city of Cologne

Source: http://www.bezreg-koeln.nrw.de

According to the results of the above SWOT analysis, Cologne is one of the well-planned and properly constructed cities in Germany. In spite of its big potential earthquake impacts, Cologne has not yet experienced any severe earthquake. In this respect, Cologne has the advantage of being able to prepare many worst case scenarios involving earthquakes and generate effective solutions before it faces with a severe earthquake. Many projects and programs leading to earthquake resilience are inevitable for Cologne when the above weaknesses are taken into consideration. In order to enhance the earthquake resilience of Cologne, some studies should be organized at the level of Federal Government and the State of North Rhine-Westphalia, namely a macro scale disaster mitigation map and a macro scale spatial policy document. At the local level, with respect to the aforementioned weaknesses, earthquake hazard and vulnerability analyses should be prepared first. In cooperation with relevant spatial planning and disaster-related authorities, an earthquake micro zoning map and a risk mitigation plan should also be prepared. In terms of building and infrastructure qualities, the existing standards, procedures and potential studies as well as earthquake insurances should be reviewed and synthesized into an integrated process. Another significant issue to be taken into consideration ought to

be building a relevant institutional organization to support all these studies and programs. Institutional capacity and organization should include not only disaster preparedness and response but also disaster mitigation and recovery activities and programs. New institutional restructuring or reorganization should provide opportunities to integrate disaster mitigation techniques into spatial planning methods. The ultimate issue in terms of earthquake resilience of Cologne is institutional and public awareness. Without working to develop effective institutional and public awareness on earthquake risk, the efforts to build up Cologne's earthquake resilience will remain futile until the event of a significant earthquake.

4. Conclusion

The proposed model of disaster resilience can be modified according to the different features of the concerned urban settlement as well as characteristics of the natural disaster which threaten that urban settlement. If applied correctly, the model will provide guidance towards a disaster resilient urban settlement. The success of the model depends on the willingness and openness of the relevant authorities to apply it. In the meantime, the checklist form of the model provides an opportunity for further development. Experience from applying the model to different urban settlements prone to various disasters can add further questions or modify the existing one. To have a potential for dynamic development, the proposed disaster resilience model can provide long-term guidance to urban settlements.

A comparative case study is a useful tool to facilitate the model building. The cities of the comparative case study reflect the typical particularities of developing and developed countries. This provides an opportunity to visualize the priorities recommended for developing and developed countries in the model. While test results of Yalova reflect the threat on buildings and survival of citizens, those of Cologne denote a need for the more comprehensive disaster mitigation method than the existing one.

ACCESSIBILITY ANALYSIS AND ITS MEASUREMENT FOR REGIONAL ECONOMIC GROWTH

Noordini C.M[1], H.J.P Timmermans[2]

Abstract

In the new global economy, accessibility has become a central issue for transportation and urban regional planning. Accessibility is an important asset of urban areas as it links transportation and land use. Accessibility also acts as a key element in analyzing the efficiency of the transportation system. By undertaking accessibility analysis with the use of GIS tools, this paper will focus on accessibility analysis and its measurement for regional economic growth. It will show how accessibility analysis has been implemented in a GIS environment. It also will support planners in providing better knowledge, thereby improving the decision-making process in the future.

1. Introduction

The dynamics of land use in economic regional development have heightened the need for improving the decision-making process, especially in assessing plans and project development. In this situation, accessibility can be used as one of the relevant elements whereby the concept itself is a key variable in land rents and decisions on density for developing urban areas (Alonso, 1964). The development and improvement of transportation planning and infrastructure seem to be important aspects for balancing economic development in the region (Holl, 2006). Consequently, analysis of accessibility should be implemented.

The concept of accessibility has been used widely in urban regional planning and transportation research, especially in connection with the ability to reach certain locations or target sites, within a particular time window with a certain transportation mode. The ability to reach a target destination needs high accessibility levels whereby land use is strongly connected to the transportation system. Accessibility needs to be measured to evaluate land use and transportation strategy in the development process.

In GIS, accessibility analysis is a common task which could be a very simple analysis or a very advanced analysis. Various studies have used GIS technology for accessibility analysis (Arentze et al., 1994; Liu and Zhu, 2004; Gutiérrez et al., 2010; Zhang et al., 2011; Salze et al., 2011).

[2] Professor, Eindhoven University of Technology, The Netherlands -H.J.P.Timmermans@tue.nl

This research will give an account of accessibility analysis and modeling in urban and regional economic growth for the Kuala Lumpur area. This paper is organised as follows. Section 2 describes the accessibility measure used. In section 3 we explain the methodology to select the accessibility measure. In section 4, we describe an application of the accessibility measure in the study area. This paper is concluded in section 5 with a discussion of the implication for transportation and land-use planning policy. Lastly we discuss some related work in progress.

2. Accessibility

A considerable amount of literature has been published on specifications of accessibility measures. According to Halden (2002) in order to integrate spatial planning and transportation planning, some accessibility measure should be used. Accessibility has been measured in a variety of ways. Different specifications emphasize different aspects of accessibility. Therefore, it is important to choose an accessibility measure that best suits the purpose of the research project.

2.1 Accessibility measures

Geurs and Wee (2004) identified four components of accessibility: the land use component, the transportation component, the temporal component and the individual component. The land use component describes the land use system which consists of the amount, quality and spatial distribution of opportunities. The transportation component describes the transportation system which is expressed as the disutility of an individual to cover the distance between an origin and destination using a specific transport mode.

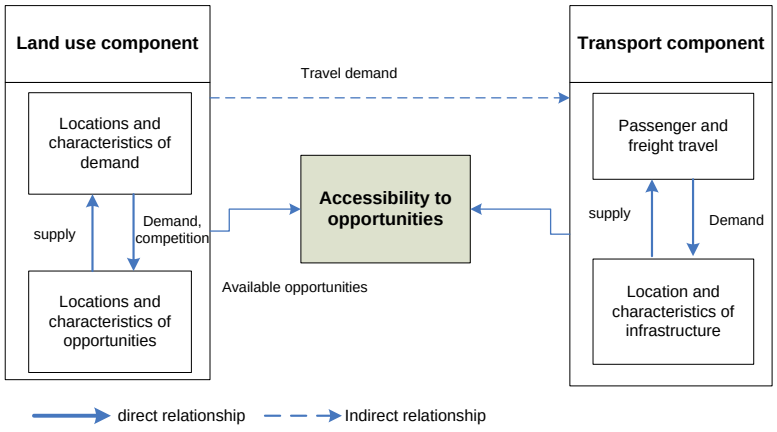

Figure 1: The relationship of accessibility components
Source: Modified from Geurs and Wee, 2004

Based on Figure 1, land use is the most important component in determining travel demand which its link to the transportation component. Each of the components has a direct relationship with the accessibility to the opportunities.

2.2 Accessibility measure

From the literature, we identified that accessibility measures can be classified into four different approaches — 1) Infrastructure-based; 2) location based; 3) person based; and 4) utility based. In the urban planning and transportation domain, these four approaches have been used in various projects related to research on jobs, population, retail services, public services, health services, education, recreation and land use (Geurs & Ritsema, 2001). The infrastructure-based measures consider only the characteristic of the transport network of the area under its consideration such as journey time and congestion. The location-based approach is usually based on location measures such as distance, cumulative opportunity measure, potential, measures based on balancing factors of spatial interaction models, and measure derived from time-space geography (Geurs & Ritsema, 2001). A well-known accessibility measures is Hansen's Accessibility Index (Hansen, 1959), which is shown in equation (1). The general equation for this gravity-type measure, or potential model, can be written as

$$A_i = \sum_j O_j \, f(d_{ij}), \qquad i = 1,2,\ldots,m;\ j = 1,2,\ldots,n, \tag{1}$$

where,
$f(d_{ij})$ is the impedance function,
O_j is opportunity at point j,
m is the number of origins,
n is the number of destinations.

The most frequently used impedance functions are the inverse power function, $d_{ij}^{-\alpha}$, and the negative exponential function, $\exp(-\alpha d_{ij})$. Here, α is a constant representing the effect of distance decay on accessibility.

In this paper, we focus only on one of these measurers-the cumulative opportunity measure. The cumulative opportunity measure (also known as isochoric measure, coverage approach, contour measure, proximity distance and proximity count) is one of the basic and early methods of accessibility measure introduces and discussed by researchers (Al-Geneidy, 2010, Vickerman, 1974, Wach and Kumasai, 1973). This measure can be easily interpreted and is often used by planners in urban planning and geographical studies. In this approach, the number of opportunities that can be reached within a determined cost (travel time or distance) is counted. Although it is a crude measure, it does provide information of the size of the potential market and as such as useful for analysing the location configurations of firms. The measure can be summarised as:

$$A_i = \sum_{j=1}^{J} B_j \, O_j \tag{2}$$

where,
A_i = Accessibility measured at point *i* to potential activity in zone *j*
O_j = Opportunity/destination in zone *j*
B_j = A binary value that equal to 1 if zone *j* is within the determined threshold and 0 if otherwise.

The person-based approach analyses accessibility at an individual level which can be described as activities that any individual can get to involve in the given time frame. Finally, the utility-based approach which El-Geneidy & Levinson (2006) claim is one of the most complex and data intensive measurements. This measure is founded in economic theory. This approach has been used by several researchers in transportation in the context of accessibility to jobs (Koenig, 1980; Handy & Niemeier, 1997) and land use (Miller, 1999). The general equation for log sum as an expression of accessibility can be expressed as follows:

$$A^i_n = \ln \left[\sum_{\forall \in Cn} \exp \left(V_{n(c)} \right) \right] \qquad (3)$$

where,

A^i_n Accessibility measure for individual *n* measure at location *i*
$V_{n(c)}$ Observed temporal and spatial component of indirect utility of choice *c* for person *n*
C_n Choice set of person *n*

3. A methodology of selecting an accessibility measure for analysis

The process involves in selecting an accessibility measure for transportation study can be described as below:

Purpose of accessibility analysis
The first step is to determine the purpose of conducting an accessibility analysis. In this study, the focus of attention is to improve accessibility of firms, recognizing that a variety of transportation modes such as public transit and private automobiles should be designed in the study area to accommodate it.

Compute distance and access
The measure of network distance using GIS-based network analysis with generating multiple network buffers to enclose all network locations varying distance from centre point of three zones in the study area. Each transportation network component such as train station, bus terminal station, highway and major road network will be included as accessibility networks which facilitates the calculation of accessibility.

4. Application

4.1 Study area

Kuala Lumpur is one of the districts in Klang Valley region (Figure 2). As the capital state of Malaysia, it is recognized as a tourist attraction, and a cultural and economic centre for the country. The area was buoyant by the development of commercial, industrial and residential activities which made Kuala Lumpur and its conurbation grow rapidly compared to other states in Malaysia. With a population of 1.6 million people (Department of Statistics Malaysia, 2008) and an area covering up to 244 sq. km., Kuala Lumpur has a comprehensive road and rail network to help workers, residents and tourists commute especially to the city centre. In Figure 3, we can see that most of Kuala Lumpur area is covered by road networks especially the highways and major roads.

Figure 2: Klang Valley region

Figure 3: Kuala Lumpur Transportation Networks.

4.2 Analysis and result

The pattern of accessibility in Kuala Lumpur area

Cumulative Opportunity measure

Accessibility measure in the study area was calculated using the cumulative opportunity measure for distance 500 meter, 1500 meter, 3000 meter, 5000 meter and 10 000 meter for three zones, which are Zone A - City Centre (Central Business District – CBD), Zone B – North and Zone C – South, bounded by Kuala Lumpur district edge. The purpose of this analysis is to demonstrate how many transport facilities reachable within a certain distance. These analyses give an indication of the potential market in the study area which not considering any competition effect. This method is easy to understand and calculated, but only the opportunity in between 10 000 meters away is valuable while those 10 001 meters far are not important and not valuable.

Results

Table 1, Figure 4 and Figure 5 illustrates the results of a number of transportation features located within less than 500 meters and more than 10 000 meters from three zones for the analysis.

Table 1: Results of transportation features located within determined distances in Zone A

Distance / Transportation features	<500m	500-1500m	1500-3000m	3000-5000m	5000-10000m	>10000m
Major road	6	36	71	64	77	12
Highway	0	1	5	14	22	8
Train station	0	17	16	11	18	1
Bus terminal	0	1	3	1	0	0
Airport	0	0	0	1	0	0

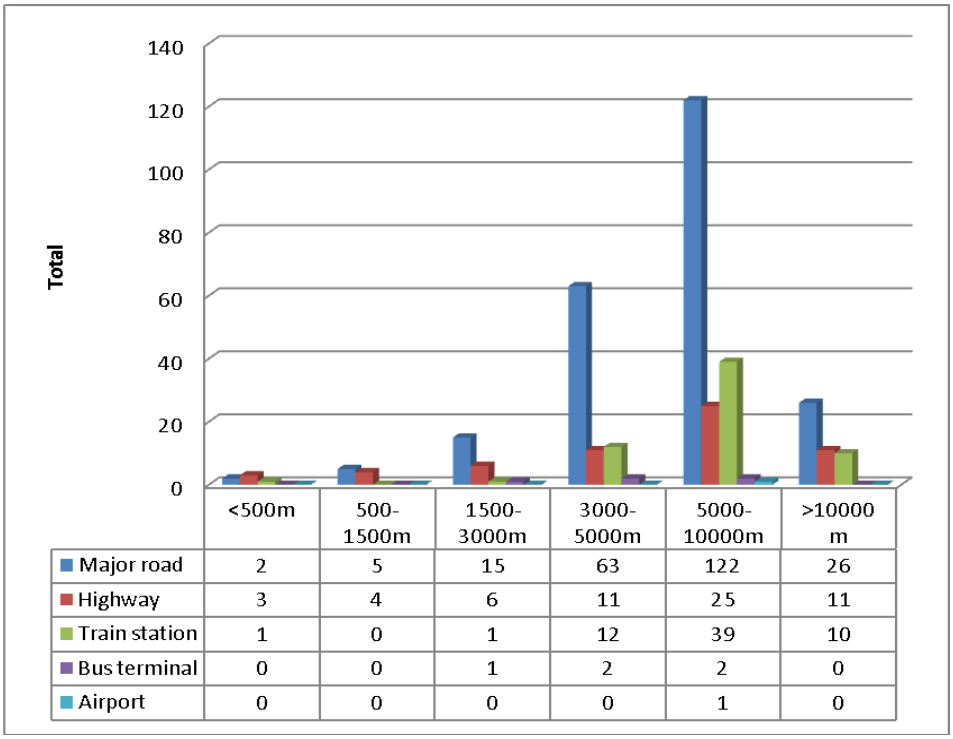

Figure 4: Results of transportation features located within determined distances in Zone B

Because of the density of land use in the City Centre, only six major roads can be accessed within less than 500 meters from the centre and there are no others' transportation features that can be reached within that range. Similar pattern can be seen in Zone B and Zone C accessibility to highway and major road whereby small number of major road network can be access within less than 1 500 meter from the centre. In the three zones, most highways are accessible further away from the centre since that the highway is served as a link to the other sub districts and major city nearby Kuala Lumpur.

	<500m	500-1500m	1500-3000m	3000-5000m	5000-10000m	>10000m
Major road	1	4	15	21	22	62
Highway	2	6	8	12	17	11
Train station	0	1	8	9	37	8
Bus terminal	0	0	0	0	4	1
Airport	0	0	0	1	0	0

Figure 5: Results of transportation features located within determined distances in Zone C

The train networks are the most popular transport mode for Kuala Lumpur commuter due to less travel time. Currently, the public transport network in Kuala Lumpur covers rail with 63 stations. In Zone A, most of the stations are located within 5 000 and 10 000 meters (18), followed by an area within 500 and 1 500 meters (17), 1 500 to 3 000 meters (16), 3 000 to 5 000 meter (11) and less than 500 meters and more than 10 000 meters (1 each) respectively. In Zone B and Zone C, most of the train stations are also located within 5 000 and 10 000 meters (39 and 37 respectively), but only one located less than 1 500 meter in both zones. This show that the concentration of train stations in between the centre and the edge of Kuala Lumpur gives an equal distribution of train services from downtown to other areas.

Generally, the main bus terminals are located in the range 1 500 to 3 000 meters from the centre of Zone A. In Zone B, it is situated between 1 500 to 10 000 meter radius and in Zone C, four of the bus terminal situated within 5 000 and 10 000 meters range. The location of the main terminal is nearby the major road and highway due to the fact that the main terminal serves for long distance journeys all over Peninsular Malaysia. There is one small airport located in the study area which is used by The Military. This airport is located approximate 4 000 meters from the City Centre.

From the analysis, we can summarize that most of the transportation features are located within 500 meters to 10 000 meters from the centre within the three zones. The concentration of the road networks and the rail networks are more towards 3 000 meters away from the centre possibly due to easy access by workers and the location of jobs and residential area.

For more detail overviews, we apply analysis by intersecting the zones. From this analysis, we discover that the intersections cover almost the central part of Kuala Lumpur (Figure 6) which encompasses 91 sq. km. of area (37 per cent from whole

Kuala Lumpur area). The ~~areas~~region incorporate the most transportation networks throughout the study area, especially the train networks (45 stations) and bus terminal (4 terminals). Besides, the connections of highways and major roads are good in this area. Based on firm data available for the study area, we are also able to find out 58 per cent from 55 071 of firms can be found in this area. It proves that better transportation networks, particularly in development of highways and major roads appear to be an important determinant of firm location choice, especially in urban economic research (Maoh et al., 2005).

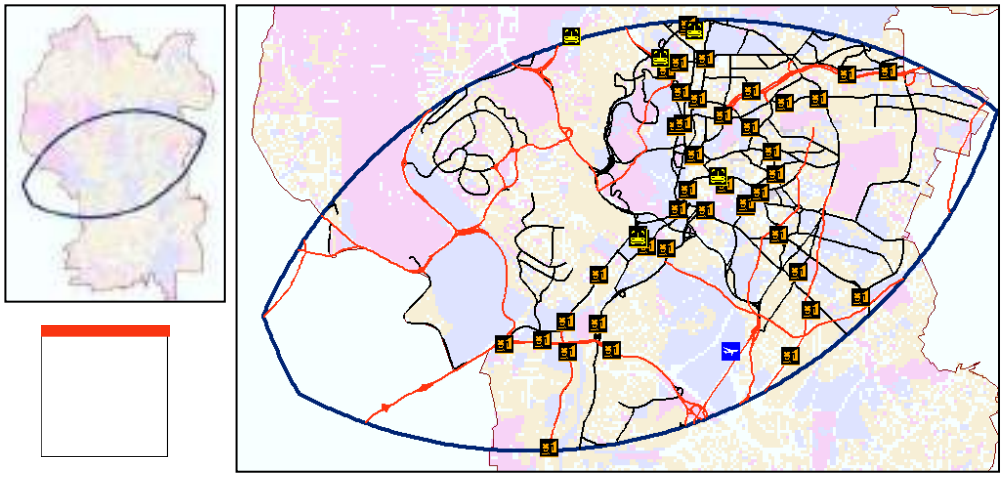

Figure 6: Intersections area of the three zones.

5. Discussion and Conclusion

In this paper, we have presented the results of an accessibility analysis measure on transportation networks with GIS tools for regional economic growth in urban and transportation planning. From the analysis, it shows that for the most part of Kuala Lumpur area can be access through the transportation networks. The central parts of the city appear to have the best accessibility because relatively it was the hub of commercial and business chain. However, in contrast, better transportation network could encourage firms to locate outside of congested urban areas for more opportunities of cheaper land price and labour (Rothenberg, 2011).

Accessibility measure can give an implication for transportation and land-use planning policy. The location model was developed to give planner and decision maker more insight into the location of existing firms and could give an improvement of transportation network in the future. The uses of every type of accessibility measure however, have advantages and disadvantages. For example, the application of cumulative opportunity measure is simple to calculate. It also considers all opportunities are equal because not taking into account the impedance of reaching the origin. This measure also very efficient to determine changes in

accessibility of a location and closely linked to the rational view of transportation system and makes it as a valuable tool for communities (Cerdá, 2009).

The present application of accessibility measure is still in progress. Other related work is a development of potential accessibility index measure for more details levels of accessibility for each sub-district in Kuala Lumpur area. The result from this analysis will be used afterwards for producing analysis for firm location model, which will be applied using econometric approaches.

Acknowledgement

The authors would like to thank the Klang Valley Federal Territory and Universiti Teknologi Malaysia for their permission to use the data for this research study.

MOVING BEYOND THE ROLE OF FANTASY IN CONSTITUTING PLANNING ORGANISATIONS AND THEIR AGENCY

Michael Gunder[1]

Abstract

Planning organisations are generally considered the producers of public policy plans. In this paper, drawing on the planning and organisational theory literature, I wish to consider planning organisations as also producers of fantasies. These are fantasies that organise the collective desires of a polity and construct the visions that guide and shape the agency of the organisation, itself. Further, in contrast to differentiating between fantasy and reality this paper will take a psychoanalytical approach to fantasy where fantasy helps to structure a subject's reality and, in aggregate, that of a subject's society. This is a perspective which acknowledges a constitutively unclear division between these two concepts of a materialised reality produced by our actions and the fantasies that generate this observable materialisation.

Exploring this issue is important, as the paper will argue that this fantasy construction underlies much that constitues planning policy practice and regularly occurs even when planning actors know that these desired fantasised outcomes cannot possibly be achieved within a plan or policy. The paper will describe how a regular reliance on the improbable fulfilment of desired fantasies is why planning itself continues to be socially wanted, even though its plans often fail to achieve their stated objectives. Moreover, the paper will argue that planning needs to acquire a different relationship to fantasy, one in which planning and the human subject is no longer 'in thrall' to fantasy and the improbable desires that planning fantasies often propagate.

1. Introduction

> *the approach to the Real is at best fitful, the retreat from it into this or that form of intellectual comfort perpetual* (Jameson, 2002, p.274)

Planning organisations are generally considered the producers of plans, and related spatially orientated policies, as well as the monitors of their implementation. In this paper I wish to consider planning organisations, be it a government ministry, a local authority planning department, or even a planning consultancy firm, as constructors of not only plans and policies, but in doing so, also as constructors of ideas that are actually desirous fantasies of what might be. These are fantasies that may partially organise both the collective desires of a polity, or society, and these are also fantasies, or visions, that may initially and subsequently guide and shape the agency of the organisation, itself. As Fotaki (2010, p.704) observes 'the role of fantasy as a stimulant of various social and political endevours has not been given its

[1] University of Auckland, Auckland, New Zealand – m.gunder@auckland.ac.nz

due emphasis in political and critical social theory or public policy analyses'. This paper will argue, following Jason Glynos (2011, p.378) that 'fantasies are ineliminable and essential to action, whether these are characterized as progressive or regressive'. Further, the paper will also contend, as well as demonstrate, that 'without the explicit acknowledgement of fantasy, the workings of organizations, culture and ideology cannot be fully understood' (Fotaki et al 2010, p.641).

The paper will commence with a largely Žižekian derived Lacanian explanation of fantasy and its constituents, drawing on both the planning and organisational theory literature. This will include an explanation of the psychoanalytical role of fantasy, ideology, language, *jouissance* (enjoyment) and the inherent human desire for a sovereign good[2]. The two sides of fantasy will then be considered, for every fantasy has two components: what is promised, and of equal importance, the reason why this promise is not being delivered. The paper will then consider the role that cynicism often plays in planning agency, especially when planning actors do not fully engage with a position, vision or fantasy construct being proposed by their organisation, but they somehow have to carry on planning, anyhow. The paper will then consider how fantasy and our, at best, often only cynical decaf resistance to it, tends to maintains the status quo and restrict our range of alternative agency. In response, the paper will then call for a new ethical engagement with planning fantasies, a position where the illusions provided by fantasy no longer bind and restrict our agency in the world. The paper will conclude with a consideration of what this new engagement with planning fantasy might mean for doing planning more effectively.

2. Fantasy, *Jouissance* and the Ideology of Planning

In contrast to differentiating between fantasy and reality, this paper takes a psychoanalytical approach to fantasy, where fantasy helps to structure a subject's reality and in aggregate that of a subject's society. In this regard, fantasy acts as crutial means to simplify the anxiety inducing complexity and often apparent inconsistencies of reality, so that social reality appears as a coherent materalised, yet simplified, whole (Gunder, 2011a). In this psychoanalytical view, 'fantasies are not designed to allow us to flee an unsatisfactory world, but rather to render the world satisfactory by reassuring us that the Other – the social environment within which we struggle to find our bearings – possesses the correct, calming, or consoling answers to our most pressing questions' (Ruti, 2010, p.2). In planning, these might be questions of how to provide the good city and the good life; how our cities can be made more sustainable, liveable, or globally competitive, and the ilk (Gunder and Hillier, 2009).

Fantasy plays an important role in helping to structure 'our reality, often in the least expected scenarios, ordering our emotional investment within a larger narrative of reconciliation and stability… fantasy is what attempts to conceal all fissures… turning our worldly experience into something coherent and appealing' (Bloom and Cererstrom, 2009, p.163). Yet, in doing so, while 'fantasy formations shape the basic orientation of our existence', they also tends to 'curtail our lives by causing us to proceed mechanically exactly at those moments when a degree of self-reflexivity would help us to arrive at a more constructive outcome' (Gunder, 2011b; Ruti, 2010, p.1). Fantasies obscure and make us not look too closely at the conditions of our social reality, especially when fantasies help constitute for the subject a 'clear' sense of identity, worth and direction for action.

[2] That is, 'there is a Good that trumps all others; a supravalue that will allow us to resolve [all problems]' (Catlaw and Jordan, 2009, p.297).

For fantasies help facilitate our ordering of the complex world under simple hazy labels of desirable identification and apparent substance – our sublime objects of ideology (Žižek, 1989), so as to posit 'the symbolic order as a dependable structure that ensures the solidity of meaning and cultural life' (Ruti, 2010, p.2). Further, without this simplification, social reality would simple dissolve into an amorphous and incomprehensible mass (Žižek, 1997). In doing so, fantasy also acts as an ideological mechanism to anchor our emotions within these symbolic labels, so that narratives are allowed 'to provide the co-ordinates for our desires and, by extension, teaches us how to organize and express our emotions' (Žižek, 1989; Bloom and Cederstrom, 2009, p.160). In other words: 'fantasy links a level of meaning with a level of enjoyment, or if you will, connects narrative and affect' (Bloom and Cederstrom, 2009, p.173; Gunder, 2011a).

This is an ideological process, so that 'the ideological significance of fantasy can be understood in the context of its capacity to "grip" the subject, whether as part of a social practice or as part of a political practice'(Glynos, 2011, p.378). In this regard, '[f]antasy not only provides the framework, or affective coordinates, for integrating emotion into narrative but in fact directly structures individual experiences as eternally part of a larger affective story' (Bloom and Cederstrom, 2009, p.164). It essentially binds us in our ideological interpellations, so that 'individuals are constantly being inscribed into larger ideologies through fantasmatic narratives' (Bloom and Cederstrom, 2009, p.164). Further, in doing so, this reflects a 'constitutively blurred boundary' between the two concepts of a materialised reality produced by our actions and the fantasies that help to generate this materialisation (Glynos, 2010, p.22).

For Lacan (1998, p.32), all considerations of social reality, including the fantasies and ideas that help materialise it, relies on language and its signifiers:

> *There is no such thing as as a prediscursive reality. Every reality is founded on a discourse.*

Further, all organisations of government agency, particularly ones which are considered to be bureacratic, such as a planning organisation, have as a central feature 'an emphasis on writing as a foundational and principle practice': that is drafting spatial plans, or alternatively phased, constructing discourses of what spatial reality should become (Styhre, 2008, p.644). Yet for Lacan (2006), language, discourse and the wider symbolic order itself is always 'other', an alien construct which the subject is forced to adapt to when entering society. For the 'symbolic order includes the desires and constructions of internalized others such as parents or institutions and the conventions of language handed down through generations of others', so that '[w]hen we use language… we can only express who we are in the words of others' (Driver, 2008, p. 189). Further, these words tend to always be incomplete, because we must adapt ourselves to them, they never can say exactly what we want. Language and the symbolic are always incomplete and lacking.

Consequently, for Lacan, as well as Freud, the human subject is 'not at home in the world as it is' (Nichols, 2008, p.471). The subject's reality always has a hole in it, it is lacking completeness (Žižek, 2008, p.327). This is a lack of *jouissance*, in the Lacanian lexicon, a lack of enjoyment, but not an enjoyment that may be construed as pleasure. Pleasure is produced by what Lacan calls the 'big Other' which in aggregate constructs the symbolic order constituting culture, society, and our very conception of social reality, itself (Žižek, 1998). *Jouissance* is external to societally sanctioned pleasure, it resides in the subject's unconscious, in what Lacan calls the the registry of the Real (Evans, 1996, p.148). The Real is

a concept which is never clearly defined by Lacan, for it is, at best, 'what resists regimes of representation and what remains residual to any symbolic or linguistic system' (Styhre, 2008, p.647). In this regard, 'Lacan (2006) helps us to comprehend how fantasy bridges our psychic life (the Imaginary) with socially constructed reality (the Symbolic) and prevents us from encountering, what Lacan calls, the Real', that 'which is outside everything that can be (legitimately) symbolized, is literally too terrifying and must be avoided at all costs' (Fotaki, 2010, p.641).

Hence, *jouissance,* arising from the subjects's unconscious, is 'a basic compulsion to enjoy; to achieve consummate satisfaction and therefore heal the gap, or "wound" in the order of being' (Žižek and Daly, 2004, p.3). But this resolution is never possible, what is only created is a fundamental fantasy that this 'wound', or lacking gap, can be resolved, so that we can be a complete and whole subject: a subject finally *at home in the world*. Essentially, this is a fundamental fantasy that 'there is some "sovereign good" that is capable of shielding us from the terror of living' (Ruti, 2008, p.486). Yet this is a fantasy situated in the symbolic actuality of an incomplete language of the Other, where 'subjects are divided between the conscious effort to know identity and fulfill desire and the unconscious disruptions that inevitably make such efforts futile' (Driver, 2009, p.56).

Jouissance is both structured and also 'domesticated (with)in the fundamental fantasy of a harmonius world that can ultimately be constructed [at least for most English speaking first world actors] by means of establising proper liberal democratic and capitalist social relations – our [desired] way of life' (De Cock and Böhm, 2007, p.826). Indeed, it is planning and related design disciplines that gives the subject its literal vision of their desired *home in the world*. This is via the appearances of completeness that these disciplines provide, via the 'material articulation of a logic that lies at the foundation of the city': 'the urban archetype' of the desired city to be, as layed out in the spatial plan (Gunder, 2010; Nichols, 2008, p.471). This is always a plan promising a set of 'stabilizing fantasies, staging a future of happiness, [which] offer the possibility for subjects to acquire an experience of stability and harmony' (Bloom and Cederstrom, 2009, p.165). Consequently:

> *planning is predicated on a fantasy that the discipline successfully provides the solutions necessary in order to provide certainty and harmony for the future of our built and natural environments…. the global spatial planning community… constantly discovers or invents new iconic hooks (or master signifiers) of identification and desire on which to hang problems and deficiencies (lacks) which subtract from the security and certainty of well-being and which also provide their solution, often in terms of scientific narratives or ideas…. these are largely fantasy constructs of, at best, ideological belief, which planning practitioners then deploy locally in their practices.* (Gunder and Hillier, 2009, pp.31-2)

But the writers of plans, the planners, are also lacking, hence they are themselves desiring human subjects. Accordingly, fantasy also plays a part within the function of any planning organisation, itself. Indeed, all organisations, not just planning agencies, 'use narrative to regulate and ideologically interpellate their workforce in accordance with their institutional desires, allowing organizations to create an institutionally friendly "story event" out of an "unpatterned, arbitrary" antenarrative… setting out the shared "purpose being pursued" according to [their institutional] desires' (Bloom and Cederstrom, 2009, p.162). But planning agencies, unlike many other organisations, then externalise these institutional desires, as part of their core function. The guiding internal fantasies of the planning agency are externalised on the polity being planned through the organisation's products: its drafted plans and policies. Often these fantasies are initially generated by a political or other leadership vision of what

ought to be, so as to fill a particular lack of incompleteness and provide harmony; in other cases, through the application of what is considered 'best planning practice' in the name of dominant planning label or signifier such as 'sustainability', 'liveability' or 'globally competitive city' (Davidson, 2010; Gunder, 2010; Gunder and Hillier, 2009). Sometimes these two generators of fantasy are interchangeable and reinforcing of each other. For example, the overarching aim of the newly amalgamated Auckland Council's first Draft Spatial Plan is to make Auckland[3] 'the most livable city in the world' and this planning vision is also echoed by the Mayor's Foreword to the document:

> *It is my privilege as the first Mayor of Auckland to develop a vision for Auckland. When I came into office, I said that my vision is to make Auckland the most liveable city in the world.* (Auckland Council, 2011, p.1)

For Lacan (2006) subjectivity is consituted by 'the concept of the fragmented and split subject defined by the impossibility of ever fulfilling its desire to achieve unity (with the other) and to attain the state of blissful wholesomeness', this is a subject who, therefore, forever desires and seeks an impossible 'object that was never there' (Fotaki, 2010, pp.706-7). Accordingly, 'the fantasy of effective policy, of purposeful organization and of harmonious society' all derive 'from an impossible desire' for this harmony, security and unity (Fotaki, 2010, p.710). In this regard, being 'the most liveable city in the world' acts as a metaphorical call for an aspect of this sovereign good of perfect completeness. This is a vision that is first, so claimed, 'inspired' the mayor and then the planners who drafted the Spatial Plan which the Council then subsequently imposed on the wider Auckland community, for who could possibly oppose being *at home* in the 'most livable city in the world'!

3. The two sides of fantasy

Contemporary spatial planning is 'encouraging the emergence of particular development trajectories' (Healey, 2008, p.8). These are desired future ideas of how we should be, or trajectories of becoming. If realistic and potentially achievable, these are perhaps appropriate aspirations. If they are inprobable states unlikely to be achievable, these desired states are, at best, mere fantasies. Yet by delineatating them in a strategic spatial plan, or similar, these fantasies are given material substance and virtual being as though they already exist (Hillier, 2007, p.100). They help constitute our materialised social reality. But here the frequent failure of desired planning fantasies to be able to deliver also requires another dimension of fantasy construction.

Accordingly, two narratives tend to comprise every fantasy: what the fantasy promises to deliver and also why the fantasy fails in this delivery. Every 'fantasy names a narrative structure involving some reference to an idealised scenario promising an imaginary fullness or wholeness (the beatific side of fantasy) and, by implication, a disaster scenario (the horrific side of fantasy)' (Glynos, 2011, p.376). This is the alternative dimension to fantasy. This is the explanatory fantasy of why the desired harmonious fantasy has not been permitted, or cannot be permitted, to be fulfilled. Importantly, this de-stabilizing fantasy tends to be 'not benign in nature', rather it most often is inclined to 'be perpetrated by malicious forces aiming to destroy what an individual hosts most sacred' (Bloom and Cederstrom, 2009, p.165).

Žižek (1989, 1997) calls one common trope in this ideological process of justification: 'the

[3] The eight local councils of the Auckland region of New Zealand were amalgamated into one metropolitan council in October 2010 (see: Gunder, 2011a, p.334).

theft of our enjoyment'. In this regard, 'the concept of scapegoat plays an important fantasy role in suggesting that our enjoyment might be regained, but only as a state of future potential, if we maintain the prevailing ideology by being resolute against this 'thieving' Other' (Gunder, 2011a, p.334). While the structure of the obstacle to the achievement of the fantasy may vary, it plays a very important role. For the full realisation of a desired fantasy is impossible. This is because a 'subject (as a subject of desire) survives only insofar as its desire remains *un*satisfied[4]' and 'the obstacle, which often comes in the form of a prohibition, or a theatening Other, transforms this impossibility into a "mere difficulty", thus creating the impression that its realization is at least potentially possible' (Glynos, 2011, p.377). Indeed, for Lacan (2006), the very 'concept of desire emphasizes the persistent *absense* of satisfaction, rather than the pursuit of attaining it' (Catlaw and Jordan, 2009, p.292 – emphasis in original). Perhaps this is the reason that the final goals of most spatial and related strategic land use plans are never achieved, indeed most plans are replaced by new ones long before their original plan period duration has been reached, be it originally five, ten, twenty years, or longer (Gunder and Hillier, 2009, p.24).

Another significant facet of many fantasy narrative constructs concerns their transgressive dimension. Here the subject may gain *jouissance* by intentionally transgressing the values, or ideals, that the subject openly professes and are required in the fulfilment of the fantasy narrative. For the fantasy of becoming a 'sustainable city', this might be this might be a planner who intentionally travels by car when publically asserting the 'need'; to only use public transit (see: Gunder and Hillier, 2004), or by cynically arguing for the need to act sustainablely, while actually acting in a non-sustainable manner (Davidson, 2010). So for many fanatsy narratives, 'what gives a narrative a specifically *psychoanalytic* inflection is the fantasmatic logic structuring the subject's desire: it furnishes the subject with an ideal, an impediment to the realization of an ideal, and the enjoyment linked to the transgression of an ideal' (Glynos, 2011, p.377).

4. The decaf cynicism of planners in their workplace

By their very nature, plans and their related visions act 'as a strategic means for implementing specific institutional changes… in this mode of control, individuals [tend to] relate their organizational commitment to their own dreams and longings… they attribute negative feelings to, and view as unstable to these desires, those who seek to "dash their dreams"' by opening challenging the plan or policy (Bloom and Cederstrom, 2009, 172). This even applies in cases where actors know that the proposed vision, or fantasy, that is being presented cannot possibly happen. Yet to show solidarity, they often go along with the 'impossible' fantasy. For example, an economic GDP per capita growth rate of five percent which underlies the forecasts of the Draft Auckland Plan (Auckland Council, 2011, p.71) cannot be maintained in a developed economy year-on-year for decades[5]. Even knowing of this impossibility, Council planners were still able to publically state that this will occur, as a consequence of achieving the Spatial Plan. Further, they could quite cynically maintain that this forcasting illusion was

[4] Perhaps best exemplified by the negative consumer experience that most of us experience after the big purchase. This is the feeling of disappointment, let-down and emptiness that often occurs once the highly desired new consumer item – the car, TV, computer, or whatever – that we have pined after for months is finally ours; and, hence why for most of us, the only resolution of this emptiness is to go out and shop some more (see: Gunder and Hillier, 2009, pp.84-7)!

[5] Particularly, when historical economic growth rates for the Auckland region had averaged only 1.0 percent for the five year period 2005-2009 (Auckland City Council, 2010, p.15), not to mention the impact that this 5% annual economic growth rate would have on other Spatial Plan objectives for liveability, such as those of affordable housing and greater transportation mobility.

possible in public meetings about the plan, even when acknowledging, off the record, that the growth rate underlying the plan was, at best, a politically inspired aspirational goal that was indeed impossible (personal conversation).

Žižek (1989, p.32) refers to this as 'cynical distance'. This applies where 'the material fact [is] that the vast majority of today's subjects continue to act as if they did not know what they say they know' (Sharpe, 2004, p.112). We know the fantasy cannot possibly be true, it is simply an ideological foil to obscure the inconsistencies within society, or to provide an optimistic vision of hope, but we publically pretend to believe in it anyhow (Davidson, 2010, pp.394-5). As Davidson (2010, p.403) observes: this cynicism equates 'to the "real" politics of the city, seeing the rhetoric (or rather ideology) veneer as a mask' obscuring the actual practices being undertaken.

Even when this cynicism is openly manifested, it is often done so only in humour or skepticism. Cynicism 'involves an open acknowledgement that if we give workers and management the chance, some of them will tell us that they are not really buy into the dominant ideology', yet 'even if workers know and profess not to be in the gaze of power, even if they can see very well what is happening and are not duped by corporate visions, mission statements, and rituals and instead actively rearticulate their own sense of self, they nevertheless still submit to it in practice' (Contu, 2008, p.371). In the Zizekian, or Lacanian discourse, these acts of cynicism are a form of resistance or even acts of transgession, but in being so, they 'are akin to a decaf resistance, which changes very little'; rather it 'is resistance without the risk of really changing our ways of life or the subjects who live it' (Contu, 2008, p.367). Decaf resistence is how ideology often works, we know better, consequently we are cynical, but we still do what is expected of us, anyway! Indeed, this 'is the very fantasy sustaining and reproducing our way of life in liberal captalistic workplaces', including that of the planning office (Contu, 2008, p.372).

However, this is not without a significant cost. The 'more subjects are invested in fantasies, the more likely they are to read all aspects of their practice in terms of that fantasmatic narrative, and the less likely they are to "read for difference"', that is, they are less likely to challenge the narratives and logics constructed by that fantasy (Glynos, 2010, p.33). As Gunder (2011b) observes, this tends to reduce innovation, or the acceptance of alternative perspectives, that conflict with the values of the accepted fantasy construct. A dominant exemplar of this is sustainability. If the underlying premise of a plan, no matter how much a fantasmatic vision, is legitimised by assertions that it is consistent with sustainability, it is very difficult for planners to support an alternative course of action, for to do so would seem less 'sustainable'. Yet sustainability, in itself, 'is the clearest expression of the structure of fantasy in the Lacanian sense'; for it is an unquestionable and unchallengeable *statement of motherhood* in its apparent implicit protection of nature, even though it is without any clearly definable meaning in itself (Gunder, 2006; Swyngedouw, 2010, p.310). At least for planning agency, sustainability acts as Žižek's (1989) definitive *sublime object of ideology*. It is an object, or perhaps better stated: *fantasy*, not open to challenge, or question, once deployed.

5. Changing our relationship to planning fantasy

If fantasies largely 'determine the ways in which we relate to the world, and consequently influence the ways in which the world responds to us, the disbanding of fantasies, potentially at least, allows us to begin to imagine alternative ways of living and relating' (Ruti 2010: 1). Accordingly, Glynos (2011, p.378) following Lacan's 'Ethics of the Real', calls for a alternative orientation to fantasy, that is 'not abandoning fantasy or going beyond fantasy, but

rather acquiring a different relationship to fantasy, one in which the subject is less "in thrall" to it'. For the problem with fantasy construction and its affect 'arises when the subject uses fantasy primarily as a way to protect itself from ambiquities, uncertainties and other features that evoke intimations of anxiety', rather an 'ethical use of fantasy would entail a much greater openness to ambiguity and thus possibilities for critical distance and alternative becomings' (Glynos, 2011, p.382).

For Lacan (1992, p.237) the ethical act should not be pathological, nor at the service of any sovereign good. This also implies to not to do just what is expected of us, 'to do the right thing', simply if we wish to be perceived as 'good' by the Other (see: Gunder and Hillier, 2004, pp.229-31). Rather, for Lacan (1992), the true ethical act is to be authentic to some strong inner certainty of what constitutes correct action. This is in contrast to some superficial desire 'to do the right thing' that serves our personal self-interest, perhaps by keeping the 'boss' happy, so as to get a 'well done' pat-on-the-back, or at least the avoid of her displeasure. For Lacan:

> *"The heart of all ethics" is encountering "something that happens to us, surprises us, throws us out of joint", something that causes a "rupture, a break or interruption"—this is the Lacanian Real (Zupancic, 2000, p. 235). It is the examination of this dissonance; such as an expectation that we will do something even though we may think that it is not right or good, and the subsequent adaptation of our actions to ignore, accommodate, or overturn this 'dis-ease', that constitutes the ethical act.* (Gunder and Hillier, 2004, p.231)

Accordingly, an 'Ethics of the Real is an ethics of taking risks and making radical decisions, [by] not compromising a fundamental desire' (De Vries, 2007, p.40). For Žižek (2008, 2009) this is a revolutionary act that risks everything, the agent's status, respect, her very identity, everything that the subject holds dear. Rather than 'the "decaf" co-option of acts of resistance… the only solution seems to be the idealization of another category of real acts of pure resistance, which are impossible to co-opt and neutralize' (Stavrakakis, 2011, p.308). Consequently, at least for Žižek, a 'Real' ethical act is one 'that changes the sociosymbolic network in which we and our way of life makes sense' (Contu, 2008, p.374). This is the radical, or even revolutionary, act that fundamentally changes the symbolic order – the social reality – of the world that we know. Yet, Stavrakakis (2011, p.307) asks, following Johnson: is this standard of Žižek's radical transgression, as to what constitutes a 'Real' ethical act, not too high?

Rather, what Stavrakakis (2011, p.311 – emphasis in original) proposes that 'what is needed is to move in the direction of articulating an alternative conception of the act, one which may link Lacan's insights (operating at both the real and symbolic levels) with a radical democratic project, able to promote the idea of a continuous re-enactment of the act as well as to imagine and construct a (conceptual, affective and material) *space* where such re-enacting becomes possible here and now.' Further, Stavakakis (2011, p.311 – emphasis in original) continues that this 'is today the challenge not only for political theory and practice, but also for planning theory and practice… an act that presupposes a certain *reflexivity*, an awareness of its own limits, of the fact that it will never lead to the full realization of subjectivity'. Phased differently, Stakakakis is calling for a radical challenge to the way we do politics and planning, a challenging that is not just a one off nihilistic act, but rather, a radical challenging that is ongoing and reflexively cognative that any fantasies that our imaginary discourses construct promoting satisfaction and completeness – that is, constituting an utopian promise – are doomed to fail and can never fully deliver. Further, I would suggest that this is an act consistent with the Lacanian clinical goal which is 'concerned with orientating the subject

towards the truth of her being and disentangling the subject's desire from externally imposed demands, values, wants, or ideals not in order that we can get what we really want but to reveal the singular way in which we will never get it' (Catlaw and Jordan, 2009, p.292)!

Hence, perhaps the concept of a trajectory of becoming, which may be subject to frequent change and re-direction, as our collective desires and circumstances change, as proposed by Hillier (2007, 2011) in her Deleuzian predicated multiplanar approach to strategic planning, might be one way to conceive such a radical way to do planning. This might be considered a move away from highly desired end states of transcendental utopian ideals and the impossible fantasies that our traditional planning, or should I say dreaming, tends to promise. The desire to have an undefined but desired principle of trying to create a 'liveable city' for as many residents as possible, might be one such realistic trajectory of becoming, rather than a seeking the impossible aspirational utopian ideal of being 'the most livable city in the world' for all of a city's residents.

Rather, than striving for one impossible absolute end state, which is set in concrete, this approach allows a series of ongoing acts, a trajectory in a general direction of betterment. Further, this is consistent with a Lacanian ethics of the Real because it allows 'an ethics situated beyond the sovereign good' of the existing symbolic order consitituting what we think constitutes our social reality, so that we have 'the possibility of experimenting with new post-fantasmatic types of ordering and space' (Stavrakakis, 2011, p.312). Further, this is a 'disbanding of fantasies' that will enable 'us to better listen to the idiosyncratic particularity of our desire, and in so doing to begin to forge a singular identity apart from the social conventions that seek to determine the parameters of our being' (Ruti, 2008, p.486). This is a move away from allowing our fantasies to 'restrict our movement in the world, holding us captive to the idea that the basic structure of our lives is determined in advance rather than constituted in the process of living' (Ruti, 2008, p.497). Perhaps this type of approach can break the ideological spell of our fantasies. Perhaps it will allow us to engage the world in new and creative ways, ways that can fully engage with our diverse, and evolving desires, in a world of ever changing circumstance.

6. Conclusion

This paper has considered the role of fantasy in planning organisations and as it is imposed by planning practice on wider society. It has examined fantasy from a psychoanalytical perspective drawing on the work of Lacan and Žižek. It considered how fantasy relates to the human subject through the unconsious seeking of *jouissance* and what this implies for ideology. The paper then considered the two sides of fantasy: its promise and its justification for failing to deliver its promise. The 'decaf' cynicism of the 'knowing' planners in their workplace was then explored. The paper then called for a new engagement with fantasy.

The regular reliance on the fulfilment of improbable, but desirous fantasies is why planning itself continues to be popularly desired, even when its plans often fail to achieve their stated objectives. Accordingly, planning largely maintains the status quo of space in our neo-liberal world of globalisation (Gunder 2010, 2011a, 2011b). This paper calls for radical change to the conservative role for planning. It calls for a new engagement with fantasy, one where planning actors are no longer 'in thrall' to fantasy. This is a new dimension to reflexive planning. One that is aware of both the conscious, and also the unconsious dimensions of the human subject, so as to truly take on board Kant's (1990) call for enlightenment: to dare to know for oneself! To do so, at least for planners and the planned, calls for planning to stop giving the illusion of delivering the security of certainty. Rather, this is a call for planning to

move on from its contemporary fantasy creation role and begin to effectively engage with the uncertainty that actually constitutes the world.

THE SIGNIFICANCE OF EUROPEAN POLICY IN THE CONTEXT OF DECENTRALIZATION OF PLANNING: THE CASE OF THE NETHERLANDS

David Evers[1]

Abstract
That EU regulations impact spatial planning systems and practices in member states is a well-known fact. In the Netherlands, both spatial planning policy has been affected as well as the traditional Dutch 'comprehensive integrated' approach to reconciling competing land-use claims. Not all of this 'impact' is a direct result of European rules; the choices made when incorporating directives into national legislation and the structure of the state and civil society also strongly influence the way that EU policy comes to bear on planning systems and planning decisions. In a word: governance matters. This paper will explore the effects of EU policy within a changing governance context: the far-reaching reforms towards decentralization and deregulation. This raises the somewhat paradoxical hypothesis (considering the government's Eurosceptic disposition) that the influence of Europe is due to increase, or at least to become more visible, with the reforms.

1. Introduction

Over the past decade, the key planning concept in Dutch spatial policy at the national level has been that of the main spatial structure or "*ruimtelijke hoofdstructuur*" (RHS) in Dutch. Other than previous concepts such as growth centers, concentrated deconcentration, Randstad/green heart, buffer zones, mainports or the compact city which have a substantive meaning, the RHS[2] is more related to governance: it indicates where national government interests are at stake. In the words of the Spatial Memorandum: "The areas and networks which the government considers to be of national importance from a spatial point of view are reflected in the national main spatial structure" (Ministry of VROM et al., 2006). This philosophy is mirrored in the Memorandum's slogan: "decentralize when possible, centralize when necessary." The recently published follow-up, the National Policy Strategy for Infrastructure and Spatial Planning (SVIR) follows this course with renewed vigor (Ministry of Infrastructure and the Environment, 2012). It drastically reduces the number of national interests by abolishing virtually all urbanization policy measures, and in so doing, has reduced the physical size of the RHS. As the influence of spatially relevant European policies have remained roughly the same, one can posit that an increasing share of the Dutch RHS is of European origin. This might seem rather counterintuitive given the vocal opposition of Dutch politicians towards "meddling from Brussels" over the past decade.

[1] Netherlands Environmental Assessment Agency (PBL), The Hague, The Netherlands, David.Evers@pbl.nl
[2] For sake of consistency, the Dutch acronyms will be used.

If this hypothesis is true, this will have implications for Dutch planning practice, which is traditionally based on integrated comprehensive decision-making (CEC, 1997). As they usually pay no heed to territorial specificities, EU sector policies – especially when rigidly articulated – sometimes come into conflict with a planning practice which attempts to optimize the use of space and fairly balance competing land-use claims. Empirical research on area-development projects in the Netherlands has found that anxiety about potential delays or fines for noncompliance with EU regulations has caused developers and other involved parties to be extremely cautious. As a result, land-use plans are drawn up which seek to be as "Euro-proof" as possible by inserting detailed legal provisions that leave little up to chance. A side effect of this practice is that interests that are covered by EU policy, such as clean air and biodiversity, gain precedence over those which do not, such as the provision of social housing (Zonneveld et al., 2008). Although a Euro-proof plan is legally the safest option, it can produce suboptimal solutions as not all interests are taken equally into consideration. This trend for placing legal security above optimized land use will be intensified by a law that allows the national government to pass on liability for EU policy compliance, including any punitive fines incurred, to lower tiers of government (Eerste Kamer, 2011).

A second consequence of the current reforms are shifts in governance vis-à-vis the European Union. The decentralization and deregulation of spatial policy has been accompanied by cutbacks in funding. On the one hand, this can lead to reduced attention for national interests that have been decentralized (rather than abolished) in absolute terms, which, by corollary, increases the weight of European policy in relative terms. On the other hand, the cutbacks may prompt a search for new sources, including European funds. As these are not given freely, but require an entire system of monitoring, co-financing and cross-compliance with other European policies, this will heighten the influence of the EU on domestic policies at the subnational level. Moreover, as many funds include requirements for international cooperation, some Dutch regions might experience a shift in attention (and potential allegiance) from the national government to, for example, their German or Flemish partners when drawing up spatial policies or carrying out spatial development projects.

In short, the decentralization of national spatial policy instigated by a predominately Eurosceptic government is likely to increase, rather than diminish, the influence of the European Union in the Netherlands.

In order to support this claim, this paper will first sketch out how the EU affects the planning system and spatial development in the Netherlands (Section 2). Next, the paper will describe the changes being made in Dutch planning (Section 3). The final sections reflect on how these changes affect the extent to which European Union policies impact on spatial planning and development in the Netherlands.

2 European policy and Dutch spatial planning

For a long time, the impact of the European Union on spatial developments was not readily visible. On the one hand, EU policy is generally not place-based but generic and policy aims usually do not take into account specific impacts on particular locations. On the other hand, as European policies are often incorporated into national legislation, the impacts are often attributed to domestic, rather than European, regulation. Over the course of the 2000s, the relevance of the EU for planning has become widely accepted in the Netherlands (e.g. Van Ravesteyn & Evers, 2004; Jansen-Janssen et al., 2006; VROM-raad, 2008), especially around mid-decade when a large number of construction plans were suspended by the Dutch courts for being in conflict with EU air quality standards. This section will explore some of the ways in which Dutch planning is affected by the European Union. First, a conceptual framework is presented and the different kinds of impact (i.e. on practice, content and governance) will be discussed. Next, several specific sector policies will be elaborated to illustrate this.

Impact defined and explored

How is Dutch planning being influenced by European policy? When addressing this question, one can first make a distinction between *substantive* and *procedural* impacts. The first type affects the content of planning – land-use or spatial development – while the second category affects the planning process, such as the timing, sequencing and duration of tasks, but also which parties are involved and how they relate to one another. The impact type is not necessarily related to the rationale behind the European policy. Policies designed to address a substantive issue, such as water quality in the Water Framework Directive, can sway institutional relationships, such as those resulting from partnerships at the level of river basins, and therefore practices. Conversely, procedurally oriented policy can have substantive impacts, such as the Strategic Environmental Assessment, which although only inserting an extra task into the planning process, has affected the content of countless plans. The figure below depicts how EU policies can directly affect spatial developments (1) or planning practice (2). Most of the time, however, this impact takes place through the policy system of the member state (3). In addition, many domestic policies (4) which are unrelated to European policies, also affect planning practice and content. The thesis of this paper is that the latter (4) is losing ground in relation to the first three.

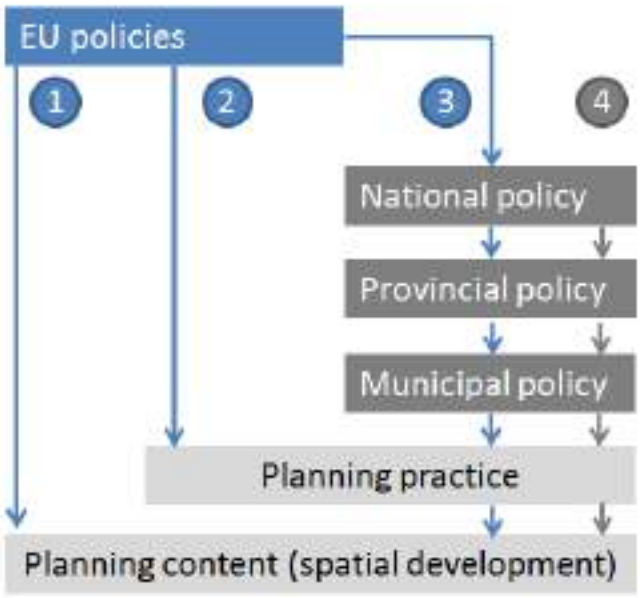

Figure 1: divergent impact routes

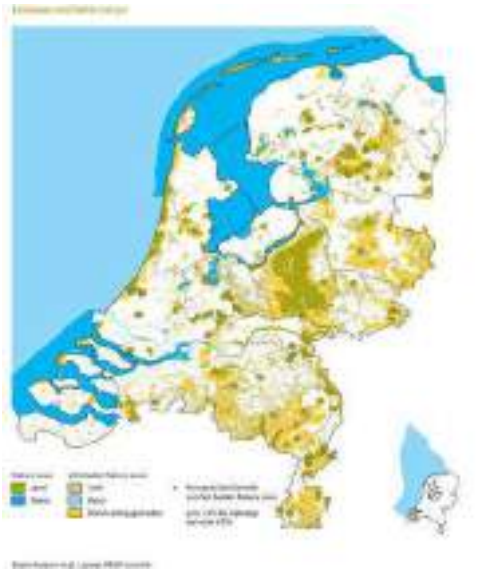
European RHS in the Netherlands
Due to the lack of a European spatial vision depicting a European main spatial structure (RHS) such as has existed at the national level since the Spatial Memorandum, this will need to be constructed by compiling and mapping out the spatial effects of various sector policies. As such an effort would entail a research project in itself, and is therefore out of the scope of this paper, only a few policy areas will be discussed in which the effects are known and divergent enough to be interesting (environment, competition and agriculture). A more thorough investigation would have to comprehensively address all areas of European intervention.

Environmental policy
A good starting point for mapping out the European RHS is environmental policy, as its institutional footprint on planning and spatial development is considerable. The most explicitly spatial environmental policy is undoubtedly European nature/biodiversity policy, Natura2000. This policy demands that measures be taken to prevent the quality of designated habitats from deteriorating. It is very difficult to zone urban development in or even near areas which have been designated as special protection zones within the Natura2000 network. Moreover, areas which contain pockets of protected species outside of the protection zones (hotspots) are not exempt from the reach of the directive (Figure 2a). Therefore, the areas designated as Natura2000, the adjacent spillover areas for protected species and hotspots should all be considered as comprising part of the European RHS.

Once designated, changing the status of a protected zone (i.e. downgrading to allow other uses) is no easy task (Backes et al., 2011). It is comparatively easier for areas where the state of preservation is good, but is generally not the case in the Netherlands, especially as regards the habitats directive (see Figure 2b). As these areas are protected by European law, they enjoy a higher level of protection than other nature areas in the Netherlands. It is therefore not inconceivable that an area with a higher societal value (e.g. due to its cultural or historical qualities) would be cleared for development sooner than one falling under the Natura2000 policy.



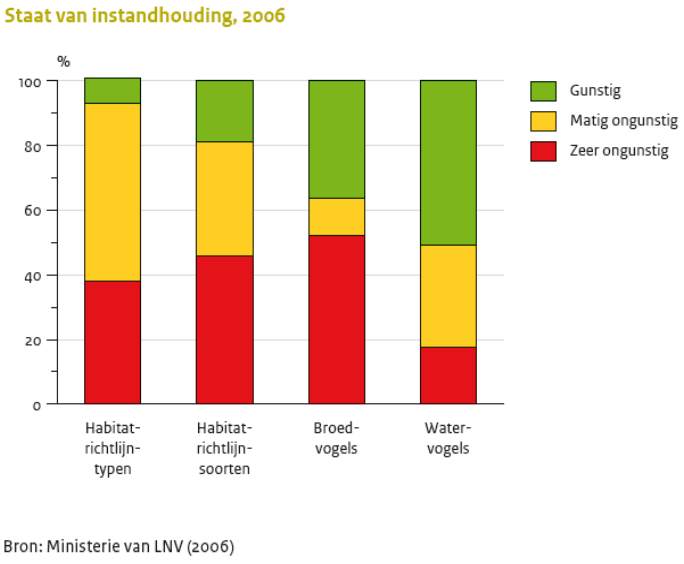


Figure 2a: Kuiper et al., 2011, p. 47 Figure 2b: Backes et al., 2011, p. 19

Another key environmental EU policy, particularly for the Netherlands, is the Water Framework Directive (WFD). This directive requires that plans be drawn up at the level of (transnational) river basins to ensure a minimum level of water quality. The Netherlands has been, euphemistically put, not very successful in achieving its targets (see Figure 3a) and has the worst surface water quality in the EU. The Netherlands has repeatedly requested clemency from the European Commission. As the Netherlands is obligated to taken measures for the areas which do not meet WFD standards, these areas can be considered as part of the RHS.

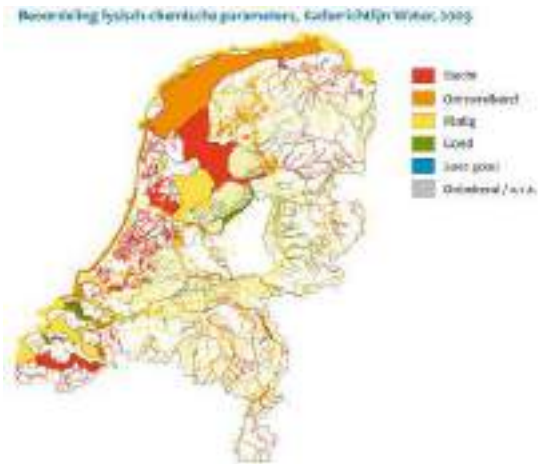

Figure 3a: PBL, compendiumleefomgeving

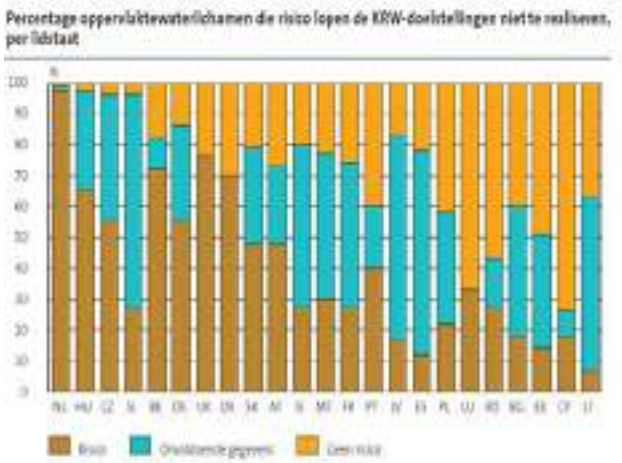

Figure 3b: PBL 2011, p. 82

When implementing the WFD, the Netherlands consciously chose to keep the water plans formulated under the directive legally distinct from the spatial planning system. For this reason, the WFD has much less impact on planning than Natura2000, although the measures taken to improve water quality – e.g. reintroducing meanders in rivers – certainly do have spatial effects. The decision to separate the sectoral concern for water quality from statutory planning has had the advantage of avoiding the problems related to the air quality directive, where developmental projects were suspended by the Council of State, but on the other hand those implementing the water plans do miss a potential ally.

Finally, EU Environmental policy is not only substantively formulated. The Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA) are purely procedural regulations, the timing of which is an important element in the process architecture of spatial development.

Competition policy

As a second policy example, competition policy usually works in quite a different manner than environmental policy. Whereas the latter is typically formulated in terms of substantive aims, competition policy seeks to ensure the functioning of the internal market by setting and enforcing the rules of the game. For this reason, competition policy is generally expressed as general regulations that are directly applicable to all and which seek to create a level playing field.

The rules on state aid, for example, seek to limit the disruptive influence that public subsidies can have on the market. The ban on state aid is one of the fundamental cornerstones of European integration, and is included in the EU treaty (art. 107). There are various ways to determine whether a particular investment should be considered state aid. Although the EU-

treaty offers several exemptions, it is primarily the communications by the European Commission and jurisprudence by the European Court of Justice which have provided clarity over the years.

Significantly for planning, state aid is initially very broadly defined, both in terms of who is providing it (not only governments, but also quasi-public bodies) and how it is provided (not only monetarily but also by selling goods below market price) (Wolting *et al.*, 2012). All public support above a certain threshold should be announced to the EC, which then makes a judgment of whether or not to consider the transaction or policy measure as state aid. If so, it can opt to raise no objections or initiate an investigation into the matter, which may result in sanctions. According to DG Competition's online database, 64 spatially relevant cases have been registered for the Netherlands since 2000. The majority of these have been considered state aid, but not necessarily harmful to international competition, resulting in a declaration of no objection. Examples include support to the peripheral regions in the north, subsidies for wind farms and various environmental arrangements like emissions trading. The cases in which an investigation was instigated are listed in Table 1. One can notice that some cases have a directly physical component (e.g. support to harbors or municipal projects) while others relate more to the planning process (e.g. reorganization of pig farm structure, housing associations). Even the practice of an active land policy (through transactions of ownership) to support social housing has come under EU scrutiny in recent years (Tasan-Kok *et al.*, 2011).

Location	Investigation initiated
National	C96/2001 Reorganization of pig slaughterhouses
National	C26/2001 Support to road transport
Den Helder	N603/2002 Support to Visser shipbuilding to counteract Spanish aid
Krimpen	N606/2002 Support to Dredgers-Merwede shipbuilding to counteract Spanish aid
Enkhuizen, Nijkerk en Wieringermeer	C10/2003 Yacht harbors
Haaksbergen	C33/2005 Support to MARKT Passage Plan Project
Amsterdam	C53/2006 Citynet Amsterdam
National	E2/2005 Funding of housing associations
Leidschendam	A.24123 Land sale Leidschendam in 2007
Rotterdam	C4/2008 Investment in Ahoy concert hall

Table 1: Eur-lex.europa.eu

Another area of competition policy relevant to spatial planning is public procurement. Ever since the Scala judgment at the end of the 1990s against the municipality of Milan, it has been clear that the legal right of landowners for self-realization of zoning plan provisions (as enshrined in the Spatial Planning Act) does not supersede European public procurement regulations. Another case which has caused more than a little confusion is the so-called Auroux judgment against the city of Roanne in France. In this instance, a urban development scheme granted to a particular developer was considered to be a public contract, and therefore required to undergo a European tendering process. On the grounds of this decision, various Dutch parties have complained to the European Commission about municipal land development practices, for example in Eindhoven and Ede. In 2010, the European Court of Justice provided further clarification in the so-called Müller case about when an urban development should be considered a public contract: (1) when the public party has a direct

economic interest, (2) a building requirement is imposed and (3) conditions are set that exceed pure planning requirements (Wolting *et al.*, 2012, p. 66). Although these criteria do not apply to all urban developments in the Netherlands, some certainly do. Especially cases where spatial projects have been blocked or modified due to state aid violations can be considered for inclusion on the RHS map of European policies.

Finally, it is possible that EU competition policy can influence the content of spatial policy. In 2011 the European Court of Justice ruled against a Catalonian policy which seeks to limit the number and size of hypermarkets in the region. The European Commission felt that these rules limited the freedom of establishment of businesses, and was therefore in conflict with the EU Treaty. Considering that many Dutch provinces have similar provisions regarding retail development, this judgment could force them to revise their planning policies (Evers et al., 2012). For decades the Netherlands has prohibited out-of-town shopping center and hypermarket development on the basis of such rules. If these are now considered in conflict with European law, this might engender a major shift of shops to out-of-town locations and the entrants of powerful players such as Wal-Mart, Auchan and Carrefour to the Dutch market.

Agriculture and regional policy

Competition and environment are obviously not the only EU policy areas that affect spatial planning. Another important example is agricultural policy, which through its system of price controls, direct support and rural development has an impact on rural land use (e.g. kinds of crops grown) as well as spatial processes such as concentration and growing economies of scale. For this reason, areas receiving subsidies can be considered part of the main spatial structure (see Figure 4a for the areas which receive the most support per hectare under Pillar 1), such as the pillar 1 and 2 and less favored areas. Moreover, agricultural policy can impact on planning processes, for example, by changing the payoffs and hence negotiating capacity of farmers in land-exchange schemes (in which development permits are linked to demolition of other structures). By the same token, reforms to CAP will also have a spatial impact: the trend from production support towards rural development and nature management (e.g. support to High Nature Value farmland) will redraw the map of CAP subsidies in the Netherlands (see Figure 4b). European regional policy has a similar, and even more explicitly spatial, effect as the CAP: it brings about spatial transformations (e.g. construction of business parks and infrastructure) and modifies spatial development practices and governance by requiring transnational cooperation and co-financing and the coordination of projects at the Nuts 1 level (requiring the cooperation of provinces). Support granted in the framework of the trans-European networks (TENs) can also be considered in this light.

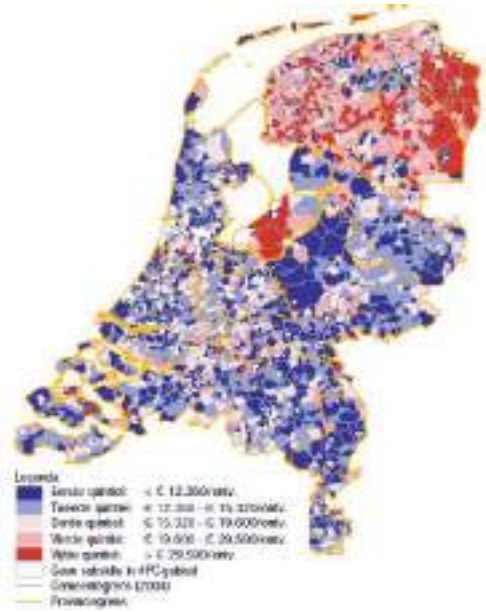

Figure 4a: Hermans *et al.*, 2006, p. 30

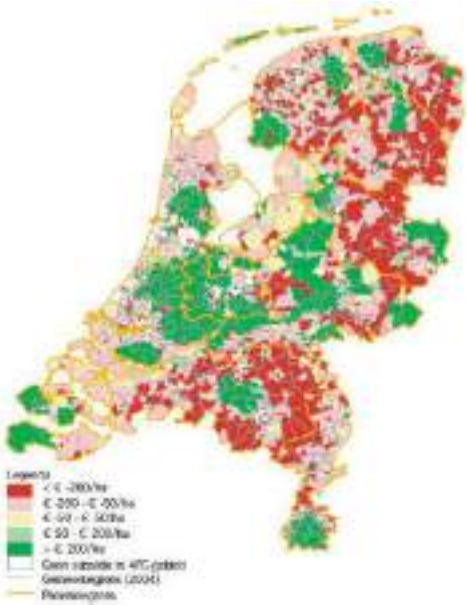

Figure 4b: Hermans *et al.*, 2006, p. 37

In summary, the three themes – environment, agriculture and competition – can be plotted out according to how they influence spatial planning (Table 2).

	Content	Process
Environment	*Natura2000 / WFD*	*EIA/SEA*
Competition	*Retail*	*State aid / procurement*
Agriculture	*Income support*	*Land trading schemes*
Regional	*Urban development*	*Regional coordination*

Table 2: impact on planning

Finally, the themes can be summarized by stacking the geographic distribution of policy effects as layers in a GIS. The result of this exercise is shown in Figure 5, which can be seen as a first approximation of the RHS of EU policy in the Netherlands. In some cases selections were made for the sake of legibility. For example, only the top 40% of pillar 1 was displayed for CAP impact, and pillar 2 support omitted entirely as its monetary value does not reach the pillar 1 cutoff point. Although this map is not complete, and some layers indicative (e.g. regional policy) it does show that a majority of the land mass of the Netherlands is influenced by one or more EU policies.

3 Dutch spatial planning in transition

Dutch spatial planning is considered emblematic of the comprehensive integrated approach in which competing land-use claims are balanced against one another, and to some extent reconciled in urban design. In practice, spatial planning is primarily concerned with the issue of where and how urban development should take place. This is reflected in the kinds of spatial concepts which have been produced over the years –concentrated deconcentration (polycentricity), growth centers, and the compact city. As stated, the neutral balancing of interests is coming under pressure by sectoral European policies because these are being given preferential treatment. At the same time, Dutch spatial planning is undergoing major reform in three fundamental ways: a reform of statutory planning, a reform of planning policy and a reform of planning institutions (Van der Wouden *et al.*, 2011). These will be treated briefly in turn.

As regards the statutory planning system, the Spatial Planning Act of 1962 was replaced by an entirely new act in 2008. One of the main changes was the abolition of the plan hierarchy and reactive checks for compliance, and the introduction of a proactive system in which each governmental tier can apply the same legal instruments – including the local land-use plan – to defend their territorial interests. In addition, the law also made a clear distinction between visions, which are not legally binding, and ordinances, that are (Needham, 2007). As the planning community was acquainting itself with the new rules, they were altered again by the introduction of the Crisis and Recovery Act, intended to speed up the planning process, and the Environmental Licensing Act (Wabo), intended to simplify it by amalgamating procedures. At present, another law is being prepared to replace the Spatial Planning Act entirely and merge it with environmental legislation in a single Environment and Planning Act (RLI, 2012). The fall of the government in April 2012 has cast uncertainty over this process.

As far as policy is concerned, the decentralization and deregulation of planning set in motion since 2000 has accelerated. The government's coalition agreement states that "spatial planning should be left up to provinces and municipalities as much as possible" (VVD & CDA, 2010). This statement of intent became manifest in the National Policy Strategy for Infrastructure and Spatial Planning (SVIR), which abolishes all substantive urbanization policies at the national level, and introducing a procedural requirement called the "ladder for sustainable urban development" as a replacement. Instead of imposing targets on infill development and designating and protecting open areas, the ladder proposes three consecutive steps that sub-national governments need to take when drawing up land-use plans: (1) determine that a quantitative/qualitative need exists, and if so, (2) determine whether sufficient land exists within urban areas and if not, (3) plan development near multi-modal transport infrastructure. There is no sanction for non-compliance with the ladder. The national government still assumes responsibility for ensuring that a well-functioning spatial planning system exists, but no longer assumes responsibility for its content. This fundamental shift in the philosophy of national spatial planning has produced a situation where the main spatial structure is the result of partly overlapping sectoral interests (economic development, Olympic games, nature, energy, transport). In this respect, national spatial policy is coming to resemble that of the European Union.

Urbanization policy	Spatial Memorandum (2006)	SVIR (2012)
Urban areas	Intensification policy Bundling policy Location policy for businesses and retail Urban networks	Ladder for sustainable urban development
Rural areas	National landscapes Green in and around the city Buffer zones between cities Ecological structure with robust connections Concentration of intensive agriculture	Consolidated ecological structure

Source: Ministry of Infrastructure and the Environment, 2012, pp. 108-113

Finally, both the institutions and the institutional environment of national spatial planning have evolved. Regarding the first, at the beginning of the 2000s, the research department of the spatial planning agency (RPD) was transferred to an external institute (RPB), which was later merged with another institute for environment and nature (MNP) to become the Netherlands Environmental Assessment Agency (PBL). This externalization of knowledge, as well as various internal reorganizations over the decade, has arguably weakened the governmental capacity of national planning. Regarding the institutional environment, one of the most important developments is the severing of ties between planning and housing through the privatization of housing associations, the gradual completion of the Vinex[3] housing targets, and the recent ministerial reshuffling which has placed the departments for planning and housing in two separate ministries. In the process, the department of planning has been merged with water management and been dropped from the name of the Ministry of Infrastructure and the Environment. Oddly, the most important substantive goal in the SVIR, economic development, is still housed in the Ministry of Economic Development, Agriculture and Innovation (like planning, "nature" has also been removed from the Ministry's name).

In view of the combination of the turbulence in statutory spatial planning, the ongoing decentralization and deregulation, increased focus on sectoral objectives and disintegration of linkages between the planning department and other ministries (signified in the single authorship of the SVIR), it has become increasingly unfeasible to create a national framework which spatially integrates sectoral policy. In fact, this task is now squarely laid at the feet of the twelve provincial governments.

4 Ramifications

How do the changes in Dutch spatial planning sketched out above relate to the impact of European policy described earlier? On the basis of three points, it can be argued that the measures taken by the predominately Eurosceptic government will lead to a relatively greater influence of Europe on the territory of the Netherlands.

First, we observed that part of the national RHS is already European in origin (Natura2000) or European in effect (measures taken to improve water and air quality). In fact, the most

[3] Vinex is a Dutch acronym for the spatial planning policy drawn up in 1991 which designated areas on the edges of cities for development.

politically charged land-use conflicts are European in origin (e.g. locations for wind farms and CCS to meet EU renewable energy targets, even though these did not make it to the European RHS map). Indeed, by drastically reducing the number of national interests in spatial policy, simple mathematics dictates that the proportion of the RHS mandated by Europe increases in relative terms. Unlike the Dutch national government abolishing its urbanization policies, there is no indication of a retreat from spatial policymaking: on the contrary, there seems to be increased attention for the spatial dimension at the European level. The Barca report has stressed the importance of place-based policies (CEC, 2009), and the inclusion of territorial cohesion in the EU Treaty has opened the floodgates for new policy initiatives. Even without formal competence for planning, it is clear that urban development is a growing concern, and the Commission report *Cities of Tomorrow* (CEC, 2011) might be considered a prelude to a green paper. In addition, European influence could be intensified further in the Netherlands, or at least be made more visible, with the current operation to strip national policy of all goldplating. This strategy carries a risk: lowering standards to the European minimum removes a policy buffer against infringements, which would result in even more direct involvement of the European Commission in domestic policymaking.

Second, the decentralization of planning can perpetuate and intensify overcautious behavior by subnational governments. Corollary to the finding that parties involved in area-based developments attempt, out of ignorance or apprehension of European regulations, to seek full legal cover, it is entirely conceivable that municipalities and provinces will impose all kinds of extra research requirements, exclude certain options a priori and call for the elaboration of detailed plans that attempt to account for myriad contingencies. In addition to increasing the bureaucratic burden, this will produce substantively different plans. For example, this ‘will to certainty’ can express itself in a preference smaller development projects, where the risks are more manageable. When in doubt, provinces will be more inclined to grant less latitude to municipalities when it comes to European requirements, especially after the enactment of a law which allows the national government to pass on accountability, and potential fines, to subnational governments (Eerste Kamer, 2010). The abolition of the robust connections of the national ecological structure (EHS), coupled with the obligation to sell land obtained to this end back to farmers, highlights the complex governance issues at stake. If these physical links are indeed needed to achieve Water Framework Directive targets (they were included in the package of measures presented to the European Commission), and if the European fines for non-compliance are passed on to provinces, their resistance to the national government’s plans is as understandable as it is predictable (Kuiper *et al.*, 2011).

Third, the government's policy stance on domestic governance will affect relations with and the impact of the European Union. The relationship between area-based urban development and EU (sectoral) policy namely plays itself out against a complex institutional environment of multilevel governance with a large constellation of players. This environment is not at all conducive to the application of simplistic governance principles such as the "two-layer rule" called for in the coalition agreement (which states that a maximum of two governmental tiers may be involved in any one matter). It also is difficult to reconcile with the government's principle that governmental bodies should "mind their own business". In spatial planning as well as European policymaking there are unavoidably very many parties and very many intertwining interests, making it counterproductive if not absurd to impose strict distinctions between who can and cannot get involved. Given this, the current changes regarding planning may – again, paradoxically – result in strengthening the bond between subnational governments and Europe. The decentralization of planning has been accompanied with cutbacks. At the same time, many provinces wish to continue to carry out tasks which have not been decentralized, but abolished entirely (e.g. urban infill). For this reason, the prospect of bypassing the national government and attracting additional funding from Europe, such as structural funds, is increasingly appealing. As these sources are linked to conditions which reflect European, rather than national, policy priorities, this further increases the influence of the EU vis-à-vis the national government. In a recent letter, the association of provinces protested against the government's stance that cohesion funds should be used only for the poorest regions in Europe. Similarly, the national employer's association has also urged the national government to be more attentive in taking advantage of EU subsidies.

5 Conclusion and reflection

In addition to the three ways in which the decentralization of planning has increased the influence of the EU on spatial planning, this development has implications for how conflicts between local spatial planning and EU-policy can be resolved. As a forum where member states agree to common standards and rules, EU-policy is not just a matter of 'downloading' (i.e. transposing directives into national legislation) but also provides the opportunity to 'upload' insights from practice and policy alternatives to the European level. In the past, the Netherlands has succeeded in putting a number of issues on the European agenda. International cooperation is often crucial for solving domestic problems, especially when one is a small country with an open economy residing at the crossroads of Europe. Many EU environmental policies with which the country currently struggles, owe their very existence to intensive lobbying from the then environmentally progressive Netherlands. The Floods Directive is a more recent example of a policy that has been 'uploaded' by the Netherlands. Similarly, the friction encountered in the Netherlands between the planning system and sectoral policies can be raised in European policymaking circles. But this requires that governments work together and understand one another. At present, only national representatives take part in the European Council (not provinces and municipalities) and it is the national government which is responsible for translating European agreements into rules to be carried out at lower tiers of government. Often it is this translation, not the EU policies themselves, which are at the root of conflicts with the planning system (VROM-raad, 2007). It would therefore make sense for the national government to remain involved in thinking about spatial implications of sectoral policy. Finally, in order to anticipate undesirable side-effects of EU-policies it is advisable to become involved in the European policymaking process at a very early stage. Since the Dutch subnational governments have neither the network nor the

status to be very influential in this phase, it would make sense for the national government to involve itself more – not less – in European policymaking. The fall of the CDA/VVD coalition government in April 2012 might again mark a shift from the Eurosceptic and planningsceptic stance taken in recent years. If so, the above points should be taken on board when considering the impacts of European policy in the Netherlands.

European Spatial Planning for the Twenty-first Century

Andreas Faludi, Delft University of Technology, OTB Research Institute for the Built Environment

Whether, as the European Commission is proposing in the 'Fifth Cohesion Report' (European Commission 2010a) and the draft regulations (European Commission 2011) territorial cohesion will be more central to Cohesion policy and to the pursuit of 'Europe 2020' (European Commission 2010b) is important. However, there are deeper issues concerning the direction which the European Union (EU) should be taking, for which Faludi and Peyrony (2011) have outlined scenarios, and also and in particular what space or territory is: Is the habit of dealing with it as if it was like a property, with the government representing the people the owner correct? Here it is argued that viewing territory as more diffuse and negotiable leads to a better understanding, both of European spatial planning and of European integration:

> Awareness that the terms we use so casually are rooted not in 'nature,' but in the poetic imagination, has the effect of freeing deliberation and debate from a vocabulary of obfuscation and reveals ... the contours of a Europe that is … about deconstructing frontiers so as to bring to light a civilizational space that is … intensely urban, cosmopolitan, multilingual, and less hierarchical than in the past. (Loriaux 2008, 2)

In this light, the paper addresses three issues:

(1) the relations, in terms of spatial planning, of the EU and its Member;
(2) the meaning of territory under conditions of European integration and, indeed, globalisation;
(3) the implications for spatial planning of challenging the conventional meaning.

Section 1 discusses territorial cohesion. Section 2 criticises 'territorialism.' Section 3 focusses on 'territoriality.' Section 4 discusses 'soft spaces,' a concept that eschews the assumption of territory being a box and of territoriality a government monopoly. The Conclusions temper any expectation of a break with existing practices. Such practices will continue, but be embedded in new ones.

Territorial Cohesion and European Spatial Planning

There is a lively debate on territorial cohesion, with the consultations on the 'Green Paper on Territorial Cohesion' (European Commission 2008) its high point so far. (Faludi 2010a, 162-167; Sykes 2011; for a review of official positions see Janin Rivolin 2010) One can discern two views:

(1) Territorial cohesion must be measured, invoking indicators that stand for desirable or undesirable, as the case may be, qualities of territories. This 'substantive' view highlights the need for research of the kind which ESPON engages in. Indeed, the very concept has emerged in response to a substantive

issue, the future of 'Services of General Economic Interest' challenged by EU liberalisation policies where provisions are difficult to justify on purely economic grounds. Avoiding their marginalisation is an element in one territorial cohesion 'storyline,' 'Europe in Balance.' (Waterhout 2008) Relevant indicators are the object of the ESPON project 'Indicators and Perspectives for Services of General Interests in Territorial Cohesion and Development.' Two more storylines, 'Competitive Europe' and 'Clean and Green Europe,' are likewise substantive.

(2) Territorial cohesion is about the packaging of policies with territorial impact into cohesive wholes; in terms invoked by the Barca Report (2009) about territorial development policies being integrated, Waterhout's 'Coherent EU Policy' storyline. This 'procedural' view insists on coordination between sectors. The European Spatial Development Perspective (ESDP) calls this the 'spatial approach' representing a new dimension of European policy, saying that projects in different Member States '…complement each other best, if they are directed towards common objectives for spatial development. Therefore, national spatial development policies of the Member States and sectoral policies of the EU require clear spatially transcendent development guidelines.' (European Commission 1999, 7)

The ESDP thus sees planning in an umpire role, but argues also for attention to 'spatial factors' because '…it will no longer be possible to compensate for regional productivity disparities by consequently adjusting exchange rates.' Invoking this 'Europe in Balance' storyline and merging it with the 'Clean Europe' one, the ESDP attaches itself to EU regional policy, specifying 'balanced and sustainable spatial development' as its goal. 'Coherent European Policy' thus stands next to substantive storylines, but the prime movers as regards those are the EU sectors. Pursuing the Convergence and the Regional Competitiveness and Employment objectives, regional policy is one such sector. The unique selling point of European spatial planning is the coordination of regional, environmental, agricultural, transport and so forth policies, ensuring that such policies acquire added value by forming coherent packages, taking account of where they take effect, the opportunities and constraints there, now and in the future. (Faludi 2010a, 170)

This is not to deny the interrelations between a procedural and substantive view. The withdrawal of services, due to liberalisation, from sparsely populated areas runs counter to the express wish '…that people should not be disadvantaged by where they happen to live or work in the Union.' (European Commission 2004, 27) Flagging this inconsistency is what the EU policy on such services – invoking as the first one the concept of territorial cohesion – is about.

Coordination between policies impacting upon territory raises the question of the scale at which this should happen and whether statutory spatial plans are the vehicles. At national level, statutory plans are, however, problematic, and even more so at that of the EU. Since it does not work with statutory plans but rather by promoting development, French *aménagement du territoire* has been the EU model. The *Délegation interministérielle à l'aménagement du territoire at à l'atractivité*

régionale (Datar) responsible operates from a position between ministries using seed money to engender their cooperation. It also administers the multi-annual so-called *contrats de projets État-région (CPER)* similar to the contractual approach in EU Cohesion policy.

The intention behind the ESDP was strengthening the spatial dimension of EU policies, but because there was no EU competence, the Member States kept it to themselves (Faludi, Waterhout 2002) and the Commission in the end ceased supporting it. The term spatial planning or spatial development was replaced by that of territorial cohesion. French experts sometimes confide to each other that this means *aménagement du territoire*. Although criticised for eschewing a national spatial development perspective à la ESDP (Geppert 2009, 264), this does work with spatial scenarios, for instance the '*France* 2020' study (Guigou ed. 2000), with '*France 2040*' presently in the works. This represents a form of strategic spatial planning, a concept that has been hailed in the UK as signalling a broader, more deliberative approach than 'town and country planning.' (Allmendinger, Haughton 2009, 620; Haughton, Allmendinger, Counsell, Vigar 2010, 32; Sykes 2011, 382) The upshot is that, for as long as one does not equated spatial with statutory planning, to invoke 'European spatial planning' and the pursuit of 'territorial cohesion' interchangeably is justified. Indeed, ever since the Informal Meeting of Ministers Responsible for Territorial Cohesion at Rotterdam in 2004 kick-started the making of the Territorial Agenda (see Faludi 2009) largely the same planning experts and ministries as before are now working under the territorial cohesion flag.

Territorialism

The message here is that the relations of the EU with its members should be looked at in conjunction with the meaning of territory. If that meaning is challenged, then so are the relations of Member States and the EU and *vice versa*.

There relations are normally for political scientists to consider. The latter often take assumptions about territory as read. Baudelle, Guy and Mérenne-Schoumaker (2011, 16) point out that in the modern era territory signifies a stretch of land that has been appropriated by a prince, with its limits taking the form of material frontiers. According to Loriaux (2008) the French revolution changed this relation of princes with their – often dispersed – territories. The people were implicated by means of Romantic constructs, the invention of nations and their birth rights to ancient homelands, with identities and languages of their own which were literally beaten into children by newly established national educational systems. Modern territory is thus a container holding a nation, with fixed boundaries and the distinction between inside and outside basic to the notion of the state: The inside is subject to sovereign rule and the outside a matter of international relations.

Under globalisation, Scholte (2000, 3) signals, however, the '…advent and spread of what are alternately called 'global', 'supraterritorial', 'transworld' or 'transborder social spaces.' In terms discussed by Murphy (2008), Scholte discusses a new metageography. Metageographies generally, Murphy (2008, 9) says, shape common views and also policies and actions. As regards the EU, '…a metageography clearly

persists that casts states as the … most important internal spaces and that treats political-territorial developments at other levels in terms of the ideological norms that underpin the modern state system.' Gatawis (2000, 5-6) discusses views that deny the EU a territory beyond the sum of the territories of its members but this view has been challenged, even in the German literature (Ritter 2009, 14) where it has been put forward in the first instance. The story of European spatial planning is an example of the influence of norms of the modern state system demanding the maintenance of territorial control.

As indicated, Scholte (2000, 47) challenges this metageography calling it 'territorialism' under which '…macro social space is wholly organized in terms of units such as districts, towns, provinces, countries and regions. In times of statist territorialism more particularly, countries have held pride of place above the other kinds of territorial realms…' In reality, connections are at least partly detached from this territorial logic. In global transactions, 'place' is not territorially fixed, territorial distance is covered in effectively no time, and territorial boundaries present no particular impediment. In the terms of Castells (1996), the 'space of flows' overgrows the 'space of places.' Social space cannot, therefore, be understood in terms of territorial geography alone, and thus not in terms of administrative districts, towns, provinces and so forth, circumscribed by borders marking the limits of the jurisdiction of responsible authorities.

According to Murphy the current 'cartography of social life' – Scholte's territorialism – is the outcome of historic choices, '…of efforts to achieve particular ends with concrete implications for how things are organized and how people think about the world around them.' Invoking a concept to be discussed, Murphy points out that the '…territoriality of the European state system helped to produce a geographical imagination that privileges the "nation-states" over river basins, vegetation zones, population concentrations, or other possible regionalizations…' Other metageographies are possible and, in view of globalisation and European integration, necessary. In terms of Loriaux (2008, 2) territorialism is up for 'deconstruction,' by which he means '…interrogating myths of self and others, and through that interrogation, the discovery of new possibilities that are more powerfully mobilizing and legimitizing.' Scholte (2000, 57) concurs: 'If contemporary human circumstances have gained a substantial global dimension, then we need to develop an alternative, nonterritorialist cartography of social life.'

Rather than about metageography, Loriaux (2008, 13) speaks about 'ontopology,' a conceptual organisation, or mental map, of space. Ultimately, this is based on a myth created through a 'speech act.' It thus comes '…not from culture, language, or physical geography, but from the commitment to transcendent purpose, a *telos*.' (Loriaux 2008, 14) However, '…we need not be prisoners of *just any* myth.' (Op cit., 15) Culture and language are constructs. So are frontiers, the containers of populations and states forged into nations, allegedly so as to defend them, thus ignoring the fact that nations, too, are inventions. Loriaux thus shows that the boundary between France and Germany is the outcome of a series of specific acts, from Julius Caesar's distinction, ignoring the situation on the ground, between Gallia

and Germania – Tacitus and also Ptolemy report small German groups all over the place (Heather (2009, 36) – to the forced assimilation of regional variety by parcelling the Rhineland into competing national entities.

This may be seen as an argument for empowering regions as being closer to citizens (Faludi 2012), but a more fine-grained territorialism does not meet the criticism of space being seen as parcelled out into boxes. In this respect it is worth quoting the paper introducing the, now omnipresent concept of multi-level governance, saying that the '…polar conceptions of a Europe of the regions versus a state-dominated Europe are unsatisfactory … [E]lements of both may coexist in a conceptually untidy, multilatered polity. (Marks 1992, 223) As against the view of someone who has introduced the very concept of multi-level governance, its more common interpretation, for instance in the 'White Paper on Multilevel Governance' by the Committee of the Regions (2009) is clearly 'territorialist.' It '…considers multilevel governance to mean coordinated action by the European Union, the Member States and local and regional authorities, based on partnership… It leads to responsibility being shared between the different tiers of government concerned...'

With his partner, Marks now identifies this hugely popular territorialist interpretation of multi-level governance as but one of two types. (Hooghe, Marks 2001, 2003, 2010; Marks, Hooghe 2004) Thus Type I:

> … conceives of dispersion of authority to jurisdictions at a limited number of levels. These jurisdictions – international, national, regional, meso, local – are general purpose. … The membership boundaries … do not intersect. … In this form of governance, every citizen is located in a Russian Doll set of nested jurisdictions, where there is one and only one relevant jurisdiction at any particular territorial scale. Territorial jurisdictions are intended to be, and usually are, stable for several decades or more, though the allocation of policy competencies across levels is flexible. (Hooghe, Marks 2010, 17-18)

Type II is more like the untidy arrangements which Marks has signalled when coining the term of multi-level governance. The 'Russian Doll' figure of speech for nested jurisdictions '…where each doll/scale is understood as largely capable of being considered on its own, even while located in its (fixed) position within a preordained hierarchy' (Mahon, Keil 2009, 14) embodies territorialism. The figure is often invoked. Thus, Hajer (2009, 24) says about the increasingly redundant 'classical-modernist order' as based on the assumption of territorial, democratic institutions being conceived of as a series of matrouchkas. Levels of government are thus look-alikes that fit inside one another.

Amin identifies 'new regionalism' as being based on the same territorialism. Accordingly, the mainstream view of cities and regions '…is one which continues to conceptualise them as territorial entities.' Here comes the Russian Doll: 'The resulting image is that of a world of nested or jostling territorial configurations, of territorial attack and defence, of scalar differences, of container spaces.' (Amin 2004, 33) However, cosmopolitan forces produce a world of '…cities and regions without prescribed or proscribed boundaries.' (Op cit., 34) Criticising the idea that a new

regionalism might boost democracy, Amin denies that '…there is a defined geographical territory out there over which local actors can have effective control and can manage as a social and political space.' (Op cit., 36) A relational reading offers a different reading '…where the local brings together different scales of practice/social action.' (Op cit., 38)

Already early on, Harvey (1969, 208) criticised the absolute view of space as a neutral container, a filing system or abstract-frame-of-reference underlying absolute space, contrasting it with a view of space as a positional, 'relational' quality of the world of material objects. He gave location theory, conceptualising cities as influencing the properties of the spaces around them as an example. The distinction is filters through to planning thought.

Territoriality

Like Murphy and Hajer, Scholte (2000, 59) invokes territoriality where he says that the end of territorialism does not spell the end of territoriality, according to Sack '…a spatial strategy to affect, influence, or control resources and people, by controlling area.' Territoriality is often equated with state territoriality, but as the ESDP has already said in a statement that these days represents nothing but accepted wisdom: 'With growing economic and social integration, internal borders are increasingly losing their separating character and more intensive relationships and inter-dependencies are emerging between cities and regions of the Member States.' (European Commission 1999, 7)

Hajer (2009, 27) diagnoses the result as 'territorial synchrony' waning. Thus the '…unity of political centre, public, and problem is lost.' This makes it difficult to find the potential for reasoned elaboration. Indeed, states often lack the power to solve policy problems resulting in '…discrepancies between the geographical reach of political institutions and the scale of public problems.' (Op cit., 29) The response is network governance, with much policy work taking place next to or across established orders. 'Policy-making nowadays is most often a complex negotiation among actors with disparate backgrounds and divergent goals. The weakening of the state goes hand in hand with the growth of a civic politics and the emergence of new citizen-actors and new forms of mobilization..." (Op cit., 33) This shifts policy-making to an 'institutional void,' which chimes well with Marks' diagnosis of an untidy multilateral polity emerging.

If, as the critique of territorialism implies, states no longer have a monopoly on territoriality, does this mean that territoriality is no longer a useful concept? Echoing Hajer on the state being no longer able to provide physical security, welfare and effective socio-economic management, Brugess and Vollaard (2006, 1) ask whether the state is the appropriate problem-solving unit to deal with issues of environment, economic prosperity, finance, migration and terrorism. They point out that expert functional networks transcend the territorial limits of jurisdictions and raise the question of whether European integration and globalisation herald the end of citizens' attachment to national territories and whether mobile citizens look for better performance from non-state providers regardless of borders. In view of one of the

characteristics of the Westphalian state being the territorial demarcation of its supreme authority, they formulate the fundamental issue: Is state territoriality '...an image of the past?' Replying, they say that territoriality is a fluid and dynamic concept. 'The process of unbundling territoriality on one level might imply that a simultaneous process will occur at another level, as for example in the case of the continuous ceding of competences from the national to the EU level. However, the unbundling of territoriality may also entail non-territorial forms of organisation. (Op cit., 7-8)

Where it is being unbundled, there this means that territoriality must be negotiated, which is no revolutionary finding. 'Governing' turning into 'governance' is accepted wisdom. In planning, state territoriality working through statutory planning and publicly financed territorial development thus becomes territorial governance. The problems this raises for territorial representation – the privileged source of democratic legitimation (Faludi 2012) – are not discussed here.

Soft European Spatial Planning?

Previous sections have cast light on territorialism and territoriality, rejecting spatially distinct territories and constituencies as the exclusive framework. The problem of European spatial planning is to deal with the mismatch between conventional views and reality on the ground. Dealing with emergent soft or, as the academic literature also has it, relational spaces, planning itself must be soft.

Planning has been subject to criticism for its rigidity. Challenging 'Euclidean' planning, Friedmann (1993) pointed out that planning is located in a world of stable entities which is being superseded by multiple space-time geographies. Challenging planning for assuming a Euclidean world is to the point. In its statutory form, spatial planning relies on state territoriality, but Burgess (2006, 102) proposes '…a complex combination of territorial and non-territorial functional principles.' Much geographic thinking addresses such issues. Harrison (2012) and Harrison and Growe (forthcoming) as well as Olesen and Richardson (2011) give overviews. Haughton, Allmendinger, Counsell and Vigar (2010) on soft spaces is also relevant. 'Soft planning for soft spaces' (Faludi 2010a) going beyond the territorialism characteristic of the metageographical thinking underlying much of planning – in fact of thinking about European integration as such – helps in contemplating its future.

Asking for a new politics of space, Amin has been quoted as denying that there is a defined geographical territory over which local actors can have effective control. Globalism has become the everyday filter through which sense of place is being developed and expressed. 'The result is ... a heterotopic sense of place ... made up of influences that fold together the culturally plural and the geographically proximate and distant.' (Amin 2004, 37) Cities and regions no longer offer territorially defined public spheres. Any '…particular geographical site can only be a nodal connection in a hydra-like network space that never coheres into a local public sphere. Cities and regions are nodes in many public spheres ... An obvious implication is that there is no pre-given place for a politics of regionalism.' (Op cit., 38)

Working with varied geographies is a response to the plural public sphere involved in the making of a region as '…spatially diffuse and geographically mobile. It calls for a politics of place that has to work through this constitutive condition, not one that fakes, as does the new regionalism, a minor national politics of assumed territorial insides and outsides and an imagined regional identity.' (Op cit., 40) Referring to other work questioning the assumptions underlying UK regional policy: that London is the fount of all things 'political;' that the solution to this state of affairs is localism; that politics has to be territorially bounded (Amin, Massey, Thrift 2003, 2), Amin advocates a 'cosmopolitan regionalism.' Cosmopolitanism is a concept discussed, amongst others, by Beck (2006). Delanty and Rumford (2005) see it as a hopeful perspective for Europe.

Summarising, Amin (2004, 42) says that he is seeking to articulate '…a relationally imagined regionalism that is freed from the constraints of territorial jurisdiction.' An early planning example picking this up is by Graham and Healey (1999) criticising the bedrock-concept of the 'object-centred Euclidean conception of space.' They review notions of space under which places become complex arenas. Graham and Marvin (2001) take this further: Cities depend on infrastructure provisions. There is change from systems being run as state monopolies oriented towards equitable provisions for all to providing them through the market. This makes for a 'relational' geography: cities becoming fragmented, with relations with distant places sometimes being more important than with contiguous ones, and with a tendency of walling off nodal points from their surroundings, thus spelling the end of the 'integrated ideal' of comprehensive urban planning.

Davoudi and Strange view space, not as a set of nested containers, but as something that depends on the processes and substances making it up. In this relational view, 'place formation' becomes a process of carving out 'permanences' from the flow of processes creating spaces. 'The organising spatial principle … would be one of multiple overlapping networks with continuous flows of people, resources and knowledge. Such networks and flows would be represented and visualised through the use of 'scenarios' and 'fuzzy maps' showing untidy and complicated flows...' (Davoudi, Strange 2009, 38)

Like others, these authors refer to Healey. Re-affirmed more recently, Healey's concern is with place governance 'with a planning orientation.' She points out that '…those with a 'stake' in what happens in a place are not only local residents, or citizens, of a specific administrative-political jurisdiction. "Stakeholders" may come from other places...' (Healey 2010, 32) Place not only refers to material objects, nor is it coterminous with any jurisdiction. So a jurisdiction '…may not be coterminous with the key relations that need to be mobilised to address particular place-management and development problems and potentialities.' (Op cit., 69) In the concluding chapter, Healey summarises what place-based governance with a planning orientation is about: improving the conditions of life for people in terms of their relations. In so doing, '…it is important to move away from conceiving such relations as a kind of nested hierarchy of systems… Instead, systems are better imagined as overlapping, loosely bounded and 'loosely coupled' sets of relations.'

(Op cit., 226) Without mentioning the terms, it is clear that Healey rejects territorialism and a narrow focus on state territoriality.

Based on a case study of Thames Gateway, Allmendinger and Haughton expose similar views. Thames Gateway shares its boundaries with no other statutory body, but there is a strategy team and a Strategic Partnership. The emphasis is on scales other than those of statutory planning and on planners cooperating with other actors. 'The clear geographical and professional boundaries of planning, plus the hierarchical and silo ways of behaving are already planning history.' (Allmendinger, Haughton 2009, 618) The authors review the literature on rescaling – one of the branches of literature articulating spatial issues – arguing that rescaling involves

> …not simply a shifting of emphasis across existing scales of the statutory planning system, but the insertion of new scales for planning intervention, plus an apparent predilection for promoting new policy scales, initially at least through the device of fuzzy boundaries. ... The emergence of these 'soft spaces' is an important trend...
>
> So whilst planning still needs its clear legal 'fix' around set boundaries for formal plans, if it is to reflect the more complex relational world of associational relationships …, planning also needs to operate through other spaces, and it is these we think of as 'soft spaces'. ... The resulting relational geography of planning requires attention to a variety of associational networks across a wide mix of administrative/political spaces, 'soft' spaces, and other scales. (Op cit., 3)

The concept of soft spaces appears also in the title of the book which followed this article. (Haughton, Allmendinger, Counsell, Vigar 2010) Without couching his analysis in terms of soft spaces, Harrison (2012) analyses practice, in this case regional planning in North West England. Referring to key maps illustrating three subsequent strategies, Harrison shows how relational thinking is waxing and waning under the staying power of territorialism. In a parallel paper, with Growe, in which there is reference also to the work on soft spaces discussed above, Harrison discusses the Concepts and Strategies for Spatial Development in Germany adopted by the Federal Government and the governments of the *Länder* in 2006. The focus there is on 'European Metropolitan Regions,' soft spaces with no equivalent politico-administrative bodies. In the face of pressure to safeguard equality of opportunities, a constitutional goal and a concern that territorial authorities are keen to be seen to promote, the ensuing policy was made '…spatially inclusive by identifying "areas of influence" which are inclusive of the rural areas located beyond the metropolitan region but are to varying degrees functionally connected…' (Harrison, Grove forthcoming, 7/8) According to this study territorial and relational viewpoints are not mutually exclusive and state and territorial politics still matter in that new regional spaces are mediated through existing institutions.

Harrison and Growe also discuss cross-border region as examples of 'unusual solutions' (see also Deas, Lord 2006) to problems created by formal territorial structures. Indeed, cross-border and transnational planning puts such issues into

focus. Amongst other examples, Herschel analyses the Euroregion Neisse-Nisa-Nysa – Tri-Country Border Region sitting astride the borders between Germany, Poland and the Czech Republic. This Euroregion

> …seeks to use its multi-nationality to its advantage… Rather than representing 'edgeness' and 'end of territory', borderness is re-interpreted and projected as a strength, a sign of connectedness and international reach. The emphasis on an inherently more dynamic quality of governance, compared with more institutionalised, bureaucratic notions of government, suggests a concern with maximising indigenous capacity to overcome geo-political and geo-economic disadvantages … This involves developing a clear regional profile as a 'border bridging region' that recognises the importance of forming a sense of regional image and identity … (Herschel 2010, 163)

These were case studies of soft planning of the type of which Faludi (2010, 172ff) says that it is pointing the way for European spatial planning. They exhibit inventiveness as regards conceptualising new territories criss-crossing existing jurisdictions leading to an 'unusual regionalism,' the concept coined by authors who also applaud the '…admonitions to develop imaginative configurations that straddle national and regional boundaries in line with spatial planning imperatives' by the Commission. (Deas, Lord 2006, 1850) In this way, they contribute to deconstructing established spaces by which, as indicated, Lariaux means '…interrogating myths of self and others, and … the discovery of new possibilities that are more powerfully mobilizing and legimitizing.'

As far as European spatial planning as such is concerned, its practice so far has been couched in terms of Member States *versus* the EU, as if there were only two spatially bounded scales. This has been the basis for the positioning game around the ESDP and territorial cohesion. At the same time, there is much 'soft' planning at the cross-border and transnational scales going on. Always keen on transcending borders, the Commission promotes this. Spatial visions for each of the INTERREG transnational cooperation areas, cross-cutting national boundaries as they are, have been only a partial success. Macro-regional strategies are of a different alloy in that, on request of the Member States concerned, the European Council has asked the Commission to get involved. Complying, the Commission brokers agreement on concrete actions. As Stead (2011, 163) points out, they represent examples of the 'spatial rescaling' which Allmendinger and Haughton and others see as responsible for the emergence of soft spaces. Faludi (2010b,c) sees macro-regional strategies as portending a future form of soft spatial planning.

The soft approach and the refusal of contemplating new funding mechanisms for macro regions have not always been understood. The question is whether, without the prospect of funding soft planning has a future. In this respect it is significant that Commission proposals for after 2013 foresee, not only a larger share of available funding going to INTERREG, but also macro-regional strategies playing an, albeit unspecified role in fund allocation. That is, of course, how it should be: the spending

of taxpayers' money being influenced by – amongst others, because there are always multiple concerns – exploratory strategies that 'shape the minds.' (Faludi 2006).

Conclusions

The paper has criticised territorialism and territoriality. However, none of the authors anticipate wholesale replacement of existing systems. Deconstructing them does not mean destroying, but opening up future avenues. As regards the three issues identified at the beginning of this paper, the conclusions are:

(1) Concerning relations, in terms of spatial planning, of the EU and its Member States one must surpass 'Russian-Doll' thinking and the territorialism underlying, accepting that territoriality is not a monopoly of the state but must be shared;
(2) Territory is not a fixed entity enveloping all aspects of social and political life but the object of negotiation and compromise, and thus open to multiple and contested interpretations;
(3) Spatial planning is about inserting imaginative visions into the on-going reconstruction of the fabric of life, including the plurality of territories which this implies.

This means deconstructing frontiers. This can hardly count as novel, given the quest for a borderless Europe which implies, as Deas and Lord have been reported calling it, new configurations straddling borders. Loriaux has been quoted in the introduction as holding out the prospect of such border deconstruction bringing to light '…a civilizational space that is … intensely urban, cosmopolitan, multilingual, and less hierarchical than in the past.' This seems as appealing a perspective for European spatial planning in the twenty-first century as one can get.

Balancing commercial and heritage scapes: Atmosphere, vitality and sterility in the urban conservation spaces of Shanghai

Dr Andrew Law

a.m.law@newcastle.ac.uk

1 Introduction: fear for a loss of place and urban heritage in China; to re-develop or not to redevelop

A cursory glance over the current literature on Chinese urban development and place reveals very critical positions (Mars, 2004; Abrahamson, 2011). Reflecting on the urbanscapes of Shanghai, Mars (2004) has argued that Chinese cities are cities without history; as Mars suggests Chinese cities are ever increasingly adopting:

> shapeless low-rise expansions… punctuated by a myriad of up-market housing projects — densely organised neighbourhoods of repetitive blocks fringed with small trees and parking lots. They are a cross between Celebration (a suburban enclave

developed by the Disney Corporation for the faint at heart, where unhappiness has been officially banned) and The Projects (a concept for inner-city vertical slums for non-Caucasian Americans where happiness is hard to find). They offer the suburban comforts of cheap and tranquil living in Hong Kong-style tower block neighbourhoods. And they all look the same. (Mars, 2004)

However, a more careful examination of this process by He and Wu (2007) shows that a major driving force in the shifting urban landscapes of China has been the growth of 'property-led redevelopment'; specifically as He and Wu attest

attracting a huge amount of domestic and international capital, real estate development effectively solves the problem of financial deficiency in urban redevelopment, which has troubled the local government for a long period. With the capability of instantly promoting economic growth and effectively changing economic image, real estate development has thus acquired an irreplaceable place in the urban economy and provides the major driving force for urban redevelopment (He and Wu, 2007: 194).

But with the rise of this new property-led development, He and Wu also caution that whilst generating economic growth:

urban renewal programmes have devastated the diversity and vibrancy of neighbourhoods… In a period of booming urban redevelopment, tremendous demolition and relocation have been occurring in Chinese cities. It is estimated that from 1990 to 1998, Beijing demolished 4.2 million square metres of housing in the old city… (He and Wu, 2007: 194).

A consequence of this development as He and Wu point out is that countless forms of urban heritage, including the physical and social and cultural heritages of the people living in these traditional houses have been destroyed; Reflecting on these issues, then writers such as Friedmann have lamented the loss of traditional urban street spaces such as the Hutong's in Beijing. In a recent article discussing the loss of place, (2010) Friedmann comments that:

by the turn of the millennium, Beijing's centuries-old hutong were vastly over-crowded, and that the physical infrastructure of the housing was, to put it mildly bad in need of updating and repair. Still hutong alleyways had been part of Beijing's cityscape for over 500 years, and their inhabitants had created a distinctive environment and way of life. I don't want to dwell on this process of erasure or place breaking, but if place is something to be valued… and if there is anything to the notion that cherishing a neighbourhood in which one has spent a significant part of one's life is a significant concept, if sense of place and identity are at issue, then the

demolition of places large and small proposes immense human costs (Friedmann, 157-158).

Clearly then, in the contemporary literature, two main themes capture a great deal of academic studies; these are the themes of property led redevelopment and a senseless loss of place , resulting in the loss of traditional streetscapes and community based forms of social, cultural and economic heritage. Although there have indeed been detractors from this position;

Specifically in recent work on the Lilong's in Shanghai, the Thai writer Non Arkaraprasertkul (2009; 2010) has vehemently argued that the views of these writers in the fields of geography and sociology have often been overly-nostalgic and preservationist in focus; as a result, Arkaraprasertkul has argued that these thinkers have often ignored the actual needs of poorer Chinese people living in these houses; in sum, Arkaraprasertkul's comments could lead us to the suggestion that often a lot of conservationist sentiment applied to China's older quarters are reflective of a kind of conservationist nostalgia from afar, a nostalgia that can also be equated with a Western tourist gaze that is urgently

seeking to preserve spaces of what s/he might term an ‘authentic’ China (my words rather than Arkaraprasertkul’s position);

Rather than viewing Chinese urban space as a tabula Rasa, Arkaraprasertkul’s position is more nuanced and whilst he certainly advocates demolition, Arkaraprasertkul proposes the construction of new Lilong like, low-medium rise high density houses to preserve the physical and social character of these unique Chinese urban spaces.

Thus, Arkaraprasertkul suggests that

> the traditional Lilong house is no longer the most appropriate urban housing for Shanghai…However, it is suggested that a viable solution is low medium-rise high-density, multi-functional, community-orientated urban housing that will preserve the unique nature of individual vibrant neighbourhoods (Arkaraprasertkul, 2009: 12).

2 A *critical conservationist* position

Whilst the arguments of the authors so far are relatively fair, they ignore several major points; firstly, whilst much demolition is certainly taking place, in recent years, many local urban municipal officials in China are also recognising the role of traditional urban quarters in marketing Chinese cities as unique tourist sites; thus, whilst it is

certainly true that demolition is growing at an unprecedented scale, a great deal of commercial led conservation is also taking place that presents a great number of opportunities for social, cultural and economic groups alike; secondly, whilst demolition and the construction of new high quality housing may indeed serve the functional needs of a new generation of Chinese people, the strong demolition argument still ignores the more intangible and tacit bonds that have been created between local people and their housing for years; whilst Arkaraprasertkul's argument certainly makes a lot of sense in an anti-sentimental way, it still seems to ignore the way that people often memories around stone and specific places (no matter how dilapidated these places are); whilst it would certainly be unfair and even oppressive to suggest that Chinese people should be expected to live in antiquated historic houses, that have no facilities, this does not mean that these houses need to be demolished in their droves; whilst Arkaraprasertkul's anti-sentimental argument certainly encourages us to be reflexive, it can be strongly argued that this position is still nevertheless, pretty extreme; moreover, as writers such as Pendlebury (2009) have suggested, often proponents of demolition have often been less cognizant of the different social, cultural and even economic uses of urban heritage over the years;

thus, whilst residents might not want to live in these traditional homes, the potential value for these spaces in terms of their local, cultural and economic viability may yield strong dividends (see Pendlebury, 2009: 113); thus, as research demonstrates in recent years, traditional urban neighbourhoods and older quarters in China is now becoming home to newer kinds of creative business and/or art spaces; whilst this new kind of redevelopment has also brought with it lots of gentrification and tourism, these spaces have also been the site of new and interesting spaces of place-making where artists and/or cafe and restaurant owners have sought to create an alternative 'vibe' to the usual monolithic spaces of the contemporary Chinese city.

Whilst it would be dangerous to suggest that these spaces should mean the eviction of the original residents that live there, nevertheless, it is certainly important to note that (like the west) these new 'alternative' spaces in the Chinese city have certainly brought something of an anti-dote to what appears to be the continual demolition, redevelopment and blandization of urban space; In what follows, then, it is the argument of this author, that whilst traditional residents should have the final say about their 'heritage-space', it is suggested here, that rather than straightforward demolition of these classical spaces, compromises

maybe arrived at between developers, residents and conservationists that could potentially lead to a mixture of new build, (and sometimes demolition), conservation and commerciality that could lead to the production of new kinds of interesting and creative urban space.

In the writing that follows, then, this paper will explore the conservation of some new spaces in the Chinese cities of Beijing and Shanghai; specifically and exploring these cases, it will be argued that whilst there are many pitfalls in the conservation of traditional Chinese urban spaces, nevertheless, conducted in a particular way it is argued here that developers, conservationists and residents may benefit by a combination of mixed-use approaches to traditional urban spaces that satisfies a variety of needs; however, in making these claims it will also be argued here that successful urban conservation is never straight forward and the potential for space to become inscribed and constructed through the lens of more powerful agents is a continual threat.

In this regard, whilst this paper argues for a pro-conservationist perspective, it is also suggested here, that a *critical conservation* approach to China's built landscape's must also include a great deal of reflexivity and mindfulness with regard to the various agents and stakeholders that are seeking to conserve the space; thus, as Jordan

(2006) has written about the conservation of ‘resistance spaces’ in Berlin, even in subaltern spaces, louder and powerful voices can reside; in the following sections, I shall now examine a few examples of urban conservation throughout urban China; I shall draw attention to what I believe are various kinds of interesting and perhaps less interesting attempts at conservation.

However, before we continue, I want to discuss how we might determine interesting from uninteresting urban conservation, because these narratives are purely subjective; to unpack these ideas, I want to firstly explore ideas of sterility and vitality since, these terms often haunt ideas of conservation practice; then, turning to case studies in Shanghai, I want to draw your attention to the different ways in which conservation has been conducted in the city. To explore, Shanghai, I want to suggest that particular static and sterile practices of conservation have been indeed developed in the city; however, by exploring some alternative sites, I want to argue that vital spaces of conservation also exist in the city that may offer simple alternatives to what I shall call the sterile/demolition alternatives.

3 Definitions of urban sterility and vitality.

Ideas of urban vitality and sterility can be related back to the now well critiqued work of Charles Landry; in his article "Urban Vitality: A New Source Of Urban Competitiveness" (2000), Landry argues that vitality is based on the

raw power and energy of a city which needs focusing and directing towards a purpose for it to reach viability. Creativity is the catalyst for vitality, which the creative process focuses. It becomes sustainable and viable through innovations which are of long term benefit to the city. Vitality involves levels of activity - things going on; levels of use - participation; levels of interaction, communication, transaction and exchange; levels of representation - how activity, use and interaction is projected outwards and discussed in the outside world. Viability is concerned with long term self-sufficiency, sustainability, adaptability and self-regeneration. It is necessary to promote vitality in order to achieve viability. Vitality describes the mass of activities, which in and of themselves are not necessarily good or bad. Activity, use and interaction need to be focused towards a set of purposes, goals and objectives for them to have any substantial, positive impact (Landry, 2000).

Of course Landry's focus can be related to a whole-series of creative city style approaches that have been associated with a form of 'hipster embourgeoisment' and conservative ideas of self-reliance (see Peck, 2005); but despite the problems with Landry's work and ideas, the

concept of urban vitality, involving high levels of interactivity, interaction and communication is certainly an interesting concept; one way of reworking the notion of urban vitality might take place through the concepts of Deleuze and Guattari who construct ideas of vitality through notions of immanence; here for Deleuze and Guattari, loosely speaking, immanence refers to the vital potential (in a non-essentialist way) of multiplicities or acausal heterogeneous assemblages of relations (bodies without organs) to produce new events, things, lives and subjects.

> This streaming, spiralling, zigzagging, snaking, feverish line of variation liberates a power of life that human beings had rectified and organisms had confined, and which matter now expresses as the trait, flow or impulse traversing it. If everything is alive, it is not because everything is organic or organized, but, on the contrary, because the organism is a diversion of life. In short the life in question is inorganic, germinal, and intensive, a powerful life without organs, a body that is all the more alive for having no organs (Deleuze and Guattari, 1980: 499).

Here then, Deleuze-Guattarian ethics often champion deterritorialisation's or spaces of pure immanence and becoming where acausal interactions take place, and as result of these processes new

meanings are acquired and traditional definitions and ideas are reconceptualised; in short Deleuze-Guattarian ethics encourages us to take seriously spaces of chance, randomness, hybridity and *potential* where difference is ubiquitous and where everything and anything is possible.

Taking these ideas and placing them in the urban realm, we can think of vitality in terms of the potential that urban spaces have to produce interactions, becomings, social relations, interactions, divergences and differences. Thus, rather than the 'harnessing of creative energy' for the sake of economic production (in Landry's terms), my suggestion here, is that space is creative and vital when we open up the potential for space to be utilised, interpreted and valued by as many different people as possible; in this way, quite simply, vital space is inclusive space; inclusive space, is that which can draw different types of people together, and can produce interactions and creative outcomes that could not have been realised prior to the meeting place of subjects, relations or events.

Taking ideas of vitality seriously then, we must also consider that space can also produce sterility. Thus if vital space increases flows, interactions and unpredictable becomings, sterile space refers to sites

where life has slowed down, to moments of ‘rootedness and/or bonding, which halts flows and/or social processes’ (Law, 2010: 129); and as I will suggest sterile space, can be produced by a number of features that can reduce inclusivity; this might include the excessive commercialisation of a space; or sterility might come about as a result of the dominance of one group and/or one set of meanings in that space. In short, my claim here is that, spaces are sterile if the potential for different readings, or interactions with a space are limited or traduced.

However, whilst the following writing champions these Deleuze-Guattarian ideas of space, it is also suggested here that these concepts be read as a tool rather than an explain all theory; indeed, whilst this author believes in the possibility of creating inclusive spaces by way of hybridities and heterogeneous becomings, it is recognised here, that subjects’ definitions of inclusive spaces will always already be never complete or singular; in this way rather than seeing inclusive space as an end process, it is the argument of this author, that spaces must be read as ongoing processes which will at times suit some people rather than others; however, as I am suggesting whilst it is impossible for urban planners or designers to please everyone, nevertheless, our task, when constructing space is include as many encounters as possible, be these

physical, social, cultural or economic encounters, since these will always already open up the potential of an urban site.

Encountering conservation space:

In the case of conservation spaces, the potential of these spaces is critical to the creation of more open or inclusive spaces; whilst conservation spaces may seem fixed and/or closed (that is because in essence these spaces are dominated by the preservation or conservation of a series of buildings and/or intangible heritages), the conservation of certain physical forms or relations, does not mean that these spaces have to be fixed in time. Indeed, as I shall suggest in the writing below, whilst the physical fabric of a conservation site may stay the same, new readings, interpretations, uses and even physical re-readings of a space maybe incorporated and or blended with a traditional conservation site/space to maximise the widest number of outcomes and encounters possible.

To explore these issues now, I want to explore the recent history of conservation in Shanghai; as the reader will note, I will firstly explore the more sterile aspects of Shanghai's conservation spaces, before I turn

in more detail to new and contemporary experiments that have been developed to open up traditional heritage spaces in the city.

4 background to the history of conservation in Shanghai:

As He and Wu have pointed out 'from 1995 to 2004, more than 745 thousand households were relocated, and over 33 million square metres of housing were demolished in Shanghai' (He and Wu, 2007: 194). Of these demolitions, as a variety of writers have pointed out, many older buildings, traditional quarters and indeed traditional historic concessions have been destroyed. But with the dawn of the new century increasingly old historical buildings began to be 'rediscovered for their economic value' (Ren, 2008: 24). Thus in 2002, the former mayor of Shanghai Xia Liquing, argued that historic buildings should be viewed as an additional to the progressive development of the city; as Xia Liquing believed the historic quality of Shanghai's urban heritage was critical to its future:

Shanghai is a famous city whose rich historical and cultural content is accredited by the state. The process of constructing a modern international metropolis must take into consideration all the processes of new developing

districts and the conservation and the renewal of old districts within an integrated historical context. . . . [T]he 21st Century is full of promise. In the new century, we will build Shanghai into the largest economic shipping centre in China, placing it in the first rank of historical cultural cities. (Liquing 2002: 148)

Moreover, in 2004, the new mayor of Shanghai Han Zheng developed a slogan that seemed to bring the city's historic past into a modern context: "Building new is development, preserving old is also development" (Ren, 2008: 31);

Thus, as Olds (1997), Weiping Wu (2004), Pan, (2001; 2005), Ren (2008) and Jansson and Lagerkvist, (2009) and others have argued the rise of conservation in Shanghai and particularly the conservation of Lilongs, Shikumen houses and several traditional 1920s and 1930s buildings has emerged within a wider place-making strategy to market the city and produce nostalgia. As Pan (2005) has stated:

> Colonial Shanghai rekindled collective memory and in the process of remembering, itself was re-invented. With its success in the colonial past in setting trends, finding opportunities, and witnessing miracles, Shanghai

> provided a somewhat 'infectiously decadent, but alluring background and setting' (Dai, 1997: 158) especially for those working in the film industry…
>
> … the stereotypes reflected in 'Shanghai nostalgia' were the images of colonial Shanghai as 'Paris of the Orient', 'Whore of Asia' and the 'Paradise of Adventurers'. Yet… it was the native producers who orientalised the oriental to serve their strategic needs (Tinashu Pan, 2004: 13-14).

Here then the importance of this colonial nostalgia, as Jansson and Lagerkvist claim, is that it conjures up imaginaries of cosmopolitanism, tolerance, and financial success (Wu, 2004: 167); moreover, as these writers attest, a valorisation of 1920s and 1930s has allowed developers to 'world' the city and produce it as a 'leading commercial hub' (Jansson and Lagerkvist, 2009: 43).

Particularly, Jansson and Lagerkvist argue that:

> In order to turn this increasingly global city into a leading commercial hub of East Asia, planners and politicians, commercial interests and entrepreneurs have jointly encapsulated the city by employing a Shanghai nostalgia for the Golden Age of the 1920s and 30s (Pan 2005) and by calling for a retroactive future gaze, reminiscent of the inter-war era, planners and policy makers create a hyper-real sense of futurity, inclusive of futures past and futures never fulfilled (Jansson and Lagerkvist, 2009: 43).

Thus, as Ren has eloquently stated, rather than 'hindering urban growth' the new local governmental strategy of historic conservation 'serves the same development goal in globalizing Shanghai. Historical elements in the built environment are selectively recycled to produce a new transnational space' (Ren, 2008: 23).

5 The selection of conservation space?

Arguably, then, the conservation of Shanghai's historic colonial built heritage has, in many ways, meant that other ideas of heritage, buildings and identities have been side-lined. Firstly, in line with the marketisation of the as 1930s heritage colonial heritage, Weiping Wu (2004) has suggested that a great deal of historical conservation in the city has been concerned with the Bund which lies at the centre of the city near the Huangpu river; the bund which of course, was the central trading point during the colonial period (and unofficial heart of the city) houses approximately 250 classical and grand buildings. Moreover, as Wu states the wider waterfront near the bund has also been labelled a

historical protection zone by the government and the main street between the buildings and the water has been widened so tourists can walk there.

Here whilst the conservation of these buildings is certainly important, Wu states that

> the Bund's preservation really has less to do with restoring the buildings than it has to do with widening the street and becoming a new tourist attraction. It is motivated more by the vision of a new Shanghai to rival the old than simply nostalgia for the past glory. Through this promotion of the heritage industry, the government also asserts itself forcefully in the city's future development (Wu, 2004: 171).

Interestingly also as Wu states government departments have also been located here to encourage connections between the contemporary administration and a long history of grandeur, cosmopolitanism and wealth.

Conservation and the Lilong's

But where the bund and the concessions have survived, poorer historic urban spaces (and more dilapidated areas) in the city have faced demolition. Specifically as writers have pointed out, one space in particular that has been subject to a great deal of demolition are the

Lilongs. Lilong, as Arkaraprasertkul (2010d) has claimed literally means "neighbourhood lanes", where *Li* (in pinyin) literally refers to neighbourhoods and *longs* refer to Lanes. The Lilong's as Arkaraprasertkul and others point out refers then to a material physical fabric of lanes and courtyards (and courtyard housing) that were built in the 1840s; after Shanghai became a treaty port (after the Opium Wars), 'British developers built Lilong houses to provide basic accommodation for Chinese labourers. A typical *Lilong* neighbourhood is a walled area community composed of a main lane running all or half-way across each housing block connected by perpendicular branch lanes' (Arkaraprasertkul, 2010d; page 1).

Image 1

Moreover, as Arkaraprasertkul, has pointed out, 'the Lilong was modelled after Western row houses with the Chinese characteristic lanes and courtyards… …houses are clustered to resemble the basic traditional Chinese houses, allowing many families to live together in the same compound' (Arkaraprasertkul, 2009: 17).

Another feature of the Lilong's is the houses or Shikumen (means stone gate); importantly, like western town houses or western terrace houses in the UK, the Shikumen have two to three stories and distinctively they often come with prominent stone gateways.

Image 2

The Shikumen that are attached to each other like terraces are made up of high brick walls that enclose narrow front yards, that are hidden from view. As French has argued at the height of their popularity there were approximately 9, 000 Shikumen in Shanghai housing 60% of the population; however, with continued demolition and the popular growth of the high rise, the proportion of inhabitants in the Shikumen are much lower (French, 2010: 246).

However, whilst the Lilongs can be defined in terms of their physical heritage, writers have also pointed out, that the Lilong's have a long intangible social and cultural heritage. As Arkaraprasertkul has written then,

Because each unit does not have much living space, and the Lilong rows are laid out parallel to each other in a close proximity, lanes are used by Lilong inhabitants as a living space, which is common to the Chinese who see outdoor activities as prominent to communal life. These activities that take place in the lanes range from exercises – particularly Tai-Chi – to commercial activities, hawker businesses, barbers; to recreational activities as well as service, mah-jong, cooking, laundry drying, outdoor eating, sewing food preparation (Arkaraprasertkul, 2009: 20-21).

Having visited the Lilong's in Shanghai myself, I have also witnessed first-hand this impressive urban culture which sits semi-hidden within a vast labyrinthine network of narrow streets, little alcoves and hidden courtyards.

Despite the fact the Lilong's have remained for centuries, in the last few years, as the land they reside on has gone up in value, as a result of speculative building (because they are in the city centre), these buildings have often been demolished; furthermore, as writers have pointed out, often traditional residents have been bought out by the Shanghai municipal council in return for new modern (westernised) apartments with decent sanitary facilities and kitchens (features that are often lacking in the original buildings. However, rather than keeping the

Lilong's for posterity often these buildings are destroyed to make way for commercial developments of huge residential high rise towers.

6 Renovating the Lilong's and Shikumen: The Xintiandi and the Tianzifang areas

Despite the general demolition of the Lilong's conservation has taken place in some places; As Wang and Lau, (2009) have argued, the Lilong's with their colonial association and their complex labyrinthine structure has fascinated tourist's officials and developers alike. Specifically and pointing to one development in particular the Xintiandi (a series of renovated Shikumen houses that has become a retail-shopping district,) Wang and Lau, (2009) have contended that

> Through so called adaptive reuse, US architects [Greg Yager and Scott Kilbourn] demolished old structures and reconstructed them to provide a 1930s appeal. Meanwhile after changes were instituted to the interior space, these lane-houses were converted to wine and dine and retail and entertainment complexes. The project fuelled a wave of nostalgia for the city's splendid past, as it has been previously called the 'Paris of the Orient'. Historical buildings were appreciated as being cool and fashionable, invoking a sudden vigour to every aspect of city life (Wang and Lau, 2009: 59).

The Xintiandi redevelopment, designed by Benjamin T. Wood and Nikken Sekkei International has generally been regarded as a success by many and recently, in an article in the New York Times, the redevelopment has been viewed as a

> "entertainment environment" stuffed with modern restaurants, clubs, cafes and boutiques, accessorized with old bricks, stone gates and ornately carved wooden balconies from the dense warren of old courtyard houses that previously filled those blocks. Xintiandi proved so successful a model for urban redevelopment that it spawned at least dozens of duplicates across the country. Developers now use the term "to Xintiandi" when asking their architects for more aspirational China-lite designs (Iovine, 2006)

However, whilst the Xintiandi might now be viewed as a vital space, (and a space that has been ultimately saved from demolition/land speculation) various comments have suggested that the over commercialisation of the space has brought with it a new kind of cultural sterility. Discussing the Xintiandi project then, Ren has claimed that this new kind of development has turned a historic part of Shanghai into a posh entertainment quarter for '"wealthy Chinese" locals and people

from other provinces, and foreign ex-patriots' (Ren, 2008: 31). Interestingly Ren points out, that the people who use the space and who now live near these spaces are not young affluent professionals looking to live near 'employment opportunities' in the city centre. Rather the people who move in are usually older people with money who are looking to buy older houses as 'assets' with the expectation that these buildings will eventually appreciate and produce a financial return.

All in all as Ren points out, with changing tastes

> historical preservation is driven by expectations for potential economic return through raising property prices as well as attracting investment and tourists. Old historical buildings in Shanghai, once regarded as worthless in the frenzied development boom of the 1990s, have been rediscovered for their economic value (Ren, 2008: 31).

But most importantly here as Ren suggests, what is being conserved here are only 'the shells of old buildings', and social preservation 'a practice of not only preserving historical buildings but also consciously preserving the lifestyles of residents' is not being adopted (Ren, 2008: 31). Ultimately as Ren contends here, the original residents of these spaces (residents who are usually retired or over 60; or

poor) are being increasingly displaced from these new ‘heritage zones’ (op cit, 31).

Admittedly and paying attention to Arkaraprasertkul’s critique of conservationist sentiment, many of the original residents might relish the chance of living in new and comfortable modern apartments; however, as Hammond (2006) has shown whilst many of the residents may well desire the comforts of new apartments, many people long for the personal social relationships and indeed the architectural fabric of the Lilong’s. In his recent study then, Hammond illustrates his thesis through *The Sense of Community Index* (SCI) and open-ended interviews;

> Results show that sense of community was clearly higher in the Lilong than current apartments. Results indicated 57% of all SCI questions regarding Lilong were answered in a favourable manner towards community compared with 44% regarding their current apartments. The open-ended interviews strongly support the findings of the SCI. Sense of community has diminished during the massive migration of millions of Shanghainese out of Lilong (Hammond, 2006: 55-56).

Thus, whilst Hammond acknowledges that many of the new residents love the new living standards of the apartments they have

moved to (especially in terms of sanitation), residents still long for the deep social interaction that was fostered in these traditional spaces. But most importantly – and less well explored by Hammond – Hammond's results also show that whilst some ex-residents are very much pro-demolition many of these ex-residents also wanted to see some of the Lilong's conserved for educational purposes.

After suggesting that s/he would like to see 99% of the Lilong's demolished, one of Hammond's respondents commented then:

Hammond: And if you leave them should people live in the 1% that they leave or should they just be like a museum?

Respondent: - Yeah. Maybe just like a museum. I think Shanghai should still have several Lilong like on Shimen Road. Just like a museum to teach others. The only people who choose to stay in Lilong do it because it is convenient to downtown. It's like my old Lilong, you could just walk to Huaihai Road or Nanjing Road (ex-resident of the Lilong's in Hammond, 2006: 78).

Here whilst the respondent was very much pro-demolition of the old, noticeably there is a strong conservation sentiment in this respondent's comment which reveals a sense of nostalgia and a pedagogical responsibility to new generations of Chinese people.

7 Distinctive places: Luwan and The Duolon Road

Whilst the bund and the Lilong's are two of the most prominent spaces that have achieved conservation status in the recent development drive, it is also noteworthy that a few distinctive or exceptional spaces (as identified by the municipal government) have also been ear-marked for conservation; specifically as commentators have observed mainly, the spaces of conservation are either buildings and/or concession streets that can be found outside of the central city. Some of these concessions are now home to a series of luxurious shopping spaces and entertainment zones, like the Xintiandi. As Pan (2004) has pointed the upper quarter in Shanghai particular has been hit by mass gentrification particularly in the Luwan. Luwan which was originally part of the French Concession, is well known as one of the most prestigious sections of the city and as Pan notes, the 'historical building of the Colonial French police station has been renovated and become home to cafes, restaurants and stores selling brand name merchandise' (Pan, 2004: 119).

In the north also another major district that has been subject to this new kind of commercial conservation has been the Duolon Road (originally called Darroch (窦乐安). The Duolon Road built in 1911

exists in the Hongkou District of Shanghai and was built by the Municipal Committee of Shanghai (a committee of Western businessmen); interestingly the road was built outside the international settlement (the British, French and American colonies); interestingly in the 20s and 30s this road became associated with a series of cultural elites and various famous Chinese writers who lived on the road producing new writings and ideas. Writers included such as Lu Xun (lǔ xùn 鲁迅), Mao Dun (máo dùn 茅盾), Guo Moruo (guō mò ruò 郭沫若) and Ye Shentao (yè shèng táo 叶圣陶) to name a few.

Again like Xintiandi, the development approach to the Duolon Road taken by the government has been one of commercial conservation approach where historic space has been constructed as a site for tourists and shoppers alike. And as can be gathered from the various reviews of this space, the Duolon Road has become a very attractive site for tourists and shoppers to the extent that the Shanghai News and Press Bureau of the City has praised the Road as a 'cultural street' that has witnessed a 'hundred years' of Shanghai's history (Cultural-China.

But again, like the Xintiandi, the Duolon Road has also been met by similar criticisms. Thus in the last few years writers and commentators such as Pan Lu (2008)[i] have argued in very political and

economic terms that the Duolon Road has become an unsuccessful historical simulacrum:

> Yet there is a rupture between historical value, market value, and the everyday dynamics of the surrounding neighbourhood. Being too much concerned with exhibiting every inch of cultural relics possible, Duolon Road loses in some way its charm by musealizing itself instead of enlivening its history as a part of its ongoing life… A perceptible economic depression has not left Duolon Road since its reopening. Somehow, by failing to retrieve its former cultural capital, Duolon Road has been reduced to an unsuccessful simulacrum of an old Shanghai that is simply no longer to be found (Pan, 2008: 3)

What is important here as Pan points out is that spaces like the road have been musealized; that is quite simply by attempting to over-emphasize the historical fabric and signifiers in the space, the space ends up producing a sense of 'depression' or sterility that feels lifeless and unenlivening.

In opposition to these spaces, Pan Lu argues that the Shaoxing Road located near to the French Concession is much more interesting. Essentially Pan Lu suggests that one of the most endearing qualities of

the Shaoxing road is that the shops in the road belong mainly to migrants and international arrivals, who have re-interpreted many of the old spaces constructing them in their own style. As Pan Lu contends what is exciting about these spaces – *and what is economically popular about these spaces* – is that the 'local imaginary of the old local milieu [has been given] new life' (Pan, 2008: 5).

But if she is praiseworthy of these developments, then, later in this paper, Pan Lu argues that Bund 18 formerly known as the Macquarie Bank (built in 1923) is possibly one of the most successful architectural developments in the city. Particularly Pan Lu admires the way that in its renovation the bank acquired a 'new life of its own': Thus, Pan Lu states that

> A UNESCO award was given to Bund 18 for its successful renovation in 2005, for its well-balanced combination of historical value and present-day functionality. 'Renovation' as proposed here by Italian architects richly experienced in renovating Venice, is supposedly not to remake the past but rather to provide it with a new life of its own. In this most nostalgic example of architecture we find yet another expression of nostalgia: not as a form of yearning for the return of (or to) the past, but rather as a tool for making history (again). (Pan Lu, 2008: 10).

Here Pan Lu's comments are important in that they suggest a new way of using architectural heritage in the city; as Pan Lu suggests here, an approach that allows historic buildings to be reused in modern or president day functional ways brings new life to the space; thus, rather than spaces steeped in a shallow commercial nostalgia, Pan Lu offers an alternative to the new contemporary *commercial heritage-conservation* drive.

8 the rise of heritage simulacra

Finally and perhaps most importantly in completing my survey of architectural heritage in conservation in Shanghai, I now want to finally discuss the rise of some new simulacra spaces in Shanghai. On one night in the city in September 2010, I was lucky enough to come across an underground Mall in the people's square (in the centre of Shanghai); as I ascended the steps into the Mall I was astounded to find that the Mall had been produced a replica Lilong - see image below:

Image 3

Clearly as you can see from these images, an entirely faux series of Lilong's with faux back lanes have been built by city constructors; and moreover, as I wondered through these faux-lanes I was surrounded by nostalgic images and displays for 1930s Shanghai. As Arkaraprasertkul might argue, these replica lanes could represent a neat compromise between a contemporary conservationists and nostalgia seekers that are seeking to preserve some essence of the Lilong past, and a contemporary Chinese urban population that is looking to live in well-conditioned modern contemporary apartments. But as I walked around this space and the painful attempts to preserve some sense of a nostalgic image of 1930s Shanghai I was hit by waves of sadness; possibly, the kind of sadness that is perhaps displayed in the writing of Philip K Dick when his science-fictional characters come across simulacra's of the past, or even animals – see for instance 'Do Androids Dream of Electric Sheep' (1968). What was evident to me, was that the lanes' have been 'preserved' like this in a faux simulacra space because there is in fact a very strong nostalgia for these lanes (even if many people do not want to live in them). And on walking through the lanes, I was struck by the feeling that developers had almost produced this mall

in a desperate attempt to conserve some image of this Lilong heritage before it is all completely demolished or lost by developers. This simulacrum Lilong Mall represented to me, an implicit understanding that people were already resigned to the fact that the Lilong's will be demolished.

And it is because of this attempt to produce a poor and disneyfied imaginary of the Lilong's in this highly sterile commercial space that makes me believe ultimately that within Shanghai there is still some strong underlying cultural attachment to these spaces; thus for instance in the opening lines of Wang Anyi's The Song of Everlasting Sorrow, we are hit with the following lines:

> Looked down upon from the highest point in the city Shanghai's *longtang* – her vast neighborhoods inside enclosed alleys – are a magnificent sight. The longtang are the backdrop of this city. Streets and buildings emerge around them in a series of dots and lines, like the subtle brushstrokes that bring life to the empty expanses of white paper in a traditional Chinese landscape painting. As day turns into night and the city lights up, these dots and lines begin to glimmer. However, underneath the glitter lies an immense blanket of darkness – these are the *longtang* of Shanghai (Wang, 1995; 2008: 3)

9 Conclusions: vital or sterile spaces? Mixed-use conservation spaces?

In conclusion then this paper has made the claim that there is a case of the conservation of China's traditional urban quarters; of course, as I have pointed out, the conservation of these spaces must not mean however, that the living standards of people are compromised; indeed as Non Arkaraprasertkul (2009; 2010) rightly points out, conservation nostalgia for the Lilong's could mean that many people are imprisoned in poor living quarters (by modern standards) that cannot be easily renovated.

In this way, this paper, to some extent argues that there perhaps is a case for some demolition and relocation if Lilong quarters reduce people's quality of life. Moreover, as Arkaraprasertkul suggests perhaps the rebuilding of new low-rise houses – in the style of the Lilong's – might meet the needs of a variety of social actors from residents, to economists to conservationists alike; and since high rise – as we have

seen – is often blamed for the destruction of traditional neighbourhood ties, then it would seem that the replacement of the Lilong's by new kinds of low-rise housing with Lilong features would be a more than excellent compromise. But this paper has suggested something else. Drawing upon the work of Hammond and others, it has also been argued that conservation of the Lilongs and Shanghai's built heritage should remain for pedagogical and even social psychological reasons; indeed, as I have suggested, in this short work, many of the conservation spaces we have discussed are very much tied up with wider collective and even personal ideas of memory and heritage; and in this regard, whilst demolition might be the answer for some, as I have contended here, for some the traditional buildings of Shanghai also serve as important markers – or anchors – of an age gone by. Particularly as we saw in the work of Hammond for some the historic buildings of Shanghai might actually serve as witnesses of the past, as spaces of educational value; and so in this way, it is the argument here, that there is still indeed a need for historic conservation in Shanghai – especially of spaces such as the Lilong's.

But whilst this paper has provided a pro-conservationist position, it has also been suggested that built conservation might also take place

on more social and functional terms; in this regard, I have argued for what I have called a *critical conservation* position that is wary of what we might describe as 'sterile conservation space'. Indeed, by reviewing many of the distinctive conservation spaces of Shanghai such as the Xintiandi, Luwan and The Duolon Road it has been claimed here that strong commercial approaches to these spaces have in fact produced a very sterile form of urban conservation; particularly and drawing upon the work of Pan Lu and my own conservation experiences of these spaces, it has been argued here that hard commercialisation may reduce the vitality of a conservation space to the point that the space may as well be demolished. Ultimately part of the problem of commercialisation, as I have said, is that developers often embolden the more nostalgic and hyper-real aspects of the heritage space, to the point that the space becomes sealed and or static in time – a process of museumification.

However, and drawing upon the writing of Pan Lu and my own experiences of the city, I have suggested that alternative approaches can and must exist if we are to develop an effective conservation practice; particularly as Pan Lu rightly says, often breathing life into a conservation space, only needs to involve the re-interpretation of a space

in terms of contemporary functionality. Moreover, by exploring the role of foreigners and migrants in these spaces, Pan Lu implies that hybrid identities bring new life to what we might define as well-worn physical narratives of stone.

In this regard, as I have contended in the theoretical apparatus of this paper, the coming together of the past, with new subjectivities in unrealised ways may offer contemporary practitioners with a new approach to what is now regarded as the built heritage of one of China's most amazing and unique cities.

Critical Reviews of EIP development strategies for problems of industrial complexes in Korea[1]

Jeongseok Choi[2]

ABSTRACT

Industrial complexes have been regarded as important tools of industrial policy in Korea. In the process of industrial development, some industrial complexes have been blamed as major causes of environment-related problems. In response to social and environmental requests, researchers and policy makers have tried to introduce a new type of industrial complexes, which can deal with environmental problems and economic efficiency at the same time.

'Eco-industrial Park(EIP)' projects have already started up by the central government in Korea. EIP approaches based on industrial ecology are dealing with firms' production systems and environmental management by forming networks of mutually beneficial symbiosis that mimic natural ecosystem.

The government has already developed 5 EIPs and is planning on developing more EIPs across the nation. Throughout the EIP developments, we came to know that there have been some issues and problems in the national EIP development projects. Throughout years of experiences and researches, several important problems in recycling of resources are known because our EIP projects are implemented only on the basis of industrial parks. Recycling networks in Korea are very restrictive and relatively less effective. Also companies have seldom been interested in government-supported EIP projects, due mainly to the related laws and regulations. It has made the participation in the projects of companies less attractive to them,

The purposes of this article are to give a general view of EIP policy and its problems and give the government better ideas of solutions needed to invigorate recycling network to work more efficiently. The purpose of this paper is to emphasize that several aspects of policies and laws governing EIP should be revised to implement the new recycling system. This trial can be much of help with shrinking EIP projects and waste exchange activities leading to cyclical society.

Ⅰ. Introduction

[1] It was supported by the ETD program of Korea's Ministry of Environment.

[2] Joongbu University, Chungnam, S.Korea – ecoparks@naver.com

Problems caused by industrial complexes haven't been significantly settled so far, even though governments and industries have made a lot of efforts. Sometimes they brought about environmental accidents leading to serious conflict between locals and factories. Still industrial complexes have been regarded something unwanted and unpleasant.

With the increased environmental consciousness and strengthened environmental regulations, new approaches to industrial complexes were really needed. These days we could see the newly developed ideas applying natural ecosystem to industrial world. They are called this Eco-industrial Parks. This idea was provided by Industrial Ecology approach in the early 1980s.

The concept of EIP has been thought to be very ambiguous because of lack of generalized or standardized EIP models. Sometimes EIPs are mistaken with other types of industrial complexes like techno-parks, science-parks. EIPs have their own distinct hallmarks as compared with other types of industrial complexes.

Table 1. Comparisons between EIPs and industrial complexes

-	**Traditional ICs**	**EIPs**
Goals	Industrial Growth	Sustainable Industry
Characteristics of industries	Smokestack industry	Environmentally friendly industry
Strength of networks	Weak	Strong
Environmental regulations	End-of-pipe regulation, Direct regulation	Precautionary prevention, Indirect regulation
Viewpoints of waste	Object of disposal	Inefficiency, Potential resources, Underused resources
Relations with technology	Weak	Strong
Relations with locals	Weak	Very strong
Citizen participation	Very limited	Active
Land use	Strict land use	Mixed land use, Compact land use
Types of Regulations	Command and control	Consequentialism
Inter-companies relationship	Vertical relationship	Vertical-horizontal relationship
Types of industrial policy	black-spot policy	eco-industrial policy
Structure of industry	Artery industry-centered	Vein industry-supplemented

EIPs offer significant economic, environmental and social benefits, both to individual companies, as well as to a collection of companies. Drawing on historical and contemporary examples, proponents of EIP networks chart the following benefits: (1) Environmental benefits

linked to improved resource use efficiencies, reduced use of non-renewable resource and reduced pollutant emissions; (2) Economic benefits emerging from reductions in the resource inputs costs in production, reduction in waste management costs and from the generation of additional income due to higher values of by-product and waste streams; (3) Social benefits by generating new employment and raising the quality of existing jobs and by creating a cleaner, safer, natural and working environment(Lowe E.A, Warren J.L., Moran S.R, 1997).

However, there are several major barriers that have to be overcome. Perhaps the most significant of these is that whilst the concepts have been in existence for several centuries, ″planned/designed″ EIPs have not, and so still need time to be a proven and sustainable option. As suggested, the emphasis for the EIP should, however, be on a system approach, rather than focusing on specific streams. Clearly, there are a number of issues to be taken into account, however, the significance of each of the driving and limiting factors identified will vary depending on the geographical, social, political, environmental, economic and institutional context within which the EIPs are being developed.

Ⅱ. EIP projects in Korea

The Korea government started the EIP projects in 2003 coming up with the master plan on the EIP development by KNCPC on behalf of the Ministry of Knowledge Economy. In 2005 the government accepted three EIP projects, Banwol-Siwha, Ulsan, and Yusoo project as parts of national EIP projects. Two complexes, Chunggu EIP and Pohang EIP were added to the pre-existing EIP projects the following year. These five industrial complexes have been supported financially to make up industrial symbiosis of their own industrial sites since then.

In Korea of 2011, EIP projects which are on the second phase of the national EIP strategy are on the track. The distinct feature on the second steps of EIP development is a hub-spokes strategy, which is the world first attempt in the EIP history. To make Hub-Spoke network, other three industrial complexes, Myeonggy·Noksan, Sungseo, Kusan·Kukgang complex, joined the existing five hub EIP complexes. After all hub-spoke EIP networks in Korea consist of eight major complexes and three or four small-medium sized complexes surrounding them. Korean government and experts are expecting this EIP hub-spoke network to invigorate industrial symbiosis and thus contribute the win-win situation of the environment and economy.

Table 2. EIP Hubs & Spokes (2011)

Region	No. of HUBs	No. of Spokes	Regions	No. of HUBs	No. of Spokes
Busan	1	3	Gyeongbuk	1	4
Daegu	1	3	Chungbuk	1	4
Ulsan	1	4	Chunbuk	1	4
Gyeonggy	1	4	Chunnam	1	4

Actually it is evaluated that the first phase of EIP projects in Korea achieved a lot of benefits economically and environmentally. For example, a total of 45 by-product exchange networks have gained almost 13 million dollar economic profits so far.

Table 3. An example of Economic, Environmental Outcomes (case of Ulsan Industrial Complex)

Field	**Name of projects**	**Economic effects** (million/yr)	**Environmental effects** (Ton/yr)
Energy exchange	Steam supply by Incineration plant	$6.0	Reduction of 55,500 CO_2
	Waste heat supply of incineration plant	$3.0	Reduction of 14,810 CO_2
By-products exchange	Firming agent for sludge	$2.6	-
	Organic by-products	$1.4	-

*KICOX, 2011, Model Cases of EIP projects in Korea

Though we could get lots of outcomes, still there have been a lot of problems to solve and some hurdles to overcome so that the EIP projects in Korea make a great stride in the right direction.

Ⅲ. Reviews on some industrial symbiosis studies

Industrial symbiosis-related policy researches in Korea started in the late nineties, government-supported EIP projects fueled researches on industrial symbiosis, which led to various studies regarding EIPs and industrial symbiosis.

Especially Choi Jeongseok(1998, 1999, 2002, 2004, 2010) ushered in industrial symbiosis strategy and proved the effectiveness of industrial symbiotic networking in both economic and environmental aspects. Lee Jaejoon & Lee Sangmoon(2003) proposed several EIP

development strategies that fit for Korea's industrial world. Oh Deogsong & Kim kyungbae(2002) suggested a new kind of industrial estate design modeled on EIP mechanism. Ban Youngwoon(2008, 2009) also worked out a few important EIP tactics. Park Hoongseok tried to spread the case of Ulsan EIP project to other industrial parks at home and internationally. Besides there have been a lot of researches and studies as to industrial symbiotic network projects. Most of them have been focused on EIP policies or put emphasis upon new business practices which have obviously been making contributions to the development of Industrial Complexes and industrial symbiosis.

On the other hand, KNCPC(2003), an organization that had been charge of EIP projects at the very first has brought out a series of working papers on symbiotic networks. Taking over the national EIP projects from KNCPC, KICOX has supported not a few EIP policy projects up to this time. Among them, the policy report of 2008 came up with a new idea, which paved the way for building the world′s first Hub-Spoke EIP model. On top of that, KICOX has accepted an epoch-making EIP strategy suggested by some experts and has been trying to change the current EIP projects into low carbon oriented projects.

Internationally Journal of Industrial Ecology has been taking the lead in research fields of industrial symbiosis, EIPs, waste & by-product exchange etc. In particular a research paper by Raymond P. Côté and Tsuyoshi Fujita(2009) dealing with evaluation of state-run EIPs, an article of C. Block, B. Van Praet, T.(2011) about carbon-neutral strategies of EIPs and Pierre Desrochers′s study (2001) as to symbiosis of cities and industry were viewed as significant for Korea′s industrial symbiosis approach.

Ⅳ. Problems and Strategies for improvement of EIP projects

1. An outline of survey and interview

I conducted a questionnaire survey and interviews with experts of local EIP divisions to find out problems and get some information on policy implications. The survey with questionnaires was conducted upon 80 EIP experts with a help of KICOX from March 15th to April 2nd in 2011(KICOX, 2011). The questionnaires consisted of three categories(policy awareness, hands-on issues and policy improvement) with 18 questions. I got 43 responses included threw wrong answers. I interviewed with ten experts from five local EIP divisions so that I could investigate some problems of EIP projects.

Throughout the intensive survey, five major problems and policy implications around EIP projects were obtained and several hot issues of law and regulatory aspects. The outcomes of survey and interview are as in the following.

2. Information on waste and Database for waste recycling

Because waste policies of Korea are focused on treating environmental emissions, all kinds of waste-related statistics and their DB systems are related with end-of-pipe management or pollutant treatment by rules. Besides, as environmental statistics have been collecting on an administrative district basis, it is extremely difficult for industries and EIP organizations to know real and exact state of waste they could use in recycling network(Forbes R.M, Peter R. W, Marina F, Peter Hindle, 2007).

While EIP projects have been carried out, one of the biggest problems with recycling networks between companies was lack of data and information available for symbiosis. The survey also proved that problem, showing that 72.5%(29 experts) of respondents answered insufficient data and information on wastes and by-products as the most formidable obstacle in EIP projects.

As a matter of fact, the current statistics industrial and environmental are believed to have several problems when viewed from the side of industrial ecology. Understanding and information on industrial process or raw materials of factories are prerequisite for the industrial symbiosis. But unfortunately those kinds of information and data are usually not available for other companies at all. That's because companies don't want to let other companies know about their production process and products.

Now, it is necessary to establish new statistics and DB system for industrial symbiosis. The easiest way to ameliorate to solve statistics and DB problems is amending the existing environmental statistics into more available for any companies that want join symbiotic relationships. That contains adding waste and by-product information of Industrial complexes to Environmental Statistics Year Book(ESYB) and Annual National Waste Statistics(ANWS) respectively. New statistics and DB will have to embrace 279 industrial complexes which account for all industrial complexes made by national and local government.

On the other hand, EIP workers and researches said that the annual Korea Industrial Complex Dictionary(KICD), one of important data sources on industrial complexes, does not have environmental statistics. It means that it's very difficult to analyze both the economy and the environment of industrial complexes simultaneously in terms of industrial ecology. Therefore modifying the existing industrial complex statistics including KICD is urgently needed to help Korea's EIP strategy.

3. EIP Projects restricted spatially by the regulations

Many EIP experts have been pointing out that the EIP projects in Korea had a problem

regarding policy applications. A state-run organization, KICOX, in charge of Korea′s EIP projects, has been very consistent in carrying out an EIP policy in line with the Ministry of Knowledge Economy. It has never allowed local EIP project units to spend money on other than designated industrial activities or non-industrial complexes(Sudhakar Y, Tran Chau Nhi, Hungsuck P, 2011).

Consequently very important aspects of industrial complexes, like pollution prevention, parks and green area, energy-saving facilities, landscape, restoration etc., have been looked down on. This is believed to be one of barriers preventing EIP policy from being spread out on other realms.

The way of thinking that EIP developments should be limited to specific industrial area can be blamed for a hindrance to the betterment of EIP strategy. Place-specific EIP strategy as in Korea cannot be a great help to industrial complexes made up small & medium sized factories, small-sized, and specialized complexes. That′s because they can′t expand their symbiotic relations beyond the boundary of industrial complexes.

If we think of the general state of industrial complexes in Korea, the restriction of EIP business realm on industrial process in special area becomes one of important problems. More over 30% of 279 industrial complexes of developed and managed by national or local government is evaluated as being obsolete or needed redeveloping. These industrial complexes are now becoming a source of environmental conflict and they are subjected to a threat to close recently.

Therefore when we develop EIPs from now on, we should find out good methods to reduce environmental pollution by devising spatial design skills in non-industrial process realm. This kind of efforts may help make problematic industrial complexes environmentally friendlier and in the end can make contributions to reciprocal and cooperative relationship between industry and residents.

Although the focus of collaboration in most EIP projects has been on developing inter-firm exchange of by-products or energy, some experts state that this is only one part of EIP strategies. More areas for co-operation in Korea′s EIP projects should be identified so that EIP strategy can obtain the desired results that everyone can accept. In this respect, some EIP exports in Korea are planning to expand the EIP projects by co-operating with experts of other fields.

In fact, these challenges can be successful when they are backed by law. For example, to put those challenges into practice, landscape provisions of industrial complexes should be added to the current ″Industrial Complex Development Act″ and ″Act on Industrial Conglomeration Activation and Building Plants″.

4. Lack of motivation to participate in symbiotic networks

It is believed that one of major reasons why companies have distastes for EIP programs is lack of incentives for encouraging them to join the programs. The survey this time also came to the same thing with 35%(14 experts) of the respondents.

Clarifying incentives for taking part in EIP projects carries an important meaning to stimulate industrial symbiosis. Incentives are part of the crucial problems that EIP projects are now facing. It is recommended that government give some incentives for the participatory companies, which can be financial assistance, deregulation, R&D supports, tax break, infrastructure etc.

Throughout various economic, environmental incentives, we can boost the odds of companies' participation in EIP projects, resulting in stable recycle chains.

Industries′ participation in EIP projects will be on the rise when they can see environmental or economic performances gained from symbiotic networks. In the survey, 27.5% of respondents agreed to the importance of their own confidence in EIPs′ outcomes. Solutions to this problem might come from mutual learning about symbiotic relationship, not from just public relation as to what EIPs really are. That′s because industrial symbiosis will be more effective and successful when the relationships are made by mutual-adaptation to the wheels within wheels of up-streams and down-streams.

5. Regulations on the location of recycling industries

Unlike natural ecosystem, because there are not decomposers that mediate food chains and facilitate symbiosis in industrial world, it is almost impossible to root up waste problems in closed loops like industrial parks or estates. Environmental industries, in industrial ecological terms, industrial decomposers are prerequisite to the working of industrial symbiosis from the viewpoint of a closed system approach.

In Korea, industrial laws are prohibiting industrial decomposers from locating in industrial complexes for fear of pollution. Because Waste Management Act looks upon them as a kind of polluters, they feel pressured not to get involved in industrial symbiotic relationship so that they can avoid being taken responsibilities for pollution. Consequently, wise and smart use of wastes is shrinking and wastes have to make a long journey to be reused.

Recently experts have been seeking several solutions about discriminative environmental policy to waste-related companies. First of all, a policy believed most efficient is that waste-treatment industries should be categorized into manufacturing industry so that they can get diverse benefits and asset the same rights as other industries.

6. Absence of regionally based recycling network

It's better to link industrial complexes with recycling networks of regions than to see them as isolated islands. One reason for EIP projects not to get welcomed by locals or local governments is due to the lack of connections between industrial symbiotic programs and local communities. Actually when industrial complexes play a pivotal role for symbiotic relationship associating domestic wastes with industrial processes, we can expect much of cyclical regional economy. This can be extended to Eco-industrial Network(EIN) beyond EIPs, followed by environmentally sound regional economy.

As of now, EIP projects have rarely taken the view that neighboring areas and household wastes could be part of their symbiotic relationships, thanks to the policy that the projects have to do with industrial processes within the boundaries of industrial parks. It's time to adjust the current EIP projects to a sought-after concept of co-operating household wastes and industrial parks.

Recently Ministry of Environment has been trying to accumulate recycling industries in some special areas in the hopes of boosting scale economies in waste management and tapping into waste recycling networks nationally. To that end, the government has the plan that wastes and by-products generated in a region should be recycled in that region at first, and then they should go into recycling networks of other areas(Korean Ministry of Environment, 2011). This refers to, so called, integrated waste management systems. But the problem is how to link industrial symbiosis with domestic wastes into a recycling network. In response to this issue, I'm going to put forward a proposal of kind of a new strategy, the regionally based recycling networks.

This network means the web-based regional waste management system that regional traits and administrative districts can be taken into consideration and detailed information on major recyclables can be put together on a spatial basis(Environment & Civilization, 2012). Waste managers can have control over wastes by keeping up with waste stream of a region, while waste users are able to secure recyclable wastes with ease through this system. The regionally based recycling systems are believed that they can ameliorate one serious situation where companies that belong to a network have been complaining of difficulties obtaining sufficient wastes or by-products that can be used as materials in their recycling processes(Korean Ministry of Environment, 2012).

Ⅴ. Conclusions and some suggestions

Obviously there are not a few legal obstacles to building regional symbiotic relationship centered on an industrial complex. It's because current laws have resorted to the end-of-pipe management with little thought of symbiotic networks. This naive managerialism hasn't and

won′t be a help to an integrated waste management environmentally and economically(Sai Liang, Lei Shi, Tianzhu Zhang, 2011).

An integrated approach to environmental management and industrial regulation is needed to encourage by-products exchange network. But still environmental regulations aim to control pollution media such as water, air, soil etc., and manage individual factories and polluters.

Companies, in EIP networks as well, have a lot of obligations to comply with very strict regulations while raising the productivity and reducing the pollution at the same time. This explains a primary reason why industries are reluctant to join the EIP programs.

Currently there are 18 laws regarding the environment and five laws dealing with industrial complexes in Korea. Among these laws, in particular, four Acts (Waste Control Act, Act on the Promotion of Saving and Recycling of Resources, Act on the Promotion of Industrial Clusters and Plant Establishments, Act on the Promotion of Change into Environmentally Friendly Industrial Structure) are closely related to symbiotic networks. According to this study's implications, in the short term it's better to remedy some shortcomings of EIP strategies from a perspective of industrial symbiosis.

In the long run, it might be way effective when a special law in charge of industrial symbiosis between industrial complexes and their local communities is rolled out. However, in reality, amendments of those four laws are preferred if the difficulty of enacting legislations for industrial symbiosis like EIP projects. Now it will be crucial for the two strategies, an EIP policy of Ministry of Knowledge Economy and a regionally based recycling tactic of Ministry of Environment. This kind of combined approach can pave the path for achieving the integration of region, economy, and the environment.

ABSTRACT

The effects of excessive planning regulation on planning implementations have been often analyzed in planning literature and presented in planning conferences. Rigid legislation and lack of flexibility in policies have often proved to be one of the gravest impediments in implementing good planning, effective, and supported by the public which is planned for. Administrative structure and local conditions can also play a decisive role in the final quality of planning outputs.

The present article analyzes a case study quite indicative of the controversies which might accrue from strict and restrictive legislation, high degree of bureaucracy in administrative procedures, and lack of horizontal coordination between administrative sectors. The specific case is particularly interesting because it upsets the usual phenomena of urban sprawl consuming and destroying rural land, and goes to the opposite direction, with forest "threatening" parts of the city, legally developed and with official urban plan.

The case study refers to the revision and expansion of the Master Plan of the City of Kavala, in Greece, which is in its final stage of approval. Kavala is surrounded by forest areas which constitute a buffer zone around the city. The Department of Forests is managing the forest area and is responsible for the implementation of the legislation regarding protection of forest land. It has also veto power, concerning the preparation of the Master Plan of the city, in cases where urban expansions are planned on forest land. The characterization of forest land, according to the relevant legislation, does not apply only to present forests but also to land that appeared as forest in the first maps of the Department of Forests, since 1920s and 1930s. In the case of revision/expansion of the Master Plan of Kavala, the Forest Department went few steps further than vetoing urban expansions. They claimed that part of the urban zones of the existing Master Plan and the related City Plan -officially approved since 1980 and developed with legally valid building permits thereafter- was forest land, and should be excluded from the urban zone. Furthermore, they based their claim on legal grounds stemming from the constitutional protection of forest areas. This created a legal paradox, since "de-urbanization" of this kind is not provided by planning legislation, and –according to decisions of the Council of the State- is illegal.

This article will analyze the legal aspects of the above deadlock, will examine its sociopolitical and economic consequences, and will refer to an innovative approach proposed by the planning team to overcome it, which could be used as exemplar for similar cases.

INTRODUCTION

The general framework

According to a number of theorists, governance refers to the set of rules, processes and behaviours affecting the way in which powers are exercised. It includes the State, the private sector and the civil society. Governance is the result of the written and unwritten policies, procedures, and decision-making units that govern processes at different levels and control resource allocation within and among institutions. It involves interaction between formal institutions and those of civil society, the complex mechanisms, processes, and institutions through which citizens and groups articulate their interests, mediate their differences, and exercise their legal rights and obligations. In the governance area the State (both central and local) creates a conductive political and legal environment, the private sector generates jobs and income, the civil society facilitates political and social interaction -mobilizing groups to participate in economic, social and political activities. (Campbell, Hollingsworth, and Lindberg 1991; Hollingsworth, Schmitter,and Streek 1994; Hyden 1992; Kooiman 1993; Rhodes 1996, 1997).

Urban governance refers to local governments, urban society and citizens. It assumes a multiple stakeholder scenario where collective problems related to quality of urban life issues can no longer be solved only by public local authorities but require co-operation of other players (citizens, administrative sectors of various levels and specializations, business, voluntary sector, media, etc.), it deals with formal rules (laws, regulations, plans, programs) and informal rules (codes of ethics, customs, traditions). Urban governance is inherently political, concerned as it is with the interplay of stakeholders. (Pierre, 1999; Evangelidou, 2002).

Planning regulations, policies and implementations are interacting and interrelated sectors of urban governance. Their structure and functional characteristics constitute important operative factors directly affecting the level of quality of urban governance. Inversely, the analysis of the various levels of actions generated by urban governance practices may explicitly interpret the interplay of planning regulations, policies and implementations in urban functions.

The present article focuses on the effects of excessive planning regulation on planning implementations. Rigid legislation and lack of flexibility in policies have often proved to be one of the gravest impediments in implementing good planning, effective, and supported by the public which is planned for. Administrative structure and local conditions can also play a decisive role in the final quality of planning outputs. On a first level of approach, case studies may exhibit these effects in a powerful and persuasive way. Their full interpretation, though, may be achieved on a second level of approach, by relating them to the analysis of the various levels of actions generated by urban governance practices. In this way, the link connecting theory and real life implementations may be completed.

Levels of action related to urban governance

Actions related to urban governance can be analysed in three levels. These levels, as slightly reframed by Toonen (1990) and described by De Jong et al (2002), are:

- *The constitutional level:* the whole set of legal and socio-cultural conditions, rules, norms and values that provide the context in which decision making processes and relations take place. Hesse and Benz (1990) call these *Grundregeln* (ground rules). These are rules of conduct or procedure governing the affairs of a community and enforced by a political authority. (The American Heritage® Dictionary of the English Language: Fourth Edition. 2000). These rules are comparatively “static” in not encapsulating change in action, variety or dynamic development.

- *The level of policy areas*: The system of financial, political and organisational relations between various social, economic, administrative etc. actors within a state structure. In this study, this level coincides with a policy sector and refers to plans or courses of action, as of a government, political party, or business, intended to influence and determine decisions, actions, and other matters. (The American Heritage® Dictionary of the English Language: Fourth Edition. 2000). Policies are used in order to achieve goals or objectives, they are more flexible than laws, they might propose alternatives, they are not enforced by threat of punishment if violated, and they have to be supported by active participation of concerned agents, as a prerequisite for their implementation.

- *The operational level*: the whole set of exploratory activities, procedures, techniques and administrative forms used by individuals within the constitutional and institutional framework. This operational level concerns the concrete process of decision-making.

The above three levels of action complement each other in the course of exercise of urban governance. The degree of their balanced coexistence and interaction constitutes a significant success factor for the attempted action(s). In planning, laws usually set the constitutional framework within which planning policies are introduced and planning practices are implemented. They have a supportive role to planning policies and they aim to secure good planning practices and urban and regional development, towards desired destinations.

THE GREEK GENERAL CONTEXT

In contemporary planning history of Greece, effective coexistence and complementary function of policies and laws were seldom achieved. This has affected a lot effectiveness in planning implementations. The relationship of laws and policies in planning and their dependency on specific factors were analyzed through the description of subsequent periods of “planning eras” (Lalenis, 2001) and to the identity of Greece as a member of specific “families of nations” (Newman and Thornley, 1996). Greece, as it concerns legal style, it has elements of both, the Napoleonic and the Germanic families. Consequently, there are differences in the legal style of various laws, and this depends a lot on the sector of administration which introduces them.

Greek State was developed as a very centralized organization, exercising powers and maintaining control over all sectors of public life. Although a capitalist society with conservative governments for the most of its history, the state developed a system of patron-client relations with the lower and middle class strata who became strongly dependent on it, in such a way that their main interest "was not so much in increasing production and in planning the economy but in the strengthening of their position in the state apparatus for the purpose of directly appropriating the surplus” (Tsoulouvis, 1987). For this purpose, a high degree of vertical cooperation was maintained within the State apparatus, but horizontal cooperation was –and still is- minimal. Administrative sectors traditionally have been operating in “vacuums of power”, avoiding any coordination in their function with other sectors, with which they might share overlapping fields of activities. In this way, they were securing their monopolies of power in specific sectors of society. In attempting a reference to the levels of action related to governance (as mentioned above) one can conclude that in such a centralized system, interaction of administration with various stakeholders, public, local authorities etc. was inevitably reduced to a minimum, while the State was retaining the right to control actions by legislating – something for which it had the exclusive responsibility. Thus, the constitutional level seemed to be dominant while the level of policy areas was underdeveloped, and the operational level remained under total control of the various sectors of the State, but still, greatly ineffective. Here it has to be noted that this last level was often the arena of conflicts between antagonizing sectors of the State in their efforts to maintain their vacuums of power.

LEGISLATION, STRUCTURE, CONSULTATION, AND FOREST PROTECTION AND MANAGEMENT IN MASTER PLANS

The backbone of urban planning legislation currently in Greece is Law 2508/1997. According to it, urban planning is expressed in two levels of plans: the first level consists of plans with a strategic character and general directions about land uses, survey of existing conditions, forecasts, alternative ways of development, organization of financial resources, protection of the environment and sustainable development, priorities and phasing of implementation etc. Master Plans of urban areas constitute part of this level (Melissas 2007). The second level consists of plans characterized by design of greater detail of physical characteristics, larger scales of plans, building regulations, and definition of sites of specific uses (schools, nurseries etc.). It includes city plans and revision/extension of them, implementation acts, and special types of studies, such as neighborhood revitalization, brownfield regeneration etc.

Master Plans –which are in the focus of this paper- have a certain structure consisting of three phases: the first contains the analysis of the study area and the preliminary proposal(s), and the other two contain the final proposal and the implementation programme (YPEHODE, 2000). Their area of concern is the area within the administrative boundaries of a municipality. Thus, they deal with the urban environment, the peri-urban zones, and the non urban land of various uses of the municipality (agricultural land, industrial areas, forests etc.). Master Plans are implemented by the related municipalities. Their preparation is organized and supervised by the municipality of reference, but they are approved (promulgated) by the central government, and specifically, by a regional branch of it, the "Decentralized Administration". The official approval of a Master Plan is made with a Presidential Decree which is published in the Official Journal of the Greek Government (FEK).

Part of the preparation of a Master Plan is the consultation process. It is compulsory mainly at the end of the second phase, where the final proposal and the implementation programme are presented. The outputs of the consultation are then used as inputs for the third and final phase that leads to the promulgation. Consultation is organized by the municipal council. Most times it is rather rigid, since "official" participants are only authority consulter groups and organizations (Lalenis, 1993), as well as administrative departments. Means of consultation are restricted to public presentations, and final decision is made by the Decentralized Administration. Input by the municipal council and the other participants, is only of advisory nature, and it is submitted in the type of written comments, remarks and proposals to the regional administrative unit. Consultation broader than the above is voluntary, and it comes as a common decision of the municipality and the planning team.

The predominant nature of the constitutional level of action even in this type of consultation is apparent, since the organization of consultation in the specific points of plan preparation process, the list of "official" participants, the details of submission of written remarks etc. are prescribed by law, and any diversion might lead to the nullification of the Master Plan. At the same time, other elements as flexibility in timing and phasing, variety in participation strategies, positive discrimination in "sensitive" social groups etc., are usually excluded from the compulsory parts of consultation, and this considerably weakens the level of policy areas of action.

It is crucial for the comprehension of the case study which follows, to mention that according to related legislation, participants in consultation are supposed to submit their written input to the municipality within a period of two months after the official public presentation of the Master Plan. In case that some participants fail to meet the deadline, it is assumed that they agree with the presented proposals and the process goes on. This bears an element of possible contradiction in cases that one or more of the departments and administrative units which fail to meet the deadline, might be dealing with uses of "special protection". These are legally designated, and as such, of particular importance for the

preparation of a Master Plan. Their main categories are: forests, archaeological sites and cultural heritage, sensitive environmental areas, agricultural areas of high productivity, and military installations (Melissas 2007). They are protected by the Constitution and any intervention related to them in the Master Plan has to be approved and co-signed by their equivalent department or ministry, otherwise the Master Plan may be nullified. These categories are indicated in Master Plans as ASP (areas of special protection –PEP in Greek)) followed by the specification of their nature (i.e. ASP of forest land).

Forests, in particular, have been a sensitive "heel of Achilles" in Greece in the last decades, since there have been suffering mass destruction by illegal woodcutting, illegal housing, and fires[1]. (Kathimerini, 2007). The fires of August 2007 where huge forest areas were burned, human lives were lost, and many villages were destroyed, shocked people all over the world. Consequently, protection of forest ecosystems constitutes a major social, political and financial matter in Greece.

The characterizations as "forests", or "forest land", or "areas for reforestation" are legally specified for areas which are not urban, they are not included in city plans, and they do not bear any other characterization such as archaeological sites, natural or cultural monuments, or areas of designated land uses of important technical nature. The Greek legal order has an adequate legislative framework of forest protection, while the constitutional amendments of 2001 provided provision for an official record of forests (forest cadastre), the prohibition of the alteration of the nature / characteristics of forests and woody lands, and the compulsory process of reforestation of destroyed forests and woody lands. Given the context of the above constitutional commands, the Council of the State (CoS), came forward with adjudications aiming to prohibit any kind of development in forests. CoS decisions adjudged that inclusion of forest areas in existing city plans or future extensions of them, is, under any circumstances, unconstitutional.

For the areas for reforestation, in particular, CoS ruled that they should regain their initial form as forests, prior to any consideration of altering their official characterization and accommodate other land uses. Reforestation, when declared, is compulsory and it includes both public and private forests. Legal experts claim (Zigouri, 2008) that compulsory reforestation might become a disproportional burden on private property since, according to decisions 576-577/2006, and 3848/2005 of CoS, no right of compensation arises because reforestation doesn't constitute expropriation of any sort, doesn't imply any change of property status, and hence, there is not any cause for reduction of its value. Nevertheless, the declaration of a private area as an area for reforestation repositions this area in a new category where any other land use apart from the reforestation is prohibited. Thus, it is reasonable to expect a reduction of its real value which could justify a demand for reasonable compensation. Even so, though, compensation could be problematic, since inability of the municipality or the state to reimburse the land owner, would not mean nullification of compulsory reforestation.

Given the up to now absence of a Forest Cadastre, supported by clear, updated maps, designation of areas as forests, forest lands, or areas for reforestation has always been the exclusive responsibility of the Forest Departments and the Ministry of Agriculture and Forests. Decisions of this kind were at risk of been inaccurate, since they were based in either old (since 1930) administrative acts without attached maps, or in old maps of a scale 1:50.000. Furthermore, they could not be contested in administrative procedures, but only to the highest levels of Judicial hierarchy, in the Supreme Court. This made any appeal or objection to such decisions practically impossible. It is only recently that a new law, Law 3889/2010 "Financing environmental interventions, Green Treasury, Forest Cadastre, and other arrangements" allowed for some possibilities for change. According to it, new and technologically sound forest maps are supposed to be created for all Greece, with certain procedures

[1] "Transgression of 200.000 ha in East Attica" It is estimated that more than 3,5 million ha of forest land have been transgressed so far, for housing and agricultural development, while the arbitrary houses occupy about 1,5-1,7 million ha. Kathimerini Journal, 1.12.2007, p.8.

and certain ways of financing them. In their final stage of preparation, they will be exhibited to the public, and a process of appeals is prescribed, similar to the equivalent for the preparation of city plans.

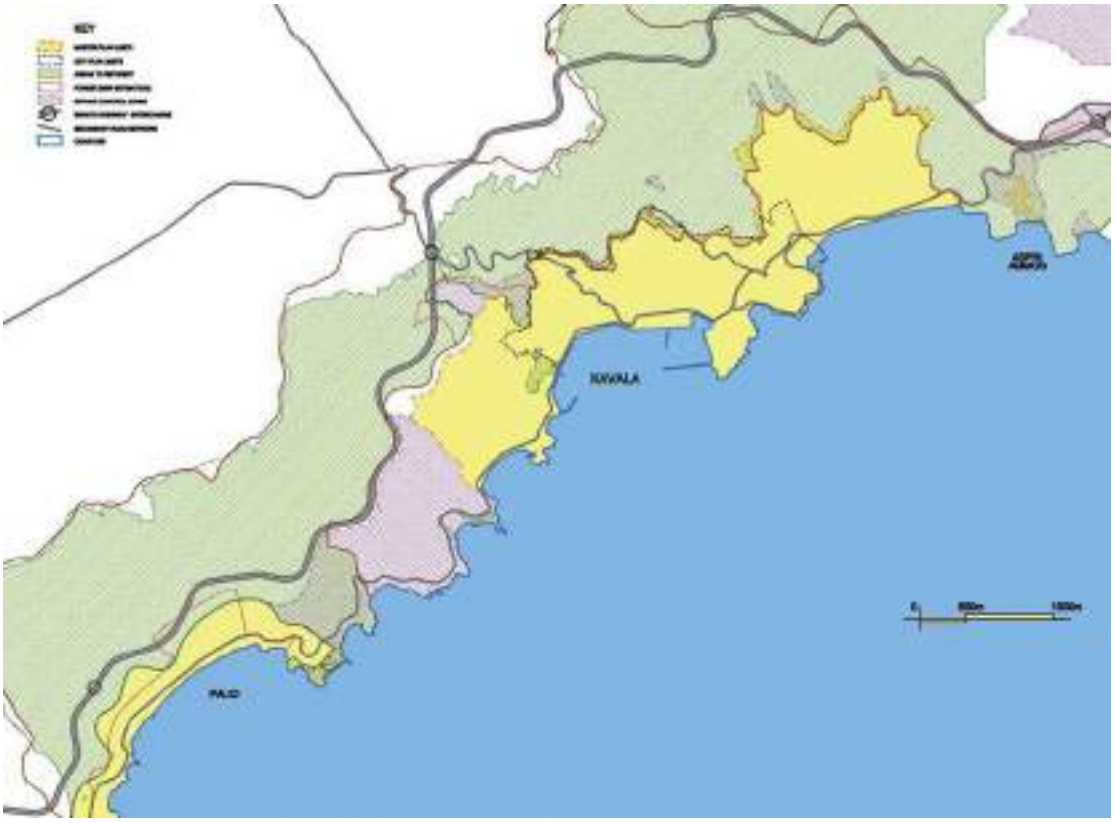
THE CASE STUDY: FOREST OVERTAKING URBAN AREAS IN THE MASTER PLAN OF KAVALA, GREECE

Kavala is the second largest city in northern Greece, and the principal seaport of eastern Macedonia. It is situated on the bay of Kavala, across from the island of Thassos, and on the southern slopes of Symvolon mountain. Its population size (80.000 people) classifies it as a middle sized city. Kavala is the major tourist center in North Eastern Greece, a transportation node where seaways, air transport, the Egnatia international motorway, and rail transport meet.

The first urban planning in Kavala was recorded during the Ottoman Empire, when Kavala was a major tobacco elaboration and exportation center. A City Plan, in the form of a map, was made in 1929, and subsequent revisions and extensions were prepared in 1936, 1939, 1958, 1980, and 1989. The first Master Plan was approved in 1987 and the last revision / extension of the City Plan (1989) were conducted according to the guidelines of the Master Plan (Loukakis, 1997).

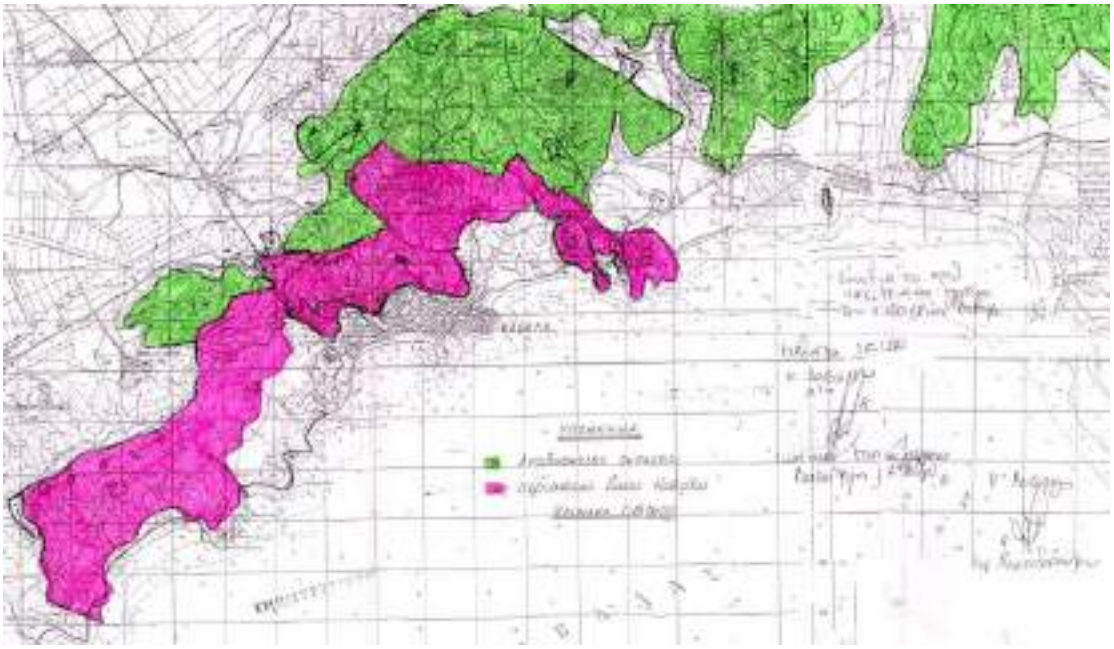
The city boundaries were set by the Master Plan, and in particular points -mainly in the northern part of the city- they concurred with the boundaries of the surrounding forest land and reforestation areas. A big part of these boundaries was later consolidated by the construction of the Peripheral Road Axis of Kavala. Other areas surrounding the city were designated as zones of “mild” tourist development, peri-urban zones designated as future extensions of the City Plan, and peri-urban green belts.

A revision-extension of the Master Plan of Kavala started at the end of 2006, and it was financed by E.C. Structural Funds (Operational Programme “Environment” - EPPER). At 2008 the final proposals were brought up for consultation (see above in page 4). The Department of Forests and Forestlands, to whom the proposals were sent, responded with a document and an attached map, which set fire to the preparation process. According to it, areas assigned by the approved Master Plan as residential areas, and developed as such since 1987, were now characterized as areas for reforestation, suggested to appear in the Master Plan as “areas of special protection – reforestation areas”. Similarly, areas designated as zones of tourist development, social infrastructure, and social housing by a Presidential Decree of 1989 (ZOE) for development control around Kavala -and developed as such since then- were also characterized as reforestation areas. The above assertions were made despite the fact that the long period of implementation of the Master Plan and the subsequent City Plan had created significant legitimate interests in land owners who invested mainly in residences, in good faith for the reliability of the administration. The Department of Forests based the legitimacy of their demands in the assertion that both the approved Master Plan of 1987 and the 1989 P.D. (ZOE) were invalid, at least at their parts dealing with forests and reforestation, since in neither of them there was written approval and co-signing of the Department of Forests for these matters. In the map of the Forest Department the – supposed to be- boundary of the reforestation areas was set inside the urban area, separating, thus, part of it from the rest of the city.



Map 1. Land uses in the Master Plan of Kavala and the new boundaries of reforestation areas set by the Forest Department. (Elaboration by authors).

Investigation of the claims of the Forest Department in the archives of the preparation of the Master Plan and the ZOE P.D. during the period 1984-1989 revealed that the Forest Department had received written invitations and had participated in all the consultation meetings that were organized. It had also been invited to submit its written comments, remarks, corrections etc. in the two months period prescribed by the legislation (see also page 5 above). The Forest Department had never submitted written remarks because, –as they invoked at that time- the maps in their disposition were old and of a scale 1:50.000, and thus, it was impossible to express an opinion about the Master Plan proposals. The mentioned maps were only in paper, since they were attached to Regulatory Acts of Reforestation approved at 1927, 1948, 1956, 1962, 1979, 1980, and 1981. Nevertheless, since no comments had been received by the Forest Department in the two months period, the preparation of the Master Plan went on, assuming that there was consent for the proposals (see also page 5 above).



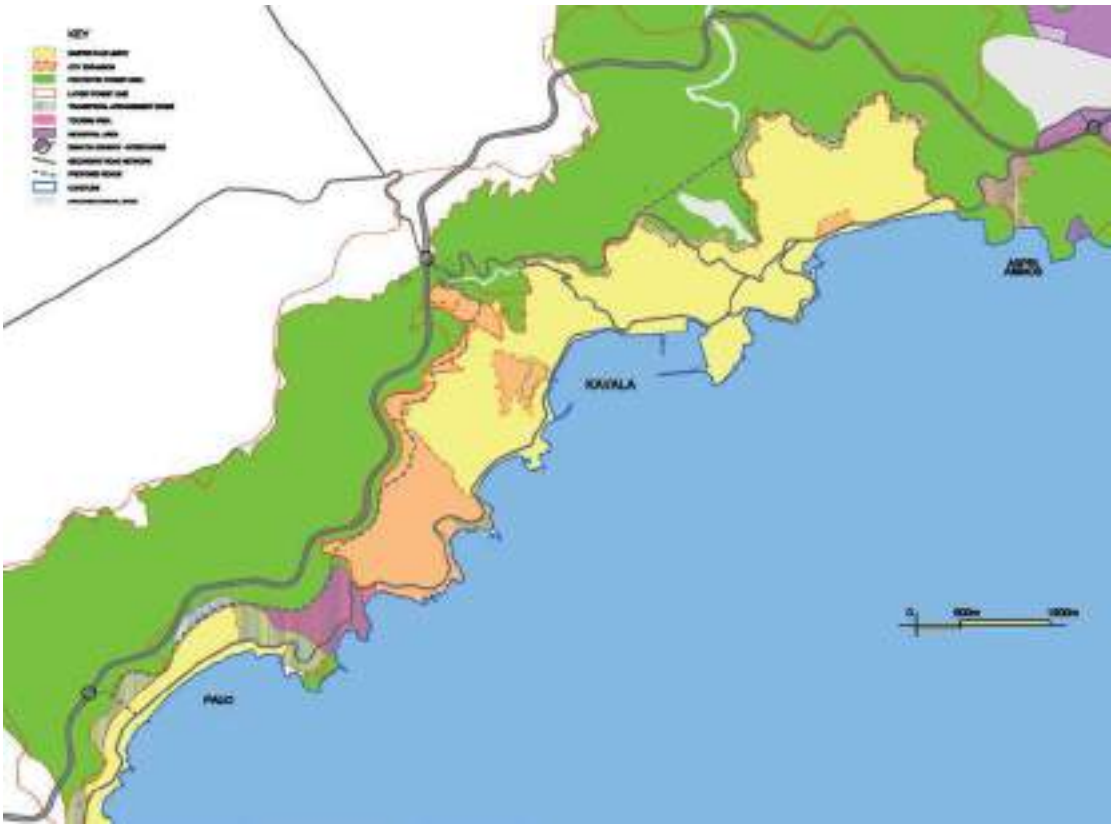
Map 2: Sample of the 1:50.000 maps of the Forest Department attached to Regulatory Acts of Reforestation (copy of the original).

The map which was attached to the document sent by the Forest Department to the Municipality of Kavala as part of the deliberation process for the revision – extension of the Master Plan was prepared in 2008 in digital form. The designation of the boundaries, though, was still based in the preexisting old paper maps, while the officially approved Master Plan of 1987 and the ZOE of 1989 were not taken under consideration[2]. The legal consequences of the intervention of the Forest Department could be grave, because –among other things- existing constructions with legal building licenses would have their legitimate status jeopardized, the new Master Plan would be at risk due to the expected reactions of the local residents, while the "de-urbanization" of areas included in approved urban plans is not provided by the relative legislation.

The inaccuracies in transferring the boundaries of the reforestation areas from the old paper maps to the digital map of 2008 were also indicated in the report of a team of experts, assigned by the Municipality of Kavala at the end of the same year. The team found that the reforestation area declared in the Regulatory Acts of Reforestation was smaller than the one shown in the digital map by 628,4 ha. Another issue which came into question was the one of the legal capacity of the mutually refuting documents. Master Plan and ZOE were officially approved by Presidential Decrees, while the document of the Forest Department was not an official administrative act, and it could be disputed on the grounds of expressing only individual opinion. On the other hand, protection of forests is clearly supported in the Constitution, and until recently, the Forest Department was the undisputed guardian of the constitutional provisions. Finally, appeals against the decisions of the Forest Department –as prescribed in Law 3889/2010- could not be implemented in the preparation of the new Master Plan because: a. they were specifically prescribed for the preparation of the Forest Cadastre and only for this, and b. the study for the Forest Cadastre for the areas surrounding Kavala was not expected before 2014. This was too late for the Master Plan since it was supposed to finish by the end of August 2012, according to the E.C. programme that financed it.

[2] When asked for the reasons that the Master Plan and the ZOE P.D. were not taken under consideration in the new forest maps, the director of Forest Department claimed that their legal obligation was to abide just to the Forest Code. He also declared their "right to ignore" the Master Plan and the ZOE P.D., since the Forest authorities had not co-signed for their approval.

Given the above, the planning team who prepared the Master Plan proposed a way out of the deadlock. According to it, the zones in dispute would be characterized as "Zones of Transitional Arrangements" with abeyance of building permits (new or revised) for a period until the preparation of the Forest Cadastre in these areas. Then, they would go through the process of appeals, and the outcome would become their permanent status by a revision of the Master Plan. This proposal was thought to be flexible enough to allow the Master Plan to be approved on time, while the future use of the disputed zones would be decided by a legal process accepted by the Forest Department. In the meanwhile, there would be no construction activities –something that was also close to the demands of the Forest Department. The difference between the proposed transitional status and the status of "zones of special protection" (PEP) –as demanded by the Forest Department- was that if characterized as PEP, these zones would be almost impossible to become again urban zones, since this changes are not considered to be an improvement for the environment[3], and the modifications would not have any justification.



Map 3: "Transitional zones" as proposed by the planning team (elaboration by the authors).

There is also a recent opinion of the Legal Advisory Council of the State (340/2011) related to the above, which states that residential areas included in officially approved urban plans and developed accordingly since then, which for some reason they were not co-signed by the Forest authorities, they should be considered as lawful urban areas and they should continue with their urban functions.

The planners' proposals and the above opinion of the Legal Advisory Council of the State were notified to the Forest Department which, in turn, responded to the Municipality of Kavala with the 25714/27.1.2012 document, rejecting the proposals and reaffirming the initial claims for the characterization of the areas in dispute as "zones of special protection – reforestation areas" (PEP). In several consequent meetings organized by the Municipality of Kavala and the Decentralized Administration of Macedonia-Thrace, there was no way out of the deadlock. It seemed as different participants were using different languages to communicate, with inevitable result the lack of

[3] This is according to successive related decisions of the Council of the State.

communication. It is characteristic that when the representatives of the Forest Department were asked about a possible procedure to change the characterization of the disputed areas from reforestation to urban uses, they responded that in order to do so, all constructions would have first to be demolished, forest should be recreated, and then the process of changing characterization could commence!! This, of course, was the "sticking to the letter" and "narrow" interpretation of the related decisions of the Council of the State[4], which, applied under the specific circumstances, seemed totally unreasonable.

Currently, no progress has been made towards resolving the above stalemate. The Forest Department insists in its proposals, but apart from stopping the revision of the Master Plan from being approved, it hasn't taken any legal initiative to nullify the old Master Plan and stop constructions in the disputed zones. At the same time, building permits are being issued as regularly, and the E.C. programme financing the study of the Master Plan (EPPER) is rapidly approaching at its end (end of August 2012). This means that if the project hasn't finished until then, the Commission will demand the money paid for the project, back from the Municipality of Kavala.

CONCLUSIONS

In an attempt to analyze the case study of this paper and relate it to a theoretical framework, one should attempt an investigation in the character of the Greek State. It is developed as a very centralized organization with a complex bureaucracy and an overgrown and ineffective public sector. Parts of it have been operating in sub-sectors developing "vacuums of power", and avoiding any coordination with other sectors. In this way they secure their monopolies of influence on specific sociopolitical and economic actors (Tsoulouvis, 1987). Inevitably, interaction with various stakeholders –beyond their "clientele"- such as public groups, local authorities etc. is usually reduced to a minimum, while the State is retaining its exclusive right to control actions by legislating. Legislating, on the other hand, is not effectively coordinated between the various administrative sectors, so that controversies and mutual retractions of pieces of legislation are not rare. In the sphere of implementations, administrative sectors often choose to exclusively implement some laws and ignore others, depending on which ones secure their position in the arena of governance. The above structure and function are grave impediments for the generation and evolvement of effective and innovative policy initiatives.

Planning, as an important element of urban governance, also suffers from the above. In contemporary planning history of Greece, effective coexistence and complementary function of policies and laws were seldom achieved. Planning was mostly attempted by legislation and not by policies because: 1. local administration had few rights and responsibilities in planning and even fewer resources. This disadvantageous position led to inability to formulate policies on the local level, which is the most suitable environment for such. 2. Central government was not in favour of genuine and broad participation processes in planning that has always been a prerequisite for effective policies. To the contrary, they were introducing laws that were not negotiable, did not necessitate participation and were enforced by authority. Furthermore, they could vacillate between conflicting and contradictory laws, bylaws, modifications of laws, and implementations of laws, initiated and implemented by different centers of authority (Ministries), or by different political parties, with related and partly overlapping subjects, in a complex system which, amidst the antagonism of institutions, guarantees a "monopoly of knowledge" (Voivonda et al, 1977, Athanasopoulou, 1998). Rigid legislation and lack of flexibility in policies have often proved to be one of the gravest impediments in implementing good planning, effective, and supported by the public which is planned for. Administrative structure and local conditions can also play a decisive role in the final quality of planning outputs.

[4] For the areas for reforestation CoS ruled that they should regain their initial form as forests, prior to any consideration of the possibility to alter their official characterization and accommodate other land uses.

The case study of this paper seems to provide explicit examples of the above statements. It is quite indicative of the controversies accruing from the interaction of excessive planning regulation on planning implementations, lack of horizontal cooperation between sectors of administration and local government, conflicting laws, and lack of policies in the domain of urban governance.

In attempting a reference to the levels of action related to governance (as mentioned in the introduction of this paper) one can conclude that in the case study the constitutional level seemed to be dominant. Antagonism of institutions (Municipality of Kavala and the Forest Department) was expressed by contest of the legal arsenal of each side. Furthermore, the might of each one of the two actors was not tested in a consultation process where other stakeholders (and especially not of the type of consulter goups) (Lalenis 1993) could also play a significant role, but according to the relevance of the legal tools that they were using to elements and levels of the hierarchy of the Legal Code of the Greek State (the Constitution, the Council of the State). In these conditions, the level of policy areas was rudimentary. Few attempts were made from the side of the planning team studying the Master Plan, and the Municipality of Kavala to formulate a policy approach that might lead to mutual compromises and help to overcome the deadlock, but they were easily discarded by the Forest Department which insisted in the by-the-letter implementation of the forest legislation. Finally, the operational level, which is usually the reflection of the antagonisms of the other levels, went to –and still is- a total stalemate, which is further threatened by the deadline of the end of August 2012, when the Master Plan is supposed to have been approved. Conclusively, the lack of coordination and complementarity among the three levels of action predefines the failure of the particular act of urban governance.

Local spatial planning versus UNESCO WHL Management Plans: a comparison of two cases in Sicily

Francesco Lo Piccolo & Davide Leone
Dipartimento di Architettura
Università degli studi di Palermo

Abstract
This paper aims to investigate the relationship between tourism and planning in UNESCO World Heritage List (WHL) sites, with special reference to the relation between Management Plans and other (local and regional) planning instruments and policies able to influence the promotion of sustainable and responsible development. This will be explored through a confrontation between two important tourist locations in Sicily: Agrigento (the Valley of the Temples) and the Aeolian Islands, which have both been recognized as World Heritage Sites by UNESCO. The analysis of these case studies will point out the challenge of integrating different management and planning regimes – which mainly refer to a performative model – in a (still) very conformative planning system. The article will show how supranational policies often lose their efficacy in relation to regional and local planning systems, being in opposition to such systems. The selection of the two Sicilian case studies is particularly appropriate under this perspective, as they represent significant or even extreme examples of the gap between the supranational performative approach of the UNESCO WHL MP model and the conformative nature of the Sicilian planning system; this is due to the different nature and characteristics of the Sicilian planning law and regulations and the UNESCO WHL MP guidelines.
The comparison, proposed in the paper, will explore the influence and mutual relationships between the two UNESCO sites and the planning instruments and policies. The main questions of the paper are: In which way the above mentioned framework of planning instruments takes into account the UNESCO sites? What is the role of planning instruments and policies to facilitate integration and reconciliation? Which are the strategies implemented by the planning system and its regulations in order to manage and improve the tourist flows, according to a sustainable planning approach? On the other hand, does the UNESCO heritage label (and its related policies and management plans) guarantee international and global control over local changes and planning decisions?
The paper will underline how the interrelation among the WHL MP and other (local and regional) plans is on the one hand necessary and on the other hand problematic, due to the diversity of planning systems in each country. Consequently, the paper will consider the legal implications for local planning systems due to the fact that each national and local reality has to spot the most adequate configuration for WHL MP, in the light of existing laws and specific cases. The paper will also show the difficult integration between planning instruments operating in the same area, but managed by different actors, with different time schedules, resources and law effectiveness.

1. Introduction

This article aims to investigate the relationship between tourism and planning in UNESCO World Heritage List (WHL) sites. Its focus is the relationship between WHL Management Plans (MP) and other (local and regional) planning instruments and policies able to influence the promotion of sustainable and responsible development. This will be explored through two case studies of important tourist locations in Sicily: Agrigento (the Valley of the Temples) and the Aeolian Islands. Both have been recognized as World Heritage Sites by UNESCO. The analysis of these case studies will point out the challenge of integrating different management and planning regimes – which mainly refer to a performative model – in a (still) very conformative planning system (these terms

will be explained in the next section of the article). The article will show how supranational policies often lose their efficacy in relation to regional and local planning systems, being in opposition to such systems. The selection of the two Sicilian case studies is particularly appropriate under this perspective, as they represent significant or even extreme examples of the gap between the supranational performative approach of the UNESCO WHL MP model and the conformative nature of the Sicilian planning system; at the same time, the Agrigento Valley of Temples and the Aeolian Islands present differences which are both helpful to highlight difficulties in the use of standard procedures and guidelines for local contexts and specific purposes.

Some introductory remarks on the role and impact of the UNESCO WHL on tourism economy (and its features) are necessary. The aim of UNESCO is not only the preservation of places declared as human heritage sites. The macro-objectives to be achieved by means of the WHL also include international peace and security and the improvement of quality of life (UNESCO, 1972). Within these macro-objectives, sustainable development and sustainable forms of tourism and fruition are the central (Pedersen, 2002; UNESCO, 2005). It remains questionable whether the aims and targets of the UNESCO WHL are automatically, and everywhere, congruent with the workings of the tourism sector.

The Convention Concerning the Protection of the World Cultural and Natural Heritage (World Heritage Convention), adopted by the General Conference of UNESCO in 1972, established a unique international instrument that recognizes and protects both the cultural and the natural heritage of outstanding universal value (UNESCO, 1972). Through these systems of protection, WHL contributes to sustainable local and regional development (Rössler, 2006). Most nations are certainly interested in promoting monuments and sites for the WHL in order to improve prestige and economic growth in the form of tourism: a country obtaining a place on the WHL can be compared to a restaurant receiving a Michelin star (Brattli, 2009, p. 37). A large literature shows how tourism benefits from the UNESCO WHL label. Yet, simultaneously, UNESCO promotes awareness of world heritage sites and advocates principles of sustainable tourism (Drost, 1996; Evans, 1999; Jones and Munday, 2001; Lyon, 2007). This raises important questions. Yet, the impicit assumption that UNESCO WHL 'automatically' promotes sustainable development and sustainable forms of tourism is questionable.

Brattli (2009) suggests that the use of a common world cultural heritage – in an actor-network context where multiple and even conflictive interests take place – has first and foremost a rhetorical purpose. For example, Di Giovine (2009a) highlights the convergence between a concern for heritage and the concerns of the global tourism industry, linking the obsession with authenticity endemic in tourism with the complex issue of "authentic" heritage site preservation. The rhetorical purpose of the UNESCO label is evident in the 'sustainable' attribution which is often awarded to all the tourist activities which are developed in the UNESCO sites, notwithstanding the nature and impacts of each activity or initiative.

Therefore, if the convergence of the targets of the 1972 UNESCO Convention and the WHL with tourist activities promoted at local or global level are not taken for granted, what is the role of planning instruments and policies to facilitate integration and reconciliation? Which are the strategies implemented by the planning system in order to manage and improve the tourist flows, according to a sustainable planning approach? On the other hand, does the UNESCO heritage label (and its related policies and management plans) guarantee international and global control over local changes and planning decisions?

2. Preservation versus (tourism) development: the contested role of the WHL Management Plan

Potential conflicts between sites' preservation and development have gradually become objects of attention for UNESCO, with an increasing focus on management as a solution (UNESCO, 2002 and 2005). In order to outline the importance of proper heritage management, in 2002 the WH

Committee adopted the Budapest Declaration[1] where Member States are invited to support the protection of heritage, trying to assure a proper balance among preservation, sustainability and development. The general strategy of the Management Plans (MPs) is based on the conservation of listed sites for future generations, thus applying the sustainability principle to the management of cultural heritage. It is compulsory to submit the MP for new sites entering the list. This plan is then extended to all sites, included those already inscribed. The Convention requires the governments to encourage MP preparation for all the WHL sites, including older WHL sites, which had no MP, (Blandford, 2006, p. 356). Such obligation has been strengthened after the negative experiences in some cases, at world level, because of the lack of adequate management systems.

Consequently, the submission of a MP has been a prerequisite of WHL inscription, in order to guarantee an effective and efficient work of goods' protection and management. The MP is intended to specifically reveal how possible conflicts can be solved and how conservation of a candidate site will be managed, administered and monitored in the future (Blandford, 2006, p. 356). The MP is not only involved in the protection of goods\objects, but also in their management as one of the several targets to achieve is the integration of the management of protected goods to the life of the economic and social community they belong to (Solar, 2003).

When the good is not protected or managed according to the established terms and when the state does not have to solve a problem or cannot solve a problem, the Convention establishes the possibility to remove such item from the List, depriving it of the title of Outstanding Universal Value (OUV); to this end, there are provisions regarding regular inspections[2]. The UNESCO World Heritage Committee, in considering site nominations, has put increasing emphasis on the requirement for MPs as a "vital long-term framework for the ongoing management and conservation of the OUV of sites" (Blandford, 2006, p. 356). Thus, UNESCO avoids a position where countries which do not take their responsibilities seriously can undermine the system itself.

Starting from the values which led to the inscription on the UNESCO's WHL, the MP arranges a management system that carries out an integrated analysis of the site status, spots the changes in action, assesses future scenarios that can be reached through targets and possible interventions and also assesses their impact on the locality. It also chooses the strategies to attain prefixed goals and verifies their achievement using indicators which are monitored systematically. Consequently, a strategic MP leads to the formulation of projects that are incorporated into the annual work programme; many of these measures can be found in the development plans covering the sites (Lyon, 2007). The two fundamental elements in a MP are thus its strategic aspects and its operating features. The MP, as Palo (2007) states, should not be intended only as an instrument of protection and preservation as an end in itself, but should establish an effective management model for historical, cultural and natural resources. This model should also be able to address the choices on urban and economic planning for the development and enhancement of a wide area. Within this perspective, the MP represents the connection between different planning instruments and policies in order to: a. preserve over time the integrity of values leading to the registration within UNESCO's WHL; b. combine the protection and preservation through the integrated development of local economic resources such as tourism; c. involve numerous actors (even those having opposing interests) in a common and local decision-making process (Feilden and Jokilehto, 1998;

---

1 http://whc.unesco.org/en/decisions/1217/

2 The basic principles representing the reference foundations for the MP in order to define its contents are: concepts of universal value, cultural and landscape system, methods of deliberative democracy, assessment and peculiar features of cultural values, model of endogenous development, local culture and its development, local tourism, collective property rights, risk analysis and integrated management. The management of a WHL site is based on a detailed analysis of its significance, which has in turn been part of the nomination procedure (Turnpenny, 2004; Lyon, 2007).

UNESCO, 2005; Blandford, 2006); for example, the MPs can address issues arising when visitor numbers and conservation demands are in conflict (Evans, 1999).
This aspect underlines how the interrelation among the MP and other (local and regional) plans is on the one hand necessary and on the other hand problematic, due to the diversity of planning systems in each country. This is also the reason why the UNESCO World Heritage Committee does not submit a single model of MP. Each national and local reality has to spot the most adequate configuration for this instrument, in the light of existing laws and specific cases (Wheatley, 1997; Pedersen, 2002; UNESCO, 2005). In our experience, this difficult relationship between supranational and local levels is to be ascribed primarily to the different, and even opposing, nature of planning models, that is performative versus conformative. Mastop and Faludi (1997, p. 820) borrowed from Barrett and Fudge (1981) the distinction between performance and conformance: "Conformance means concurrence between the original plan and changes in the outside world. Performance has to do with the way in which a strategic plan holds its own during the deliberations which follow its adoption."
In some European countries (Italy included), plans and policies at a broader level – Provincial or Regional – treat local implementation in terms of 'conformance' meaning that plans (or even projects) at a local level must conform to the broader strategy of the 'general' plan. The main 'nature' of the plan is, consequently, regulatory, usually through a land-use zoning design. As stated in Janin (2008, p. 170) "in conforming planning, the capacity of shaping spatial development is indeed pursued by the attempt to impose a 'correspondence in form, manner or character' to development projects, and implementation is intended as 'an action in accordance with the standards' established by the authority"; in practice, implementation often does not occur, as shown below. This cultural, political and administrative approach is quite often extended to other super-national levels, as in the case of EU policies or in the case of UNESCO MPs. Scholarly literature (Alexander and Faludi, 1989; Mastop and Faludi, 1997; Faludi, 2000) as well as many examples highlight the limits of conforming planning. This is mainly to do with the difficulty of plan implementation in the context of 'putting together' (in a conforming, top-down approach) multi-level collective strategies within a growing plurality of local visions, ideas or projects of spatial development. On the other hand, the EU – and also UNESCO – has developed territorial (spatial) governance processes based on a principle of 'performance'. In this approach, "the capacity of shaping spatial development passes rather through the opportunity of obtaining from specific projects 'the fulfilment of what claimed, promised or requested' by the plan. Thus implementation looks primarily at the 'achievement' or 'accomplishment' and at 'carrying into execution' the aims of the plan" (Janin, 2008). According to Faludi (2000, p. 300), if plans "improve the understanding of decision makers of present and futures problems they face" and help them in making sense of their situations, plans may be said to perform their role.

3. The WHL Management Plan and the planning system: universal versus local?

In the case studies we will analyse, the gap between performative and conformative approach is at the base of the difficulties in the implementation of WHL management plans. However, there are also other sources of conflict, notably the general conflict between conservation and development (Tunbridge and Ashworth, 1996). This can be intertwined with the relation (potentially controversial) between universal criteria and local actions. Recent literature has shown the limits of a global perspective imposed by the UNESCO WHL criteria and procedures (Di Giovine, 2009a). Yet, the member states have to adapt their requests to the UNESCO criteria, if they want to have any chance of seeing their monuments/sites placed in the WHL. The World Heritage List and the World Heritage Committee can control and define the nature of heritage on the one hand and the limits to development on the other hand.
However, if such international regulation guarantees a global control to spot and preserve sites of extraordinary value through strict standard procedures, this "universal" control has limits. For

instance, Labadi (2007) highlights that the criteria for assessing the sites' OUV and their authenticity, have been conceptualized, explained and understood from a European perspective; analogous consideration are also pointed out by Di Giovine (2009b). Silverman and Ruggles (2007) state that universality still is subject of a complex debate, as non-Western countries have objected to the idea of universal standards externally imposed because they consider these standards as reflecting Western, rather than universal, values[3].

Consider, too, the relations between procedures and contents of the WHL MP and those of local and regional planning systems. The status of World Heritage Site is a material factor in planning policy and development, and it is also material in the decision making process on planning applications affecting the sites (Lyon, 2007). But these factors are differently considered in each national context. In the UK, for instance, Blandford (2006) highlights that, although the UK planning system through designations to the WHS Tentative List acknowledges some conservation needs, these are not specific to World Heritage Sites' criteria; at the same time, there have been no specific statutory planning controls that apply to WHS. In general terms, the WHL MP is based on a model of continuous and coordinated planning where different instruments integrate and contribute to the building and sharing of choices. In different states not all planning systems comply with this model.

In Italy, the National Ministry for Cultural Activities and Heritage, during the Conference held in Paestum (May 25\26, 2004), has developed and submitted a MP model[4] in order to show local authorities how to connect it to the reality of managing their actual sites. The Italian Law introduced the MPs of UNESCO sites through the Law February 20, 2006, n. 77 "Special measures for the protection and the fruition of Italian cultural, landscape and natural sites, inscribed on the "World Heritage List", under the protection of UNESCO". This law identifies the Advisory Commission for the management plans of UNESCO sites and local tourist systems, established at the Ministry for Cultural Activities and Heritage. The Commission approves the MPs for the WH Italian sites and ensures the contents of the different MPs proposed in relation to the sites. In reality, the MPs differ in their site nature and in their internal structure and dialogue ability with other plans.

The MP represents, within the Italian law, a flexible instrument able to create a dialogue with plans of different nature (local and regional, regulative and strategic) to guarantee the site protection and its development as a cultural and tourist resource. However, some problematic aspects emerge. The first is that the competent Ministry is the Ministry for Cultural Activities and Heritage which, in Italy, is not in charge of the land use planning. The second problem is that MPs have been basically implemented in Italy as established by UNESCO, without any compliance with the Italian planning and protection system. In fact, Italian MPs – apart from dealing with sites which widely differ in features, size and issues - are forced to tackle a planning system that is highly fragmented because of the competences and the plurality of regional planning laws. In Italy, regional planning laws are very different from each other and do not often present the flexibility required to comply with the MPs needs, as they still refer to regulatory policies and instruments and as they are far away from a more strategic, development-led approach. In such contexts, the limits of conforming, statutory planning regard the disappointing results in implementation due to the difficulty in reconciling multi-level collective strategies to a plurality of local plans or projects of spatial development (Janin, 2008, p. 168).

---

[3] For example, Brattli (2009, p. 30) shows that "both the WHL and the World Heritage Committee function as an obligatory passage point which defines the character of the physical remains from the past (…). One has either to accept a given definition of the past and cultural heritage or to perish." Despite this, there are significant differences in the way heritage is perceived and managed.

[4] According to the Italian law, the MP serves two functions: guaranteeing an adequate site protection and promoting cultural activities regarding the site. The MP, in compliance with the guidelines established by the Ministry for Cultural Activities and Heritage, faces a five-year time horizon.

4. Two WHL sites in Sicily

The 1978 Sicilian planning law is a blatant example of this situation. The Sicilian planning law is the earliest planning law in Italy. It basically implements the 1942 Italian legislation and structures the planning instruments governing the region with great emphasis accorded to the Master Plan, in a statutory, conformative approach. The Master Plan essentially regulates land use, focuses on the communal domain and is effective for 20 years.

The Sicilian regional planning law is inadequate as a vehicle for engaging with supranational, multi-level planning instruments whose action is rapid and flexible. Within this framework, it is difficult for UNESCO MPs to work as effective instruments of promotion and preservation. Under such conditions, the WHL MPs do not either work as guidelines for the master plan or become instruments able to structure what is developed and decided in other plans. Thus, the gap – as described in the previous paragraphs – between different plans and planning levels, and the consequent difficulties of getting agencies responsible for different kinds of plans to work together, does often occur.

Sicily includes five sites inscribed on the UNESCO World Heritage List:

- The Archaeological Area of Agrigento (1997)
- Villa Romana del Casale, Piazza Armerina (1997)
- The Aeolian Islands (2000)
- The Baroque Towns of the Val di Noto (2002)
- Syracuse and the Rocky Necropolis of Pantalica (2005)

The sites widely differ in their nature, territorial extension and institutions involved in the management of the site inscribed on the WHL; such a phenomenon does not only concern Sicily, since during the 1990s the interpretation of World Heritage has evolved to a great extent. Consequently, a series of places, sites and landscapes have been included on the UNESCO WHL (Rössler, 2006). Thus in Sicily we find: single monuments such as the Villa Romana del Casale in Piazza Armerina; complex and widespread urban systems, such as the Baroque Towns of the Val di Noto; large sites of extraordinary environmental value, such as the archipelago of the Aeolian Islands; sites of historical and archaeological value such as Syracuse and the Rocky Necropolis of Pantalica as well as the Archaeological Area of Agrigento.

In order to highlight the technical, political and structural factors which make the implementation of WHL MPs problematic in their local application, we will mainly focus on two regional sites: the Aeolian Islands and the Valley of the Temples of Agrigento. The reasons behind this choice are numerous and based on three fundamental issues:

- The timing and status of the two MPs
- The significance and peculiarities of the two tourist areas
- The different features of the two UNESCO sites

With regard to the first aspect, the two chosen sites are the only ones in Sicily to present an approved and operating MP for a long enough period to allow an analysis of the effective impacts of this instrument on the same sites and on tourism within them.

As far as the second aspect is concerned, the two areas are considerably different, but, at the same time, need to address the flows and the tourist offer towards sustainable and responsible tourism. The Aeolian Islands represent a landmark for regional tourism; despite the efforts made to “extend the season”, the archipelago is still marked by a huge summer presence and a high offer that, even if well-structured and of good quality, threatens its valuable environmental system. On the other hand, although it is one of the most visited, the tourist area of the “Valley of the Temples” is among those less seasonally adjusted in the region and registers a weak hotel-booking demand that is under the regional average. Finally, both the sites are places where the conflict between preservation and development is very strong and even dramatic.

The third reason behind the choice is based on the considerable structural difference between the two sites: the first is an archipelago inscribed on the WHL for its unique natural and environmental

features; the second is an archaeological site of world importance. Clearly, two sites so different need preservation and promotion strategies that are different, but both aim to increase and change tourism as well as the conflict between preservation and development. At the end, the choice of two such different cases allows us to address various issues and aspects of the implementation of WHL MP in scenarios of potential conflicts such as:

- The Aeolian archipelago and the conflict between mass tourism and sustainability of site;
- The "Valley of Temples" of Agrigento and the conflicts between development and the preservation of heritage landscape.

Despite these differences, both cases show a remarkable gap between the performative model at the core of the WHL MP and the conformative model of the local and regional planning systems in implementing a sustainable policy for tourism development. Such a gap is not just peculiar to the Sicilian region, but can be easily identifiable – in a worldwide review – in other contexts. Currently, this entails that the MPs become passive instruments, only able to implement the actions promoted by other planning instruments; when this occurs, their role in promoting sustainable tourism development is weak if not questionable.

5. The Valley of the Temples of Agrigento

In 1997 UNESCO acknowledged the value of the "Valley of the Temples" and declared it as "heritage of Humanity". UNESCO explained its choice by stating that the area is universally acknowledged for its historical value and it also highlighted that the area is a tangible evidence of a lost civilization thanks to its buildings and the agricultural landscape in which it is inserted[5]. At the time of the site inscription on the WHL, the MP was not compulsory, so the site has been exclusively regulated until 2005 by the Archaeological and Landscape Park Plan of the "Valley of the Temples" (FIG. 1).

The areas identified by UNESCO are relative to the Core area that coincides with the A zone, the most protected in the Archaeological and Landscape Park of the "Valley of the Temples" which manages the site. This area extends over 1,440 hectares and is characterized by the presence of anthropic and infrastructural structures representing the heritage of a period (from the '50s up to the '80s) when the building industry has strongly affected the development of Agrigento (FIG. 2a and 2b) destroying its original bond with the archaeological site and the landscape (Rossi Doria, 2002). The history of the city of Agrigento and its development models have become paradigmatic for the history of Italian urban planning in particular because of the clash between property speculation and heritage of the Greek settlement situated at the edge of the modern built-up area. The contrast became evident and even dramatic with the 1966 landslide at Agrigento, representing a sort of divide in the environmental sensibility of Italian urban planning (Martuscelli, 1966). In an attempt to stop the massive land speculation and the urban sprawl, around the Core area, and to testify to the importance of the Valley of the Temples, a wide Buffer Zone was established; it coincides, once again, with the perimeter of the Archaeological and Landscape Park of the Valley of the Temples (Campioni & Ferrara, 2005).

5.1 Main features and problems of tourism in the area

The Valley of the Temples is one of the most popular destinations of the Sicilian tourist offer. In recent years, the site has registered a presence of about 600,000 visitors (an average of 632,539 between 2003 and 2009) and it is the second in the whole region in relation to revenue: about

[5] In particular these temples are among the most impressive and best preserved of the Greek world. Agrigento has a special place among the classical sites because of the way it has preserved the original imposing site – so typical of Greek colonial settlements – very substantial remains of a group of buildings from an early period, not overlaid by later structures or converted to suit later tastes and cults (Lo Piccolo, Schilleci, Marotta, 2008).

2,500,000,00 € per year[6]. An analysis of the tourist presence in the decade 1999-2009 (FIG. 3) shows a considerable jump between 2001 and 2002, a year when visits more than doubled, increasing from 319,776 (2001) to 683,066 (2002). This is mainly due to a change in the area subjected to a fee payment, that was extended to the whole site[7]. Tourism in Agrigento is less affected by the typical problems related to fluctuations throughout the year which generally marks the tourist activities of the Sicilian region; however, there are still variations: the most busy month for the sites is August (89,592 visitors in 2009) with a daily average of 2,890 visitors, while the least crowded month is January (7,964 visitors in 2009)[8]. So, despite being less evident than in other places, the problem of the seasonal adjustment of tourist flows also affects Agrigento.

Data analysis of the hotel accommodation capacity shows the difficulties of getting visitors to stay in the area. The most interesting data, arising from the analysis, concern an average guests' stay, which is 2.3 days (ISTAT, Italian central statistics institute). Visitors tend to pass through Agrigento; consequently, in Agrigento, the offer of accommodation in hotels is 2,233 beds. The daily average presence, in the Valley of the Temples alone is about 1,750 tourists, with a great discontinuity during the year. Therefore, from an overall data analysis, it is evident that the tourist offer is unable to preserve tourist flows through an offer differentiation. Moreover, the presence of quality tourist facilities is very scarce: there are no five-star hotels in Agrigento, as most of them are just three-star accommodation facilities.

The main issue, arising from the analysis of tourism in Agrigento, surely concerns the low levels of take up of accommodation in the city as well as in the province (Giambalvo, 2007). In order to address this, it is necessary to carry out three convergent strategies: the improvement of general accessibility, the increase and differentiation of tourist offers in a wider area, which is rich of environmental and leisure resources[9], as well as the general improvement of tourist services. Analyzing the trend of arrivals, departures and stays in Agrigento, we observe that the site has reached its maturity i.e. tourist flows tend not to increase; however, the operators' perception is that the site is largely underused (Bazzanella, 2007). The life cycle model of tourist destinations (Butler, 1980 & 2006) identifies the start up, development, maturity and finally stabilization or falling phases. This site has followed the phases of the offer's start up and consolidation; however, such process has not been guided, so it has not fully develop in proportion to its potential. The shortcomings accord with the lack of both a regional and local tourist strategy (Callea, 2007). Also significant is the conflictual relationship that the city of Agrigento has developed with the Valley of the Temples, so that, instead of being considered as a development source, it is seen as a limitation to voracious development and speculation. In fact, "The Valley of the Temples" has not always been recognized, not even by its inhabitants, as an opportunity and a development resource. The inscription on the WHL surely ratifies and certifies the exceptional nature of the site, also defining its economic role in the tourism development of the area. Yet no efficient policy has been undertaken in order to pursue this declaration, which then serves simply a rhetorical purpose.

Moreover, in Sicily, most tourism economies spill over into adjacent areas because of the incapacity of the local tourist system to keep tourists *in loco*. In Agrigento most of the visitors take organized

---

[6] According to the data elaborated by the Department of Cultural Heritage and Environment of the Region of Sicily

[7] A great increase between 2001 and 2002 is due to the fact that in 2001 only the entrance to the Temple of Zeus was considered (the only one subjected to a fee payment until 2002), while starting from 2002 the whole site was taken into account.

[8] Data source: the Archaeological and Landscape Park of Agrigento

[9] With this purpose, the Sicilian Regional Law 10/2005 "Regulations on tourism development in Sicily and urgent financial measures" have been addressed to a tourist system based on "relationality" and forms of alternative accommodation, in order to add new values to the tourist offer. In Agrigento, the regional law considerably affected the redistribution of tourist flows towards extra-hotel accommodation facilities.

tours arriving by bus and leaving the same day. The "informal" tourism, despite its being less detectable than the case of the Aeolian Islands, is noticeable and considerable. Regional studies state that informal tourism in the province of Agrigento reaches a presence equal to 76,6% of the entire provincial tourism presence (Regione siciliana, 2001). The two phenomena of unauthorized building and second homes, particularly evident in this area, have allowed the offer of unofficial tourist facilities which cannot structurally increase the tourist offer, creating unfair competition if compared to regulated structures (Giambalvo, 2007).
The WHL MP, though dating back to 2005, carries out a detailed analysis of tourism in Agrigento testifying to what is said above. The MP defines as the main problem of local tourism the improvement of the general tourist offer, in order to increase the average length of stay in days. The UNESCO site's MP also gives its opinion on the services related directly to the site, which are defined as "insufficient and qualitatively scarce".

5.2 The WHL MP and its interaction with the local planning system

The analysis provided by the WHL MP pictures a situation where an important item of cultural heritage, despite attracting huge tourist flows (it is the second largest in Sicily), is not able to create tangible economic benefit for the area. The MP elaborates a SWOT analysis where some specific issues on tourism are identified:

Strengths	**Weaknesses**
Offer potential represented by several historical, art, cultural and natural resources in the area.	Short average stay time and visits limited to the Temples areas. Tourists flows relatively concentrated in the summer. Current weak offer of accommodation facilities and tourism services. Low number of enterprises working in tourism.
Opportunities	**Threats**
Satisfying tourism demand on each expenditure level, increasing tourist flows within a sustainable perspective. Guaranteeing a minimum quality standard in accommodation facilities as well as in other services. Structuring a network of quality services connected to the Site attraction and able to meet the demand including toilet services, elderly and handicapped assistance, resting facilities, gadgets and souvenirs, parkings, etc. Creation of proper urban services able to support attendance peaks and guarantee a minimum level of guests assistance.	Impoverishment of the Valley landscape and deterioration of the preservation status of cultural heritage. Lack of integration with other tourist circuits and regional tourist offer.

The MP defines, starting from the SWOT analysis, its *vision* for the Valley of the Temples, taking into particular account the Plan of the Archaeological and Landscape Park "Valley of the Temples", approved in 2008.
The three priority targets set in the WHL MP are:

- Protection and enhancement of cultural and human heritage in an 'extended area' approach;
- Site usability in order to improve the accessibility and interrelation with other tourism circuits;

- The Valley of the Temples considered as a driving force of the area's economic development.

Such targets involve seven axes:

- Protection and enhancement of archaeological, historical and architectural heritage, landscape and nature;
- Site accessibility and usability promotion;
- Development of sustainable tourism;
- Promotion and communication of the site image;
- Development of other related economic activities;
- "Cultural re-appropriation" and local community involvement;
- Adaptation of knowledge, monitoring and interaction with other planning instruments.

Of particular interest is the "sustainable tourism development" axis; with regard to this, the WHL MP identifies certain indicators in order to assess the effectiveness of the actions adopted. The proposed indicators are:

- Average tourist stay (from Italy\abroad)
- Percentage of visitors' presence between October and March in relation to the whole year
- Number of current cultural itineraries
- Number of activated training courses for weaving factory operators
- Number of integrated tourist packages offered

If we look at the first two indicators, data on the average tourists' stay and the percentage of visitors' presence between October and March do not show any significant improvement in recent years, showing a low efficacy of the WHL MP in the promotion and development of tourism activities. Although most of the axes of the WHL MP relate to the tourism economy, if we look at the proposed measures, they do really appear as a series or collection of actions which were already formulated in other pre-existing planning instruments rather than as a coherent system of innovative policies. This weakness is mainly due to two factors. Firstly, the clash between the performative model of the WHL MP and the conformative nature of local plans and regulations, whose consequence is to have the WHL MP as a recipient of other plans' actions and previsions. This, paradoxically, gives as a result an 'inverse', and totally inefficient, process of conformity, which is that of the WHL MP in comparison with other local, pre-existing plans. Secondly, MPs – at least in Sicily and thus far – have not been able to generate and/or distribute economic resources as, for example, local development partnership programmes did (Lo Piccolo & Schilleci, 2005), being consequently considered as just a 'second rate' or minor opportunity in the local political agenda.

If we look at the management system and at the number and type of the various agencies involved, the WHL MP of the Agrigento Valley of the Temples works as an integration instrument of the Plan of the Archaeological and Landscape Park of the Valley of the Temples (approved in 2008), established by the regional law 20/2000. With this purpose, the Park authority is also responsible for the management of the UNESCO site.

At the same time, within the Sicilian planning system, the master plan, based on a strictly conformative model, mainly deals with land use. The time which passed between the final editing of the Master Plan (2004) and its approval (2009) represents a further problem in relation to the Management Plan (MP) role. The Management Plan should have a 5-year time horizon, but has to face a Master Plan started in 1997, completed in 2004 (one year before the MP) and effective from 2009 (one year before the MP's horizon).

In addition, even in its contents the Master Plan clashes against some principles of preservation and sustainability. For example, although around the "Park A area", area of maximum protection, we can find a Buffer Zone where the city Master Plan establishes only activities supporting agriculture, in the Park A area of the Valley of the Temples the city Master Plan establishes new roads which contrast to the Park Plan regulating the same area protected by UNESCO (Cannarozzo, 2009). Moreover, the Master Plan ignores the boundaries of the Archaeological Park A area. In this regard,

we notice a contradiction related to the UNESCO area: on the one hand, the Master Plan states that the archaeological area is one of the major resources of the region, yet on the other hand, it shows its inability to enter a dialogue with the body responsible for the site management.
Although the Master Plan agrees with some general principles of the WHL MP, it does not effectively implement any real action or policy. In fact, as said before, in the Sicilian planning system the Master Plan mainly concerns and regulates land use, leaving the action and intervention phase to other planning instruments, which are forced to conform to its guidelines and previsions. For this reason, the Master Plan has a weak interaction with the WHL MP.
For instance, in the general report, the Agrigento Master Plan aims at reducing the vehicular traffic which burdens the Valley of the Temples because of the tourist buses. In this regard, the Master Plan provides a reorganization of parking and access areas, establishing shuttle buses services to get access to the Valley of the Temples; however, the Master Plan does not provide specific answers to questions regarding the reorganization of tourist buses as well as their parking and possible integration with other tourist services. To this end, the plan includes two strategies: on the one hand, it attempts to separate the Valley of the Temples from heavy traffic flows; however, on the other hand, it does not provide a new organization of the access system, with provisions that guarantee neither the sustainability principle nor the target to develop a tourist circuit beyond the visit to the archaeological site.
The UNESCO WHL MP also has to deal with other instruments affecting the site area:

- The guidelines of the landscape territorial plan
- The general town planning scheme (Master Plan) of Agrigento
- The PIT n. 34 “Valley of the Temples” (a local development partnership programme)
- The Agrigento Area Contract (another local development partnership programme)
- Special protection systems
- The Plan for the Archaeological and Landscape Park of the Valley of the Temples

In particular, the WHL MP faces (or even clashes with) instruments of different nature as some are instruments addressed to landscape protection and others are instruments addressed to economic planning and investments distribution. This is in a context where economic planning has often a prominent role which overwhelms spatial planning, thus becoming an instrument working against the contents of regulatory land-use plans (Lo Piccolo and Schilleci, 2005).
At the same time, the WHL MP, elaborated in 2005, cannot take into account a series of instruments established after that time:

- The Strategic Plan for the city of Agrigento
- The landscape plan of the environmental context n.10: Sicilian central-southern hills

The increase in the number of planning instruments working with different aims and times does not allow the MP to elaborate effective interventions and actions. Basically, the MP has to dialogue through instruments regulating the land use and instruments offering investment strategies. However, it is neither able to address choices on the land use nor to address economic activities. Therefore, the MP has to accept and implement what has been elaborated by other planning instruments and programmes. Thus, the promotion and protection system of the UNESCO sites runs the risk of becoming another constraint for the area, without representing an added value for local economies. Moreover, it reinforces a tendency to randomly ‘cut and paste’ elements and strategies included in other plans rather than an integration among several levels and instruments starting from clear, shared and indefeasible targets.
In general terms, the WHL MP recognizes in several plans a shared attitude towards the UNESCO site of the Valley of the Temples. In detail, both the Master Plan and the PIT (integrated land-use planning, which is a sort of local development partnership programme) aim to consider environmental qualities as the fundamental basis for promoting development in Agrigento; they also seek to build a system of rules and occasions to strengthen the usability and to allow the preservation and enhancement of attractions. However, beyond this statement of principle, the plans in force in the Agrigento area work in a dramatic environmental situation: the massive urban

development (legal and illegal) surrounding the Valley of the Temples (FIG. 4). Therefore, today, although the government instruments promote a protection policy, they do not propose any strategy or action able to heal the serious situation afflicting the Valley of the Temples area which has become, since the Agrigento landslide (Martuscelli, 1966) an example of the ruin caused by the Italian building sector.
In this context, most of the actions promoted by the WHL MP are the result of the systematization of actions coming from other planning instruments, in a difficult interaction between the performative attitude of the WHL MP and the non conformity of outcomes and the non implementation of local plans which are – legally and procedurally – based on a conformative model.

6. The Aeolian Islands Archipelago

The Aeolian Islands were inscribed on the World Heritage List in December 2000[10] as natural heritage item. According to the justification for inscription on the WHL, the islands' volcanic landforms represent classic features in the studies of evolution of vulcanology world-wide[11]. The Aeolian archipelago represents the top of the emergent volcanic apparata (partially active) of a submarine magmatic arc in evolution; thanks to this, the archipelago is considered as a source of primary interest by Earth Sciences.
Its natural beauties, vulcanological and geological features as well as its history witnessed by ancient writers and poets, need effective protection and heritage preservation and also policies able to conserve the integrity of the values for which the Aeolian Islands were inscribed on the WHL. The Aeolian Islands' UNESCO MP analyzes the archipelago's natural beauties and the action programmes addressed to prevent the tourist flow from undermining environmental resources in order to guarantee their long-term preservation and enhancement (FIG. 5). In other words, it aims to be considered as a project for the islands' revitalization pointing at the stimulation of sustainable development, through innovative planning. Moreover, within this perspective, we should consider certain site management actions started before the WHL MP's drafting, such as the interruption of pumice mining activities to preserve the local identity.

6.1 Main features and problems of the tourist system

The recent evolution of both economy and production show that the Aeolian Islands, based on primary industry in the past, are now connected to tourism activities. Agriculture has largely lost its economic value; with the exception of vineyards, capers and some olive groves, trees groves have been largely abandoned[12]. With regard to fishing, the Aeolian Islands boast a great tradition. The Aeolian fishing trawler fleet consists of about 150 boats. This allows ten fishermen cooperatives and many family units to earn their living.
The Aeolian economy is strongly based on tourism. Activities related to trade and other services represent a good source of employment. However, they are activities subjected to seasonal demand, producing critical effects on the local reception system and services. Trade, hotels and restaurants represent 45.6% of local entrepreneurship, in terms of local units' number. This is the reason why a balanced and sustainable development of the Aeolian local economy should be supported by

[10] The deliberation of UNESCO was undertaken on December 2nd, 2002 in Cairns, Australia, after six years of inquiry.
[11] The Aeolian Islands, representing an outstanding example of ongoing volcanic activities, with their scientific study from at least the 18th Century, have provided two types of eruptions (Vulcanian and Strombolian) to vulcanology and so have featured prominently in the education of all geoscientists for over 200 years.
[12] The situation is different in the island of Salina, where agriculture is still present along with Malvasia wine production, which has a national and international reputation.

policies of territorial marketing aiming at the seasonal adjustment of tourist flows.
Despite an increase higher than 30% in the number of local units in these sectors, from 2003 to 2006 their relative influence, compared to the overall economic structure of the Aeolian islands, dropped in trade by 33.5% to 31.9% and in hotels and restaurants by 14.8% to 13.6% (Ruggieri, 2008). Moreover, the rate of accommodation capacity (ratio between available bed-places and resident population per 100 inhabitants) shows alarming data as from 2004 to 2005 a drop of 13 points has been registered. If in 2004 there were 38.95 bed-places available for 100 inhabitants, that in 2005 became 25.94. It is evident that the offer related to the official accommodation capacity is falling. According to Cooper et al. (2005), this shows that the tourist product has reached its maturity stage that will probably be followed by either a decline or renewal.
However, the Aeolian tourism market boasts highly respectable figures both at provincial and regional level. According to AST (Azienda di Soggiorno e Turismo - Stay and Tourism enterprise), the Aeolian Islands cover 10% of arrivals and presences registered in 2005 in the province of Messina and 2-3% of those identified at regional level the same year.
AST data do not offer an adequate description of the Aeolian tourist flows as they do not consider unofficial arrivals and presences, known as the so-called "informal" tourism. According to a recent study on 2003 tourist flows (Scaletta & Siracusa, 2004), that year the total of unregistered presences reaches 234,056, about 60% of the official figure. The calculation of the number of bed-places available daily in the market is not official (4,800) and provides a figure similar to the official one (4,870), as it would require to double the official estimates in order to reach a more realistic assessment of presences (TAB. 1). Moreover, if estimates are made of electrical energy consumption and solid urban wastes production, we observe an increase in "the quantification of the informal" with peaks at 10 times higher than official figures - an overall presence higher than one million in August 2003 in the municipality of Lipari (Parroco & Vaccina, 2005). We can also consider data concerning the number of pleasure craft units. The phenomenon is highly developed and considerably affect Aeolian tourism. From recent research, it emerges that for each official resident tourist there corresponds approximately one nautical tourist between April and September (Mendola & Ruggieri, 2005). According to the data provided by OTIE[13] analyzing 2007 flows, the total nautical presences are 90,720 of which 76,073 are Italian and 14,648 are foreign. This implies that the estimate of tourists grows to include approximately another 360,000 units, on the basis of an average of 4 guests per pleasure craft unit. With regard to the profile of the average tourist (official plus nautical presences), 93% is Italian, with a high prevalence of people coming from Sicily (32.18%) and Southern regions (42.4%) rather than Northern regions (almost 20%), while only 6% comes from foreign countries.
The monthly distribution of arrivals and presences shows the seasonality of tourist flows. According to Parroco & Vaccina (2005), 60% of arrivals and presences per year is concentrated in the summer months, 40% is distributed over the two intermediate seasons, while winter months show values almost close to zero. The seasonality of tourism demand in the Aeolian Islands is considerably stronger among Italian tourists than foreign tourists. Thus, the definition of a tourist offer that is seasonally adjusted and addressed especially to the attraction of foreigners would help to limit the high seasonality of Aeolian tourism as well as its impact and overload effects.
The different instruments and studies operating within the archipelago area show how the current pattern of tourism, marked by a high concentration of visitors in certain months of the year, creates many problems of environmental impact (Parroco & Vaccina, 2005; Ruggieri, 2008). Another issue which arises concerns the significant quantity of "informal activities" in the tourist system, that is the informal accommodation of guests subject to payment (Volo, 2004). This category of tourists strongly affects the environment (one only needs to think of the increase in water consumption) without paying taxes. The condition allowing this particular form of tourism is the

[13] OTIE (Observatory on Tourism in the European Islands), (2007), Flows of nautical tourism, the Aeolian Islands, www.otie.org

presence of a huge building capacity that is not utilized, due to the 70s master plans and the unauthorised building, which is still fairly widespread in the archipelago (FIG. 6).

6.2 The WHL MP and its interaction with the local planning system

The MP of the Aeolian Islands (Angelini, 2008) is divided in seven parts: the first part represents the preparatory phase for the MP and presents the criteria which merited the inscription of the islands on the WHL, the methodology adopted and the responsible subjects; in the second part we find the analysis of the Aeolian heritage; the third part deals with the rich biotic and geovulcanological heritage and offers an analysis of the structuring aspects of the socio-economic system (economy, tourism, etc.), of the urban system, landscape, transport, and services (water, electric energy and wastes); the fourth part goes into matters related to protection and risks; in the fifth part some intervention strategies are proposed in order to preserve, enhance tangible and intangible resources and in order to guarantee a sustainable and environment-friendly development of the archipelago; the sixth part outlines control and monitoring strategies for these intervention proposals; in the last part, the position of the Aeolian Islands in the WHL is strengthened, establishing further merit criteria related to the site seen as a natural good and also proposing a new candidature of the site as cultural heritage.

In order to achieve a high level of efficacy in the implementation, it would be prior and crucial to reach a collaboration and effective involvement of institutions and local actors in the site protection and preservation programs. This leads to the involvement of *stakeholders* having specific and general interests in the implementation of the area revitalisation in order to achieve sustainable development policies.

The prior targets identified by the Aeolian Islands' WHL MP are the following:

- Establishment of a body responsible for the management of the site inscribed on the Unesco WHL
- Effective identification of the *mission* in the promotion of socio-economic development and recognition processes for the population of the "Outstanding Universal Value" of the area.
- Conversion of strategic policies into management targets, coherent and integrated, in relation to: historic and art heritage conservation; urban and landscape conservation; economic and tourism development; social ability to allow a person to identify him\herself in his\her own cultural heritage.
- Ability to assess and readdress the policies carried out through a dynamic and cyclic control and monitoring system.
-

The WHL MP identifies some specific targets in relation to the tourist system:

- Stimulation of responsible and deseasonalized tourism
- Conservation and enhancement of natural ecosystems
- Conversion of the management model for services and resources towards autonomy and sustainability
-

In order to obtain an overall analysis of the endogenous and exogenous factors, crucial for Aeolian tourism, the WHL MP elaborates a SWOT analysis where some specific issues on tourism are identified (Ruggieri, 2008):

Strengths	*Weaknesses*
Presence of fishing traditions Specialization in services-producing sector Environmental and landscape constraints Natural resources of particular value Archaeological resources Museums and itineraries Typical wine and food products Traditional architecture Wide offer of apartments	Condition of insularity Ineffective transport system and consequent tourists' need of external services Considerable seasonality in tourism Mass tourism Strong presence of "informal" accommodation structures Strong seasonality and impact of pleasure craft tourism
Threats	*Opportunities*
Instability of tourism demand Lack of control over tourist flows Imbalance of other economic activities Impact of mass tourism on environment and services	Possible access to Community and regional funds Use of UNESCO logo Environmental protection and naturalistic usability Increasing tourism demand related to natural phenomena Good quality product

If we look at the local administrative system, the Aeolian Islands archipelago consists of seven islands divided into four administrative divisions (municipalities). The biggest municipality is Lipari, including the small islands of Vulcano, Panarea, Stromboli, Alicudi and Filicudi. The other island composing the archipelago is Salina that is further divided into the administrative divisions of Malfa, Santa Marina di Salina and Leni. Consequently, the Aeolian Islands are regulated by several planning instruments that, over time, have assured the area management and preservation against invasive and not eco-friendly anthropic uses.

The fundamental protection instrument is the Landscape Territorial Plan for the Aeolian Islands, in force since 2001. The plan covers the whole archipelago, deploying a complex series of analyses also studied in the drafting of the UNESCO MP. The overall analysis led to a protection regime which considers cultural and landscape goods as a synergistic whole. This instrument, elaborated since the end of the 1970s, has largely contributed to the protection of the Aeolian Islands, in accordance with a regulation banning new building constructions. Alongside the Landscape Plan acting within the same domain of the UNESCO MP, we recently find (2006) the Provincial Plan of Messina that, compared to the Landscape Plan, regulates a wider area. The Plan sets the minor islands within the domain of the central Tyrrhenian cities.

Numerous actions and instruments adopted in the area have differently involved the archipelago: the PIT n.12 (Eolo, Scilla and Cariddi), the GAL (Gruppo d'Azione Locale - Group of Local Action) for the Aeolian Islands and the Territorial Pact for the Aeolian Islands. These last three instruments are local development partnership programmes collecting economic resources; despite their limits, they are crucial for the renovation and management of the local contexts (Lo Piccolo & Schilleci, 2005) and they should be integrated in the management system proposed for the UNESCO site. In this respect, the PIT of the Minor Islands just identifies a series of actions able to increase tourist offer especially in relation to archaeological sites' usability.

The Communal regulatory planning system, considering the administrative borders, consists of four distinct domains:

- Malfa, with a Building Program (the earliest version of the Master Plan) effective since 1992;

- Leni, with a Master Plan Scheme (which is a document preliminary to the Master Plan) effective since 1991;
- Santa Marina di Salina, with a Building Program effective since 1981;
- Lipari, with a Master Plan Scheme effective since 2010.

The Lipari Master Plan is the only one among the instruments just listed that could have been able to effectively interact with the WHL MP. However both the drafting and the approval of the Lipari Master plan have been protracted for about twenty years, with high level of inefficacy. Despite this, some targets and previsions included in the Master plan are consistent with the WHL MP and its purposes. In detail, the Lipari master plan identifies the archaeological areas and several other interesting tourist sites and defines as an historic centre any anthropic settlement of the Minor Islands. This seriously reduces the areas allocated to the construction of new residential buildings, in order to promote sustainable development and to stop or to reduce the excessive number of houses that are seasonally utilized and serve to boost "informal tourism" (FIG. 7). The master plan, according to general regional planning strategies (Regional Law 10/2005), proposes some small rewards based on volume in order to convert existing structures into hotel and extra-hotel accommodations facilities. The area of former pumice quarries, whose closure is underlined as essential to keep the site in the WHL, is the biggest available area to increase the tourist offer by setting-up a museum related to the pumice stone. This action, promoted by several bodies such as the *Soprintendenza* (Provincial Department of National Heritage) and the PUMEX (former mining company), is meant to increase deseasonalization.

The analysis of the instruments' chronology and nature shows how difficult it is to integrate the local planning system with the WHL MP which, also because of the lack of management authorities, run the risk of becoming an instrument only able to reassert the constraints already imposed by other instruments. The issues just underlined highlight how it is structurally impossible, in the current situation, to support an effective integration of plans regulating land use and instruments for the management of UNESCO sites.

7. Conclusions

In the analysis conducted by Blandford (2006) on the criteria and guidelines for WHL MPs in the UK, it is evident that one of the key-issues is the use of the WHL MP in order to boost chance in the nomination process rather than in the following phases of management and plan implementation. Thus, it is confirmed the significance of "join the club" as the main target rather than the importance of the following stages (once the target of being inscripted and labelled in the WHL is reached). The object of this article is the analysis of what comes after the target of the inscription on the WHL has been attained, focusing the attention on the improvement of the tourism offer and management.

The inscription on the WHL is generally considered a factor which contributes to an increase in the site popularity, in its "appeal" and consequently in tourism promotion. In our experience, however, this is just a rhetorical assumption, as data do not confirm this. In the Agrigento case, the analysis of trends in the tourist flow and hotel occupation in and around the site does not show any significant increase after the promulgation of the WHL MP. With regard to the trends in tourist arrivals in hotels, we do not observe any particular increase: the only encouraging data concern guest average stay going from 2.37 days in 2004 to 2.71 in 2007. In relation to extra-hotel structures, we register a steeply increasing trend boosted by regional policies: however the trend does not show jumps or discontinuity that can be related to the WHL MP. The comparison of tourism trends with the MP targets shows its real ineffectiveness, which is to be essentially ascribed to its structurally scarce integration with other plans and planning policies. In the case of the Aeolian islands, the historical series 2000-2009 of tourists' presence has not shown a progressive trend starting from the

inscription of the Islands on the WHL. This datum[14] proves that the inscription on the WHL does not seem to have affected Aeolian tourism. Moreover, the strong decrease in the average stay (ratio between the number of nights spent to the number of customers) has declined from 4.52 (2000) to 3.9 (2009). The trend surely confirms that one of the main targets of the UNESCO MP for the Aeolian Islands has not been reached and has even been neglected.

In the analysis of the two Sicilian case studies, our first questions were: how much do the WHL and the Management Plan influence the tourist offer, shifting it towards a "sustainable" approach? and how does the MP orient or collaborate with other planning instruments\systems (and vice versa) in order to enhance more effective and sustainable tourism policies? According to our analysis, the WHL MPs have a slight influence on those tourism policies addressed to increasing and qualifying demand. In fact, the qualification of the tourism demand should be reached through:

a. deseasonalization (The Aeolian Islands);
b. long and medium term cultural tourism (The Aeolian Islands and Agrigento);
c. tourism spread over the whole reference area (The Aeolian Islands and Agrigento);
d. emerging activities and "informal tourism" (The Aeolian Islands and Agrigento);
e. responsible tourism (The Aeolian Islands and Agrigento).

These actions have not been implemented yet, as the natural and simple effect of the UNESCO WHL logo is not able to stimulate, by itself, the implementation of the above mentioned strategies, without a systemic supranational planning policy integrated with other local planning systems and strategies.

Blandford (2006, p. 360) highlights that UK MPs have used a multidisciplinary, performative approach to assess the wide range of pressures that have and will influence change in the WHL sites, achieving a balance between conservation, tourism and public access, contribution to local communities, and contribution to sustainable economic growth. However, this does not occur in many other national and regional contexts, such as Sicily according to the case analyzed thus far, where the local very conformative planning regimes clashes with the performative approach of the WHL MP model. In fact, the latter applies in practice through the promotion of non-binding spatial policy programmes and the consequent promotion of initiatives and projects which prove themselves capable to 'perform' (Alexander and Faludi, 1989; Faludi, 2000) an agreed collective strategy, while local planning systems and instruments are still based on a conforming approach and a (formal) regulatory tradition.

If the 'implementation gap' between plans and interventions in the real world are inevitably endemic (Mastop, 1997), a conformative approach in the implementation of supranational guidelines and plans in local contexts is destined to fail. The reason is that local plans will look at a plan such the UNESCO WHL MP as a statutory plan, and here all the differences at the normative level arise, impeding any real fulfilment. On the contrary, in a performative approach "the prime concern should not be with whether or not the plan is followed, but with whether the plan plays a role in those decision situations in which it was meant to be used" (Mastop and Faludi, 1997, p. 820). In fact, how much a WHL MP can coordinate existing planning instruments in national contexts depends on two main issues: 1. how much the WHL MP is also identified as a declaration of principles as well as an operative framework through which responsible authorities and national and local communities are engaged in an active protection, in an adequate preservation activity as well as in a compatible enhancement able to comply with the identity and cultural needs of the protected area; 2. how much it is integrated at a normative level with local laws regarding land use planning. The paradoxical result, in our experience, is that in the Aeolian Islands as well as in the Valley of the Temples, the MPs – instead of assuming a 'leading role' in promoting innovative strategies and actions – become a 'collection' of objectives and measures which derive from other (already adopted) planning instruments and programmes, in an 'inverse' process of conformity.

---

Blandford (2006, p. 360) underlines that – whilst recognizing the primacy of conservation – in the WHL MP it is important that other "drivers" and "agendas" are fully understood by interfacing with all stakeholders. However, in our cases, the MP is more effective on preservation and conservation rather than on the promotion of effective actions aimed to increase local economies and sustainable development. Moreover, the actions for site promotion fall within the competence of other programs and policies and the MPs are engaged in their implementation and "sponsorship". In both cases (Agrigento and Aeolian islands), the MPs are slightly connected to the Master Plans, whose choices and management have (negatively) affected the tourist system, favouring for instance the "informal" dimension of this economic sector, through a great presence of second homes and illegal buildings. Actually, in both cases the issues related to the tourist system stem from the peculiarities of the anthropic settlement and from the recent urban development processes: second home and illegal buildings that on the one hand threaten environmental resources and on the other hand increase negative factors in the tourist offer, whose main problem is "informal" tourism. This aspect is not covered by the MP and is only partially faced by regulative plans. Once again, the interaction between the MP and other plans and planning policies is weak but necessary for the immediate future in order to achieve the desirable changes identified earlier in this paper, including sustainability in tourism.

This is a technical, but also political, problematic aspect, which underlies a substantial anomaly: on the one hand, the WHL MPs have to manage sites that differ in nature and size and that are built according to a single (performative) model; on the other hand, the fragmentation of local (regional) urban planning laws establishes a series of different processes, procedures and time-horizons[15], based on a regulatory and conformative tradition. It is evident that a higher and more effective coordination or integration between the two approaches is difficult but necessary. If the inscription on the WHL puts the site (and respective national and local governments) under the international spotlight, this 'observation' process has two consequences: the increase of the image promotion and the increase of protection and related policies in order to promote sustainable development, which works as a deterrent (representing the threat of being removed from the WHL). For this reason, the monitoring process should not just take into account the preservation initiatives (as happens up to now), but also the level of interaction between the WHL MP and the other local plans, in order to 'bridge the gap' between the performative nature of the former and the conformative tradition of the latters, which could be re-oriented towards a more performative approach in their implementation, under the guide (and eventually the threats) of the UNESCO policy.

Getting the Balance Right? Mining Interests, Planning Law and Sustainable Human Development in South Africa

Mark Oranje[1]

Abstract: In the 140-odd years after the first diamond was found in South Africa in 1866, mining catapulted the country from a predominantly agrarian society into a modern industrial nation. For the biggest part of this period, mining drove and planning law and human development followed. This 'order of importance' was largely the result of the huge wealth and influence of the mining houses, the (perceived) importance of the sector for the development of the country, and the broader skewed power dynamics of colonial and apartheid rule.

Over the last decade, national government enacted new legislation by which it has attempted to ensure that mining is made more serviceable to broader societal reconstruction and development. A key component of this new legislation has been a provision to ensure that mining companies make tangible contributions to socio-economic development and human settlement in 'mining areas'. At the same time, significant amendments have since the late 1990s been made to municipal governance and development planning legislation with the aim of ensuring progressive, assertive strategic planning by municipalities. Recent legal pronouncements are also adding further clarity to the mining and land use planning interface.

While these and other significant steps have been taken in the legal and policy domains to set the balance right, very little actual, empirical research has been done to establish what the outcomes 'on the ground' have been and if, how and to what extent the *actual* interface of mining companies with planning law, socio-economic development and human settlements has changed as envisaged.

In this exploratory study, the extent to which the changes in the legal framework have actually assisted in ensuring (1) a greater degree of balance, and (2) a more symbiotic relationship between mining, planning and human development, is explored in a predominantly rural districts with a long mining history. Use is made of (1) interviews with key role-players in the mining industry, municipal and provincial government, the private sector and communities, and (2) documented material. Key questions that are explored are: How do mining companies interact with municipal planning and planners, spatial planning law and sustainable human development and settlement reconstruction?

[1] Professor and Head of Department of Town and Regional Planning, University of Pretoria, South Africa, 0002. Tel: +27124203535. E-mail: mark.oranje@up.ac.za.

How is this different from pre-1994 kinds of engagement and interaction? Is there *real* change, or is it just a case of legal compliance?

1. Introduction

In the 140-odd years after the first diamond was found in South Africa in 1866, mining catapulted the country from a predominantly agrarian society into a modern industrial nation. Even today, mining remains a key driver of South Africa's economic development. This situation is also set to undergo little change, for, after more than a century of intensive extraction, South Africa is (still) regarded as one of the richest countries in the world in terms of mineral reserves, and one of a handful of countries with mines with more than 100 years of remaining service at current exploitation levels (Leon, 2012).

The exploitation of the country's mineral wealth has, however, since its earliest days been a highly contested activity. Largely as a result of the huge wealth and influence of the mining houses, the (perceived) importance of the sector for the development of the country, and the broader skewed power dynamics of colonial and apartheid rule, mining drove and planning law and human development followed for the biggest part of the country's modern history and mining extraction period. Key questions that have been raised in this contestation revolve around issues of benefit, cost and ownership – i.e. who owns the resource, who gains from its exploitation and who carries the cost? Of major concern in these regards has been the impact of the activity on its host community and the manmade and natural environments in which it is located. While there have been significant direct and indirect economic benefits for many such communities, there have also been high costs in the form of (1) pollution and mining-related diseases; (2) environmental degradation; and (3) the introduction of value-systems and human interactions that challenge existing norms and values and human rights abuses.

Over the last two decades, the mining sector of its own accord, both locally and abroad, has made enormous strides in cleaning up its act and setting up a guiding framework of what is regarded as good practice in (1) the protection and enhancement of human rights and (2) co-development of host communities in mining areas (see International Council on Mining and Metals, 2003; 2009; 2011 and Ruggie, 2011). From its side, the South African government has introduced a new progressive legal framework by which it has attempted to ensure that mining is made more serviceable to broader societal reconstruction and development (see Republic of South Africa, 2002; 2004; 2008). A key component of this new legislation has been a provision to ensure that mining companies make tangible contributions to socio-economic development and human settlement in 'mining areas'. At the same time, significant amendments have since the late 1990s been made to municipal governance and development planning legislation with the aim of ensuring progressive, assertive strategic planning by municipalities.

Recent legal pronouncements have also added further clarity to the mining and land use planning interface.

Notwithstanding the many positive changes the mining sector has made in the wake of the new voluntary and legally-binding codes of conduct, the industry is often still treated as if it has not changed its ways, is a super-exploiter and is not complying with stated legal provisions. At the same time, the persisting levels of deep poverty and the slow pace of broad-based economic transformation in the country, coupled with the seemingly extraordinary profits made in the mining sector, has seen the activity becoming a key discussion point in debates about the future of the South African economy. A strong theme in these discussions has been that of nationalisation of the industry, and if not that, then ways of securing a greater tax income from the activity.

Despite (1) the introduction of the legal and voluntary steps to 'set the balance right'; (2) the importance of the industry for the South African and regional economy; and (3) the prominence of the debates out the future of the sector in the political arena, public debates and the popular media, very little actual, empirical research has been done to establish what the outcomes 'on the ground' have been and to what extent the *actual* interface of mining companies with planning law, socio-economic development and human settlements has changed as envisaged.

In this exploratory study, the extent to which the changes in the legal framework have actually assisted in ensuring (1) a greater degree of balance, and (2) a more symbiotic relationship between mining, planning and human development, is explored in a predominantly rural district with a long mining history. The questions that are explored are: How do mining companies interact with municipal planning and planners, spatial planning law and sustainable human development and settlement reconstruction? How is this different from pre-1994 kinds of engagement and interaction? Is there *real* change, or is it just a case of legal compliance? It is hoped, that in undertaking research that considers the sector from a more multi-pronged angle, a contribution will be made towards moving the debate beyond disdain, rhetoric and critique, and into an arena where more informed debates and decisions about the future of the sector and the communities that are closely tied to its prospects, can, and will be had.

The structure of the paper is as follows: The next section provides a brief overview of the changes in the legal framework in the mining-community-municipality interface in South Africa post-1994. This is followed by a short discussion of (1) the district in which the research was conducted and the reason for its selection as the area in which to do the study, and (2) the methodology that was used in the study. The next section provides the data, which is followed by a discussion of the findings in terms of the three questions that the research sought to answer. This is followed by a series of concluding thoughts.

2. Changes in the Legal Framework Governing Mining, Municipal Planning and Land Use Management post-1994

The most significant change in the legal framework governing mining activities, has been the introduction of the *Mineral and Petroleum Resources Development Act, Act 28 of 2002*, which, in accordance with its preamble, seeks to *'… make provision for equitable access to and sustainable development of the nation's mineral and petroleum resources'* (Republic of South Africa, 2002: 2). Key objectives of the Act in pursuit of this goal are *inter alia* (1) the protection and management of the environment and the management of the country's mineral and petroleum resources through environmentally-responsible exploitation, so as to ensure economic and social development for current and future generations; (2) the promotion of local and rural development in the areas where mines are active, and the social upliftment of communities hosting, affected by mining and that supply labour to mining operations; and (3) far greater participation in and ownership of, and receipt of benefits from the mining industry by historically disadvantaged persons, i.e. Black South Africans, women and persons with disabilities.

In order to achieve the stated objectives, the Act, Amendments to the Act and Regulations passed in terms of the Act *inter alia* make provision for:

- The severing of the mineral rights from the owner of the land and placing these in the hands of the State and the introduction of detailed legal procedures to apply for prospecting and exploitation rights;
- The prescription of regulatory and progressive compliance measures, including conducting an environmental impact assessment and the preparation of an environmental management programme or plan by those seeking to acquire a prospecting, mineral, exploration and production right;
- The development and setting of a *'housing and living conditions standard for the minerals industry'*;
- The development of a broad-based socio-economic empowerment Charter to set the framework, targets and time-table for ensuring that previously disadvantaged South Africans enter and benefit from the mining industry;
- The provision of assistance to historically disadvantaged persons to conduct prospecting or mining operations;
- The making of provision for communities to lodge applications for mining rights on land that they own or will receive ownership of; and
- The placing of a requirement on successful applicants for mineral rights to (1) contribute to the socio-economic development of the areas in which they are located, as well as the communities hosting, affected by and/or supplying labour

to their mining operations, *inter alia* by the preparation of and reporting on the implementation of *Social and Labour Plans* (SLPs); (2) assist with the realisation of the objective of ensuring active participation in, and drawing of benefits from mining and beneficiation operations by members from historically disadvantaged groups prior to embarking on mining operations; and (3) ensure community participation in mining operations by affected communities (Republic of South Africa, 2002; 2004; 2008; Department of Minerals and Energy, 2004; Leon, 2009; Booysen *et al*, undated.).

In accordance with Guidelines prepared in support of the Act, the SLPs that have to be prepared must include (1) comprehensive Human Resources Development Programmes that include Employment Equity Plans; and (2) Local Economic Development Programmes that will ensure poverty eradication and upliftment of the communities living in the areas where mining is undertaken (Department of Minerals and Energy, 2004: 4). This is *inter alia* to be ensured through the involvement of these communities in mining and beneficiation actions and by setting out processes to save jobs in the case of the downscaling of operations and/or mine closure (*Ibid*). The Guidelines also clearly indicate that SLPs must ensure consultation and cooperation of the mining company with (1) the municipalities in the areas in which they are located, as well as (2) municipalities in the *'major labour-sending areas'*, in their planning and development activities, notably in the preparation and implementation of their Integrated Development Plans (see the discussion on these plans in the next paragraph below) (Department of Minerals and Energy, 2004: pp. 8; 2007: pp. 16; Mabuza *et al*, 2010). A later set of Guidelines (Department of Mineral Resources, 2010: pp. 17) go further and specify that, *'The mine or production operation must furthermore consult with other economic development frameworks like Provincial Growth and Development Strategy (PGDS), National Spatial Development Strategy (NSDS), National Priorities and any other relevant stakeholders. The Mine or Production Operation must, through consultation with communities and relevant authorities provide a plan. The plan should be in line with the IDPs of the mine communities'.*

In addition to the Mineral and Petroleum Resources Development Act, Act 28 of 2002, the post-1994 government passed the *Local Government: Municipal Systems Act, Act 33 of 2000 and* a set of *Regulations* in 2001 in terms of the Act, which *inter alia* provide for the preparation of a strategic five-year plan by every municipality in the country, called the *Integrated Development Plan* (IDP) (Republic of South Africa, 2000; 2001). This Plan, which includes a *Spatial Development Framework* (SDF) that is meant to both reflect the spatial outcomes as envisaged by the IDP, is also meant to provide strategic guidance in the preparation and implementation of the municipality's land use management system. Both the IDP and the SDF have to, in terms of the Municipal Systems Act, 2000, be prepared in a highly participatory way involving all stakeholders and seek to align and integrate the plans, strategies, investment and spending proposals of (1) all spheres and sectors of government active in the municipality, as well as (2) all

the major private sector actors in the municipality (Republic of South Africa, 2000; 2001). As such, this Act, mandates the involvement of mining companies in the preparation of municipal IDPs and SDFs, and binds them to locating and programming their infrastructure investment and spending plans in accordance with these plans.

Two recent court cases have provided another dimension to the interaction between mining companies and the State (see Business Enterprises at the University of Pretoria, 2012). In *Maccsand (Pty) Ltd versus City of Cape Town and Others (12 April 2012)*, the Constitutional Court made a clear distinction between mining and land-use planning legislation and ruled as follows: While the Mineral and Petroleum Resources Development Act, Act 28 of 2002 (MPRDA) is concerned with mining, the Land Use Planning Ordinance, 1985 (LUPO), in the Western Cape Province governs the control and regulation of the use of all land. These laws serve different purposes within the competence of the spheres of government charged with the responsibility of administering them: While the MPRDA governs mining, LUPO regulates the use of land. However, the exercise of a mining right granted in terms of the MPRDA is subject to LUPO. An overlap between the two functions occurs due to the fact that mining takes place on land. This overlap does not constitute an impermissible intrusion by one sphere into the area of another, because spheres of government do not operate in sealed compartments. There is nothing in the MPRDA suggesting that LUPO ceases to apply to land upon the granting of a mining right or permit. By contrast, Section 23(6) of the MPRDA proclaims that a mining right granted in terms of that Act is subject to it (i.e. LUPO) and other relevant laws. The implication of this pronouncement is that, while permission may be granted to mine, mining cannot take place until the land in question is appropriately rezoned. The South African constitutional order provides that one sphere of government or organ of state may take a decision whose implementation may not take place until consent is granted by another sphere of government or organ of state within whose area of jurisdiction the decision is to be executed. Each is concerned with different subject matter. If consent is refused, it does not mean that the first decision is vetoed. The authority from whom consent was sought would have exercised its power, which does not extend to the power of the other functionary. This is the case, despite the fact that the effect of the refusal in those circumstances would be that the first decision cannot be put into operation. This difficulty may be resolved through cooperation between the two spheres of government or organs of state. Failing which, the refusal may be challenged on review.

In the second case, *The Minister for Mineral Resources versus Swartland Municipality (12 April 2012),* which was heard together with *Maccsand v The City of Cape Town,* the judge concurred that a party who is granted a mining right or permit in terms of the MPRDA may start mining operations only if the zoning of the land in terms of LUPO permits it.

3. The John Taolo Gaetsewe District Municipality: Overview and reason for inclusion in the study[2]

The John Taolo Gaetsewe District Municipality is one of five District Municipalities in the Northern Cape Province, and is located on the northern border of the South Africa with Botswana. The district, which is 27 293km² in size, comprises three Local Municipalities, the Gamagara, Ga-Segonaya and Joe Morolong Local Municipalities. According to the 2007-Statistics South Africa Community Survey, the district is home to 172 454 persons, which put in the 47th place out of the then 52 District Municipalities in the country in terms of population size. The density of settlement is very low by national and international comparison (7 persons per km² in 2011). Other than sizeable population concentrations in one large regional town (Kuruman) and six smaller towns (Mothibistad, Bathlaros, Moropeng, Kathu, Olifantshoek and Dibeng), the bulk of population (more than 50%) is spread across a vast landscape dotted with approximately 185 rural villages and medium to large farms. Nearly 44% of the population live in deeply impoverished conditions in the Joe Morolong Local Municipality, primarily on land which once formed part of the former apartheid-era Bantustan of Bophuthatswana. The district is marked by a harsh semi-dessert climate with annual temperatures ranging between 8ºC and 28ºC, and an annual rainfall ranging from 500mm in the south-eastern part of the district to 200 mm in the north-western part.

The district was for many decades home to large asbestos mining activities, which came to an end in the early 1980s. Large iron ore and manganese reserves and deposits of a range of semi-precious stones in the area, coupled with the commodities boom of the last decade, has seen a resurgence and massive expansion of mining in the area. Most of the mines are open-cast, with the district also being home to one of the largest open-cast iron ore mines in the world (Sishen), from where iron ore is carried by train on one of the longest iron ore railway lines in the world to the port of Saldanha, 861 km away on the south-western coast of South Africa. The last decade has also seen the arrival of multi-national mining companies in the area, largely in pursuit of the manganese reserves in the area. In addition to the mining industry, and its associated transport and logistics sectors, the two other, far smaller economic activities in the area are extensive agriculture in the form of cattle and game farming, and subsistence agriculture.

The *reason for selecting this district as area in which to do the study* is as follows: The author was part of a team that was appointed to undertake a review of the Spatial Development Framework of the district in 2011. This appointment provided the ideal opportunity to not only get access to (1) an area that is not only far removed from the major urban complexes of the country, but also (2) to the many stakeholders that would need to be interviewed in the kind of study that was envisaged. In order to ensure sound research ethics, the author (1) obtained informed consent from the project manager in

[2] The information discussed in this section was obtained from the *Spatial Development Framework* of the John Taolo Gaetsewe District Municipality (John Taolo Gaetsewe District Municipality, 2012).

the municipality to undertake the study, and (2) throughout the study, explained the dual-focused nature of his questions, interviews and requests for data to all interviewees. Given the emphasis in the preparation of the Spatial Development Framework on producing something that would be to the benefit of all that live and work in the district, which is also the reason for undertaking this research, no clashes of interest were encountered.

4. Methodology

Use was made of two sources: (1) documents and (2) semi-structured interviews. The former consisted of (1) planning documents, notably plans, policies, strategies and development frameworks prepared by the John Taolo Gaetsewe District Municipality, the Local Municipalities that fall within the area of the jurisdiction of the district and the Northern Cape Provincial Government; and (2) information on the activities of mining companies as provided on the websites of mining companies. The *interviews* entailed (1) one-on-one interviews; and (2) focus group sessions with representatives of the mining companies active in the area, municipal and provincial officials, consultants, local politicians and traditional leaders. These interviews were informed and enriched with information gained from a series of public participation meetings, conducted as part of the review of the John Taolo Gaetsewe District Municipality. All the interviews and public participation meetings were held in the period March 2011-February 2012.

While the documents and interviews provided a wide and a rich source of information on a myriad of issues and aspects surrounding the mining industry, the emphasis throughout the data-gathering and analysis session fell on exploring the way in which mining companies interfaced with the State, communities and each other in response to, and in accordance with the legal requirements for involvement with and support of: (1) the integrated development planning and implementation activities by municipalities and provincial governments; (2) the Local Economic Development plans, projects and programmes of municipalities and communities; and (3) the sustainable long-term development of the district. As such, the data gathered was both (1) quantitative (i.e. dealing with economic growth, human settlement formation and change and environmental indicators); and (2) qualitative (i.e. the views, opinions, concerns, aspirations, hopes and dreams of those interviewed) in nature.

5. Findings

The findings are structured under four themes: (1) views of the representatives of the mining companies active in the district; (2) views of representatives of provincial and municipal government officials and municipal councillors in the district; (3) views of community and traditional leaders and community members; and (4) documented evidence of investments by mining companies in the district.

5.1 Engagements with Representatives of the Mining Companies

All of the representatives that were interviewed were fully aware of the (new) legal requirements on mining companies and specifically, their own operations. In in a number of cases, interviewees indicated that they had good working relationships with (1) officials and councillors in municipalities, and (2) traditional and community leaders in the area. References were also made to stakeholder-structures on which they served and the involvement of the mines in (1) initiatives by organs of state and communities to initiate and support local economic activities and to increase job creation in the areas in why were located; (2) the provision of bursaries for learners in the area; (3) the construction and maintenance of infrastructure in the region, including the very costly maintenance and upgrading of local and regional roads; (4) the provision of housing; and (5) the construction of community facilities, such as clinics, class rooms and sporting facilities. While the level of enthusiasm for this involvement in the area and its people varied from very keen to mere compliance, there was not a single interviewee who expressed the view that such investments and contributions, while sizeable, should not be made.

What did, however, emerge in a number of interviews, was a distinct irritation, which in some cases was closer to a real frustration with a number of aspects around the way in which the public/State sector worked. These included (1) the perceivably far more laid-back approach and much slower speed at which 'things moved along' in the public sector; (2) the lack of adequately trained and committed officials to give full and real expression to the requirements of the new laws; and (3) the lack of integration and implementation in the plans, decisions and funding decisions in the three spheres of government.

In a number of the interviewees respondents from the mining sector would explain their frustration by explaining where they were coming from. What these explanations emphasised was the enormous difference between the nature and scale of a mining operation and the public sector and the way one had to function to survive in the mining sector. This business environment included (1) 300-plus carriage-iron ore trains of more than 3.2 km long; (2) hundreds of iron ore and manganese trucks running 24/7, all year-long; and (3) huge amounts of capital had to be invested in the construction and maintenance of mining infrastructure (i.e. ground preparation, erection of structures, machinery and training and relocation of workers), while being super-exposed to a highly competitive business climate and erratic fluctuations in supply and demand on a global scale. This harsh business and operational climate, it was argued, meant that miners that wanted to 'make it', and flourish in the sector had to show enormous dedication to task, work very hard and long hours, have an astute focus on what matters for the company and the mining operation, a pragmatic, can do, no-nonsense approach and have an acute awareness of the bottom line. This meant that there was no room for error or any waste of time, which it was argued, meant that it was often very hard to

fathom the very different work environment, lack of plan implementation and seemingly very different work ethos in some areas of the public sector.

On another note, a concern was expressed that (1) the enormity of the costs involved in setting up a new mine, and (2) the investments and contributions required in terms of the new mining laws, meant that older, larger, capital-rich companies were at a huge advantage relative to smaller, emerging, start-up companies who had not yet built up such reserves or access to such funds. This, it was argued, ran counter the government's objective of boosting small and medium-sized companies and new, start-up Black-owned enterprises. Coming to the same question from another perspective, it was argued by an interviewee that it is for this reason that it would not be the larger, established, in most cases global, companies that would contravene the legal requirements, but rather the smaller ones. A number of interviewees argued along similar lines that (1) the huge financial and reputational risk for global mining companies associated with contravening human rights and environmental regulations, and (2) the far longer period of exposure to both the world of mining and the rules and regulations that go with it, meant that these companies were far better than the newer, younger companies at ensuring legal compliance (see also Mabuza *et al*, 2010 for a similar finding).

With regards to the recent court cases that had the effect of requiring of mining companies to ensure that their surface activities complied with the land use rights on the properties on which they were located, there were no qualms. In most cases, representatives from the mining companies had met with municipal officials and appointed town planning firms to undertake the necessary steps to ensure that they complied with the relevant land-use controls. In others, the mining companies had instructed their legal sections to undertake the necessary steps to ensure that they were legally compliant with regards to the land use regulations.

Finally, and somewhat unexpectedly, even though prompted on the matter, none of the interviewees indicated that there was any form of corruption or bribery in the interface between mining companies and officials and leaders in the public sector or community leaders or members that they were aware of. This does of course not mean that it does not take place; it may simply mean that the mining companies have no interest in stirring controversy or engaging in debates and issues that have no direct, positive outcomes for their operations, and that could land them in costly litigations.

5.2 Engagements with government officials and councillors in the district

In the case of these role-players, the views regarding the mining industry were more mixed. While there was a generally positive view towards the industry, and a real appreciation for the endeavours of the mining companies in complying with the legal requirements, there was a clearly expressed wish for the municipality and the community to benefit more from mining activities. In addition to this, a frustration with the way in which mining companies disposed of their legal requirements was expressed

by a number of interviewees. This frustration revolved around mining companies, while spending the required components of their turn-over in the area, doing so (1) in an *ad hoc* way, and (2) in accordance with the commitments and timing of the mining company, and not necessarily in terms of what the municipality wanted to see done/invested at a particular point in time and space/place. While the Municipalities in the district (the District and the three Local Municipalities) had at various points set up economic development forums consisting of the mining companies, community members and other stakeholders in the district, these often only lasted for a short while and/or did not integrate their actions with those of other structures, especially so the planning units in the Local Municipalities in which they were located.

Officials tasked with preparing the legally required Integrated Development Plans (IDPs) and Spatial Development Frameworks (SDFs) for their municipalities, also complained about the lack of disclosure on the side of the mining companies as to their envisaged and planned future activities/operations. This not only made the 'forward planning' by municipalities difficult, but also meant that the identification and/or setting aside of land for especially housing for workers in the mines and the planning for massive infrastructure investments, could not be done, or where it was done, was done on a hunch, and not based on 'real figures'. The result of this was (1) housing shortages when new mining operations were initiated; (2) a mushrooming of informal settlements and contraventions of land use rights; and (3) shortages in key municipal services – refuse removal, water and sanitation and electricity. As for compliance with land use regulations, while officials expressed the view that mining companies cooperated very well in this regard, the concern was expressed that it does require from the municipality to take a strong position that 'the law will be enforced' and to actually do so. The situation according to one of the officials was simply that, '*while mining companies will in most cases comply with what the law requires, they in some cases needed to be reminded of this obligation'*.

An area in which a high level of unhappiness was expressed by not only municipal, but also provincial officials was the impact of the mining operations on the roads in the district and the wider region. The key challenge here was that the roads were planned for 'normal rural use', not for hundreds of heavy, fully loaded mining trucks moving across them on a daily base. Given the high costs associated with road construction and maintenance, and the huge investments required in social investment in the country post-1994, and especially so in some parts of the district, the State simply did not have the funds to keep roads in a running order by themselves. While it was indicated by both officials in the provincial and municipal governments that the mining companies often assisted with the upgrading of roads, this was generally done in an *ad hoc* way and not based on, or driven by a comprehensive roads master plan. In addition to this, the view was expressed that the mining trucks were working to the detriment of other economic activities in the area by often causing long delays on the roads to and from, and in the district, and by taking huge trucks through the central business district of the major town

in the area (i.e. Kuruman), in the process hurting this retail, education and administrative hub. Finally, the trucking industry was said to have led to a massive increase in prostitution and associated social ills in the central business district of Kuruman and also increased levels of air pollution in the region.

As for the question of improper behaviour or corruption in the dealings between the mining companies and officials, again, while it was stated in a number of interviews, that it may happen, not a single interviewee indicated that they themselves were aware of such activities in their areas of work. One of the officials wagered the opinion that, due to the urgency of mining companies to get their operations up and running, and the slow pace at which decisions sometimes move in the public sector, it may be that mining companies may have been tempted to nudge the process along in improper ways. The official was, however, quick to add that there were no such cases that he was aware of.

In a number of cases, it was mentioned by officials that unresolved questions and tensions (1) amongst councillors and (2) between councillors and traditional leaders around the economic development of the district and the future spatial development pattern of the district, have made planning for the district difficult, and has not been served by mining companies speaking to, and seeking to address the needs of individual leaders who often had very different views about the future.

5.3 Engagements with the community and traditional leaders and community members

In the case of these interviewees, while the views were generally still more located on the positive side, they were far more mixed. While nobody complained about the economic activities and jobs the mining industry had brought to the area, there was a high degree of unease at the fact that only some benefitted and not more or all of the community members. While some community members expressed the view that they lacked the skills to be employed in the industry, and that special education programmes needed to be put in place to ensure this, there was a also a view that the companies *'brought in their own workers form elsewhere'* and were not interested in employing local labour in especially the better paying positions, irrespective of how well they were trained. Rather than wait to be employed by mining companies coming in from outside, a number of local community members and traditional leaders indicated that they were interested in undertaking their own mining operations.

A number of community members indicated that they were not necessarily interested in working in or on a min, but saw secondary economic opportunities in the prevalence of the mines and their workers in the area, notably in the areas of agriculture (food production) and housing provision and road construction. Making use of these opportunities, they argued, however, required capacity building and financial support, which they believed should be provided. At the same time, they indicated that

preferential procurement practices should be put in place to assist local small-scale, start-up companies.

A number of community members expressed concerns about the levels of pollution caused by the mining industry in the area, notably the dust from the mining dumps. In addition to this, many references were made to the damage caused by the asbestos mining in years gone by, which has, despite rehabilitation activities, rendered many parts of the district inhabitable, and also led to respiratory diseases (asbestosis) and numerous deaths. It was especially the combination of having to suffer the negatives of the industry (pollution), while not being offset by receiving greater benefits from the activities that many felt to be *'just wrong'*.

In a few cases, the view was expressed that while the mining companies were involved in (1) the construction, upgrading and maintenance of municipal infrastructure provision (notably water and sanitation services) and roads and (2) the building of class rooms, community halls and clinics, more should be done in the deeply deprived rural areas with the funds generated in the mining industry. On this score, it was stated that the dominance of the mining industry meant that many members of rural communities, especially the youth, yearned for a high-paying job in the mines and were no longer interested in doing what they had done for generations, i.e. agriculture. The high levels of water-usage by the mines, and the pollution of the mining activities of especially the groundwater reserves in the district, were seen as further aggravating the situation, and leading to a growing reliance on the mining sector for jobs and an ever-greater loss of connection to earlier ways of making a living with their associated traditions and indigenous cultural practises.

In the case of the community members, there were clear signs of suspicion amongst a number of interviewees regarding the interactions between mining companies and government. It was often grimaced that corruption and unfair advantaging does happen, but again no one single case could be mentioned as to where it had actually happened. In one of the community meetings, it was argued that there is not enough transparency in the interactions between representatives and mining companies, notably in the local economic development forums on which both groups served, and that this had to be addressed by at least making the minutes of forum meetings available to the public.

5.4 Investments by mining companies in the district

This analysis revealed that mining companies active in the district have made hundreds of millions of Rands of social investment in the area[3], *inter alia* in the following: (1) the

[3] Unofficially a figure of more than R500-million (approximately $62) being invested by mining companies in the district over the last ten decade (2000-2010) was mentioned in an interview with a manager of a mine in the district. Officially, Kumba, the largest mining operation in the area, invested R134 million in 2010 and R73.6 million in 2011 respectively on the implementation of social and community development projects, and a total of R264.6 million on the implementation of its Social and

construction and upgrading of schools, class rooms and hostels at schools; (2) the provision of support for early childhood centres; (3) the provision of bursaries for learners in the district to study at tertiary institutions; (4) the provision of support to libraries; (5) assisting with the establishment of a higher education institution in the province; (6) putting in place internship and mentoring programmes in the mining industry for youths from the district; (7) the provision of one-stop business support services; (8) the sponsoring of sport activities and events and the upgrading of sport facilities; (9) the construction, upgrading and maintenance of municipal infrastructure, especially water provision and sanitation services, in the district; (10) the provision of mobile health units, support with the construction of clinics and primary health care services; (11) the setting up and support of community farming activities; (12) the provision of assistance with the establishment and development of new small-scale, local enterprises; and (12) the making available of technical expertise (e.g. engineering services) to under-capacitated municipalities; (BHP Billiton Development Trust, undated and Kumba Iron Ore, 2010; 2011a; 2011b).

6. Discussion

The study sought to explore the way in which mining companies interface with the State, and communities in response to, and in accordance with the legal requirements for involvement with and support of: (1) the integrated development planning and implementation activities by municipalities and provincial governments; (2) the local economic development plans, projects and programmes of municipalities and communities; and (3) the sustainable long-term development of the areas in which they are located.

The findings suggest that in the district that was studied, the interface, while not perfect, is far removed from the negative image that the often down-beat headlines around the sector may suggest. By and large, the interface is approached and experienced in a positive way. In addition to this, the mining industry was found to be (1) providing employment opportunities and livelihoods in an area with otherwise very little other economic activities; and (2) making a significant contribution towards the provision and maintenance of municipal services, local economic and community development ventures, education, bursaries and sport facilities and socially beneficial activities in communities. As for the law, mining companies did what the law prescribes in what could be described as an engineering efficiency-mode. There is just way too much to lose by not doing so in terms of retraction of the mining licence (the right to mine) and the danger of reputational risk. It is, however, in this careful pursuit of legal compliance that a major concern lies, *viz.* in doing what the law prescribes and not more or less than that, the spirit of the legislation and the real reason, of ensuring a joint, collective approach towards planning and development in an area, may not be served. It can very

---

Labour Plan commitments and enterprise development in the period 2006-2011 (Kumba Iron Ore, 2011a: pp. 47 and 2010: pp. 13).

easily become an individual pursuit of each mining company of admittedly socially and economically very beneficial objectives, but without the 'bigger bang' that collaboration between the different mining companies could have achieved.
In addition to this, while the investment by the mining companies is crucial, it is only one part of the story – the other parts lie with the public sector and the community. Should especially the public sector, especially in cases where communities are deeply impoverished and hence not be able to contribute little else but their time and labour, not deliver what and when they can, the input by the mining sector will have far less of an impact than it could have had. Relating this to the Integrated Development Plans and Spatial Development Frameworks that municipalities have to prepare to (1) plan and (2) guide the future development of their municipal areas, the reality is simply this: should a municipality not have a very well-directed implementation strategy, and stand strong as to where investment has to be made, mining companies could invest anywhere, in no specific order, and with no specific cumulative impact in mind. In such cases, a mining company could be fully legally compliant by constructing a road segment in an impoverished rural part of the district, and assisting the movement in that segment of the district, but not necessarily be serving the collective or the the longer term development of the district or the wider region.

Associated with this issue, is that of capacity-building of officials and community members about the mining sector, how it works and how to engage it to ensure optimal outcomes for all concerned (see also Mabuza *et al*, 2010, pp. 4). At the same time, there is a need to ensure that mining companies are aware of and familiar with (1) the objectives and enabling, regulatory and supportive legal and policy framework of government, notably with regards to municipal government and (2) ways in which to support especially this sphere of government.

While the piecemeal, *ad hoc*, compliance-driven un-integrated, unsynchronised investment by mining companies may over the short to medium-term result in the municipality not succeeding with the implementation of its plans as envisaged, the result may over the longer term be that (1) living conditions on the ground and (2) economic prospects for communities do not change. Given the widely shared view amongst communities that they are not benefitting enough from the mining activities, this may lead to growing levels of unhappiness with the mining industry and even hostility towards the industry. Clearly this would not be in anyone's interest, and could, given the limited investment in other sectors of the economy in the district, leave the district highly vulnerable, should mining companies either be forced to suspend or close their operations.

While the new legal framework for mining and municipal planning has put in place a series of measures to ensure greater involvement by mining companies in the preparation and implementation of plans and proposals of government and investment in the communities and places in which they are active, the successful implementation of

the law requires leadership on the side of the representatives of the State and affected communities to provide the public voice, direction and vision in response to the very strong voice and intent of the private sector, as presented by the mining companies. One way in which this could be done is through the introduction of a governance model/structure in which the public, community and private interests are all represented in a structure that is focused on (1) the long-term planning for the district; (2) the programming of investment and spending in support of this plan; and (3) the preparation, implementation, monitoring and review of this investment and spending programme. Such a proposal, however, falls outside the ambit of this study, and will, as such, be left at that.

8. Concluding thoughts

While there are without doubt real, negative externalities to the mining industry, this exploratory study has revealed that mining companies operating in the district that was studied, are not mute to these, and have approached the new legal requirements placed on the mining industry in a positive way and are complying with these requirements. What the study, however, does suggest, is that while the new laws are a good start, more will have to be done, with a view to 'up-scaling' the legal regime to ensure (1) greater synergy in the investment by the State and individual mining companies in mining areas, and (2) that communities living in mining areas, enjoy a greater share of the benefits of these activities. Far more research in mining areas, such as that undertaken in the study is, however, required before such steps are taken.

Acknowledgements

The author would like to acknowledge with sincere thanks (1) the assistance of Mr Gerrie van der Westhuizen in securing the interviews and meetings with interviewees in the district, and providing transport to and from many of these engagements; (2) the community members, municipal and provincial officials and councillors who often with great enthusiasm, shared their views and opinions during meetings and interviews; and (3) representatives from the mining industry, who gave their time and shared their views and experiences.

ABSTRACT:

Over the past half a century Serbia experiences major societal turbulences – post Second World War reconstruction, nationalization, frequent changes in constitution, several changes of societal practice (centrally planned economy, self-management, decentralization, etatization at the republican level, etc.), the dissipation of former Yugoslavia, fall of communism and establishment of a multi-party system, privatization, and market economy. All these changes are followed by continuous alterations of the legislation used to guide development and arrangement of Serbian settlements and cities . Spatial and urban planning doctrine and practice adjusts to the overall societal context and its main traits. By mid1980s the planning system in Serbia is highly integrated and participatory in its nature. Unfortunately, the mostly negative circumstances of the 1990s prompted a rather incoherent response from urban and spatial planning professionals and other entities involved in the land development process. The 21st century starts on a positive political footing – the move toward a true democracy, but is obstructed by the dynamics of initial capitalist accumulation and partial and slow implementation of social and economic reforms.

We find the state of Serbian planning quite complex – driven by conflicting professional cultures and highly politicized set of other actors who represent narrow private or commercial interests. The system still lacks the capacity to exert strong guidance and implementation of generally well conceived plans and to promote (let alone protect) public interest. It is our tentative conclusion that the institutional and societal (political and economic) problems are more of an obstacle than the laws themselves. It is not the laws but their implementation that is based on flawed institutional processes and difficult societal circumstances. The legislative activity seems to be only the means of

masking the practice that disregards or abuses the laws. Yet another initiative for changing the current law that is motivated by the investment interests may be indicative of this situation. Meanwhile, the National Spatial Plan of Serbia (voted in 2010) strongly reflect the controversial situation: clearly explained in this brief review, its content is a compilation of wishes, visions rather than quantitative analysis – instead of numeric data, almost 200 strategic priorities (!) are given, showing misuse of both terms of *strategy* and *priority* as well as ignorance of economic possibilities of the country. So, we could state that spatial planning laws and system are not only born but also may be strangled by the societal circumstances, as is the case in Serbia.

The research presented in this paper demonstrates that planning is deeply embedded in the societal context and that urban planning legislation clearly reflects that. The level of political and administrative centralization and the loci of political power seem to exert substantial influence over the planning system and practice. The professional cultures involved in planning -- planners, architects, engineers, economists, sociologists, geographers – are also prominent factors. Those professional groups are in search for self-identity and the boundaries of the planning field. They are active parts in the formation of the Serbian planning doctrine and planning system, often pulling in different direction. While this is a long-standing and ongoing productive and creative "battle" that will certainly continue in future, what is currently needed is for Serbia to settle on an operational and effective practice that would exert some order and care in the process of urban development. Institutional improvements and a firm action in curbing corruption and opportunism in urban transactions and land development would be an important first step.

Key words
Planning system, transition, constraints, planning practice, Serbia.

1. INTRODUCTION

Mentioning Serbia to someone, it will bring out the recollection of social earthquakes that occurred in the past 20 years – wars with neighbours, sanctions, refugees, deep economic crisis, bombing, the fall of the dictatorship, assassination of the Prime Minister and the end of the last two Yugoslavias. In the same period, one system collapsed and another was and is still being established now in the new independent Serbia.

The move from a centralized to a market economy is never easy and it requires from government and citizens anywhere to make difficult choices. But while countries other ex-communist/socialist countries started this process in 1989, Serbia did not initiate its reforms until early 2001. Economic, social and institutional deterioration of the 1990s left a more difficult legacy than the stabilization and reform vagaries facing other countries in Central and Eastern Europe at their transitional beginnings. Serbia unlike those lost its international markets due to international economic sanctions. Also, since the state was going through a long period of deep crisis it was considered politically risky to impose any kind of financial discipline and there wasn't enough strength to build government institutions.

After the democratic revolution in 2000 the path of economic and political reform, if not always linear, has been definite and has had impressive accomplishments especially in making good macro economical climate. However, the Republic today still lags behind many of its neighbors, particularly in the rate of unemployment (over 20%); low per capita GDP of about US$ 3,525; high poverty rate (about 20%); low competitiveness (87th on the world list); striking internal and external imbalance (10.7% inflation rate and high balance-of-payments deficit amounting to 45% of the GDP in 2011); very uneven regional development by European standards (Yugoslav Survey Online, 2011). Unfortunately, now that it has reached the same level of economical development as in 1989, Serbia is standing at the point where the benefits of a market democracy have not yet been materialized and there are still other painful steps ahead that should be taken which will mostly cost already poor layers of society. Foreign direct investments inflow to the country which would mitigate these negative effects and accelerate economical growth is not sufficient (7.7% of GDP) due to Serbia's bad image, existence of risks and high rate of corruption. Social collapse is manifested through the loss of traditional values, break up of family structures, decreased family size (very small birth rate), and growth of single and elderly households. Public interest is unprotected in all spheres – social security, health, education, and spatial policy. Finally, many new laws are introduced (including the new Constitution), but are not well codified and harmonized – the fact that leads to their frequent misinterpretation or misuse.

Recovering from the legacy of 1990s and the transition, Serbia is at the same time burdened with the crimes committed in the name of its nation, swinging between alternatives – right wing and the political centre, on how to deal with it. Directly connected with it stands the future of its European integration, and all that it implies. In general, uncertainties regarding EU expansion as a political issue of EU and compliance with the International Criminal Tribunal for the Former Yugoslavia as a political issue of Serbia could reduce the value of EU integration as a key motivator for reform. Attention to reform is also diverted by the status of the 15 % of its territory called Kosovo and Metohia. Regardless of outcome of the negotiations between internal and external actors, there is a potential for negative and possibly destabilizing effects in Serbia. Other destabilizing factors are coming from constant infighting among democratically oriented political parties which form today's government, weak public sector and transition delays which have created opportunities for a rise in the influence of nationalist and populist parties. This has also resulted in a lack of political and public consensus on every important state issue, key transition policies and consistent political will to make difficult but necessary reforms.

Taken together, there are too many questions and uncertainties regarding Serbia's future in general and a lot of them are highly dependent on international scene and factors. Consequently, there are those that depend on reaching the consensus between internal players which doesn't make them any less complicated or more predictable.

Other questions are: In this country of uncertainty and bad experiences, how is a planner, a spokesman of long-term goals of development, progress and better quality of life, the carrier of mostly good news, being seen by the ones he is planning for? How does the planning work in a country like this? Since the first one is rhetorical, we will try to answer the second question further in the paper.

2. PLANNING IN TRANSITION

In almost two decades that have elapsed since the overthrow of state socialism (or communism) in Central and Eastern Europe (CEE), substantial changes have occurred in the nature, role and functioning of government and other institutions involved in spatial development and urban policy (Taşan-Kok 2004). Urban planning and policy responses of localities have been quite diverse, reacting to specific and often dramatic conditions: political democratization, reintroduction of market principles, the state's fiscal crisis, massive privatization, commercialization, discontinuation of "welfare state" programs, and intensified international financial transactions and investments in urban areas (Tsenkova and Nedović-Budić, 2006). The new circumstances have prompted not only new institutions but also a "new notion of planning" that strives to regain its legitimacy, become more flexible, and adapt to the new economic and political circumstances (Kornai, 1997; Maier, 1994). In those dynamics, an idiosyncratic mix of old, new and innovative practices interjects into the transforming reality (Nedović-Budić, 2001).

The transition of societies and cities from communist to post-communist, therefore, involves — among other things — new systems of government (or governance); new legal, constitutional and institutional frameworks; new economic order; new rules of social integration; and new policy choices for privatization and redistribution of public assets (Harloe, 1996, Andrusz et al., 1996, Offe, 1997)**.** The theory of transition is rooted in the democratization theory that views transition as primarily a political process.[1] Transition specifically of urban phenomena and processes, too, is viewed as essentially political and economic, and perhaps not distinguishable from the transition in general (Holmes, 1997; Wu, 2003).

The case of former Yugoslavia and present Serbia illustrates well the changes that a planning system undergoes in response to the changing political regime, socio-economic system and institutions. While the planning systems in other Central and Eastern European countries have been under transition during the post Second World War and the more recent post-communist period, the Serbian case is particularly heavy in societal dynamics and scope that went beyond what could be considered a typical experience and context of a communist or a post-communist CEE country (Vujošević and Nedović-Budić, 2006; Nedović-Budić and Cavrić, 2006). In Petovar's (2003) words, Serbian cities are "between the state and the citizen." The more extreme variations in how planning profession and practice operated in former Yugoslavia and how they responded to the societal circumstances from 1989 on offer a rich set of observations that would point to the relationships between planning law and its broader context on one hand and planning practice on the other hand. The lingering transition (or what Thomas (1998) terms "the moment of discontinuity"), which in Serbia seems to have been more complex and less predictable than in other post-communist countries in Europe, also allows for an extended

[1] The main features of transition theory are: 1) a comparative approach; 2) an emphasis on democratization (civil society, political society, rule of law and constitutionalism, state apparatus, economic society with an institutionalized market); 3) categorization of the pre-transition situation as authoritarian, totalitarian, post-totalitarian, sultanism; 4) the determining influence of the past on the path of transition (path dependency). The theory also includes a 'moment of discontinuity' defined as a period where the structure and function of a country or city does not correspond to the external environment with which it has to interact. Transition is the period, stage, process, or policy that encompasses this moment and leads from one period or situation to the next (Stark 1992; Thomas 1998).

time period for studying the processes and issues that underlie the formation of a new planning system.

Pajović (2005) maintains that "urban law and system 'spring' from society, are 'born' with a state, and 'grow' in the space for which they are tied, in which they are 'rooted'" (p. 6). Drawing on this notion, the paper focuses on changes in planning legislation in Serbia as the defining factor of its evolving planning system and as an important reflection of the dynamic socio-economic, institutional and political context.

3. PLANNING SYSTEM IN SERBIA: SOME STUMBBLING BLOKS

As in the other ex/communist/socialist countries, former state-centred planning system broke down also in Yugoslavia at the beginning of the 1990s. In the following decade, along with the events we mentioned and the new key factors that transition introduced: political plurality, privatization and market economy, Serbia witnessed a deep crisis of planning, not only because of the chaotic state of the country but also as a reaction to too optimistic and rigid planning that characterized previous period of communism/socialism. There was some effort to meet the challenges of these turbulent times with the creation of the new legal arrangements and the adoption of the Spatial Plan of the Republic of Serbia in 1996 but in fact, the practise showed to be a mixture of old habits and few institutional changes which couldn't match the impact and of the new political, economical and social factors. The planning system as a whole was recognised like a "strange mix of heterogeneous elements from a number of disparate modes i.e. 'crisis – management - planning', 'planning – supporting – wild – market - and-privatization', 'project – based - planning' etc." as in Vujosevic (2002; p.59). This unsuccessful retouching of the planning system that happened in the mid 1990s is well illustrated with the fact that in the next 7 years besides the national spatial plan only 2 spatial plans (one for water accumulation and one regional) have been adopted while 15 others were in different phases of elaboration. Such a system of spatial and strategic planning was characterised as:

- More or less developed spatial-geographical environmental system of criteria, i.e. a way of thinking on the spatial conditions for locating networks and development; Certain crucial mistakes of planners, which we encounter from time to time still do not discredit this planning dimension;
- Utterly undeveloped and inadequately established assessment and evaluation system of the financial-economic feasibility of planned solutions and an even more serious problem of the complete lack of an passable economic development strategy, without which the spatial plan is placed in an unreal economic space and time;
- Not of lesser significance is the social system development out of which should derive the idea on the needs, values and goals of a social community for which we make plans. This system, as yet, has been subjected to a mere improvisation in plans (urbanisation, housing, renewal, public services, special assets);

While Serbia's planning was trying to keep its head above the water, so called Western planning was entering another phase of its evolution. The consequences of globalization, deregulation, decentralization, negative processes in the environment and in the case of Europe its integrations, lightened the necessity of new more innovative

mechanisms and instruments that would shape a more 'plan-led' practice. This has resulted in promoting sustainability, subsidiarity, efficiency, cooperation, communication, coordination, spatial and strategic planning, schemes, initiatives, networks etc.

One year after the democratic change in Serbia, in 2001 works on reforming the system of planning began. The intention was to fill out the gaps created in the previous decade and to answer to the new political, economical, social and spatial context of planning as well as to incorporate new concepts and instruments that were at that time dominating the Western one.

The main carrier of this reform was the new Law on planning and construction, adopted in 2003. The intention was to bring planning closer to the citizens, to make the procedure of acquiring building licence easier and more in a concordance with European practice, to differentiate the public and other land and to make a step towards denationalization and to bring planners back on the scene by giving them more plans to work on and more responsibility (Djordjevic, 2003). Essential task to provide the framework for the prosperous development of the settlement, municipality or the state has been given to the local or state government.

The main pillars of the Law were:

- comprehensiveness (only one law that regulates the matters of planning, land and construction instead of precedent 30; plans are regulating all the conditions for every kind of construction);
- moderateness (instead of solving and defining everything, planning is more concentrated to the public interest);
- adequateness (the list of possible planning answers to different issues is extended);
- responsibility (planners have the professional license issued by the new Chamber of engineers under certain conditions; planners also have full responsibility for the quality of the product - plan);
- applicability (spatial plans contain the Contracts for implementation and urban plans have the mid-term programs);
- simplicity (every construction is welcomed if it is in a concordance with the plan, also there is a limited number of rules which can be interpreted by every professional)
- democracy (the rules determined in plans are equal for all);
- decentralization (every municipality has its spatial plan, rules and conditions for construction depending on its particularities).

Regarding planning the Law, besides its professional institution and planers' licences, regulates planning board of commissioners, Republic Agency for Spatial Planning, system of plans, their contents, institutions responsible for their adoption and hierarchy within the spatial planning, as well as subject, programs, contents, types, adoption and alterations of urban plans and other urban-architectural solutions within the urban planning.

Even though this new legal framework was debated inside the professional circle, other solution wasn't offered. Being given the new rules, not all the planners managed to take full advantage of them. While urban planning seems much stronger and more resistant in Serbia's risk society, spatial planning is far more fragile maybe because the

lack of advantages the other one has: lower stakes, longer tradition, higher number of workers and engagements[2].

Hence, the unique instruction for leading the spatial development of the country as whole and elaborating spatial plans of lower tiers is the Spatial Plan of Republic of Serbia, voted in 2010. But even though the Republic Agency for Spatial Planning along with respectable number of planning experts created the Programme for .Implementation of National Spatial Plan there is still no political will or pressure from planners to really adopt this document and continue the process. It just may be that this process is waiting for the Kosovo and Metohia resolution to definitely mark the borders of the territory that the Plan should regard. This is unfortunate for at least two reasons; first, Serbia's political elite is deliberately postponing the decision on proposed status in order to gain more time to change its position in negotiations, and second is actually a question: who really thinks that in any case scenario (supervised independence or supervised autonomy), Belgrade will really have the right to make strategic decisions about spatial development of Kosovo and Metohia as a part of its territory. In any case, Serbia should as soon as possible gather the strength and the will to create valid and updated long-term development strategy together with sector policies at the national level to steer the economic and overall societal development and offer a relevant framework for the policies and plans of lower levels.

Going down from national level of planning which lacks the system of general strategic policies, we are coming to the void presented in undeveloped regional level. Except the Regional Spatial Plan of Belgrade's Administrative Area, even though they were anticipated in the Law, no other regional spatial plan was made without serious problems. The matter of regionalization which was announced as one of the main topic of the new Constitution slipped from its contents when it was presented and adopted at the end of 2006. Again, there was no strength to deal with such a political issue. Serbia according to the Constitution has two Autonomous Regions (Pokrainas) Voivodina and Kosovo and Metohia. Their institutions have the authority over Region's spatial planning. Also, the Constitution allows the creation of more of these autonomous regions if it is the will of their citizens expressed on a referendum. It is lately that Serbia will not have regional institutions authorised and responsible for regional spatial development and planning for a long time, since the existing counties, at least for now, are as far from building them as these possible but nonexistent autonomous regions. There is however, a type of plans that stands between national and local level and which is being produced - these are the spatial plans for areas of special use. Most of them are concerning the areas of protected nature, water accumulations, basins of lignite and infrastructure corridors. Unfortunately, these along with some other regional policies which are appearing now consist of *ad hoc* measures expected to solve only urgent problems or to justify already made decisions on capital investments. They are being carried out in retroactive and non-coordinated manner, without adequate research provided and financial but even more so, organizational and institutional planning support for their implementation.

Local (municipal) spatial plans, together with spatial plans for areas of special use, are being produced more than ever. Accordingly to the current Law, these plans

[2] See: Nedović-Budić, Z., Djordjević, D., Dabović, T. (2011). The Mornings after…Serbian Spatial Planning Legislation in Context. European Planning Studies, 19(3), 429 — 455.

determine the starting point, the spatial development objectives and land use, organization and protection rules of the planning area. In theory, the number of municipal spatial plans and general plans for municipal centres, both sorts having strategic developmental aspirations can climb up to 189 each. For now they are unique wheals that are turning in Serbia's planning and the main source of our planners' existence. They are accommodating the quantitative development of planning in Serbia but most of them are not showing any shift in methodology which would enable the planning to respond quickly to changes occurring in all societal domains but foremost in the economic sphere. They are backed up by poorly assessed economic and social needs development analyses (sometimes even badly assessed spatial dimension), so that they come down to the physical/geographic definition of the often illusory planning objectives, solutions and propositions. Without applying integrative planning method, more ex post and ex continuo instead of prevailing ex ante evaluation these plans will hardly contribute to quality improvement or more importantly to a prosperous development of the planning area. There lays the chief indifference of the authorities and citizens to participate in elaboration of such plans, let alone be guided by them. The current planning practice is therefore, predominantly planners´ centred; implying that it is the planner who identifies the problems and seeks for planning alternatives. There is little or no room for different interests and ideas, intersectoral coordination and synchronization or partnership between public and private actors. Consequently, there is hardly any room for various stakeholders and shareholders to take part in the planning process and the ensuing implementation phase. Stojkov, Subotic, Djordjevic (2004) are characterizing such a system of spatial planning as:

- More or less developed spatial-geographical environmental system of criteria, i.e. a way of thinking on the spatial conditions for locating networks and development; Certain crucial mistakes of planners, which we encounter from time to time still do not discredit this planning dimension;
- Utterly undeveloped and inadequately established assessment and evaluation system of the financial-economic feasibility of planned solutions and an even more serious problem of the complete lack of an passable economic development strategy, without which the spatial plan is placed in an unreal economic space and time;
- Not of lesser significance is the social system development out of which should derive the idea on the needs, values and goals of a social community for which we make plans. This system, as yet, has been subjected to a mere improvisation in plans (urbanisation, housing, renewal, public services, special assets);

How can we explain this failure of spatial planning and which are the pillars we should build to make it more developed and more stable for turbulent times that could come in the future?

4. CONCLUDING REMARKS

Uncertainty is the only thing we can count on in Serbia nowadays. It seems that never-ending transition and predomination of neoliberal concept in both economical and social issues is still leaning our planning against the wall. Moreover, nothing is clean

from the planners' point of view: who are the main players and referees, which are the rules of the planning game and even where the playground boundaries are. Planning has always been a kind of calculated risk, but here and now it seems like it is just pure and simple risk. The situation is critical on all levels, from national straight to local, due to the absence of the regional level. Most of the planning institutions adhere to a traditional rigid planning model, which is deterministic, inflexible, with fixed land use regulations. The planning system is predominantly planners' centred, implying that it is the planner who identifies the problems and seeks for planning alternatives rooted exclusively in rational methods and objective determinants. There is little, or no room for different interests and ideas and consequently, hardly any room for various stakeholders and shareholders to take part in the planning process and the ensuing implementation phase.

With the transition, planning was supposed to mitigate the negative effects of the new player - market to the public interest. But, seems like our planning didn't find the mechanisms to mitigate those effects created by the market inside it. Planning institutions in pre-transition period were exclusively in public sector. We now have on one side, some big planning institution, partially financed from the state's budget usually with the monopoly over elaboration of one group of plans and on the other side, smaller ones which are being privatized. Both are thrown to the market and are trying to acquire as much engagements as possible in order to secure enough financing. They are producing more plans for less money in a shorter period of time. As a result, these former public agents diverted by the new hostile conditions given by undeveloped market and neo-liberal environment are still presenting traditional rigid planning model, deterministic and inflexible, with fixed land use parameters and regulations. Seems like the turbulent times in which the most important task is to survive didn't give them a chance to develop and to introduce more innovative and novel models in view of participative, strategic and action plan oriented planning.

The other problem lays in insufficient recognition of importance and purpose of planning among politicians and the lack of persuading voices and pressure coming from the profession, as well as in the loss of its legitimacy. To illustrate the confusion and neglect politicians express when planning is concerned we are informing that spatial planning was situated first under the Ministry of Capital Investments, after that Ministry of Infrastructure and now under the Ministry of Environment, Mining and Spatial Planning.

Democratic and economic reforms are not only critical to an overall successful transformation in Serbia, but also inextricably linked to achieving successes in each reform area which also includes planning. Democratic processes are an essential component of Serbia's economic growth and stability, and economic growth is essential to create the conditions for a continuing stable democracy. Reform in the social sector is also necessary in order to secure their better performance. When Serbia as a whole ensures safer environment it is certain that our planning will be able to redefine its priorities and to concentrate on the development of coherent theoretical and methodological framework as a main goal. On that path, following the stable democratic course of the country, planning has the chance to:

- advance the normative-institutional framework,

- make the new generation of national policies which would enforce the overall system of governance and harmonize the work of ministries and other planning institutions at the national tier,
- concretise and operationalize concepts of sustainable socioeconomic, spatial and urban development,
- define clear criteria and indicators to measure the achievements of plans,
- research for defining future alternative development scenarios,
- evaluate the expected short and mid term investment projects and programmes from the standpoint of the long term development needs,
- elaborate and put into operation the up-dated system of techniques and mechanisms which enable a more efficient and reliable development governance.

After showing some positive results in solving these tasks, but continuing to solve them, it is essential to establish some coalition for planning and enhance its legitimacy. So, expert and political forums, but more importantly development of education and training system not only for professionals but also for governmental officials and citizens, will be a step forward in learning planning and learning how to plan and communicate with various stakeholders, understand and articulate their interests in order to advance the relationship between them. This can give more appropriate meaning and contents to integrative approach, sustainability, subsidiarity, efficiency, cooperation, communication, coordination and networks which are currently recognized as empty concepts in our planning.

Hopefully, the system will be strong and stable enough not to collapse again in case of another "earthquake" and able to continue due to inertia with the fewest casualties possible.

STRATEGIES ON THE INVESTMENT AND RESUSCITATION OF ABANDONED PROJECTS

CASE STUDY: SELANGOR & KUALA LUMPUR

Soraya binti Othman[1]

Abstract

Real estate development has an enormous impact on society since it produces shelter as a fundamental need for survival. Ironically, Malaysia's real estate sector has been struggling for more than two decades due to the increase of abandoned projects. Since Asian Financial Crisis, the property sector in Malaysia has undergone tremendous and significant changes over the years. As a result, the land became idle and abandoned projects became a critical issue. The problem has reasonably caused hardships and affected the financial status of many purchasers where majority of the purchasers involved are from lower income and civil servants. Abandoned projects also affect other related industries such as suppliers of construction materials, transportation companies, contractors and consultants. The symptomatic of various problems has reasonably reflected the weakness of government and gave a valuable lesson for them to be extra careful when analyzing the developers' capability before issuing the developers' licenses. A housing project is classified as abandoned when there is no activity at the project site, continuously, for more than six months after the expected date of delivery of vacant possession. Statistically, the plight remains as a major thorn of the society. The enormity of the problems appears to be deteriorating as verified by local media and non-profit organizations that often devote considerable

[1] The University of Tokyo, Tokyo, Japan – sorayaothman@urban.t.u-tokyo.ac.jp

time and energy focusing on the problem. Utilizing the economic stimulus package, a special government agency named Syarikat Perumahan Negara Berhad (SPNB) has been set up in the spirit of resuscitation. Property companies who are equipped with know-how and expertise are also encouraged to have the willingness in the prospect of brownfields redevelopment. Nevertheless, due to the greater risk of the investment, the number of white knights is still insufficient. This could perhaps be due to the fact that the resuscitation of abandoned project is a complicated affair involving various parties namely developer, purchasers, bridging financiers, consultants and land owners. Hence, it is the concern of this research where experts from reputable property developers that have successful and reliable history by being appointed as project revivers were being interviewed. With the existence of related analysis, this study intends to provide proper justification of the factors that lead to the willingness of Malaysia's developers to play the reviver role as part of corporate social responsibility. The study also exposed the important factors, criteria and strategies in determining the best investment decision on abandoned projects and ascertains the project's viability by using investment models and analysis. In conclusion, this study indicated that Malaysia's investors are prepared to invest in abandoned projects bearing in mind that the project is marketable and has investment opportunity. In order to alleviate the problem of abandoned projects, Malaysia should have stringent rules to prevent any company to become developer unless they have certain amount of capital in order to be used as resources for the project development. Moreover, before a project could be approved by relevant authorities, rigid effort is needed to review the viability of the project.

Keywords: Abandoned Project, Brownfields Redevelopment, Real Estate, Developer, Investment.

1. Introduction

Malaysia's property sector has been struggling for more than two decades due to the increase of abandoned projects. The problem has reasonably caused hardships and affected the financial status of many purchasers where majority of the purchasers involved are from lower income and civil servants. Abandoned projects also affect other related industries such as suppliers of construction materials, transportation companies, contractors and consultants. The problem occurred due to the utilization of Sell Then Built (STB) concept in Malaysia, where the purchasers are the financier

of the project as well as the investors who give property developers money beforehand through housing loan with financial institution, with an objective to build residential property. The problem remains as a major thorn of the society until today. Datuk Ng Seing Liong, Immediate Past President of Real Estate and Housing Developers Association Malaysia (REHDA) clarified that the cause of abandoned projects was caused by inexperienced developers who fail to manage cash flow projection and lack of capability to realize the critical situation when the cost overruns involved in constructions. Banks are also not prudent and cautious enough by making errors of over lending to developers (The Edge, 3 February 2009). Poor planning and incomprehensive market study where the mismatch of supply and demand patterns exists in project location also contribute to poor sales performance.

Ministry of Housing and Local Government will focus its attention on helping to revive housing projects that have been abandoned in order to alleviate the difficulties of the buyers as well as the developers affected by such projects. Due to aftermath of the Asian Financial Crisis, the federal government has set up a special agency named Syarikat Perumahan Negara Berhad (SPNB) to rehabilitate hundreds of abandoned property projects nationwide. In Budget 2009, SPNB has been allocated RM200 million of the RM7 billion economic stimulus package for the rehabilitation of abandoned housing projects (The Edge, 13 March 2009). Prior to the seriousness of the issue, in November 2011, an amendment has been made towards the Housing Development (Control And Licensing) Act 1966 where it stated that the parties who are responsible with the act of abandoning property projects will be considered as committing criminal offence where they will be fined (around 83,000 USD to 166,000 USD) or jailed up to three years, or both. Furthermore, under the Government Transformation Program Roadmap, one of the Ministry's Key Performance Index is to revive at least 35 abandoned projects by end of 2012.

Accordingly, in February 2012, the policy has been changed where SPNB will no longer rehabilitate abandoned projects. Another way of taking over and resuscitation of abandoned projects by the ministry is through making appropriate recommendations to the Commissioners of Buildings who will fully manage it by working with both financiers and property developers (being referred as white knights) which can include further injection of funds, improving the design of the houses or even reducing its price. As part of the responsibility, property companies

who are equipped with know-how and expertise are encouraged to have the willingness to invest in reviving abandoned projects as it is certainly crucial for developers to uphold their responsibilities by supporting community welfare. Ministry of Housing and Local Government will only act as advisor to project revivers and other affected parties in order to ensure their full co-operation and commitment to revitalize the scheme. The situation is supported with a speech announced by former Minister of Housing and Local Government, Datuk Seri Kong Cho Ha (2009):

> *"The ministry is not in the position to take over abandoned projects as it will cost a substantial amount of taxpayers' money. Also, they must understand that there are many unsolved problems associated with abandoned projects such as claims from buyers, bank borrowings and other liabilities, which are best left to the professionals to resolve. That is the reason why the ministry takes on the role of a mediator who looks for white knights to help revive abandoned projects."*

In reality, there are not many project revivers who are willing to invest in abandoned projects for the fear that it is a risky investment if compared with investment on new project developments. It is because managing and reviving abandoned project is a complicated affair involving developer, purchasers, bridging financiers, landowners and other parties. In order to reach a consensus, the whole process will take time since each party wants to protect its interest. However, despite all the hurdles and challenges, there are also some project revivers who have sufficient resource and willingness to take over abandoned projects in Malaysia. Therefore, the issues that can be discussed in this research are the factor that prompts the project revivers to revive abandoned projects at first place and their strategies on the investment and resuscitation of abandoned projects. There are limitations on this research, as it was mainly focused on developers who undertake abandoned projects in Selangor and Kuala Lumpur. This paper is based on interviews with the developers who are specialized in property development and always support community welfare by undertaking the task of turning around several abandoned projects. The developers involved were a subset of the larger group who were willing to be interviewed.

The results of this study help to identify the factors that influence project

revivers to revive abandoned projects that could be applied by the government to encourage developers to become white knights while seeking for solutions of abandoned housing woes. With the existence of related analysis, this study intends to provide proper justification of the factors that lead to the willingness of Malaysia developers to play the reviver role as part of their responsibility. The results of this study could also expose the strategies in determining the best investment decision on abandoned projects and ascertain the project's viability by using investment models and analysis.

2. Statistic of Abandoned Projects In Malaysia

In 1988, there were 184 cases of abandoned projects estimated by the Housing Ministry concerning properties worth approximately RM1 billion (Housing & Property, 1988). Subsequently, since 1990 to December 2005, there were 13,286 housing development licenses which have been approved by Ministry of Housing and Local Government. As at December 2005, the ministry has guaranteed that 8,544 of these projects were completed and delivered with Certificates of Fitness for Occupation (CFs) issued. Of the balance, 4,234 are smooth on-going projects, 166 deemed sick, 164 delayed and 168 abandoned.

Table 1: Statistic of Abandoned Projects

State	**Total Abandoned Projects**			
	Until June 2008	**Until February 2009**		
	Number of Projects	**Number of Projects**	**Number of House Units**	**Number of Buyers**
Johor	37	32	9,280	5,419
Kedah	20	9	1,445	709
Kelantan	8	3	519	367
Melaka	14	7	1,109	570

Source: Ministry of Housing and Local Government

Table 1 reveals that the problems are not new, as they have been previously recorded for over two decades. However, the problems still persist and the government has to play its essential role with the increasing problems of abandoned project accordingly. The solution is important in order to discover the way out for many aggrieved buyers who are being kept in the dark and not offered with a clear picture of what was happening. The crucial problem faced by house buyers is the monetary losses and difficulties in servicing the interest on housing loans they have taken as well as paying for monthly house rental.

3. Abandoned Projects

3.1 Definition of Abandoned Projects

Accordingly, Ministry of Housing and Local Government has defined abandoned projects as follows:-

i) Construction and development works on site of the project that has been terminated for the preceding six months or more. Such termination has either occurred consecutively or occurred during the period within which the project must be completed or beyond the required completion period. Completion period means the period within which the developer has to complete the construction of the housing units. For the landed property, the completion period is 24 months calculated from the date of the sale and purchase agreement being executed, whilst for flats the completion period is 36 months from the date of the execution of the sale and purchase agreement; or,

ii) Within the said duration of six months, the developers concerned had been wound up and has been put under the control of the Official Receiver; and,

iii) The housing controller is of the opinion that a particular housing developer fails

to carry out their obligation as a developer.

3.2 Implications of Abandoned Projects

Wachsmuth (2008) stated that abandoned projects have public-health-and-safety argument since they are deemed as plague in the society and could possibly attract vermin, garbage dumping, fires and crime. According to a research made by Mallach (2006), implications of abandoned projects are strictly not fair to the public since the problem has an economic argument and dispute to the country. Abandonment cost cities money and the public has made substantial investments in building infrastructures namely transits, roads and utilities. In addition, abandoned projects not only may generate less property tax revenue themselves but also could negatively affect property values of neighboring buildings.

In Malaysia, Housing & Property (1988) stated that many of the purchasers have already started paying installments to either Treasury, banks or other financial institutions whereby on the other hand, they also need to pay for the monthly house rental. The purchasers are often on the losing end as the laws in Malaysia do not favor victims of stalled projects and they do not have protection under the existing laws. Consequently, abandoned projects have made their way to affect the credibility of Malaysia's government. This is supported by the statistic of projects that are no longer being viable for revival or that no company is interested in reviving it.

Given with the situation, it could signify a loss to the economy and the lack of integrity among the government servants. Radzi and Aminah (2009) mentioned that the abandoned projects reflect the weakness of government and give a valuable lesson to them to be extra careful when analyzing the developers' capability before issuing the developers' licenses. Former Prime Minister of Malaysia, Dato' Seri Abdullah Ahmad Badawi reckoned, *"Profits are privatized, while losses are nationalized."* Thus, it mirrors the depressing circumstances for the nation to bear with the impact of abandoned projects.

In conclusion, developers also receive the impacts of abandoned projects as some of the projects need to be ended due to the finance cutting by the financiers especially when the economy situation is at the worst level. As a result, the

developers are blacklisted by the authority. This situation indirectly gives a negative impact on the image of developers as purchasers can no longer have faith in them. The developers might also find it very hard for them to be active in project development. It can be concluded that the problem of abandoned housing projects in Malaysia is serious and can best be approached through an interdisciplinary frame of reference, taking into account the technological as well as social, economic, psychological and legal aspects of housing.

4. Case Study: Abandoned Projects In Selangor and Kuala Lumpur

4.1 Selangor

Selangor is situated on the west coast of Peninsular Malaysia and it surrounds the federal territories of Kuala Lumpur and Putrajaya. It consists of nine administrative districts and the total land area of this state is approximately 7,956 square kilometer. Selangor is the richest state in Malaysia in terms of Gross Domestic Product (GDP). Figure 1 signifies the statistic of abandoned projects in Selangor Darul Ehsan.

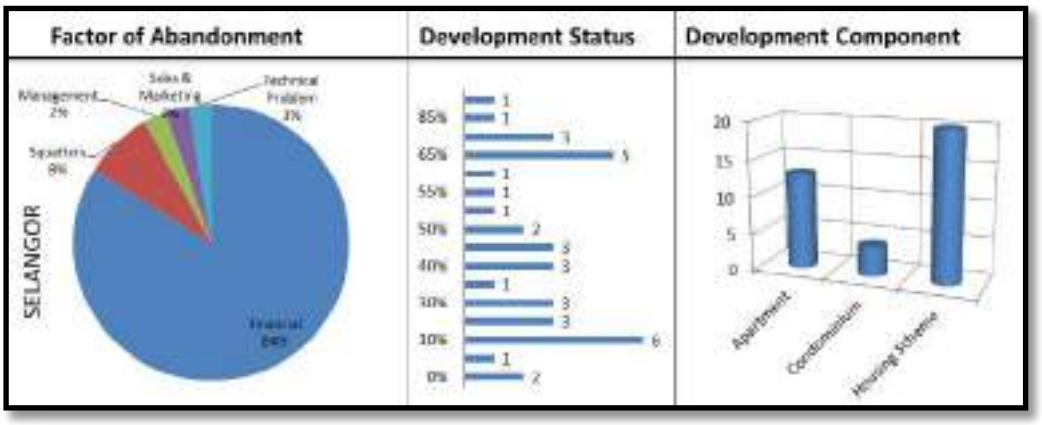

Figure 1: Statistic of Abandoned Projects In Selangor Darul Ehsan

4.2 Kuala Lumpur

Kuala Lumpur is the capital and largest city of Malaysia. It makes up an area of 243.65 square kilometer and it is the fastest growing metropolitan region. Figure 2 signifies the statistic of abandoned projects in Kuala Lumpur.

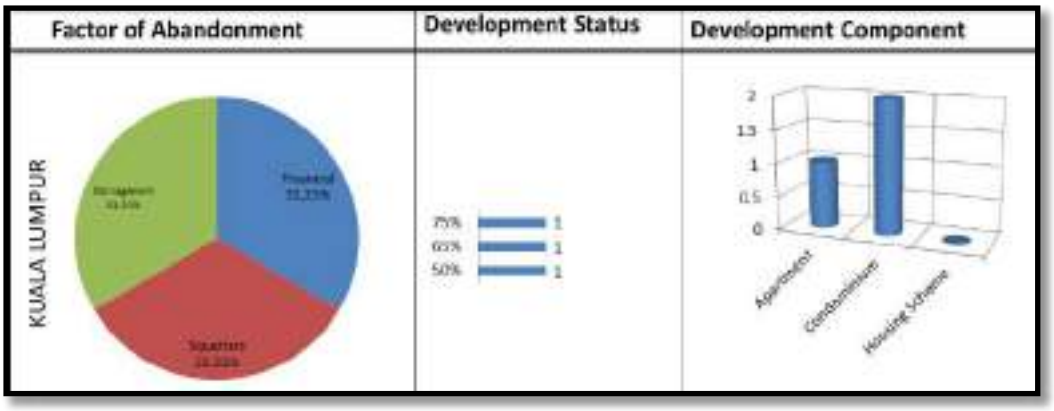

Figure 2: Statistic of Abandoned Projects In Kuala Lumpur

5. Results and Discussion

5.1 Factors Influencing Project Revivers To Revive Abandoned Projects

Based from the analysis, there are a number of factors influencing project revivers to revive abandoned projects in Selangor and Kuala Lumpur. The factors are investment opportunity, goodwill, corporate social responsibility, creating more jobs and a better living environment and helping the existing buyers. It could also be interpreted that profitability, reputation and commitment prompt project revivers to revive abandoned projects. Figure 3 illustrates the summary of influencing factors which successfully encourage project revivers to revive abandoned projects in Selangor and Kuala Lumpur.

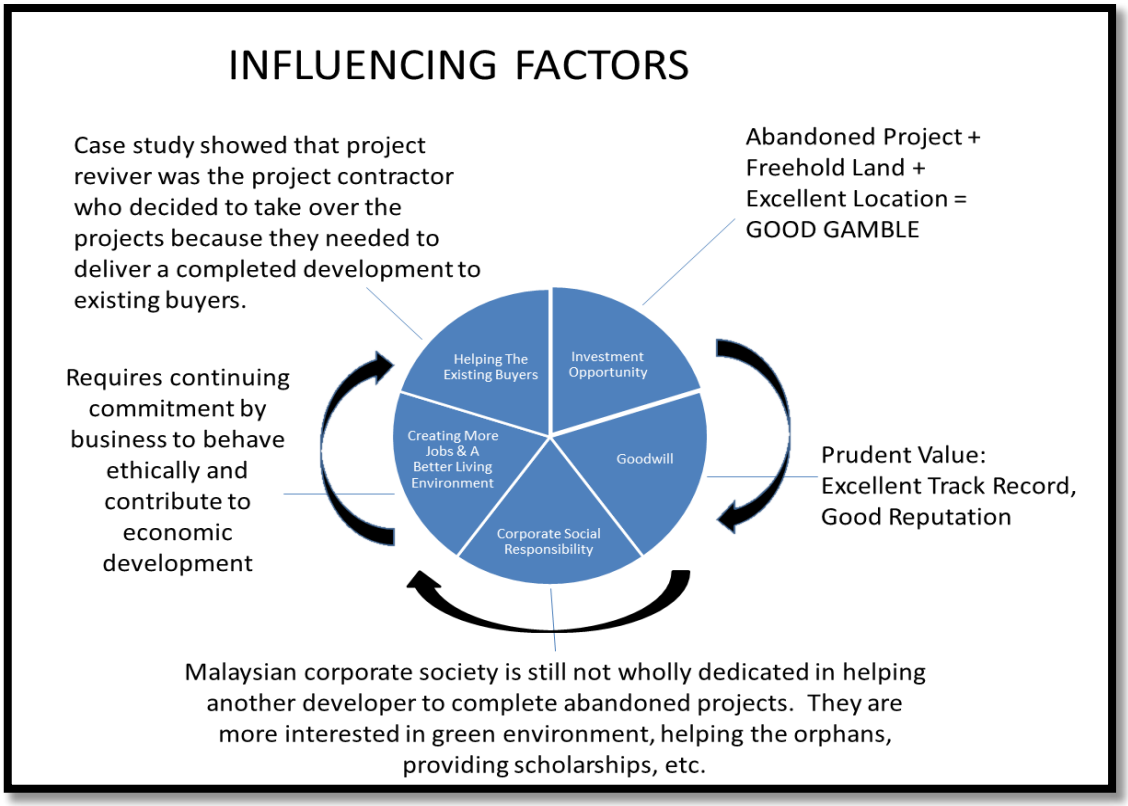

Figure 3: Factors Influencing Project Revivers To Revive Abandoned Projects

From the aspect of investment opportunity, whenever the developer thinks that the revival is viable due to its positive attributes like location, they do not mind to take over the project. Investment opportunity is also essential as it promises high

return to stakeholders. The statement is supported by James A. Graaskamp in his classic 1972 article, “A Rational Approach To Feasibility Analysis”: A real estate project is ‘feasible’ when the real estate analyst determines that there is a reasonable likelihood of satisfying explicit objectives when a selected course of action is tested for fit to a context of specific constraints and limited resources. To sum up, abandoned projects that have viability to be revived also have potential to derive more profits to company throughout the process of investment and resuscitation. The second factor that influences project revivers to revive abandoned projects is goodwill. Goodwill is used to mirror the reality that an ongoing business had some “prudent value” beyond its assets. For instance, the “prudent value” can be referred as a good reputation of the firm that is capable to derive potential synergy within the business. Goodwill is very frequently referred to as an “intangible asset”, that is to say, something the existence of which is spoken of, but is not palpable. In summary, company’s goodwill could grant an excellent track record which is a very significant implication for any property developer.

Besides goodwill, corporate social responsibility which can be defined as a commitment to improve community well-being through discretionary business practices and contributions of corporate resources (Kotler and Lee, 2005) is also one of the influencing factors. It can be concluded that Malaysian corporate society is still not keen and wholly dedicated in helping another developer to complete abandoned projects. Next, the fourth factor is creating more jobs and a better living environment. It requires the continuing commitment by business to behaving ethically and contributing to economic development while improving the quality of life of the workforce and their families as well as of the community and society at large. To sum up, as a member of society, project revivers have the responsibility to provide job opportunities and a high-quality surrounding for built environment. The least influencing factor is helping the existing buyers. In the case of the resuscitation on an abandoned project, the project reviver was essentially the project contractor for the development at the beginning stage of the project. Consequently, the old developer could not put together a payment to the contractor and at the same time, they could not deliver the apartments to relevant parties which are the purchasers. Finally, the project reviver decided to take over the projects after making considerations on the important fact that they needed to deliver a completed development to existing buyers.

5.2 Criteria of Abandoned Projects To Determine Viability

Based from the analysis, there are a number of criteria of abandoned projects that need to be considered by project revivers to determine the viability in Selangor and Kuala Lumpur. It could be interpreted that project revivers must look at marketability factor, level of risk and financial status of a project before deciding to do the resuscitation. The criteria are as follows:-

i) Abandoned Project's Background, according to Gallinelli (2004), when someone buys a piece of real estate as an investment, one must view it as the purchase of an income stream. Therefore, when a property's value lies in an excellent location, we need to translate the subjective views into objective cash flow terms. This is because location is very important in order to establish the marketability factor of the project. In conclusion, several characteristics which are related to abandoned project's background needed to be inspected thoroughly before determining the viability of abandoned projects namely the location, size of site, previous contractor, consultants involved, information of existing buyers, type of development, number of sold and unsold units, bridging loan, end-financing, sales & purchase agreement and land ownership.

ii) Internal Rate of Return (IRR), Jaffe & Sirmans (1986) reckoned that the internal rate of return (IRR) is the rate that equates the present value of the cash flows with the present value costs of investing. Some property developers do not mind to take over abandoned projects with small internal rate of return (IRR). Meanwhile, the property developers who have excellent reputation in the industry are only concerned with abandoned projects that could give a bigger percentage of internal rate of return (IRR). Therefore, it can be concluded that IRR is a subjective matter and varies according to the objectives of the developer. Based from the analysis, the percentage of internal rate of return (IRR) on the investment of abandoned projects is between the ranges of 20 percent to 30 percent.

iii) Legal Issues, Ngai (2006) stated that there are a lot of legal issues involving court and authority that might delay the resuscitation of abandoned projects. Therefore, any developer should be aware of the level of legal issues involved within the project. To sum up, every black and white has to be in order and every legal

complication needs to be settled before another developer embarks on the abandoned project. It is also important for both parties to come to an understanding that there should be a Due Diligence between the parties. Due Diligence can be defined as a process of enquiry and investigation made by a prospective purchaser in order to confirm that it is buying what it thinks it is buying. For instance, in the case of abandoned projects, the Due Diligence between new developer and old developer should be implemented to ensure that the old developer disown all their rights regarding to the project.

iv) Resuscitation Cost, resuscitation cost needs to be considered by projecting a discounted cash flow consisting of building cost, infrastructure cost, preliminary cost, insurance, contingency cost, professional fees, supervision work, surveying work, government charge and other related cost. As a conclusion, modern real estate investment analysis has generally adopted the residual method, discounted cash flow, net present value and internal rate of return to determine the viability of abandoned projects.

v) Status of Land Ownership, the particulars needed to be checked about the status of land ownership are the information on land owners, land owner's agreement on resuscitation and the land itself is free from any issue. In summary, it is important to check on the status of land ownership in order to avoid dispute or disagreement with land owners in future.

vi) Status of Previous Developer, it is essential to ensure that the previous developer is still on course of the development operation or vice versa. As a conclusion, the criterion is very necessary for the future of resuscitation and can help alleviating the trouble and burden of reviving abandoned projects.

vii) Balance On Claim, more often than not, after knowing the percentage of project completion, project revivers can estimate the balance on claim for the abandoned projects. Therefore, the balance of claim must be confirmed with end financier and previous developer before making an investment decision.

viii) Related Information, the information consists of contract drawings, contract documentations, and list of quantity, specification, implementation bond and many

more need to be acquired. The information is important for the purpose of planning and development.

ix) Bridging Loan, bridging loan can be defined as an instance of short term loan provided by the financial institutions to developers to guarantee that the projected cash flow runs smoothly. Therefore, project revivers must acquire information on bridging loan's financier and verify the amount of bridging loan taken by previous developer.

x) Number of Units Sold And Buyers Involved, the number of units sold and buyers involved is considered as the less significant criterion that needs to be considered by project revivers before making an investment decision. In order to ensure that the investment is feasible, total number of units sold must exceed a certain required amount by project revivers.

5.3 Strategies On The Investment and Resuscitation of Abandoned Projects

There are a number of strategies on the investment and resuscitation of abandoned projects in Selangor and Kuala Lumpur. The strategies that are needed by the project revivers are to ensure that the project must meet the internal rate of return (IRR) of the company, to conduct meeting with purchasers, to sort out all issues, to do a rebranding, to develop a new concept, to apply for extension of completion period and to provide rental guarantee scheme. It could also be interpreted that project revivers must be cautious, reliable, creative, innovative and resourceful in order to ensure that the investment on abandoned project is feasible.

Before determining the investment decision towards the revival of abandoned projects, project revivers must ensure that the abandoned project meets the internal rate of return (IRR) of the company. They are also responsible in conducting a meeting with purchasers, Ministry of Housing and Local Government and end-financiers in order to avoid disagreements in future and to boost the reputation of company's goodwill. Even though the company is happy to help house buyers fulfill their dreams of owning their homes, at the end of the day all the projects undertaken must meet the internal rate of return (IRR) of the company. Thorough studies would be conducted to ascertain any legal encumbrances and the potential rate of success of

a project. In addition, internal rate of return (IRR) is also significant to reflect the percentage requirement of Return On Investment (ROI) per annum for stakeholders' common fund. From the aspect of conducting meeting with purchasers, it is very essential for project revivers to contact the affected purchasers from the database given by old developer. The meeting should also be attended by representatives from Ministry of Housing and Local Government together with the association of purchasers in order to have an open discussion about various issues regarding the changes of developers and certain implications of the revival. Even though not all purchasers can attend the meeting, it is adequate to have a representative from the association of purchasers to embody the other purchasers.

Other than that, project revivers should also sign an agreement with existing purchasers and need to reach more than 50 percent concession before being able to revive the project. In addition, project revivers must also conduct a meeting with purchasers and end-financiers to instill the confidence among end-financiers to not cancel on the purchasers' loans. In summary, the meetings are very crucial to ensure that the revival of abandoned projects runs efficiently. As one of the developers in the interview revealed:-

> *"We need to conduct meetings with purchasers together with Ministry of Housing and Local Government. We must tell them to waive for Late Delivery Damages, bearing in mind that the current scenario has seen an increase in material price. Thus, the purchasers need to pay more. However, we do not want to be seen as overcharging and that is the reason why we need the Ministry of Housing and Local Government to intervene. The purchasers need to be told that it is a fair request. If they do not want to pay extra, they cannot get the building, financial institutions will chase them and they cannot claim anything from old developer who perhaps has gone bankrupt."*

Subsequently, in order to avoid dispute and disagreements that may include many related parties, it is very important for project revivers to be very careful when it comes to dealing with contracts and documents. Relevant paperwork must be arranged in order and the project revivers must ensure that every related party should sign the contracts and documents. For instance, the type of contracts and documents

consist of Due Diligence, new Sales and Purchase Agreement and Joint Venture Agreement. The contracts and documents are used as evidence in order to alleviate the problem of legal issues in future. In order to change the perception of investors and regain their trust, doing a rebranding towards abandoned projects is an essential strategy. Project revivers must be innovative by having new products to provide to target market. Marketing promotion is also important to inform the public that the abandoned project is ultimately revived. For instance, Jana Towers used to be an abandoned project in Subang Jaya. The project revivers have decided to rebrand the development by changing its name into Subang Olives. However, the project revivers should take a safe measure by not changing the old design that has been approved by the government. This is because changing the design is a very bad idea since construction is very sensitive to cost and time. Meanwhile, project revivers can develop a new concept in order to attract new purchasers by providing facilities like concierge and courier services and assistance for bill payments and online bookings. The idea can be made possible through a partnership with a multi-service provision company or any other company that provides the same service.

Other than that, project revivers can redo the entrance statement to be more grandeur, to paint the building brighter, to add a few more facilities, to build a bigger swimming pool, to decorate things, and to provide more landscape, amenities, and facilities. To sum up, the development of new concept can initiate a platform for project revivers to expand a selling point for the project in order to attract potential purchasers. Project revivers can also opt to make a request to the Ministry of Housing and Local Government. This is important for the project revivers to appeal to the legislation of their powers vested to the Controller of Housing by extending the completion period of the agreement. As a conclusion, the extension of completion period is able to give project revivers sufficient time to revive the abandoned projects that meet the required building quality.

Finally, the rental guarantee scheme can be provided for commercial development such as shop lots, office buildings and service apartments. Project revivers can give five years-rental guarantee return for commercial development and options to extend the guarantee return for potential investors. However, project revivers must ensure that they can already gain required profits at the early stage of development in order to cover the cost occurred of rental guarantee scheme.

6. Conclusions

From the finding results, it indicated that the investment opportunity was the significant factor that influences project revivers to involve in the revival. In addition, this study has achieved the expected results where the investment opportunity was not the significant influencing factors, but it can also be emphasized to be influenced by factors such as goodwill, corporate social responsibility, creating more jobs and a better living environment, and helping the existing buyers. In other words, profitability, reputation and commitment prompt project revivers to revive abandoned projects. These results stressed that Malaysian investors are prepared to invest in abandoned project bearing in mind that the project is marketable and has investment opportunity. The overall finding can be illustrated in Figure 4.

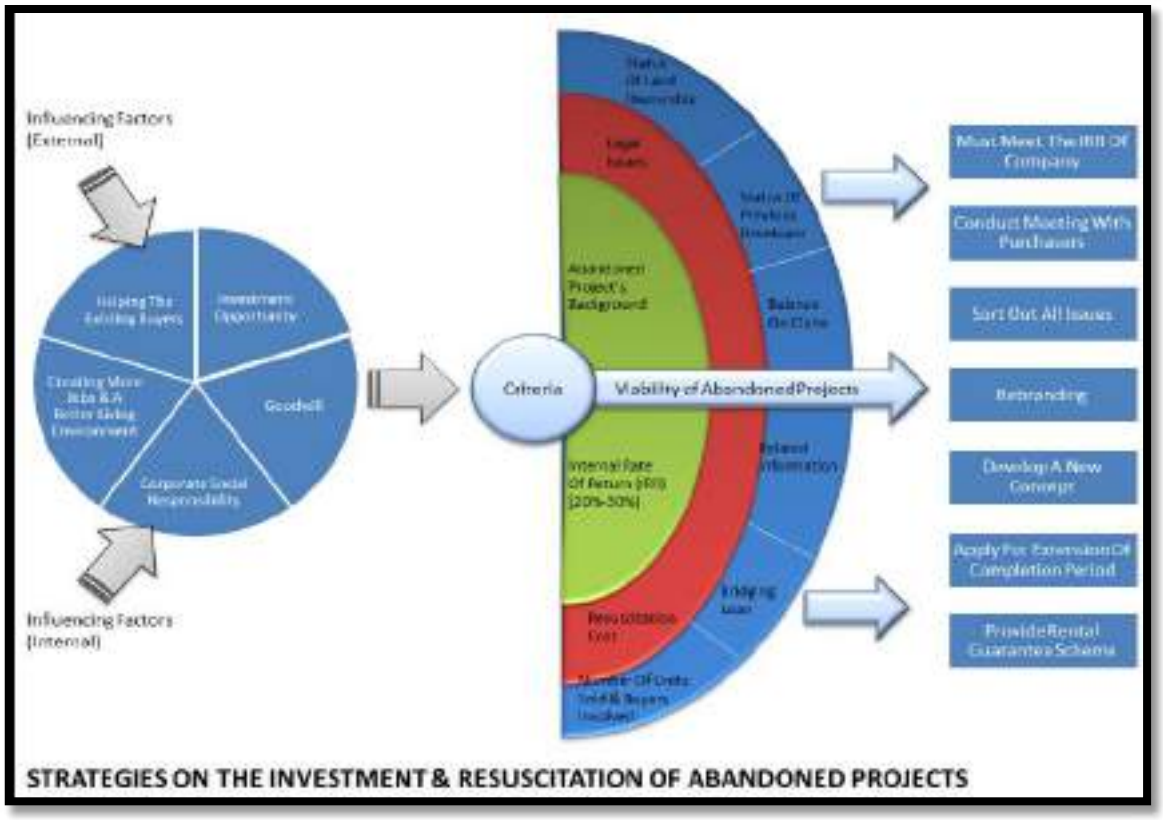

Figure 4: Strategies On The Investment and Resuscitation of Abandoned Projects

There are several relevant suggestions from various stakeholders that can be made based on the research findings. These suggestions can help the government in alleviating the problem of abandoned housing projects namely:

Government Agency

i) Strict regulation for license issuance and renewal option is only opened for excellent developers.
ii) Outline a draft document of city's new master plan that records a number of goals and recommendations related to developing and implementing a strategic demolition and resuscitation plan for abandoned projects
iii) A public hearing should be held to reflect the thoughts of residents in the area in order to request for marketability opinion from the public to lessen the problem of oversupply and property overhang.
iv) The government should develop a special agency for the purpose of enforcement where transparency is essential through the publication of names of blacklisted companies.
v) Requirement of housing development insurance before an applicant can become a licensed housing developer.

Financial Institution

i) The implementation of Islamic Law where the owner of the house (Islamic Bank) will be liable and it must be the guarantor for the completion of housing units.
ii) Sustain a reasonable interest rate with a vision to support Built Then Sell (BTS) concept.

Housing Purchasers

i) Build a strong committee among buyers in order to monitor the progress of project.

Other Parties

i) Non-profit organizations should be encouraged to provide a capital injection on the resuscitation process of abandoned project.
ii) Non-profit corporation must be created in order to coordinate housing development and provide planning and technical assistance to the problem of abandoned projects. Other than that, there could be a joint venture between financial institutions such as Bank Negara Malaysia and community-based corporation to revive abandoned projects.
iii) Insurance companies could include insurance for abandoned projects.

ESTABLISHMENT OF NATIONAL ECONOMIC SPACE: JANSEN'S URBAN PLANNING IN SOUTH ANATOLIA

Emel Karakaya[1]

Abstract

Starting with İzmir Economy Congress in 1923, even distribution of economic development had been main spatial strategy for Turkish government (İnan, 1989a). For this reason, between 1923 and 1940, 117 urban plans for Turkish cities and towns were prepared (Karakaya, 2010; Keskinok & Karakaya, 2010). In addition, principle of etatism had gained its legitimacy in the establishment of national economic space through urban planning after 1929 crisis. The main policies to determine policy-oriented urban planning were establishment of a national economy and arrangement of the space in nation-state in this period (Keskinok, 2010). In the first and second development programmes (İnan, 1972; İnan, 1989b), there were regional foci created as agricultural and industrial development regions. Being one of the development regions, Adana, Ceyhan, Mersin, Tarsus and Gaziantep were taken to the agenda of planning to accomplish economic development of southern region.

This study examines relation between Nation-Building process and urban planning process with an emphasis on agricultural and industrial development region established in the south of Anatolia by Hermann Jansen plans. The article gives answer for question addressing translation between Nation-Building process as a political concept and its correlation with urban planning as spatial context. Thence, this translation investigates the socio-spatial dynamics of Nation-Building process of Republic of Turkey with an emphasis on southern development region planned by Hermann Jansen.

Keywords: National Economic Space in Early Republican Turkey, Hermann Jansen, South Anatolia agricultural and industrial development foci, Nation- Building process.

[1] PhD Student, Research Assistant, İzmir Institude of Technology, Dept. of City and Regional Planning, İzmir Yüksek Teknoloji Enstitüsü Şehir ve Bölge Planlama Bölümü 35430 Gülbahçe Kampüsü Urla/İZMİR TURKEY, e-mail: emelkarakaya@iyte.edutr

1. INTRODUCTION

Tekeli (2005) defines Nation-Building project of Turkey with four spatial elements as follows;

1. Ankara's declaration as capital city
2. Railway Programme to provide unity of internal market
3. Industrialization Programme
4. People's Houses [Halkevleri].

However, Turkish modernism movements which is triggered in the late Ottoman Period and found its form in the Early Republican Turkey has a multi-layered structure and aiming at societal and intellectual transformation through economic development. These layers have characteristics of being philosophic in terms of its planning and rationalist dimension; institutional with its nation-state based structure; economic with its massive production pattern and; societal with its fiction of modern citizens and modern life. The foundation of institutional structure depended on the foundation of economic, societal and philosophic structures in which urban planning had the key apparatus to succeed. In this respect, the Nation Building project, as a socio-spatial process, has two additional spatial elements as (Karakaya, 2010);

5. Selection of agriculture, trade and industry focal (in relevance with industrialization programme and railway network)
6. Planning programme and urbanism.

Newly established state had needed a frame for spatial arrangements to achieve objectives of Republican cadre and foundation of institutional layer in Turkish cities "to form an anti-thesis in the clarity to the classical Ottoman towns" (Ökeşli, 2009, p. 45). For this reason, urban planning was seen as an agent for the success of the Republic and 117 cities and towns were planned between 1923 and 1940 period.

To construct the Republic in city space and in social life, newly emerging science, urbanism, was used as an agent (Bilsel, 1996) and foreign architects and urbanists were invited to the Republic. After declaration of Ankara Planning Contest in 1927 to create the new capital city, Hermann Jansen's plan and his planning principles would be the mold to shape the dough of Anatolia (Atay, 1933; Kezer, 2009). Following Ankara experience, Hermann Jansen planned several cities and towns in Anatolia and he accompanied planning experiences in the Republic of Turkey. Ankara, İzmit, Adana, Mersin, Tarsus, Ceyhan and Gaziantep are cities and towns planned by Hermann Jansen between 1923 and 1940.

This article investigates the relation between Nation-Building process and urban planning practices with an emphasis on agricultural and industrial development region established in the south part of Anatolia by Hermann Jansen plans. Scope of article encompasses period between 1923 and 1940, which is defined as the Early Republican Period (Karakaya, 2010). The main question to answer in the study addresses

translation between Nation-Building process as a political concept and its correlation with urban planning as spatial context. Therefore, this translation investigates the socio-spatial dynamics of Nation-Building process of Republic of Turkey with an emphasis on south development region planned by Hermann Jansen. To do so, the study uses an inter-textual analysis method for urban plans, İzmir Economy Congress 1923, First and Second Development Programs of Republic of Turkey, declarations published in articles, periodicals and journals for agricultural and industrial development in the south Anatolia between 1923 and 1940s, and archives such as Turkish National Library. The study investigates design principles used for physical and economic development in city space proposed by urban plans.

The study is divided into two main parts. In the first part establishment of national economy and spatial arrangement of national economy in Anatolia are discussed. The second part is on Hermann Jansen's urban planning in southern growth pole. Mersin, Adana, Tarsus, Ceyhan and Gaziantep urban contexts and urban plans are discussed in terms of the relation between development of the growth pole and Jansen's planning principles.

2. CONSTRUCTION OF NATIONAL ECONOMY AND SPATIAL ELEMENTS OF NATION-BUILDING

Ankara was declared as the capital city on October the 13th, 1923, before establishment of the Republic. Obviously, the capital city Ankara gives evidence for spatial reorganization apparatus in achievement of National Economy. Obviously, the intention lying under idea of new capital was integration of Anatolian lands (Altaban, 1998; Keskinok, 2010). Leaving old capital had an anti-imperialist attitude (Tekeli, 1980), became an imperative for national integration (Keskinok, 2010) and a political movement (Tankut, 1993).

In the early Republican period, formation of national economy was seen as achievement of national integration, urban-rural unity (in production and transportation) and foundation of alternative cities, growth poles and regional foci against primacy of İstanbul. This part discusses formation of National Economy in institutional manner and its spatial apparatuses to found "national economic space".

2.1. Institutionalization of National Economy

Anatolia, in 1923, was representing an agricultural society with feudal ties and a very limited industry that total population of labors was 76216 amongst 12 millions of total

population (İnan, 1972). The Republican cadre was aware that economic development, production, and industrialization were crucial for an independent National Economy to realize Republican Revolution. To illustrate, in the opening speech of the Grand National Assembly of Turkey on March the 1st, 1922, Atatürk was asserting the idea of political and economic independence for development of Nation. The first initiative for institutionalization of economic development and independency was First İzmir Economy Congress which was held on February 4, 1923 (İnan, 1989a) while the negotiations of Lausanne Peace Treaty were given a break.

The First İzmir Economy Congress had a fundamental role in the construction of National Economy till 1930s. The congress became first step for institutionalization of economy, definition of an economic development programme and it became the place for declaration of Economic Pact [Misak-ı İkisadi]. The Economic Pact was asserting principles, very basic of which were 1.development of domestic production and trade, 2.industrial investment, 3. encouragement of agricultural production and 3.development of Transportation and infrastructure (İnan, 1989a).

The pact aimed at creating national capital for economic sectors; agriculture, trade and industry. Application of Economic Pact required a series of rules and regulations, institutionalization and customs policies in all sectors. However, 1929 economic depression would cause an obligation for change in political attitude towards statism.

According to Keskinok (2010), 1929 World Recession provided a base for the statist and populist policies in 1930s. Despite acceptance of Turkey as a "People's State" in 1921 Constitution (Boratav, 1998; Keskinok, 2010) and reveal of representative attitude towards farmers and labors in İzmir Economy Congress 1923 (İnan, 1989a), populist and statist principles had gained their legitimacy after 1930s. When the Congress of Industry gathered in 1930, an industrialization programme in the scope of Anatolia was designed. Thereafter, First Congress of Agriculture in 1931 was headlining integration of industry and agriculture. This objective would embody with the First Industrial Plan in 1933, establishment of Sümerbank (cotton-production) in 1933 and the Second Industrial Plan in 1936. The realization of these policies would find their place through creation of new growth poles in Anatolia by urban plans.

2.2. Spatial Elements of National Economy

Before 1929 World Recession, decisions taken in İzmir Economy Congress brought about two main spatial strategies. The first of these was developing transportation

network and infrastructure (Figure 1). In the Ottoman Period, railway investments constituted a tree-type model to carry production of Anatolia to port cities (Figure 2). The network was composed of connection lines carrying agricultural products and raw materials to Mersin, İskenderun, İzmir, and İstanbul ports through three main routes reaching to Ankara. Herewith, first spatial arrangement of the Republic was developing railway network in Anatolia. In the opening speech of the Grand National Assembly of Turkey on March 1, 1922, Atatürk underlined the idea of political and economic independence for development by referring to railway development.

Figure 1: Reception of first train carrying Zonguldak coal; Ankara train station, 1939, "*We are an unprivileged classless coherent mass*" in the poster (http://e40003.me.metu.edu.tr/Ankara/)

The second main strategy was urban planning. After İzmir Economy Congress, it was agreed that economic primacy and dominance of İstanbul would be an obstacle for the success and ideals of the young Republic. There had to be new growth poles in Anatolia for success of Republic and the fair distribution of the wealth. Accordingly, urban planning became main apparatus that in the opening talk of Grand National Assembly of Turkey on November 1, 1927, Atatürk emphasized urban planning to reach economic targets;

> *"Dear friends, I will review our economic life. I immediately declare that when I call 'economic life', I mean that agriculture, industry, trade and the public works [bayındırlık in the meaning of urban planning] are correlative. I accept these as a whole that can not be considered separately".*

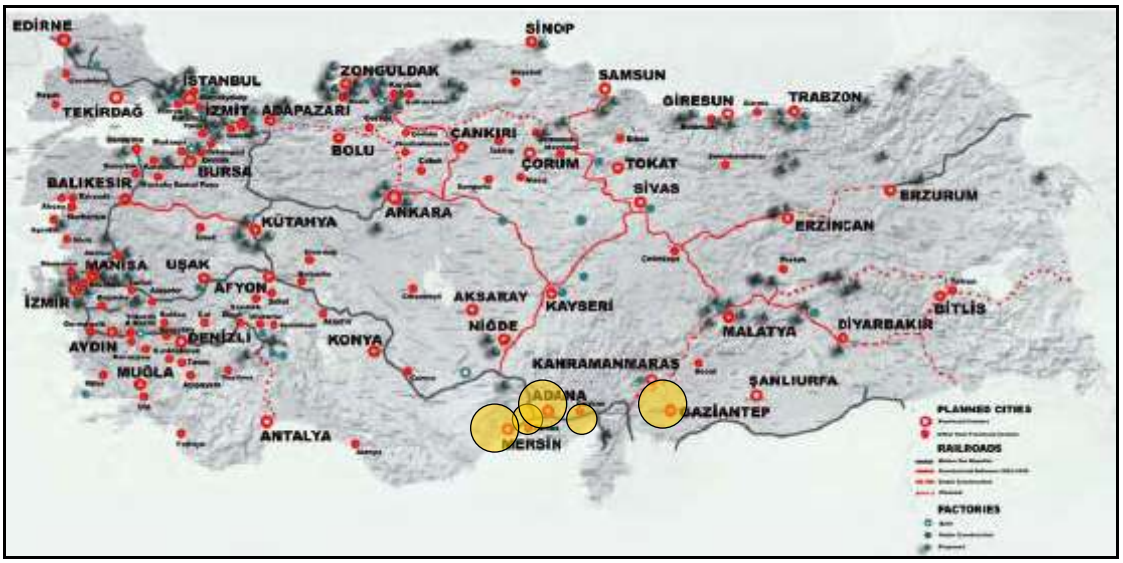

Figure 2: Railway Network development, planned cities, industrial development between 1923 and 1940 and cities examined in this study (Çağatay Keskinok's Personal Archive)

Obviously, İzmir, as a port city, was planned by Danger-Prost collaboration in 1923 right after the Congress. Similarly, Bursa plan was prepared by Prost in 1924. Further, Ankara was planned by Lörcher in 1924. Nonetheless, Republican cadre did not find plan applicable and satisfactory. Ankara plan would be prepared by Hermann Jansen in 1927[2] as a planning model for the rest of Anatolia. Ankara would be the perfect symbol for the success of the Republic by developing new social norms (Altaban, 1998) for national modernization project (Tekeli, 1998).

For preparation of plan, an international competition was declared and Jansen became the winner of the competition thanks to his planning attitude towards historical core of Ankara, working, living and socialization spaces. Jansen's planning principles that were depending on natural, historical and social properties of city (Jansen, 1937a) were found parallel to the ideal of the Republican cadre. In this respect, jury chose the modest proposal of Jansen for its human scale attitude.

[2] Ankara, after the declaration of the capital city, was planned by Lörcher in 1924. Nonetheless, plan was not found applicable and satisfactory. Although Cengizkan (2004) claim that Lörcher Plan constituted the main form and principles of Jansen plan, Jansen plan was concerning historical fabric and had attention on new residential areas. For further information, Karakaya (2010).

After 1929 turning point, 1930s became the era for mass application of second spatial strategy; urban planning related to statist and populist principles in urban and rural space. By the First Industrial Plan and the Second Industrial Plan, a term for continuous planning by integrating urban planning and economic planning began (İnan, 1972; İnan, 1989b). For continuous planning, economic development programme was linked to urban planning through creation of new development centers and growth poles, one of which is South Anatolia. Jansen (1936, p.21) declared, "Urban planning is developing economically debilitated cities and citizens" in his conference in Ankara People's House in 1936 before his planning activities for southern growth pole started. In other words, most of urban plans for Turkish cities and towns had the intention to create new economic development centers in the second half of 1930s. Selection of cities and towns to be planned were not decided concomitantly, most of those were prioritized centers on railroad network with agricultural and trade potential (Tekeli, 1980). For this reason, Yenen (1939) declares that flourishing[3] urban centers of Anatolia would be trade and industry centers while flourishing towns would be developed as agricultural foci or industrial foci. Therefore, policy applications of the Republican cadre were introduced to Turkish urban planning in two planning typologies to create growth poles (Karakaya, 2010).

1. Trade and Industrial Development Centers: After Ankara planning experience, a number of cities were planned in Anatolia in relation to decisions and strategies taken by industrial plans and strategy of developing alternative growth poles alternative to İstanbul. These cities were created as industrial centers or as trade centers located in the transportation nodes and enclosed to agricultural or industrial production nodes (Karakaya, 2010). Southern growth pole was created as a national foci that hinterlands of Adana, Mersin, and Gaziantep were prominent in agricultural production and Mersin was the port city to trade these productions. Although Gaziantep did no link to railway routes, the city was on Silk Road. Adana, Mersin and Gaziantep cities had historical importance for their trade potential and cultural structure.

2. Industrial and Agricultural Development Sub-Centers**:** Parallel to railway network construction and development of industrial nodes, several towns were planned as agricultural or industrial centers in Anatolia in 1930s. Among numerous examples, Tarsus and Ceyhan were planned as agricultural production of their fertile hinterland.

[3] Yenen uses the word "bayındır" to define developed, flourishing and potential cities. He uses word especially for towns that were still reflecting traces of their prosperous historical background .

3. JANSEN'S URBAN PLANNING IN SOUTHERN GROWTH POLE

3.1. Herman Jansen and His Planning Principles

Hermann Jansen (1869-1945) studied architecture at Technical University of Aachen. Following, he worked in Berlin as a professional between 1898 and 1945 and his planning activities in Turkey between 1927 and 1939 became most important in his career (Ökeşli, 2009).

Hermann Jansen, as an urbanist and architect, continued his education and his career in a milieu that was suffering due problems emerged with industrial revolution. Discussions for cities and urban centers were emphasizing results of industrialization and dehumanization of cities (Ökeşli, 2009). European urbanism, as a new scientific area (Bilsel, 1996), was legitimizing an urban fabric that is sensitive and together with natural, historical and cultural entities. Two academic debates under these conditions; Camillo Sitte's Sittesque (or Picturesque) approach and Garden City movement would affect Hermann Jansen.

Firstly, Jansen, as a student of Camillo Sitte, concentrated on aesthetics and artistic principles. Sittesque School with the followers of Sitte such as Eugen Fassbender, Felix Genzmer, Karl Hocheder and Hermann Jansen is said to be the "Romantic Period" of city planning (Collins and Collins, 1986) or it was said to be pictorial rather than romantic (Ökeşli, 2009) .

Sittesque or *Picturesque* argued a return to the medieval towns' humanized scale. This attitude would also highlight preservation of historic fabric and would create a response for planning according to engineering principles (Collins & Collins, 1986). He emphasized organic character of urban fabric. Contrary to Haussmann's straight lines and wide boulevards' (Tankut, 1993), he contended irregularity in urban pattern and aesthetic purposes (Karakaya, 2011).

Secondly, Ebenezer Howard's basic view was "to marry" town and country for emergence of a new hope, new life and new civilization as Fischman (1989) identified. Like Sitte, Howard was defining integration for urban areas. Collins and Collins (1986) claims that English garden suburbs were influential for development of views of Sitte in urban areas, and later Garden city would become Sittesque himself in terms of union of Garden City Theory with Sittesque layouts in Germany. Similarly, Batchelor (1969) expresses that Ebenezer Howard's Garden City idea came to Germany after promotion of Sittesque and two approaches were integrated. Thereby, Hermann Jansen was concomitantly affected by two ideas and these became notions for his planning. Sanitation issues of Garden City idea and aesthetic principles of Sittesque formed a synthesis for Jansen's planning principles. Common points of both approaches like

zoning, sanitation, aesthetics, low-density housing and green belt also became general principles in Jansen's planning (Tankut, 1993).

3.2. Southern Growth Pole and Jansen's Planning

For economic independence, creation of growth poles had found its spatial arrangement in "Development of Trade and Industry Centers" and "Industrial and Agricultural Development Sub-Centers" in the Early Republican Turkey. For identification of Southern Growth pole, this part firstly defines characteristics and spatial context of cities and towns in the growth pole till the establishment of the Republic. Then, urban plans prepared by Hermann Jansen are discussed in terms of planning principles, proposals of plans for economic development and new spatial arrangement.

3.2.1. Formation of Spatial Context towards Early Republican Period

Because Adana, Tarsus, Ceyhan and Mersin are located in Çukurova and Gaziantep, on the other hand, is located in the east of Çukurova, in between Çukurova and upper Mesopotamia, it is required to evaluate the importance, development, and specifications of Çukurova and Gaziantep distinctly.

Çukurova Region is composed of fertile lands, along Seyhan and Ceyhan Rivers, and continually inhabited urban settlements since Cilician times. Though its fertility, multi-cultural ethnic structure and historical background, the actual development did not emerge until the second half of 19th century in Çukurova. When civil war started in America, cotton became more precious and one of the substantial raw materials in the second half of nineteenth century (Ökeşli, 2009; Ökeşli, 2010; Selvi-Ünlü, 2009; Ünlü, 2009; Toksöz & Yalçın, 1999; Erman et al., 2007, Özüdoğru & Erman, 2011). "Tarsus, Adana and Ceyhan were the cities producing cotton and Mersin port was enabling overseas transport with railway connection (Ökeşli, 2009, p. 46). Herewith, Çukurova region became a node for agricultural production and trade of raw material through Mersin port.

Urban development and spatial arrangements for Adana and Mersin cities, as urban centers, started with modernization efforts of Second Constitutional Monarchy Period in Ottoman Empire. In this period, the first development plan for Adana was prepared for area between railway station and existing city in 1910 with a baroque style (Ökeşli, 2010). Mersin, on the other hand, emerged as the port city encompassing a wide hinterland in Çukurova (Ökeşli, 2010), although it was a village in the early nineteenth century. Mersin quickly developed as an international trade city after American Civil War and development of Mersin- Adana railway and highway in late 1800s (Ünlü, 2012). Moreover, the emergence of Mersin as a port city was a result of that Tarsus and Silifke ports were silted up (Selvi-Ünlü, 2009). After that, commencement of planned period and industrialization started in Republican Period in Adana and Mersin.

Tarsus and Ceyhan cities were agricultural towns in Çukurova in late 19th century. Indeed, until early nineteenth century, Tarsus was an important trade center and was a port city (Selvi-Ünlü, 2009). Through ancient Kydnos River (Berdan River or Tarsus River), Tarsus was connecting to safe dock in Rhegma Lake which made it a prominent trade and Commerce City. However, when the river split up, and American Civil War gave birth to raw material demand in Western Europe, Tarsus evolved to an Anatolian agricultural town mostly producing cotton. Ceyhan plain similarly became house of civilizations, notwithstanding, Ceyhan town did not have a historical background and continuum of civilization like Mersin, Adana and Tarsus. The town was firstly settled after Turkish seignior period as a Turkish rural settlement (Ceyhan Governorship, 2009) and was "proclaimed as a borough on 12 December 1893" (Aslan, 2011, p. 47). Development of Ceyhan dates to increase in population and change in social life after great migrations due Crimean War in the second half of nineteenth century and Wars in Balkans along 1910s (Aslan, 2011; Çomu, 2011). New comers were so talented in agricultural production and in craftwork (Aslan, 2011) which would increase the importance of Ceyhan in its hinterland.

Lastly, Gaziantep, which was named as Ayntab and later Antep, was a trade city on Silk Road connecting Anatolia to Persian Gulf (Basra Gulf) As a cosmopolitan city of the Ottoman Empire, city started to lose its importance when it was administratively connected to Aleppo State in 1818 (Günyol et al., 1982). Moreover, opening of Suez Canal in 1869 caused a change in the direction of Silk Road (Tatlıgil, 2005). The trade center of the region changed its direction to south (Egypt) and Antep would survive as a sub trade center in its region till 1900s. However, the location of city was strategic that it was connecting Anatolia to Aleppo and had fertile lands. Great author Orhan Kemal defines fertility of Antep with colors of red and green that 'soil is crimson and above is lush' (Gültekin, 2011). Nonetheless, when the Republic of Turkey was founded, there was no railway connection to Antep (Figure 2) and it would not be established until 1954 (Günyol, et al., 1982; İller Bankası, 1972). Beyond these, Antep had great importance during the War of Independence that the city fought against French Mandate for ten months (Günyol, et al., 1982). "Gaziantep Defend" was central for defence of south Anatolia. After that, Antep was honored with name "Gaziantep" [War Veteran Antep]. As a hero of War of Independence; economic development and urban issues of Gaziantep gained importance for Republican cadre (Şavkılı, 2008).

3.2.2. Jansen Plans

The motto of Burhan Arif Ongun's urbanism exhibition in Ankara People House in 1936 was "Urbanism is one of the biggest matters that the Republic succeeded in" (Ongun, 1936, p. 31). Due foundation of Ankara urban frame, Jansen's principles could

"reconstruct the rest of Anatolia with the same mold" by planning[4] Tarsus, İzmit, Mersin, Gaziantep, Adana and Ceyhan. This part evaluates Jansen plans in Southern national foci. Urban plans of Tarsus, Mersin, Gaziantep, Adana and Ceyhan are discussed in terms of Jansen's planning principles, spaces of production proposed in plans, and spaces of living and socialization.

Adana Planning Experience: City along Seyhan River

Jansen's first study for Adana was in 1935 for a limited area planned in 1910. Ernst Reuter (1940) would evaluate this experience as more economic to apply, safe in traffic circulation and appropriate to modern planning principles when compared to old plan (Figure 3).

.

Figure 3: Hermann Jansen's plan in the left and 1910 plan in the right (Architecture Museum TU Berlin, Inv. Nr. 23366; Reuter, 1940, p. 19).

This plan was proposing two urban parks, Seyhan Park and Atatürk Park, integration of housing areas with Seyhan River by a green belt, schools and a theatre (Jansen, 1940). Indeed, it was creating a new neighborhood area between old city[5] and railway station. Atatürk Park, proposed in plan was the center for spaces of socialization (Figure 4) while Seyhan Park was a recreational space in riverside (Ökeşli, 2009).

[4] Approval of plans in general were as follows; Tarsus and İzmit in 1935, Mersin and Gaziantep in 1938, and Adana and Ceyhan in 1939.

[5] "Old city" is used to define existing urban core both by urbanists and politicians in the Early Republican period. The reason of this identification lies in the old- new conflict of the era. As we mentioned "new" was representing modern against old. In this respect, this study also uses old city concept to define existing city, and "new city" to express new development areas.

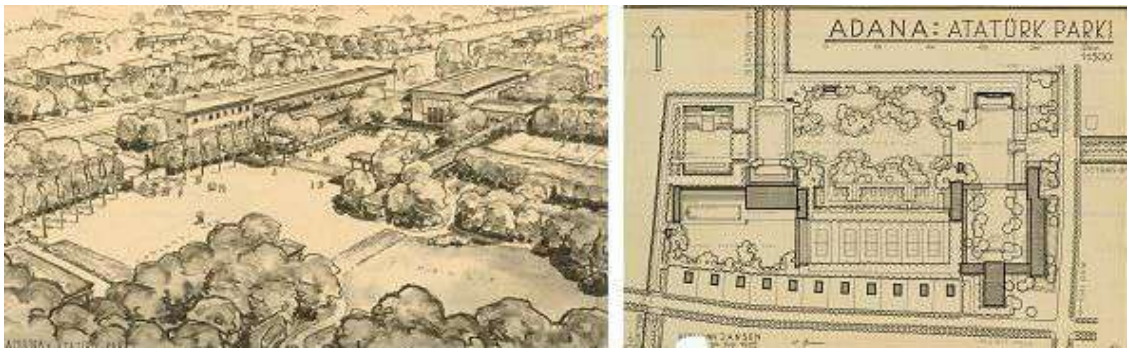

Figure 4: Adana Atatürk Park (Architecture Museum TU Berlin, Inv. Nr. 23350 and 23348).

Afterward, Jansen prepared a comprehensive urban plan for city. Plan offered development in the both sides of Seyhan River with zoning as basic principle. Old city was preserved and new development was located around old city. New industrial development was proposed along railway route and was combined with Workers' District [Amele Mahallesi]. The industrial development in Jansen's proposal was separate from old industrial district on the opposite side of Seyhan River (Figure 5). The reason for this was preservation of agricultural lands and designing a compact urban form around old city (Jansen, 1940).

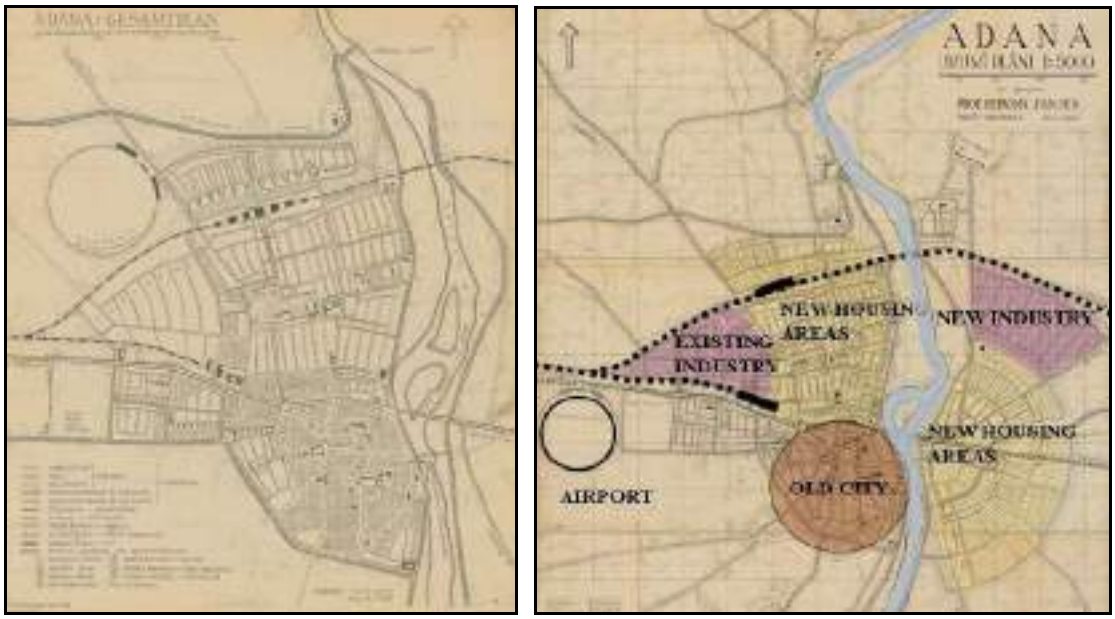

Figure 5: Adana Urban Plan and zoning (Architecture Museum TU Berlin, Inv. Nr. 23360 and 23367, 23368, 23369 merged).

Spaces for recreation were continuing along Seyhan River and socialization spaces were penetrating into new housing areas from recreational areas. Greenbelts were designed to separate industrial areas and housing areas.

New housing development was designated according to *Siedlung* approach (Ökeşli, 2009) and had traces of Garden City. Neighborhoods were also distinguished with green areas as spaces of socialization.

New administrative district was developed in old city. Jansen (1935) was insisting on conservation of historical urban fabric. However, he was declaring that administrative, cultural and commercial centers of cities should not be separated from the old core; they had to be in and around old core. In this respect, old core was not left, but was integrated with new development and was regulated with pedestrian paths and greenery areas.

Mersin Planning Experience: Southern Sea Gate

Mersin, as a cosmopolitan port city was intended to be developed as a first-degree port city in the early years of the Republic (Karacan, 2005) and this aim would find its identification in Hermann Jansen's Mersin plan. Jansen's modest planning attitude that reasoned the first prize in Ankara planning competition (Tankut, 1993) was also observable in organization of space in Mersin experience (Ünlü, 2012).

Figure 6: Mersin Urban Plan and zoning (Architecture Museum TU Berlin, Inv. Nr. 23454).

Plan was basically composed of three zoning decisions; industrial areas, warehouses and new port located in the eastern part, new housing development, recreational belt and spaces of socialization (along and in housing areas) in the west, and the old city core in between these. Old city core was connecting working areas and living spaces.

The industrial development was located between new port and railway. Workers' District was located to the north of old city core and was connecting to industrial areas through railway. The district was developed with Garden City and siedlung approaches apparently.

Administrative center was developed along old ports; Customs Port [Gümrük İskelesi] and the Port [İskele], and making an urban plaza in the existing urban square Gümrük (Customs) as in Figure 7. "Jansen designated Customs Square as a vital and functional area for community life" (Ünlü, 2012, p. 6). Commercial center was also located in the old city.

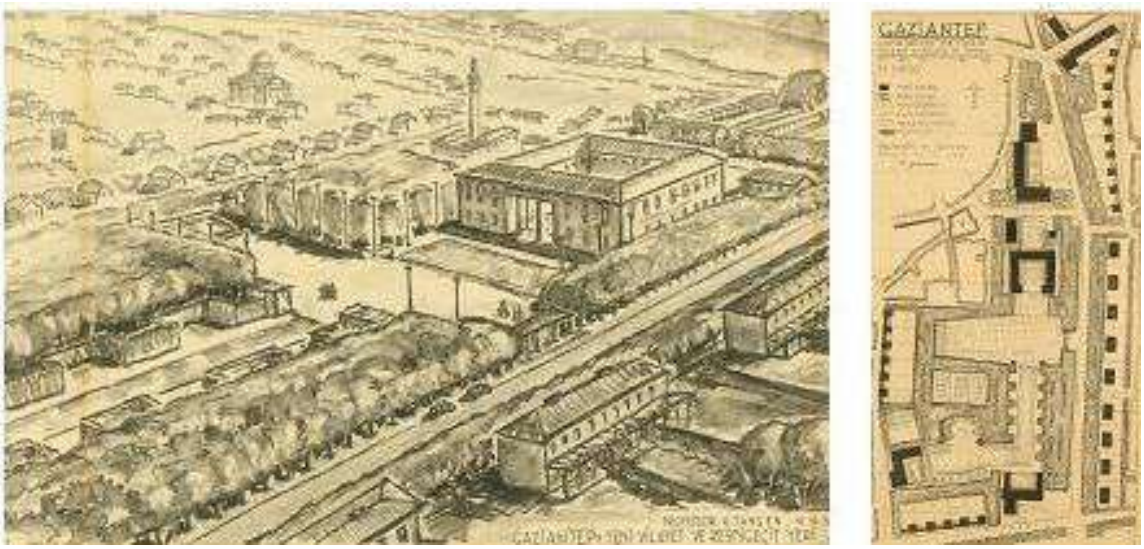

Figure 7: Mersin Atatürk Park and Hükümet Square (in Gümrük square), and Mersin City beach (Architecture Museum TU Berlin, Inv. Nr. 23452, and 23453).

Old core was separated from industrial site with a green zone and spaces of socialization were creating a unity between old city and new city. Sports, recreation and socialization spaces were arranged in the east-west direction continuing along new residential areas and reaching to the western border of city. The western border of plan was Efrenk stream and there was a city beach designed at the end of the city.

Gaziantep Planning Experience: A modern city on Silk Road

Hermann Jansen's Gaziantep plan had further specifications when compared to Adana and Mersin plans in the context of spatial arrangement and abundance of spaces of socialization and recreation.

First, the plan was proposing railway connection to the city in the northern part of old city. The other important proposal for transportation was widening highway to Aleppo in the south of old city along east-west direction.

Figure 8: Gaziantep urban plan, zoning and spatial arrangement (Architecture Museum TU Berlin, Inv. Nr. 23416).

The plan had three zones. These zones were generally distinguished with railway route, Aleppo highway, sports district (including hippodrome) and Alleben stream, which is passing along the north of old city. Similar to Mersin plan, industrial development and Workers' District in the northern part was distinguished from the old city by Alleben stream and railroad. In the southern and western part of old city, new housing development was proposed. Housing units were identified as three-storey garden houses. Further, administrative center was located in the old city between Aleppo highway and Alleben stream (Figure 9). This area was an intersect between greenbelt and the old city.

Figure 9: Gaziantep new governorship building and the official parade area (Architecture Museum TU Berlin, Inv. Nr. 23410 and 23412)

Jansen's planning attitude towards historical, natural and topographical elements can be obviously seen in Gaziantep experience. Jansen emphasized Castle and tumulus (Türk Tepe) by greenery. Alleben stream, as the natural asset of city, was designed as a recreational corridor both separating and integrating old city and new city. Topographic elements were handled as a design tool especially for arrangement of new housing areas in the southern part. Moreover, city could be watched from vista points designed in the northern and southern hills that city was presenting a pitoresk.

Main green belt was along Alleben stream and it was surrounding the old city to southern direction. In the north of Alleben stream, a sports area was designated with a hippodrome. Restaurants, children's' playgrounds, People's House, Martyrdom Monument (Figure 10) and so on were some of proposed uses in Alleben greenbelt.

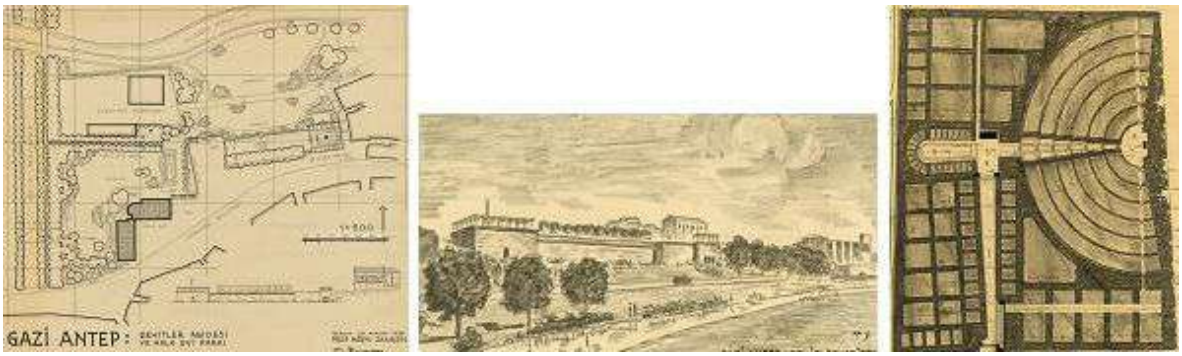

Figure 10: Gaziantep Martyrdom Monument and People's House; and New Cemetery respectively (Architecture Museum TU Berlin, Inv. Nr. 23409, 23410 and 23406)

In the south and north recreational areas, there were teahouses [kır kahvesi] in plan borders, and military barracks was forming south border of city. In the western border, a city gate was designed, while northeastern gate was designated with a new cemetery. Due Gaziantep Defence and martyrs of the War of Independence, the cemetery was designed as a monument (Figure 10).

Tarsus: urban- rural integration

Jansen's Tarsus plan, as plan of a rural settlement, had different characters than planning approaches of urban areas. Jansen in conference titled "Professor Jansen's idea about small cities" was declaring that "character of small cities should not be changed and these should not be planned like big cities" (Jansen, 1937b, p. 40).

Jansen's conference was indeed about Tarsus. Tarsus, for Jansen, was one of the most beautiful small Turkish cities that its historical and natural assets had to be appraised. In this respect, Jansen's Tarsus plan was focusing on water sources, streams and rivers of city. Plan was composed of two zones; greenbelt between water elements, the old city, and new development areas of dwelling units and industry (Figure 11).

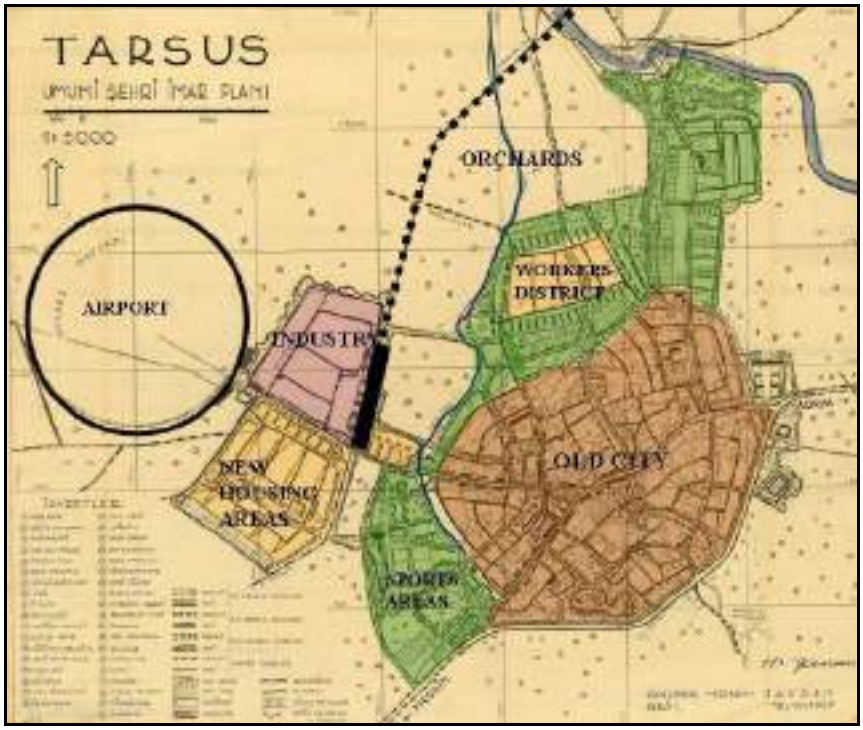

Figure 11: Tarsus urban plan (Architecture Museum TU Berlin, Inv. Nr. 23469).

Jansen (1937b) was defining the old city of Tarsus and greenery areas of the town as a pitoresk. Furthermore, Jansen was insisting on architectural assets of Tarsus. The architecture of Tarsus was unique and Jansen was offering a modern style for new housing areas designed according to architectural principles of existing settlements. For housing units, the plan qualified two-storey garden houses.

In plan, administrative center was designated in old city and it was combined with an agricultural bazaar in the north of official parade area. As the city was an agricultural town, administrative center and bazaar was the symbol of urban- rural integration. Spaces of socialization were designed to form a modern Anatolian town integrating with its rural hinterland.

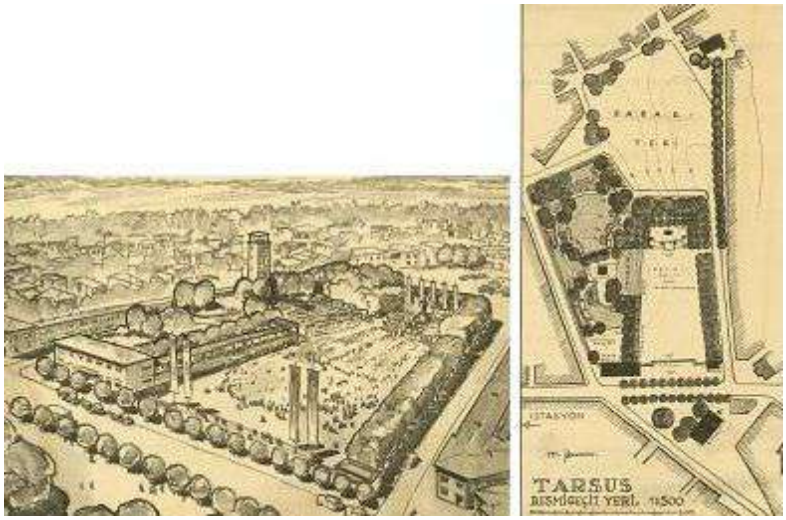

Figure 12: Tarsus Administrative Center, Official Parade Area and Agricultural Bazaar (Architecture Museum TU Berlin, Inv. Nr. 23466 and 23465)

The plan was also achieving urban-rural integration by preserving orchards of the city, which are buffer between cotton production lands and the city (Jansen, 1937b).

Ceyhan: urban-rural integration

Ceyhan, in 1930s, was in the appearance of an Anatolian village lying along Ceyhan River in north-south direction (Figure 13). The railway station was in the South of the city. People came to Anatolia due population Exchange [mübadele] were inhabited to Ceyhan in 1924 (Çomu, 2011), thus there was an increase in population of town.

Figure 13: Ceyhan town in 1930s (Architecture Museum TU Berlin, Inv. Nr. 23389).

Jansen plan was, in fact, suggesting an order for development of city (Figure 14). But, main principle of plan was a compact urban form and preservation of agricultural lands. So, plan recommended infill development and a new development area in eastern part.

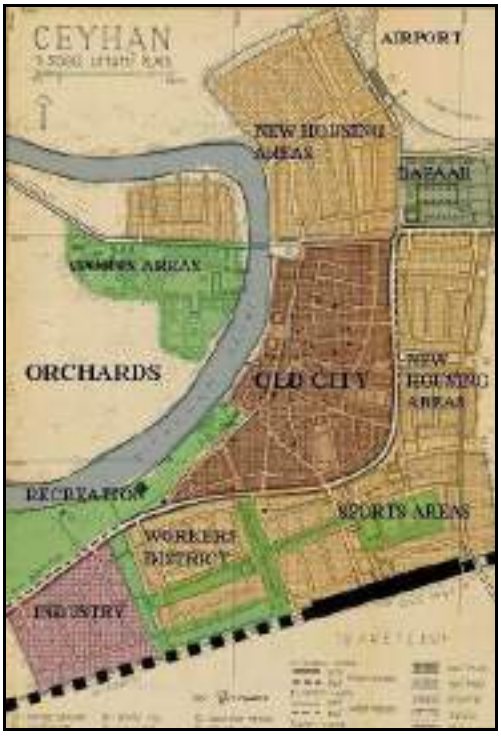

Figure 14: Ceyhan urban plan (Architecture Museum TU Berlin, Inv. Nr. 23395).

The plan had an orientation through water asset, Ceyhan River, and was using riverside as a greenbelt. Workers' district and industrial area was also distinguished by green areas and a new development area was proposed in the western side of river, in the north of historical bridge.

Administrative district and a youth park were designed in the old city. The administrative district, Atatürk square, was a gate of the old city opening to Ceyhan River (Figure 15). The eastern gate of the city was the symbol for urban-rural integration that agricultural bazaar was integrating urban core and its rural hinterland.

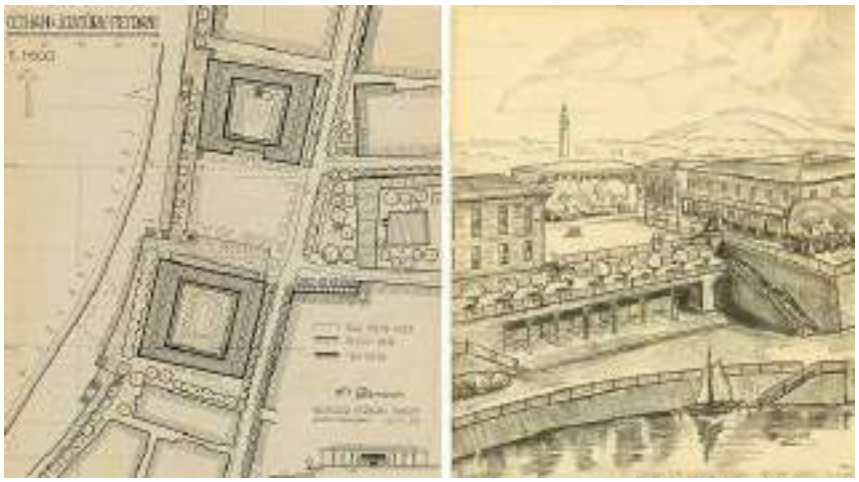

Figure 15: Ceyhan Atatürk square (Architecture Museum TU Berlin, Inv. Nr. 23396 and 23397).

CONCLUSION

The Republican Revolution had basic strategies composed of development of National economy and transportation, social progress and development of urban and rural frame. Urbanism and urban planning became key apparatus to reach aims of the Republic between 1923 and 1940.

For construction of National Economy, institutionalization and spatial arrangement of economic policies were compulsory that the Republican cadre procreated both a series of strategies for economic sectors and new growth poles, National foci and regional centers to apply those strategies in Anatolia. Southern Growth pole, which was one of National foci, was comprised by Hermann Jansen's planning in Adana, Mersin, Gaziantep, Tarsus and Ceyhan. Through urban-rural unity, agriculture-industry-trade

integration and new spaces of production, Southern growth pole was aimed to found a "national economic space".

Correlation between Hermann Jansen's planning principles and the Republican cadre would encompass economic development in urban and rural areas of southern area. For this reason, Adana was planned as an industrial town to operate cotton production in its fertile hinterland. Gaziantep also had a fertile hinterland on Silk Road, the gate to Middle East, and it was planned as an industrial-trade city as the hero of the War of Independence. Adana and Gaziantep were urban centers of urban-rural unity in spaces of production. Mersin, on the other hand, was developed as a Mediterranean trade center with agricultural and industrial production as a sea gate in Mediterrranean region. Tarsus and Ceyhan, as small Anatolian towns, were designed as modern Turkish towns encompassing historic, natural and cultural assets.

The Planning Habitus

Notes from São Paulo Experience

Nilton Ricoy Torres

Abstract

This paper is organized in two sections. The first, deals with the propositions advanced by Bourdieu, by focusing on his theory of structural constructivism. It draws on notions such as “habitus”, “field”, and "dynamics of struggles within the field", in order to assess the extent to which Bourdieu constructs can help to understand the dynamic of planning practice in Brazil. The second section assesses four working hypothesis dealing with Bourdieu concepts of social field and **habitus** and, with the dialectical relation between **structure** and **agency** in the planning process. The empirical analysis and theoretical confrontations are simultaneously developed by taking the experience of Brazilian planning practice and particularly that of Sao Paulo city. The concepts of field and habitus are analyzed in detail, and then connected to notions such as power, domination and class struggle, which according to Bourdieu are central for understanding the process of structural change. The paper attempts to sketch a framework for analyzing planning practice as a field of struggles, where conflicting social forces seek to keep or change the social structure.

Key words: Habitus, social field, planning, urban governance, power.

Introduction

This work deals with planning as a practice of governance and takes Pierre Bourdieu notion of “*habitus*” and “social field” as driving concepts. The objective is to identify the nature and the *modus operandi* of this practice, aiming to clarify the role of the governance agents on the social structures transformations. The concepts of habitus and social field are taken from the struggles that take place within the planning and governance fields, as these struggles are directed to accumulate power and impinge domination. The first part of the paper discusses the main concepts of the structural constructivist theory of Bourdieu, and in the second four hypotheses about planning and urban governance as a social field are analyzed and evaluated. These hypotheses are extracted from Bourdieu theoretical propositions and then confronted with the reality of urban governance by taking Sao Paulo planning and governance experience.

By articulating Kuhn ideas of scientific revolution and paradigm change with Bourdieu concepts, the paper evaluates the extent to which planners practices within the urban governance field can contribute to change or to perpetuate the existing social relations.

This paper intends to develop an interpretative reflection on the public administration in Brazil in order to shed light on some aspects of planning as a practice of governance. The test of these hypotheses is accomplished by comparing them with existing governance and planning practice reality, in both professional and academic fields. The following section presents an operational synthesis of Bourdieu method aiming to raise research questions that can be of interest to fields such as planning, geography, management and policy sciences.

1. Bourdieu meta-theory of practice

Bourdieu's critical structuralism seeks to unveil the nexus between the social processes of change and the subjacent structures to these processes, by analyzing the mechanisms of both domination and production of ideas and the genesis of individual behavior. The main objective is to overcome the social sciences opposition between objectivism and subjectivism. The notion of habitus is developed as a mediating concept between the structural and behavioral determinism, aiming to break through the common sense duality between the agent and the social structure. By capturing the "internalization of exteriority and the externalization of interiority", the *habitus* seeks to explain the way society becomes 'deposited' in social agents as forms of 'durable dispositions' and 'structured propensities' to think, feel and act. Such capacities will guide the agents in their creative responses to the constraints and requirements imposed by the social structure they take part.

The method of analysis is empirical and systemic and the fundamental premise is that the social dynamic occurs inside the group (field) within which individuals (agents) as bearers of specific attributes (habitus) establish confrontations among themselves seeking group hegemony. The field is organized by specific values or kinds of capital that are produced within it. The social dynamic is framed by struggles between agents seeking to keep or change the ways capital and power relations are distributed within the field. The struggles and conflicts inside the field follow strategies that are driven by the habitus which constitutes the determinant element for the action. The field is constituted by the positions the agents occupy which determine the way individuals or groups behave within the field. To the concepts of '*habitus*' and "field' Bourdieu attaches a myriad of secondary concepts that evolve among themselves in order to underpin a relational understanding of the social phenomenon.

1.2. *Habitus*

The concept is developed not only to escape from the rational objectivism of structuralism that reduces the individual to the structural determinations, but also to avoid the philosophy of consciousness which makes the individual solely responsible for

the construction of reality. The habitus is a generative scheme of shared of perceptions, judgments and categorizations designed to mediate the relationship between structure and agency, and which constitutes itself historically. In other words, it serves to explain the dialectical relation between the social structure and the agent[1]. According to Bourdier, the habitus is a 'matrix of dispositions' which is acquired through inculcated social experiences and which can be understood as practical wisdom. That matrix bounds the ways of perceiving, feeling and thinking that leads the agent to act and react differently according to each situation. The dispositions are not mechanical neither determinist. Instead, they result from a complex process of mutual incorporation and interdependency between the structure and the agency. The agent acquires them by internalizing the social structures. Such structures while the repository of individual and collective history, are internalized to the point that the agent ignores their existence. They are both mental and bodily unconscious routines that allow the agent to act without thinking, because they are product of an unconscious learning that are expressed by a "natural" behavior in a given environment.

The *habitus* is a system of long-lasting and transferable dispositions operating as a foundation of social practices and representations attached to a specific form of existence. The *habitus* frames and is framed by our actions and emerge in the form of symbols, beliefs, tastes and preferences that characterize the social status of the agent. It is embedded in social relations and works to sort and classify these relations. Once embedded, the habitus becomes a natural component of the agent's behavior. The embodiment of the habitus occurs in two ways. The first, through family education and class rules and, is implicitly and unconsciously inculcated in the agent's mind. Second, it is an explicitly and methodically organized process that comes from formal education, the cultural industry and the mass media.

The habitus are plastic and flexible dispositions and manifests itself in the daily social relations in different ways. It emerges as a tacit knowledge and as a world view, being expressed as reactions to experiences, game perceptions, hypotheses, intuitions, sensibilities, ways of doing, feelings, predispositions, expectations, sense of place, time and timing perceptions, preferences, desires, knowledge of each one's positions within the field, logical sense, aspirations, inspirations, tactics and strategies. The habitus is central to social life organization since it works as an immanent rule to guide the agent daily interactions and the construction of practical knowledge what allows the agent to operate in the world. Thus, the habitus defines individual behavior so that it works to determine the modus operandi, motivations, preferences, aspirations and expectations of

[1] Bourdieu (1984); Hiller (2001:2).

the social agents. The habitus offers no ready solutions for every situation or context, but it is an improvised response to the circumstances of the moment. The habitus is basically adaptive as it changes and adapt to each new situations and to each change in the social structure: new behaviors, new technologies, new realities, new conditions and restrictions. Constantly, the actor must and is forced to innovate their habitus in order to adapt himself to the new situations and social demands. The critical reflexivity in the process of habitus' adaptation accelerates its transformation. In this way the habitus works as a dynamical attribute: at the time the agent enters a field or game which is not familiar, there is a habitus' transformation and the agent develops new facets of himself. By changing his habitus the actor adjusts his way of seeing, perceiving, judging and valuing the world, which in turn will determine the physical and mental way he acts. Thus, the habitus, as social structures embodied by the agent, can be understood as ''practical knowledge ... of worlds that result from the division of classes ... (age and gender, social class)", which runs below the level of consciousness and speech[2]. The habitus is the mechanism for transmitting and "inculcating" norms, values and beliefs of the group which operates in the socialization process of the agent and, which in turn, will become the principles of action, attitudes and opinions of the individual in his daily practice. Once internalized, the habitus is converted into a provision that will produce perceptions that creates meaning and practices that make sense of reality.

The habitus is not a natural space but a socially built construct that is incorporated into the mental structures of the agents. It is a mechanism that allows the production and reproduction of social practice, since it is a structured perception on how to act and behave, in accordance with rules of the field. The habitus is shaped by mimetic and participatory actions in line with the logic of social interaction within the field. It is through the practice of repeating that the agent learns a way of being and assimilates them as correct. In this process, he incorporates a worldview, a particular way of being and doing which in turn, will distinguish him from the others.

It is through the habitus that the agent takes place in the social field and allows others also occupy their respective spaces in a relationship of complementarity and reciprocity. The social agent is multiple and variable and develop "multiple habitus", for he is not inextricably immerse in a sole habitus, but cam move from one habitus to another and develop adaptive behaviors within the same habitus.

The habitus is always seeking to overcome the antinomies that emerge from the past and future tension. Bourdieu argues that the habitus varies according to changes in the social

[2] Bourdieu (1984).

and historical conditions. By this, the habitus incorporates new perceptions which will contribute to preserve or transform the structures of the social field. By legitimating the agent actions, the habitus contributes to re-signify that action in such way as to keep or change the acting of that agent within the social field. The habitus is both a product (effect) and produces (cause) history. As a producer it yields individual and collective practices that affect the social structure. As a product it emerges as a construct from of the social structures it has created. In other words the habitus – as a result – is framed by the incorporation of social structures, and as cause it frames the individual actions and representations.

Because the habitus acts as a regulator of the social actions both in the subjective and objective dimension it can be used to evaluate the subjective attitudes that structure individual representations and also the generation of new social practices. Each subject experiences life according his position in the social structure and such experiences determinate his subjectivity forming a kind of "matrix of appreciations and perceptions". This matrix will serve as a guide for the actions of the agent in later situations. By having the habitus as a foundation, practices and representations can be directed to the actor's goal, without engaging clear and conscious actions about the purposes or take complete control of the operations necessary to achieve them. These provisions are objectively regulated and regular, but not the product of obedience to rules. They are collectively orchestrated, but not coming from a guideline.

1.2. The Field

For Bourdieu, the field is the space that delimits the structure in which the habitus operates. It is a structured social space in which actors struggle to achieve their goals. It is the *locus* of praxis that mediates the relationship between actor and structure. Each field has its own structure and autonomy in relation to other social spaces, and is governed by specific rules of operation and stratification, which serve to regulate the relations among social actors within that space.

The field is a structure shaped by social practices and social interactions, in which specific rules prevail to determine what is practical, objective and rational, which is appropriate, acceptable or reprehensible and, what should be encouraged or restrained. These values will then consolidate the habitus of a particular context. A field can be understood as an arena of disputes where the agents play, develop strategies and fight for resources: symbolic goods and social positions. Inside the field individuals struggle to control production and to legitimate the goods produced within the field. These assets consist of various types of capital: cultural, economic and social *status*. These capitals have different degrees of importance and vary according to the field. Their possession determines the social position of individuals within the field. Individuals owning

significant amounts of capital are considered important within the field and will occupy dominant positions within it. The subjects occupy closer positions within the field, according to the quantity and, type of capital they own. They are far away; if they differ in the volume and type of capital they hold. Bourdieu explains that economic wealth (monetary capital) and accumulated culture (cultural capital) generate internalizations of dispositions (habitus) which works to differentiate the positions occupied by the agents.
Bourdieu seeks to overcome the dichotomy between subjectivism and objectivism, by merging the system of objective positions with the system of subjective dispositions of individuals. The habitus that exists within a field works to mediate between: 1) the invisible system of structural constraints (which shapes the actions of individuals and institutions), and 2) the visible actions of these actors (which structures the relationships). It follows that the field is not a static structure, but results from both the history of the various positions and the provisions they favor[3]. The field survival and the field boundaries depends on the interests therein, on agents' psychological and economic investments, and on the institutions embedded in it. For Bourdieu, fields are established by processes of social differentiation and modes of being and knowing the world of their members, which will determine its specific object and its principle of understanding. Bourdieu constructs the concept of field by taking a constructivist view of structuralism. He seeks to analyze fields as objective structures, apart from their member's characteristics. The analysis concentrates on the structures of different fields, approaching them as product of the incorporation (geneses) of existing structures[4]. Fields are then conceived as "universes" (such as universe of arts, of politics, of music, of science) which emerges as autonomous spaces inside the social world. Society, is seen as set of fields (universes or spaces) displaying concrete relations, specific functioning logics, which are incommensurable, not reproducible and irreducible to the logic of other fields. A field is then defined as (1) a "field of forces" over which domination is exercised; (2) a structure that restrain the agents action inside it; (3) a "field of struggle" among agents that fight to preserve or change the field structure[5]. Any field has an internal structure of relational spaces (inside which agents and institutions coexists in different structural positions) and an external space (which is not field)[6]. Internally, a field is constituted by an objective structure of positions and by a subjective structure of dispositions. In this process the field builds the habitus and the habitus shapes the field[7]. Therefore, the field is the exteriorization or the objectivation of habitus and the habitus is the internalization or the incorporation of the social structure.

[3] Cf. Bourdieu (2001, p. 129)
[4] Ibidem
[5] Bourdieu (1996, p. 50).
[6] Ibidem.
[7] Bourdieu (1992b).

The agent's position within the filed influences the way he access and consumes the field social and cultural objects and the way he produces and accumulates values[8]. The field is the place where the agents (individuals, groups or institutions) establish objective disputes and compete to command a specific type of capital. Inside the field the agents are seen as homogeneous habitus bearers, because they play the field games and compete for field positions and capital[9].

The field owns universal properties found in all fields, and specific ones that belong to a particular field. The universal properties are: (1) the field habitus; (2) the structure; (3) the laws for regulating the struggle for domination; (4) the *doxa*, or the consensual opinion. The specific properties are defined by the *nomos* (general laws governing the field's life). The *doxa* is a consensual discourse that all agents can agree, and works as a collective understanding – a common sense. The *doxa* involves issues which are accepted as natural, such as the systems of classification of reality. The concept of *doxa* was developed to elucidate the Marxist conception of ideology (as false consciousness). It is understood as a particular point of view, which is the dominant class point of view, and which is presented as universal belonging to all field members[10]. The *nomos* are stable general rules that regulate the field operation. The fields have different *nomos* because each field has a different historical evolution. For instance, the XIX century artistic field nomos was, "the art by the art"; the twenty century modern architecture had as nomos "the search of rationality between the form and function". These nomos must be accepted and legitimated by means of historical processes of struggle that takes place inside the field. The nomos is like a ruling principle which is inculcated in our minds by a socialization process.

All social fields are constituted by smaller subfields, which display the same characteristics of the circumscribing field. As social spaces formed by unequal distribution of various kinds of capital, the field and subfields are marked by class struggle among the agents, Some agents seek to keep the field structure other seek to change it, aiming to modify the hierarchical principle (economical, cultural, symbolical) that regulates the positions inside it. Dominant classes are those which succeed imposing their typologies of capital as the field hierarchy criteria. This struggle is waged in the political field and results mostly, in struggle for power.

The field is also marked (1) by the relations of force emerging inside it ; (2) by strategies (of defense or subversion) used; (3) by external pressures it experiences; (4) by other fields' conflict interpenetration and, (5) by other fields' ideas. The autonomy of a field

[8] Bourdieu (1984).
[9] Ibidem
[10] Bourdieu (2010).

depends on the volume and pattern of dominant capital. The search for autonomy requires constant interpretation of reality and refraction from influences and contaminations introduced from outside. Life within the field is not determined by the external pressures, but by the internal translation of these refracted pressures. The external struggles (economic, political, etc.) contribute to change the relation of forces inside the field, but such influences are always mediated by the structure of the field, which stands between the agents conduct and his social position. The relative autonomy of the field stems from its ability to establish its own rules, even when under pressure or influence from other fields.

2. Habitus and practice in the field of planning and governance

This section deals with planning, through the practice of urban management with reference to the propositions advanced by Pierre Bourdieu. The goal is to test the explanatory and generative elements of Bourdieu theory -considering the governance practices undertaken through planning - and to evaluate to what extent the results provide evidence to clarify specific situations related to this practice. The analysis focuses on the agents' practices. The focus of analysis is the practice of agents that directly or indirectly participate in the universe of planning as urban governance. The objective is to explain the principles guiding the action of those agents. The planning universe itself is the object of reflection. It seeks to analyze the structure of planning as a field of practices and assess to what extent this structure depends on the state tutelage.

The following text evaluates four hypotheses about the practice of planning as a process of urban governance. They are explicitly drawn from Bourdieu theoretical framework. The hypotheses tests are carried out with reference to episodes, events and situations experienced by the agents and institutions over the recent history of planning practice and governance in the city of Sao Paulo.

2.1 Hypothesis 1: The agents integrating the planning field incorporate habits that are common to all members, regardless their ideological views or field position.

Evidence suggests that urban managers, both conservative and progressives perceive planning as a "strategic instrument" with the mission to organize and discipline the social and economic physical space. The planning experience in Sao Paulo tends to confirm such hypothesis. By analyzing reports, discourses and practices of government, it is observed a convergence of perceptions, understandings and actions among the agents of the planning field. The recurrent and consensual idea is that planning, as governance instrument is a process of rational articulation of means, in order to discipline and control the social object of intervention: the urban thing. Over the years, most of the products that emerged from the planning field in Sao Paulo were statements

about the need of rationalizing and organizing the urban development in order to avoid “diseconomies,” “waste,” “exclusions,” and damages to the various kinds of uses, activities and interests within the urban space. The ultimate goal is to develop a cohesive and harmonious space in order to rationalize the actions of various actors in the urban environment.

From the reading of the master plans and public programs produced over the past 30 years in São Paulo, one can observe a clear logic of intervention and control. The habitus that emerges from this planning practice, regardless the different administrative regimes that followed, suggests the prevalence of a homogeneous perception and a common understanding on the role of "strategic" planning as an instrument to promote and coordinate the several towns within the city. As Bourdieu states, by participating in a field, the agent incorporates a system of specific provisions, which allows him to play the game inherent to the field. Taking the planning for a social field, as Bourdieu suggests, it is not inconsistent to conclude that planners incorporate habitus common to all members of the field: that sees planning as a strategic tool to propose technical, logical, and rational solutions to the issues of urban development.

As it can be noticed the habitus is not dependent on the agent ideological views, because it is already inculcated as a disposition in the agent perceptions of the world which determines how natural to have planning in order to predict, organize and provide solutions, for it would no sense being otherwise. The habitus are unconscious mental routines that allow planners to act without having to reflect on their actions. Governing seems to be a natural and reasonable attitude of those seeking "appropriate" solutions for urban problems – the object of the intervention. After all, planning is the antipode of market chaos and the anarchy that reigns in the worlds of liberalism. Without control and some form of restriction and policing over the chaos, the social order and the city could collapse. The habitus are like consolidate and unreflective certainties that produces a rationality which is not reducible to reason. They are products of learning and of a process which we no longer have consciousness and expresses itself as a natural way of being and thinking in a given context.

The daily discourse of planning shows that there are significant ideological differences among the agents of governance, regarding the meaning of their practices. In fact, these differences emerge, for example, in defining an appropriate solution to a given situation. Thus, for instance, while for some the housing issue and access to a shelter is the central object of urban governance – a mean for reducing social injustice and exclusion – for others, housing is a secondary problem, facing the imperative of recovering the depressed areas in the city. Despite the differences, what is homologous between both views is the belief in public intervention and on the ability of technical solutions. The Strategic Master Plan of Sao Paulo city, enacted in 2002, is a remarkable example of the

antinomy between the ideological antagonism and the habitus convergence. In this experience we observe more clearly how homologous habitus and opposing ideologies are connected together in a single discourse: On the one hand, the discourse of technical rationality prevails, and imposes controls to land use and land development seeking to organize the space for the convenience of the capital. On the other, the plan includes, in admirable way, all innovative dispositions of The Statute of City[11] in order to support the democratic planning and the social inclusion discourse. Finally, as an immanent totality to all these visions and discourses, hovers the idea of tactics and strategies, something like collusion among military generals, through which the planner is given the prerogative to set the rules and direction of the game.

2.2 Hypothesis 2: The planning habitus are practical knowledge that is inculcated in the agent through: (1) professional participation on governance institutions staffs, (2) tacit learning accumulated throughout professional practice, (3) formal education.

In the planning field, it is observed that habitus are assimilated in three different ways. First, through professional activity and tacit learning acquired over the practice. It is in daily confrontations with professional challenges, experimenting success and failures, that the planner constructs his way of doing and being which will constitute the field habitus. According to Bourdieu, the agents acting inside a field are directed to adjust their thinking, perceptions and actions to the objective requirements of that social space. It is through a process of adjustment and change to field requirements that the social agent constructs his practice. Those experiences he gets through field interactions are gradually integrated to past learning and that will constitute a matrix of knowledge generation that will guide the planner future practice. Bourdieu sustains that: "practical knowledge is a construction that triggers classifications systems and these are used to organize perceptions and appreciations that structure the practices"[12]. Planning practice thus constituted, is defined as knowledge built and embodied over the agent professional life. Along this trajectory, the planner incorporates knowledge about planning, about images and roles of planner, about beliefs and convictions of their practice. The *habitus* built in this way, becomes a social constraint which lead the agent/planner reproduce the social conditions of its own reproduction, which, in turn, will become the generative principle of action of the urban governance.

Second, habitus is also embodied through the culture (or habitus) that preexists in governmental institutions in which public policy is carried out. In these contexts, persists a diffuse and universal discourse about the planner social and administrative responsibility with the city. The planner in governmental contexts increasingly

[11] This is the Brazilian Federal Law enacted for regulating the urban development.
[12] Bourdieu (2010).

incorporates an awareness of his mission as the "*corpus publicus*" member which can be summed up as to care for the "common good", the "public interest" or the "general welfare." To be in the planning agent position as a member of the state, means to work for the public interest (or state interest). The "intrinsic culture" of Sao Paulo planning (habitus) is another unique way of assimilating the field's game. In the case of Sao Paulo, this culture is marked by the way of doing planning that has as its starting point the synoptic view, i.e. planning as a process that goes from top to bottom, in which the act of planning has its genesis in the development of a Strategic Master Plan that defines the general guidelines for development. The synoptic "need" becomes integral part of a tacit knowledge that comes from non-written rules which are incorporated to the administrative practices of government. To the planner eyes (habitus), it does not seem that the practice may be different. Through the Habitus, planning must run from general (*global guidelines*) to particular (*local solutions*) in a deductive process that provides control and articulation capacities of the proposals and actions.
A third way of incorporating the planning habitus is through professional education and by different modes of inculcating a way of thinking which is transmitted through the academic settings, research institutes and universities. There are several streams of thought within the academic world offering different conceptions on the meaning of planning and about its social, political and ideological roles. Such streams of thought have different premises, axioms and methods which are transferred (inculcated) to the students through the study years. These students will later constitute cultures and schools of planning which will determine the way of seeing perceiving and doing planning.

2.3 Hypothesis 3: Planning can be understood as a habitus incorporated to practices; that is it is a set of dispositions and habits that determine the way of doing planning.

Planning as a habitus can be understood as a set of dispositions defined by beliefs, ways of thinking, of understanding and perceiving. They are assumptions which are materialized in the form of truths, rooted ways of doing and perceiving. The planning habitus perceive planning as a way of carrying out a rational and strategic management, capable of articulating the administrative action to achieve the control of the urban processes. This habitus understands that the planning action starts from general formulations (global guidelines) by integrating the several dimensions of the urban space (land use, transportation, and housing) and articulating them to actions of the various administrative branches (works, health, transportation, culture, infrastructure, etc.). Likewise, as product of already established habitus, the planning is constituted through the game of repression and tutelage, in which the police action becomes an integral part of planning. Inculcated in the minds of the planner, there is a concern of protecting the public interest and a sense of social responsibility, motivated by the ideas of zeal, vigil and command.

According to planners, without planning and under the exclusive action of market forces, the city enters the chaos. Approaching the world through planning habitus, planners take the regulatory power of planning in order to minimize spatial dysfunctions and social injustices. They think that the competent state intervention and struggles within the field can promote social inclusion, enforce the social function of private property and guarantee the right to the city.

Bourdieu states that each field has a *doxa* formed by the common sense view that expresses as an ideology through which the world is accept as it is. They are like perceptions, appreciations and values shared by all inside the field. In the field of planning the *doxa* is established by the idea that planning is a rational, strategic and calculated process, for resolving the impasses and maintaining the field game. This *doxa* includes directing, coordinating and regulating and in order to achieve that planning must prohibit, restrain or encourage. For this reason, the planning *doxa*, includes implicitly, the idea of "reproduction", because it emerges as a point of view of the dominant class, but are presented as universal interests belonging to all members of the field.

The *nomos* are stable general rules that regulate the game in the field. In the field of planning these rules are linked to the field *raison d'etre*, i.e.: planning exists to rationalize government actions, maximize benefits, prevent undesirable situations, control agents' actions and penalize misconducts. As a general rule, planning exists to fulfill these functions. Regardless the meaning of the actions (to focus on the functionality of the market or to favor the social income balance), the *nomos* of planning is always to act through the state in name of public interest.

The land use policy of Sao Paulo, for instance, reproduces old habitus long ago consolidated in the way planning is carried out in the city. Such habitus perceive the city as a *bricolage* of areas with specialized land uses (zones) and different densities. The goal is to control the urban land use and urban development, in order to maintain and the city economic functionality and guarantee the reproduction of social relations. For that reason Sao Paulo zoning ordinances are seen as normal, natural and the most efficient way of governing the urban activities within the city. In the view of planners (habitus) inside the planning field, it seems to have no other way to administrate the land use besides the tutelage mechanisms and symbolic violence exercised through legal punishment. In this way, the land use management in Sao Paulo can be seen as a habitus deeply rooted in both the mental structures of planners and the objective structures of urban governance institutions. The zoning ordinances in Sao Paulo perform a fundamental role of promoting (and perpetuating) the idea that planning is a force or police instrument to control deviations, anachronisms, and dysfunctions among the

various land uses in the city. The idea of segregating the urban land in diverse ghettos of people and activities, as well as the idea of "protect ting" uses and places (zones) from those undesirable people and activities was and still is a dogma (habitus) of Sao Paulo Planning tradition. Although such habitus is slowly changing –consequence of struggle within the field – and the idea of existing a mixed urban land use starts to be conceived, struggles inside the planning field still goes on, since it is never admitted an urban space with mixed social classes. The conception (habitus) that the city territory has to be divided in different areas and zones is still fundamental.

2.4 Hypothesis 4: The field of planning produces two kinds of values (capitals) which both the economic field and the political field depend on. Planning has the power of legitimating political decisions through the technical and scientific rationality discourse and by coordinating the distribution of public money through the governmental budget. The police and regulation power attached to planning acts as a strong instrument of income distribution, by redirecting public resources.

The capacity of legitimating political decisions and to provide a less arbitrary image to closed and sectary office deals is one of the most coveted products of the planning field and yields, as suggest Bourdieu, symbolic capital. It's the capacity of producing this kind of capital that allows planning to articulate proposals and justify essential referrals for an effective public administration. Planning carried out by planning agents' becomes a form of symbolic capital, since it functions as strategy domination because it sets limits, imposes conditions, formulates assumptions, proposes goals that will little by little become the *nomos* of the entire population. The nomos, according to Bourdieu, synthesizes the dominant view and is imposed to all society (dominated groups). Therefore by submitting their proposal in the form of "the city we want" or "Sao should not stop" or the "health city", planning agents, in fact, defines a conception of city attuned to the dominant interests and expressed in the plans and policies. It can be argued that the habitus which commands planning practice (and science) can incorporate worldviews and perceptions that ultimately manipulate values, constrain possibilities and condition guidelines.

In the context of society as whole, planning is a strategic field because it produces values of main importance to the struggles in other social fields, since it is the locus where the distribution of economic and political capitals is legitimated. This power allows the planner command various ways of distributing capital on the territory and that enables to change the balance of power and capital among various agents. For this reason, intense struggles take place within the field of planning, since its operation becomes strategic for keeping or changing the relations of domination within society.'

Conclusion

Bourdieu's key contribution for our understanding of planning as urban governance is, in my view, the idea of *habitus*, and its confrontation with a specific situation from which practice emerges. It advocates that, there is no absolute truth or pre-conceived action template to follow, because practice is the actor's casual answer to issues he faces at each moment. In the case of planning, we can infer that the habitus of planning in different historical times, places and situations proves to be a key variable in the *modus operandi* of the planning field.

Planning as a habitus is a possibility and a field of research and opens an opportunity for investigating planning through the practice of planning. In this new field of study there is no pre-given determination, because there is no permanent, or priority object of analysis. The focus is not on the structures of planning or on the social actors, but on dialectic relations they establish. Bourdieu approach allow us understand planning as a structured field of forces and practices, which are permeated by structured and structuring habitus. Planning, thus defined, allows us capture planning practice as a habitus that emerges from internalization of the structures (of planning) and the structural changes in planning as a product of externalization of planners' interiorities.

ABSTRACT

At the heart of strategic metropolitan planning are 'standards'. The term usually refers to the 'rules, regulations and specifications' that underpin the institutionalized practice of urban planning. Planning standards are used not only to regulate and manage what happens within the built environment but also to improve the quality of life of places within a city. Surprisingly, it is difficult to find much discussion of planning standards within the English-speaking literature on metropolitan planning especially in regard to how they have shaped planning practice, when and why they were devised, how they have evolved over time, plus to what extent historic and place specific factors have come to shape them. This is certainly the case in the Australian context even though this is potentially a very fruitful area of historical investigation. Using the case study of metropolitan Melbourne, this paper explores when and why planning standards that regulated the provision of public facilities made their way into the metropolitan planning schemes of this city, plus why they have changed over time and what implications this may have had for this large Australian city which was recently nominated as the world's most liveable city. The investigation makes a number of key findings. First, the adoption of planning standards in Melbourne was conditioned by locality-specific contingent factors – politics, administrative powers, public discourse and economics – as well as external structural factors - developments in overseas planning practice and the cyclical rhymes in international and national capitalism. Second, different historical phases of the city's metropolitan development gave rise to

differing attitudes towards the ‘status and practice’ of urban planning which directly impacted upon the provision of public facilities to the citizens and communities that could be found in this city. Third, those communities in greatest need for public facilities and services have always suffered the most, as the political and administrative support for their provision has varied over time. The recent rise of neo-liberalism over the last 2 decades in Australia, for example, has meant that successive Victorian state governments have been reluctant to make significant social infrastructure provision commitments in their metropolitan planning schemes for Melbourne. Fourth, the socio-spatial divide that has historically existed between the people who have lived in the central-inner and outer-fringe regions of the city has been allowed to deepen, through the unequal distribution of public urban facilities and services. This has therefore nurtured conflicting perceptions of place and the people who inhabit them in a rapidly polarising metropolitan area. Finally, the paper concludes with a series of policy recommendations that propose to redistribute public facilities and services more equally and thereby improve the quality of life of the outer-fringe communities of metropolitan Melbourne.

Introduction

In comparison to many European cities Melbourne is a relatively young city. Founded only in the early 1830s, it grew quickly after 1851, when gold was discovered in the surrounding hinterland. Melbourne would now be transformed into a modern metropolis. But much has happened in the intervening 150 years. Melbourne is no longer regarded as a city of international significance. In the last 3 decades, Sydney has surpassed it both in terms of population size and economic importance. Surprisingly then, Melbourne was ranked ahead of Sydney and other major cities as the world's most liveable city in 2011 by the Economic Intelligence Unit. The ranking is based on different qualitative and quantitative indicators across 5 broad areas including social stability, health care, culture and environment, educational facilities and infrastructure. Essential to this and any other liveability ranking method must be an attempt to establish whether the citizens of a city have access to appropriately located social infrastructure. This has and only partially continues to be the case in Melbourne.

The citizens of Melbourne are fortunate as they live in a safe and well equipped modern city where health care, schools, good roads, public transport, open space and a wide array of cultural and recreational facilities are generally within easy reach of many. This did not come about by chance but it is the by-product of many years of planning on the part of strategic and social planners working at both the state and local government levels of urban policy-making. It is therefore surprising to discover that there are no accounts of who undertook this urban planning work; to what standards did Melbourne's planners adhere too with regard to the delivery of public services and facilities, plus were these standards devised locally or borrowed from elsewhere. Essentially then, very little to date has been written on the nature and role of planning 'standards' in Australia, especially those that relate to the provision of publicly funded services and facilities in Melbourne.

This conference paper seeks to fill a void in the Australian research record by reconstructing the planning history of Melbourne but from the vantage point of when

social infrastructure delivery standards were incorporated into metropolitan plans of this city. Specifically, this paper will attempt to address the following questions: (1) what form have planning standards taken that are concerned with the provision of community services and facilities; (2) when were they first introduced; (3) what may have been their origins; plus (4) how did they evolve over the last 100 years with respect to the metropolitan development and planning of Melbourne.

Standards: The Hidden Rules and Codes of Metropolitan Planning

At the heart of strategic metropolitan planning practice are 'standards'. The term usually refers to the 'rules, regulations and specifications' that underpin the actual act of plan preparation and regulation. Standards are "...used to determine the minimal requirements to which the physical environment must be built and must perform" (Ben-Joseph, 2005b: 3). "...Standards are...[therefore] set to control the physical setting of the urban area and contribute to ensuring the...welfare, convenience, efficiency and public interest" (Ratcliffe, 1978: 291). They now extend to virtually all facets of the built environment including land use zoning, sub-division, population density, building quality, height restrictions, privacy provisions, configuration of roads, open space requirements, location of public amenities, and so on (Ratcliffe, 1978). Standards are clearly an integral part of a planner's tool kit to design and regulate the built environment but this has not always been the case.

Many contemporary urban planning standards can trace their origins back to the late nineteenth and early twentieth century's when the pioneers of the planning profession sought to improve living conditions in urban areas which were afflicted with health, safety and allegedly morality problems (Ben-Joseph, 2005a, xiii). Of course, there are examples of much older building and town planning standards dating back to ancient civilisations of the biblical era (see Ben-Joseph, 2005a), but most of our contemporary standards are less than a hundred years old. It is surprising that so little historical research has been undertaken into this facet of urban planning despite its obvious importance (see exceptions Ben-Joseph, 2005a, 2005b; Keeble,

1972; Ratcliffe, 1978; Wilkinson, 1985). What research has been done on urban planning standards has usually been locality based and pre-occupied with land use zoning, the sub-division process and buildings (see Ben-Joseph, 2005b; Delafons, 1969; Hoyt, 1933). None of this work has had an Australian focus. Even less work has been done on standards concerned with the provision of public services and facilities other than a small amount on urban parks and children playgrounds (Granz, 1992; Gold, 1973; Theobald, 1984). Again, there is a discernable gap in our understanding of what has happened in the Australian context, despite a growing interest in the planning history of Australia's cities.

Planning standards dealing with the provision of public services and facilities have been limited in both number and scope. Most have taken the form of so-called 'hard' social infrastructure such as public facilities and buildings which are considered essential to supporting community life. This often included children playgrounds, sporting fields, public parks, kindergartens, schools, libraries, town halls, community centres, baby health care centres, plus other types of recreational and cultural facilities. According to the work of Veal (2008a), public service and facility standards have usually been quantified in four different ways:

1. Fixed ratio – a prescribed level of facility or service provision for a specified number of people. For example, 1 kindergarten is needed for every 3000 people, or 10 acute aged care beds are needed for every 7,000 people aged over 65 years;
2. Area-percentage – a prescribed amount of area is suggested for a specified number of people. For example, 2.83 hectares or 7 acres of open public space per 1000 people, irrespective of where the people might live;
3. Catchment area – a service area has been identified and a set level of facility or service provision has been prescribed. For example, a household located anywhere within a designated neighbourhood should not be no more than 400 metres walking distance from a bus stop or public park;
4. Facility quota – the number and size of services and facilities have been prescribed for different types of residential communities. For example, a neighbourhood should have a children's playground and public garden, whereas a town will possess the

open space facilities of several aggregated neighbourhoods as well as major sporting fields and a large public park.

Imbedded within these specific kinds of planning standards are a host of ideological and technical assumptions which have been increasingly questioned over the last few decades and lead some to suggest that other approaches should be used by planners to decide whether communities are in need of publicly supplied services and facilities (see Gold, 1980; Marriott, 1980a, 1980b; Veal, 2008a, 2008b). It is beyond the scope of this paper to review this debate but it is worth noting that this dissention exists even though such standards continue to influence the decision-making of urban planners.

Melbourne: The Case Study

Melbourne is located in the south-eastern part of mainland Australia within the state of Victoria. It is the 2nd largest city in Australia behind Sydney in terms of population however it is the largest city in the state of Victoria of which it is also the state capital. At the last national census in August 2011, the population count for the city stood at 4,077,036 people, many of who live at very low-densities when compared to European cities. The metropolitan area is 8806 km² (or 3,400 sq miles) and stretches for more than 100 kilometers from south to north making it physically larger than Sydney. Its large metropolitan area is divided into 31 local government authorities that share planning responsibility with the state government of Victoria. The latter devise urban planning policy and overall strategic direction for Melbourne whereas local government authorities modify them for their specific locales and monitor land use development within their respective jurisdictions. Melbourne is typical of many other Australian capital cities as its urban development has been characterized by continual outward sprawl underpinned by the notion of a 'quarter acre block of land and house' for everybody. This, coupled with the popularity of the private automobile after the late 1950s, led to an auto-centric urban structure, with many outer areas being deprived of reliable public transport and adequate public facilities.

The Historical Provision of Social Infrastructure in Metropolitan Melbourne, 1835 to 2010.

The first form of town planning in Melbourne occurred in 1837 by laying out a rectangular grid of approximately 3 miles long and 1 mile wide parallel to the Yarra River. The city grew slowly until the discovery of gold in 1851. Melbourne then expanded quickly in size as it became a gateway to the goldfields and an expanding pastoral hinterland that transported its produce via ship back to England. It was therefore not long before Melbourne began to experience the same problems that had beset many older industrial cities of Northern Europe including a lack of basic public amenities, over crowded housing, poor roads, a need to secure clean water supplies, plus disposing of human waste (Barnett, 1979; Briggs, 1968; Dunstan, 1984; Grant & Searle, 1978). A growth in noxious industries and an inability to effectively dispose of human waste fuelled a fear of cholera and diarrhoea that had already claimed thousands of lives in Britain during the 1860s (Dunstan, 1984).

Amid the ensuing urban growth and public health fears, land just outside of Melbourne's town boundary was set aside for public parks in the 1850s, as a way of countering the unsanitary living and working conditions of its inhabitants by providing them with the opportunity to exercise and breath clean air (Whitehead, 1997). In addition, public parks were also viewed as a place where people from different social backgrounds could mix, a process that could help elevate the manners and morals of the working classes (Granz, 1982; Whitehead, 2005). This initiative was derived from the early English notion of the public park. Together, 11 major public parks including a botanic garden acted as a kind of green belt around the central city (Whitehead, 2005). But decades of public debate over the unsewered city and the rising number of deaths from diseases associated with unsanitatory conditions had not rectified the sewerage problem (see Dunstan, 1984). A royal commission was finally appointed in 1888 and it proposed the building of a metropolitan wide underground sewerage system by a single body not unlike the

short-lived London and Metropolitan Board of Works (Dingle & Rasmussen, 1991). The Melbourne Metropolitan Board of Works – hereafter MMBW - was established in 1891 just as a global economic depression descended upon the city and the rest of Australia.

By the start of the 20th century, housing located within central and inner Melbourne had begun to physically deteriorate and the first signs of slum conditions were now apparent, aided by the lingering effects of the 1890s global economic depression that was extremely severe in Melbourne (Cannon, 1966; Davison, 1978). Journalist reports of the time fuelled a growing unease amongst the city's middle classes towards the slums and the people who lived in them (Mayne, 1990). Successive state governments held enquiries into the problem such as the 1914-18 Royal Commission on 'Housing Conditions of the People in the Metropolis' but took little action. Concerned individuals and social reform groups therefore turned overseas for solutions. Some individuals who at this time engaged in the public debates over Melbourne's slums undertook overseas study trips to Europe and the USA attending planning conferences, collected information from foreign publications, organized visits of foreign experts, plus helped form associations that would engage in political lobbying to rectify this problem (Freestone, 2010; Garnaut, 2000; Grubb, 1976b; Ward, 2002).

Agitation to do something about slums had begun during the 1890s and gathered momentum just before the outbreak of WW1 (Russell, 1972). At the centre of the anti-slum movement was the belief that dilapidated and overcrowded housing acted as a kind of contagion that threatened the physical and moral health of the slum dweller. In other words, 'if people are put into a bad environment it will produce bad people. Bad people will make a bad environment worse' (Davison, 1983: 144). The slums were also said to harbour public health problems that could spread to other parts of the city. But of even greater concern was the belief that they were sites of moral degradation. Particular concern existed for the moral and physical wellbeing of children who needed to be rescued from this unhealthy environment. Melbourne's

social reformers turned to England and America where since the 1890s a number of social reform movements – eugenics, the settlement movement, the child saving movement - offered a range of environmental determinist solutions to the problem (Davison, 1983). The more moderate of these reform movements asserted the 'slum child' could be saved by making available free services and facilities inside the slums including children playgrounds, baby health clinics, kindergartens and food programs (Davison, 1983).

Not surprisingly, the first kindergarten was set up in the Melbourne inner suburb of Carlton in 1901 and six years later the first children's playground opened there in 1907 (Davison, 1983; Spearritt, 1974; Whitehead, 2004). The first baby health centre appeared in Richmond in 1917 (Sheard, 2005). By the early 1920s, Melbourne's inner suburbs which housed the city's poor working classes were 'encircled by a cordon' of free kindergartens, playgrounds and baby health clinics, funded by private donations and local municipal councils (Davison, 1983: 161). It is worth noting that these early urban reformers choose to focus public debate on the people who were trapped inside the slums rather than the structural causes of the problem such as the city's poorly regulated capitalist property and labour markets (Gardside, 1988). Out of this middle class reformist zeal would come the first formal planning standard dedicated to the provision of a public facility in Melbourne: the child playground.

By the end of the nineteenth century, children playgrounds had been established in English and American cities, to improve the physical and moral welfare of children (Bird & Garnaut, 2010; Whitehead, 2005). Some were supervised and segregated according to the gender and age of the children. Initially, individual social reformers such as Charles Bean, James Barrett and Madeline Murray had campaigned for their adoption here in Melbourne. By 1912, the Guild to Play had been formed and lobbied for more playgrounds which were subsequently built in working class Clifton Hill, Collingwood, South Melbourne, Port Melbourne and Flagstaff Gardens before the end of WW1 (Apps, 1944; Whitehead, 2005). Many neighbouring middle ring

municipalities would go on to build pubic playgrounds during the inter-war period for their middle class ratepayers and children.

The state government took some time to codify this development in legislation even though a 1915 report by James Morrell to the Victorian minister of public works on planning developments in American and British cities, had pointed out a growing trend in the provision of municipal parks and playgrounds (see Morrell, 1915). It was not until 1922 that the Melbourne Town Planning Commission – hereafter MTPC - was established to deal with the tremendous amount of urban growth that occurred after the end of WW1, but a final report was not completed until 1929. The MTPC was modelled on the American notion of a supra-regional 'city planning commission' that would use the latest planning concepts and techniques devised in America to develop a 'master plan' for Melbourne (Freestone, 2000, 2004; Freestone & Grubb, 1998). The final report was significant not only because it was 'Melbourne and Australia's first comprehensive metropolitan plan' (Freestone & Grubb, 1998: 134), but it also stipulated for the first time a planning standard for the provision of a public facility.

The 1929 report recommended that the following provisions be made for the supply of new public parks and playgrounds:

~ ¼ acre of playground space for every 1000 people

~ a playground to be no further than ¼ mile distance from child users

~ 3 acres of playing field for every 1000 people

~ 1¾ quarter acres of general parkland for every 1000 people

In total, 5 acres had been prescribed of general parks and playgrounds for every 1000 people, a technical standard that could now be used to establish whether different parts of a metropolitan area conformed. Disappointingly, the plan was never gazetted into law by the state government and the MPTC was dissolved, shelving its plan for the next 2 decades. Speculation has surrounded the question of why this happened with some commentators suggesting it was due to the onset of the 1930s Great Depression, the anti-planning attitudes of a conservative state government or a loss

of support from local government councils which feared the emergence of a planning authority that could usurp some of their powers (Freestone & Grubb, 1998; Grubb, 1976a; Lewis, 1995; Sandercock, 1975).

Of greater interest to this paper is the question regarding what were the origins of these open space standards. First impression suggests they came directly from America as part of the 'Americanization' of Australian planning that occurred in the 1920s (Freestone, 2004). Research indicates that American social reformers associated with the US Recreation Movement and the National Playground Association of America had devised distance thresholds, area percentages and population ratios by the start of the twentieth century (Wilkinson, 1985). Closer investigation reveals these concepts had in fact been borrowed from England. Theobald (1984) has found that the distant threshold notion - people should not be more than ¼ mile from open space - can be traced back to the 1880s and a London based organisation known as the Metropolitan Public Gardens Association. Reference can also be found to a ½ mile or 600 yard distance threshold between facilities and worker homes in Ebenezer Howard's book To-morrow: A Peaceful Path to Real Reform published in 1898 (Mann, 1965).The idea that a town should allocate a certain percentage of its area to open space is to be found in the work of an Englishman, Robert Hunter, who was writing in the early 1890s (Theobald, 1984). Allocating a specified amount of playing space to children has been found in several reports produced just before the start of WW1 by the London Board of Education (ibid, 1984). Hence, the first planning standard concerned with the provision of a public facility in the metropolitan planning of Melbourne was derived from England but refined and transported here via a new technocratic based approach to urban planning that was being developed in America.

Just as the 1890s depression had brought economic hardship and poverty to the people of Melbourne so would the 1930s depression. As in the past, working class households bore the brunt of bad economic times, many of who were living in or close to the already deteriorated inner suburbs of Melbourne. Overcrowded

dilapidated housing was a classic feature of Melbourne's slum areas during this period. Once again, the spectre of slums and their potentially dangerous occupants returned to the public debate, producing a range of responses from the city's middle classes. Some formed themselves into secret para-military organisations ready to quell any political uprisings (Cathcart, 1988). Others joined charitable organisations and distributed outdoor relief to the needy (Mackinolty, 1981). Some sought to document the city's slum problem through research and journalistic reporting such as Oswald Barnett. Then there were others who joined professional groups such as the Victorian Town Planning Association to lobby the state government to act which it finally did in 1936 by setting-up the Housing Investigation and Slum Abolition Board. It produced a damning report into the 'appalling living conditions to be found in these inner suburbs where unemployment was still high. It stressed the dangers of doing nothing about the slums where moral and political unrest was festering' (Dingle, 1984: 220). In response, a conservative state government agreed to establish a quasi-planning housing authority called the Housing Commission of Victoria in 1938, but it achieved little (Sandercock, 1975).

The outbreak of WW11 deflected public attention away from the slum problem even though the Commonwealth introduced rent control provisions as a wartime anti-inflationary measure. Residential rents were frozen at 1939 rates thereby encouraging private landlords to further neglect their already dilapidated inner city rental properties (Nelson, 1980). A new awareness for the need to devise and introduce comprehensive planning standards did not come from the Victorian planning profession or the state government, but a progressive Commonwealth Labor Government determined to eradicate slum housing that had been made worse by the 1930s Great Depression. To achieve this goal, a Commonwealth Housing Commission – hereafter CHC - was set-up that produced in 1945 probably the most comprehensive planning report every produced in Australia by either a commonwealth or state government (Troy, 2010).

In the area of public facility provision, the 1945 final report of the CHC recommended certain facilities should be provided as a ‘minimum’, at the same time when houses were built and that they had to be within a reasonable walking distance. This included shops, playing areas, an infant health and pre-school welfare centre, meeting hall, plus schools (CHC, 1945: 113). To not provide them, the report remarked, “…any housing development may be a social failure” (CHC, 1945: 113). It is unclear what might have been the basis of this claim but by the late 1930s there were already several well-known English studies on new housing estates and the problems its residents experienced due to inadequate supplies of community facilities, transport and job opportunities (Mann, 1965: 131).The report also recommend ‘later-stage’ facilities be supplied when the social development of a housing area warranted them including kindergartens, club rooms, small halls to be used for theatres and art exhibitions, a library, gymnasia, youth centre, canteen, swimming pool, adult health centre, religious buildings, children playgrounds and additional sporting fields (CHC, 1945: 113). Unfortunately, a peculiar feature of the Australian political system is that the Commonwealth, neither during war or peacetime, has the constitutional power to enforce its recommendations upon the various states and so many of these innovative ideas were never fully implemented.

Again, it would appear that several semi-official reports issued during and at the end of WW11 in England – the Barlow Commission (1940), the Dudley Report (1944), the New Towns Final Report (1946) and the 1944 Housing Manual – may have had an influence on the range of services and facilities considered necessary by the CHC on all new Australian housing estates (see Goss, 1961; Mann, 1965). Another important English development that now helped shape urban planning in Victoria was the 1944 Greater London Plan. It contained the notion of a ‘neighbourhood unit’ that has been widely attributed to the inter-war era ideas of American social reformer Clarence Perry (1939). New towns or suburbs were now to be based on the British adaption of Perry’s concept of discrete residential communities of 5,000 to 10,000 people who all lived within close proximity to a neighbourhood centre that supplied a range of basic services as well as some ‘common’ facilities - primary schools, halls,

churches and open space – that would foster a sense of community belonging (Goss, 1961; Mann, 1958, 1965; Mumford, 1954). An aggregation of several neighbourhoods formed a town or suburb which supplied an additional number of retail, commercial, educational and recreational services and facilities.

The notion of a neighbourhood unit was a crucial next step in the development of Victorian planning standards for Melbourne because it was underpinned by a host of service and facility provision requirements. These standards were partly evident in the 1948 metropolitan plan for Sydney and the 1948 Australian lecture tour of Patrick Abercrombe who had embedded them in his Greater London Plan (Carter & Goldfinger, 1945; Howe, 2000). In 1949, the MMBW was given the responsibility of preparing a metropolitan plan for Melbourne, a task it completed in 1954. Drawing upon a range of influences – the 1929 MTPC plan for Melbourne, the 1944 Greater London Plan, the 1948 Sydney Plan, plus the latest data collection and planning analysis techniques from the USA – the 1954 MMBW Plan for Melbourne did not try to arrest the urban sprawl that had once again come to characterize the city's post-war development. Instead, it made recommendations to guide such development by preserving urban farmland as a kind of green belt, set aside land for freeway and recreation uses, plus zone land for future residential development guided by notions of neighbourhood units that would provide new home owners with basic services and facilities (McLoughlin, 1992; Sandercock, 1975).

Less well known about the 1954 MMBW Plan are the numerous recommendations made for the provision of services and facilities which are possibly the most comprehensive ever proposed in Victoria. Using both overseas and local service standards it recommended:

~ 7½ acres of open space per 1,000 people (ie., 3 acres of sporting fields, 1 acre for other sports, 2 acres for parks and gardens, plus 1 ½ acres for children play-grounds). Excluded here are public golf and horse racing courses;

~ 5 acres for a primary school of 500 pupils;

~ 15 to 20 acres for a secondary school of 600 pupils;

~ 15 acres for a technical school of 600 pupils;

~ an infant welfare centre with 1 nurse per 5000 people within ½ mile walking distance from every users home;

~ 5 acres for a 200-300 bed hospital with 7 beds for every 1,000 people;

~ each neighbourhood should have 10 shops per 1,000 people which should be within ¼ mile walking distance for all residents;

~ community retail centres will have 1 ½ to 3 ½ extra shops for every extra 1,000 people whereas larger retail centres should have 5 ½ to 7 shops per extra 1,000 people and a major regional retail centre will have a further 1 ½ to 2 shops for every extra 1,000 people, plus a further 50 to 60 shops;

~ a community centre should be no further than ½ mile from a neighbourhood shopping centre. (MMBW, 1954, Volume 1, pp. 97-165)

Throughout the 2 volume report, the phrase ‘planning standard’ is repeatedly used, as its authors had tried to produce a series of benchmarks that were intended to be used as a guide for providing services in the future growth areas of Melbourne.

Surprisingly, the 1954 Metropolitan Plan for Melbourne was never gazetted into law but implemented as demand required over the next decade and a half through a 1955 Interim development order by a newly elected conservative state government that mistrusted both the urban planning profession and centralised planning. Conservative state coalition governments would go on to control Victorian parliamentary politics for the next 27 years and in the process stifle any genuine attempts to better plan

metropolitan Melbourne. Throughout this post-war period, Australia and Melbourne would experience uninterrupted economic prosperity, not seen since the economic long boom of the 1870s and 1880s. By the mid 1960s, Melbourne had sprawled out of control, forcing a reluctant Victorian state government to now pass the Town and Country Planning (Amendment) Act of 1968 and finally gazette an out-of-date 1954 MMBW Plan, as well as commission an update. The 1971 Plan – Planning Policies for the Melbourne Metropolitan Region – produced by the MMBW acknowledged the rapid rate of population growth that had and would continue to occur in Melbourne, plus it repeated an earlier recommendation made in 1967 that outward urban growth could be best managed by 'urban corridors'. To some extent, the MMBW at the time was following an emerging trend in Australian urban planning by opting for corridor guided urban growth (Morison, 2000), but it was also a very practical solution to a serious problem. It was simply not possible to finance and supply physical infrastructure -sewerage, water, gas, electricity, telephone– as well as social infrastructure –schools, parks, baby health centres, halls and recreation facilities- to all the rapidly expanding new suburbs at the same time. Instead, if people could be restricted to the proposed growth corridors situated along established transport and service trunk lines, then some of these issues could be reduced. But not everybody had the luxury to decide where they might live especially the urban poor of Melbourne.

Despite two decades of post-war economic growth, there were many people who had not benefited and were compelled to live in cheap housing located amongst the industrial western and northern suburbs of Melbourne, as well as the derelict old inner areas (Henderson, et al., 1970). These housing areas had either always been denied services and facilities or they could not be provided due to the rapid pace of post-war urban expansion. Such discrepancies had been detected between the well-supplied eastern-southern suburbs and the poorly supplied northern-western suburbs of Melbourne. In fact, the 1971 Plan warned the state government that unless this spatial disparity was addressed, there would be an out-migration from the service and facility poor areas to the service and facility rich areas. However, the 1971 Plan

offered few suggestions on how this spatial disparity could be overcome, triggering widespread condemnation for its failure to integrate social and physical planning (McLoughlin, 1992).

In response, the MMBW undertook several studies into the continuing socio-spatial disparities of Melbourne that were being exacerbated by the rising levels of unemployment associated with the 1970s global economic recession. The research repeatedly showed that the working class residents of western, northern and inner Melbourne were in greatest need for more public services and facilities, but they received them at a painfully slow pace. Reduced fiscal resources now lead the state government to question whether further outward urban expansion could be sustained in these difficult economic times (McLoughlin, 1992: 60). The seeds for the need to adopt an urban consolidation approach were now formally sown in the MMBW's Metropolitan Strategy released in 1980. One of the five main focuses of the 1980 strategy was the future delivery of community services and facilities where it was remarked that:

> "…The wellbeing of a community depends not only on the adequate provision of such basic services as water, drainage, sewerage and roads, but also on the quality and availability of such community facilities and services as schools, kindergartens, health services, clinics and welfare offices. School facilities, like other services, are affected by an imbalance of demand and supply…Pockets of need for particular facilities occur throughout the metropolitan area. In particular, the region generally to the north and west of central Melbourne is one such area where the provision of additional community facilities has been seen as desirable" (MMBW, 1980: 40).

Once again, the MMBW had acknowledged a problem with the inter-regional distribution of social infrastructure across Melbourne, but it offered only 'vague platitudes' on how this issue could be addressed (Logan, 1981: 39). Finally, in 1982,

27 years of uninterrupted conservative state government came to an end in Victoria with the election to office of a reformist-oriented state Labor Government. This government started its ten-year period in office with a promise to tackle a long backlog of badly needed policy reforms including the delivery of more urban services and facilities (Considine & Costar, 1992; Costar & Hughes, 1983). Unfortunately, no specific service delivery standards were ever supplied in any official public documents including its metropolitan strategy – Shaping Melbourne's Future – released in August 1987.

Shaping Melbourne's Future was very much a product of the austere economic times that confronted Victoria and Melbourne in the late 1980s. As a metropolitan strategy it set the tone for other strategies that followed it because they would all be preoccupied with the economic wellbeing of the metropolitan region. The Australian economy would take almost another decade to recover from the global economic recession therefore the main themes of this metropolitan strategy was to offer assistance to the private sector by upgrading the highway network, providing more infrastructure for commercial and industrial development, plus deliver public facilities and services in a co-ordinated way to new housing in growth corridors. Disappointingly, the 1987 Plan offered little in the way of any explicit service and facility delivery standards that the community could expect, when compared to earlier metropolitan planning statements and strategies. This is a significant emission from a government that claimed its reform agenda was guided by the principles of 'social justice and equity'.

The global economic recession dragged on into the early 1990s with severe impacts being felt in Victoria and a newly elected neo-liberal state government did little to assist the hardest hit areas - western and northern areas of Melbourne as well as the outer south-eastern areas - that possessed largest concentrations of working class households. Unemployment rose quickly in these areas and they had the greatest unmet need for more public services and facilities. In this context, strategic metropolitan planning was now largely disregarded and pushed down the priority

list, even though the newly elected conservative state Government initially produced a Melbourne Metropolitan Strategy statement in June 1994 (Vic. State Govt, 1994a). Public services and facilities were given only the most cursory mention. An overly economic approach to state management led to the electoral defeat in 1999 and the ushering in of a 'third way' style state Labor government that held office until late 2010. It sought to find a balance between sound economic management with a concern for social and environmental objectives that were spelt out in several post-election policy statements – Growing Victoria Together and A Fairer Victoria. In 2002, it released Melbourne 2030, the first genuine metropolitan strategy since 1987. It was a comprehensive statement of planning intent and offered a wide range of initiatives across nine key areas including the creation of a 'fairer city'. The strategy states:

> "…Melbourne 2030 plans for a fairer distribution of social and cultural infrastructure, and for the better coordination and timing in the delivery of new services in development areas…By working with local communities, gaps will be identified in major social and cultural facilities in areas such as health, education, justice, recreation and the arts. These gaps will then be addressed…" (Dept. Infrastructure, 2002: 39)

Exactly what might be the criteria or service delivery standard that would allow urban planners to decide if gaps did indeed exist across different parts of Melbourne was never spelt out. Many of the remedial initiatives offered to achieve a fairer city are very general in nature and only identify a small number of social infrastructure. This was certainly much better than its predecessor had proposed however there was still very much of a pre-occupation with ensuring the economic wellbeing of the metropolitan area. This largely explains why there was no explicit commitment to spelling out a clear set of social infrastructure delivery standards as the social needs of the community had become a lesser priority for state government in these neoliberal economic times. Hence, it almost seems as if the provision of public services and facilities has become a perennial concern for strategic metropolitan

planning in Melbourne over the last 30 years, however what the precise service and facility delivery standards might now be are never made public anymore.

Conclusions

A number of recurrent themes emerge from the historical investigation undertaken here into public service and facility provision standards for Melbourne. First, the adoption of planning standards in Melbourne was conditioned by locality-specific contingent factors – politics, public discourse and unmet human need – as well as external structural factors - developments in overseas planning practice and the cyclical rhymes in international and national capitalism. Exactly who was in control of the Victorian state government has had a profound impact on commissioning and implementing strategic plans for Melbourne as was shown with the 1929 and 1954 schemes. Throughout most of the 20th century, conservative state governments ruled Victoria and they were reluctant to engage in much urban planning, forcing individuals and reform groups to become involved especially until the end of WW2. The pressure to do something about Melbourne was also conditioned by a fear of 'slums' and the people who lived inside them because it was believed that they could infect the rest of the city with their illnesses and low morals. Slum dwellers could be rescued from their surroundings by a range of initiatives including the provision of publicly funded services and facilities. Surprisingly, middle class reformers and state governments did not explore in any serious way the role that fluctuating economic times had played in the creation of slums, plus the associated problems they generate. In fact, Melbourne expanded as a city in good economic times – 1850s to 1880s, 1920s, 1950s to 1970s – which necessitated some forms of urban planning intervention, but there were also the bad economic times – 1890s to 1910, 1930s to mid 1940s and mid 1970s to 2000 – that witnessed a contraction in urban planning activity. Melbourne, like the Victorian and Australian economies, have always ridden the booms and busts of international capitalism.

Second, Melbourne has always been a socially polarised city, with the poor and working classes initially occupying the central and inner city areas, whereas the upwardly mobile working and middle classes living in middle distant housing areas. As the city expanded, the poorer working class households were pushed out into the western and northern suburbs of the city, as well as the extreme outer edges of the south-eastern suburbs. These communities have historically been and remain in greatest need of public facilities and services but political and administrative support for their provision has varied over time in accord with the rhymes of the economic cycle. The recent rise of neo-liberalism over the last 2 and half decades in Australia, for example, has meant that successive Victorian state governments have been reluctant to make social infrastructure provision commitments in their metropolitan planning schemes for Melbourne. Difficult economic times have contributed to maintaining a faith in neo-liberalism where the economy comes ahead of the social needs of the community. The only discernable change to this spatially patterning has been the extensive gentrification of the inner areas over the last 4 decades that has now become an expensive housing area that excludes the poor.

Third, this socio-spatial division of Melbourne has been allowed to deepen, through the continued unequal distribution of public urban facilities and services. Since the late 1960s, urban planners had been warning successive state governments of the growing socio-spatial inequalities that exist between the western-northern and southern-eastern sides of the city, as this study has shown. Remedial action has been undertaken but at a somewhat slower pace than is possible largely due to the fact that policy priority remains the wellbeing of the metropolitan economy. This has therefore nurtured somewhat conflicting perceptions of place and the people who inhabit them in a sprawling metropolitan area whose inhabitants have seemingly accepted that social polarisation and inequitable access to public facilities and services is an inevitable feature of life in Melbourne. Television programs and films have even been made to lampoon the alleged differences that many assume exist between the people who live in the poor and better off sub-regions of Melbourne. Very little has changed over the last 150 years except the so-called slum housing and

its occupants have been shifted out of the inner city and into the western and northern suburbs of Melbourne as well as some outer fringe areas. It remains to be seen whether new 'urban social movements' will arise to counter this situation as had happened in Melbourne between 1890 and 1940.

Fourth and finally, it is clear that something has to be done, even if fiscal stringency has to be observed by neo-liberal state governments. A number of reforms can be considered in order to achieve a more equitable redistribution of public services and facilities, if everybody living in Melbourne is to benefit from living in the world's most liveable city. This can include a better co-ordination of state government and its various departments in the current and future delivery of such services and facilities; the re-location of public resources from the over-supplied inner and middle regions to the under-supplied western, northern and outer fringe regions that have large unmet needs; a reinstatement of genuine strategic metropolitan planning that accords equal weight to the economic, social, physical and environmental dimensions of the city. Urban planners cannot do this alone unless they have bi-partisan political support from the competing political parties that have to date controlled state government. It has taken Melbourne almost 100 years to re-acquire international standing amongst the major cities of the world but it remains to be seen whether it can hold onto it world's most liveable city status if more urban public services and facilities are not supplied to its more vulnerable residents.

ABSTRACT

This study aims to quantify and find out underlying causes of public bus transit travel time variability using data collected in the capital city of Turkey, Ankara. Public transit service in Ankara metropolitan area is mainly based on the bus system operated by both public and private sectors. Bus transit system is generally mixed with other traffic (Right-of-Way C); therefore, it is expected that travel times are subject to high degrees of variability. The system is organized in a hub-and-spoke fashion with the hub at one of the city centers (Ulus or Kizilay) and the spoke in the urban fringe. As regards travel time variability in public transit bus system, three models are developed to account for variation induced by operational regions, trunk roads, and individual lines. Besides, two different sub-models have been developed with respect to dependent variables used: Standard Deviation and Coefficient of Variation of travel times. Three main causes of travel time variability have been identified and tested in this study: temporal dimension, spatial dimension, and service characteristics. Model results indicate that all of these factors affect travel time variability. We generally conclude that uniform organization of the system has to be changed in order to control travel time variability.

Key Words: Travel Time Variability, Public Transit, Ankara Public Bus System

1. INTRODUCTION AND MOTIVATION

While there is already a large body of research on travel-time variability and its use as a policy variable in the domain of private transportation, relatively little has been investigated in terms of public transport, either theoretically or empirically. Indeed, the public transit system's reliability is a vital issue affecting its status as a desired alternative to private transportation. In other words, attracting ridership to public transit is based, inter alia, on its reliability and travel-time variability (Bowman and Turnquist, 1981). Contrary to private (automobile) transport, public (bus) transit has many designated points for passengers to board and alight. Therefore, public transit has a frequent cycle of decelerating, stopping (or idling), accelerating, and moving. Travel-time variability in public transit may be affected by a number of factors, including passenger volume and its distribution along the route, vehicle types and vehicle design, drivers and driving habits, transit administration and operations as well as network design. For example, travel-time variability for public rail transit, which uses exclusive rights of ways, is associated with punctuality in its operations (e.g., Olsson and Haugland, 2004). Conversely, for the public bus-transit system, which commingles with other traffic, changes in traffic conditions, traffic signals, etc., might easily induce variations in travel times—similar to private transport (Strathman and Hopper, 1993).

The nature of transit reliability may be divided into different study areas. One area is the punctuality of service operations at the dispatch unit, which primarily relates to administrative structure, operations in the field, vehicle fleet size, etc. (e.g., Furth and Muller, 2009). An analysis of this area might include physical models of allocating transit vehicles of a certain size to a number of dispatch units. Another study area may focus on the busses' timeliness at the point of departure and of arrival. Although closely related to the punctuality of service operations, a prompt arrival might also be subject to numerous other factors (El-Geneidy et al., 2009). Reliable punctuality may be valued differently with respect to the characteristics of the departure point, arrival point and their spatial separation. Waiting at an unsheltered bus stop, standing in an overcrowded bus, or sitting in an empty bus may be valued differently. Each of these scenarios has a well-established a-priori temporal affinity among users that is associated with the time of day, week, or year.

This study aims to quantify and identify the underlying determinants of public bus transit travel-time variability in the Ankara (Turkey) metropolitan area. In addition, we discuss

possible remedies for alleviating travel-time variability. In this study, we draw upon data collected from five one-week periods of public bus transit operations from 2009 to 2010 in the Ankara metropolitan area[1]. Ankara is the capital city of Turkey with a metropolitan population of nearly 4.5 million people. The metropolitan area has an approximate radius of 50 km from its center.

The existing public transport system serving the Ankara metropolitan area is complex and heterogeneous in terms of operators, technologies, vehicles, and routes. Variation in any one of these factors requires a different organizational and administrative structure. The transit service in Ankara primarily relies on an extensive bus and minibus system, along with two metro-rail lines, namely Ankaray and Batikent Metro Rail Lines, and a suburban rail line running east-west[2]. The bus transit system is comprised of public buses operated by the Greater Municipality of Ankara and privately operated buses and minibuses (the number of privately run vehicles has remained stable for nearly 30 years). The entire public transit system is administered by the Public Transit Authority of the Greater Municipality of Ankara (abbreviated as EGO in Turkish). The routes, ticket prices and service levels of the entire transit system are regulated by a central council, the Transportation Coordination Center (abbreviated as UKOME in Turkish), which is headed by the metropolitan mayor.

Both publicly and privately operated transit buses may traverse parallel routes serving the same neighborhoods. Some routes are served only by public or private operators, but passenger volume on these routes tends to be either low or variable depending on the time of day or week. Thus, private operators, as small-business owners, hesitate to work on these routes; instead, they exert constant pressure on the UKOME to assign them to more lucrative routes. The bus transit system generally operates amidst other traffic (i.e., Right of Way C) in Ankara. As a result, it is subject to travel-time variability caused by traffic conditions. In this study, we focus on public bus transit service, which has market dominance in the metropolitan area.

To analyze travel-time variability, we rely on statistical measures of standard deviation

[1] First Panel: December 14–20, 2009; Second Panel: March 15–21, 2010; Third Panel: July 19-25, 2010; Fourth Panel: October 11-17, 2010; Fifth Panel: December 20-26, 2010.

[2] The suburban rail line ceased its operations temporarily on August 1, 2011, because of new junctions and road construction that cross or run parallel to the railroad.

and coefficient of variation of bus transit travel time. We hypothesize that the travel-time variability of publicly operated bus transit is subject to three sources of variation: the temporal dimension, the spatial dimension, and service characteristics. Three groups of models have been devised for operational regions of public transit, trunk roads and individual transit lines, respectively, in the metropolitan area. Altogether, there are five operational regions that comprise the entire metropolitan area. In addition, three highways have been identified. Two of the highways, Eskisehir Road and Istanbul Road, connect residential areas in the west with the metropolitan center (see Map 1 below). The third, Ataturk Boulevard, crosses the metropolitan area in a north-south direction. The majority of the metropolitan area is served by these highways, where the traffic varies significantly with respect to the time of day and week. Seasonal variation (especially between the school year and the off-school season) is also evident on these highways.

This study is organized into six sections. The second section provides background information for the study. The third section elaborates upon the characteristics of the public transit system in the Ankara metropolitan area. The information derived from the five-week panel data collected over the course of one year is presented in the fourth section. The fifth section describes the model used in this study and its results. General conclusions and policy recommendations for the public bus transit system in the Ankara metropolitan area are presented in the final section.

2. BACKGROUND

Contrary to private transport, public transit imposes additional costs and inconveniences on their riders. Riders must cope with unfamiliar areas, crowds, the weather, walking, waiting, and sometimes transferring (Horowitz, 1981). Moreover, users attach different values to each of these components, thereby subjecting the public transit system to vast heterogeneity among its riders. Apart from total travel time, transit users are quite sensitive to arriving on time, travel-time reliability and variability (Nash and Hille, 1968; Hartgen and Tanner, 1970; Wachs, 1976; Jackson and Jucker, 1982; Taylor, 1982; Bell and Casser, 2000). Travel-time variability in public bus transit is affected by both internal and external factors. Internal factors are associated with features such as the vehicle type, passenger capacity, fare-collection process, and the number of bus stops on the route (Strathman and Hopper, 1993; Hensher, 2007). External factors of public transit travel time variability primarily relate to traffic conditions, characteristics of the service area, the route and the level of passenger demand. Traffic conditions may be

associated with recurrent traffic congestion during certain times, such as peak hours, or non-recurrent incidences, such as traffic accidents, road maintenance, etc. (Noland and Polak, 2002).

Strathman and Hopper (1993) report that travel-time variability increases during the afternoon peak, with longer headways and high passenger demand. Bates et al. (2001) have developed a methodology for applying existing models of travel-time variability to scheduled transit services. In this setting, deviations from scheduled departures and arrivals are considered to be sources of disutility because such deviations may cause variations in expected travel times.

In a study conducted in US cities, it was observed that automobile speeds are 1.4 to 1.6 times faster than bus speeds (Levinson, 1983). In the same study, bus travel times and speeds were related to stop frequency, stop duration, and bus acceleration and deceleration times. The elimination of two stops per mile and a 5-second decrease in idling time (from 20 to 15 seconds) was found to produce a 4.30- to 6-minute time saving per mile, which is greater than the time saved by eliminating traffic congestion (Levinson, 1983). Restructuring and reorganizing transit services, especially by reducing the number of bus stops, changing the fare-collection method, and altering the door configurations and widths on high-density routes are important policy elements in reducing bus travel times (Levinson, 1983). By using components of bus travel time such as idling time, travel time, traffic-signal delay time, general traffic delay time, etc., another study found significant time variations in the bus services operating on differently configured routes in different regions of the city (Maloney and Boyle, 1999). According to Abkowitz and Engelstein (1983), travel time is strongly affected by trip distance, the number of passengers, boarding and alighting procedures, and intersections with traffic signals. More importantly, the same study reports that scheduling deviations at early points along the route propagate further deviations downstream. In addition to improved control and corrective actions on transit operations, shorter routes may well improve travel-time variability. Thus, it is also important to account for heterogeneity caused by different routes and the regions served by these routes.

According to Taylor (1982), metro-rail networks, which are generally free from the main causes of travel-time variability, offer more reliable and faster services to transit users than bus networks. Therefore, it is important to develop policies promoting metro-rail lines as the main transit mode that is supported by buses. Nonetheless, as bus

transit systems are less costly and more flexible than rail transit in the short run, bus systems may be more appropriate in rapidly growing cities in developing countries. The bus system and its operators enjoy high patronage in developing countries; however, the development is not sustainable because urban traffic congestion is much worse in developing countries, where road length and density is much lower than in developed countries (Cervero, 1998; Gakenheimer, 1999; UITP, 2001; Gwilliam, 2003). Moreover, public transit riders suffer from uncomfortable conditions, and the buses comingle with the general traffic. In comparison, private cars appear to be a faster and more comfortable alternative. Accordingly, the ills of the public bus transit system accelerate automobile use in developing countries (Gakenheimer, 1999).

It is important to maintain current public-transportation services in developing countries while improving the transportation infrastructure and service quality. However, the existing operational status of the bus transit systems does not support this approach. Among the many necessary actions required to improve bus transit services in developing countries, an important task is to reduce bus transit travel-time variability, which negatively affects the reliability of public transit. Therefore, this study's primary aim is to analyze the causes of travel-time variability in the public bus transit systems of rapidly growing, motorized cities, as in Ankara, the capital of Turkey.

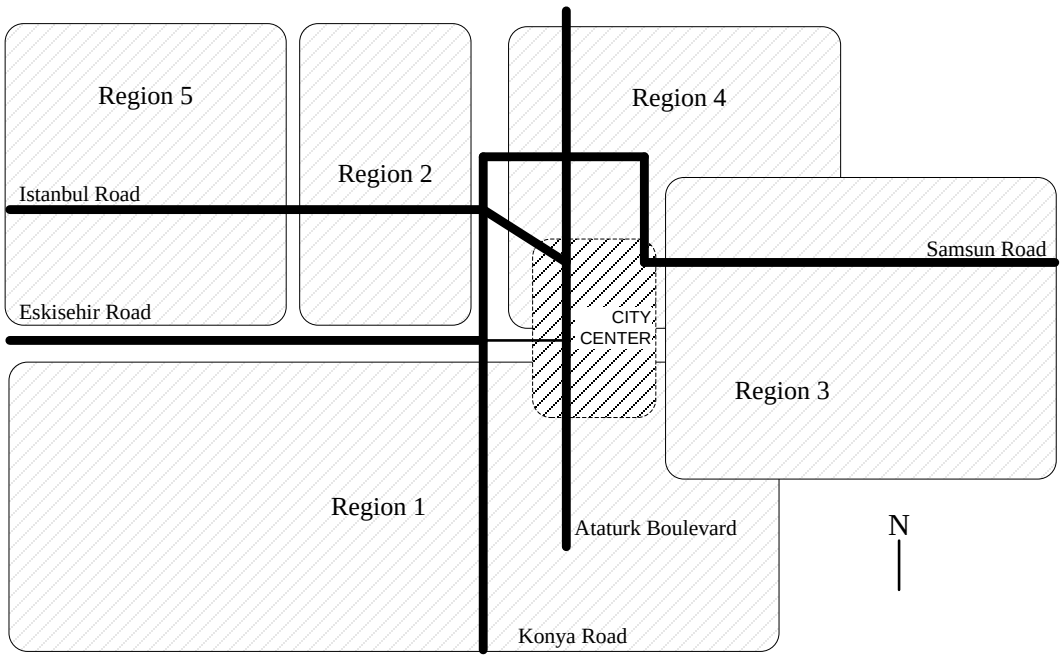
Within Turkey, Ankara is one of the fastest growing cities in terms of private vehicle ownership, which poses an important challenge for the city's public transportation system with its current and expected trends in the future. Although the public transit system represents a majority of motorized trips, 65 %, patronage of public transit is destined to decrease in the face of rapid motorization and urban sprawl. However, automobile transport is more costly than public transport because of high fuel prices[3]. Although the travel costs for public transit are lower than for private transport, public transportation has lost ridership for failing to be reliable and accessible, as the transit lines focus on the city center. Although three additional metro lines are currently under construction, and several other lines are planned for the next phase of rail network expansion, the future of public transit in Ankara is not promising if business continues as usual. In fact, metro rail-line projects had been stalled for approximately ten years because of insufficient public funds in the Greater Municipality's budget. Recently, the legislation regarding

[3] In 2008, Turkey ranked first in retail fuel prices in Europe (http://www.gtz.de/de/dokumente/gtz2009-en-ifp-part-2.pdf, Accessed on February 12, 2012).

roles in urban transportation projects has been modified to enable the central government's involvement in metro rail-line projects. It is expected that these lines under construction will become operational within 5-10 years.

3. PUBLIC TRANSIT SYSTEM IN THE ANKARA METROPOLITAN AREA

The Public Transit Authority of the Greater Municipality of Ankara maintains the public transit bus system in 5 operational regions (Map 1), which together account for the entire metropolitan region and have varying characteristics. The Greater Municipality of Ankara operates the public bus system along with two metro-rail lines. The suburban rail system is operated by the Turkish State Railways. The remainder of the public transit system is operated by small proprietors. Except for the suburban rail system, all of the transit fares are strictly regulated by the municipality. Public bus and metro-rail transit require pre-paid magnetic ticket cards to travel, while the privately operated buses and minibuses accept only cash. The fares for both systems are nearly identical and are fixed on all routes. However, there are some advantages of using multi-ride magnetic cards, such as fare reductions and lower fares for transfers, from which cash-based privately operated transit buses and minibuses are exempt. As the data are collected from magnetic card readers, the scope of this study is limited to the public bus transit service only.



Map 1

In sum, there are nearly 400 public bus transit lines operated in five regions. Nearly all of the buses execute a u-turn to complete their journeys, which end at the point of departure. A bus terminal is where the buses idle, as well as the point of departure and return. While different bus lines follow different paths through the neighborhoods near the bus terminals, their routes often converge outside of their respective neighborhoods, and nearly all of them meet at the metropolitan center. Therefore, the transit system emulates a hub-and-spoke network with the metropolitan center typically serving as the hub and the bus terminals as spokes. Passengers travelling between regions must transfer at the hub, the metropolitan center.

Although the entire metropolitan area is equipped with bus stops for transit access, the proportion of sheltered bus stops is small, and few are equipped with a timetable or route information. However, one can be certain before going to a bus station that an arriving bus travels to the city center. There are no rules governing the location of bus stops. The Transit Authority applies ad hoc criteria for establishing bus stops, taking into account the location and density of residential areas as well as activity centers. Bus stops are typically placed every 300 meters along a route. However, the location of a bus stop or the route of a line is subject to change when a certain number of local residents sign a petition requesting a bus stop or transit service near their homes. Therefore, bus lines and bus stops are often subject to change without any reference to generally accepted principles of transit operations (e.g., Vuchic, 2005). This practice often causes disruptions to bus transit service in terms of speed, comfort, etc. In addition, the unnecessary elongation of bus lines in neighborhoods inevitably increases the travel times of public bus transit.

The hub-and-spoke type of network exhibits limited flexibility and sensitivity to variations in demand in both time and space. All public transit lines connect the residential areas of the metropolitan area with the city center. Therefore, one must change buses in the city center to reach another destination. Transfers in the city center entail a 5-10 minute walk as well as additional monetary costs and wait times. If reaching a destination requires transfers, one may prefer to utilize privately run minibuses that stop for passengers to board or alight at any point on their routes, thereby decreasing walking times. Some of the main public-transportation routes are thus privately operated and include no fare reduction.

4. DATA

The data set used in this study was collected by the Public Transit Authority (EGO) of the Greater Municipality of Ankara in five one-week panels: December 14-20, 2009 (the first panel), March 15-21, 2010 (the second panel), July 19-25, 2010 (the third panel), October 11-17, 2010 (the fourth panel), and December 20-26, 2010 (the fifth panel). Each line in the data set contains information regarding the bus line number, the bus identity, the driver's identity (not associated with a single person), the departure/return times to the bus terminal, along with the number of passengers carried.

A trip begins with the insertion of the driver's card into the reader machine at the bus terminal; it ends with the card's insertion upon returning to the same terminal. The times of departure and return are recorded by the reader machine when the driver's card is inserted at the start and end of the trip. Passengers are counted by the reader machines, as each passenger inserts a magnetic card into the machine when boarding the bus (note that free passengers—police officers, postal-delivery staff, etc.—and senior card holders do not use a magnetic card; thus, they are exempt from the tally). However, we expect similar numbers of these unaccounted for passengers on all of the bus lines.

For the first panel, there were 369 public bus transit lines, while the total number of lines for the second, third, fourth and the fifth panel were 370, 350, 385 and 388, respectively. The service frequencies by day of the week are shown in Figure 1. Service frequency is at its lowest during the summer season, which is primarily due to the school holiday season.

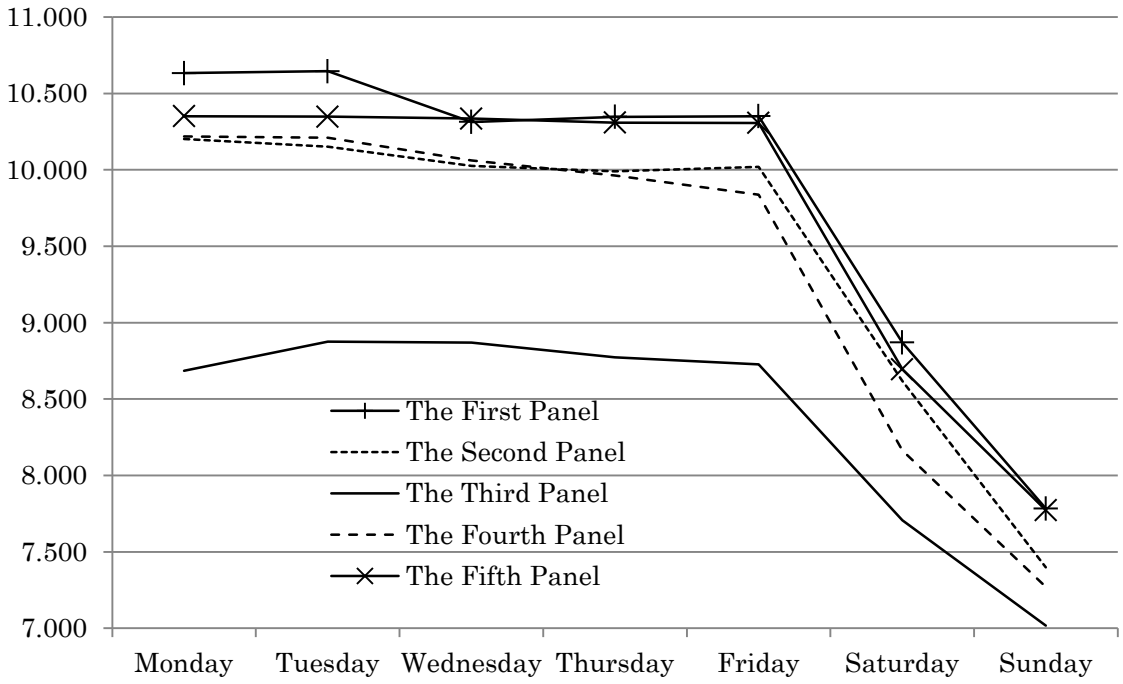


Figure 1 Service frequencies by time of week.

The average number of passengers per bus and the total number of passengers carried per day of the week for each panel are displayed in Table 1. If we assume that an average bus has a capacity of 80 persons, for all panels except for the third, the bus load is at approximately 80 % capacity during the weekdays; weekends reveal a consistency of approximately 60 % of capacity for the first, fourth and fifth panels. When the total numbers of passengers carried are compared for each panel, a consistent decrease in the total passenger number is observed. This decrease implies that metropolitan residents' preferred transportation mode is changing: they prefer to commute using their own (likely newly purchased) cars or switch to privately operated buses or minibuses, which run more frequently and flexibly. As expected, passenger demand is at its lowest in the summer season (except for Sunday in the second panel). Other sources of variation may include activities that occur in diverse locations around the city, seasonal cycles and changes in consumer preferences regarding modes of transportation.

Table 1. Average number of passengers per bus and total number of passengers carried

1: Average number of passengers per bus
2: Total number of passengers carried

Table 2 displays the distribution of average travel times according to day of the week. The average round-trip travel time is 73 to 85 minutes. The summer season (i.e., the third panel) and Sundays are associated with the shortest travel times (the average travel time is 73 minutes on Sundays in the summer) due to low traffic levels in the summer and on Sundays. During the summer season, many individuals travel outside of Ankara, and the remaining residents spend Sundays at home, in nearby locations or in non-central areas.

Table 2. Distribution of average travel times by time of week

Time of Week	The First Panel		The Second Panel		The Third Panel		The Fourth Panel		The Fifth Panel	
	1	2	1	2	1	2	1	2	1	2
Monday	80.66	35.42	81.78	36.76	78.86	34.71	83.20	38.12	82.92	37.89

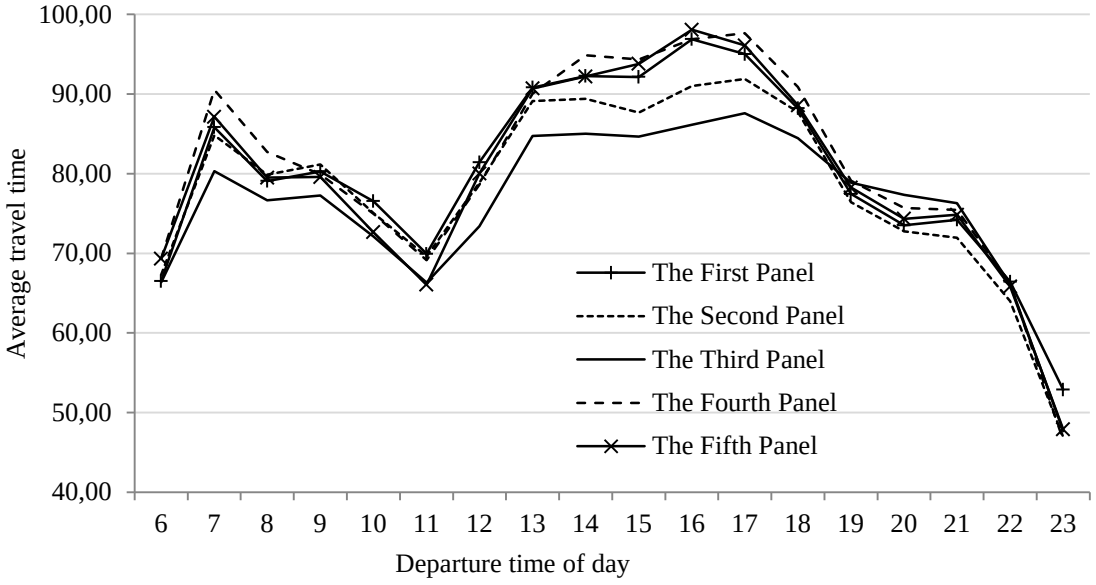
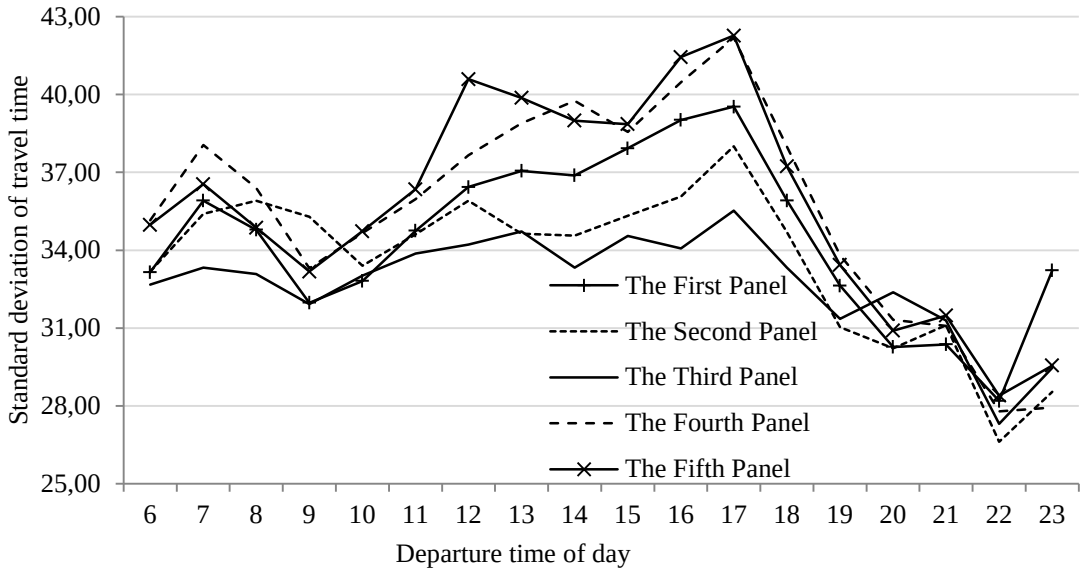
1: Average travel time
2: Standard devition of travel time

As displayed in Figure 2, the temporal distribution of travel times points to a two-peaked diurnal distribution. The earlier peak, which falls between 7:00 AM and 9:00 AM, is sharper, while the later peak covers nearly the entire afternoon and evening and is higher. All panels have a decreasing trend in terms of travel times after evening hours. Although one can detect seasonal differences in both average travel times and their standard

deviations, they generally follow similar trends throughout the day.



-a-



-b-

Figure 2 Distribution of travel times by time of day.

As noted above, the bus transit system in the metropolitan area is organized within five operational regions. Trips between a region and the city center normally produce travel times in accordance with the distance of that region from the city center. For example, Region 5 is the remotest region from the city center (see Map 1 above) and therefore has

the highest travel time, ranging from 106 to 113 minutes. In terms of travel-time variability, two measures used in this study are associated with the statistical measures of standard deviation and the coefficient of variation. While standard deviation measures the deviance of travel times from the average travel time, the coefficient of variation divides standard deviation by the average travel time (the computation of these measures is given below).

We detect different levels of travel-time variation in different regions, which might be due to geographical, road-network features and the number of bus stops in these regions. Generally, Region 1 and Region 3 reveal the highest and lowest levels of travel time variability, respectively. Region 1 is elongated along the east-west axis, with the north-eastern part close to the city center. Therefore, it is probable that the travel times of bus lines serving the western area are significantly longer than the travel times of those serving the eastern past. This geographic variation may produce additional variation in travel times. Among all regions, Region 3 is the closest to the city center and thereby exhibits the lowest levels of travel time variability. When we change the statistical measure from standard deviation to the coefficient of variation, the ranking changes at the high end. The highest degree of travel time variability is found in Region 2, which has a shorter travel time. This difference is primarily due to a low level of variation among the standard deviation of travel times across regions.

5. MODEL DEVELOPMENT AND ESTIMATION

In this section, we disentangle the sources of travel-time variation of the bus transit system in Ankara. Three main sources of variation are accounted for in the models. The first source of variation is expected to lie in the temporal dimension. Time of day and time of week are two of the temporal variables present in the data set. Data analysis reveals that both of the variables cause variations in travel times. In the longer term, there is also seasonal variation, the most significant of which occurs during the school season. From September until June, with a short winter holiday in February, the school year is one of the main causes of traffic congestion in Ankara, as there are too many inter-zonal school trips along with commute trips within a similar window. Return trips from work or school create congestion in the opposite direction as well. All panels except the third fall in the school season; therefore, we expect significant differences in variation between the third panel and the others.

The second source of variation is expected to lie in the spatial dimension, as the public

bus transit system is operated in five different regions with unique physical characteristics. Almost all of the bus lines connect the neighborhoods in operational regions with the city center; out of its local neighborhood area, a bus line shares the same route (usually a highway) with other lines of the same region or neighboring regions. Therefore, differences in travel-time variability might also be affected by a highway that serves a region. The existence of a highway might increase the operational speed, which in turn might compensate for delays caused by passenger boardings in the local neighborhood. There are significant differences in the lengths of the regional highways, a fact that may cause variation in travel times with respect to operational regions.

The third source of variation analyzed in the models is service characteristics. The number of bus stops on a line and the types of bus are expected to be the two significant sources of travel-time variation caused by service characteristics. The number of bus stops, especially in the populous neighborhoods, may result in variation due to the time devoted to passenger boarding and alighting at each stop. Regarding the latter, bus types are generally differentiated according to age. Although the vehicle fleet is relatively new and is composed of similar types of vehicles, vehicle age is expected to cause variations in travel time.

This study utilizes three groups of models to investigate the sources of travel-time variation. Each group includes two individual models with different dependent variables, i.e., statistical measures of standard deviation and the coefficient of variation of travel times. For each group of models, dependent variables have been computed by using average travel times according to the time of day, time of week and time of year with respect to five operational regions (*Model 1*), three main highways (*Model 2*) and individuals bus lines (*Model 3*).

The average travel time according to time of day, *d*, time of week, *w*, and time of year, *y*, is denoted by ${}^{dwy}t_a$. The standard deviation, sd_{dwy}, of bus transit travel times is computed as the square root of the average of the total squared deviations of travel times, ${}^{dwy}t$, from their respective averages, ${}^{dwy}t_a$, i.e., $sd_{dwy} = [(1/N)\times\sum^{N}({}^{dwy}t - {}^{dwy}t_a)^2]^{1/2}$, where N is the number of bus dispatches during a time of day, and the time of day represents one-hour intervals between 06:00 and 24:00. The coefficient of variation, cv_{dwy}, is calculated by dividing the standard deviation of bus transit travel times, sd_{dwy}, by the average travel time, ${}^{dwy}t_a$, i.e., $cv_{dwy} = sd_{dwy}/{}^{dwy}t_a$. Two of the statistical measures used

in the models bear different meanings: whereas the standard deviation provides a measure of dispersion around average travel times, the coefficient of variation is a normalized measure of travel-time variation with respect to average travel times.

The first group of models (*Model 1*) has been designed to reveal variation in each region using aggregated variables for each region. The second group (*Model 2*) focuses on three of the highways along with surface streets using aggregated variables for each highway. Running in an east-west direction, Eskisehir and Istanbul Roads connect vast residential areas in the west with the metropolitan center (see Map 1 above). The final highway, Ataturk Boulevard, combines the northern and southern parts of the metropolitan area while crossing the metropolitan center; therefore, it is congested throughout the day. The last group of models (*Model 3*) focuses on the individual bus lines to determine differences that are not considered in the previous model groups.

Table 3 presents the descriptive statistics of the continuous variables used in the models. The first two models differ from *Model 3* in terms of dependent-variable calculation. In *Model 3*, the standard deviation and the coefficient of variation of travel times have been calculated using the whole day to compute travel-time variability measures. In addition, we have trimmed the data for *Model 3* by eliminating the lines that have service frequencies below 10 (36 % of the sample is excluded, leaving us with a data set of 7,424 cases). For all of the models except for *Model 3*, we have included temporal variables that account for hourly changes in travel-time variability.

Table 3. Model variables

Model 1: Region based model *Number of Cases: 3150*	Min	Max	Average	Std. Dev.

Average Number of Passengers	0	173.80	57.94	25.31
Number of Daily Service Frequencies	10	152	39.40	22.33

Models have been estimated using generalized linear model routines of PASW Statistics R18 using the maximum likelihood estimation method. We have analyzed the model estimation results with respect to temporal and spatial dimensions followed by service characteristics, as displayed in Table 4.

Temporal Dimension

All of the models reveal significant variation with respect to time of year. Moreover, travel-time variation increased over the course of one year. As the bus transit system does not have exclusive rights of way, it can be concluded that traffic conditions worsened in one year from 2009 to 2010. This finding also implies the positive effects of motorization, urban sprawl, and inadequate transportation infrastructure on travel-time variability. Among the days of the week, Wednesday generally exhibits the highest source of variation across all models. Wednesday marks the weekly peak in terms of passenger demand; therefore, the additional number of passengers may increase the total passenger boarding and alighting time, which in turn increases the variation in travel times. During boarding, each passenger must insert a magnetic card into the card reader that subtracts one fare and prints the relevant information on the back of the card (a picture of the machine is provided in Picture 1). This process takes 5-15 seconds per person (233 measurements carried out by the authors of this study show that 95 % fall in this range).

Picture 1. The magnetic card machine installed in public transit buses.

Hourly variation is significant for nearly all of the hours included in the standard-deviation based *Model 1*. According to this model, the greatest variation occurs during the evening peak hour between 17:00 and 17:59 hours. However, in Model 1, which is based on the coefficient of variation, travel-time variation is increased during mid-day hours (Figure 3). According to Figure 3 above, one may conclude that longer travel times in the morning and afternoon are more reliable than shorter travel times during other times. Recurrent traffic congestion has been consistently observed during peak hours, as there is constant passenger demand in the peak hours. However, off-peak hours are subject to greater changes in passenger demand, a fact that is primarily due to the passengers who do not use magnetic cards, such as public servants or senior citizens, and non-recurrent congestion caused by traffic accidents, road maintenance, etc. As most of the trips include the city center in their routes, the effects of traffic and unexpected events are more evident during mid-day hours.

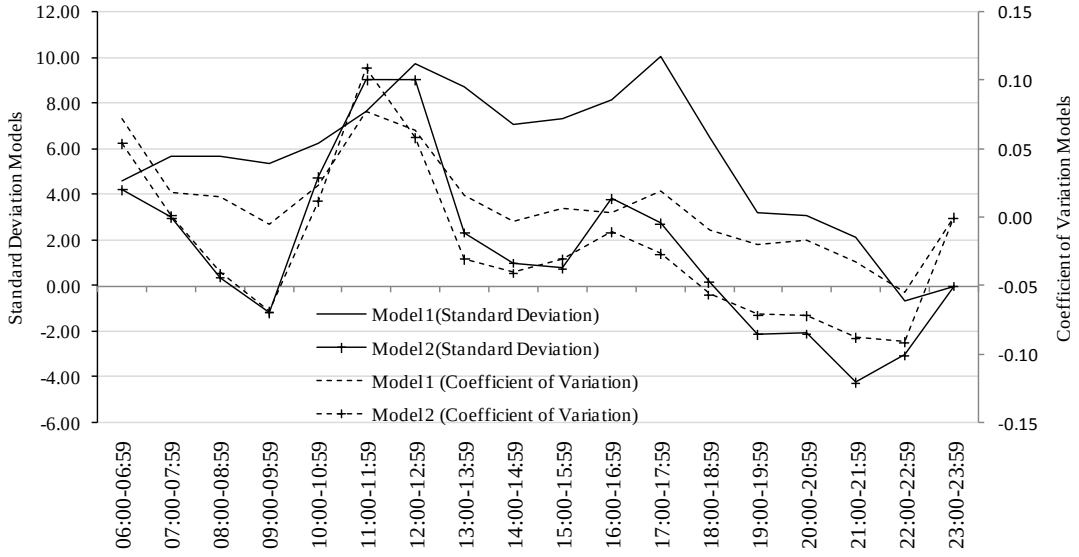

Figure 3. Time of Day coefficient estimates for *Model 1* and *Model 2*.

Spatial Dimension

Aggregation at each respective region, i.e., *Model 1*, points to Region 3 as the most reliable region and Region 1 as the least reliable region in both the standard-deviation and coefficient-of-variation models. Considering the characteristics of these regions, the results are not surprising. While Region 3 is close to the city center, has the smallest area, shortest total road length and highest road density, Region 1 has the largest area, longest road length but one of the lowest road densities among all operational regions. Moreover, Region 1 is modest and heterogeneous in terms of land use and covers part of the city center where government offices and universities are located. Upper- and middle-income Ankara residents generally live in Region 1. Therefore, higher car-ownership levels along with worse traffic conditions are expected in Region 1. There are also differences between the urban patterns of the regions that affect the travel-time variability in bus operations. The suburban districts of Regions 1 and 5, recently developed, have modern but scattered residential areas; hence, bus lines generally transverse of the streets. Conversely, Regions 2, 3 and 4 include traditional homes and informal (i.e., squatter) houses, along with residential areas with narrow and steep streets that limit the bus operations to the main streets. These characteristics of the operational regions affect travel-time variability in these regions.

Highway-based models include the bus lines on one of the three highways. According to the model results, we have found that the most reliable highway is Istanbul Road. It is also the fastest road in the Ankara metropolitan area, according to our inquiries at the Public Transit Authority. Istanbul Road, which crosses Region 5 and 2 in an east-west direction, has fewer bottlenecks than Eskisehir Road, which crosses Region 1 in an east-west direction. Region 1 was found to be the least reliable region in *Model 1*. Therefore, the results of the model establishing Eskisehir Road as the least reliable road are as expected. One of the reasons for this finding lies in the characteristics of Eskisehir Road and the areas it serves. Most of the public offices and major universities, as well as newly established central business districts, are in the areas served by Eskisehir Road.

The final group of models, bus-line based models, analyzes the differences on each line throughout the day. According to the estimation results, the most reliable lines are found on Istanbul Road, which has fewer intersections. Notably, there are different results in parameter values between the region-based and line-based models. As the focus switches to individual lines in the line-based model, regional variances appear to be nullified by daily line-based operations. The line-based models do not take hourly variation during the day into account; nonetheless, all of the hourly variations might be captured by the regional variations.

Service Characteristics

Among service characteristics, the ratio of new buses in the fleet is the most effective variable in decreasing travel-time variability in both *Model 1* and *Model 2*. The reason for this finding likely lies in the technical characteristics of the new vehicles. First, these vehicles are installed with automatic gears, which prevent possible time losses in acceleration and deceleration. Second, these vehicles are more reliable and easily maneuverable on surface streets, where older vehicles without anti-lock breaking systems are unable to maintain a constant speed.

In terms of service characteristics, another anticipated result pertains to the number of bus stops in the line-based model. As the number of bus stops per line increases, travel time variability tends to increase, a finding that supports previous studies of travel-time variability. Furthermore, the estimation results regarding the relationship

between the number of passengers and travel-time variability are not surprising: as the number of passengers increases, travel-time variability increases. The fastest time periods during the day are generally off-peak hours in the early morning, late evening and at night, when there are fewer passengers. Other times typically experience 70 to 110 % of total bus capacity.

6. CONCLUSIONS

Three variations of travel-time variability prevalent in the Ankara metropolitan area have been investigated in this study: spatial (i.e., operational region), route (i.e., highway), and bus-line based travel-time variability. Spatial travel-time variability is computed by aggregating variables of interest over five operational regions in Ankara. Similar aggregations have been carried out separately for route and line-based models. Each operational region differs in various respects, including street length, existence of highways, a suburban or inner-city character, and the distribution of activity centers. This heterogeneity results in travel-time variability particular to each region. Highway-based models are expected to capture differences in travel-time variability among buses operating on three different highways and surface streets. Line-based models reveal individual differences between individual bus lines.

As expected, we have identified significant regional differences in Ankara, a city typical of developing countries characterized by a dual nature. In urban sectors of

developing countries, traditional and modern areas are located side-by-side. In general, modern areas are more apt to be located on the urban fringe, as modern residential areas can easily be established in these expanding areas. As modern areas are associated with topographical advantages and networks of broad streets, bus lines tend to be longer in these areas. Especially in the westernmost portions of Ankara, Regions 1 and 5 include modern residential areas that feature wide streets. Bus lines tend more to cover all of the residential districts that have wide streets, whereas this level of service is not observed in more traditional regions, i.e., Regions 2, 3 and 4. This finding suggests policies that re-organize bus operations with respect to regional differences in an urban area. Because the densities of traditional regions are higher than the densities of the modernized regions, bus-stop spacing standards should be established according to the neighborhood density. The implementation of such an approach in the Portland, Oregon, metropolitan area has demonstrated that bus-stop consolidation improves bus transit times (El-Geneidy et al., 2006).

Highway-based travel-time variability has narrowed our focus to four different routes with different characteristics. Two of these, Eskisehir Road and Istanbul Road, connect the modern residential areas in the west with the metropolitan core. The two roads differ with respect to various characteristics, including the right of way (Eskisehir Road has quasi-transit lanes in some sections), speed (Istanbul Road is generally faster than Eskisehir Road), signaled intersections (Istanbul Road has more signaled intersections), and bottlenecks (Eskisehir Road has more bottlenecks than Istanbul Road). Ataturk Boulevard is the main highway that connects the northern and southern parts of the metropolitan area, traversing the city center (see Map 1 above). All of the lines on these highways perform better than those on the surface streets. El-Geneidy et al. (2009) also lend support to bus-only shoulder policies, bus-stop consolidation, serving major streets with fewer stop signs and the implementation of smart transit signals. Highway-based models call for lane privileges and signal priorities in the inner city to improve the travel-time variability of bus transit services. Moreover, by reducing the number of bus stops on some of the transit lines, the transit time along Eskisehir and Istanbul Roads may decrease travel delays caused by unnecessary stops. All transit lines on the east-west corridors, which connect different suburban neighborhoods to the city center, coincide on Eskisehir or Istanbul Roads. However, because they have bus stops at different locations along these roads, bus-stop consolidation may improve the performance of

public-transit services on these roads.

Bus-line based models further narrow the models to individual lines. The variable results obtained through these models indicate heterogeneity among the bus lines. Regions with high travel-time variability in particular point to the existence of bottlenecks and the inadequacy of the street layout for individual lines. Notably, the regions with high travel-time variability are either traditional or informal neighborhoods, where the transportation network requires significant improvements.

In fact, the current bus transit operating system provides the entire metropolitan area with identical transit service without regard to variation induced by regional, temporal or line-based characteristics. A high degree of heterogeneity reported in the models calls for a more flexible organization of transit services. The model results suggest different policy implications. For example, highways may be used to pool all of the passengers traveling to the city center. Passengers might be transferred to high-capacity buses at certain points where most of the bus lines converge. This tactic may be helpful in alleviating regional variations in bus-line operations and increasing speed and reliability on the highways. Moreover, this change would significantly shorten the bus lines and restrict them to surface streets in the neighborhoods where bus terminals are established. Regions 1 and 5 are well-suited to this type of structural and operational change.

The results of line-based models also support the idea that the existing point-to-point bus-line operations must be changed, as there is significant variation among the regions that are connected to the city center using the same type of vehicle. The establishment of transit-only lanes may also alleviate travel time variability in certain respects. Reserved lanes in the city center at noon and during the evening hours would increase travel-time variability.

This study has produced valuable results regarding the macro-organization of the bus transit system: that is, reorganizing the transit system based on the characteristics of operational regions, highways, time of day and time of week will produce significant gains in transit reliability. Further research calls for a close monitoring of a sample of transit-vehicle operations based on the bus design, distribution of passengers on the route, driver behavior as well as detailed land-use and route characteristics.

1. INTRODUCTION

According to Sperling and Claussen (2004), the inherent dilemma of motorization in developing countries is that "…for many, vehicles are desirable as a secure and private means of travel, and as status symbols…but personal motorization also imposes enormous costs, especially in cities. The well-known litany includes air and noise pollution, neighborhood fragmentation, and high energy use". Especially, the energy use will be of prime importance in the near future as oil consumption in developing countries will be two thirds of the global increase between 2002-2030; surpassing total energy consumption of developed countries around 2030 (IEA, 2004). A significant part of the energy consumption is expected to be consumed by the transport sector, in which private transport is estimated to constitute a significant part. On the other hand, sharp increases are expected in passenger car ownership levels when per capita income level reaches a level between US$3,000 and US$5,000 (Dargay and Gately, 1999). Besides, Ingram and Liu (2004) estimate that in developing countries passenger car ownership is expected to increase at a rate more than income growth. A possible explanation to this is social determinism—a sociological explanation—which associates car ownership in developing countries exclusively with middle class life styles, and stresses the social forces on the middle class to sustain a mobility level tied to car ownership (Vasconcellos, 1997).

Since 1970s in Turkey, there has been car production for the domestic and the international markets, which has been strongly supported by successful alliances of the international car makers with the domestic partners (Tekeli, 2009). Since 1980s, economic development spurred by the economic restructuring of the economy has proceeded hand in hand with urbanization. Besides economic liberalization, customs union with the European Union eased import and export of passenger cars. In addition to traditional Fiat and Renault alliances, now in Turkey, big international car makers such as Ford, Toyota, Honda, Hyundai have passenger car production units in Turkey.

Overall result of these developments is a tremendous increase in the passenger car ownership levels in Turkey—in 17 years from January, 1995 to January, 2012 number of cars owned has increased from 2,876,616 to 8,185,556 which equals to a mere 2.8 times increase.[1] Although the actual figures have increased a lot, passenger car ownership is still in its infancy when one considers that the increase has been from nearly 45 passenger cars to around 110 passenger cars per thousand people in the same period. The increase in passenger car ownership has first gained momentum in provinces such as Istanbul and Ankara where per thousand people passenger car ownership levels are around 138 and 198 respectively as of 2011. When these figures are compared with those in Europe of in North America, one can notice that private car ownership in Turkey is still in its infancy. In other words, the current condition of the passenger car ownership is on the verge of fast increase.

As traditional compact urban structure of the Turkish cities is insufficient to locate the increasing number of private cars, various sorts of problems arise in terms of traffic conditions, land use changes and daily quality of life. Accordingly, the compact urban form has been dissolving with the increasing motorization in the past 20 years. However, this is continuing only with the sprawl of the residential areas. Residential areas near city centers have been transforming into new employment centers or remain as decaying areas with the flight of new members of “the automobile club” (Dupuy, 1999).

In this study, we try to uncover the underlying regional dynamics of motorization in Turkey. To do so, we use macroeconomic and demographic statistics based on provinces and derive statistics that explain regional differences in motorization and its pace. The study has been organized in four parts. The second part presents information about historical development of

[1] Turkish Statistical Institute, Accessed: April 15, 2012.

passenger car ownership in Turkey along with other countries, i.e., France, Germany, Greece and the USA. In the third part, we devise statistical variables which account for passenger car ownership levels at the provincial level. By this, we try to relate motorization to the urban development and local economic conditions too. General conclusions are presented in the last part according to the results derived from estimation given in the fourth part.

2. PASSENGER CAR OWNERSHIP IN TURKEY

In the past 17 years from 1995 to 2012, passenger car ownership in Turkey has nearly tripled from 2,876,616 to 8,185,556. In the same period, GDP has increased nearly 2 times, the population of Turkey increased by 1.3 times, the urban population increased by 1.7 times.[2] The increase in passenger car ownership is evident and eminent. There are many factors affecting private car ownership in Turkey. As a developing country, economic development and increase in economic wealth are prime factors behind passenger car ownership. However, there are many other factors too. One may contemplate factors such as condition of the public transit, social status gained by private car ownership, status of the prospective owner, household size, etc. Whatever the factors are, if the production is not enough to meet the demand, the increase will be limited to a certain extent. This was the case especially in 1970s and 1980s as there were only two car producers active in Turkey.

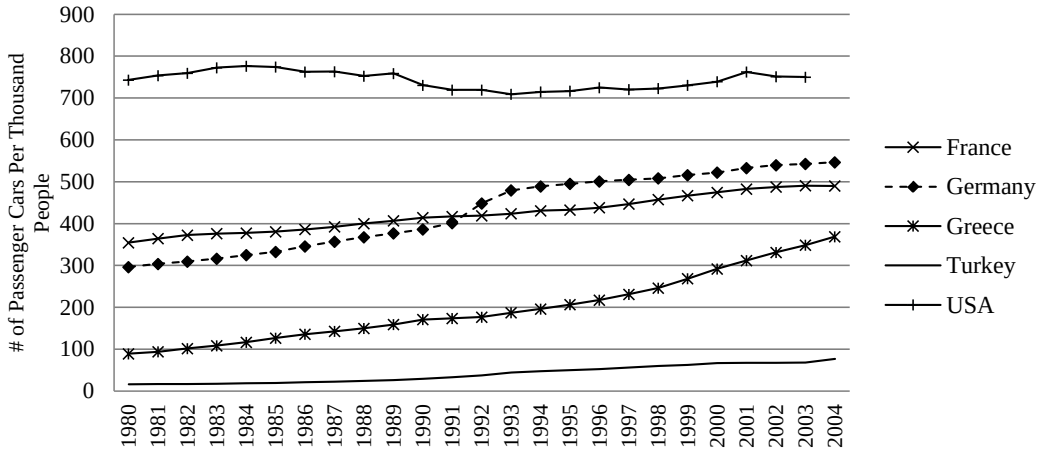

Figure 1 Passenger cars per thousand people in France, Germany, Greece, Turkey, and USA (Source: UNEP Geodata Portal, Accessed May 19, 2012)

[2] Population figures are available for 1990 and 2011.

Before 1980, import of passenger cars was restricted, only foreign cars imported earlier and those produced domestically by foreign car producers were being used. In 1980, structural reforms besides economic liberalization in Turkey have opened the domestic market to cars produced abroad. However till 1990s private car production was not enough to meet the increasing demand. Besides, there were economic obstacles too, viz., household income was not enough to purchase a passenger car. From 1980 to 2004, while Turkey reached 77 cars per thousand population (from 16 cars), Greece attained 369 cars per thousand people (see Figure 1).

If car ownership is to catch up with the levels in the developed world, one may expect that the levels are to increase levels more than 400 passenger cars per thousand people. USA shows the upper limit for car ownership, which is between 700 and 800 passenger cars per thousand people. For all countries except USA in Figure 1, there is nearly a perfect match between GDP per capita and passenger car ownership levels, i.e., correlation between income and passenger car ownership is between 0.90 and 1.00.

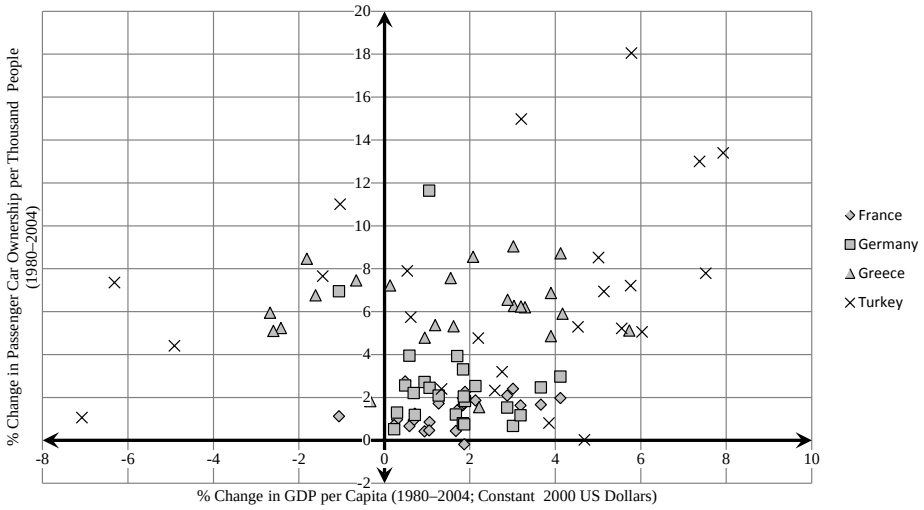

Figure 2 Income vs. passenger car ownership in France, Germany, Greece and Turkey (1980-2004; Source: UNEP Geodata Portal, Accessed May 19, 2012).

Figure 2 depicts the relationship between income and passenger car ownership better. Almost all of the extreme values are associated with Turkey in Figure 2. At all times, even when GDP per capita decreased, passenger car ownership increased at varying degrees, and mostly the accompanying increase in passenger car ownership was higher than the GDP per capita increase. In both Germany and France, the increase in passenger cars is in consonance with the increase in income, but increase in passenger car levels in both Greece and Turkey is

generally higher than the increase in incomes. This might be due to the relative saturation in European passenger car levels, which is well below USA levels. On the other hand, both Greece and Turkey are well behind saturation levels, hence the higher rates of passenger car increase with respect to income increase.

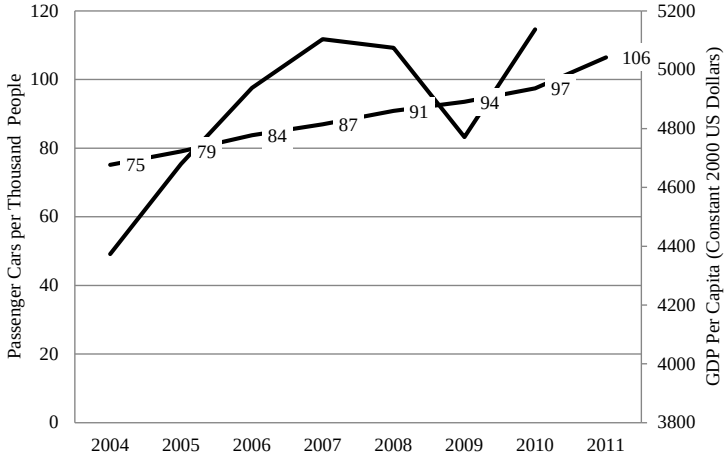

Figure 3 Passenger car ownership per thousand people and GDP per capita between 2004 and 2011 in Turkey (Source: UNEP Geodata portal and Turkish Statistical Institute, Accessed: May 19, 2012).

In Figure 3, passenger cars per thousand people in Turkey have increased 41.63 % in 7 years from 2004 to 2011 (the total number of passenger cars increased by 50.66 % in the same period). From 2004 to 2010, on the other hand, GDP per capita has increased by 17.46 %, which supports the outcome that the increase in income supports a higher increase in passenger car ownership levels, i.e., income elasticity of passenger car ownership is higher than 1). However, passenger car ownership is still in its infancy and it is expected to increase at least at these rates in the future. If the current trend continues with the same smoothness into the future, in 15 years from now, passenger car ownership is expected to be at around 225.68 per thousand people in 2027, which is more than two fold increase. However, it is highly probably that this smoothness might turn into a steepness, which means that the 226 passenger-cars is an estimate from below.

3. PASSENGER CAR OWENERSHIP AT THE PROVINCIAL LEVEL

As of 2011 (August), per thousand passenger car level is highest in the capital city of Turkey, Ankara, and lowest in Şırnak, in the South-East region of Turkey (Figure 4). The gap between the highest and the lowest figures is tremendous; the highest level is nearly twenty fold of the lowest figure. The distribution of the car ownership displays a strong regional disparity in

Turkey. South-East Region of Turkey departs from the rest of Turkey with poor level of passenger car ownership. This region is buffered with another low level region to the west. Western Turkey is dominated with passenger car ownership levels between 100 and 150 passenger cars per thousand people.

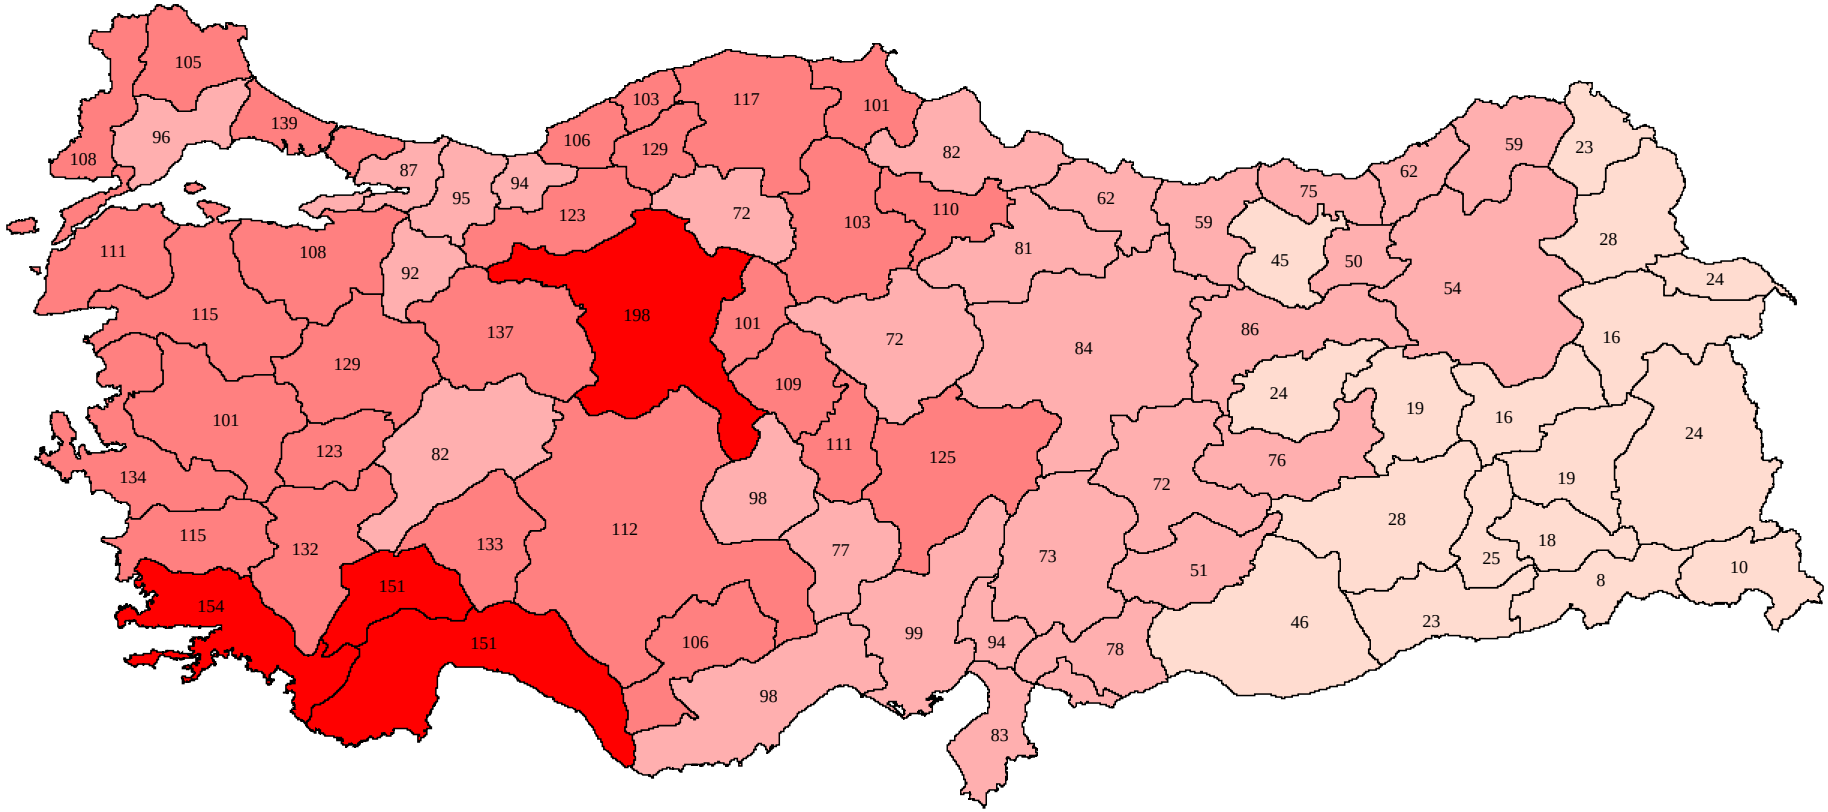

Figure 4 Distribution of passenger car ownership per thousand people in Turkey in 2011 (figures are given within provincial boundaries, scales of red represent increasing intervals of 50 cars per thousand people).

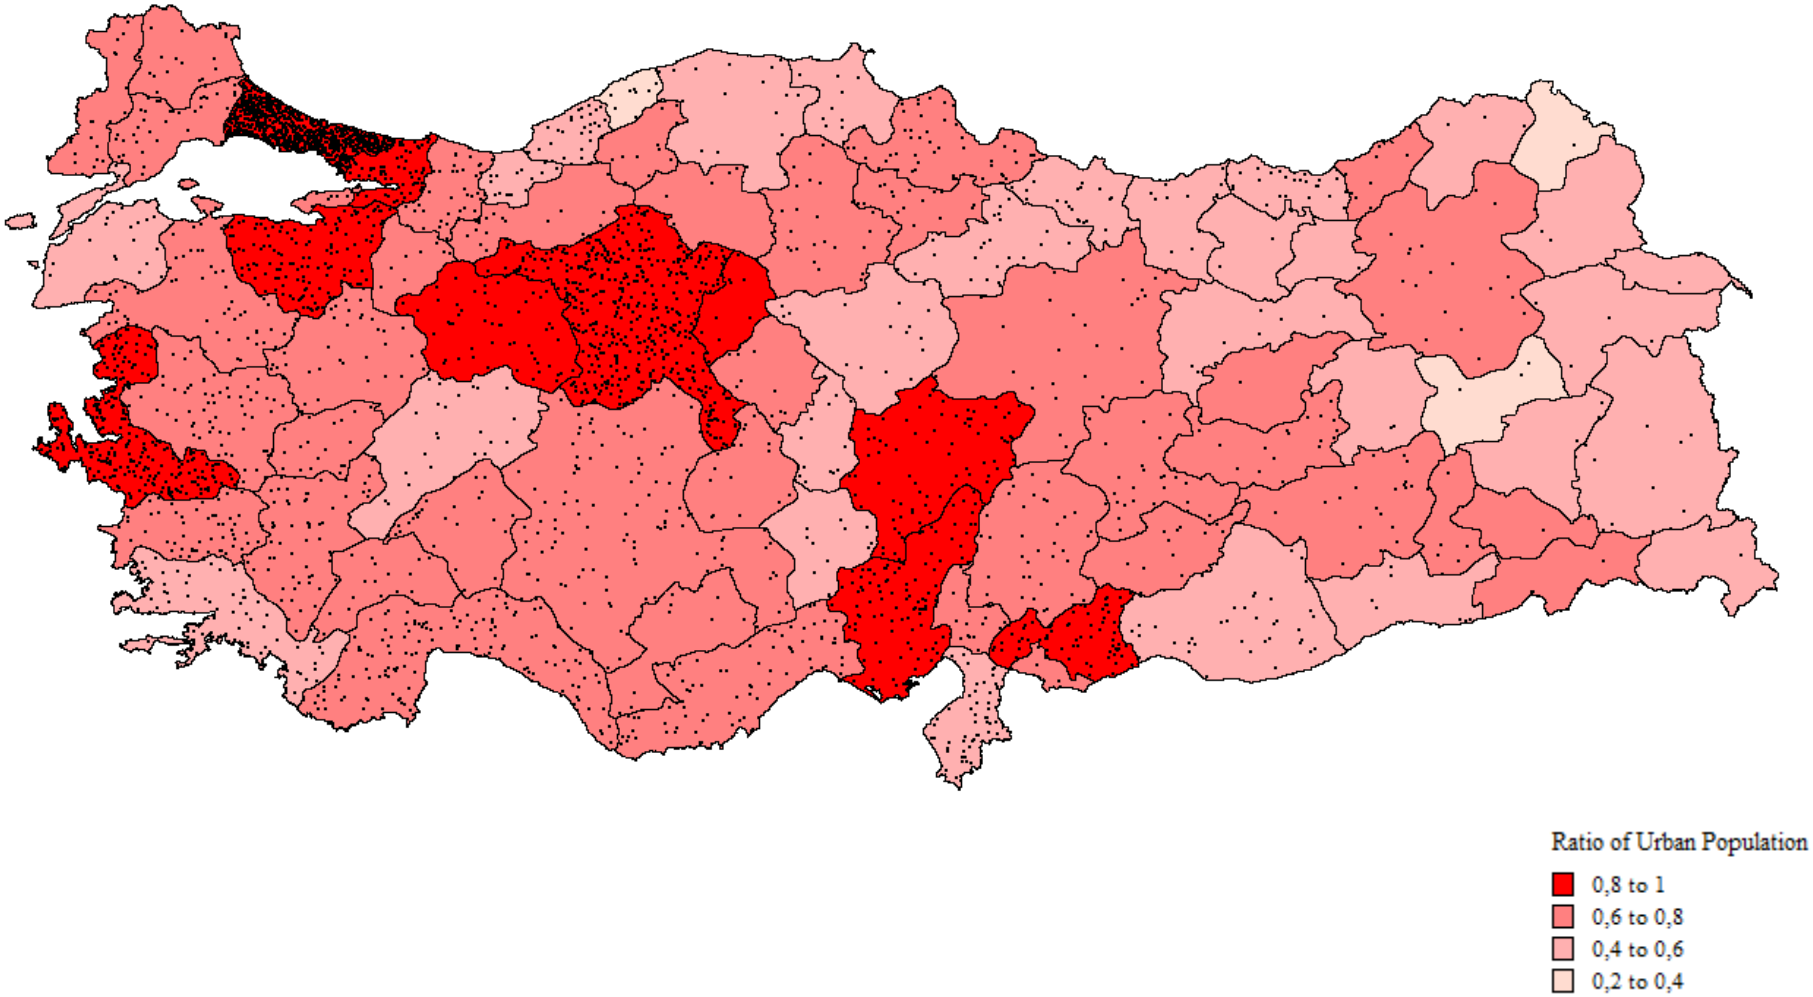

Figure 5 Ratio of urban population and total number of passenger cars in 2011 (1 dot represents 1,500 passenger cars).

Figure 5 shows the relationship between urban population and the number of total passenger cars. Although one can find relationship between urban population and number of passenger cars (correlation coefficient between ratio of urban population and total number of passengers cars is 0.52), the relationship might be spurious to a certain extent as provinces in the west at the same urbanization level with the provinces in the east have more passenger cars—possibly income is a strong intervening variable between urban population and passenger car ownership. On the other hand, one may contemplate that the total number of passenger cars in some of the provinces indicates the severity of the traffic congestion. According to this, Istanbul, which is the most populous province in Turkey with a population around 13 Million people, is almost exhausted by passenger cars.

Figure 6 Urban population vs. passenger cars.

Figure 6 depicts a perfect relationship that does not change in time: relative urbanization of a province in Turkey perfectly matches with its relative motorization in level Turkey. Following Tekeli (2008), we have derived a measure that characterizes directional change and its magnitude of both urban population and number of passenger cars in a province. Let the urban population of a province at time *t* is up_t, total urban population of Turkey at time *t* is UP_t, number of passenger cars in the province at time *t* is pc_t, and the total number of passenger cars in Turkey at time t is PC_t. Then the relative motorization of a province with respect to its relative urban population is as follows:

$$RMwRP_t = \frac{\frac{pc_t}{PC_t}}{\frac{up_t}{UP_t}}$$

When $RMwRP_t$ is equals one, then a province has attracted passenger cars in consonance with its relative position in Turkey with respect to its urban population. Figure 6 above has proved that there is equal to 1 approximately. Average of $RMwRP_t$ is 0.81 in 2000 and it has risen to 0.94 in 2011. When we consider the change between two years, e.g., 2000 and 2010, then a very different computation has to be made in order to find the direction of change, i.e., *DrChRMwRP*, and its magnitude, i.e., *MgChRMwRP*.

$$DrChRMwRP_{t\rightarrow t+n} = arctan\left(\frac{\frac{pc_{t+n}}{PC_{t+n}} - \frac{pc_t}{PC_t}}{\frac{up_{t+n}}{UP_{t+n}} - \frac{up_t}{UP_t}}\right)$$

$$MgChRMwRP_{t\rightarrow t+n} = \sqrt{\left[\left(\frac{pc_{t+n}}{PC_{t+n}} - \frac{pc_t}{PC_t}\right)^2 + \left(\frac{up_{t+n}}{UP_{t+n}} - \frac{up_t}{UP_t}\right)^2\right]}$$

When computation is made and accompanying conversions are made, we can classify motorization in terms of passenger car ownership in provinces with respect to relative population. In order to understand the change better, a two-dimensional graph can be divided into eight parts as given in Figure 7, by which we can classify the change. For example, directional change that falls in I-A means that positive change in relative population is higher than positive change in motorization, III-B means that negative change in motorization is higher than negative change in population.

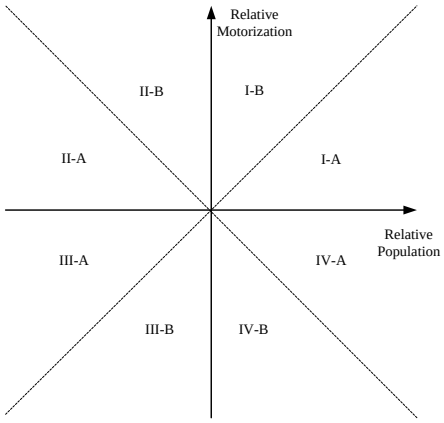

Figure 7 Change in two dimensional graph.

Table 1. Motorization With Respect to Change in Urban Population Between 2000 and 2010.

QUADRANT	RELATİVE CHANGE			
	A		B	
	Province	Magnitude	Province	Magnitude
I	İstanbul	28,362	Samsun	13,026
	Gaziantep	5,170	Antalya	5,286

			Ağrı	0,852
			Hakkari	0,753
			Kastamonu	0,605
			Kırşehir	0,580
			Sinop	0,421
			Nevşehir	0,394
			Tunceli	0,394
			Bingöl	0,351
			Burdur	0,343
			Karaman	0,342
			Siirt	0,262
			Iğdır	0,171
III	Trabzon	3,493	Balıkesir	5,735
	Tokat	2,657	Zonguldak	4,384
	Ordu	2,297	Bolu	2,633
	Giresun	2,080	Eskişehir	2,115
	Bitlis	1,993	Aydın	1,778
	Erzincan	1,533	Edirne	0,995
	Rize	1,336	Kırklareli	0,636
	Kars	1,082	Artvin	0,621
	Gümüşhane	0,694	Kütahya	0,616
	Van	0,565	Çanakkale	0,245
	Amasya	0,563		
	Ardahan	0,303		
	Uşak	0,135		
IV	Ankara	23,690	Kocaeli	9,538
	İzmir	8,616	Bursa	5,514
	Adana	6,607	Denizli	2,319
	Manisa	1,409	Sakarya	1,099
			Bilecik	0,301

According to the relative change, 81 provinces are categorized into one of eight compartments of changes along with their magnitudes of change. According to the results, only three provinces with strong economies attract more population than passenger cars, ceteris paribus.

Provinces that fall into I-B show strong motorization in terms of passenger cars. Of these provinces, Samsun, Düzce and Tekirdağ show strong levels of motorization. On the other hand, provinces, where relative motorization decreases more than population increases, are Kocaeli, Bursa, Denizli, Sakarya and Bilecik. Of special interest are those cities where relative passenger car ownership increases more than population decreases.

4. CONCLUSIONS

Motorization is on the verge of fast increase in Turkey. It is expected to increase two or three fold in the next two years or so if the current trend maintains itself into the future. However, there are vast differences between provinces. West of Turkey strongly differs from the East of Turkey; the passenger car levels in the former are significantly higher than the latter. Passenger car ownership is highest in Ankara where there are 198 passenger cars per thousand people, it is lowest in Şırnak where there are 8 cars per thousand people.

There is almost a perfect match between ratio of provincial urban population in Turkey and ratio of provincial passenger car population in Turkey. In terms of relative urban population change in the provinces, relative motorization also shows strong variation. Accordingly, eight modes of change are detected. Although motorization is increasing and, moreover, it is on the verge of fast increase, we expect that the increase will assume strong variation among provinces. In the past 10 years, real motorization was detected in 35 provinces, where the rate of passenger car increase is higher than the rate of population change. These cities are medium sized cities in fact. We expect that real motorization is expected to take its toll in these cities.

Track: Planning Theory and Methods

Vanessa Watson[1]

CO-PRODUCTION AND COLLABORATIVE PLANNING – THE DIFFERENCE

ABSTRACT

The concept of collaborative planning has had a long and fruitful lifespan in planning theory. Like other central ideas it has now been tested, assessed, critiqued and refined. One conclusion is that in those contexts where conflict and deep difference make collaboration a difficult or impossible ideal (Watson 2009), planners should search for alternative ways to think about how planning processes could still find ways to be inclusive. The idea of co-production, from other disciplinary fields, is potentially emerging as contender for this position. However, co-production itself has a complex lineage, with different interpretations of the term having evolved in different parts of the world, and important differences as well between the idea and its practice. A regional divide may be emerging in the use of the term: from that originating in the work of political economist Elinor Ostrom to the practices of Slum Dwellers International (SDI) in cities of India and Africa.

There is always a danger, when concepts 'hop' disciplines and contexts, that they are simplified and misinterpreted. It would be particularly problematic if co-production was simply to be seen as a new term for collaborative planning. If it is the case that the term co-production is beginning to raise interest in the planning field, then it is critical that the nuanced differences between it and collaborative planning are understood. The purpose of this paper is to explore some of the varied roots of co-production and how it is framing practices in informal settlement upgrade projects through SDI.

The methodology employed in constructing this paper uses discourse analysis of published literature and web-based material to understand the varied meanings of these terms. The conclusions are of relevance to planning theory where there is a history of debate on the term collaborative planning, as well as discussions on how it might differ in different socio-economic and institutional contexts.

Keywords: collaborative planning, co-production, inclusive planning/action

1. INTRODUCTION

This paper aims to do some conceptual 'ground-clearing' in the area of state-civil society engagement, as well as to encourage planning theorists to take note of certain new forms of engagement which are happening in some parts of what might be called the global South. Innovative tactics and strategies adopted by global South urban communities and NGOs as they attempt to improve living environments might be equally useful in these kinds of struggles in the global North, but to date there has been little attention paid to these movements by planning theorists who have been primarily concerned with forms and variations of collaborative and communicative planning.

These new forms of state-society engagement have been labelled as 'co-production' – following a term introduced some time ago by political economist Elinor Ostrom. Old and new co-production do have elements in common, yet in other ways they are significantly different, and the appropriation of the term in this way can give rise to confusion, given different interpretations in time and place. The first aim of this paper is to examine the differences between these two interpretations and manifestations of the word co-production, with a focus on an explanation of its current use in relation to the work of Slum Dwellers International. The second aim is to consider some of the more interesting and positive strategies and tactics taken up by new co-production, as well as its limitations.

If Brownhill and Parker (2010) are correct in suggesting that we are now in a 'post-collaborative' era, and with growing attention to planning issues in the global South, then new co-production could be of interest to globally-inclined planning theorists. A major limitation with much of recent planning theory on state-society engagement is that it has drawn on ideas and experiences from a very limited part of the globe: the Euro-American territories. While transplanting any such ideas out of their context of origin needs to be considered with great caution, it still holds that at the level of principle different regions can productively learn from each other where concerns are common.

Regional differences offer fertile ground for comparative, in depth, case study research following the recent lines of thinking on this kind of research method (see McFarlane, 2010; Robinson, 2011). With little of this yet in evidence to support this paper, it relies on what secondary sources are available to point to areas in which the terms and practices have commonalities or differences. I am not suggesting that new co-production is the only form of state-society engagement emerging in cities of the global South nor am I suggesting that the practice is unproblematic – self-interest, exclusion and corruption are as likely in these forms as they are in any other, and it is important not to romanticise them. At the level of *principle*, however, new co-production deserves closer attention as a way in which poor urban residents try to improve their access to services and possibly a more secure foothold in the city. As significantly, for this paper, it is a process in which planning expertise (of a particular kind) sometimes plays a role.

2. DEMOCRACY DEBATES IN THE GLOBAL SOUTH

In the past decade or so there has been a steadily increasing interest in supporting democracy and civil society in countries of the global South. From the 'good governance' agenda of the World Bank to more recent (considerable) donor support for NGOs committed to social mobilization,

there has been growing faith in the ability of poor communities (rather than governments) to create inclusive and more equitable societies and cities by claiming their 'rights as citizens'. Chatterjee's (2004) argument (in a book entitled subtitled: *Reflections on Popular Politics in Most of the World*) that there is a deep divide between 'civil society' consisting of a formal political elite and 'political society' – made up of the majority who have to rely on alternative and informal ways in their relationship with the state – certainly has relevance, both in and beyond the global South.

Experiments in different forms of local citizen engagement, such as Porto Alegre's participatory budgeting, have been labelled 'best practice', available to be tried out anywhere else in the world (Cabannes, 2004). NGOs able to upscale these 'good practices' through global networks have attracted particular attention and support: Shack/Slum Dwellers International (SDI) has been prominent here, although not the only example of such networking. Arjun Appadurai (2001) has suggested that these local groupings, as they link up through transnational advocacy networks, are instruments of 'deep democracy', and are redefining concepts of governance. Emerging issue-based global networks, Appadurai argues, present a post-Marxist and post-developmentalist vision of new forms of democracy, networks being a mechanism through which the poor show that they are better able to provide for basic needs than 'the usual candidates' – the market, the state and global development agencies (p 41).

At the same time there has been a growing critique of what is seen as a naïve and simplistic faith in notions of 'community', 'citizenship' and participation, and above-all, an assumption that Western liberal democracy can be easily transplanted into any context, where communities will 'see the light' and mobilize to secure their rights from the state. Roy (2009) uses the term 'civic governmentality' to describe the strategies of SDI-linked SPARC in Mumbai as well as Hezbollah in Beirut. She sees these organizations, not as a zone of contact or mediation between state and community, but as engaged in the process of constructing and managing a 'civic realm' while both resisting and complying with top-down rule. This involves a 'civilizing' of political society (P 161), fostering civic identity and broader civic commitment. But Roy (2009) provocatively asks if SPARC and Hezbollah can also be seen as agents in/of urban redevelopment (p 168) in that their engagement with land redevelopment inevitably leads to new processes of inclusion and exclusion of the poor.

A further body of literature now points to ways in which power and patronage routinely infuse participation processes in development projects. In a useful review of this work, Robins *et al* (2008) argue that donor or agency driven community empowerment programmes frequently run up against entrenched political cultures of patronage and paternalism which are commonplace in everyday political life in many parts of the global South. They suggest that there is a logic to such practices: they are essential components of strategies of survival, creating conditions of access to vital resources and cannot be wished away by introducing political models from elsewhere. Hence poor communities will often shift between clientelism and rights-based citizenship claims, using apparently contradictory discourses opportunistically (a strategy of 'tactical bricolage'). It is important, therefore, not to confuse the emergence of organizations 'giving voice' and the actual processes in which marginalized groups engage in order to secure political and material gains.

It is within this context of debate over new forms of democracy that the paper turns to the use of the term co-production to describe current NGO work in parts of the global South.

3. 'NEW' CO-PRODUCTION:

In a 2008 article Diana Mitlin explains the work of the NGO federation known as SDI, as co-production. She defines this as a political strategy used by citizen groups and social movement organizations to '…enable individual members and their associations to secure effective relations with state institutions that address both immediate basic needs and enable them to negotiate for greater benefits' (Mitlin, 2008, pp. 339).

Mitlin (2008, pp. 340) explains the usual, or prior, understanding of co-production as initiated by Ostrom as '… the joint production of public services between citizen and state, with any one or more element of the production process being shared'. However, she argues, this approach is increasingly being used (in a different way) by the urban poor as a way of politically consolidating their base and extracting gains from the state. Acknowledging that accessing services is often reliant on large scale capital investments (for example in waste-water treatment) which can only be undertaken by the state, poor communities choose to engage with local government on these issues. Mitlin (2008) argues that (new) co-production is different from standard 'participation' or 'partnership' arrangements. It is more effective than 'lobbying' or 'protesting' in terms of actually gaining benefits, and the non-confrontational nature of the process allows greater participation from women, and better chances of securing political gains.

The (new) political strategy of co-production described by Mitlin and Appadurai involves a particular set and sequence of practices (now termed SDI 'rituals') which were tried and tested in the context of urban India over the last several decades, and have since been internationalized through the global work of SDI. Appadurai (2001) explains the broad approach of the Indian Alliance as populist and wary of experts and professionals. Rather, any 'outside' involvement (NGO appointees who may have technical expertise) aims to organize and mobilize the poor and set up a network of mutual learning opportunities. The argument is that the poor know best about how to survive in poverty. The approach is highly political but specifically non-party political. It is therefore a position of accommodation and negotiation rather than confrontation, and of slow learning and accumulation of gains, or 'a strategy of patience'.

Small scale savings schemes are of central importance to the organizations having (following Appadurai, 2001) ideological status in the organization: they are an entry point for relationship building between individuals and groups, they express a moral discipline in the organizations and a commitment to the public good, and they highlight the role of women as prime savers. A further ritual is 'precedent setting', a term used to describe the collective building of shack and toilet models (often in central public places and events) but, argues Appadurai (2001: 34), at the same time the attachment of the legal term 'precedent' to such models '…moves the poor into the horizon of legality on their own terms'. There are thus tactics of language but also of material and organizational action, in particular, self-surveys and enumerations, toilet festivals and housing exhibitions.

The tactic of self-enumeration and mapping was originally developed by the SDI-affiliated Indian NGO, SPARC (Society for the Promotion of Area Resource Centres), amongst pavement

dwellers in India. Over the last ten or so years, but with examples dating back as far as the 1980s (Patel et al., 2009), poor urban communities in informal settlements have increasingly adopted these tactics in order to reinforce and specify their demands for land and services and to increase their 'visibility' to the state. Sometimes these strategies have been followed by 're-blocking' in which shelters have been re-organized by their occupants to make more orderly spaces for the insertion of claimed basic services. Appadurai refers to this as creating 'governmentality from below'.

Chatterji and Mehta (2007), in theorizing the self-enumeration movement, have argued that the articulation of power and knowledge in practices of government manifest in technologies of mapping and enumeration by which the state makes society visible to itself, and these can end up creating new types of social collectivities. Populations generated by these governmental practices, which mark and categorize them in particular ways (as 'slum dwellers' or 'pavement dwellers') can end up seeing themselves as communities capable of resisting these technologies (P. 131). As a result, slum dwellers have used the survey like government does, to transform themselves into a quantifiable population, and to create documentary proof that they exist as a collective that can speak back to government in its own language (P. 143). In India, NGOs have used the surveys specifically for mobilization and to make slum dwellers aware of a new identity based on abstract citizenship rather than on caste or religion (P 159). NGOs therefore see the survey as an ongoing activity and not a once-off event.

The scaling up of SDI has spread these tactics from their origin in India to informal settlements in other parts of the world and the SDI website now lists 34 countries where self-enumeration processes have been undertaken. In what could be described as a growing global self-survey 'movement' amongst poor urban communities, these traditional tools of planning and governance – the survey, the map and the plan – have been appropriated and used as a mechanism to further the claims of marginalized groups to urban space.

Similarly toilet festivals and housing (shack) exhibitions have political purpose: to demonstrate that the poor have the knowledge and expertise to construct their own housing and facilities, and that the standard flow of expert knowledge can be reversed (Appadurai, 2001). In fact it has been these learning strategies between communities that has been a central feature of their work. 'Horizontal exchanges' involve groups of poor moving between sites to share knowledge and gains in savings, construction and engagement with authorities. They also help to indicate to those in authority that the poor also travel and have wider linkages, giving an element of authority and legitimation. McFarlane (2011, pp. 69) refers to these exchanges as 'translocal urban learning assemblages' of materials, practices, designs, knowledge, personal stories and local histories, with the notion of assemblage placing an emphasis on urban learning and alignment between the social and material at different sites.

The next section compares and contrasts earlier uses of the term co-production, making the point that there are some similarities but also some significant differences between the ways in which this term has been used previously and more recently.

4. OSTROM'S COPRODUCTION

Political economist Elinor Ostrom defined coproduction as '…a process through which inputs from individuals who are not "in" the same organization are transformed into goods and services' (1996, pp. 1073). The focus in this literature is on the provision of public services (sanitation systems, schools etc) where involvement of the state with communities can create synergies through parties contributing in different but complementary ways: communities (she suggests) have local information, time, skills etc and the state has resources and technical expertise. Moreover, state and society have different production capacities: for example, states can produce trunk services while citizens can produce related feeder services. The suggestion here is that state and citizens (service beneficiaries) have different but complementary forms of knowledge which together can improve the final outcome. Where citizens can substitute for the state in service provision then it is simply a case of working out which can operate most cost-effectively at a given scale (Mitlin, 2008).

Ostrom's work has strong links to social capital thinking and theories of urban governance in the US from the late 1970s, where her position was one of encouraging decentralization to bring government closer to citizens. Co-production, she argues, fosters social capital as communities organize around service provision and management. There is no direct mention of mediating social movements or NGOs here: the relationship is a direct one between communities and officials. There are important assumptions here that were at the same time being explored in the parallel 'public participation in development' literature in the development studies field. These assumptions (in both Ostrom's and participation debates) were that all community members and households would gain equal access to these services, that exclusion on the grounds of income, gender, ethnicity etc would not play a role, and that the relationship between state and citizens would be fair, consensual, and not corrupt or politicized. In other words power did not play a role in Ostrom's co-production, or if it did, then it could be contained.

Since Ostrom's 1996 article there has been further work[2] aimed at refining the term, primarily from the public administration literature[3]. Joshi and Moore (2004) argue that co-production emerges in the context of weak states, where governments are unable to provide services or lack information about need variation. Brandsen and Pestoff (2006) point to a difference between co-governance (planning and delivery), co-management (joint production) and co-production (citizen production). Hints that co-production could contribute to political change and could deepen democracy did not appear in this literature until later (Bovaird, 2007) but Miltin (2008) suggests the cases cited here are all strongly top-down.

These explorations of co-production do not specifically concern themselves with public participation (other than to suggest that officials working in co-productive mode would act rather differently). In fact there appear to be few linkages between this largely Northern public administration/economics literature and the rapidly growing body of literature from the 1970s on participation and development in global South contexts, where direct involvement of service beneficiaries (sometimes termed 'self-help') became standard and where the participation processes that accompanied these ('community participation') came to be regarded as very important. Within this literature there were opposing strands of thought as to why participation should be important – from 'project efficiency' reasons to 'community empowerment' positions,

[2] Also see New Economics Foundation www.neweconomics.org
[3] See Mitlin (2008)

and later (1990s) to World Bank and USAID interpretations of involvement as a way of securing 'customer satisfaction'. With donor interest focusing on 'civil society' from the 1990s, the role of NGOs as intermediaries between state and civil society as a way of achieving development became increasingly prominent, with a growing emphasis from the early 2000s in participation as a 'right', due to every citizen. It was within this context of a growing move to community mobilization that the social movements such as those affiliated to SDI have emerged.

5. STATE-SOCIETY ENGAGEMENT: WHAT CAN PLANNING LEARN FROM CO-PRODUCTION?

Ideas about social action have dominated the field of planning for at least as long as they have in the public administration and development disciplines. There is no one consolidated position or theory here – rather a set of differing ideas and debates informed by different (although primarily global North) contexts, and drawing on a range of different intellectual traditions. The questions driving this theorizing have, however, been similar to those behind co-production in all its variants: how should state and society engage in order to improve the quality of life of populations (sometimes with an emphasis on the poor and marginalized); how can professionals act to promote social justice and more equitable outcomes of state intervention? Both, as well, have tended to draw on case studies of practice as strong informants of theory as well as broader social theory which has offered a social constructivist perspective. The value of social networks (social capital for Ostrom) and communicative rationality (for planners) have elements in common although are not always closely connected.

Communicative / collaborative planning approaches and co-production (in older and newer forms) would find common ground in that neither takes a radical approach to social change. Both take an incremental, evolutionary and social learning approach to shifting actions of the state in particular directions. SDI takes this approach as it argues that there are certain roles and functions (such as trunk infrastructure) that the state can carry out and communities cannot, and that confrontation strategies (particularly protests and violence) tend to exclude women. The strategy of patience and slow gains is an accepted part of SDI work, although this has often attracted criticism both from communities and other NGOs wanting quicker wins. Building and sharing local knowledge and resources (through micro-savings) is also a central part of SDI strategy, given the starting assumption that the poor know best how to live in poverty. Here SDI co-production is significantly different from the tactics of current 'right to the city' movements which (frequently) take the approach that it is the duty of the state to deliver on constitutional rights such as housing and services, and that either overt protest and/or legal challenges are the best ways of securing gains for the poor. The SDI counter to this is that protest may secure delivery, but the product is unlikely to be appropriate to need unless the poor have been directly involved in shaping outcomes.

Both older and newer co-production also assume a context of democracy, where 'active citizens' are prepared to engage collectively and individually to improve their material and political conditions. Appadurai (2001) sees SDI co-production as a way of deepening existing forms of democracy. However, this is an assumption which may not hold in many parts of the world, particularly in some of the regions where SDI operates. It is useful to return to the arguments of Robins *et al.* (2008) who suggest that everyday political practices are often very different from

those anticipated by NGOs, international agencies or governments and professionals, hence '…civil society organisations do not automatically possess the democratising properties associated with the public sphere under liberal democracies' (Robins *et al*, 2008, pp. 1072). In Africa, for example (where SDI now has affiliates in 17 countries), political cultures are significantly hybridised, with elements of Western liberal democracy co-existing with (and interpenetrated by) politics of patronage and clientelism. Where day to day survival is a priority, people adapt plural strategies, often simultaneously: in some cases this may mean acting like a citizen in a liberal democratic state, in other instances it may imply establishing and exercising personal and possibly corrupt relationships in order to secure gains (also see Watson, 2003). Such relationships go against the grain of both collaborative planning and co-production, yet they cannot be either wished away or policed in situations where societal ethics have been stretched to accommodate such practices as acceptable.

In other respects however, participatory planning approaches and co-production (both old and new) have different objectives. An obvious difference is that in both Ostrom's view of co-production and SDI partnerships, engagement with the state has the purpose of achieving both planning and delivery of outcomes (land, housing, services and facilities) and as well, for SDI, their community-based management thereafter. Older and newer co-production have very different reasons for wanting to push state-civil society engagement through both planning and delivery stages. Newer co-production is far less concerned with achieving cost-efficient projects and effective local government (although these may be important preconditions) and far more with skilling and empowering marginalized communities to manage their own living environments, to deal effectively with state structures, to structurally advance citizen control over state resources and to pass on tactics for achieving this to other communities through global networks.

Differing as well from Ostrom's co-production is the way in which SDI affiliates regard their relationship with the state, described by Mitlin (2008) as a partnership, but a highly political one. The immediate goal may be to secure outcomes in terms of service and land delivery, but such initiatives also aim to shift forms of democratic practice and power, to create an alternative form of governmentality – Roy's (2009) 'civic realm' which both complies with and resists top down rule, and Appadurai's (2001) 'counter-governmentality'. Understanding the role of knowledge and power is central to these processes, and hence the need to exercise power through self-enumerations and mapping and to control the production and interpretation of this critical information.

There are two further areas in which new co-production techniques depart significantly from Ostrom's co-production and much of what is usually included in the scope of participatory planning and development. The first is less reliance on talk and debate and more on showing and learning by doing (Mc Farlane, 2011). Engagement with the state and other agencies thus has strong material and tangible expressions. Community built demonstration models – of houses or toilets – are an important element of SDI and Federation 'rituals' to physically demonstrate outcomes to the state and other communities which may be learning from the process. Similarly the acquisition of knowledge by communities is not from texts or consultants, but from learning exchanges with communities in similar circumstances to see first-hand what they have built. The

philosophy here is one of experiential learning: that direct experience is the most effective way to gain knowledge.

The second innovation is the intention to upscale local practices through networks. The global networks of SDI now span three continents, with a focus on India and Africa. Learning exchanges focus on local experiences but then these are distributed rapidly through the network. In reverse, collective global learning experiences (a global 'portfolio' of experiences and successes) can be mobilized by local affiliates giving them significant additional clout when negotiating with their own local or even national governments. The number and type of social movements have also been organizing globally (also see WIEGO – Women in Informal Economies Globalizing and Organizing, and GPEAN in the planning education field). Being networked globally gives organizations authority to respond to and pronounce on global issues; to be rapidly informed on local issues across a wide range of contexts; and they also give status to organizational statements and claims, and presence at global events. Their power lies in their information, their ideas and their flexibility.

6. CONCLUSION

The purpose of this paper has been twofold. The first is to draw distinctions between various forms and concepts of state-citizen engagement which have emerged at various points in time, from various parts of the world and from a range of disciplinary backgrounds. Planning theory frequently draws on ideas and theories from other disciplines and clarification of the origin of these concepts is important. Hence there is a significant difference between the idea of co-production developed by Ostrom within an economics and public administration field from the 1970s and the way in which the term is being used more recently by social movements in the global South. There are also important differences to draw between co-production (old and new) and planning's interests in state-citizen engagement.

The second purpose of the paper has been to suggest that, particularly with regard to new co-production, there may be a great deal in these practices and ideas that could be of interest in planning theory. Much planning thought on state-citizen engagement to date has emerged from thinkers and practices in the Euro-American regions, where these relationships take on particular forms shaped by the political histories of these countries. With some of the most intractable urban problems now located in cities of the global South, along with a host of new and innovative ideas in these cities on how to explain and respond to them, it seems that new co-production may be of particular interest to planning theorists.

Abstract
Even though the physical borders have disappeared, one easily notice the border between the Netherlands, Germany and Belgium through differences in the shape and measurements of urban development. Dutch city extensions are considered orderly, large and compact, while for instance urban development in Flanders – the northern, Dutch-speaking part of Belgium - appears to be more haphazard, smaller and dispersed. How can we explain such differences between countries that border each other, and have the same climate - and soil conditions? The seemingly simple answer is: institutions. Unravelling how this works exactly is, however, a much more complex endeavour.

This is the aim of this paper. We want to understand how institutions shape the urban morphology. The city-building behaviour is structured by institutions with regard to urban design, land policy, housing markets and so on. We explore these relationships by comparing three neighbouring regions: the Netherlands, Flanders and North Rhine Westphalia (Germany).The focus is on housing development because the differences seem to be most profound in that segment of spatial development.
This paper addresses particularly the effect of national and regional institutions and not so much of local institutions. Local institutions are important for understanding differences within a country or region and not so much for understanding differences between them.

The conclusion of this paper is that there are many institutions that, in combination with other institutions or for itself, influence the morphology of urban development. In our comparison the morphology of North Rhine Westphalia is a combination of the small scale developments in Flanders and the formal master planning in the Netherlands. This study might help the Dutch in finding ways for more small scale developments and to find ways to develop after during and after the current financial crisis.

CONCEPT

1. **Introduction**

Even though the Schengen treaty has abandoned border control in much of Europe, Dutch, Belgians and foreigners alike easily notice the border between the Netherlands and Belgium through differences in the landscape and in the shape of urban development. Dutch cities are considered orderly and compact, while urban development in Flanders – the northern, Dutch-speaking part of Belgium - appears to be more haphazard and dispersed. How can we explain such differences between countries that border each other, have quite comparable physical and social-economical conditions? The seemingly simple answer is: institutions. Unraveling how this works exactly is, however, a much more complex endeavor.

This is the aim of this paper. We want to understand how institutions shape the urban morphology. Following a social-constructivist ontology (e.g. Giddens, 1984) we start from the premise that institutions are made by agents, whose behavior is subsequently shaped by these institutions. This also counts for city-building behavior; this behavior is structured by institutions with regard to urban design, land policy, housing markets and so on. We explore these relationships by comparing three neighbouring regions: the Netherlands, Flanders and North Rhine-Westphalia (Germany). The focus is on housing development because the differences seem to be most profound in that segment of spatial development.

This paper starts with defining a conceptual framework for comparative institutional analysis of housing development and its relation to morphology. Section 2 explores some key differences in morphology between newly built residential areas in the Netherlands, Flanders and North Rhine-Westphalia. In the core section of this paper, we single out effects of the institutional environment on these morphological differences, clustered around four aspects of the development process: the interplay between municipality and land owners in the initial phases of development; the nature of the involvement of the municipality: as an investor or a facilitator; the organization of the process in time: open-ended or project-based; and the involvement of small investors like private persons. The paper concludes with a some remarks on the importance of both institutional and morphological analysis in understanding housing development, and with some suggestions for further research.

2. Conceptual framework for comparison

In this section, we develop a conceptual framework that enables to describe the relationship between morphological phenomena, on the one hand, and the institutional environment in a particular country, on the other. For this, we need 'intermediate' variables that describe the characteristics of the development *process* that can be linked to both morphological and institutional characteristics (section 2.2).

The morphology of a residential area comes about through the interaction of different stakeholders (project development companies, municipalities, land owners etc.). They all have their interests, and different abilities to influence the outcome.

CONCEPT

Institutions are the rules (formal or informal) that coordinate or structure the interaction of these actors (Needham 2010). (Cf. section 2.1.)

Figure 1 shows schematically the relationships between three variables being explored in this paper: *institutions* shape the conditions for actor interaction in the *process* of development, and characteristics of the process influence the *morphology* that results from it.

Other factors may be important determinants of the development process or the morphology as well. Regional *market circumstances* on the housing or land market set the conditions of development processes. At the same time, these market conditions may themselves be a result of the institutional environment (or changes in this) that create shortage or otherwise structure the market (Jokovi et al 2006, Besseling et al 2008, Ball 2003, 2006).

Of course, morphology of residential areas is also determined by *design conditions* of different types: for example local physical conditions or the 'taste' that rules the imagination of potential buyers, but also more 'institutional' conditions like esthetic municipal regulations. In this paper, these are only taken as context factors, they are not it's prime research object. It focuses on morphology in as far as it is a product of development *processes*, and not as product of *design*.

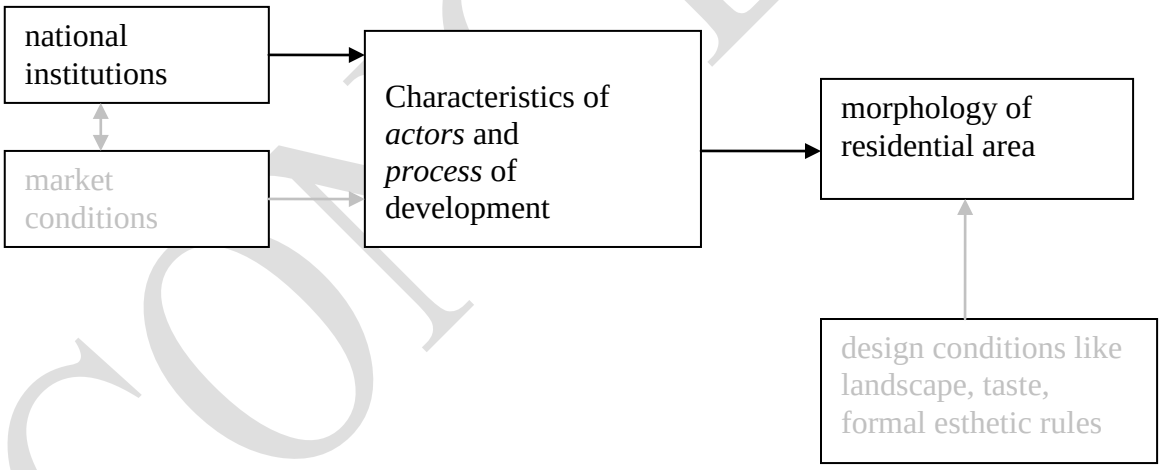

figure 2.1: main variables in this research

2.1 Institutions

Many actors are involved in housing developments. Their interaction is coordinated by formal rules (under private or public law), as well as by practices they are used to, and by the expectations they have (Needham 2010) expectations of one another, of the course of the process, and of the kind of outcome. These latter are all more informal 'rules', that nevertheless may be crystal clear to all participants. Ostrom (1999) defines institutions as all the 'rules-in-use' in a particular 'action arena'. They shape actors' possibilities in trying to reach their goals within the arena. But institutions may also structure the actors preferences that underlie their goals.

CONCEPT

The 'action arenas' that are relevant to housing development are three 'markets',: land assembly and development, house building, and house sales (Ball 2003). These are present in every country, overlapping totally in one country and more independent in another. They are always linked, in that the outcome of one process can be leading for the next, and calculations about next process may structure the first. Institutions may be relevant for every market, or for just one of three.

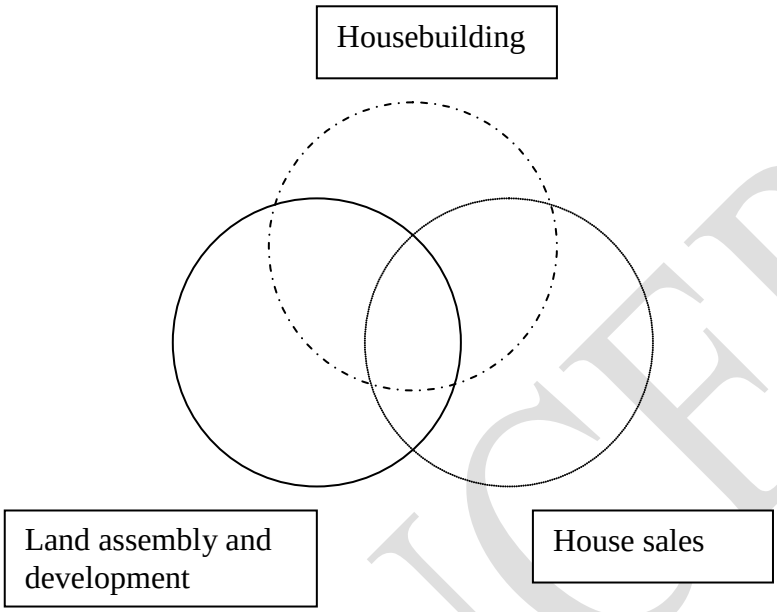

figure 2.2: structure of housing provision (Ball 2003)

Together, the kind of participating actors and their preferences, the action arenas in which they interact (by negotiating, by demand and supply), and the institutions that coordinate this interaction, are the structure of housing provision (Ball 2003) of a particular country, that constitutes the 'environment' for any particular housing development processes. Institutions for land assembly and development are for example rules that define rights of ownership, land zoning, compulsory purchase or the provision and financing of infrastructure. For house building, one can think of rules that regulate the supply of social housing, or rules that define the role of the architect vis-à-vis a client. For house sales, one can think of mortgage conditions, or rules of tenure that make it interesting to invest in private renting houses or not.

2.2 Characteristics of actor and process of housing development

Institutions structure the interaction of actors in the process of housing development, by enabling and constraining their actions (Giddens 1984) In this paper, we are interested in three type of effects on the course of the process that we expect to have an impact on important aspects of morphology. The first two effects have to do with the actors involved in the process, the second with the time-span of the project.

CONCEPT

First, how do institutions influence who has access to the development process and who has not? For what type of actors the rules-in-use are favorable, for what type of actors not? For example: can private persons enter the process as developer, or can only professional development companies participate? Are there many actors involved, or only few?

The preferences of these actors in this paper are not treated as given. The second relevant effect is therefore: how do institutions influence the way actors that are involved see their interest in the process? For example: does the municipality has an interest in the process as an developer (under private law) or only as an public body under public law?

Third, how do institutions influence the time span of the process? For example: are participants necessitated to finish the development process within a given time horizon, or not?

The number and type of actors involved or left out, their interests in the development process, and the time span of completion, all have their bearing on some crucial morphological differences between the three countries, that are discussed in the next section.

CONCEPT

3. **Key morphological differences**

The morphological analysis in this paper is limited to greenfield developments in urban agglomerations. This means that we do not consider brownfields and urban renewal, and also leave rural areas and villages out of consideration. For the morphological analysis we differentiate between three scales: the city and its agglomeration, the development area (the site), and the street.

At the scale of *the city and its agglomeration*, in the Netherlands we see large city extensions next to the existing city. Usually there is only one site under construction. In Flanders we see, besides the notorious 'ribbon development', a lot of small developments woven into the existing loose urban fabric; In North Rhine Westphalia one sees several sites of intermediate size simultaneously under construction next to the city.

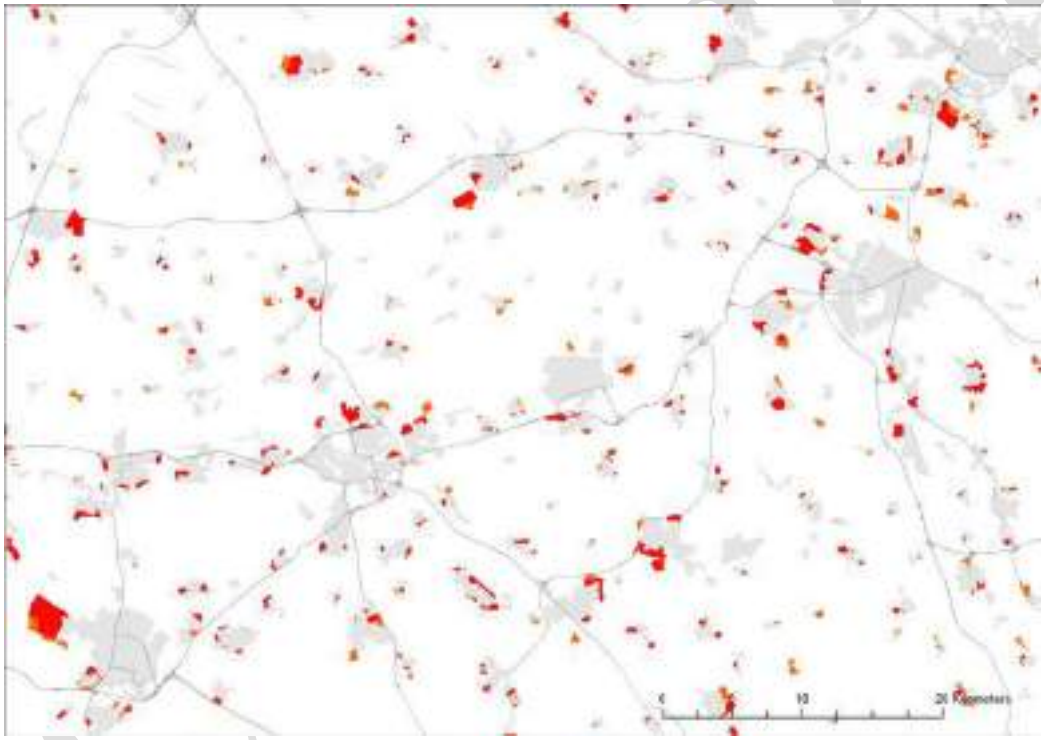

figure 3.1 urban extensions (housing) between 1990-2000 (in red) and 2000- 2006 (in orange),North Brabant region between Tilburg and Den Bosch.

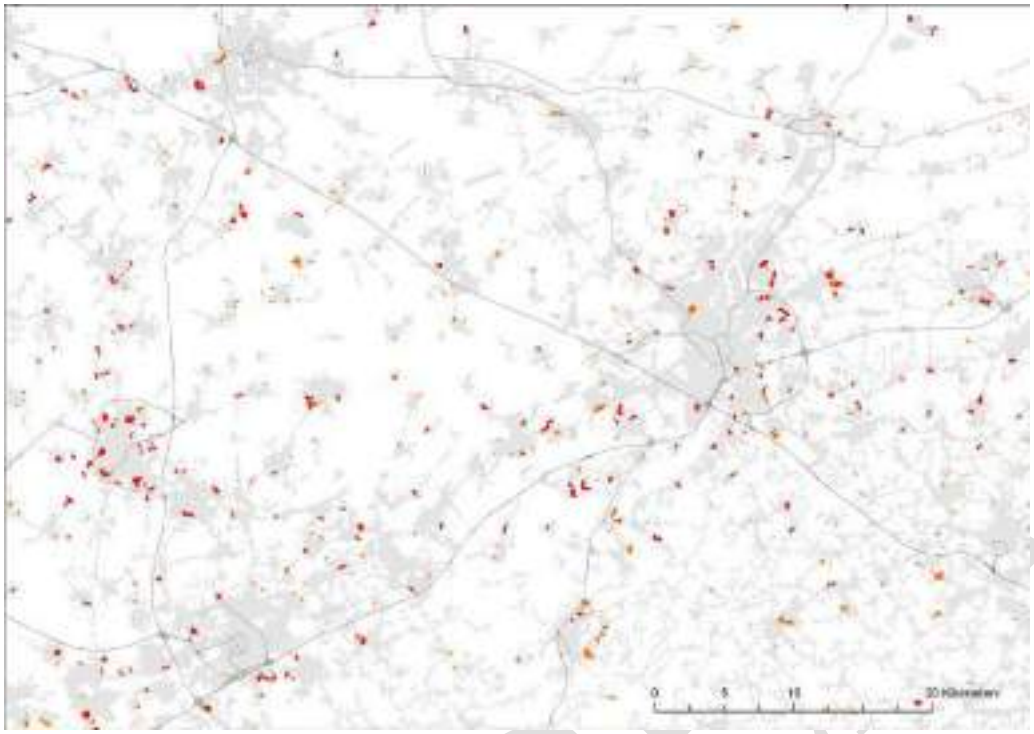

figure 3.2 urban extensions between 1990-2000 and 2000 and 2006 respectively, Gent region between Gent, Kortrijk and Brugge

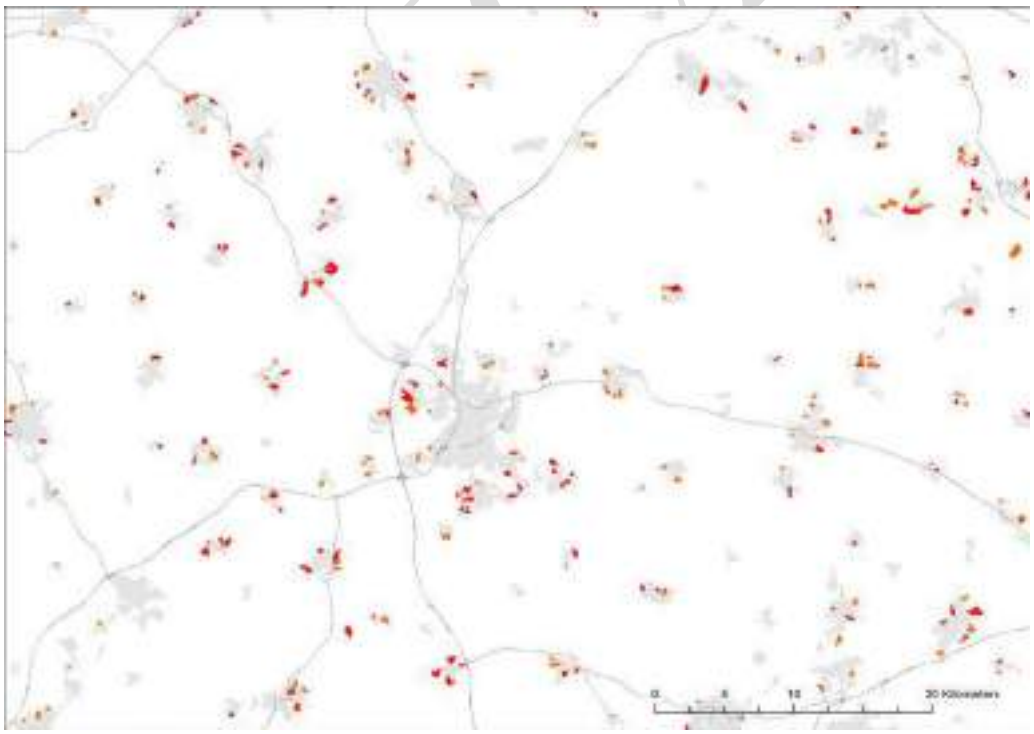

figure 3.3 urban extensions between 1990-2000 and 2000 and 2006 respectively, Munster region

At the scale of *the construction area*, one notices that the large new-development sites in the Netherlands are sub-divided into many neighbourhoods that all have their own theme and atmosphere. The Dutch urban extensions and its neighborhoods are part of a formal master plan in which a hierarchical traffic scheme, clustered facilities and 'geometric' street patterns are very easy to indicate. The small Flemish developments, usually around 10 to 20 dwellings along a dead end street, links to the existing infrastructure. The lay out of the developments in North Rhine Westphalia is more similar to the ones in the Netherlands but much smaller in size.

CONCEPT

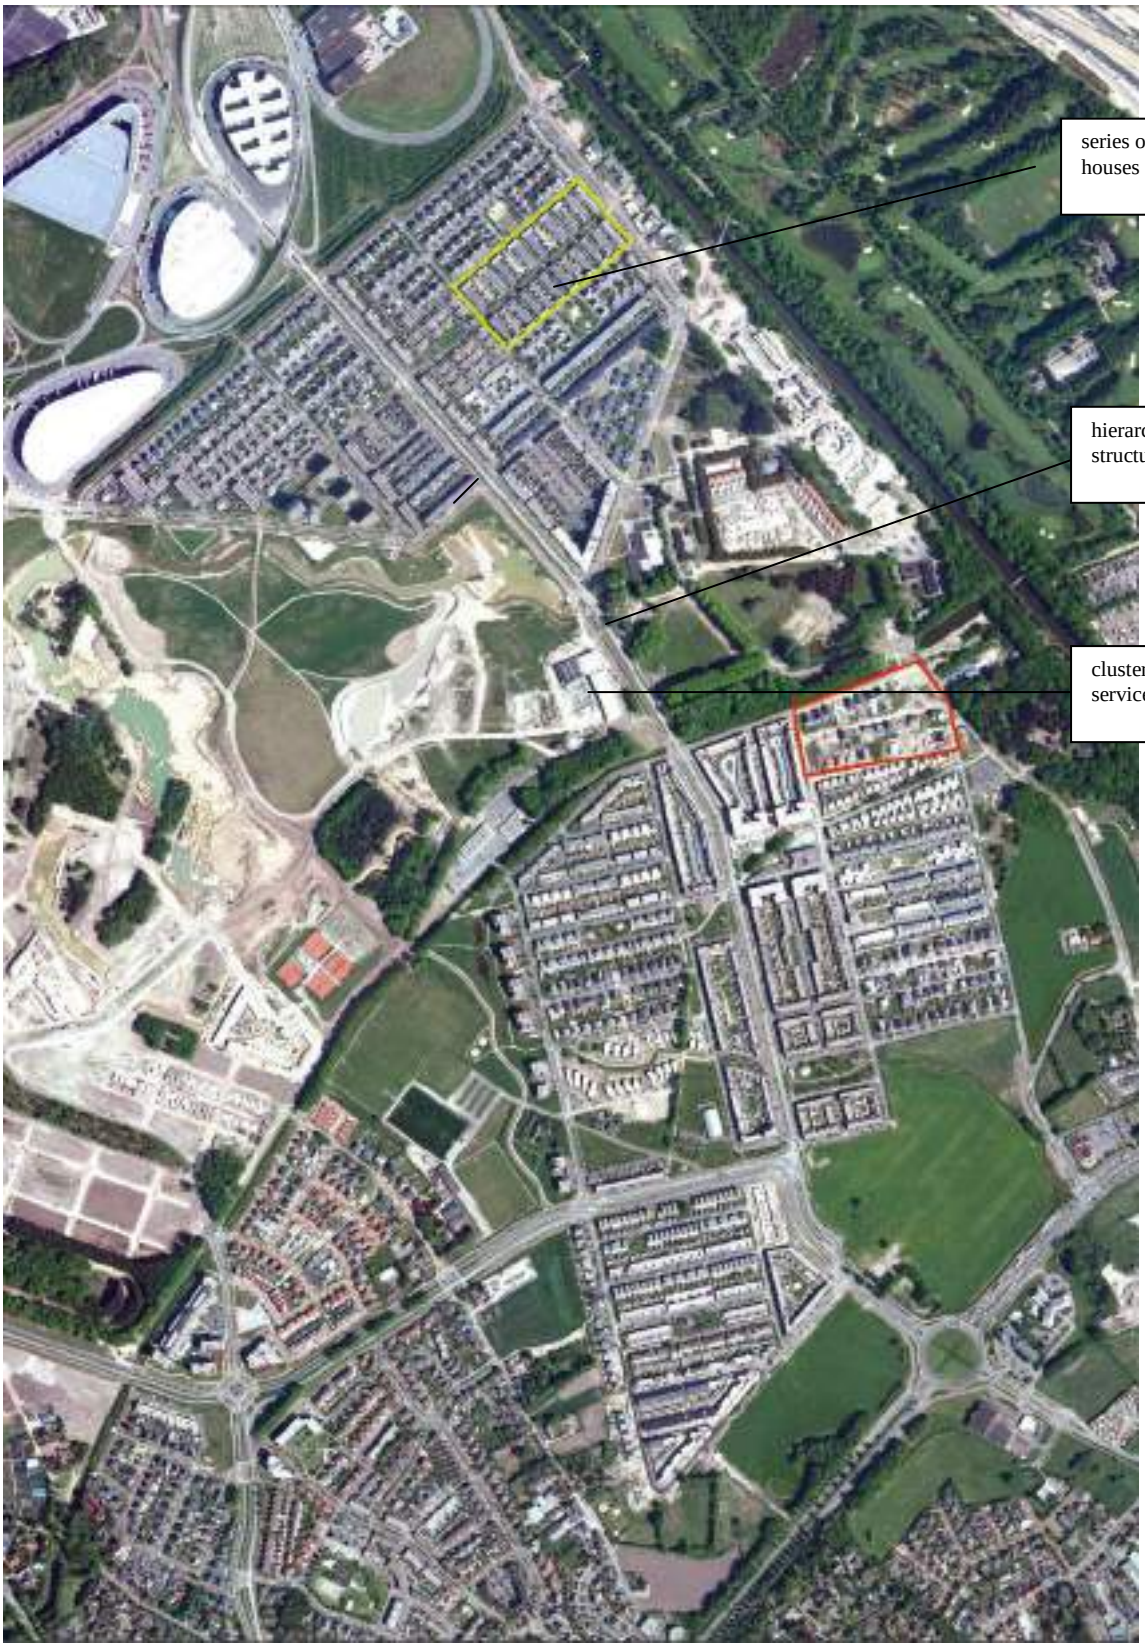

Figure 3.4 Typical morphology of city extension Eurosense BV 2008

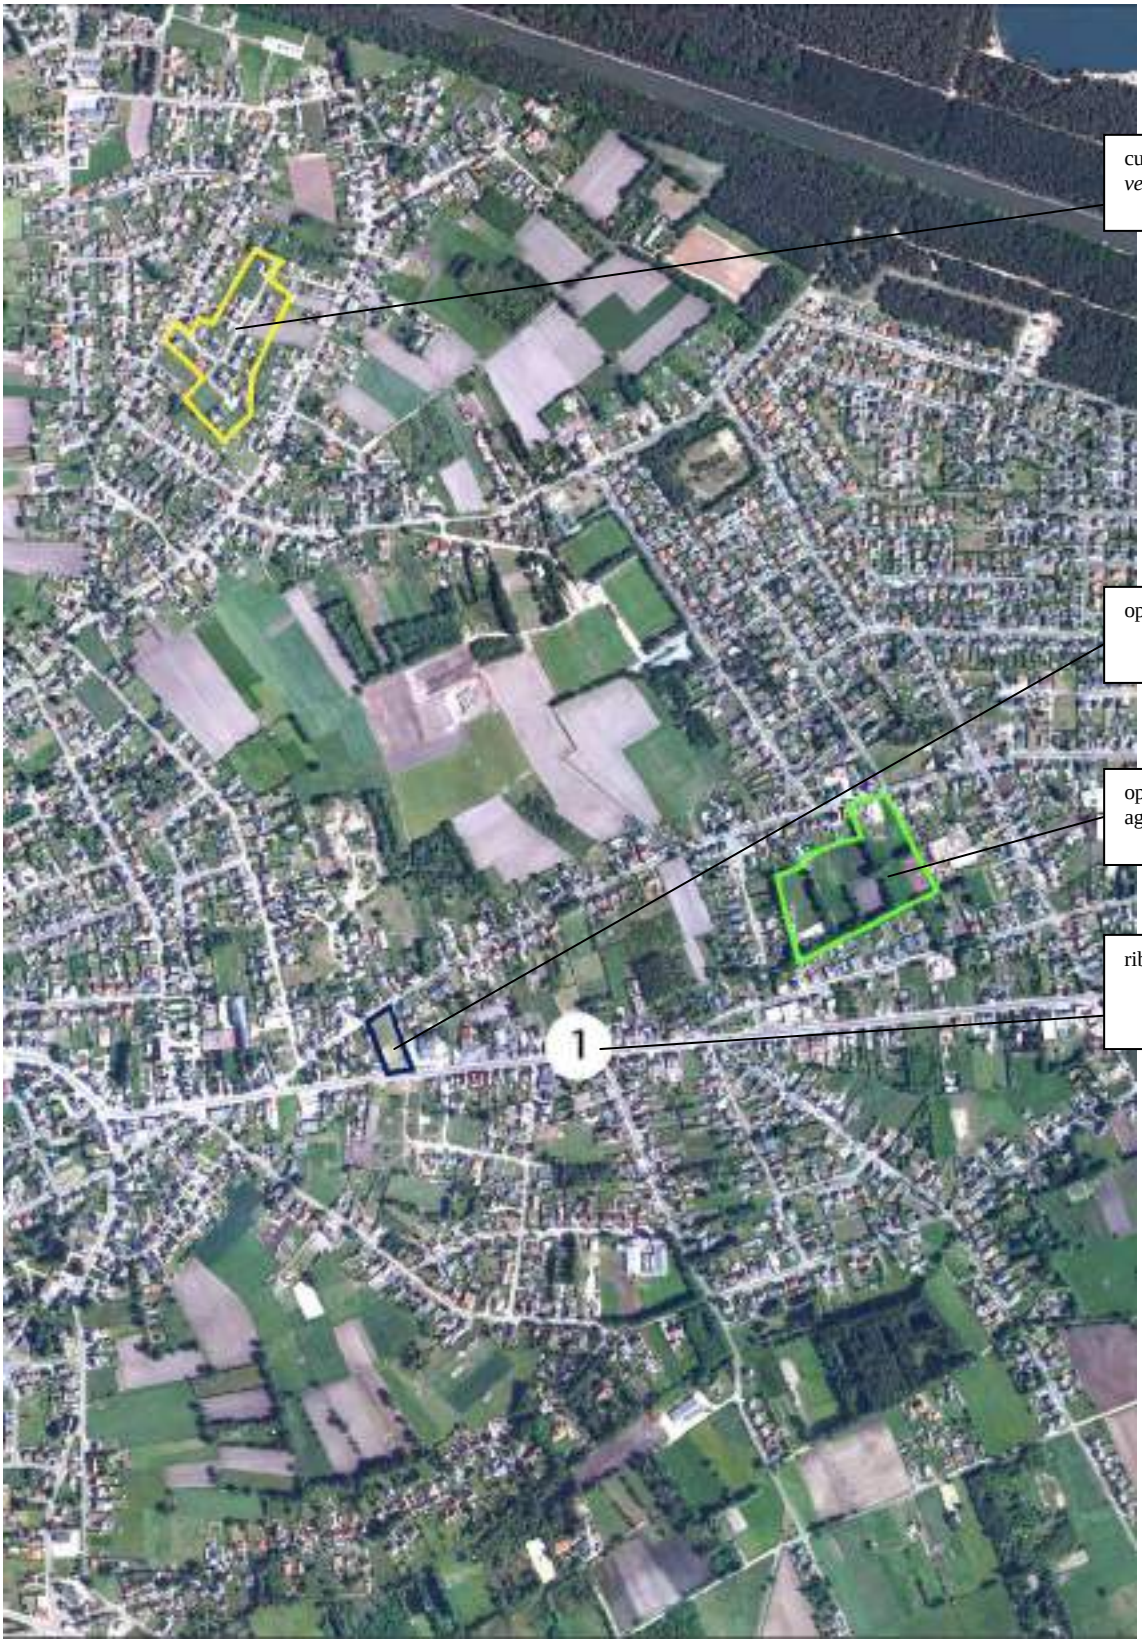

Figure 3.5 Typical Flemisch morphologyEurosense BV 2008

Figure 3.6 Typical German morphology of city extension Eurosense BV 2008

At *street level* we notice large differences in variation: The Dutch streets look very homogeneous; dwellings in one street, with usually terraced houses and some apartment buildings, are visibly constructed at one time, and have the same building style. Sometimes up to four parallel street are part of the same series. In North Rhine Westphalia we see not only see terraced houses in small series but also a majority of detached houses. Most of the houses in Flanders are privately developed detached housing, but during the last years there has been a tendency towards bigger series.

The result is a low visual variety at street level in the Netherlands. In Flanders and North Rhine Westphalia we see a higher variety at street level.

CONCEPT

4 **How institutions structure processes and morphology**

In this section, the influence of institutions on the typical morphological characteristics discussed in section 2 is illustrated by means of four aspects in which housing development differ between countries: 1. the interplay between municipality and land owners in the initial phases of development; 2. the nature of the involvement of the municipality: as an investor or a facilitator; 3. the organization of the process in time: open-ended or project-based; and 4. the involvement of small investors like private persons. The first two practices are of interest for the morphology (size, structure) at regional and construction site level, the third and fourth for variation at street level.

It is clear that none of these practices of housing development in themselves can explain the resulting morphology. Not only there are important non-institutional factors (section 2), but each practice in itself does not cover all the institutions relevant for the morphology, either. Only together they should give a more or less complete picture of the institutional differences that are the most relevant for the morphology.

4.1. regulating urbanization: the interaction between municipality and land owners

In the Netherlands, urban development is very much a product of planning by the local government. It is the municipality that takes the initiative by preparing a change in the zoning plan, designating new residential areas. In order to develop a site the municipality cooperates with a limited set of large participants: property development companies, housing associations and large investors (e.g. pension funds). In most of the post-war period, the municipalities were in control of this process almost alone. They bought the land from first owners like farmers, developed the land and provided the infrastructure, then sold it to cooperating partners. Since the 1990s, municipalities lost the position to decide alone in this process. Increasingly, project development companies and other investors anticipated on municipal changes in land zoning, acquired strategic land positions in order to ' buy themselves into' the process of housing development (Segeren 2007). Still, the zoning competency gives the municipality the monopoly in starting the initiative, changing the zoning plan is its trump card in the negotiations with the developing actors.

For the private sector these investments were interesting because they could count on some very strong constants in post-war government policy: the objective to guarantee a housing production that matched quantitative and qualitative demand - as predicted by scientific housing demand studies predictions (*woningbouwopgave*) -; and the core policy belief (Sabatier 1993) in integrative and comprehensive planning as the only way to channel the rapid urbanization process, already dating from the end of the 19th century but reinforced by high population growth after WWII. De Klerk (2008) dates this ambition for integrative urban development back to the early 1900s: Since then, the municipality wanted to "bring all aspects, sectors and parts of the city into coherence and a logical hierarchy of interests: the urban traffic system, regional transport system, public health, city building, housing, preservation and creation of townscapes, parks, public gardens and recreation for inhabitants, all

CONCEPT

grounded on a financially sound estimation of land development." (p. 270). In the post-war period this belief found its expression in two leading principles in housing policy, the already mentioned 'woningbouwopgave' and the so called 'neighborhood principle': a residential area should be set up as a new, social entity in itself: it is not enough to build new houses and to provide the necessary infrastructure, but the new residential areas should be planned so that they contain all the necessary amenities for the population in its diversity: old and young, richer and poorer, catholic, protestant and socialist (Van der Cammen & De Klerk 2004): schools, recreation, churches, public transport, retail, and recreation all should be present and adjusted to a hierarchical relationship to the town centre. Although in the nineties this 'neighborhood principle' was considered old fashioned in some of its idealistic 'society engineering aspects, the thrust of its ambition of integrality is still alive in related concepts like 'integrated area development' (*gebiedsontwikkeling*).

Both policy beliefs: the belief that government should guarantee the provision of enough housing, and integral planning, contributed to a preference of municipalities for concentrating housing development on sites of considerable size next to the city: only big developing sites could provide the basis for the necessary amenities, and on large development sites it is possible to design relatively independently from the existing fabric of the city a rational road structure and new amenity clusters. At these large sites, large project development companies have an advantage over small ones, in that they can most take advantage of the economies of scale in land development, house building and financing (De Klerk 2008), and reduce the risk for municipalities that its policy objectives are not being met.

The housing process in the neighboring Flanders differs drastically from this practice. There, the initiative to develop new houses on greenfield sites is taken not so much by the municipality as by the land owner. Since the creation of the regional spatial plans at the end of the 1970s, there has been an excess of land zoned for residential use (De Decker 2011, Loris 2011), although it may still be in agrarian or other use. Therefore, not the moment of decision by the municipality to change the zoning plan is the start of housing development[1], but the decision of individual land owner to develop the land himself or to sell it to an allotment company ('*verkavelaar'*), who develops only the land and sell the plots, or develops the houses as well like a project development company. The excess of land zoned for residential use has a long history. Unlike the policy in the Netherlands of channeling, concentrating and integrating urbanization, the Belgian urban development is historically directed to the goal of private ownership of single family dwellings on the countryside. Only in the 1960s, planning by zoning instruments began to develop in Flanders. In the absence of a binding regional plan, in the beginning municipalities used these instruments to maximize possibilities for urbanization within their borders. When finally at the end of the seventies the regional planning documents in Flanders were drawn up, the necessity to incorporate these areas was one of the

[1] Although this may happen, in for example the 'woonuitbreidingsgebieden', originally meant for affordable and social housing but often not used because of the small importance of the social sector in Flanders. Here, the government holds the 'key' to development by turning it into a normal residential area (*'woongebied'*) in the land zoning plan..

CONCEPT

reasons of the excess of residential zoned land. The recent Flemish policy objective from the Flemish Spatial Master plan (Ruimtelijk Structuurplan Vlaanderen) of 1998 to try to concentrate urbanization is therefore severely hampered by the reservoir of land that judicially is already zoned for housing. Therefore, although the allotment company who is able to buy a plot of unserviced land is obliged to apply for permission, his permit cannot be refused when he services and sets up the land according to municipal guide lines and conditions. The same goes for the private person that takes the decision to develop his own plot alongside existing roads.

This practice has led to the kind of morphology of urbanization, as showed in section 3, where urban development grows both along existing roads, and in the form of new small housing projects (*'verkavelingen')* that are being built in between, and connected to, existing roads. In comparison with the Dutch urbanization, it is a rather 'chaotic', patchwork- like pattern. New building sites pop up within this existing pattern or as an extension of it. Much more than in the Netherlands location and size of a house building site are determined by coincidence: An allotment company may be able to buy a piece of land, or a private owners may decide to leave it empty.

Designating house building sites in North Rhine-Westphalia resembles much more the Dutch than the Flemish way. Like in the Netherlands, the municipality's choice to change the land zoning plan is the key for starting the development process. Although municipalities have to take into account the higher regional plans, the bigger cities are rather free to designate residential building sites in their *Flächnennutzungsplan*, a more strategic plan which is used to channel urbanization, and *Bebauungsplan*, the document that is juridical binding for citizens and developers. Although these plans - like in the Netherlands - are the expression of the municipal urban development strategy, the building sites are more dispersed and of much smaller dimensions.

What is the reason for this? Of course, population growth in the last decennia has been much less in North Rhine-Westphalia than in the Netherlands, but the dispersed character of urban development does not necessarily make the total amount of houses built much smaller than in the Netherlands. [2]

A striking difference, however, is the philosophy of the adjustment of new housing projects to existing amenities. Whereas in the Netherlands new amenities and houses are planned together at one and the same time, we found in our case study in North Rhine-Westphalia what we call the practice of 'amenity-directed planning'. In planning a new housing site, the municipality tries to avoid that the new site overburdens existing public services like schools or kindergartens, which would make the opening of new services necessary. As these services, are not being financed by the value capturing of the land of the building site as is the case in the Netherlands (cf. section 4.3), in this practice there is often little incentive to increase the dimensions of the site. Without claiming that this is the single reason for the comparatively small dimensions of the housing sites, 'amenity-directed planning' fits

[2] For example, the municipality of Münster, one of the case studies in our research, in the last two decennia had a housing production that was comparable to that of Dutch cities.

CONCEPT

well within the practice of dispersing housing development instead of concentrating it.

When the land is zoned as residential area, the municipality can start a parcel readjustment procedures (*Umlegung*), in which the land is serviced and new parcels given back to the land owners (deducted the costs of the land servicing and recoup of the value increase due to servicing). In an alternative procedure, that of the vorhabenbezogener Bebauungsplan, it is the land owner that takes the initiative. After drawing up a contract with the municipality, he services the land according to conditions of the municipality, hands over the public grounds, and only after this the municipality makes the changes in the land zoning plan become definitive.

So, in this the initial phases of the housing development process, the land assembly and land servicing, the cooperation between land owners and the municipality is quite different in the Netherlands, Flanders and North Rhine-Westphalia.

Dutch municipalities tend to cooperate with a limited group of big project development companies, housing corporations and investors in order to realize an integrated municipal plan of relatively large dimensions. It is important to notice the two sides of this cooperation. On the one hand, Dutch municipalities often *cannot avoid* cooperating with these large companies and organizations. Their land ownership gives them development rights. As long as land owners are prepared to realize the plan as designated in the land zoning plan, municipality has to cooperate with them. There are different models of cooperation. In some the land owners sell their land to a low prize to the municipality, who services the land and sells it back to an agreed prize, and the private party develops the houses and sells them. In others, municipalities and private sector companies together establish a private company that develops both the land and the houses (PPP).

But not only municipalities cannot always avoid to cooperate with private sector companies, at the same time municipalities are often inclined to remove small land owners, like private persons, from the development process. In the most extreme case, Dutch municipalities informally ask project development companies to buy land in an area of future housing development. But also in less 'normatively questionable' practices, municipalities use their pre-emption right to buy out land owners, or eventually threaten to use compulsory purchase. As a consequence, in the development of the large housing sites, there is seldom an important part to play for private persons land owners as co-developer. These are actors, that cannot contribute to economies of scale. Moreover, they could frustrate the timely realization of the development (section 4.3) as well as obstruct the desired, so-called property-neutral development of the site.

Property-neutral development designates the process, in which realization of a well-designed, integral plan for a housing location is not hampered by existing property structures. It is a tabula rasa method: existing structures and landscape elements are removed, and a totally structure is being made. Although the urban designer has the freedom to hint at landscape elements present at the location before - a country road with old trees, an old building, the landing strip of a former regional airport - he is not forced to do so by the wishes of the land owners.

CONCEPT

By buying out the remaining small land owners, actors with possibly an emotional relationship to their particular property, who have no interest in economies of scale, are removed from the process. This turns an important switch in the process that determines size and structure of the site.

In contrast, in Flanders small land owners are the drivers of the urbanization process. Housing development in Flanders takes place through all the numerous initiatives of small to middle sized land owners who start to build themselves, or sell their land to (relatively small scale) allotment companies or project development companies. The important role of small land owners is understandable, as traditionally Flemish municipalities have much less integrative ambitions than their Dutch counterparts. Property-neutral development is not necessary.

The comparison with North Rhine-Westphalia is more interesting in this case, as municipalities do foster these ambitions. Nevertheless, German municipalities seem more indifferent to the size of the land owner, and treat both large and small land owners as possible housing developers. Institutional differences - the availability of policy instruments - between the Netherlands and Germany can shed some light on the reasons.

In North Rhine-Westphalia municipalities have at their disposal the instrument of land readjustment (*Umlegung*). At the same time, it is comparatively difficult - almost impossible - to expropriate land owners for housing purposes. So, municipalities can only force land owners into cooperation by also granting them some voice, that is, in the readjustment process where they might have their special wishes, and accepting them as potential developers.[3]

In the Netherlands, compulsory purchase of the land of private persons for housing development is juridical a realistic possibility, although it may have a very high prize. Dutch municipalities, however, do not have the option to force land owners into cooperation to development without paying them a lot of money, like the *Umlegung*. Therefore, when they want to realize their integral plan in a property-neutral way, they have to offer private land owners large sums of money- for which reason private person land owners often aim at expropriation by withdrawing their cooperation of the municipal plans.

In this way, the availability of land policy instruments is one of the factors that preserve the national differences in the municipal attitudes towards small land owners, and their participation in the housing development process.

4.2. active or facilitating land policy of municipalities

In the Netherlands, in most cases the municipality is itself one of the land owners, and it traditionally participates in the development process under private law (De Klerk 2008), by means of a municipal land development company, besides its public roles. Until the 1990s, municipalities often acquired themselves most of the land necessary for development from the first land owners. When this was not possible anymore, the new models of cooperation with professional developing land owners

[3] Especially in the 'voluntary' variant (*freiwillige Umlegung).*

CONCEPT

emerged that are described above. In these cooperation models, municipality still is (co-)owner of all the land at the moment of land servicing, and sells it afterward to developing parties. Municipalities used to set land prices according to the real costs, but from the beginning of the 1990s a covenant between Dutch government and the private sector determined that land values had to be calculated according to the residual method, which enabled municipalities to share in the value increases in a favorable house market. In Flanders as well as North Rhine-Westphalia, municipalities act less often as land owners on greenfield locations. Flemish municipalities normally acquire only small parcels for public amenities or to enable or unlock greater development. In North Rhine-Westphalia it used to be common for municipalities to buy land for urban development in general, but nowadays, there is relatively little land acquisition, and mostly for social or affordable housing.

The Dutch municipal practice of actively acquiring land in order to make housing development possible, has its effects on the morphology of the site in that it strengthens the role of the municipality as one of the developing actors, instead of its role as regulator of the market. The municipality becomes one of the interested parties for economies of scale and timely realization of the site (section 4.3).

This practice is rooted in a double motivation for municipalities. First, land ownership gives control over planning content and process. Parceling out en servicing the land is one of the best way to guarantee the integrated character and overall quality of the site. Moreover, land ownership used to be the best way to guarantee an ambitious percentage of social housing of 30%. And the freedom to set the prizes made it possible to recoup costs of land development, as well as to stimulate social housing. All these reasons of 'planning content' were repaired only in 2008 by a new land policy law (grondexploitatiewet), that made them possible without active land policy. As we shall see (section 4.3) in Flanders and North Rhine-Westphalia municipalities have other solutions for these problems.

Moreover, ownership of the land also gives control over the process: it means the freedom to choose private sector companies that participate in the development, although this was undermined by the increase of land positions of project development companies (Segeren 2007), and by jurisprudence of European Competition directive (Buitelaar 2011).

Second, next to reasons of control, there are reasons of financial gain. Municipal land ownership is a means for Dutch municipalities to share in the value increase of the land - both as a result of zoning changes and of servicing - that would otherwise accrue to private companies only. In Flanders and North Rhine-Westphalia, it is indeed the private sector that does (partly) profits from these value increase. For what reason Flemish and German municipalities do not aspire to the role of land ownership, as land prices in prosperous municipalities as our case studies Munster and Gent have been rising and municipalities have the possibility to get their share?

An important factor explaining these differences is to be found in the differences between the systems municipal financing in the three countries. As showed in figure 4.1,

CONCEPT

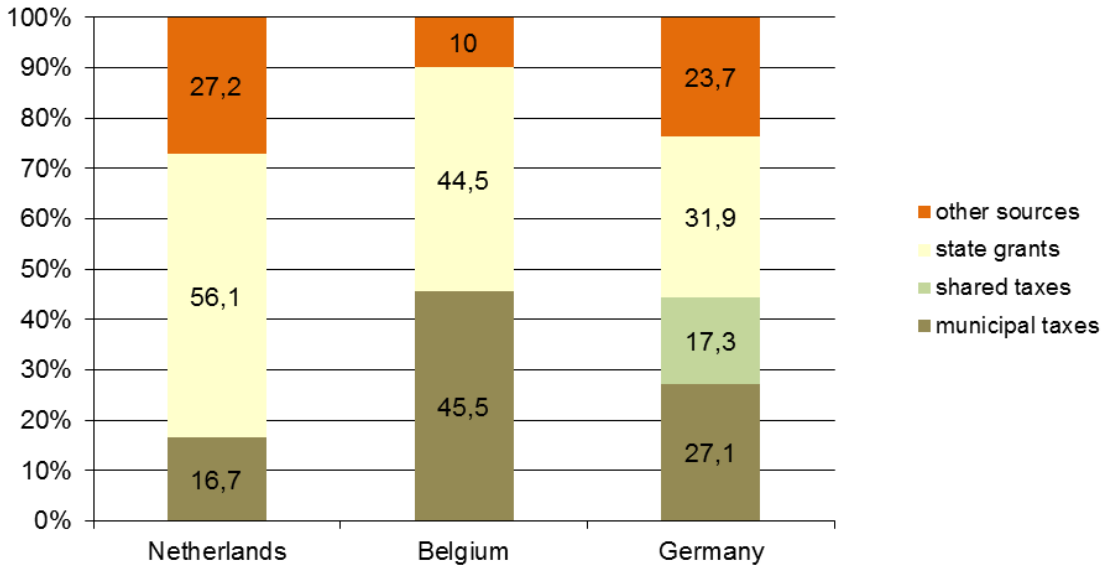

figure 4.1: income of municipalities in the Netherlands, Belgium and Germany (loans not included) in 2006. Hoorens 2008.

a relatively small share of Dutch municipal income derives from municipal taxes. Belgian and German municipalities dispose of more own taxes, the rate of which they can set themselves (within limits). A smaller proportion of their income derives from state grants.

The dependency on state grants decreases the leeway for Dutch municipalities to set its own policy priorities. Although not all state grants are earmarked, their size is fairly precisely calculated on the basis of the normal, necessary and statutory municipal expenses (e.g. social security grants). Local lobby groups monitor whether municipal expenses are according to the grants.

Besides, municipal income from the most important municipal tax on real estate property (OZB) is being leveled in the state grants: a higher capacity for municipalities to extract revenues from this tax means a lower state grant. This leaves municipalities little financial freedom for 'extra', non-statutory projects and ambitions. Therefore, Dutch municipalities have tried to find extra funds by participating in land development, in order to take advantage of favorable real estate market conditions. Although average profits for all municipalities were not very high, and although it is not a secure income source, each individual municipality could decide to try to imitate its most successful neighbors, and take the risk. Indeed, in average municipalities managed to increase their revenues from land development (Korthals Altes 2008) until the financial crises.

Municipal income from land ownership is negligible in Flanders and North Rhine-Westphalia.[4] Interestingly enough, in Flanders and North Rhine-Westphalia housing development is seen as a method to increase municipal income as well (cf. ILS 2006 for North Rhine-Westphalia). But there, extra revenues are a consequence of an increase in the amount of (high income) citizens[5], and, in North Rhine-Westphalia, an increase in the area of (serviced) land. The important difference with the Dutch system is, therefore, that municipalities in Flanders and North Rhine-Westphalia do not have to acquire land themselves and to bear financial risk in participating in the development in order to increase their revenues.

4.3. project approach vs. open-end process

In the last two sections, we have discussed some institutions that shape the conditions what type of actor participates in housing development. Who has access and who does not? In this section, we focus on differences with regard to the time span of the development process.

Comparing the Netherlands with Flanders and North Rhine-Westphalia, it is striking that the Dutch development process of greenfield locations is organized as a *project*: not only are all different functional parts adjusted to one another by integrative design (section 4.1), they are being realized within a limited *time period* as well. The development process has a time horizon, within which the 'project' of building a new residential area will be finished.[6]

In contrast, many of the greenfield housing development sites in Flanders and North Rhine-Westphalia are being developed in a process with an *open end*. In de 'verkavelingen' in Flanders parcels may remain unbuilt for decades. Owners consider them as an investment for later, or reserve them for their children. These plots also may never be built on, for example when the owners keeps it as a permanent extension of his garden. In North Rhine-Westphalia, too, it may last a very long time before all houses are realized. In Münster, the municipality kept a list of all sites where free parcels were available, some of which dated as far back as the early 1990s! These differences in organization lead to a difference in the variation (at street level) of the sites. In the Netherlands, all houses are being built in the same time period. Therefore, apart from variation or homogeneity *by design*, all buildings underlie the trend with regard to architecture and dwelling type that was fashionable in the time of building. Moreover, in Dutch residential areas, one does not find empty parcels, nor parcels that are included to the garden of their neighbor: all parcels of a block or street have the same size.

Differences in the institutional environment set some important conditions for this different organization of the housing development process. Two aspects of the

[4] Percentage in Flanders unknown, but municipal land ownership on greenfield locations is practically absent (source: interview). In NRW income from land ownership was only small part of the 1,5% 'selling of property' in 2008 (source: ILS).

[5] although at least in Germany there is a leveling mechanism with state grants like in the Netherlands. The Dutch system, however, is the most radical in this (Allers 2005).

[6] For this purpose, the development of a housing site is often managed by a separate project-organization, sometimes in joint-venture with project development companies. This reinforces the project-like character of the housing development, as the organizational mission of the project group is to finish the project in time.

CONCEPT

time span of realization have to be distinguished here. On the one hand, participating developing actors have an interest that the development is realized within a *short period.* As the land acquisition has to be pre-financed, every year that the land is not being built on, means loss on interests. The difference between the Netherlands and its neighbors is that Dutch municipalities participate in the process as private land owner and share the necessity to finish the project as quickly as possible with the private sector investors (section 4.2). Besides, municipalities as a public body are confronted with policy housing targets from the regional inter-administrative housing agreements (woningbouwafspraken). What is more, in the Vinex-period (1995-2005) central government subsidies for housing development were tied up to the time schedule of the subsidy scheme.

But the second aspect of the time span of realization is just as important. Housing development has a project-like organization not only because a quick realization is important, but more general because of the necessity of a more or less *simultaneous realization* of the houses. This has to do with financial settlement agreements between participating developing actors. These agreements serve a wide scope of different purposes: to spread evenly large pre-investments, to finance part of the unprofitable part of social housing, to share market risks in the housing sector, to finance a part of amenities, to compensate for unequal development possibilities in different parts of the site, all these are reasons for a comprehensive and often complicated contract between the participating actors (including the municipality) on the financial settlement of the project. These kind of agreements require a moment in time to make the clearance, to close the bill - for example at the moment when all participants have had their revenues. As the revenues on which the agreement was based only materialize at the moment of house sales, an open-end-process like in Flanders or North Rhine-Westphalia is no option in the Netherlands.[7]

In Flanders and North Rhine-Westphalia, these financial settlements agreements that financially link the realization of different parts of the site to one another are less frequent. In both countries, the size of the housing development is comparatively small, which diminishes the possibilities for settlement within the site itself: there would not be enough 'mass' to finance non-profitable elements. Therefore, some elements at the site like amenities that in the Netherlands would be co-financed by other, profitable elements, are being financed separately by other means, for example the municipal budget. They do not depend on the realization of other elements of the site. In both Flanders and North Rhine-Westphalia, however, some mechanisms that fulfill some the functions of the Dutch settlement practice do exist, but they put less pressure on in-time realization.

In Flanders, the allotment company or project development company has to acquire a permission in order to parcel out and service the land (*verkavelingsvergunning*). The permission contains a detailed description on the infrastructure, set-up of public space, type of buildings, use of materials etc. After the servicing has been done, the *verkavelaars* hand over the public grounds to the municipality for free. But the permission can also contain extra demands by the municipality, the expenses. In the 'larger' sites (more than ten houses) these expenses

[7] Besides: these kind of financial settlement are favourable for large sites, as this increases the possibilities for settlement, also with small margins.

CONCEPT

minimally require to realize some social parcels or social housing. Thus, although there is no financial settlement between different participating actors, nevertheless the allotment company/ project development company has to compensate internally the losses on one part with gains on the other.[8]

A similar case is the German procedure of the '*vorhabenbezogener Bebauungsplan*', a special form of changing the land zoning plan. In this procedure, it is not the municipality that provides the infrastructure and other amenities, as is normally the case, but the private developer himself. Like in Flanders, the private developer hands over all public grounds afterwards to the municipality for free.

Both in Flanders and in North Rhine-Westphalia, a quick successful sale of the houses may therefore be as important for the private project development companies as it is in the Netherlands. But different from the Netherlands, the municipality in these situations is not involved financially. From a financial point of view, it can allow itself to approach the housing development as an open end process.

In the 'normal' procedure of public infrastructure provision in North Rhine-Westphalia, however, the municipality is financially involved in the development project, in that it builds and pre-finances the public infrastructure. With the procedure of the *Erschliessungskostenbeitrag*, a municipality can recoup 90% of these costs. The difference with the Dutch case is here, that the *Erschliessungskostenbeitrag* is paid by the land owners irrespective whether they have already developed the real estate. Whereas in the comparable procedure in the Netherlands (*grondexploitatieplan*) the municipality can recover costs only at the moment when the land owners have realized their real estate revenues.

In short, in all three countries a long time period in which housing or other real estate is not yet realized, constitutes a financial a financial risk. But in Flanders and North Rhine-Westphalia, this risk is borne by the private sector, not by the municipality.

4.4. the involvement of small investors

In the Dutch practice of large scale housing development, not only there is little room for participation of private person land owners (section 4.1), but also at later stages in the process small investors normally do not play an active, independent role. In Flanders and North Rhine-Westphalia, functioning markets for ready-for-building parcels exists for private persons or small building companies. By contrast, in the urban areas in the Netherlands these markets have been lacking. Only very recently, more 'experiments' with 'do it yourself building' are starting up in urban areas, partly as an answer to the decreasing building production due to the economic crises since 2008.

[8] Although the losses may be lower than in the Netherlands, for the reason that all the infrastructure and other public services for social houses are constructed and paid for separately by the regional (gewestelijk) government.

CONCEPT

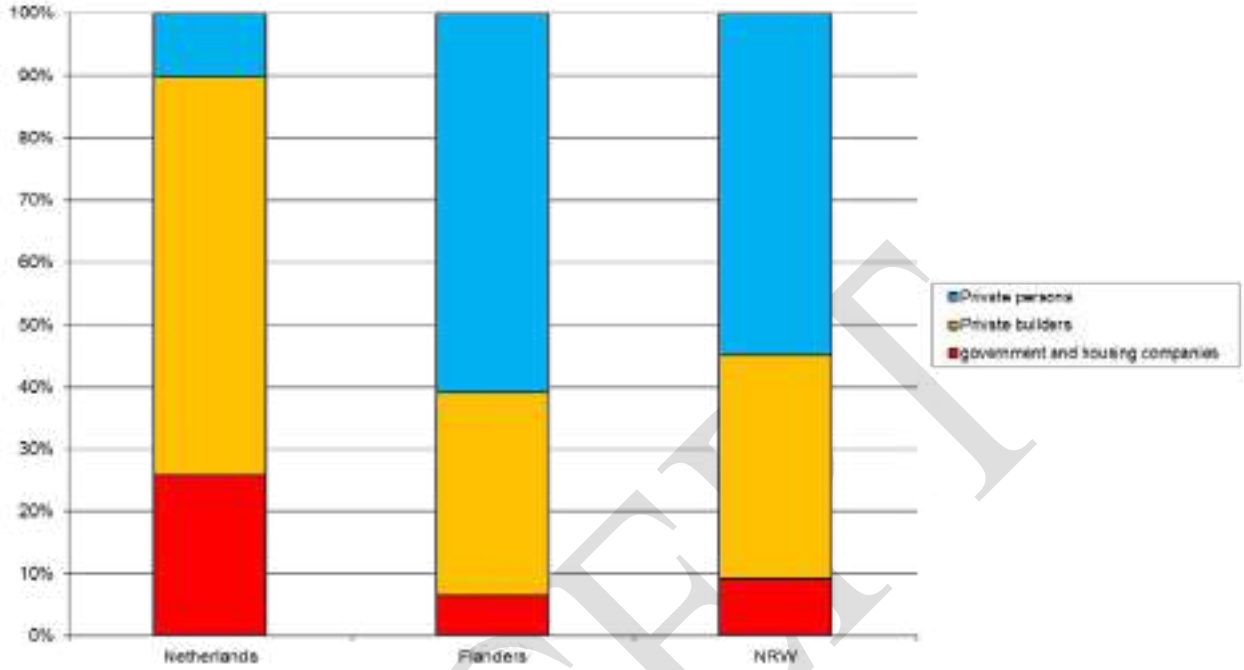

Figure 4.2 Housebuilding commissioning actors
Sources: CBS, De Decker et al (2010) and North Rhine-Westphalia Bank,
Compilation: PBL

The common practice in the Netherlands is to build houses in series (85% of dwellings is part of a series of more than 10 dwellings, 50% of more than 50 dwellings). Not surprisingly, building in series decreases variation in architecture and dwelling (sub)type

The majority of dwellings at Dutch greenfield locations are apartments and row houses. But also single family detached homes / two family semi-detached homes are being built in series. In Flanders and North Rhine-Westphalia, the dominant housing type on greenfield sites is the single/two family detached/semi-detached home, or (in North Rhine-Westphalia and recently Flanders) in comparatively very small series.

Of course, land prices play an important factor here. Land prices in Dutch urban areas on average are much higher than in the neighboring countries. The residual value of land has increased as house prices increased sharply, which came to an end only with the financial crisis of 2008. These increases are attributed both to regional housing shortage, according to some an effect of institutional factors like the spatial planning restrictions (Besseling e.a. 2008), or sudden changes in the structure of housing provision (Jokovi 2006), as well as to increased income and improving loan possibilities (Van Oort e.a. 2008) for consumers. Developing and building companies that can economize on production costs, can present higher bids on the land market. Building houses in large series, enables building companies to

CONCEPT

economize on costs of material, construction, and supervision. Building dwelling types of higher density like row houses and apartments means higher returns per square meter. Figure 4.3 is a good illustration of this development: in the Netherlands, financial room for buying land increased because of increasing house prices and relatively low increase in costs. The residual value of the parcel under an average dwelling in North Rhine-Westphalia is nowadays much lower than that of the parcel under a Dutch average dwelling.[9]

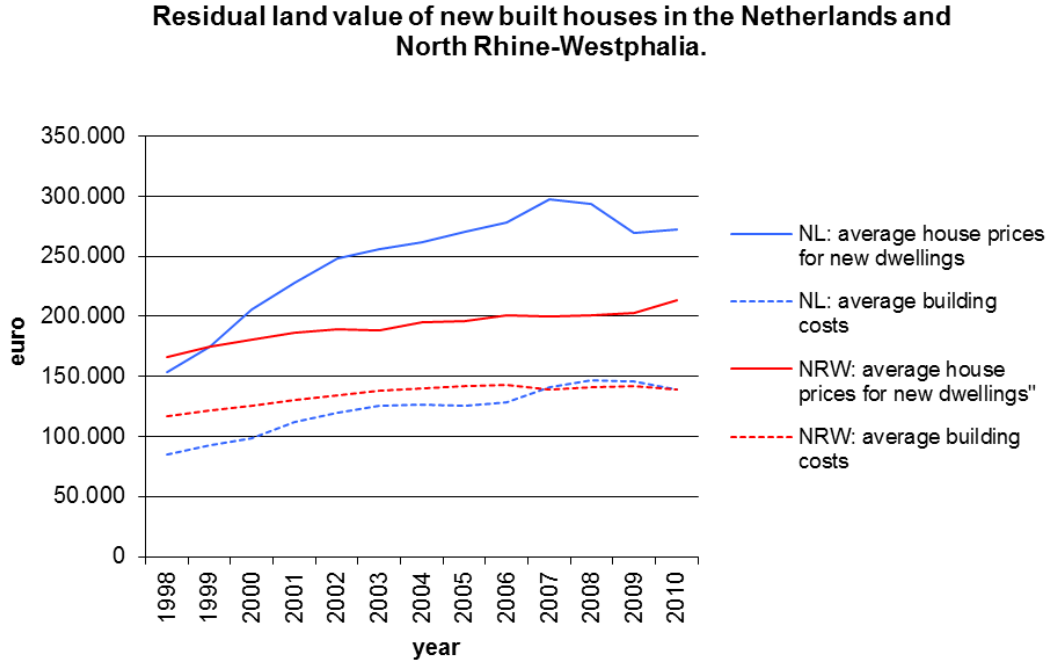

Fig 3.6 Residual land value of new built houses in the Netherlands and North Rhine-Westphalia.
Sources: CBS. OTB (Monitor Nieuwe Woningen), Obere Gutachterausschuss North Rhine-Westphalia

Although high land prices undoubtedly constitute a very important factor in the explanation of typology and variation of Dutch newly built residential areas compared to Flanders and North Rhine-Westphalia, it is questionable whether it constitutes the *only* factor. Why individually commissioned housing is normal in areas in North Rhine-Westphalia where land prices are comparable to that in the Netherlands? Let us take a look at two institutional factors, that structure the supply and the demand side in the market for newly built houses.

At the supply side, we have seen more and more project development companies and housing corporations (Buitelaar e.a. 2008) taking land positions in order to buy themselves into the housing development process (section 4.1). As their motive is to take advantage of high prices on the housing market, they will normally not sell the parcel (after the servicing of the land) to a third party, but build on it

[9] Unfortunately, it was not possible to retrieve comparable data for the Flemish case. But land *prices* in Flanders recently reached comparable values as in NRW.

themselves.[10] As municipalities have a tradition of cooperating with large, professional organizations, as described in section 4.1, they have little interest to guarantee access of private persons to the market for serviced land.

But institutional factors also structured the demand side of this market. Although some 30% of Dutch respondents of housing surveys say that they would like to build their own house (against the 10% that actually do), it is not clear how high the demand is in reality, as there is hardly any opportunity for it in urban areas. Contrary to North Rhine-Westphalia the wish to have a say over the construction of the own dwelling apparently for some is so overriding, that in situations of high land prices, they choose to commission row houses, or collectively build an apartment block.

Dol et al (2010) make use of ideal types to describe the national differences in housing markets. Following Martens (1990), they characterize the Netherlands as a *dynamic* housing market, whereas Belgium and Germany belong to the *static* housing markets. These ideal types refer to a particular collective images about housing (culture), as well as to an institutional and market structure that has developed around it.

In these two market types, people have different expectations of a house (Toussaint et al 2007). In a static market like in Flanders or North Rhine-Westphalia, ownership of a house is once-in-a-lifetime. The decision to buy or build an own dwelling is only taken when you are settled, and other factors in life like career and relationship are relatively stable. Therefore, one takes the decision to buy or build a house at an relatively late phase in life, before that time, renting is the normal option. Once you bought a house, ideally one will live there for (almost) the rest of one's life and the house is *adapted to one's changing needs*: maybe in the beginning one wants to let part of the house in order to save costs, and take all the house for oneself when the children are older. When income is higher, maybe one wants to extend the house. And maybe one wants to adapt the interior to one's needs when one is old. Moreover, much more than in dynamic markets , home ownership is seen as part of the pension, as one live there 'for free', or even let (part of it) for extra income.

In dynamic markets like the Dutch one, peoples have other expectations of home ownership. At different stages in life, you do not so much adapt the house, but sell it and buy another (bigger) one. Home ownership starts relatively young, and with different conditions (career, relationships, family) it is normal to move to another home that fits more your needs. It is not a 'course-of-life-house', but a 'resale-house'. The house is seen as an financial investment, but less as a secure 'pension in stone' but more as something that increases in value in an favorable market.

These leads to a different demand on the market, with morphological consequences, too. First, in static housing markets, houses need to be more *adaptable*. A detached house on a relatively large plot is more adaptable than row houses and apartments. Numerous alterations of the houses yield a more varied street view. Second: as home ownership comes close to a 'life destination', it is more important to have the house built according to one's own personal ideas, ideally

[10] Segeren (2007) describes this as one of the reasons for institutional investors not to wait for the supply of serviced land, but to buy unserviced land themselves.

CONCEPT

tailor-made. Whereas in a dynamic housing market, the overriding concern is that market value should be preserved, the house should not be so eclectic or personalized that the ability to sale is being affected.

The different expectations of home ownership are supported by differences in institutions between the two types of housing markets. In the dynamic Dutch market, institutions that support individually commissioned housing are lacking. For example, in Flanders and North Rhine-Westphalia, architects are much more adjusted to advise and coach private persons in the construction process (Dol e.a. 2011). In Belgium, architects are liable for flaws in the construction. In Germany, municipalities have set up departments to help private person in the process of individually commissioned housing in the social or affordable sector.

Institutions that structure the financing possibilities for home owners, too, differ according to housing system. In the German static housing market, mortgage banks apply a much lower loan/value ratio than used to be the case in the Netherlands (80% to 115% in 2007). In other words, Germans have to save a lot of money before being able to buy or build, and institutions like *'Bausparen'* prepare for this. In the Dutch situation, mortgage conditions were eased during the 1990s/2000s, which supported the resale of houses.

But private persons wanting to build a dwelling for themselves are not the only type of small investors that is more or less absent in the Dutch housing development in urban areas. First, in Flanders and North Rhine-Westphalia there are more small builders active on the urban market, that is far more favorable for them than in the Netherlands. Building normally for private persons, small builders in Flanders or North Rhine-Westphalia may sometimes invest in developing a couple of house themselves. Second, in the Netherlands, there are practically no private persons that invest in house building with the motive to let - in part or as a whole. The private renting market is relatively small in the Netherlands (figure 4.4). Private landlords are present in older neighborhoods, but do not often invest in new houses at greenfield locations. By contrast, the private renting market in Germany is rather large and building for private renting is made fiscally advantageous. In total it is even more promoted than home building for owner-occupiers (Braun& Pfeiffer 2004,

CONCEPT

cited in Haffner e.a. 2009).

CONCEPT

5. **Conclusion**

Although morphology of recently developed residential areas on greenfield sites depend in many ways on local and contingent factors, the overall institutional environment determines morphology to such an extent, that it is easy to see the difference between a Dutch, Flemish or German area. Institutions structure the process of housing development, not as to determine form, but as to make some morphology as outcome of the development process more likely than others. In this way, the institutional analysis in this paper supplement other explanations, and gives a more complete account of morphological differences than mono-causal explanations like taste, the rate of population growth, or market circumstances alone. It is also supplementary to research that focuses on the influence of institutions on actor interaction, and leave the analysis of physical outcome to the field of urban design.

In this paper, we have identified some key mechanisms through which housing processes influence form that can be traced back to differences in institutional environment. The first type of mechanism is the *in- and exclusion* of actors from the housing development process. Without saying that this is a conscious process, institutions make it possible to in- and exclude actors with a certain type of interest - for example interest in economies of scale, or a timely completion of the site. The second type of mechanism is the *time span* of the building process. For example, the practice of settlement agreements between participating developing actors reinforces the necessity to complete a housing developed site within a short time period, as opposed to a more open ended and haphazard development.

Institutions give some parties the possibility to influence these mechanisms than others. For example, in large areas in Flanders municipalities do not have the possibilities to exclude private initiatives for housing development anymore because the zoning plan already designates the land for housing. In North Rhine-Westphalia, the rules for compulsory purchase constrain municipalities to exclude private person land owners from the housing process, and at the same the rules for *Umlegung* enables them to approach private persons as co-developing participants.

These institutions are originally man-made for a particular purpose, but when they become the rules-in-use, they subsequently structure the purposeful interaction and become taken-for-granted *practice*. This ' structuration theory' of Giddens (1984.) according to which action and structure are mutually constitutive, has been illustrated in this paper with four practices in housing development in different countries. In these practices, processes reinforce themselves. For example, institutions favor large building sites, so that private persons and small building companies do not have much chance on the Dutch urban housing development markets. Big building companies take over the market at the expense of small ones, private persons cease to know how to commission housing, it becomes hardly an option any more in the Netherlands and the demand for it decreases.

This example brings us to a third and final mechanism through which institutions influence morphology. Not only do institutions structure in- and exclusion, time

CONCEPT

span, and differentiate the possibilities for actors to influence this, but institutions also influence *preferences* of participating actors, what they consider as their stake in housing development. For example: the income-structure of Dutch municipalities make it more pressing to participate privately in land development to share in the value increase of the land (apart from the public interest stakes they might have in active land policy). Or Dutch private persons do not consider it their interest to enter the housing development process in order to commission the building of a rented dwelling, in contrast with Germany where fiscal policy subsidizes this.

Including these 'demand'-factors in an institutional analysis brings it close to cultural or discourse theories, that take 'housing cultures' and ' administrative cultures' into account (Toussaint 2007). Further research, studying more precisely the interplay of cultural and discursive factors with structural factors like institutions would yield a more complete account of the mechanisms that form our urban environments.

CONCEPT

THEORIES OF TEMPORARY USE, CREATIVITY, AND PLANNING

Quentin Stevens [1]

Abstract

This paper examines various definitions and applications of the concept of 'creativity' within recent theoretical, empirical and planning policy studies of 'temporary uses' of derelict urban spaces in European cities, in order to articulate how these understandings of creativity and temporary suggest a transformation of the aims and methods of planning itself. Temporary land uses have always been tolerated by urban planning, but it is only very recently that they have come to be seen as important to cities' economic vitality and future growth. Creativity has, similarly, always been a defining characteristic of urban economies, but the conscious objective of urban planning to attract, stimulate and support particular creative actors is relatively new. Through analysis of field studies, policies, and academic critiques, the paper articulates three distinct contexts where concepts of 'creativity' contribute to planners' theories about temporary use and the redevelopment of abandoned and underutilised sites: creative production, consumption of creativity, and creative governance. These three contexts are argued to be mutually reinforcing. Actors from the 'creative industries' are drawn to the low rents, distinctive architecture and dynamic atmosphere of derelict buildings; they also contribute to the material and symbolic transformation of these spaces. Existing temporary uses attract and nurture additional creative workers, and are felt to add to the general quality of neighbourhood life. Planning is proactive in nurturing temporary creative uses; but these uses also require and inspire new planning tools and approaches. This paper's distinctive focus on examining various actors who are creative, what particular interests and abilities they bring, and how they engage with each other in the urban development process, sets it apart from many academic critiques of 'artist-led' gentrification of former industrial areas, which emphasise the social and economic impacts of artists' activities on future investors and existing residents, reducing creativity to 'symbolic capital'. The paper closes with an examination of how the concepts of creative production, consumption, and governance mesh together with broadly neoliberal approaches to urban governance, highlighting that creative planning for temporary use means not just reducing the regulation of urban activity and built form, but also more dynamic planning, through continual engagement with a wider range of actors. In this context, the focus of planning shifts away from permanent built outcomes and toward social activity. Planning itself begins to increasingly resemble a temporary creative use.

[1] University College London, UK / RMIT University, Melbourne, Australia - q.stevens@ucl.ac.uk

1. Introduction

This paper examines various definitions and applications of the concept of 'creativity' within recent theoretical, empirical and planning policy studies of 'temporary uses' of derelict urban spaces, in order to articulate how these understandings of creativity and temporary use are changing the idea and methods of planning itself.

Temporary land uses have always existed in cities, ranging from circuses and squatting to warehousing and surface car parks. Such uses were tolerated, but they were seldom believed to be central to the vitality and future of urban districts. They were epiphenomena that were never seen as part of the plan. Two European studies (Bürgin and Cabane, 1999; Urban Catalyst, 2001) initiated a new area of planning thinking and research by examining the potential importance of temporary uses or *Zwischennutzung* - economically-marginal activities that temporarily occupy abandoned urban spaces - for developing economic and social activity, jobs, and new investment in cities. These studies appear to have introduced at least four new points of focus to planning thinking about temporary use. Temporary re-use is now seen to be an important economic and planning strategy for the redevelopment of former industrialised areas, one which takes place before, alongside, or instead of large-scale, long-term masterplans, and which contributes to the long-term development outcomes. Actors from the 'creative industries' are now generally understood as playing an important role in undertaking these temporary reuses and transformations. Thirdly, and conversely, such temporary occupations of sites are acknowledged by city administrations as being important opportunities for attracting and nurturing creative industries. Fourthly, planning policy, which generally focuses on long-term visions and permanent rules, has thus begun looking at ways to support and promote particular short-term uses.

2. Analysis

This paper draws upon the discourse of temporary use as it has developed through public policies, empirical research, and academic literature in Europe and to a lesser degree in North America. The paper outlines three distinct but interrelated contexts where concepts of 'creativity' contribute to planners' theories about temporary use and the redevelopment of abandoned and underutilised sites, namely: production, consumption, and governance. The paper then closes with an examination of how these concepts mesh together with broadly neoliberal approaches to urban development and urban governance.

2.1 Creative Production

Creative production is in itself seen as an increasingly-important component of urban economies. In relation to the planning and management of urban built fabric, the creative industries are also seen to have a more specific role, as an economically

productive way to use vacant, derelict urban spaces temporarily. This has elements of both convenience and strategy. Compared to other branches of industry, creative enterprises are typically small, low-capital, and flexible about the spaces they occupy. Few other branches of industry are willing and able to start operating at short notice or relocate in a piecemeal fashion, and can rapidly adapt their work practices to a wide variety and quality of existing sites, structures and infrastructures when they become available, without major capital investment (Becker, 2010). Today's creative actors are portrayed as largely 'footloose` or 'nomadic'; their production activities are not often fixed to physical and representational attributes of particular sites (MA18, 2003; Urban Unlimited, 2004; Dienel and Schophaus, 2005). However, the theory of temporary use tends to prioritise the development of new creative activities, rather than existing creative activities that might relocate from another site, but which may not engage creatively with the new host site. Temporary use is portrayed, for example, as "an attractive 'first step' for numerous start-up ventures in the creative economy" (SenStadt, 2007, p.101). A major study of temporary uses in Switzerland highlights that the percentage of creative workers engaged in temporary businesses in Zurich's former rail yards was four times the national average, and almost half the companies on the site had been founded there (Angst et al, 2009).

Strategically, it is believed that creative actors such as artists and architects are particularly well suited to utilizing disinvested, vacant spaces temporarily. They are able to perceive distinctive aesthetic, historic, and functional characteristics within derelict sites, as well as activate these potentials (BMVBS/BBR, 2008). They are 'pioneers', 'truffle pigs' who unearth valuable, latent opportunities for the benefit of other investors who follow them (SenStadt 2007; Lange, 2007, p.136). Creative producers have "a feel for unconventional and creative solutions", including experimental uses of sites (BAFU, 2010, p.8). A summation provided by Kloos et al (2007) is that existing planning policy literature on temporary uses embraces both this pragmatic view of the creative industries' capacities to make use of brownfields, as well as a more idealistic view of creative activities as having a positive influence on the wider development of local economy and urban form. More than just providing rent returns on devalorised properties, as would temporary warehousing activities or carparking, creative workers add significant symbolic and social capital to these disinvested sites, thereby accelerating their recuperation into the wider property market (Becker, 2010; Smith, 1996; Zukin, 1982). In exchange for low rents, many creative workers invest a lot of their labour and expertise in modifying these spaces and bringing the public's attention to them (Bishop and Williams, 2012). Because artistic projects often pursue goals beyond the purely economic, they will also often be driven forward even in the absence of profits (Becker, 2010). BAFU (2010, p.107) strike a rare note of caution, pointing out that 'impetuous' creativity in temporary use can be disadvantageous for later users, if it brings adverse changes, damage or excessive wear to the building stock. Creative users may be wilful and unrealistic, making it difficult for landlords to manage properties and transfer them to new long-term tenants. Urban Catalyst (2001, 86) notes that creative

workers at the end of their temporary tenancy of Berlin's *Haus des Lehrers* were "stubborn, explosive and radical", and fought against relocation.

Inspiration in the creative use of vacant properties runs both ways. Original, creative activity is believed to be stimulated by vacated urban sites: their location, architecture, and former uses; the mixtures of new actors that are accommodated within the given configuration such sites; the dense communication networks and collaborations that often arise among these actors; and the new and temporary nature of site occupation. These conditions inspire new artists as well as established ones (Bürgin and Cabane, 1999; Angst et al, 2009; BAFU, 2010). The large scale, openness, and specialized infrastructure of many former industrial sites, which can present impediments to their recuperation for other long-term uses, is often attractive for the production and display of creative works, whether plastic arts, performance, media, or architecture (BAFU, 2010; Bishop and Williams, 2012). Jacobs (1961) argued that the lower rents of older, disinvested buildings enable creative, risky experimental tenancies, but it is not the low rents in themselves that encourage creativity; low rents can also attract and support marginal businesses that are not creative.

2.2 Consumption of Creativity

A second component of creativity is the innovative consumption opportunities that new, temporary uses of urban spaces can offer to residents and visitors. Different economic uses for derelict urban spaces are not necessarily in themselves novel activities or directly useful and interesting to the wider public; an architecture studio in a former factory is still a private architecture studio. Whereas creative production emphasizes the tenants' practices, the emphasis here is on innovations in the products of creativity, and in particular consumers' experiences in and of the temporarily transformed urban spaces themselves.

Creative temporary uses are valued because they enhance the general cultural diversity and vitality of urban areas, by adding to the range of open space, social, cultural and commercial amenities (BAFU, 2010), and enabling new combinations of such activities, as well as providing them in new and interesting locations where existing urban form, property values, government regulations and private management policies had previously precluded them. These uses also compensate for deficiencies in publicly-funded delivery of social and cultural amenities (Urban Catalyst, 2001). Temporary uses of urban sites can be more experimental than permanent projects that require larger budgets and face larger risks. They can cater to smaller and more specialized audiences. Unconventional and controversial uses are more likely to be tolerated if they are only occupying marginal spaces that were previously out of use, and only of relatively short duration (Bishop and Williams, 2012; Havemann and Schild, 2007).

Temporary uses of industrial brownfields and other derelict land often centre on the physical redevelopment of those spaces for public access and use. Many

temporary uses are publicly-accessible sculpture or landscaping projects which have no intrinsic commercial function, although they may serve as attractions that stimulate spontaneous spending or long-term investment in their surroundings. This includes the provision of new kinds of informal, accessible spaces where the public can act, perform and interact: temporary places for relaxation, participative sports and games, commemoration, and protest (Bishop and Williams, 2012; Franck and Stevens, 2007; Haydn and Temel, 2006). Among 43 pioneering temporary uses showcased in a government-sponsored study of Berlin (SenStadt, 2007), a majority were novel open spaces for public use: community gardens (9), accessible open spaces for people and animals (8); sports areas (7); and artificial beaches (6). Such spaces and activities are, in contrast to creative industries, inherently unproductive, and therefore of relatively little interest to the mainstream economy. Their transcendence of the means-end rationality which governs long-term land use planning underscores their inherent worth and meaningfulness to culture. Temporary gardening is one oft-documented creative form of user engagement with urban brownfields which is nominally productive (SenStadt, 2007; Becker, 2010), but this productivity falls well short of what urban property market prices would demand.

Creative public use of formerly-vacant sites often engages with and enriches the particularity of space and local identity. For example, intensive, varied temporary uses of Berlin's *Palast der Republik* prior to its demolition sought to critique and experiment with the history and future of the building and of the East German society that produced it, to encourage a broad political, cultural and practical re-evaluation of its legacy (Urban Catalyst, 2007; Colomb, 2007). Creative temporary uses are thus argued to be 'identity-giving' (*identitätsstiftend*) (Krauzick, 2007).

In all these respects, the creativity of temporary uses is primarily seen in terms of its benefits to social development, rather than property development. Temporarily unused spaces provide physical and temporal windows of opportunity for public appropriation of real estate for alternative cultural needs that are not met by the open market. These temporary uses might not in themselves be profitable. Indeed, the aim is that the city and its citizens reap the advantages of private capital investments in the provision of services that enhance general quality of life.

Some innovative temporary consumption spaces do indirectly serve aims for economic and property development. Berlin's government has increasingly used entertainment- and leisure-oriented temporary uses as a form of city marketing, presenting such projects as "new playgrounds for artists, creatives, young travellers and tourists, thus shifting the focus (away) from the iconic sites of inner city redevelopment such as Potsdamer Platz" (Colomb, 2012a, p.243). Such offerings attract creative workers who seek a high degree of quality, variety and novelty in urban leisure offerings (Jorg, 2008). A report commissioned from Munich's city department of employment and business puts this clearly:

> Quality of life and a climate of openness and diversity are key criteria for the attractiveness of a location for highly skilled and creative workers… varied lifestyles create an inspiring and stimulating environment for creative working people… Arts and Culture are of particular importance for the quality of life of creative knowledge workers. Because the highly skilled especially demand art and culture in their spare time, a comprehensive cultural offering in the city presents highly creative people with a source of inspiration for their own creative production… Whether high culture in opera, theater and museums or the cultural scene in bars, in temporarily used army barracks, old factory buildings and brownfield sites, or temporary events in the summer such as Corso Leopold, the Streetlife Festival, and the "beach" on the Cornelius Bridge of the Isar River - these are all appealing pastimes for creative knowledge workers. In addition, they help highly creative people with ideas for new products and services that are economically viable and that set new trends. (RAW München, 2007, p.22, author's translation).

Similarly in Berlin, pioneering temporary use projects "personify unusual but attractive urban lifestyles and hence cater to a demand that traditional urban structures fail to meet… The broad range of temporary use projects in Berlin has become a PR and economic factor for the city… a catalyst for the relocation of international companies (and) an attraction for tourists" (SenStadt, 2007, p.41).

Where the theorisations of creative productivity outlined in the first section of this paper emphasise tangible material benefits, through increased economic activity and reinvestment in the built environment, creative consumption activities on disinvested urban sites are believed to enrich the general quality of urban life, in both the short and long term. The example of sport and leisure activities shows that citizens can have a participatory role in such re-activations of spaces.

2.3 Creative approaches to urban development

A third distinct aspect of creativity in the theorization of temporary use of brownfield sites links directly to urban planning practice. It is argued that governments, planners, property owners and temporary users all need to be more creative - i.e. innovative - in the rules, processes and investments they use to shape current activity on urban sites and future property development. This conforms to the broader historical case argued by Hall (1998), that in addition to cultural, intellectual, and artistic creativity, cities also thrive and develop through the technical and organisational creativity of city managers, particularly in terms of their engagements with local entrepreneurs (Jorg, 2008). In the context of temporary uses, urban planning is not merely a supportive conduit for creativity, but its target:

> Here a fundamental distinction must be made… The first thing that can be observed is the creativity and innovation within temporary uses. This

> means that within temporary uses, innovative things may arise. Secondly, temporary uses can contribute to innovative urban planning. This occurs particularly through the experimental nature that temporary uses often exhibit, which through the resultant urban development can demonstrate alternative solutions for various problems (Waldis, 2009, p.48, author's translation).

This latter conception of creativity as innovative planning centres on an expanded decision-making role for the users (i.e. tenants) of urban spaces, vis-à-vis their owners and regulators. Temporary users of sites are celebrated in theory as 'pioneers' who lead and demand the attenuation or renegotiation of official planning strategies and controls and lease terms, and the opening up of both urban spaces and planning processes to a diversity of visions and inputs (SenStadt, 2007; Groth and Corijn, 2005). Some analysts go so far as to portray creativity as a general characteristic of temporary uses (Dransfeld and Lehmann, 2008). With temporary uses, creative agents are able to demonstrate "not only the possibility but the necessity to overrule conventions, guidelines and red tape and conquer the murky terrain of legal and social obligations" (Kreuzer, 2001, p.19). Rules and relationships are negotiated across a broad scope of conditions including lease duration, uses, rent levels, guarantees, insurances, and utility costs. The public sector and site owners provide many kinds of direct and indirect financial and professional advice to attract and enable new users. New kinds of leases and permits are developed to suit tenant needs and capabilities (SenStadt, 2007). The need for creativity inevitably rests with whichever actor is taking the initiative to encourage temporary use in a given location, according to three different scenarios: user seeks property owner, user seeks property owner, or urban developer seeks property owner and user (BMVBS/BBR, 2008).

Creativity on the part of property owners involves flexibility and innovation in how they seek to meet their short- and long-term financial goals. This means "engaging in 'creative' (sic) reactivation of brownfields and underused sites beyond the typical economic recovery patterns of property" (Kloos et al, 2007,p.6), and creativity in finding appropriate sets of tenants for large sites and buildings (BAFU, 2010). "Creative rental concepts" may include short-term or even provisional leases, low rents supplemented by business profit-sharing, and cost-only rents to entice key attractors from art and culture to a location to enhance the marketability of other properties (Rosic and Froessler, 2009). Such innovations require that landlords become more exposed to short-term market risks. The flexibility, creativity and spontaneity of actors from the creative industries often clash with the expectations and existing approaches of property owners and managers. Such mental barriers require openness to dialogue (BAFU, 2010). On the positive side, temporary creative uses allow landlords to test out and demonstrate the feasibility of new uses, which also helps market sites to potential long-term users (Becker, 2010). Creativity is also applied to the place marketing process itself: temporary uses of derelict areas provide new techniques

and new imagery to attract new groups of consumers and producers (Colomb, 2012a).

These various kinds of creativity in land marketing, planning and management processes may or may not involve tenants from the creative industries. One analysis, of the redevelopment of a former slaughterhouse for "research-oriented, innovative companies, creative business and cultural institutions" (Schwarting and Overmeyer, 2008, p.62, author's translation), uses the German term *kreatives Gewerbe* ('creative business') rather than the usual term *Kreativewirtschaft* ('creative economy'), and notes that less financially successful artists can no longer afford the rents at this site. A major German government guide to temporary uses is careful to differentiate between the roles of 'creative industries' and innovative 'entrepreneurs', and uses the expression 'artistic-creative temporary uses' to clarify one case where both aspects are brought into play (BMVBS/BBR, 2008, p.92). These two aspects overlap most clearly in the environmental design disciplines (architecture, landscape architecture, urban design, interior design), where the core creative competency is the redevelopment of built form. These businesses are often heavily represented in the temporary use profiles of brownfield sites (Bürgin and Cabane, 1999). These actors are often forming small, new firms to pursue new kinds of projects, clients and funding. They can readily imagine, enhance, and capitalise on both the productive usefulness of individual properties, for their own business, and on the wider spatial and symbolic potential of the surrounding brownfield area and the redevelopment processes going on within it, when selling their services to other temporary and long-term users (Lange, 2008).

The dual aims of creatively utilising brownfield sites and facilitating the creative industries have also given rise to a new category of non-governmental, entrepreneurial mediating organizations whose role is as a conduit of information and negotiation between actors who need affordable space, the potentials of vacant buildings, and planning policies that regulate the development and use of those sites (Oswalt, 2002; Kruse and Steglich, 2006; Brammer, 2008; BMVBS/BBR, 2008; Angst et al, 2009). These organisations include 'Urban Residue', 'Golfstromen' and 'Urban Resort' in Amsterdam, 'SpareSpace' in Groningen, 'Precare' in Brussels (Jorg, 2008), 'k.e.i.m.' in Basle, and 'Coopolis' and 'Stattbau' in Berlin (SenStadt, 2007; Blumner, 2006).

For government planners, temporary uses of urban spaces by the creative industries can support the development of innovative planning strategies and policies in three distinct ways: as stimulus, delivery mechanism, or goal. As an inspiration or need for planning, temporary uses "can stimulate the creative process of urban design" (Bornmann et al, 2008, p.18, author's translation), by suggesting new combinations of uses and end-user groups, and demonstrating alternative physical development potentials. Temporary uses also inspire a rethinking of planning processes through a creative understanding of how development happens, particularly in terms of the engagement of a wide variety of

actors in decision-making and risk-sharing (Schwarting and Overmeyer, 2008). Because creative use projects on brownfield sites are often interdisciplinary, they require interdisciplinary action and policies from local governments (Becker, 2010). The complexity of creative temporary uses tends to necessitate the development of innovative forms of supervision, mediation or 'brokering' between and among government agencies, property owners and site users, and to inspire higher raised levels of citizen engagement in the planning and execution of projects (BMVBS/BBR, 2008; BBR, 2004).

In addition to seeing creative temporary uses as a conceptual inspiration, planning harnesses such uses as a practical tool to shape and test longer-term options for planning processes, regulations and physical development. Creative uses' typical attributes - small scale, low capital investment, flexibility and orientation toward rapid, visible outcomes – mean that they provide a relatively cheap, low-risk, constrained but extendable way of bringing innovations into urban planning. They present opportunities for cities to try out new policies and management approaches for urban development. Such 'laboratories' or 'test phases' develop the competence of various actors (including the government itself) and build trust between them (Becker, 2010; BAFU, 2010; Waldis, 2009). In addition to being 'truffle pigs' for later investors (Lange, 2007, p.136), artists are thus also guinea pigs for planners.

The two drivers of planning innovation outlined above can be applied in pursuit of many different planning goals, and the promotion of many kinds of land use, whether temporary or long-lasting. Although existing literature seldom identifies tools and policies that are focused on facilitating temporary creative industry tenancies specifically, suitable instruments appear to include giving creative users advice, financial support, and preferential access to sites, and providing detailed databases of available sites (SenStadt, 2007; Böhme et al, 2006). Oft-mentioned is the desirability of a user- and goal-oriented 'one-stop-shop' (Schwarting and Overmeyer, 2008) where potential temporary users - many of whom have little experience with the world of urban development and its regulation - can get advice and acquit the many necessary permissions; or less eloquently, a '*fachämterübergreifender Arbeitskreis'* (interdepartmental working group) to facilitate local government approvals for temporary projects (Schlegelmilch, 2009, p.498). As mentioned above, new non-governmental mediators have also sprung into existence to occupy this interface, often with a normative orientation toward encouraging fledgling uses.

Healey (2004) notes that creative approaches to governance and governance that fosters a creative society are not incompatible. Many analysts nevertheless doubt the capacity of formal, 'top-down' planning and its tools to be creative and proactively supportive of creative temporary uses. Groth and Corijn (2005, p.521) contrast the creative temporary uses of urban wastelands against the lack of imagination and creativity shown by long-range, large-scale planning which has allowed such wastelands to arise in the first place: "creative environments do not

spring into being as a result of top–down measures… they occur in the temporary lack of planning". Similarly, Larsen et al (2011, p.88) suggest "a possible alternative to the conscious design for creativity… sometimes creative practices emerge in the spaces that only wait for future development… sometimes the temporarily empty spaces make room for surprising innovations that otherwise would not emerge".

Bishop and Williams (2012) note that creative uses are difficult to create 'top down' because these uses are themselves intrinsically 'bottom up'; the most important prerequisites are cheap rents, flexible spaces, and freedom from constraints. In keeping with Jacobs' (1961) theorisation of the role of old buildings in ensuring city diversity, it is the absence of commercial attention to urban spaces that allows new, creative actors, who have different, risky ideas and who are not purely motivated by profit, to inhabit and operate in lively parts of the city, and thereby contribute to the processes of re-imagining, re-using and re-developing these areas. Becker (2010) suggests that the spontaneous, unplanned, short-term uniqueness of temporary creative uses is at odds with planning's general focus on fixed long-term visions. He argues that the emphasis needs to be on processual aspects: local governments showing openness to experiment; setting a clear basic framework of roles that creative actors can play, to provide clarity and certainty to their efforts; and 'creative support', rather than control, through new, flexible 'instruments of liberation and toleration' (Becker, 2010, p.81, author's translation).

Hall's (1998) emphasis on the importance of exchanges between cultural, intellectual, artistic and managerial creativity highlights that innovations in the practices of the various actors are connected: their interactions stimulate their creativity. This process is not necessarily smooth and cooperative. Angst et al suggest that in the case of Zurich's railyards, creative temporary use was inspired dialectically, through opposition to the interests of planners, government and the property industry: "the erstwhile forbidden nature of the former industrial zones and the illegal appropriation of many factories was part of the subculture that established itself (there) against speculation, discrimination and exploitation and in favour of alternative culture" (Angst et al. 2009, p.32, author's translation). The way that the temporary users engaged with regulation and order in this case also lent itself to creativity and difference in outcomes. Colomb (2012b) points to fundamental tensions between the increasing profitability and marketability of successful temporary leisure uses of urban sites, government policies that rigidly prescribe the desirable range of creative temporary uses, and the great wealth of informal, experimental, often unconventional practices, not all of which can achieve political or economic traction.

3. Analysis - Creativity unleashed: governing temporary uses

This closing section examines the implications of the contemporary emphasis on creativity in the production, consumption and planning of temporary uses, as

outlined above, for a general theorisation of the appropriate role and form of planning in shaping urban redevelopment and local economic activity. In broad terms, theory suggests the desirability of a liberalisation of both economic activity and strategic decision-making, by encouraging the participation of a wider range of small-scale private investors, producers, and consumers. More diverse inputs and less regulations imply the introduction of new ideas and approaches.

The emphasis within recent theorisations of temporary uses in European cities such as Berlin, on the key role of pioneering, artistic individuals who revitalise urban spaces and define new leisure lifestyles for highly-mobile urban residents, has ample parallels to earlier waves of gentrification that have been documented in post-industrial New York and London (Colomb, 2012a; Zukin, 1982; Hamnett, 2003; Pratt, 2009). Creative actors are portrayed within the context of a 'new frontier' that demands self-sufficiency, initiative, and independent action (Smith, 1996). Both artists and the unused spaces they discover and transform are seen as among "the few remaining pools of untapped resources" that define this particular frontier (Colomb, 2012a, p.244, citing Peck, 2005). Successful exploitation of such opportunities rests on governments allowing and encouraging mobile, creative minds to rush to these new goldfields of symbolic capital. Temporary artistic uses of urban space fit well to neoliberal demands:

> informal, spontaneous (temporary uses)… whose primary characteristic is the use of available urban, programmatic, economic open spaces… also have other features that make them perfectly compatible with the neo-liberal economy, from shifting risk to individuals to accelerating the use of space. (Pogoreutz, 2006, p.79)

> Persons engaged in the cultural sector and temporary users coincide with the current principle of short, fast utilisation cycles… the frameworks of both temporary use and subculture activities demand the same characteristics as contemporary entrepreneurial thinking: flexibility, cost-consciousness, environmental friendliness, efficiency, innovation, contemporary thinking, connectedness and liberality. (Erismann, 2011, p.23, citing Bürgin und Cabane, 1999)

Temporary artistic uses of derelict urban sites can indeed be seen as a rather practical case of post-fordist production: exploiting the niche of these amortized investments; accelerating their recommodification; optimising their economic potential by enhancing their variegation and cultivating new consumer groups; distributed networking of production; and minimal capital outlays on construction and infrastructure, focusing instead on 'mediatisation' of the product, which gives urban space the status of a service or an event (Ioannides and Debbage, 1997; Gale, 2009), or a web page or piece of software that users can "populate and repurpose" (Bishop and Williams, 2012, p.188; SenStadt, 2007). This re-production process is best achieved if there is a reduction of structural rigidities in the property and labour markets and in land use regulations (Haydn and Temel,

2006). Urban Catalyst (2001) note that in parallel to economic forces and technological development, two other significant causes of long-term vacancy on urban sites are the political and bureaucratic inertia of the planning system and mis-judgment of the demand for particular uses. Economic liberalisation thus lies at the core of the phenomenon of creative temporary uses. This liberalisation also brings about more rapid and widespread availability of sites for temporary occupation, by accelerating the amortization of existing investments in land (Oswalt, 2001; MA18, 2003). The dynamics and diversity of disinvested urban spaces stimulates artistic creativity, which in turn serves consumers' rapacious desire for novel products (Bishop and Williams, 2012, citing Jameson, 1999 and Klanten and Hübner, 2010).

The 'creative' (i.e. new) governance approaches that have been identified as appropriate for entrepreneurial temporary uses appear to cover a spectrum of levels of agency, from permissiveness through facilitation to direct participation. 'Creative' planning for temporary uses often appears to mean less planning, allowing more flexibility in land use, construction, and risk management. One proposed strategy is increased toleration (*Geduld*) of temporary projects, even when they have no formal planning permission. Such a stance implies that a creative re-use is recognised as being somehow beneficial, even when it falls outside the framework of the local government's and landlord's understandings of their own objectives and interests, or when it is technically illegal (SenStadt, 2007; Dransfeld and Lehmann, 2008). Such judgments depend on careful distinctions and calibrations between short-term and long-term benefits and negative impacts, and the availability of appropriate alternative mechanisms to measure and control these. Prevention of temporary uses that are undoubtedly undesirable is acknowledged as an important tool in ensuring that sites remain available for other potential temporary uses that might offer more benefits (SenStadt, 2007). The question arises as to if or how the potential benefits and impacts that a discovered temporary use has on its site and surroundings might be assessed, and by whom, if not through standard planning approvals. Although cases have been documented where tolerated uses later receive sanction, and even eventually permanent permission (BMVBS/BBR, 2008), a strategy of tolerance brings into question the relevance, predictability and consistency of the entire planning process.

The technical instruments available for governing temporary uses include specification of temporary uses for particular locations within local development, land-use and redevelopment plans, and permits for so called 'flying buildings' which, once approved, can be relocated repeatedly, with time restrictions on any given site. Several other tools are rather new and untested in the German context: uses that are permitted 'as of right' without need for inspections and permits, the granting of time-limited and conditional planning permissions, and the revocation of existing permissions when a building is demolished or a longstanding use ceases, as a way of opening up spaces for other short- or long-term use options (SenStadt, 2007). Many of these tools illustrate planning and its instruments

themselves becoming more temporary, focused on fine-tuning of current, localised performance outcomes instead of defining general long-term certainties. Such creative approaches are potentially complex, resource-intensive, disruptive and imperfect, but as Healey (2004, p.98) notes, "risky, experimental governance requires some redundancy (short-term inefficiencies) and learns from failure as well as success". As noted earlier in this paper, the justification for operational risks and potential failures is seen to lie in the capacity of the creative uses thereby facilitated to increase productive output, enhance local quality of life, and reform planning approaches themselves. As also already noted, the limited temporal and spatial scope of these experiments also confines their risks.

Facilitative and proactive roles for government include supporting, commissioning, financing, partnering, and marketing temporary uses. The creative potential of planning to facilitate temporary use includes "financial and creative enthusiasm for investment" (*monetärer und kreativer Investitionsfreudigkeit*) (Kruse and Steglich, 2006, p.17, author's translation). This suggests a characteristically neoliberal coupling of subsidies and deregulation. Planning's encouragement of the temporary use of urban spaces by creative actors fits the wider neoliberal shift from stable government-led urban service provision and regulation to flexible, facilitative governance, and increasing reliance upon entrepreneurial efforts and short-term, footloose private investments (Blumner, 2006; Groth and Corijn, 2005). In a time of reduced public spending, the vision of artists as "entrepreneurial self-starters" and "role models for a neo-liberal society" is not without its problems. These actors carry significant costs and risks; relatively few reap great rewards from success, and successful exploitation of an urban area forces out unsuccessful artists who cannot afford increasing rents (Lange, 2007, p.142).

The scope of roles and modes through which the public sector can shape a temporary use project so as to pursue public benefits and minimise negative impacts typically goes well beyond more-or-less antagonistic regulation. Governance of temporary uses is also enacted cooperatively by the public sector as one of many actors within complex networks. The public sector is often landlord, manager, funder, guarantor, and/or provider of goods, services, staff and expertise for temporary uses, and therefore contractual agreements provide significant scope for steering or hindering the development and operation of those activities in the public interest. Creative planning does not inevitably mean not planning. Dransfeld and Lehmann (2008, p.72) suggest that creative production should not go unregulated. To prevent temporary creative uses from unexpectedly becoming permanent and displacing envisaged long-term uses, they argue that governments and landlords should develop "creative shackles": contractual agreements between landlords, users and other stakeholders to consensually define targeted scopes and timeframes for temporary uses. Rather than just holding out carrots or sticks, planning can thus act creatively to govern temporary uses by wearing different hats, negotiating complex relationships and developing new frameworks.

4. Conclusion

In conclusion, the recent development of theory and practice related to temporary uses illustrates Healey's argument that governance is not incompatible with creativity:

> too much risk and uncertainty may inhibit creative responses ... This implies that governance processes which seek to encourage creativity and innovation … need to perform a delicate 'trick' of taking risks themselves in order to lessen the risks and uncertainties for others… Over-management… destroys more capacity than it builds (Healey, 2004, p.91).

Recent calls to support creativity through planning and creativity in planning tend to imply not just different land uses and ways of administering them, but more permissive approaches that tolerate more varied land-use activities and pursue a wider range of goals for a greater range of actors. These actors had presumably been excluded or undervalued by earlier planning practices, and both traits of creativity and temporariness point toward groups of actors (artists, ethnic minorities, young people) who have neither the political nor economic power to see their interests prevail in ordinary property markets and through standard urban development practices. The discourse of creativity also tends to suggest an emphasis on use rather than on built form, even when the practices in question often involve creative reinterpretation of the urban fabric. The focus of attention is clearly on the processes and benefits of urban development, rather than on pre-defined physical visions.

Calls for planning to introduce creative forms of control, or tighter guidance for the many kinds of new and untested land uses, are greatly exceeded by demands for more permissive planning tools that free up the unrealised potential of creative actors. It can be argued then that the emergence and spread of temporary use thinking in the German-speaking world reflects not only the decline of former urban industrial areas (which is less prevalent in Austria and Switzerland), but also as a response to the particular rigidities of German-style planning systems, with temporary uses, creative or otherwise, merely being a spur for this reaction.
The specific theorised connection between temporary use and creative industries would appear to be twofold: artistic people are good at adapting how they work to new spaces that lack tenants, and they are good at enhancing those spaces. But conceptually conjoining creative enterprise and temporary tenancy implies that creativity is economically precarious and expendable. If the ultimate goal for many creative workers is long-term employment, that should also be the goal of public policy. In this context, policy tools such as 'creative shackles' can be beneficial in clarifying for these ostensibly precious creative workers if and how particular temporary use arrangements benefit their own long-term visions.

The other side of the same coin is that even the most optimistic and selective data shows that the vast majority of urban work is not creative, in the narrow defined sense of artistic production. Innovation, on the other hand, is a desirable trait in most work practices, and attention to not-creative, but innovative, and even thoroughly commercial temporary uses of urban sites could probably reveal significant scope for enhancing land utilisation, economic productivity and benefits to end-consumers, which would suggest a very different range of objectives and potential planning tools for temporary use.

Territorial Impact Assessment of European Directives

Professor Thomas B Fischer PhD MIEMA and Tom Gore MA[1]

Abstract

This paper presents the results of a project financed by the European Observation Network, Territorial Development and Cohesion (ESPON) on the assessment of territorial impacts of European policies (i.e. directives and regulations) at regional and local levels of decision making in EU member states, which was conducted from November 2010 to May 2012.

The methodological approach of the project consisted of two main elements; (a) an analytical element, which revolved around document/ literature reviews, modelling exercises and applied work; as well as (b) an interactive learning element, for which learning networks in each, the UK, Portugal and Slovenia were established. Each learning network consisted of up to 15-20 members, representing public and private sector representatives involved in spatial / sectoral planning and assessment at different decision making tiers and from different geographical and administrative levels of a specific member state. The main purpose of the learning networks was to critically and pro-actively evaluate, comment on and influence the work produced through the project's analytical element.

The outcome of the project is a territorial impact assessment (TIA) methodology which has been tested by local and regional administrations in Portugal, Slovenia and the UK. The methodology is flexible in order to allow for application in different EU member states which have very different planning traditions and approaches. It is hoped that TIA will allow to establish a more reliable picture of the territorial impacts of European policy proposals.

Introduction

Since the 1990s interest in territorial impact assessment (TIA) has emerged and taken hold in the EU. Whilst early thinking at the European level framed TIA in relation to projects, more recently it has been framed as a policy assessment tool (Böhme 2004) and as a solution to the problem of the occurrence of unanticipated impacts arising from EU sectoral policies in EU member states. To date, these have been found difficult to detect in advance.

Whilst a single approach to TIA has yet to take form, the ESPON (European Observation Network, Territorial Development and Cohesion) Programme has conducted some significant work in this area. This paper presents the outputs of a recent project in this field, proposing a practically orientated TIA methodology, developed in conjunction with practitioners. This has been designed to be applied at the EU member state level to allow member states to anticipate policy impacts and thus to respond to emerging EU policies to minimise negative and maximise positive outcomes.

The paper begins by outlining the background to the project and the methodology adopted. It then proceeds to detail the TIA approach developed and concludes by highlighting some of the possible barriers to implementation and further research needs.

Background to the ESPON EATIA project

Conceived as a follow-up to the Action Programme of the first Territorial Agenda (2007), which encouraged further work orientated towards the introduction of TIA into the policy making process, and building on the subsequent conclusions of an EU seminar on the territorial impact of EU policies held in Amsterdam in 2009, the ESPON EATIA project sought to develop an approach to TIA which differed in two main respects from much of the previous work in the area. Firstly, the concern was to develop an approach that could be embedded at the EU member state level, differing from other ESPON work which to date has focused largely on a top-down EU level of application often searching for possible complementarities with the European Commission's impact assessment (IA) procedure. Secondly, at the heart of the approach was a concern for operational considerations. The approach was to be sufficiently simple so as to be easily comprehensible to end users - policy makers - not to have onerous resource requirements, and also, where possible, able to be latched onto pre-existing member state arrangements and procedures rather than necessitate the formulation of entirely new specialist bodies or processes. Given the variety of member state structures and administrative procedures, this latter aspect meant that the approach, by necessity, also had to be suitably flexible to be applicable in a range of governance contexts.

TIA was interpreted in the project as a supportive tool in the policy making cycle. It was seen as a means of identifying and evaluating the spatially differentiated impacts of EU policies to promote policy coherence between EU, national and sub-national policies. These impacts include those on spatial usage, governance or on wider environmental, social, economic, dimensions of a territory. The TIA approach considered in the project was to be embedded at the member state level and involve the interaction of national, regional and local stakeholders in the process. For member states this would mean that they may better understand and respond appropriately to EU initiatives by drawing on the insight of regional and local actors, whilst at the same time giving regional and local stakeholders a channel through which they could feed into the EU and national (i.e. transposition) policy-making processes. From an EU perspective, potentially, it would mean the development of policies that may be more sensitive to the spatial dimension and responsive to the territorial diversity of the EU territory, overcoming some of the significant challenges (e.g. data) of accounting for the territorially heterogeneous nature of impacts in a top-down manner, e.g. through IA.

Methodology

In light of the project's ambition, central to the adopted methodological approach was a partnership with the public authorities responsible for spatial planning in three diverse member states, the UK, Portugal and Slovenia. These authorities constituted the project's stakeholders and the three countries were to function as case studies to facilitate the development of a flexible TIA approach that would have wider applicability.

Within each of the stakeholder countries, national networks of spatial planning and policy making practitioners were established in conjunction with the national stakeholders. These groups were entitled 'learning networks' and were each made up of between 15 and 20 national practitioners from various administrative levels. The idea behind these networks was to provide a point of contact between the research team and the potential end users of the approach which was seen as being vital

in developing an approach that had practical considerations at its heart. These groups were consulted throughout the lifetime of the project and provided feedback and suggestions on various aspects of the methodology as it developed. This included three parallel workshop sessions held in each of the stakeholder countries near the beginning, mid-point and end of the project, as well as dedicated testing workshops in which selected practitioners were invited to apply and evaluate various draft versions of the proposed approach. These groups were highly influential in the design of the proposed approach which should be seen as the product of this interactive process.

A proposal for a TIA approach

In this section the approach to TIA developed under the ESPON EATIA project is presented. Following more established impact assessment traditions the approach has been structured around four sequential stages, namely, screening, scoping, assessment/analysis and evaluation. For each of these stages (1) supporting techniques and (2) governance arrangements have been developed to support the implementation of the approach at the member state level.

Appropriate *techniques* were identified working closely with practitioners in the learning networks. Whilst these had to be theoretically sound, they also needed to be pragmatic. In particular, the project's stakeholders required methods that would not have extensive data requirements, could be applied in a relatively short time frame, and were readily comprehensible. This was considered to be important in ensuring that the approach wouldn't overburden member state agencies engaged in the process, which would be detrimental to the acceptance of the methodology, and would still produce information of value to policy makers. Three main techniques are central to the approach and warrant mention here: *checklists, matrices* and *causal/logical chains*[2].

- *Checklists* are often useful in the early stages of impact assessment to ensure that key impacts of an activity are not overlooked (Glasson et al 1999; Therivel & Morris 2009; Lohani et al 1997). In the proposed TIA approach, checklists are structured around assessment criteria representing predefined important dimensions of a territory and serve to promote an early consideration of potential policy impacts.

- *Impact matrices* are a firmly established and widely recognised impact assessment tool (Glasson et al 1999). Depending on their formulation they are generally used to facilitate the identification of the effect of an action, or its sub-components, on criteria or objectives (Therivel & Wood 2005). In the TIA methodology matrices are employed to structure the assessment stage of the process.

- *Causal / logical chains* are another established impact assessment tool and have been employed previously in the context of TIA (ESPON ARTS). This method utilises expert judgement to identify the outcomes of an action by deciphering the cause-effect pathways of the intervention diagrammatically (Therivel & Wood 2005). It also has an additional role of

[2] Whilst these three techniques form the basis of the methodology, in line with the philosophy of the approach, there use still remains flexible. It is possible for these techniques to be replaced or adapted to reflect the traditions of the host member state, or to account for experiences over time, whilst still adhering to the underlying principles of the methodology.

outlining any underlying assumptions, thus promoting transparency. This approach is used optionally throughout the methodology to facilitate the impact identification process.

The *governance* dimension concerns the practical operationalisation of the approach within the administrative context of a specific member state. That is, the roles and responsibilities of specific agencies. As part of the project, specific governance arrangements were considered for implementing the approach in the UK, Slovenia and Portugal. Whilst these specific arrangements will not be detailed in this paper, general principles will be outlined that have been informed by our experiences of accommodating the approach in these governance contexts.

The following sub-sections provide a descriptive overview of the TIA framework developed, structured around the four stages of the TIA process:

1. Screening
