The analysis showed that all projects had to deal with quite similar difficulties although the level of complexity varied. Finding new uses for the cultural heritage, high initially needed financial investments and ground pollution that puts pressure on the optional financial benefits, are indicated as main difficulties. In most projects, the initiative for the heritage redevelopment is taken by the municipality. Although in all projects other key stakeholders are also involved in planning, only in two projects their participation is considered 'high'. Planning for the heritage redevelopment is mainly done by the land and real estate owner. Depending on their specific tasks and responsibilities other key stakeholders invest and bear risks. However, in none of the cases,

stakeholders outside the project scope who benefit from the re-use of cultural heritage (for example, residents of neighborhoods) contribute to the costs.

Interaction characteristics
In two projects the public and private parties formalized their cooperation in a joint venture. Five projects have a traditional form of cooperation, in which the municipality owns the land, prepares the site for building and sells it to another party. In three projects the cooperation can be typified as concession, as private parties own the land, plan and realize the development.

In most cases the interviewees indicate that financing heritage preservation is conflict topic between stakeholders. They experience difficulties in coming to an agreement on costs and benefits, as it is hard to negotiate the amount of investments, who captures the benefits, and what the added value is. A second topic of conflict appears to be related to the lack of inflexibility in plans. During the planning stage– which often takes more than 10 years - political and economic circumstances changed. For example, former expectations on sales and prices did not match the changed reality and already made plans and closed agreements were disputed. One interviewee indicates: "*the plans are translated to the current situation, but slightly different than previously meant. That gives discussion.*" Third, the ambitions in plans are often described vaguely. When actors need to specify these ambitions, they do this differently. Perceptions on the suitable new uses for the cultural heritage, housing density or public spaces conflicted in some cases. Related is the indicated difficulty to handle ambiguous preconditions or starting points. For example, in one project the cultural-historical valuable building were only listed after a private developer bought the area with the intention to demolish the old buildings and build new houses.

How actors deal with the various conflict topics in interaction varies in each project. In half of the projects, the interaction can be indicated as integrative, in the other projects as distributive. An example of integrative interaction is given by an interviewee: "*Most decisions and ideas are not written down, but all actors keep their promise and are committed. […] They are willing to change their perceptions and slightly change the plan if needed. They come up with new ideas: I saw this somewhere else; maybe it could work here too? It's not laughed at, but elaborated on, and others will offer their help*." In a project with mainly distributive interaction, an interviewee describes: "*Some people search for new opportunities, but many hold on to their own ideas and perceptions. Especially in the discussion towards finding new uses for the heritage*." In most projects there were both distributive of integrative characteristics. One interviewee indicates: "*everybody was directed on working together. However, at the same time it was very clear what the individual interests were. And that's a barrier, but it also makes sense*." Especially when dealing with conflicting topics, behavior changes. One interviewee says: *"If plans change, you see individual interests manifest themselves in the discussion"*. In some of the projects behavior also changes

during time: "*If the crisis didn't occur, I wonder what would have happened. I guess we would still be working separately, fighting each other on specific issues, and being afraid that some would gain at the expense of others*."

4.3 The impact of interaction on performance

We used the case ordered predictor outcome matrix as a first step in our search for patterns between stakeholder interaction and project performance. Therefore we analysed the separate or combined effect of the variables in table 3. This analysis did not show uniform results regarding the impact of interaction characteristics on the performance of the projects. Projects with integrative interaction as well as distributive interaction, score high as well as low on the performance indicators. Four out of ten projects have integrative interaction and high commitment to re-use of cultural heritage. However, also distributive interactions result in high commitment. Furthermore, in most cases an agreement on costs in benefits is achieved, irrespective of integrative or distributive interaction and cooperation type.

To increase validity of the research and in search for other variables, we also asked the project managers directly what they thought to be important drivers for coming to agreement on costs and benefits and re-use of cultural heritage. It appeared that the drivers the interviewees mentioned are partly related to integrative interaction. For example, knowing each other's interests, respect them and act accordingly, willingness to cooperate, having a shared frame and commitment of actors to the plan and ambition are mentioned as drivers. Furthermore, having clear and unambiguous starting points, being flexible and decisive to adjust plans, and having high ambitions for the area were considered to be important. In conclusion, although no direct relations can be analysed from table 3, interaction appears to be relevant for performance.

5. Conclusion and discussion

Based on an explorative comparison of ten projects in the Netherlands this research tried to identify barriers and drivers of urban redevelopment projects with cultural heritage. The characteristics of these projects cause (financial) complexity due to high preservation costs, difficulty to find suitable new uses and in some cases ground pollution. These issues complicate the process to come to an agreement on costs and benefits and the re-use of cultural heritage. Actors have to deal with conflicts which are mainly financial issues and in some cases the changing of plans or ambiguousness of plans. Despite these similarities, project and interaction characteristics vary strongly. Participation of key stakeholders, contribution to costs, cooperation and type of interaction varies and there appears to be no pattern in these findings. Furthermore, the comparative case analysis did not show a uniform relation between the characteristics of interaction processes and project performance. This research finding does not match with literature on negotiation processes which indicates

that integrative interaction more likely results in a win-win situation. Although the empirical results of the cross case analysis did not support this, interviewees did indicate that aspects that could be related to integrative interaction were drivers in the redevelopment process when asked directly. Some limitations and choices made in the research design might underlie this ambiguity in the findings.

First, in our analytical framework we used three indicators for project performance. Against the background of the research problem we argued that commitment to preserve heritage, agreement on costs and benefits and satisfaction of the problem owner on the division of costs and benefits, are relevant indicators for project performance. We choose to specify these indicators ourselves, as we assumed that more clear and uniform indicators would reduce the chance of different interpretations. For determining the score on these indicators we used an objective approach for the first two indicators, referring to the fact that the score is determined by the researcher, and a subjective approach for problem owners satisfaction, which means we asked the project managers how satisfied they were with the division of costs and benefits of heritage preservation. However, a wider understanding of project performance would also be relevant. Although the problem-owner is most affected by the agreement on costs and benefits of heritage preservation, satisfaction of other stakeholders on the process and outcome is also important to determine whether or not the division of costs and benefits is mutual beneficial. Therefore it is suggested to also take into account their opinions on performance in future research.

Second, we also used a framework to describe interaction characteristics. We argued that interaction consists of both deal-making and learning aspects and typified the interaction between key stakeholders in the cases as integrative or distributive. The indicators we used for this classification were based on literature. To prevent bias or socially acceptable answers we asked project managers to describe the overall interaction process and the behavior of various actors. Afterwards the data was coded to link their stories to the indicators used. In using this approach two important research dilemma's came forward: process dynamics and describing interaction.

Inherent to our view of interaction is that processes are dynamic. Actors learn and may change their perceptions and behavior, which affects the interaction. During the process several deals are made, which may steer the involvement or exclusion of actors and influences interaction. Moreover, as the project has a long time frame, the setting of the project changes and actors have to act. But what comes first? This sequence of events is essential in understanding the interaction process in detail. As the process is dynamic, the type of interaction is hard to define. In each situation and moment in time actors may act differently. On their actions and behavior, other actors will react. Actors will interact

differently with various actors, depending on the personal relation. In this study we focused on the agreement on costs and benefits in multiple-cases on one moment, from the perspective of the problem-owner. However, to overcome the dilemma's and understand the interaction dynamics even better, further in-depth research is suggested.

Finally, to find the barriers and drivers in the urban redevelopment projects we executed a cross-case analysis. The analysis helped to give insight in the general characteristics of the projects. However, to compare the projects we needed to focus, give short description and thicken the data. In the data handling, specific details may be lost. To overcome this problem– in a next step of the research -, we will conduct a longitudinal case study. In this in-depth case study we will be able to study interaction in the relation to the sequence of events. Also, the interrelation of the variables can be studied in more detail.

We hope that this paper contributes to a more profound discussion on the interaction in planning processes and the transformation of cultural heritage in urban redevelopment. We welcome feedback on this paper and suggestion to cope with the presented dilemmas for further research.

DAR SMART THE CITY TERRITORY.TOWARDS A NEW DIMENSION

Antonella Contin[1], Pedro Ortiz Castaño [2]

Abstract

Our research focuses on how cities balance both macro/micro-economic factors and their spatial structure according to cultural factors: the underlying form of residential/public areas and landscapes. It discusses the relation between new settlement, activity and space and it takes into account the way different cultures are and how their activities require diverse demands on movement, new settlement of formality, gradients and co-presence. Finally we have to determine both the way how patterns of infrastructure/space integration influence the location of different settlements, classes and social groups in the city and how is possible to solve the pathology of housing and public realm estates. The spatial form needs to be understood as a contributing factor in forming the patterns of sustainable urban metabolism, integration or segregation in the city. The starting point of this work comes out from the necessity of defining the contemporary city within its territory, through a clarification of a new scale of intervention. The framework of our research coincides with the formal and structural dimensioning of the city territory. The need for a cultural "jump" is necessary in order to identify a range of elements and relations in the urban context, rather then simply upgrade the instruments of intervention and investigation. This means a better definition of the structural pattern and spine of this reality, so as to show the discontinuity occurring in the urban development and in the cultural awareness of such phenomena.

Our incoming research on Dar es Salaam follows the strategic modeling document by World Bank Senior Urbanist Pedro Ortiz, document that is used as a methodological indication in the development of a settlement. Its design in the urban context of Dar es Salaam will follows the idea of a variable formality gradient, conveniently located as proposed by the metropolitan spatial strategy suggested by Ortiz. Such a scheme guarantees the connection of every settlement to the bus rapid transit system (BRT) and the integration with the surrounding peri-urban agriculture through local form-typology specificity. Such an approach may envisage a sustainable relation between grey and green infrastructure, the latter intended as the hydro-geological system of the territory. A strong economic attractor related to the infrastructure system should foster the reversal of spontaneous settlements back into legality, providing them with services aiming at improving the sustainable level of

the entire city. In order to cope with the historical structural transformation of the type of settlements, some guidelines on methodology and scale will be suggested, so as to structure the basis for an intervention and, as a consequence, of a specific form of the city-territory.

We promote the appearance of a new scale of settlement typologies and their consequent interrelations, and a change in the urban/rural relation. A formality-gradient type, which capitalizes on its city-center proximity its advanced services, will be determined in relation to mobility structures. Such device should also be able to communicate with the agricultural landscape, which doesn't just have the potential to provide products for consumption and sale for local communities (urban agriculture), but becomes, on the other hand, an element of urban regeneration, as it has always been i.e. in the tradition of the Italian landscape.

1. Introduction

The metropolitan Form comes from the location and integration of large-scale structural elements that coalesce the metropolitan size and extend urban-style living standards to larger populations located in sub-urban areas. Economic structures, including office buildings, factories, enterprise zones, corporate campuses, etc., along with Civic structures, such as full-service hospitals, universities, stadiums, etc., are designed to accommodate ex-urban residents. Transport structures include commuter trains, high-speed trains, airports, freeways, etc. structures that support larger, remote populations and the systems to enter them are the essential elements of the metropolitan Form. Metropolitan territory is “controlled” by a handful specific of local infrastructural nodes These nodal points shape the structure that articulates the metropolis. If these strategic points are located where the Green Environmental and Grey Transport infrastructures are most compatible, then the Metropolitan territory can be controlled. It can be a fatal mistake to impose a strategy upon a Metropolis; rather it must be formulated in conformance with the territory, and structured to take advantage, in the most efficient manner, of the available assets. In the case of the Metropolis, those assets will be the transport infrastructures and the regional size economic or social projects.

1.1 At the new scale of the city growth it cannot react with maintenance or with a partial renovation. Must transform it radically.

Incorporating discontinuous infrastructure (Housing, Productivity, Social) around the strategic nodes increases and expands their strategic importance and, as a consequence, their influence on the surrounding territory. At last, the Metropolis becomes a patchwork of dynamic urban or semi-urban patches and interchange points, where people gather because of their natural attractiveness (Green

infrastructure) and, being crossroads (Grey infrastructure), their convenience. Sent out from the points of interchange place themselves living, working, and social assets, whose borders comprise a “district” of interchange neighbours. Each district owns its distinctive character and it's similar, considering its structure and balance, to the infrastructure assets. These controlled territories form the basic structural form of the Metropolis.

The design of the Metropolis Form has to arise from a spatial concept that synthesizes the strategic assets of the districts in an overall form. Once that strategic form is recognized, then the tactical location of specific projects can be effected. Each project must reflect the strategic concept as tactically applied to that district – the Concept takes Form through the projects. This is "the art of shaping the Metropolis", that proceeds by the Ortiz‘s methodology of development. Therefore we could say that this is a discontinuous reform: the birth of interferences inside the new urban roads: a development method. In fact, rather than a formal model we can better talk about a development model, which consists both of a series of patterns that indicate a direction of the settlements growth and a series of maps which suggest a possibility of configuration/form that constitutes a characterization of the individual qualities with gradient of formality.

1.2 Compatibility between economics and planning / / efficiency and equity

The realm of economy is often considered as an exclusive realm, connected mainly to a regional scale and planning. The concept of time (seen as the metabolic product of society) within the city is not totally understood, therefore is important to think about it as a witness endowed with signs that express the presence of a culture in a specific time, as a particular life-style presence. Transport planning, particularly suffered from a conflict between efficiency and equity. Often, large political powers found more convenient upgrading already existing facilities in the central areas rather than designing new infrastructures, but still we need to consider the important possibility of creating a democratic balance, which means going towards an equivalence between the times-regions. The conflict, then, appears between convenience and compatibility of certain works and plays through a profound social sensibility in order to limit the impact of economic activities and large infrastructures, that undeniably could transform the area, on the environment. We call this "new territorialisation of the region". This aspect is in contrast to the relative immobility of the traditional cities order, based on a horizontal system of traffic -in some cases now even out dated-, and leads us to suggest an integrated model, based both on a capillary action and on the rapidity and the multiplicity of communications, which are spread throughout any direction reclaiming the land to the nature.

1.3 A paradigmatic model to order the real city growth A vision and an idea for the regional city development

Our research starts from the regional scale: the Geography space is the common ground of the physical and social cities. We have to determine a paradigmatic model that is a vision, an idea of city able to order the real city-growth. All social activities leave spatial and symbolical traces in the form of recursive patterns: how can these relate to a geographical, historical context or to a physical and spatial context, whose patterns were certainly laid down long ago, influenced by quite different social circumstances? Even more, how can they relate to some new city paradigm (megalopolis, megacity, metacity) and to the new idea of global cosmopolitism?

2. Analysis

2.1 The role of the City: a cultural leap. A methodological indication for the development of a fast growing city

The starting point of the present work is a provocation coming from the necessity to define the contemporary city within its territory through a clarification of a new scale of intervention. The framework of the proposed methodology therefore with the formal and structural dimensioning of the city territory. The need for a cultural "leap" should identify a range of new dimensions, functions and relations among the elements of the new urban context; this means, therefore, a better definition of the structural patterns and spine of this new reality, in order to show the discontinuity occurred in the urban development and in the cultural awareness of such phenomena. Starting from Lynch's definition of the model as the representation of how the space could be structured and the representation of the shape and process description, we get to the prototype to follow: model, in this case, should be read as a way "to take care of the process through which is possible to think about that shape". We considered also Choay's definition of the model as an exemplary value characterized by reproducibility. We analysed, then, the role of the model for the definition of the Groβstad as it happened in Wien with Wagner and in Chicago with Hilberseimer, we will discuss the role of the theorist plans with a demonstrative character to face the nowadays city's chaos: an implementation devise that would make it physical.

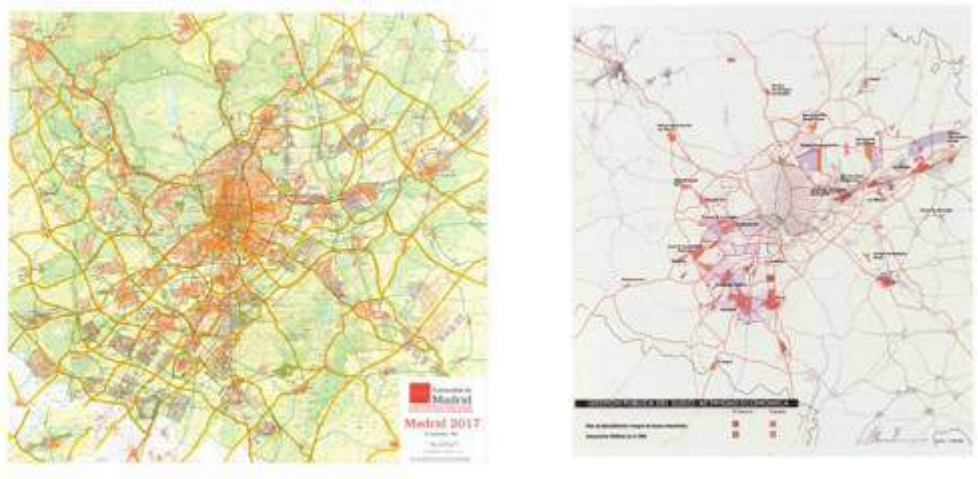
2.2 The Madrid 2016 Plan: the model

Finally we want to demonstrate that the Madrid 2016 plan is the model of a development method for the fast regional growing city. We consider the Plan Madrid 2016, made on 1996 by the Comunidad de Madrid directed by Pedro

Ortiz, the model of a discontinuous reform: the born of the interferences into the new urban roads.

In fact, rather than about a formal model we can better talk about a development model consisting of a series of patterns which indicate a direction of the settlement-growth and a series of maps which indicate a possibility of configuration/form characterization of the individual qualities with gradient of formality. This aspect is in contrast to the relative immobility of the traditional cities order, based on a horizontal system of traffic -in some cases now even out dated-, and leads us to suggest an integrated model, based both on a capillary action and on the rapidity and the multiplicity of communications, which are spread throughout any direction reclaiming the land to the nature.

That Plan connects the geography of the region and the structure of the ancient towns through a simple square geometry. That grid is shaped taming the existing infrastructures, which turn from circular to linear. The new infrastructure model is conceived as an interrelated system between commuter trains and highways.



.

Figure 1. The Madrid 1985 Plan & The Madrid 2016 Plan

The digit of the Plan is a Figural Landscape Unit (named UDE: equilibrate developing unit): every 4.5kmx4.5km square is the lattice topology, as a sign of human presence to move inside the territory. If we intend map not only as a tool that mimics reality, basically because it represents it, we could think about mapping also as an operational tool, that allows an experience of cognitive mapping. Geography, seen as the original archetypal form of Western knowledge (Febvre, 1922) should thus be redesigned to meet the challenges of the globalized society. The interpretation of the new region dimensions, therefore, is done by geometric linear lines of grey infrastructures. The interpretation of the new local

dimensions is a topological net that determines a new portion of body space (Shane, 2005).

UDE is the physical representation of the abstract idea of time (How many time it takes to cover 4.5 km?). We consider that the UDE is the measure of time: a new UDE or Patch Dynamic measures a new time. So, time is the abstract representation of the shape of the city, today. Time measures the form, i.e. as you distribute the elements of a city over time. Today in the megalopolis we are in a crisis of time: or the time is measured through the number, integral serialism, or the element itself (the Mega block or the Patch) is the measure. It the new measure of a Patch that determines its new nature.

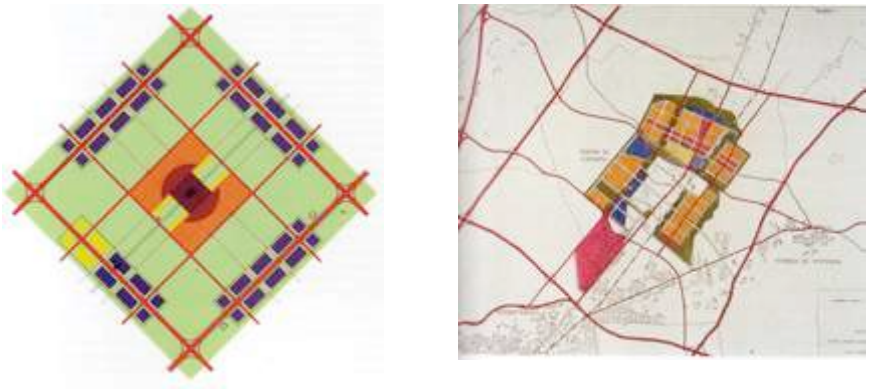


Figure 2. The Madrid 2016 Plan. The UDE model

The world is governed by a mathematical/geometrical conception, and formulas are the shadows it casts. The global order is too complicated to comprehend entirely, as already are multidimensional objects: in both cases, we can only guess through projections. For that reason we have to use models (Hilberseimer, 1927): we understand the models better, reality escapes from us. Of course we know that the lie is behind the mathematical geometric reductionism, basically because it is so powerful that we believe that coincides with the truth (Idealism v. Materialism. Neoplatonicism v. Empiricism). But the problem is that the demonstration of the model must better transfer mechanism and path of thought which made it possible to get to the UDE and understand how nowadays it works at the mega scale.

At last, in that Plan, the design of the metropolis form has to be originated from a spatial concept that synthesizes the strategic assets of the districts in an overall form. Once that strategic form is recognized, then the tactical location of specific projects can be effected. Each project must reflect the strategic concept as tactically applied to that district – the **Concept takes Form through the projects**. We consider that today this is the art of shaping the Metropolis.

2.3 The Plan Madrid 2016: the analysis

The premise

1946, in the plan Bidagor for Madrid, appeared for the first the strong directionality of the character of the entire region morphology. That was possible both thanks to geographical and topographical aspects, which were deeply relevant, and the well identified geographical, topological and ecological lines, which eventually determined the land use.

The model

Requirement of the Plan was to integrate Madrid in the competitive system of world cities, and for this purpose became necessary to rethink the urban structure, giving a correct interpretation of the leap in scale that was running.

In order to reconsider the expertise of modellers urbanism utopia, thought as hypothesis for a redefinition of the urban paradigm, the Plan of Madrid 2016 came to life in a period characterized by the paradigm of a great urban research, as well as by a technical and pragmatic one, which eventually shaped its quite innovative approach.

In this perspective the Plan, in the first instance, must refer to an urban model that is temporally and economically undetermined: urban planning and architecture become contingent transactions that must adapt to changeable political and economic aspects.

Therefore we can talk about an expression of an "idea of the city", i.e., a manifestation of an intention that turns to a condition for action, not to a mere methodology of form. That is the way to design the new regional city scale and its measure, a new spatial semantic, and to shape the figure of the contemporary time (UDE). In order to get to it, we insert the balanced formal structure, memory of its territory (the cuadricula), which can distribute and determine the position of the key elements able to structure and transform it.

The reform of the city paradigm starts from the interpretation of the urban geography of the area set in 1946 by the Madrid Regional Plan of Bidagor, who defined the character of the region, which essentially followed a natural structure similar to the one of its territory and developed itself along the lines. The Regional Plan of 1996 (Madrid 2016, Plan Ortiz) reinforces this character, so as to both counteract a kind of centripetal and centrifugal urban structure and rethink the urban area, in the perspective of another system of connections.

To switch from one old concentric urban form to a metropolitan linear form, JMT Thompson urban studies and the Milton Keynes project, British New Town (1970), are used as archetypal references for the new Plan.

As a consequence, the highway M-45 can be considered as the strength-line that structures the entire Plan. This is the historical trace (Canada Real) of the geographical-region orientation (Plan Bidagor), which rotated the axis of Madrid and eventually released the planning of the city from the city reasons only: in fact it is a no more radial, but tangential line and represents the axis of development of the city along its territory.

Innovation characters of the model

The first topic addressed in the Plan of 1996 pays attention to the status of the city-region, taking care to the relationship between paths and Regional Authorities, between geographical morphology and urban morphology. The purpose of the Plan is to unhook the areas that carry forms and textures of historical city fabrics, generating then environmental areas equivalent and connected by new joints that act as aggregators of new nodes of the structural centrality.

The Plan Madrid 2016 of 1996 was dealing with the instruments firstly of the plan-form and secondly of the movement-form (new linear infrastructural system: commuter trains and highways) as a meaningful element of the Plan, assuming that a new concept of territoriality, at the geographical scale, is based on the organizing principle of land as a meeting place and mobility (Lynch, 1980). Therefore it identifies in a 4.5x4.5km simple geometric square (cuadricula, or UDE: Equilibrated Development Unit), a grid, which permits to enter the territories, characterized by a new territorial dimension. In the Plan Madrid 2016 that simple square-shape is considered the highest guarantee for establishing new centralities, and at the same time it's able to treat and consider the network of mobility as an important and characteristic feature, which doesn't follow the historical city ground mainly because of its lack in interpreting the new scale of infrastructure. But, as Gustavo Giovannoni argued (Giovannoni, 1931), it’s possible to conserve and to develop the ancient cities only if we are able to connect them to a new net. That is an important factor, because old structures are well rooted into the territory and behave, at a regional scale, as important elements that permit to be connected with the geography of the considered territory as a fundamental resource (Geddes, 1909).

The Madrid developing model superimposes a metropolitan scale on the existing system, in order to determine a different relationship between the changed constituent parts of the Great Madrid. As a consequence, it faces the model of the radial forces. The new scale determines, therefore, another form of settlement, in which the scale logic starts from engineering soils, passing to artificial and getting to natural ones: each UDE is not identified by function, but through its geographical meaning.

The Plan sets a system of axis, a governing axis and a penetrative one, which firstly determine the development of the centre along the lines and secondly act as polar systems. The City Council of Madrid is bypassed. Thus, interfering with the

old system of "M" roads in order to define a new relationship, the morphological system is not univocally determined.

We are not speaking about an addition, but about a true reform coming out from a matter of discontinuity: this operation is not meant to save the old structure of the city as if it faced an expansion, but it determines the birth of the interferences of new urban highways.

Four are the defining elements of the Plan: Geography, Geometry, Memory and Denial of the historic city (to change and reactivate it). The Plan assumes its value through the definition of the logic of settlement-distribution, which permits the localization of interchange nodes in peripheral areas. It considers not only the inhabitants but the city-users too, according to the concept that what matters is the existence of an exchangeable organization along the space-time networks of the commuter trains (Cercanias), highways and airports.

Conclusions

The Plan Madrid 2016 identifies as the critical value of the new city dimension, the introverted and a-geographic areas degraded by the effect of implosion and explosion: because that, identifying the inequalities produced in the territory, determines the need for a social and productive re-balancing of the metropolitan area. It is therefore a proposal for a new instrumental technique and structuring large-scale intervention, able to establish a hierarchy between the places, by considering their geographical importance as strategic nodes of interchanges and, as a consequence, of density.

3. Results. An Application of the methodology for a developing regional city model

3.1 Dar es Salaam. Analysis and Strategy of development through the Madrid 2016 Plan Methodology

After the analysis of the structure of the territory through the Ortiz development abstract model, our role, as architects, is to determine a spatial configuration. By learning to control the spatial variable at the level of the complex space-patterns that produce the city, we might acquire the ability to understand both the social element of spatial form, and to detect signs of the social city behind the real city. In that perspective we present DAR SMART research, which follows the strategic modelling document by Pedro Ortiz as a methodological indication for the development of a settlement.

The design of new settlements in the urban context of Dar es Salaam will follow the idea of a variable formality gradient, conveniently located as proposed by the metropolitan spatial strategy. Such an approach, may envisage a sustainable

relation between green and grey infrastructure. A strong economic attractor related to the infrastructure system should therefore foster the reversal of spontaneous settlements back into legality, providing them with services that could improve the sustainable level of the entire city.

Metropolitan scale

In ten years Dar es Salaam has collapse its urban structure. The size and speed of its metropolitan growth as well as the demand for public services and space has overcome the urban capacity, and the limited capacity to respond administratively and financially to the pressures of urbanization has probably speeded up this process and this outcome. Response have to be provided at a metropolitan scale.

Urban radial system

Dar es Salaam has an urban radial system. From this system the coastal roads coincide with a potential metropolitan reticular system.

The metropolitan transport structure

Concentration and congestion must be avoided at a metropolitan scale. Urban axes as route form the embryo of the metropolitan structure. The south 'belt' road would complete the Metropolitan centre distribution ring. The non centripetal design of these systems avoids excesses of traffic pressure on the CBD and distributes accessibility and land use provision in a decongestive system. The elongation of these roads (freeway typology) both as a coastal gradient and inland penetration provide a spread accessible land provision that offer alternative locations to congested metropolitan centre. Meanwhile roads run along administrative boundaries to provide equilibrated and shared benefits to the provinces/municipalities affected.

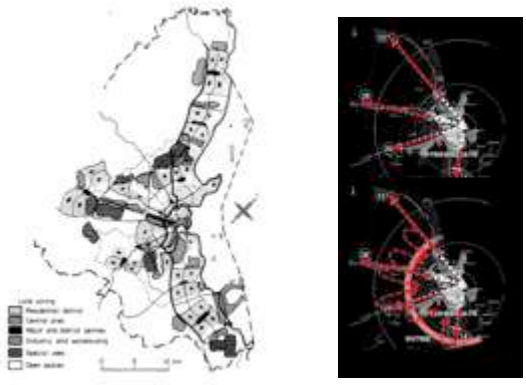

Figure 3. D4D - Dar es Salaam General Plan 1968 & Copenhagen Model Congestion

Radial growth: Finger-like Copenhagen model

The radial structure provides adequate response to the linear provision of public transport systems. It gives priority and accessibility to the centre where most of activities take place and is the destination of the majority of trips, and it is a sound urban structure. The limits of that system are on the extension of the fingers where urban trips would take too far and too long to be efficient. The orbital-radial model presents diseconomies of scale. It is efficient at small urban scales but collapses when large scales are reached.

Collapse of the urban radial Copenhagen model

1st phase: Growth takes place along the provision of transport infrastructure.

2nd phase: Cross connection takes place to avoid over dependency of the centre. This would increase non centripetal trips length and produce central congestion. Transversal connections are provided.

3rd phase: The length of the radial fingers extends to a point where infrastructures provision does not compensate. Interstitial spaces start to fill up. Land for environmental and social assets of the finger structure is taken over and the structure becomes progressively an oil stain expansive structure.

4th phase: The continuous urban pattern of homogenous settlements with multidirectional trips and insufficient traffic space provision develops into a gridlock congestion model.

Finally, the finger Copenhagen urban model has size limitations that need a different response when metropolitan scale is reached

Dar es Salaam uncontrolled infill collapse of the radial model

Dar es Salaam is experiencing the collapse of the radial finger Copenhagen model. In fact inter-finger spaces are being in filled with new urban residential settlements, some controlled, some uncontrolled. Land use enforcement (discipline) could be increased but social forces, within the power of a democracy, are stronger than the capacity of the public administration to set efficient administrative controls. We can argue that traffic situation in Dar Es Salaam is the empirical consequence of this urban process. Upgrading settlements would fix the outcome. Resettlement in the right metropolitan locations could be envisaged as an alternative or complementary policy within a necessary metropolitan model.

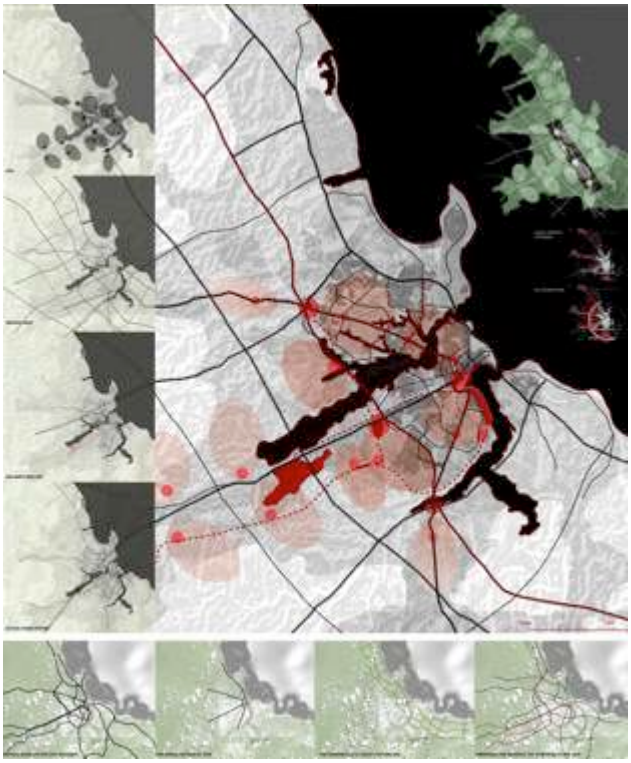

Figure 4. D4D - Dar es Salaam Analysys and Strategy.
(Matteo Motta Drawings)

Metropolitan Rail network

A very important role is played by the mass transport. The Metropolis has to be built on a commuter train system. Rapid urban transport systems BRT's have scale limitations when it comes to transport large number of people for metropolitan size distances. BRT's have an urban scale that reach efficiency thresholds when confronted with larger distance scales and larger passenger numbers. We think that the metropolitan commuting system has to make best of existing infrastructure and land rights of way assets, and the inherited assets have already shaped the metropolis in one hand and have to be as well, on the other, the support for the future structure of growth.

Vertebral system

We may try to build a vertebral system for the new dimension of the metropolis. Metropolitan models are shaped in the coordination of rail and road accessibility infrastructures: both vertebrate the metropolis. The versatility and capillarity of the rail network within the urban fabric is not reflected in the metropolitan territory. The preferential growth potential is defined prior by possible rail network extensions, and the roads network will have to be diversified to avoid

collapse of excess of growth concentration along this vertebral spine: diversified locations in advance of rail expansion will avoid as well an excess of dependency of a linear structure.

Urban rail service

The rail system has to be reinforced: rail layout is peripheral to the urban fabric and has to be completed with complementary urban transport, BRT and buses, feeding routes. Urban rail accessibility can be quite capillaries with a 3 km. maximum distance: with an increase number of stations this distance could be reduced to 1.5 km that is a 20 minutes pedestrian walk, or a 6 m. urban transport ride. For all this a specific and detailed plan needs to be initiated.

Growth potential with existing network

The provision of commuter rail services within the existing infrastructure right of way might be a short investment policy with important decentralization results. Along the 2 existing rail lines a service could be provided with metropolitan rail stations distant of an average of 5 or 6 km, so dense urban settlements can be develop around the intermodal stations which will become new urban centralities (see appendix). Interstitial spaces will be protected to allow for infrastructures, institutional facilities and commercial facilities.

The commuter train would be fed within the urban development unit by complementary urban transport with a maximum distance of 3 km, so population will reach Dar es Salaam centre by train and will bypass and deflate actual traffic problems.

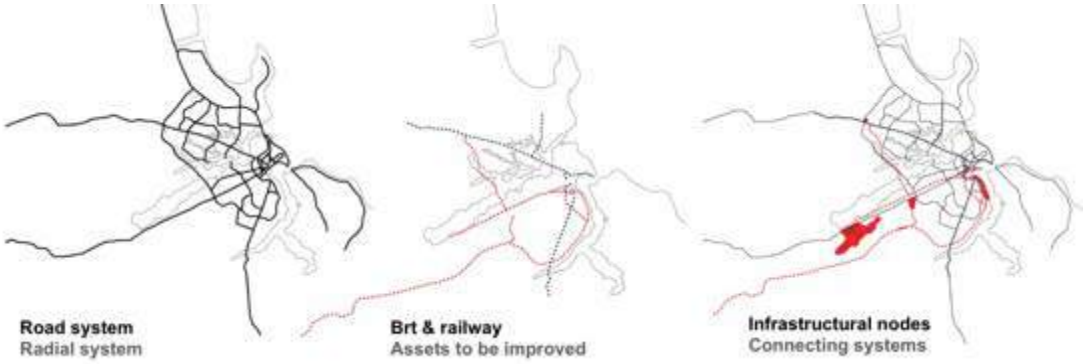

Figure 5. D4D - Dar es Salaam Analysys and Strategy. Grey Infrastructure Proposal *(Matteo Motta Drawings)*

Future infrastructure rights of way provision

If the Rail provision will be radial to maximize train accessibility to central Dar Es Salaam as an alternative to the use of private road transport, Road pattern

accessibility would be reticular to disperse accessibility along a larger well provided territory that would invite decentralization of economic activities and residential provision. The metropolitan grid will provide possibilities for further, equal access, decongestive development.

Rail metropolitan expansion

The rail network expansion would be the guideline for metropolitan settlements expansion. The metropolitan transport will shift form road to rail passenger mass transit. The ‘evolving’ metropolitan diagonals could be the support for rail lines if land provision protection is made early or if finance can confront the underground investment. Urban intermodal centrality will coincide with the reticular pattern. Future rail layout will serve consecutively the areas needed for expansion within the reticular pattern.

Regional scale facilities

Regional scale institutional and social facilities are of the type of large hospitals, universities, sports grounds, and national and regional government institutions. The accessibility to institutional and social regional scale facilities must be both public and private transport. Potential site for those facilities is in the intersection of the metropolitan rail system and the primary road system. The selection of the sites should be made by a precise urban plan for the provision of such facilities.

Regional commercial facilities

Large regional commercial facilities require retail transport, which is made essentially by private transport. Potential location of those facilities is at the crossing of the primary and secondary road network. Final decisions, in response to private initiatives, should be made with a land use pattern of criteria developed in a specific policy plan.

Regional facilities land use coordination

Both socio-institutional and commercial facilities can be coexisting or independent provided they comply each of them with their location rules pattern. Conflict does not necessarily occur as rules are differentiated, but if it does, planning should provide for resolution. Locations are potential and should be decided along the capacity and the necessity to provide a land response for their need to be built.

Environmental protection and provision

Environment capital should integrate the metropolitan fabric. Definition of environmental values must be determined before planning and incorporated as a pre established policy. Flexibility of the model allows for compatibility between environment and urban development. Environment, when overlapping, prevails.

The environmental spaces must have continuity for biodiversity networking and must filter through the metropolitan fabric to reach the core of the urban system. Environmental infrastructure can be enhance when environmental natural values are insufficient

Priorities

To respond to the challenge of growth within a metropolitan context and with the expansion model priorities of investment would be:

1) The backbone distributor-decongesting freeway:

a. Upgrade infrastructure and

b. Protect rights of way – free access

2) The first metropolitan railway line:

a. Upgrade fix infrastructure

b. Set up mobile material for mass transit passenger service

3) Urban development

a. Design and management

b. Urban intermodal centrality

4. The Dar Smart Project: Sustainability of identity. The local scale project methodology

In the global competition among cities and their territories value and growth can only be fostered through the qualities of identity. The last decade has made clear how sustainability is a key issue in setting long-term visions for our cities and it's important to promote an idea of sustainability which is economical, social and energetically and that, for this reason, is strictly linked with urban as a way to settle in a territory. Density, agglomeration, proximity produce the rich interaction networks which contributes to economic growth, poverty reduction and cultural improvement. Driving the urban metabolism towards a densification that is controlled in a sustainable way can enforce a vision able to root the global role of a city in its local characters, demonstrating the sustainability of identity, setting a smart growth.

4.1 Dar es Salaam. The city

Dar es Salaam (Tanzania) can be identified as a urban region with 3 million inhabitants exploding with a growth rate running since more than 10 years around 4-5%/yr and the 80% of the population living in informal settlements. Its geopolitical conditions are making it one of the most important African metropolises, attracting investments from the worldwide system and attentions from the international organizations. Administrative boundaries have been overgrown producing governance conflicts that require compromise, agreements and time. Time is what growth does not respect. Growth is taking place whether the administrative framework is able to manage it adequately or not; a proper flexible strategy is needed.

This can be rooted in the urban character of the city, expressed by a threatened rich porosity based on the complex overlapping of formal and informal economical structure. The great challenge is managing the urban development linked to the ongoing infrastructural projects avoiding the overflow of the formal neo-colonialist development and balancing it to build a smart welfare city.

Figure 6. Dar Smart. Green System Strategy *(Danilo Vicente Damico Thesis. Politecnico di Milano. School of Architecture and Society 2012)*

4.2 Open themes

1. Mobility: Metropolitan spatial strategy.

Net-city and mobility: private traffic and parking, public transportation and slow mobility. The envisioning of an integrated system could configure the city as a fast net that interweaves relations in specialized nodes and defines an archipelago of local enclaves with inner slow mobility and a brand new landscape. These new hierarchic relations will set a new spatial strategy for the city.

2. Urban agriculture: feeding growth.

Poverty and urbanization rates according to well know models seem to be directly proportional. The defence and promotion of local models of urban farming could allow to controvert this relation proposing urbanity scenarios which link living and feeding in accordance to local models. New living and land-use typologies can be studied considering the local property policies to propose an original model of urban farming for the low-grain developments of the city.

3. Energy and sustainable infrastructure.

The urge of making up for the present infrastructural lacks to offer higher standards of liveability suggests the development of low-cost models of urban infrastructure based on innovative technologies able to overcome the limits imposed by the low availability of electric energy; i.e. exploitation of renewable sources, low-tech water treatments, low power consumption lighting and lighting management, liquid and solid waste treatment, etc. It's necessary to set a locally fitted ecological balance for the informal evolving settlements able to produce a specific recognizable urban landscape.

4. New building typologies: between informal and formal.

It is necessary to understand the relation between formal real estate market (and its imported models) and informal settlements dynamics. Identity/cultural aspects link with typological/climate/energetically aspects under the common framework of sustainability. A wide spectrum of issues can be combined in the definition of new morphological schemes and typological solutions thanks to parametric and associative design.

5. Climate change. Natural hazard.

The importance of agriculture and the relation with the sea are great resources for the city, but the future scenarios about the climate change and sea-level rising are uncertain. They need to be monitored and their effects have to be taken in consideration for the present planning decisions (i.e. Kigamboni) producing evolving dynamic scenarios and focusing on urgent actions about water management.

4.3 Power of place and need of a Vision. An urban model based on a formality gradient

The vision project, which is a cultural project, should be verified according to an ecological equilibrium to state its sustainability, according to an economical equilibrium, to state its feasibility and according to the equilibrium of fluxes in order to state its efficiency. Only thanks to a powerful vision of this kind it is then possible to build consensus among the actors and a virtuous dynamic of interaction between public administrations and private investors able to deal with the dichotomy local/global.

Infrastructure, Landscape and Identity

Contemporary cities can be seen as complex systems that have a network armature rooted in specialized multiscale nodes and that set an archipelago of island of urban landscape with various grains. The infrastructural operations linked to the moving issues have to deal with network dynamics and with the global scenario, setting the space/time relation of an urban system. A metropolitan spatial strategy built on a public transportation net can contribute in setting an accessibility hierarchy organized by nodes of density and intensity. These nodes, linking global and local, merging different speeds, scales, grains can behave as flexible stem cells introducing in the formal or informal urban tissues original regeneration elements able to adjust uncontrolled gentrification phenomena. Accessibility to the urban system can coincide with the availability of social and cultural services, rare urban functions, safety and health structures and unconventional interactive typologies, conveniently located according to a general sustainable vision. This means exploring different possible interactions between infrastructure and urban tissue depending on whether it comes across fine grain central areas, evolving suburban neighbourhoods, loose grain informal settlements.

In Dar es Salaam the geographical endorsement of settlements and the infrastructure network set a multiple layered net with high urban potential; built by:

ARMATURES: an evolving grey net of technological infrastructure providing fast interconnection and a green net of topographical ecological corridors currently neglected

NODES: multiscalar entities to be developed as alternative centralities; they activate densification and formalization phenomena to be properly managed

SPONGY TISSUE: formality gradient patterns for the archipelago settlements preserving and enhancing porosity, managing informal urbanity, welfare equipment, urban farming

4.4 A new definition of mega block as a open pattern

The UDE model

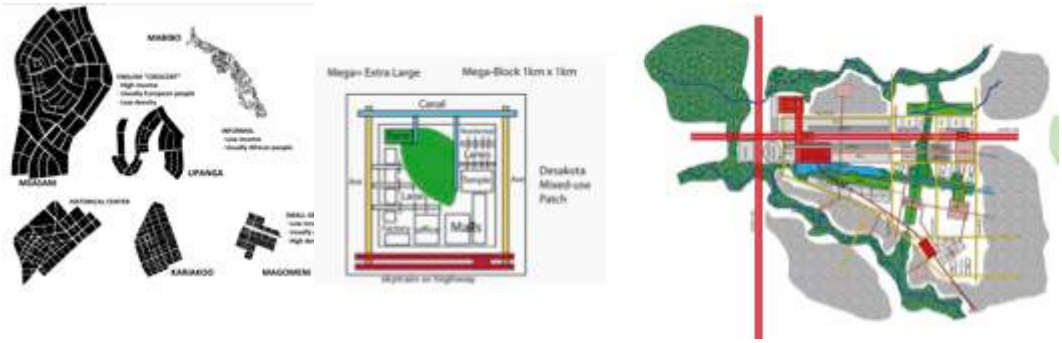

Figure 7. Dar settlements typologies. From the UDE model to the a Desakota Block (1kmx1Km) for Dar. *(Matteo Motta Thesis. Politecnico di Milano. School of Architecture and Society 2012).*

The explosive growth and regional scale involve the necessity of strategic models with a measure descriptive of different density weights and their distribution over the territory.

The Broadacre City of F.L. Wright, was structured on a micro module of 80 x 60m but looking at the regional scale with a macro module of 3.2 x 3.2 km The model designed by Ortiz to manage the regional dimension, predicts a large size of about 5 x 5 km supported by a infra-structural system of geographical matrix lines and public transport.

This system identifies different degrees of mobility and activity and different density weights in relation to the infrastructure. The core of the UDE is supported by the Commuter Train and secondary roads to handle a local scale, which determine the location of elements of public and residential areas. The biggest entity weights are placed near the matrix lines (the main road on a territorial-regional scale) and in particular close to the intersections of the infrastructures. This model shapes the regional system while provides flexibility, density weights and measures used to manage the system.

The critical task of breaking down the model to the local context has taken to a modification of the model towards a definition of the type of grain and porosity of the settlements, freeing them from a mere indication of functional issue and re-evaluating the environmental system that is not taken as background but as the material and substance of the project.

The Mega block Model (green and grey infrastructure)

The concept of mixed-uses and landscapes Desakota model between the urban spaces related to infrastructure, and rural space, characteristic of agriculture, is taken up by Grahame Shane (2011) and defined through a diagram of Mega block, as a large urban element at regional scale. The model of the Mega block provides a size of about 1x1 km, smaller than the UDE model. So, we consider it as a part of the UDE that organizes the UDE centralities: i.e. the mega block is the point where the model of Ortiz is hooked to a large grey infrastructure as railway stations, airports.

The model of Shane provides the presence of very heterogeneous activities that are mixed with each other in a pattern of "patches" dynamic, where the green is not just a background, but an active element with its proper infrastructure and activities.

The diagram then, shows how to structure a gradient of formalities between an infrastructural system heavy and "grey" and an infrastructural system light and "green". Each of them carries density weights and the co-related activities in a pattern of "mixed use patch". This "pattern", thought for South-East Asia, is decomposed into our action-planning to be integrated into the African context of Dar es Salaam, so that, the elements of agriculture, supported by an urban hydro-geological structure (channels), might go deeply inside the structure of mega block generating a porosity that from the informal part of the city goes into the formal settlements at the regional scale. In addition, the provision of a strategic system of elements of welfare allows to connect the large size with the small one: building the elements of an institutional reference, bringing services and infrastructure, it can give shape and legalize the informal settlement.

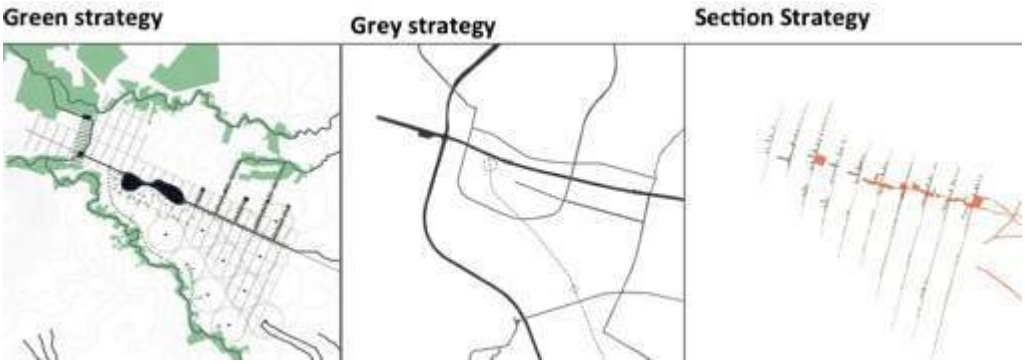

Figure 9. Dar green/grey strategy*(Matteo Motta Thesis. Politecnico di Milano. School of Architecture and Society 2012).*

4.5 Definition of eco-green armature within the concept of the gradient formality potential

A system of eco-armature, from an ecological point of view infrastructures the landscape. The open question is that natural resources can not be planned on the basis of a model, but through a rule: a rule of Form. This form always has 'content'. It leads citizens to recognize the city as an important place to plan their own life. Meaning is attributed. They become symbolic intermediaries.

The city has always been the place of urban metabolism and thus for transformation and evolution. Able to set up the dual urban and social structure, which should never be disarmed because it is not as much the backbone of a communication system, but rather the competence to interact with the site and the land: the inter-somaticity that bodies acquire orienting in a field.

Figure 10. Dar Smart . The rule of the grey/green Interference *(Matteo Motta Thesis. Politecnico di Milano. School of Architecture and Society 2012).*

This sense of direction, which occurs only if a site of the earth, is found and made, that is constructed and marked by man, can be possible then only in a place which becomes central again to human intentions, and therefore, allows man to transform in the symbols the mental processing of the memorable events (plot of desire and memory): we call these places symbolic mediator or intermediaries

5. Conclusions. An urban model based on a formality gradient

The natural and anthropological characters of a territory determine the local value of landscape as part of the identity feeling. For this reason acting on the way of inhabiting a place requires a synthetic effort that has to be systemic and set at the right scale. The transition towards formal uses of land and the related infrastructural process has to combine innovative technical solutions, typological

experimentations, and imaginative issues setting the unique and recognizable image of that territory at the scale of the urban realm.

The new infrastructural system should determine an original urban tissue based on a double formality gradient, connecting to the mobility system of the global scale - opening to urban regeneration and liveability enhancing - but at the same time improving the relation with medium/low density territories of informal settlements and urban agriculture - preserving their rich interactive social and economical system. This strategy could determine a specific local way of settling provided by specific relational dynamics, specific regulations about the private/public partitions, land-use and property.

Figure 11. Dar Smart. The Welfare Staminal and he Green Infrastructure *(Matteo Motta Thesis. Politecnico di Milano. School of Architecture and Society 2012).*

The ongoing infrastructural projects in Dar, like the Bus Rapid Transit, are introducing a new scale in the urban structure moving towards an uncontrolled development. The vision for the city has to be rooted on an idea of urban intensity that is effectively net-connected, but also deeply place-specific. The local peculiarity of the green net given by the geography of the city could be the key issue for the urban growth; its management, driving a virtuous balance of the urban ecosystem, could be the specific know-how and branding identity issue for the African green metropolis.

The proposed spatial strategy, promoting a double formality gradient pattern, considers the existing rich interactive social and economical system as a matchless resource for the city growth. It has to do with an effective local way of settling provided by an uncommon urban porosity. According to this all the required governance tools have to be fitted, so that people can feel a correspondence between laws and behaviours of land-care, minimizing the conflicts occurring in the formalization process. Virtuous interactions between the public and private sectors have to be fostered to assure an economical balance, making densification paying for welfare. Setting an urban model on this perspective could mean opening the way to a competitive strategy for the sustainability of identity.

Long term scenarios for the urban landscape

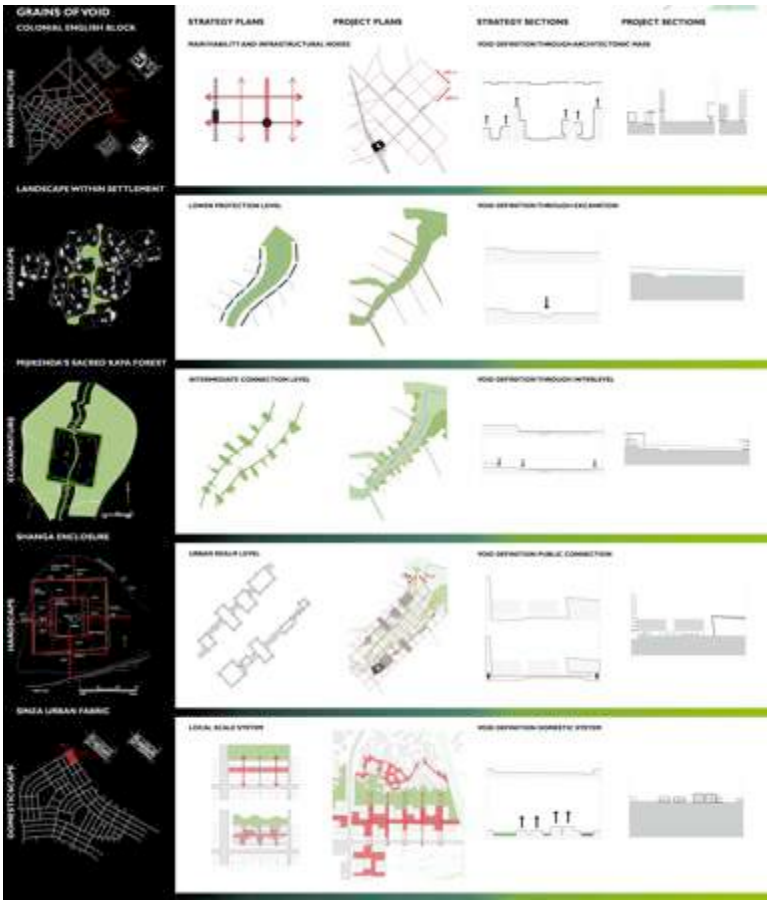

Figure 8. Dar Smart. The Formal/Informal Strategy *(Danilo Vicente Damico Thesis. Politecnico di Milano. School of Architecture and Society 2012)*

Reaching a real grade of sustainability means considering economical, environmental and social aspects in their complex relations. Space and time interlace in this issue making the decision making process even more difficult for the administrations when the spatial strategies don't include some flexibility levels and at the same time long-term wise decisions. In this perspective climate change and natural hazard are the main issues to take in consideration. Dar es Salaam will face two aspects of the climate change problem: the vulnerability of the agro-ecological system with the decline of agricultural capacity and sea-level rising with the risk of floods and the coastline alteration. Defence, attack or retreat are the three strategic options and water the element to deal with. Both the issues

must be faced in accordance with the general urban landscape strategy through a specific and conscious approach to water management, which can become the distinctive element of a conscious far-sighted vision for the city. The virtuous balance of urban ecosystem through the flexible innovative solutions which structure the urban landscape could be the specific know-how and branding identity issue for the African green metropolis.

The governance of religious diversity inside urban integration agendas: Cases from the Ruhr Area in Germany

Eva Dick

Abstract

In the last decade, integration has become a leading policy objective in Germany. The issue has also been lifted high on municipal and city agendas, albeit with changing emphasis. Recently, within what has been termed the inter-cultural paradigm, the governance of religious diversity has become a topic in many urban integration plans in the country. Based on the analysis of integration concepts of eleven metropolitan cities in the Ruhr Area this paper examines, how religious actors and inter-religious activities are included in urban integration plans, why urban stakeholders chose to integrate them in the agendas and, from a normative point of view, what relevance such activities possess for urban integration and cohesion. The paper suggests that while the inclusion of inter-religious activities and actors in integration measures aligns with recent principles of urban (diversity) management, the often political dimension of such encounters may reinforce rather than attenuate social and cultural borders and stereotypes.

Key words

Migration, urban integration, inter-religious activities, governance, Germany

1. Introduction

The objective of this paper is to discuss the governance of religious diversity and inter-religious activities in the context of urban integration policies in Germany. This will be done by asking how religion and inter-religious activities are dealt with in urban integration plans, why urban governments and administrations include inter-religious activities in these plans and about related potentials and challenges for managing diversity and building up social cohesion in increasingly multicultural cities.

Since 2000, Germany has significantly altered its legislative framework for immigration and the acquisition of citizenship, and in this context integration has become a leading "policy symbol" (Bommes, 2007, p.3) or objective. While the integration of immigrants has turned into an issue of national debate, it has also been lifted high on municipal and city agendas. This must be seen against the fact that in Germany the local level, rather than the national, has been at the forefront of addressing and implementing integration measures for years. Here, and particularly in the large urban areas to which most migrants moved, problems such as unequal

unemployment, education and housing were most directly felt, and as a consequence integration strategies sought to uplift migrants' situation in these fields.

While in the 1970s and 1980s local integration strategies largely consisted of compensating the above-mentioned 'structural' deficits of migrants, current ones follow a different approach. In accordance with the paradigm of inter-culturality, emphasis is now placed on the recognition and activation of immigrants' potentials, on the role of the majority population in a two-sided integration process (Baraulina 2007: 30) and on the 'software' of urban practices and conviviality e.g. cultural identities, values and beliefs. Also religion has become an important ingredient of integration policies, and inter-religious activities are included in many urban integration concepts (Klinkhammer et al., 2011, pp.242, 252).

I will argue that this inclusion is driven by a variety of factors: First, in the context of a migration-related growing religious diversity in German cities urban administrations are increasingly confronted with claims of different religious groups for urban participation and place-making e.g. in the context of the construction of representative religious buildings (Baker, 2008; Beaumont and Baker, 2011a; Schoppengerd, 2008). Second, the significance of inter-religious bodies "as strategic actors for the pursuit of the local governance of religious diversity"(Griera and Forteza, 2011, p.119) has gained political relevance in the context of anti-radicalization efforts following 9/11 (Tezcan, 2006, p.28). And third, the promotion of inter-religious activities in urban integration agendas can be related to a changing planning culture calling for intensified civil society activation and participation within new urban (diversity) management.

The structure of the paper is as follows. In the subsequent, second, chapter I sketch the research context and methodology of this paper. In the third section, I describe the evolution of migration and integration policies in Germany, notably at the local level. In the fourth chapter, I portray the evolution of inter-religious activities in the last decades and discuss the changing attitude of city actors towards such dialogues. In the fifth chapter the present incorporation of religion and interreligious activities in urban integration plans will be discussed, based on the assessment of integration and intercultural plans in eleven metropolitan districts of the Ruhr Area. The sixth chapter concludes with a summary and an assessment of future potentials and challenges for new state-civil society alliances in the governance of religious diversity within urban integration agendas.

2. Research context and methodology

This paper is elaborated in the context of a recently started interdisciplinary research project called "Inter-religious activities and urban governance in the Ruhr Area" conducted by the Faculty of Spatial Planning of TU Dortmund and the Centre for Religious Studies (CERES) of Bochum University. The project uses Duisburg and Hamm, two selected cities of the Ruhr Area, as case study areas and will employ a mix of qualitative individual and focus group interviews, document analysis and (participant) observation as empirical methods. Since it has only recently started the

present paper predominantly draws on literature review, as well as on an internet-based analysis of integration concepts and plans in eleven cities of the Ruhr Area, thereby reaching beyond the case study areas chosen by the research project. At the time of the presentation at the conference, some preliminary results of interviews conducted in the cities of Duisburg and Hamm may however be included.

3. Immigration and integration policies in Germany

According to Klaus Bade, migration scholar and presently chairman of the Expert Council of German Foundations on Integration and Migration, over decades migration policies in Germany were characterized by the paradox of 'a situation of immigration without [being] an immigration country' (2007, p.32). That is to say, until the beginning of the present century, Germany did not see itself as an immigration state and consequently did not have an explicit immigration policy.

In the first years after World War II refugees from Eastern Europe and the German Democratic Republic (GDR) were the principal immigrants to Western Germany (Krämer-Badoni, 2001, p.19; Hillmann and Windzio, 2008, p.10). From the 1950s until the late 1980s guest workers from Southern European countries and their families occupied the highest share among the migrant population. Inter-governmental agreements signed between Germany and the guest workers' respective countries of origin constituted the legislative framework for their temporary recruitment: The first such agreement was signed with Italy in 1955, the last one with former Yugoslavia in 1968 (Friedrichs and Alpheis, 1991, p.117)[1].

Today the proportion of the foreigners in Germany is almost 9 percent and the proportion of the population with a migration background stands at a little more19 percent (BAMF, 2010, p.189).[2] With Turkey still being the country of origin of the highest proportion of the population with a migration background, the legacy of guest worker immigration is reflected. However, in the last years an increasing diversification of national origins, as well as immigration purposes and pathways can be observed, also resulting in the diversification of religious origins of migrants (Dick, 2011, p.69).

The influence of guest worker migration is also evident in the Ruhr Area, an urban agglomeration migrants were historically attracted to due to employment opportunities in the mining and related heavy industries. Among today's foreign population in the Region, the Turkish population shows the highest share of approx.

---

[1] Agreements in between these were signed with Spain (1960), Greece (1960), Turkey (1961), Morocco (1963), Portugal (1964) and Tunisia (1965) (Friedrichs/Alpheis 1991: 117).

[2] The population with a migration background is defined as the immigrants that came to the country after 1949, as well as foreigners born in Germany and all German-born with at least one migrant parent or a parent born in Germany as a foreigner (BAMF 2008: 235).

40 percent, followed by people from ex-Yugoslavia (13 percent) and Poles (7 percent) (Regionalverband Ruhr, 2012).

Related to the intended temporary character of guest workers' stay, in Germany in the second half of the 20th century an explicit immigration policy was not deemed necessary (Bade, 2007, p.35). This situation only changed in the 1990s and migration policies started to be conceived in conjunction with strategies for migrants' political, social and economic integration. The underlying, rather pragmatic, assumption was that social costs of neglected integration would otherwise grow far beyond the costs of timely integration support (ibid: 34, Baraulina, 2007, p.28). This has also manifested itself in important legislative changes: The principal milestones in this regard represented the reform of the citizenship law in 2000 and the immigration law that came into effect in 2005. The annual national Integration Summits conducted since 2006 under the auspices of the German Chancellor as well as the formulation of a National Integration Plan in 2007 and its 2012 revision (now National Action Plan Integration) illustrate that the topic has obtained a high policy priority in Germany.

The National Action Plan Integration delineates the following priority sectors for integration strategies in Germany: Early-childhood support; education and (professional) training; labour market and employment; migrants in the public service; health and care services; local support for integration; language and integration courses; sports; integration and the media; support of civic engagement and integration and culture (National Action Plan Integration, 2011). A variety of stakeholders from the State and civil society, among them religious associations cooperated in the formulation of the plan (ibid). By way of the priority sector "providing local support for integration" the role of cities and neighbourhoods for the implementation of integration is underlined.

Since the 1970s, the municipal level has always had a particular role for the integration of the migrant population, since it was at this level, particularly in the urban core neighbourhoods, that integration problems were most strongly felt. However, local integration concepts have considerably evolved in the last decades: Whereas until the 1990s municipal actors largely made use of compensatory integration measures (Baraulina, 2007, p.29)[3], in the last decades the inter-cultural paradigm has gained momentum. In its context, a more resource-oriented approach is brought into play, in which emphasis is placed on the activation and participation of migrants in integration initiatives, the attitude of the majority population and strategies for improving mutual understanding and conviviality. At the same time, organisational networking at the local level for integration-related services e.g. with (inter-) religious bodies amongst other civil society organisations is becoming an imperative, not least in the context of budgetary restrictions (Baraulina, 2007, pp.31-32.).

[3] For these compensatory programmes municipalities or municipal actors merely act as executing agents while the funding comes from the Federal or States-level (id.: 30).

4. Religious diversity and inter-religious activities in Germany

Alongside the growing ethno-cultural diversity notably through migration in the last decades Germany has become ever more multi-religious (view religious groups and memberships in REMID). In the State of North-Rhine Westphalia in which the Ruhr Area is located, the majority of the population (approx. 75%) affiliates itself with the catholic and protestant religion. However, in the last third of the 20th century there has been a growing migration-related pluralisation through Islam (aprox. 3% of the population), Eastern religions, and through the advent of new religious movements (Religion Plural).

While this statement can be made for the country as a whole, religious pluralism and faith-related manifestations in the public space are predominantly an urban phenomenon (metroZones, 2011a, p.18; Penta and Schiffauer, 2011, pp.265-266). To the extent that members of different religious affiliations interact for faith-related or other purposes (e.g. inter-religious prayers, community building or sports events, negotiations for the erection of religious building etc.), religious diversity translates into inter-religious contact and thus becomes potentially relevant for urban integration policies.

Besides historical antecedents, inter-religious activities in Germany set off during the early years of 'guest worker' migration in the 1970s. These activities were predominantly civil society-lead, with the purpose of exchanging information about the respective other religion or, from the side of Christian groups, providing support to recent migrant arrivals. Only from 2000 onwards and notably in the context of a growing sensitivity towards religious fundamentalism, activities between (predominantly) Muslims and Christians obtained political relevance and thus came to the centre of public and media attention (Tezcan, 2006, p.28; Klinkhammer et al., 2011, pp.24.). Also in other European countries, interfaith bodies and activities have recently become more institutionalized and increasingly drawn into governance processes at national, regional and notably local levels (Griera and Forteza, 2011, pp.117-118; metroZones, 2011a, pp.18-19).

In Germany, integration is the policy field religious diversity and interreligious activities have obtained the highest relevance for. Due to the above-mentioned link with security concerns, religion and particularly Islam have become highly relevant elements of the integration discourse (Klinkhammer et al., 2011, p.242). This manifests in high-profile events such as the annual German Islam Conference initiated in 2006 by the Federal Ministry of the Interior, but also in the topical orientation in Muslim-Christian dialogue circles which tend to be dominated by integration-related questions (Klinkhammer et al., 2011, pp.251-257). While the association with integration policies seems to be particularly prevalent in regional or national-level dialogues, it can also be noted on the local level.

In the present paper however I do not inquire into the prevalence of integration themes in interreligious events. Instead the inquiry comes from the other side, i.e. the

focus is placed on the degree and the reasons inter-religious activities and encounters have become a subject matter in urban integration policies and plans in Germany.

5. Results: Inter-religious activities in urban integration policies and plans

In order to analyse the relevance of religion and interreligious topics in integration concepts and plans in cities of the Ruhr Area, the focus is placed on the eleven largest, i.e. metropolitan districts of this region (Regionalverband Ruhr).[4] These are the cities Duisburg, Mühlheim a.d. Ruhr, Oberhausen, Bottrop, Gelsenkirchen, Essen, Bochum, Herne, Hagen, Dortmund and Hamm.

Description

Table 1 displays integration definitions and fields of intervention formulated in integration or inter-cultural plans in five of the mentioned cities[5], and illustrates the role of religion and interreligious activities in the plans. Cities seem to use the terms 'integration' and 'inter-cultural' synonymously since 'inter-cultural' concepts (view e.g. of the city of Essen) tend to place emphasis on similar fields of intervention and objectives as the 'integration' plans of other cities.

With respect to the question how (inter-) religious activities and events are dealt with in urban integration and/or intercultural plans, the analysis in the eleven cities has produced the following results:

1. In most cities inter-religious activities are ***not treated as a separate field of intervention***. Rather, the plans place most emphasis on structural integration support, e.g. in the areas of education, employment, language acquisition and housing and urban development. Among the eleven analysed plans or concepts, only the "Masterplan Integration" of the City of Dortmund points out "Interreligious dialogue and promotion of acceptance of non-Christian faith groups" as a separate field of intervention. In the City of Gelsenkirchen, "inter-religious concept" forms an explicit sub-field of action under the intervention field "culture and sports".

[4] It is assumed that in these large cities inter-cultural and inter-religious relations have the highest prevalence.

[5] For reasons of readability the number of cities indicated in Table 1 was reduced to the five largest, out of the original sample of 11 cities. The information about the other five cities (apart from what is mentioned in the text) may be directly requested from the author.

Table 1. Principles, fields of action and the role of religion in integration concepts/plans in six cities of the Ruhr Area

CITIES AND PLAN	PRINCIPLES OF INTEGRATION	FIELDS OF INTERVENTIONS	ROLE OF RELIGION / IRA	FURTHER ISSUES OF INTEREST
BOCHUM Integration Concept	Process and potential orientation; Constitution as basis of action; Mutual respect; Same-level dialogue; Equal participation and opportunities; Fighting discrimination; Inter-cultural opening of institutions	Education, Language, Employment, Conviviality, Children and Youth, Elderly Migrants, Health, Culture, Intercultural Opening and Sport	-No extra field of intervention -Objective promotion of respect towards cultural and religious difference, within human rights and constitution; Informal meeting between women of Christian and Muslim backgrounds	
DORTMUND Masterplan Integration (2008)	Acknowledgement; Equal opportunities and access; Potentials and participation of all population groups	Education, school and transition; intercultural opening of admin.; language promotion; children and youth leisure; political and social participation of migrants; cooperation and dialogue with migrant organisations; interreligious dialogue; people with insecure residence status; culture and inter-culture; health; age; employment; housing; family; monitoring and evaluation; Dortmund International; Action Plan for Diversity; Action Plan for Socially Integrative City; Integrated Urban Development/Urban Renewal	Interreligious dialogue and promotion of acceptance of non-Christian faith groups is a separate field of intervention Projects in this field: - Supply options for Muslim funerals - Cooperation with Council of Muslim Communities in Dortmund -> target group are representatives of administration, Muslim faith groups, other religious institutions and members of the 'majority population' -Model project religious course for Muslim pupils	Project in 2008: visit of mosques for members of urban administration, in the context of action field intercultural opening of administration
DUISBURG* Concept of Integration "We are You" (2010)	Resource orientation; Dialogue and participation; Individual integration instead of 'ethnisation'; Common urban identity; Neighbourhood scale focus; Lived inter-culturality (*Interkulturalität als Lebensgefü*hl)	Supervision of the Duisburg Council for Integration; Cooperation with migrant organisations; Work with integration 'guides'; Inter-cultural urban portal; Inter-cultural opening of the administration;	- No extra field of intervention - Mentioned in the context of action field inter-cultural urban portal, emphasis on non-essentialised concept of diversity (not only result of cultural, ethnic or religious difference, but also	Important role of Mosque in Marxloh-neighborhood highlighted; city cooperates with and promotes the 'Board/Council' of the Mosque; encounter location of Mosque (*Begegnungsstätte*) was co-financed with EU- and State-funds, as symbol of urban

Table 1. Principles, fields of action and the role of religion in integration concepts/plans in six cities of the Ruhr Area

CITIES AND PLAN	PRINCIPLES OF INTEGRATION	FIELDS OF INTERVENTIONS	ROLE OF RELIGION / IRA	FURTHER ISSUES OF INTEREST
			other elements)	interculturality and integration, not least to high media attention
ESSEN Concept for Intercultural work in the city of Essen – Sachbericht 2010"	Dual change in perspective 1. From traditional support of foreigners (Ausländerarbeit) towards inter-cultural orientation; 2. From traditional administration management towards new public management.and new public management. Integration as a two-sided process.	In 2010: Recognition and participation; Inter-cultural opening; Language, Health and education; Qualification, Employment and self-employment; Urban society and development; Sports; Art and culture General: Teaching in language of origin; Inter-cultural concept; Inter-cultural play and learn groups; Inter-cultural language promotion and training of parents; Inter-cultural mediation; Sport and migration; Cooperation with schools	In intervention field "inter-cultural mediation", interreligious dialogue between Muslim and protestant communities in migrant neighbourhood, location of Aya-Sofia Mosque Mosques are used as locations for a number of (non-religious) integration measures, e.g. education of youth for democracy, support of youth with homework, language learning, conflict management, family support etc.; but also inclusion of family- and youth-related problems in Friday prayer in Aya Sofia Mosque	Close co-operation of city's office for intercultural cooperation with integration Council (representation of migrant' interests in the urban context); action in 2006, "Muslims for Dialogue, Integration and Peace"
GELSENKIRCHEN Integration Concept Gelsenkirchen (2006?)	"Gelsenkirchen is dialogue-oriented": **D**emocratic, **I**nter-cultural/inter-religious; **A**ttentive and sensitive; **L**iveable and lively; **O**pen for learning; **G**ender-sensitive and just	Education in and outside of schools, children and youth work; Culture, leisure and sports; Economy and employment; Intercultural opening of institutions and the administration; Urban development, housing and transport; Social and health affairs	Inter-religious concept a proper area of action under intervention field "culture and sports" including four recommendations; these are quite general and related to inter-religious communication processes, but also to physical buildings	Participation of representatives of intercultural work group (*Arbeitskreis*) 'mosque and church' in formulation of integration concept, as well as of different Christian, Muslim and Jewish groups

2. However, religion and/or inter-religious activities are mentioned as ***important elements under other fields of intervention in almost all the plans***. In most cities, inter-religious activities or dialogues appear under intervention fields dealing with (inter-) cultural affairs (e.g. in Duisburg, Essen, Gelsenkirchen, Hagen and Hamm). In the city of Oberhausen they are attributed to the field of intervention labelled "dialogue and conflict". And in Dortmund, a project of inter-religious encounter (view below) was implemented under the intervention field "intercultural opening of administration".

3. The integration or inter-cultural plans mention a ***considerable variety of inter-religious or religion-related activities*** to be pursued. For instance, in the city of Dortmund, projects involve the organisation of Muslim funerals, to cooperate with the city's Council of Muslim Communities, a model project of religious courses for Muslim pupils and a visit of mosques by members of the urban administration. For the city of Duisburg, the "site of encounter" (*Begegnungsstätte*) of the Merkez-Mosque in the Marxloh-neighbourhood hosts a variety of inter-religious events and is considered a symbol of urban interculturality and integration; a similar project is planned in the city of Oberhausen. In Essen, neighbourhood mosques are used as locations for non-religious integration measures targeted at needy families and youth, e.g. education for democracy, homework support, language learning and conflict management. The great majority of interreligious activities mentioned in the integration plans refer to Muslim-Christian events.

4. With the formulation of most integration plans involving the participation of a large variety of stakeholders from State/municipal institutions and civil society, also ***representatives of religious associations have cooperated***. For instance, in Gelsenkirchen, representatives of the intercultural work group "Mosque and Church" participated in the formulation of its integration concept, as well as members of different Christian, Muslim and Jewish groups. In the city of Bottrop, six out of 38 members of the Council for the formulation of its Intercultural Concept were representatives of mosque and church organisations.

5. Although inter-religious activities can be considered an important element of today's integration plans and concepts of the Ruhr metropolitan cities, the ***nature of State support or involvement in these activities remains unclear***. Exceptions to this pattern can be found in the following cities: In Dortmund, members of the municipal administration are defined as one target group amongst others for the mentioned cooperation with the Council of Muslim Communities and also the inter-cultural opening of the administration. And in Duisburg, city officials are on the Board of the site of encounter (*Begegnungsstätte*) of the Marxloh Mosque that was also financed with federal State and EU-funds.

Discussion

A number of factors determine the relevance inter-religious activities and events have recently acquired in urban integration policies. Based on the studied integration/intercultural concepts or plans of the eleven metro districts of the Ruhr Area I want to specifically point to the following three:

- Changing integration paradigm
- Post-secularization of urban space and societies, and
- Increasing relevance of (inter-) religious actors in local governance processes

Changing integration paradigm: The inter-cultural paradigm facilitates the entry of religion in integration policies insofar religion is treated as a base element of people's 'culture' (Tezcan, 2006; Nagel, 2012). As pointed out in chapter 2, the inter-cultural discourse has become dominant in describing migration- or migrant-related policies and strategies at the local level (Weber et al., 2010). The discursive modification notwithstanding, on the programmatic level in many urban areas 'traditional' strategies continue to play an important if not leading role (Baraulina, 2006). This is also mirrored in the integration plans and concepts of the studied Ruhr Area cities, in which 'classical' integration measures in the field of language, employment and skills promotion tend to be included (view table 1). Nonetheless, the inter-cultural paradigm transpires through the principles (integration as a two-sided matter, oriented in people's potentials etc.), labels (a few cities have set up 'intercultural' instead of 'integration' concepts) and intervention areas of all the plans. The changing integration paradigm goes along with a change in perspective on public and 'diversity management', the latter implying a much higher focus on recognition, networking and encounter between public and civil society stakeholders in the urban context (Fincher and Iveson, 2008; Sandercock, 2003).

Post-secularization of urban societies and space: A recent strand of literature is discussing the growing importance of faith and inter-faith action in the context of the post-secularization of contemporary societies and cities (Beaumont and Baker, 2011a; Baker, 2008). Cities are labelled post-secular due to a presumed "re-emergence of faith into the public realm of civil society and the built environment" (Baker, 2008, p.1), a notion that stands in contrast to former postulations of secularity of public life in modern (Western) metropolises (ibid: p.1; metroZones, 2011a). This is connected to a growing migration-related ethnic and cultural diversity, bringing about pluralized claims on urban participation and space which specifically materialize in cities and the local context (Griera and Forteza, 2011, pp.113, 117). To the extent that migrants bring their claims from the urban periphery to the centre (Arnold and Nagel, 2011), this calls for an increasing attention to such claims by urban policy makers and planners e.g. in the context of negotiating acquiescence for the construction of representative religious buildings (Schoppengerd, 2009). The management of social and spatial claims of religious

groups, particularly Muslims, becomes also manifest in the studied integration plans and their focal areas of intervention.

Increasing relevance of religious actors in local and urban governance processes: Related to the former point, in the last decade religious actors and/or interfaith bodies have gained a larger role in local and urban policies (metroZones, 2011a, pp.7, 18; Griera and Forteza, 2011). Besides the per-se pertinence and pluralisation of religious needs and claims in cities, the literature posits at least three factors shaping this: First, an enhanced capability of religious and inter-religious organisations to make their voices perceived, e.g. due to institutional formalisation and socio-political positioning (ibid: 124; Penta and Schiffauer, 2011, p.252). And second, an opened policy window for such claims and actors, e.g. due to the religious illiteracy of policy makers and planners in Western 'secularist'[6] metropolises and the political dimension of religion and inter-religious relationships in the macro-political field(Griera and Forteza, 2011, pp.124-125). Both lead to (inter-) religious groups fulfilling an important broker-function – both actual and symbolic - between municipal stakeholders and disadvantaged communities, but also between potentially conflicting ethno-cultural or religious communities themselves (Baker, 2009, pp.7-8). And lastly, the inclusion of (inter-) faith actors in urban governance processes is consistent with new discourses on public and urban management in which networking and civil society participation constitute key normative components, however also budgetary necessities (Griera and Forteza, 2011, p.125; Baraulina, 2006, pp.31-32; metroZones, 2011a, p.19). In the studied Ruhr Area cities, particularly representatives of Muslim and Christian communities participated in the development of the integration and intercultural plans, thus suggesting their growing relevance as policy actors, but also the coupling of integration with security agendas down to the local level.

6. Conclusions

This paper shows that linked to changes in the migration legislation, integration has become an increasingly important policy topic in Germany in the last decade. This development has occurred on the national, as well as State and local levels. The specific relevance of the local level and particularly large cities for both conceptualising and implementing integration strategies lies in the fact that traditionally most foreigners have moved to urban areas, among these the former industrial hubs of the Ruhr Area. Thus, as of today most large cities in Germany have come to formulate local integration concepts or plans.

[6] I am consciously adamant to make a generalizing statement about a 'secularist' urban policy and planning tradition, since this holds only true for a very limited period of time in a very specific geopolitical context, i.e. the one of the post-World War II European Welfare State (view Eade, 2011, p.154).

In the last decades the ideas about integration and thus principles nurturing local integration plans have significantly evolved towards what has been coined the inter-cultural paradigm (Baraulina, 2006). In the last third of the 20th century so-called compensating integration measures dominated, seeking to counteract perceived educational or skills deficits of migrants. This deficit-oriented perspective on integration has gradually been replaced by the inter-cultural one, placing emphasis on reinforcing potentials (of immigrants e.g. in the 'ethnic economy', but also the multi-cultural urbanity as a whole), on interventions at the local (neighbourhood or city) level, and on the mutual responsibilities of majority and minority population groups to work towards improved urban integration and social cohesion (Weber et al., 2010, pp.1-2).

While traditional measures for the structural integration of migrants still tend to engage the larger part of local integration policies and budgets, strategies focusing on the promotion of urban socio-cultural understanding and conviviality are on the rise. This paper argues that thereby the inter-cultural paradigm has facilitated the entry of religious themes and inter-religious activities and built up the voice of religious actors (i.a. inter-religious bodies) in local integration policies and planning processes. It develops this and other arguments based on the analysis of integration concepts or plans in 11 metropolitan cities of the Ruhr Area in Germany.

Apart from the inter-cultural paradigm, the paper relates the inclusion of religion and inter-religious activities in urban integration agendas to at least two further factors. First, the proliferation of ever more pluralised religious needs and claims in the urban context, primarily, albeit not exclusively, voiced by urbanites with a migration background. And second, related to the former point, the growing importance of religious actors in the field of local politics. The "opened-up policy window" (Griera and Forteza, 2011, p.125) also needs to be considered in conjunction with transforming wider policy discourses on urban and diversity management, in which civil society and migrants' participation as well as public-civic networking constitute key ingredients. Many interreligious structures and activities in Germany have existed for decades (Klinkhammer et al., 2011) and thus represent civil society activities ready to be built upon in integration programmes.

In the author's view the inclusion of (inter-) religious activities and bodies in urban integration agendas, poses both potentials and challenges to cohesion-oriented future urban diversity management. The potentials are, that the dialogue between different religious groups may effectively enhance options for inter-cultural understanding and bring to the fore the experiences of culturally and socially marginalised groups, considering that many religious groups act as advocates on behalf of the latter. The challenge lies in that the politization of inter-religious dialogue may foster cultural/religious essentialism and the fixation of participants to their ascribed 'cultural' or religious orientation, particularly in the context of overall heated-up political climates. This may eventually work against creating space for "negotiated or performative identities in which secular and religious aspects intermingle" (Baker,

2009, p.7; also view Tezcan, 2006, p.31; Klinkhammer et al., 2011, 243, Weber et al., 2010, p.15).

It also needs to be said that interreligious activities in the context of Ruhr Area integration plans predominantly attend to Muslim-Christian relations - not least as a result of regional demographics. However, since also other religious groups have become claim makers in urban and public space it seems imperative that their concerns are not left out in the process.

The analysis carried out in this paper leaves open a number of questions, notably about the exact motivations of municipal stakeholders to involve (inter-) religious agents and activities in integration policies and plans, their role in these activities and the related processes of co-operation. These aspects will be addressed in the mentioned research project "Inter-religious activities and urban governance in the Ruhr Area" the author of this paper co-directs and will thus hopefully provide complementary insights to the topic.

THE GREEN SYSTEM AND THE RETICULAR APPROACH IN THE ITALIAN PLANNING INSTRUMENTS

Filippo Schilleci [1], Annalisa Giampino[2], Francesca Lotta[3]

Biçimlendirilmiş: İtalyanca (İtalya)

Abstract

During the last decades, the importance of Urban Planning's role to safeguard green areas and to build green chains gradually increased. The latter played not only an ecological function to requalification the city's environment quality, but it becomes also an occasion to find social space.

In particular the approach changed, from a quantitative to a qualitative point of view. The first procedure reaches to achieve a minimum standard while the second one aims to satisfy ecological and environmental necessities.

The overcoming of a wrong punctual approach and the use of a new reticular one has origins in territorial scope where the new model is used to maintain and improve the ecological network. The latter encourages the ecological exchanges within different natural areas, which in this way, are not converted to island, avoiding a massive loss of species, both plant and animal (Bennett, 1991; Forman, 1995; Jongman, Pungetti 2004).

The transposition of the ecological network into an urban dimension led to the green chain beginning. This new model is not completely implemented by regulations even if often it has been part of the urban planning practices (Angrilli, 2002; Peraboni, 2010).

In the present proposal paper a dissertation about the different approaches to the green chain is proposed.

Indeed the instrumentation of Italian local planning has undergone transformations in the form and the substance: from the structure of Master Plan (PRG), planning instrument legislated by LUN 1550/42, to a new form plan carried out in Municipal Structural Plan (PSC), Urban Building Regulations

(RUE) and Municipal Operative Plan (POC) and legislated by innovative laws of regional planning

1. The urban green spaces in new Italian urban planning

Pondering on the planning system innovation and its implications as to the systemic and reticular topic of the green on local scale, just means to give an account of the evolutive way/path of the discipline in relation to the territory governance and to the "re-founding role" exerted on it by the growning debate developed around the environmental matrix themes (Gambino, 1997; Filpa, Talia, 2009). If today we're able to consider, as an acquired cultural fact, the centrality of the theme as regards urban spaces and green areas planning, yet we have not to forget the difficulty of bringing this sort of consciousness into the logics and techniques of the piano. Moreover the asymmetry between theoretical conquests and operative applications represents a peculiar feature about the history of the discipline, characterized by a chronic slowness in relation to the technical and cultural evolution of the plan. Effectively, the urban planning, that nowadays succeeds in dealing with the theme of urban green, as a new and further projection plans, still represents an exception to the rule.

On the other hand, making the environmental problems as to an attraction within the urban plan has been the outcome of a gradual process of disciplinary and legislative reformation whose matrixes have to be found in that system of laws and planning practices grown between the Sixties and the Seventies. It is a matter of pioneer experiences, to which the current discipline of territory governance is indebted, that -by the identification of the complex social, productive and environmental component of the extra/suburban area- have subtracted the agricultural areas to the logics of property management, which identify them as places-limbo waiting for future construction (Campos Venuti, 1994; Oliva, 1995).

Reformist plans, after they had metabolized the systemic approach to the second generation urbanism, they promoted, in fact, new urban and environmental politics, stimulating a progressive evolution of relations between ecology and urbanism, seeking operational tools to reconcile ecological protection with development and recovery policies.

In the late Sixties, we're witnesses to a ferment of national legislation which will mark a new approach and a new attention for the extra/suburban areas, attempting to give them back at least that productive role denied by the previous plans. These are the years of the gradual reform of urbanism, where is trying to regulate, on national level, the dramatic use of land. In this case, both approvals of the L.n. 765/67, c.d. legge ponte, and the D.I. 1444/68 mark an important step in the protection of agricultural areas for many reasons: a limit of construction activity, in the absence of fundamental instruments of planning, is imposed; planning practice is spread; the extent required density for the private construction is determined. However, apart from a few exceptions, use plans were unable of being carrier of innovation introduced by such laws, simply classifying the

agricultural areas as E zone uncritically and generalizing constraints and indexes land. In many cases it's also happened that some plans would anticipate the reform laws in a fruitful exchange between practice and theory (Campos Venuti, 1991). It's so clear, for example, how the Reggio Emilia's Master Plan of 1967 provides a model for the articulation of the agricultural areas in three zones, defined on the basis of specific characteristics, productive and environmental, which represents nowadays a lesson in method difficult to overcome. It's in the path traced by this experience that, between 1989 and 1991, in the same town of Reggio Emilia, a "Preliminary urban-ecological Draft Plan" (Reu) takes place although it doesn't seem like a prescriptive instrument but a preparatory study in drafting the report on MASTER PLAN, fixing some basic elements about the territory governance and the plan forms derived from it.

Reu, in fact, establishes the final recognition of the necessary integration between urban planning and environmental planning; it emphasizes the importance of local scale, discussing crucial questions and environmental issues up to now treated on wide scale; it encodes a multidisciplinary system of analysis able to seize the environmental dimension in its own dimension quali-quantitative; it's about the green issue not only in terms of protecting but specially with regard a planning profile.

For more than a decade, these themes have been identifing the stakes for the re-definiton of the relation between towns, environment and pianos with regard the recent laws governing local territories according to the new forms of piano introduced by them.

Rather than going into the merit of the controversy about what has to be intended citing "territory governance" as a comprehensive term, seeing as a substantial problem and not purely nominalistic, there are certain details also ought to be mentioned becuse they mark a new period of the italian practice in urban studies which, gained the awareness about the role of green areas, has focused its reforming vis on the plan as to an instrument, on its form, on its contents and techniques. In these years of heated debates and experimenting, a reform of the local urban planning has now occurred, in its two distinctive components: the structural and the operational one. Regarding with the theme of urban green, the new model of the plan permits to think, in its programatic and structural dimension, a frame of sense around a project for the green areas, shared and not-negotiable. As Federico Oliva says (2008, p.5):

«A really structural form of the general plan is essential to ensure an effective and efficient Governance of the Territory, because within the general strategy that it expresses, it will be possible maximising the tools to use: from the regulatory plans for the existing to the negotiating programs for the trasformations, from the urban policies to the infrastructure projects, from the architecture project for urban quality to an environmental one, for the construction of an ecological network, in a crucial mix of planning, projecting and governance, for which,

sooner or later, we will have to confront a fair italian translation to the term planning».

Within the new instrument, it seems to be possible focusing the action towards a territory project able to realize a connection system between free urban zones and extra/suburban open spaces in order to contain the urban pression and to identify the integration medium between settlement development and natural values and agri-productive conservation. It's a commitment with a dual functional value: ecological, because creating a system around the areas of naturalistic interest permits the natural biological exchange; anthropization, because it strengthens the fruition system of such areas for social and recreational purposes.

Thanks to the case studies of Reggio Emilia and Ferrara we're trying to confirm what we have been explaining teorically up to now, focusing the evolution of the local plan as to the theme of urban green areas. It's an erratic course but, as both cases are demonstrating, costantly changing.

2. The evolution of urban green spaces in the plans of Reggio Emilia and Ferrara.

The selected case of studies – Reggio Emilia as to the instruments of planning (1999) and Ferrara as to the Municipal Structural Plan (2009) - are two emblematic examples to understand the evolution of the systemic approach and, subsequently, of the reticular approach of urban green areas.

The two examples, concerning the first one as the evolution of the other, from an historical to a substancial point of view, make reference to the Regione Emilia Romagna that always, in Italy, improve the structural reform of the urban planning.

Since the early Seventies (70's), thanks to Ian McHarg and Nan Fairbrother, the new ideas for a strategic landscape planning have been growing in order to deliver multiple functions and for enhancing the peri-urban environment and the beginning of the green infrastructure approach.

In the urban planning, the environmental issue becomes an important and central theme and the result is a rethinking of the relationship and interface between development – environment, that thrown in crisis growth patterns followed until now.

The plan of Reggio Emilia, which is part of the third generation's current of the Italian planning, expounds the transition from a culture of expansion to a model of trasformations. The plan of Ferrara, instead, has been consolidating not only the policies for the existing recovery, but also it has been trying to connect, like a network, those areas saved from transformative choices and gives them new social meanings.

The situation of Reggio Emilia, before the new plan, was primarily characterized by an high volumetry introduced by the plan, since 1985, and by the location of such projects, which would saturated and compromise possible green areas of which the plan was lacking.

However, the new instrument of 1999, signed by Campos Venuti, was an opportunity to define and refine, for the first time in the Italy, the change to the rebalance of excess volumes and to the recovery of green areas

A practical plan with a few principles and with simple rules aimed not only to guarantee equality of treatment in respect of property management, but also to reduce the consumption of soil and increase the environmental compatibility and the permeability of the soil to urban and nevertheless, to increase green areas in both choices: in the public areas, that in the private (Campos Venuti, 2008). The instrument, in addition to defining the innovative instrumentation perequazione - development rights - intended to create an ideal combination of built and empty, unable to improve the quality of the city.

The plan of R eggio Emilia, intended as a new planning season in which urban planning became aware that the quality of a place depends on the strategies related to environment and nature in the city. There was the transition from an interest in environmental protection, so far marked by a size of a territorial area, to the recognition of the intrinsic relationship between the environmental and the city.

In Italy the interest about environment in the plan of Reggio Emilia was entirely new: the objective point was that the soil was to be permeable and compact. The improvement begins to be read as an example of a new method of qualitative evaluation of key environmental resources (Oliva, 1999; Peraboni, 2010).

New standards were defined, and showed a break with the past, the quantitative characteristic of the only instrument that governed the urban green areas: from the low values of the D.I. 1444/68, the urban planning comes to the indicators of integrated processing, and those of permeabilization of the soil or the consumption of environmental resources (Campeol, 1999).

The green areas are enhanced with functions and the principal concerned the biological necessity, with main capacity of environmental regeneration of the urban areas. For the first time the Italian urban planning - even if experimentally - introduced through the local plan, issues such as the protection of plant and animal habitats (Campos Venuti, Galuzzi, Oliva, Vitillo, 1995)

So the ecological and environmental potential emerged and levered on new structural type: the network.

The network of the green areas, called also the green infrastructure, met a number of planning issues (Benedict & McMahon, 2006; Mell, 2009). In the United

States, since 1990, «green infrastructure was identified as a strategic, multi-scale approach to land conservation and land use planning, with particular emphasis on 'life support functions' of natural processes or ecosystems. In England, the Community Forest programme was established in 1990 by the then Countryside Commission as a pilot project to demonstrate the potential contribution of environmental improvement to economic and social regeneration» (LUC, 2009, 9). Today Green infrastructure has been discussed as providing theoretical, policy and practice led solutions to the continued demands placed upon urban areas. Drawing on a number of principles from Landscape Ecology it promotes the maintenance of ecological resources within connected networks of green spaces, watercourses and greenways.

Green infrastructure planning also supports the sustainable thinking and the adaptation to address current issues of town while proposing innovative, and often community led initiatives to address them (Benedict, McMahon, 2006; Mell, 2011; Tzoulas et al., 2007).

It's possible to define an interconnected network of green space like the element that conserves natural ecosystem values and functions and provides associated benefits to human populations. Green infrastructure differs from conventional approaches to open space planning because it looks at conservation values and actions in concert with land development, growth management and built infrastructure planning. The system of green wedges penetrating and interconnected, was designed to recover and strengthen the system of eco-biological connections and guaranteed the continuity of flora and fauna within the urban areas.

In Italy one of first example of new approach is Reggio Emilia that began with an experience of integrated urban planning and guided by the new systems approach.

It, even though in theory alluded to quality standards, could not start a total qualitative review of quantitative standards.

The proposed model is concretized for the exclusion of new urban expansions and new principles of treatment of green areas. It acknowledged and defined, increasingly, urban complexity, but was unable to articulate freely. The motivation for this is attributed to the rigidity of an inflexible tool, the MASTER PLAN.

For this reason the plan Ferrara corresponds to a new plan oriented to a total integration between planning and ecology. Experience, since 2009, defines a more flexible and less rigid plan, divided into structural and operational. Its environmental system, which is derived from the word "ecological network", not only maximizes the effects of environmental regeneration, but it guarantees a better use of environmental areas that are enriched with new meanings (Schilleci, 1999; Angrilli, 2002; Bennet, 2004; Peraboni, 2010)

The ecological network established and consolidated at the territorial level, winning a local space with new meanings. Infact the Green infrastructure has its origin in two important concepts: linking parks and other green spaces for the benefit of people, and

preserving and linking natural areas to benefit biodiversity and counter habitat fragmentation (Bennett, 2006, 8)

In the urban areas the model suffers more interesting specifications and news articulations (Lotta, 2011). The features, taken by the environmental system in urban areas, is inherent its function, no longer purely environmental. This function is enhanced by social role, thanks to the inclusion of facilities and public places.

In urban areas, to protect biodiversity, preserve and promote no longer remains confined to the environmental meanings, but it crosses in the urban ecology, also comes to the social component of the urban habitat: the human component.

In Ferrara, the city is understood as a large system of relations and an intimate connection between environment and society. In this way, the plan assumes a role of contact between the community and the green area, which gives way to a genuine need for protection of environmental resources (Bodin, Crona, Ernstson, 2006). Restore contact between man and nature means to start an alternative city defined by the planning instrument "green city", that binds the different parts and peoples through a network of connections and places of ecological regeneration and self-production, where it is possible created a new social reality, maintenance and quality assurance of the human habitat.

The MUNICIPAL STRUCTURAL PLAN of Ferrara leverages on value of the collective space of the environmental system and the green network for future development of the city. The ultimate aims of integration, between ecology and urbanism may affect the involvement of the inhabitants in the active management of common goods and their development, both as a incentive and growth of a sense of belonging to a place, and as a measure to safeguard of environmental areas from carelessness (art. 2 NTA, MUNICIPAL STRUCTURAL PLAN).

2. Conclusions

Since 2009 the construction of the environmental system comes to the definition of urban ecological network and promotes, in addition to environmental protection in urban areas, the construction of the community.

The city recovers the environmental dimension in a complex system and leaning toward «luogo moderno reale e simbolico di esercizio civile» (degli Espinosa, 1990, 236) On the other hand Castells (1996) recognizes the environmental issue

and the social forces, that draw life from it, some of the main engines of transformation of contemporary society.

The case studies highlight that the environmental system characterized by a heterogeneous themes concerned, ever more, the quality characteristics.

In a different way, from a purely environmental issue, introduced by Reggio Emilia, the case of Ferrara open to a more urban and social aspects, in which environmental quality is the core component. It is necessary greater openness and integration of urban planning in other disciplines to resolve the environmental issue. And it's likely that the new structure of the Plan will automatically trigger this effect?

The lack of an established practice of co-management planning in the urban environmental heritage has its negative repercussions, but, at the same time, could the new form of plan undermine the only approach so far regulated and generally followed?

Further compounding an already difficult situation is the predominance of a strong matrix urban centric planning practices aimed at solving spatial problems of urban development. This is an understandable interest, if we reread the phenomenon from the training phase of the discipline, was born and developed to pursue and address the growth of towns and cities, and today shows its inadequacy in the changed context, where instances of redevelopment, modernization and transformation of the existing, need for protection of environmental resources prevail (Gambino 1994; Ricci, 2005).

Obviously, as reported by Oliva (2008), we cannot propose a planning model such as that established by first law of 1942. It is necessary apply the experience more fruitful through the Structural plan.

A plan has to provide management flexibility, to intervene on green areas, to establish decisions essential and not negotiable. If, therefore, there must be a general strategy to guide the process of land transformation is equally true that in Italy, the need for urban reform series, it becomes ever more essential.

FORMAL PLANNING REGULATIONS VERSUS THE NEED OF RESIDENTS: THE CASE OF DAR ES SALAAM/TANZANIA

Dr.-Ing. Wolfgang Scholz[1]

Abstract

In Sub-Saharan Africa urbanization is progressing at a rate unprecedented in human history. In most countries, the state is not in a position to apply a responsive legal framework and to mobilize adequate resources to guide urbanization. A major obstacle are the outdated legal framework and the inappropriate planning concepts inherited from colonial governments which often contradict post colonial policies and are unsuitable to respond to rapid urban growth.

The chronic underperformance of the public sector vis-à-vis rapid urban growth caused a large cumulative backlog in the provision of building land and basic services. In addition, uncontrolled informal urbanization has often caused dysfunctional settlement lay-outs and urban structures.

In Dar es Salaam, Tanzania informal settlements cover more than 70% of the city area because the statutory system cannot provide sufficient building land and settlers have to find plots on the informal land market. It shows the need for a new approach to statutory planning in order to guide urban development effectively, to create more functional settlements, to assist the urban poor to access affordable plots with basic services, and to release financial assets for the urban economy.

The paper will present results of a joint research analyzing empirically factors that determine space standards and land use in prevalent types of formally planned and informal settlements in Dar es Salaam. Goal is to identify parameters to ascertain the long-term suitability of settlements, understood as being functional and flexible to respond to future demands reflecting from socio-economic development.

At the centre of the research are the livelihood strategies of the residents. The overall aim is to evolve a responsive framework for statutory planning including spatial standards for settlements that reflect the current reality of urbanization under poverty while addressing future needs. Main actors will be local leaders and the community to ensure sustainable planning.

1. Introduction

In Sub-Saharan Africa urbanization is progressing at a rate unprecedented in human history. In most countries, the state is not in a position to apply a responsive legal framework and to mobilize adequate resources to guide this rapid urbanization. Some of the obstacles are the outdated legal framework and the inappropriate planning concepts inherited from colonial governments. They often contradict post colonial policies (Ambe, 1999) and are unsuitable to respond to rapid urban growth.

The chronic underperformance of the public sector vis-à-vis rapid urban growth causes a large cumulative backlog in the provision of formal building land and basic services and leads to growing informal settlements. The outcomes of uncontrolled informal urbanization are dysfunctional settlements and urban structures (Scholz, 2008). The designation of specific land uses by planning authorities, the range of plot sizes and the reservation of space for public uses such as social and technical infrastructure, however, are important tasks to organize a harmonious urban development for the benefit of all (UN Habitat, 2008). Statutory urban planning has to balance the development opportunities of individual plot owners with public welfare and common interests.

Today, in Dar es Salaam, Tanzania informal settlements cover more than 70% of the built-up area. They have emerged primarily because the statutory system cannot provide sufficient buildable land for the demand. Inappropriate planning standards and inefficient land allocation procedures are serious bottlenecks. Most urban inhabitants who aspire to own a house in urban areas have to buy plots on the informal land market. The development of informal settlements does, however, not guarantee functional settlement structures, efficiency in the provision of basic infrastructure and adequate security of tenure (Kombe and Kreibich, 2007).

For urban residents and the poor in particular, a residential plot represents income and employment generation opportunities and essential livelihood assets. However, income generating activities on the plot can be supported or hindered by planning regulations. Additional costs can be caused or avoided depending on what planning regulations and standards are being applied. Too rigid standards, like exclusively residential zoning where no other uses may be allowed, can have a restrictive impact on livelihood strategies of urban settlers since it can make income generating activities difficult to execute. On the other hand, the absence of any formal regulation in informal settlements can also hinder income generating activities due to inter alia restrained accessibility when densities increase or land uses conflict each other. The absence of regulations can also have a negative impact on livelihoods due to unhealthy living conditions and overcrowding. Studies conducted in informal settlements have confirmed that unregulated densification coupled with increased income generating activities can cause threats to public health and sustainable livelihoods (Kombe and Kreibich, 2007; Sheuya 2004).

The same applies as well to planned settlements as the research conducted hitherto revealed. They undergo a process of informalisation due to the lack of development control on the ground and a high pressure on land for commercial land uses and multi-storey constructions.

In many British colonies, the British Town and Country Planning Act of 1947 was adopted uncritically, and even updated versions of the legislation retained the major features in several countries (Payne, 2001). In Tanzania, the British Town and Country Planning Act of 1947 was adopted via the Town and Country Planning Act of 1956. Land use planning standards including land use zoning were based on the model of a low density, green city that reflected the ideals of a colonial version of the "Garden City". This concept may have been adequate for colonial towns with modest growth that were physically and socially contained through restrictions of rural-urban migration. But it cannot cope with the high urban growth rates since independence and, above all, it cannot be implemented by weak public administrations with limited resources (Ambe, 1999; Payne, 2001). Furthermore, it is hardly suitable for the current process of urbanization under poverty where only small plots can be afforded by the majority of settlers. After independence, in Tanzania the colonial planning standards were modified but with little attention to post-colonial socio-economic realities. The 1956 Town and Country Planning Law has only recently been reviewed (Urban Planning Act 2007) but by and large the contents have remained the same (Basteck et al. 2007). Even the internal draft (2011, see Table 1) for the recent revision of plot size standards is far beyond of what urban poor dwellers can afford and does not support sustainable and compact urban development or optimal use of scarce resources including public finances for basic infrastructure services.

Table 1: Proposed revised plot size standards (in brackets current standards)

Density	**Plot size in sqm**	**Maximum coverage**	**Maximum plot ratio**	**Minimum setbacks front**	**Minimum setbacks side**	**Minimum setbacks rear**
High	300-600 (400-800)	40%	0.4	3 m	1.5 m	1.5 m (2 m)
Medium	601-1200 (801-1600)	30% (25%)	0.3 (0,25)	3 m	3 m	3 m (5 m)
Low	1201-1600 (1601-4000)	25% (15%)	0.25 (0,2)	5 m	4 m	5 m (10 m)
Super low *(new category*	1601-2500	20%	0.2	7 m	7 m	7 m

Source: Ministry of Lands, Housing and Human Settlements Development (Internal draft 2011, not published)

Currently, urban land use planning standards still require large plot sizes that are too expensive for the Government to service and unaffordable by most social groups, especially the urban poor. In a paper presented in the expert workshop of this research project in August 2011, W.J. Kombe highlighted the costs for different infrastructure standards in relation to plot sizes. He concluded that for the stipulated plot sizes infrastructure costs would be prohibitive. This reduces the ability of local government to fulfill its obligations of service delivery and contributes to the shortage of building land.[2]

The unmet demand for affordable building land is thus largely covered by the informal land supply system which operates with average plot sizes of about 100-200 sqm. It can thus be argued that inappropriate planning standards, especially the plot sizes, have compounded the problems of urban governance, mushrooming informal settlements and the absence of basic infrastructure services even in most of the new planned and surveyed areas (own fieldwork 2011).

For decades, there has been hardly any planned residential settlement in Dar es Salaam that meets the needs for low-income groups. Even areas planned and designed for the urban poor (so called high density areas), where plots were offered below market prices, did not reach the target groups because these could not afford the land prices requested or were bypassed in the allocation process. In some cases, rising land prices even forced residents to sell allocated plots (own fieldwork 2010).

A recent initiative of the Government of Tanzania (Dar es Salaam 20,000 Plots Project) which aimed at providing planned, surveyed and allocated plots to reach all income groups has again failed due to high service costs, disadvantageous locations and non-transparent allocation procedures (Kombe and Kreibich, 2007). In many locations of the 20,000 Plot Projects prices for plots skyrocketed from an initial average of TSh 400,000[3] for a high density plot (charged by the Government upon allocation) to TSh 5 Mio. (price in the land market) in less than five years. This is more than ten times the official price charged and reflects the development of land prices for surveyed areas (own fieldwork 2011).

Most of the urban poor, therefore, can only find a place for living in the informal settlements where they can access smaller plots at affordable prices for unserviced land. In exchange they will have to cope with higher costs for services and utilities like urban transport and water from street vendors.

[2] The cost of basic infrastructure services in comparison to full service infrastructure (i.e. including private water pipes and sewage) only doubles in case of small plots of 100 sqm. However, for larger plot sizes, i.e. according to the official land use planning standards (min. 400 sqm, see Table 1), the costs increase by more than three times. This is mainly due to the increased total length of infrastructure service lines such as roads, water pipes, storm water drains etc. in relationship to the number of costumers or households being served.

[3] 1 € = 2.100 TSh in February 2012

The lack of buildable land provided through the formal system has also increased the development pressure on existing settlements. The growing commercial and service sector in the current market-led economy has given rise to land use changes towards commercial activities in residential areas. Many property owners are changing their houses to accommodate economic activities such as shops, offices, and workshops due to higher rent expectations. Land use changes from residential to commercial activities are taking place since plots for commercial activities are not sufficiently available on the land market due to an insufficient designation of plots for commercial activities in former and current planning schemes. (own fieldwork 2011)

Another aspect of the pressure on land is the redevelopment of plots with multi-storey buildings following increased land values. While this development tends to support a more compact city, most construction activities under redevelopment, however, ignore the need for adequate set-backs leading to inadequate space between buildings. The planning standards in Table 1 do not include multi-storey constructions and their higher demand for setbacks. They seem to be designed for single storey buildings only and do not deal with floor ratios or setbacks in relationship to the height of the building (own fieldwork 2010).

These facts show the need for re-thinking central elements of the statutory land use planning system focusing on the increasing pressure on land, the need to guide urban development effectively, to create more functional settlements, to assist the urban poor to access affordable building land, and to release financial assets for the urban economy.

The land use planning system also needs to reflect hitherto unused capacities at the grassroots to supplement the role of public administrations in achieving strategic urban development objectives. As far as possible it needs to incorporate local administrative institutions and locally-based conflict resolution mechanisms. This does not mean in any way that formal institutions have to be replaced. The idea here is to explore mechanisms and strategies to reassign land use planning in response to the changing socio-economic and physical conditions.

2. Fieldwork in selected settlements of Dar es Salaam

The research analyzed formally planned and informally developed settlements in Dar es Salaam, Tanzania. Aim was to find out to which extend the formal planning regulations are applied and efficient, which current development processes are going on, how these processes impact on the livelihood strategies of the residents and which land use conflicts mainly take place due to the lack of development control.
Focus was to explore current processes of land use changes, densification, intensification, the livelihood needs of the residents in terms of space and land use as well as the impact and efficiency of statutory planning regulations including land use related conflicts. Land use conflicts in residential planned areas versus the uncontrolled/unguided mixed land use development were examined and the negative ef-

fects of such developments towards the adjoining land uses, residents and the overall functionality of the settlements were studied.

2.1. Applied methods and working steps

Seven settlements were selected for fieldwork (see Table 2): Planned and unplanned settlements under high densification pressure (case Sinza A1, Gongo la Mboto B2, Kawe B3) and an unplanned settlement which underwent a process of regularization and infrastructure upgrading (case B1 Sandali). Cases Mbezi Beach A2 and Bunju A4 serve as an example for settlements developed according to the formal planning standards with respective plot sizes. Case A3 Chamazi, however, is a planned settlement as well but as a model project with far lower standards of plot sizes of 144 sqm which is half of the plot size of Sinza A1 (288 sqm) which was developed as a site-and-service project under the World Bank scheme in the 1980s (see Table 2 and Fig. 11).

Table 2. Typology of Case Study Settlements analyzed

Typology of cases	**Planning approach**	**Selected Case settlement**
A1) Planned settlement under high development pressure	Site-and-service scheme of the 1970s	Sinza A1
A 2, A 3, A4) Newly planned areas	New planned development areas at the periphery	Mbezi Beach A2, Chamazi A3, Bunju A4
B 1) Upgraded informal settlement	Regularized informal settlement	Sandali B1
B 2, B 3) Newly informal settlements	New informal settlement at the urban fringe	Gongo la Mboto B2 and Kawe B3

A first expert workshop was held on July 8th 2010. It aimed at discussing and reviewing of the proposed research issues and research questions as well as at identifying potential case study settlements. After the workshop, intensive fieldwork started in the case study settlements of Sinza A1 and Sandali B1, followed by a second fieldwork in Mbezi Beach A2, Kawe B3 and Chamazi A3 in 2011 and Gongo la Mboto B2 in 2012. During the second expert workshop, held on 10th August 2011, preliminary findings from the first four case study settlements were presented and discussed.

The methods applied during the fieldworks were expert interviews to identify areas inside the case study settlement for in-depth survey and to conduct the interviews, followed by intensive surveys and land use inventory, semi-structured interviews with residents and operators of potential disturbing activities. Strategy for the selection of interviewees focused on identifying information rich cases or cases with a high conflict potential including disturbing land uses such as noise, dust pollution, solid and liquid waste production. These problems are largely associated with activities such as bars, repair workshops, retails business and function or congregation halls. Most of these land uses have emerged against official zoning regulations and land use change regulations but contribute to the income generation of the operators

and meet the demand of clients. However, they can conflict with livelihood activities of the surrounding neighbors.

Table 3. Overview on interviewed residents and operators of businesses

Case study settlement	Commercial operators	Residents
Sinza A1	4	16
Sandali B1	5	23
Mbezi Beach A2	3	24
Chamazi A3	Not available	5
Kawe B3	2	19
Bunju A4	4	19
Gongo la Mboto B2	4	26

The interviews reflect the wide range of the socio-economic figures of the residents in the different settlements (see Fig. 1 - Fig. 5). The relatively high proportion of interviewees above an age of 50 years was intended to collect views from residents who have stayed longer in the settlement and can provide a picture on the land use changes and development trends.

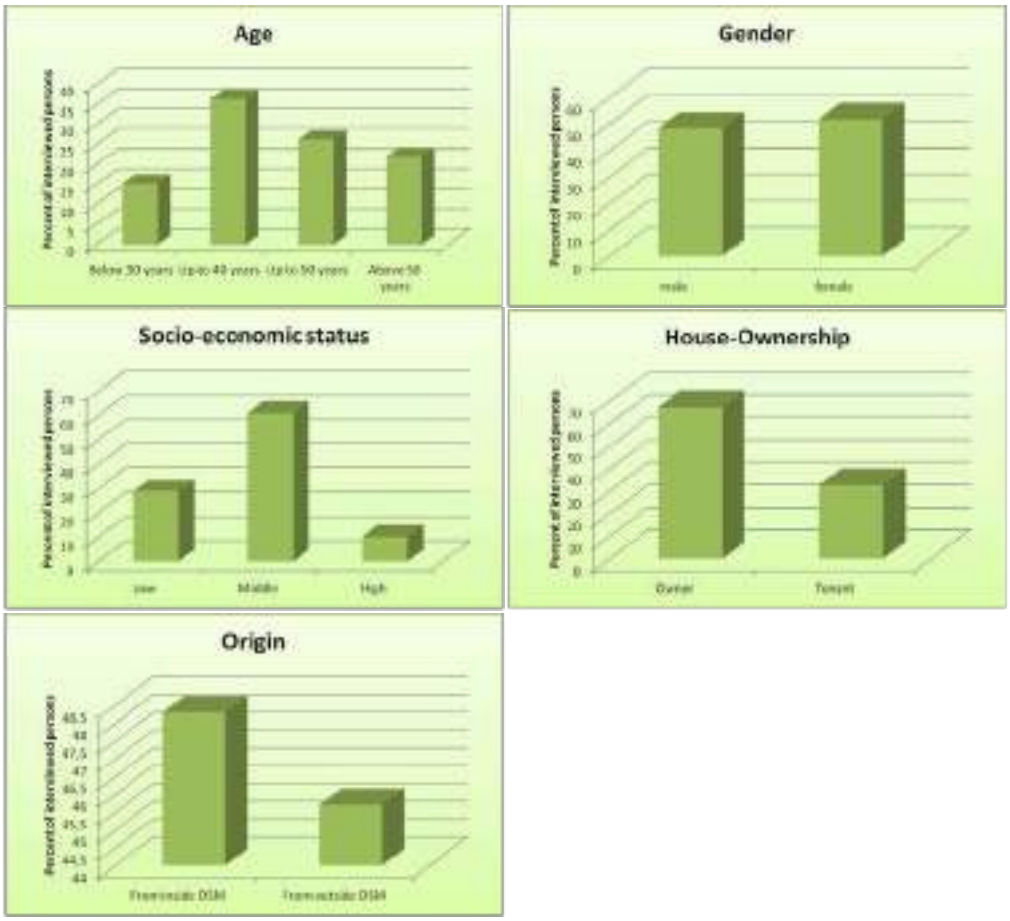

Fig. 1 - Fig. 5: Socio-economic data of the interviewed residents

When looking at the socio-economic figures, the interviews reflect the different income settings. B1, B2 and A3 are rather poor, while A1 and A4 is mainly for the middle class. A2 has been designed for the upper middle class but still rather poorer tenants live there temporally until the main construction is finished.

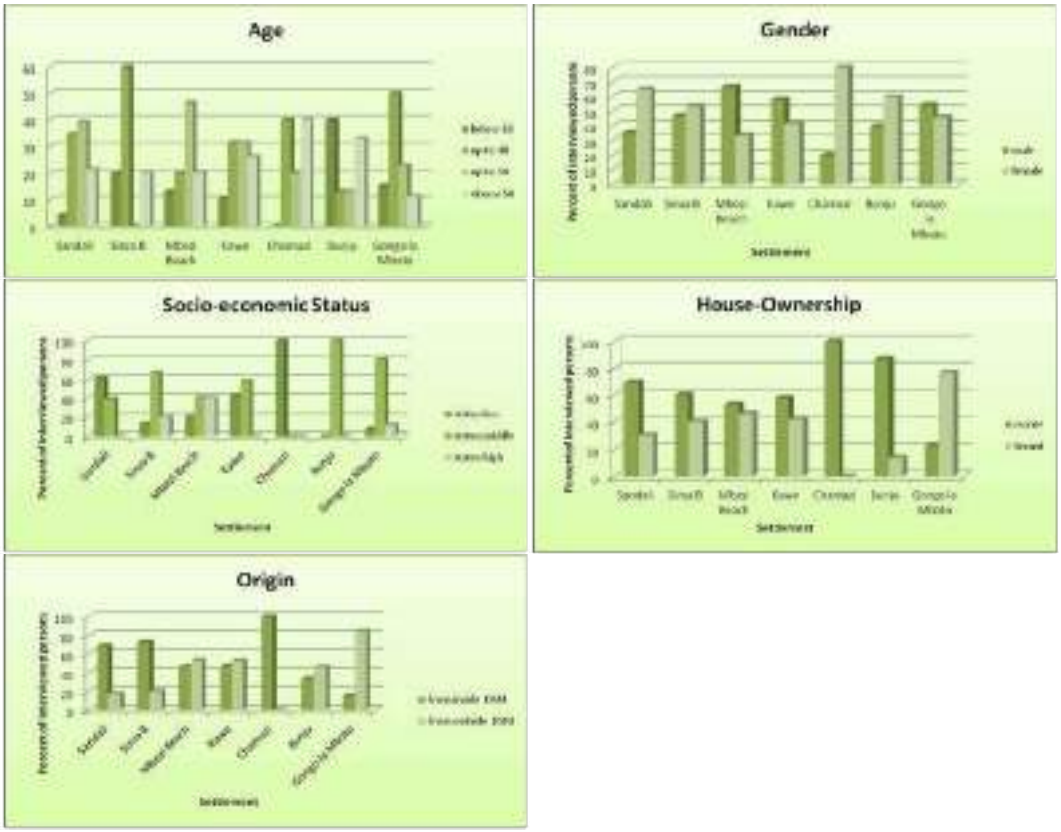

Fig. 6 - Fig. 10: Socio-economic data of the interviewed residents for each case study settlements

2.2. Findings from the case study settlements

The findings from the fieldwork were enriched by findings and conclusions from literature and expert interviews. The findings are differentiated along structure and land uses of the settlements, conflicting land uses, planning regulations and decision making, future development and wind up with a discussion whether planned settlements do not differ much from informally developed areas.

Structure and land uses

In all settlements (Fig. 12-17), the majority of the plots are for residential uses. The percentage of tenants is relatively low. In A1, B3 and A2, tenants, however, represent a significant number. For the rather affluent area A2 the figure is surprising but can be explained because many plots are not yet fully developed or construction has not yet started. In order to enhance the security of tenure, landlords are renting part

of the plot or the unfinished construction to avoid encroachment by other potential buyers (own fieldwork 2011).

Commercial uses are mainly located along main roads and at the fringe of the settlements (see Fig. 12-17). Locational preferences of the operators of commercial activities along the main roads are associated with the desire to ensure accessibility and proximity to the major costumer flow channels. However, the resulting functional structure of the settlement is a clear contradiction to the official neighborhood design concept in Tanzania inspired by Clarence Stein (1929) which designates land for communal services and commercial uses at the centre and not at the periphery of the neighborhood.

While this finding reflects the common understanding of locational preferences of such land uses, the contradiction to the official planning concept reveals an important shortcoming. Formal layout plans in Tanzania are bound to the neighborhood planning concept which designates and permits commercial activities only in the neighborhood centre but not at the periphery along the main roads. Therefore, market mechanisms are reversing the designation of the zoning concept since commercial activities tend to locate at the periphery especially along the main roads. This will have severe negative impacts on the functionality of the settlements since plot sizes, parking areas and set backs of the former residential planned area are not designed for such commercial activities and their spatial and functional needs.

Conflicting Land Uses

The fieldwork revealed that disturbances for residents caused by conflicting land uses are mostly related to noise from bars, music halls and religious buildings, less from commercial activities like workshops or repair workshops. Income generating activities such as shops, pharmacies, tailoring shops are generally more tolerated while leisure activities such as bars and worship places are less tolerated by residents in case they cause disturbances. Problems in the settlements are mainly related to conflicting land uses (uncontrolled change of the land use and tendency to mixed uses). Some of the mixed uses have a negative impact to neighboring settlers (e.g. bars etc.) while small corner shops or small scale workshops have little or no significant negative impact (A1, A2, B1, B2, B3).

Planned open spaces or road reserves are mainly used for commercial activities than as green areas (Sinza A1, Mbezi Beach A2, Sandali B1, and Kawe B3). The operators of workshops who have encroached upon communal open space in Sinza A1 (Fig. 12) have started into informal negotiations and agreements for a co-existence with the surrounding residents. The operators are not only aware of the disturbances but also of the regulations and laws that operating such activities in the area is illegal. In most cases, only a temporary permit was issued by local authorities and therefore, they try to avoid open confrontation with their neighbors.

In another case of a bar in Sinza A1 with loud music after midnight, adjoining settlers won a court case on noise reduction; however it was successful only for a short time and music after midnight started again. Sinza is increasingly becoming an area for commercial activities with hotels, bars and groceries which often disturb the residents. An easy access to main roads, good connectivity to other residential areas and suitable plot sizes, including the possibility to make use of the road reserve in front of the plot, have accentuated these commercial activities. Economic agglomerations lead to more business activities which also contribute to traffic congestions and related parking problems.

The owner of a large function hall in Sinza A1, having realized that his business can only run smoothly if the neighbors are comfortable, has recently reconstructed the premise with a parking space on the ground floor and a air conditioned sound-proof hall on the first floor. Although the high investment costs of the entire construction has increased, it makes sense, since he will not face complains from the neighbors and can run the business smoothly. Another example from Sandali B1 (Fig. 13), however, displays a different picture where workshops for used oil are operating in a residential backyard. The surrounding residents have complained about the pollution of this dangerous activity but without any reaction from the operators. The subward leader stated that he is not able to stop these activities since the operators are tenants only and the landlord is living outside the settlement and therefore not accessible for the local leader. Only after termination of the rental contract, the local leader promised to stop new activities. This case shows the limitation of locally made decisions or local regulating systems which often lack of knowledge and awareness as well as

statutory enforcement. Similar findings were revealed in the case study settlement of Kawe B3 (Fig. 15) and Gongo la Mboto B2 (Fig. 17) where land is under high development pressure. Also in these areas, commercial activities along the main road and inside the settlement around the market have given rise to conflicts related to noise, pollution and parking problems as well as increased building density. The sparsely developed cases of Chamazi A3 and Bunju A4 (Fig. 16) still do not exhibit land use conflicts due to the low density and the lack of commercial activities.

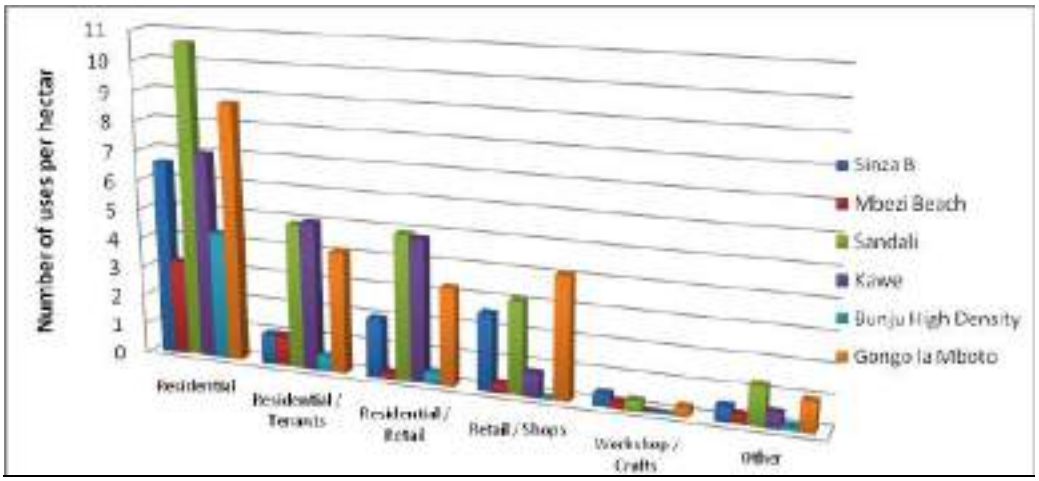

Fig. 18 Distribution of land use categories
Source: Own fieldwork 2010 and 2011

A comparison of the land uses in the case study settlements obviously shows that the informal settlements of Sandali B1, Gongo la Mboto B2 and Kawe B3 are more densely build and display a higher variety of land uses including commercial activities while than the planned settlements of Mbezi Beach A3 and Bunju A4. However, Sinza A1 as a planned settlement displays also a high density and high percentage of commercial activities. This reflects the development pressure on the settlement and the tendency to more commercial uses in the purely residential area (see Table. 4).

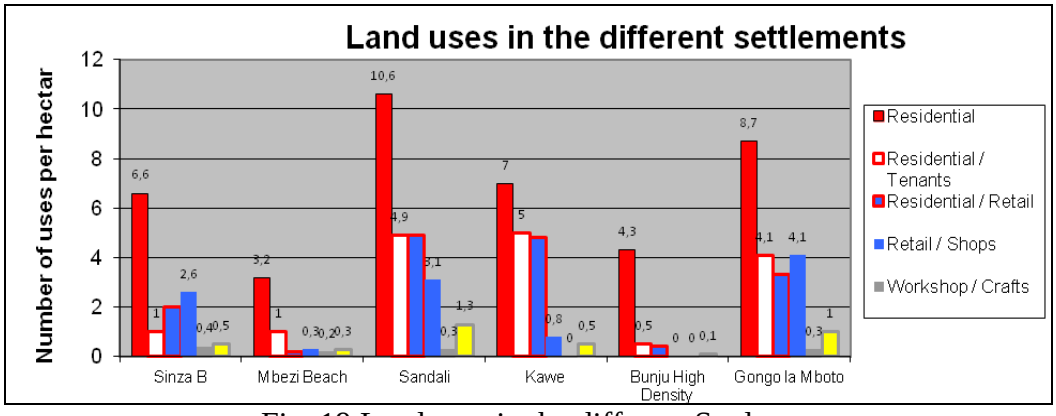

Fig. 19 Land uses in the different Settlements

Planning Regulations and Decision Making

The interviews in the case study settlements of Sinza A1, Sandali B1, Gongo la Mboto B2, Kawe B3 and partly Mbezi Beach A2 revealed that there is hardly any sensitivity or adherence to planning regulations and land use categories among the residents. Only plot boundaries are respected especially road reserves. Developers are aware that structures can be demolished if built on the road reserves.

Most respondents state that they lack of knowledge on planning regulations and potential positive or negative impacts of the regulations. This is a contradicting finding since in Sandali B1 planning instruments and urban layout plans were used during the regularization process. In this process, intensive surveys were undertaken and demolition of buildings executed to facilitate the expansion and construction of access roads and storm water drainage. The situation is similar in the formally planned settlement of Mbezi Beach A2 where a comprehensive layout plan is in place but not well known to the individual developers.

Also at the institutions at the grassroot level of the Government (Mtaa, ward level), there is a lack of awareness of planning regulations. For instance, in the subward office (mtaa) of Sinza A1 and Mbezi Beach A2 even a copy of the land use and layout plan was missing. It seems that in the understanding of residents as well as local leaders, planning only focus on the change of land use at the plot level approved individually by the local leaders and not according to the general planning scheme. Thus individual decisions happen often not according to the existing plans (Sinza A1, Mbezi Beach A2, and Bunju A4) or general regulations (Sandali B1, Gongo la Mboto B2, Kawe B3). Permission to build, extend or to change the use of a building are issued by local leaders rather based on the political influence of the applicant and thus in disregard of public interests. Therefore, conflicting land uses easily emerge. Such permissions focus only on the plot itself and ignore the neighbors' plot and the construction (concerning size, height, set backs and land use) on it.

Future Development

Congestion is seen one of the key future challenges in Sinza A1, especially because many individuals would like to build multi-storey buildings on the same plot which is today occupied by a single storey house and therefore it will increase in turn the congestion. In Sandali B1 new, modern buildings which are replacing the old structures made of rather poor building materials are seen as a symbol of a better future. However, up to now, multi-storey buildings are generally only few and the redevelopment is taking place in form of new single storey buildings. But because most new buildings are fenced like in Sinza A1 it will create a higher "visible" density, might block access to some buildings and hinder ventilation. Even in the well-planned area of Mbezi Beach A2 with relatively large plots, congestion is likely to occur. In one case two neighbors have built in disregard to the minimum setback regulations and as a result their two storey buildings are hardly one meter apart while the larger part of the plot is left open as a garden.

In Kawe B3, the density in term of plot coverage is already very high and new multi-storey buildings will compound congestion and limited accessibility and thus will cause more problems in the future.

For the case of Bunju A4, so far there are only few building extensions in the well planned more densely build staff quarter up to now. However, the on-going constructions in the privately developed areas for wealthier settlers (Fig. 16) with a higher plot coverage than permitted and insufficient set-backs can easily lead to a problematic density and land use conflicts in the future.

Are planned settlements and informally developed areas different?
There seems to be little difference between planned and informally developed settlements (cases A and B) in terms of adherence to planning and building regulations. In both, they are violated. However, the planning authorities both at national as well as at local levels consider the informally developed areas as unplanned areas in which no regulations can be enforced. Therefore, no one takes care of the basic regulations concerning set backs, land use, plot coverage and plot ratio. In planned areas, at least the settlement structure with a chess board pattern helps to avoid blocked areas.

In both types, uncontrolled building constructions, extension, in-fills and change of land use are persistently going on. This includes redevelopment towards multi-storey buildings without respecting the setbacks and coverage (Sinza A1, Mbezi Beach A2, and Kawe B3), change from residential into commercial uses (like groceries or bars) and neglecting regulations for noise pollution (bars, churches, workshops). In Sandali B1 and Mbezi Beach A2 processes of land use changes are less dominant but gradually increasing. The land uses in the upgraded informal settlement are likely to be similar to planned settlements (Sandali B1) because of processes of gentrification and the pressure of the real estate market on these settlements which are often located in attractive areas of the city. When comparing the plot coverage ratio (Table 4), it becomes obvious that formally planned areas under development pressure like Sinza A1 do not differ from informal settlements as B1, B2, and B3.

Table 4. Calculation of plot coverage ratio

Case study settlement	Total area / analyzed in sqm	Building land in sqm	Built up area in sqm	Plot coverage ratio
Sandali B1	16,032	13,385	6,255	0.5
Kawe B3	8,694/4,783	6,864/4,305	3,267/2,644	0.5/0.6
Bunju A4	50,874	44,734	4,800	0.1
Sinza A1	6,933	6,933	4,059	0.6
Mbezi Beach A2	31,000	30,364	7,007	0.2
Gongo B2	7,385	7,134	3,180	0.5

Source: own fieldwork 2010-2012

Both types of settlements, planned and unplanned, generally enjoy a good security of tenure and infrastructure supply (including improved storm water drainage like in Sandali B1). Therefore, both types are permanent settlements and not a temporally phenomenon as initially perceived by officials. Both planned and informally developed settlements undergo processes of land use changes, densification and potential gentrification following the rules of the real estate market and seek for a more economic land use.

Misguiding Concept of Plot Sizes as Land Use Control Instrument

Although some planned areas were designed as high density residential areas for low income groups, the urban poor as the target group has not benefited. The high density plots (400-800 sqm) are too large and thus too expensive for the low income households. On the informal land market most poorer residents opt for a plot of about 100-200 sqm which reflect their income status and affordability.

Today, the received colonial urban land use concepts and standards such as plot size categories and the resulting zoning in residential neighborhoods based on high, medium, low densities have not much impact on settlement development. Either many middle income residents occupy high density plots designed for the urban low income groups or these plots are used for commercial activities. Setbacks and allowed maximum plot coverage regulations are ignored (Sinza A1 and Mbezi Beach A3 and Gongo la Mboto B2 Kawe B3).

The smaller size of plots in Sandali B1 which is far below the official minimum standard size seems not to be a problem for the residents. Most residents seem to be satisfied with smaller plot sizes as they correspond with their affordability and income status. In this respect, official high density plots are still too big and smaller plots would be ideal for the poor. This could be especially the case if they are not fenced and setback requirements are observed (own fieldwork 2011)

The same applies to the newly developed settlement of Chamazi A3. In this area, a NGO is constructing houses for displaced settlers on a 144 sqm plot which is only half of the size of Sinza A1. Interviews revealed that settlers are satisfied with the plot size and the new home. However, the project is still under construction so a long term study on the suitability of the plot size is needed.

Therefore, efforts to focus on the plot size alone are not adequate to guide urban land use development. Other factors related to land use control like setback control in relationship to the height of the building and plot coverage are more promising but are presently simply not being implemented or adhered to. Landlords seem to have the understanding that after the purchase of a plot the owner can do whatever he/she wants on the plot including developments with a negative impact on the neighbors (noise pollution, solid waste production, excessive plot coverage and building height, etc). Especially, the relationship of the height of the building and increasing necessary set backs are ignored (A1, A2, B2, B3).

Fencing plots is becoming more popular to enhance security especially of the newly constructed houses held by the middle class (almost all in Sinza A1, Mbezi Beach A2, Bunju A4 and new buildings of the middle class in Sandali B1) while poorer residents still use unfenced plots. Unfenced plots allow sharing the space between neighbors and increase the space available for changing activities. On the contrary, fenced plots restrict the flexible space available between the buildings, block potential cross-ventilation and increase the perceived plot coverage ratio.

Land Use Categories do not meet Resident's Livelihood strategies

The majority of the residents in Dar es Salaam is poor. However, as noted earlier there is not any planned area dedicated to low income residents. The rigid land zoning concept and land use categories (residential, commercial, and residential cum commercial etc.) does not reflect the reality especially residents' needs for flexible livelihood including changing employment and income generating activities. Today, the planned residential areas are rather mixed use areas instead of a purely residential as planned.

Commercial uses are necessary in settlements and provide income and services for residents. However, there is a need to regulate and designate them in specific suitable areas in advance before they emerge uncontrolled. Operators of small workshops on leased land are aware of the disturbances and negotiate with residents while bars and music halls do not. Political influence and economic power seems to be the key issue.

There is no clear concept for the distribution and localization of the emerging commercial and service related activities. They are spread haphazardly in the entire settlements without a proper planning concept. In Sinza A1 half of the plots are residential cum commercial while in Sandali, the majority of the plots is still purely residential. Retail shops and workshops are located in separate buildings along the main roads. In many cases they occupy the triangle shaped spaces left open after demolition of buildings for road and drainage construction.

Since these commercial uses are necessary in settlements and provide income and jobs for residents, there is a need to allocate them in specific suitable areas. This calls for the review of the current zoning concept. It should rather address to locate disturbing uses like bars, warehouses, workshops along the main roads at the fringe of the neighborhood on the one hand and purely residential uses in the centre on the other hand. This means the spatial reversal of the neighborhood design concept used in Tanzania and the development of new land use categories in combination with plot coverage rules and increasing set backs according to the height of the building.

Idea is that as soon as sufficient and well designated areas for the critical non-residential uses are available covering the demand, land use changes could be fairly well controlled. At the same time land owners must be aware of which land uses are allowed for their plots and which not. Today, it seems that any land use can be real-

ized anywhere in the settlement and any redevelopment regardless plot coverage, floor ratio and setback or other environmental requirements, e.g. solid waste management, can take place.

3. Conclusion

The fieldwork revealed that current land use planning system especially the plot size standards and zoning concepts based on stringent land use categories are not suitable to guide the current development trends and cannot respond to the changing needs associated with search for sources of livelihood.

Focus of planning regulations should rather address issues related to mixed land uses and mechanism to guide the processes of densification and intensification in the settlements. While small scale enterprises including land uses such as corner shops and workshops find ways of negotiating with the surrounding neighbors, larger uses like open air bars or the unregulated densification processes with a too high plot ratio and/or multi-storey buildings without appropriate setbacks are developed without taking care of the needs of the surrounding buildings.

Therefore, there is a need to adjust the planning system and practice towards suitable regulations which are appropriate to residents´ needs and allow them to engage in different small scale income generating activities but also to control conflicting land uses and larger constructions. In order to implement such regulations, there is a need for simple, transparent and codified norms which can be executed on the local level by officers and persons who are not skilled and well trained in planning related issues. Besides there is also a need for clear negotiation and decision making processes that ensure the direct involvement of the settlers.

Therefore, future research will explore the need and the potential for regulation of land uses, densities and plot sizes on the local level. It will also pick up lessons learnt from the far more developed South African planning system as well as from standards applied in self-regulated informal settlements in other African countries.

THE RESOURCES OF MULTI-ETHNIC ENVIRONMENTS IN ITALY: PLANNING IN THE "CITIES OF DIFFERENCE"

Paola Briata[1]

Abstract

Immigration is a "hot issue" in many European countries and the cities represent the main gateway for the majority of the newcomers.
From the spatial dynamics and policies' point of view, the debate on urban space and immigration has been dominated by the topic of the problematic aspects of the newcomers' concentration in specific neighborhoods. In this direction, space policies have always been characterized by a dominant approach aimed at mitigating forms of concentration, breaking up the immigrants settlements' territorialities, or dispersing the newcomers groups across the urban territory.
In the last twenty years these forms of intervention have mainly resulted in the promotion of "social mixing" initiatives that this paper puts under critical observation.
In this direction, a main objective is considering some core concepts and narratives that underpin analysis and forms of intervention in multi-ethnic neighborhoods as "assumptions" that, far to be proofed, play a large part in conditioning the public debate and policy agendas on this issue, but also in orientating the researchers' ways of seeing. This objective implies a reframing of the descriptions and of the forms of intervention in multi-ethnic settlements, considering the "concentration/segregation" issue as a powerful "assumption" that is at once both descriptive and prescriptive, leading to "mixing" policies as an embedded answer to descriptions based on concentration.
Italian multi-ethnic settlements are "deeply" multi-ethnic, as people from different countries live in these areas, including the prevailing presence of Italian citizens. They are not ethnic enclaves, but "cities of difference" in the multicultural sense given by Fincher and Jacobs (1998).
Despite these peculiarities, innovative ways of intervention have not be developed, and planning in multi-ethnic contexts works with the same means and rationalities seen in other countries where the concentration phenomena are more significant.
Based on the most recent findings of some "out of the mainstream" literature aimed at describing multi-ethnic settlements in an innovative way, as well as on some case-studies, the paper aims at pointing out how much the peculiarities of the Italian environments may be useful to consider them as "urban labs" to discover the "resources" of multi-ethnic environments, and to develop new forms of research and action: challenging existing descriptions of multi-ethnic settlements, discussing innovative methodologies and intellectual approaches to these neighborhoods, and detecting alternative modes of interventions in such urban environments with a particular attention to the role – provider, enabler, conflicts' mediator, ruler – that the public hand may play in the face of the welfare restructuring.

1. Introduction

Over the last fifteen years the increasing number of foreign immigrants in Italy has led to a growing body of urban studies whose first aim is to describe how the newcomers' presence has changed the major cities and their neighbourhoods. These are mainly descriptions on how the immigrants settle, "use" and change Italian cities. Despite the variety of these settlements, a common aspect could be found in the Italian multi-ethnic environments: the absence, excluding some exceptions, of "ethnic concentration" in specific neighbourhoods. This aspect could be observed both from the "quantitative" point of view – as the immigrant's share is rarely over 20-25 per cent over the residents' population – as well as from the nationality point of view – as multi-ethnic settlements are "deeply" multi-ethnic, as people from different countries live in these areas (including of course the prevailing presence of Italian citizens). They are not ethnic enclaves, but "cities of difference" in the multicultural sense given by Fincher and Jacobs (1998).
The most common form of ethnic concentration is related to some commercial areas, and a number of sociological and economical studies have underlined how the natives tend to leave to the newcomers *labour-intensive* jobs. In this sense, immigration is also presented as a resource (Ambrosini, 2010).
From the spatial dynamics' point of view, urban studies have underlined how the newcomers' economic activities have been able to adapt to spaces left empty from the Italian entrepreneurs, assuring the neighbourhoods' vitality with reference to the services that they provide (for example the corner shops), and to the uses of public spaces (Grandi, 2008).
These studies try to construct "out of the mainstream" descriptions of the immigrants' presence, presenting it as a resource, and deconstructing a pervasive public discourse focused on the problematic aspects of the newcomers' concentration.
Given this general context, this paper carries on a research path focused on spatial policies in multi-ethnic environments in Italy. This research has made possible to focus on three main spatial forms of intervention where the immigrants' presence is significant and/or visible (Briata, 2010; 2011b):

- where an "intensive" use of public spaces by the immigrants could be found, forms of intervention based on *"breaking up the newcomers' territorialities"* (Yiftachel, 1990). This is possible through forms of urban renewal aimed at introducing functions and services able to attract also the Italian population;
- where the immigrants' share is significant in the residential buildings, *public-led forms of "rehabilitation"* aimed at enhancing the real estate pressure. These forms of intervention may imply the weaker groups – not only immigrants, but old people as well – moving to other places;
- where the ethnic economies are significant, visible or able to attract foreign clients, forms of intervention based on (a) *rules, restrictions and ordinances* – including forms of zoning that introduce "special" regimes for some areas – that may have a negative impact mainly on the immigrants' shops (b) *"commercial development" policies* aimed at attracting new Italian shops and services.

This means that, despite the urban studies have underlined the absence in Italy of "pathological" forms of concentration that could be found in other countries, spatial policies have mainly used the same tools that have been used in other more problematic realities to reduce concentration.
This paper aims at exploring the possible reasons for these choices starting from an analysis of the rationalities that usually guide these forms of intervention, exploring similarities and differences between Italian and other Western countries, and pointing out how much the peculiarities of the Italian settlements may be useful to consider them as "urban labs" to discover the "resources" of multi-ethnic environments, and to develop new forms of research and action.

2. The problematic aspects of concentration

Debates on planning in multi-ethnic contexts have been dominated by the topic of the newcomers' concentration/segregation in specific neighbourhoods (Marcuse & Van Kempen, 2000). This "label" covers a wide range of phenomena felt to be problematic: a large number of immigrants in a certain area, a high percentage compared to the total number of inhabitants in a neighbourhood, and specific forms of settlement such as the ethnic enclaves. The *spatial dimension* is most closely connected with the *urban visibility* of immigration and plays a large part in conditioning the public intervention in the issue (Tosi, 2000). In the mainstream visions of public debate and policies "ethnic neighbourhoods" are considered as "worlds apart" which create barriers to interaction with the rest of the society, hindering the integration of individual immigrants (Mustered & Andersson, 2005). For these reasons, urban and spatial policies have often been characterized by a dominant approach that aims to mitigate forms of concentration, by dispersing immigrants and/or problematic groups across the urban territory and/or breaking up their settlements' territorialities by introducing people of different ethnic, social and economic background (Home, 1997; Yiftachel, 1990). And yet the assumptions of presence and absence of concentration and diffusion that underpin this dominant narrative often remain unquestioned by academics and policy-makers.

In the last twenty years these forms of intervention have been adapted by policy discourses to changing conceptions of the role of the state in public provision, as well as to new development scenarios of the post-industrial cities that have to be attractive for business services, creative industries, knowledge-based economies and tourism. In this way, the promotion of "diversity" at neighbourhood level in terms of social class, income, ethnicity, and lifestyle has been proposed as a precondition for socio-economic upgrading of people living in deprived and "segregated" neighbourhoods (Donzelot, 2006), as a way to counteract stigmatisation putting these places "on the map" of the urban territory, and as key factor to stimulate innovation, creativity and economic growth (Fainstein, 2005).

In these directions, policies aimed at stimulating diversity or "social mix" in social housing estates, inner city areas or decaying historical centres have been carried out in a wide range of countries – e.g. United Kingdom, France, Germany, the Netherlands, Sweden, Belgium, United States, Canada and Australia – becoming a sort of *mainstream approach* to "problematic" neighbourhoods, including those characterized by a significant presence of immigrants (Mustered & Andersson, 2005). In most cases, urban policies aimed at reducing ethnic concentration have resulted in actions aimed at attracting in specific neighbourhoods people of different background to "dilute" the immigrants' presence and/or in actions aimed at the newcomers' dispersal across the urban territory *(ibid)*.

Despite the absence of an academic debate on these issue, this approach has influenced also the forms of intervention activated in Italy: social mixing is considered a good thing *tout court*, a sort of "magic word" able to justify different forms of intervention carried out in different "problematic" environments: from the historical centres to the outskirts areas (Briata, 2011a). .

At the international level, in the last years a growing body of literature has critically analyzed social mixing policies, focusing both on the *principles* that underpin these initiatives, as well as on the *results* that have been observed where they have been implemented. A brief summary of these positions is provided in the next paragraphs.

3. Principles and problems of social mixing policies

3.1. Ways of pursuing social mix

Despite the different patterns of socio-spatial segregation that characterize the different countries – e.g. anti-segregation policies have mainly been promoted to deal with the problematic aspects of the *banlieues* in France, while in United Kingdom there is a strict, relationship between the narratives of social mix and the inner cities' regeneration – a number of common aspects in conceptualising and pursuing objectives of diversity could be underlined. In particular, social and functional mix are presented as strictly interrelated objectives, and policies aimed at stimulating diversity should involve housing, retail business, services and public spaces (Urban Task Force, 1999). Despite this, in many countries social mix objectives have mainly resulted in policies aimed at promoting mixed tenure, housing price level mix, or building type mix to attract wealthier and/or middle-class residents in deprived and problematic areas (Bolt, 2009). In the last years, a growing body of literature has critically analyzed anti-segregation policies focusing both on their principles, as well as on the results that have been observed where they have been implemented.

3.2. Social mix to stimulate local development, upward social mobility and cohesion

Analytical works by planners, geographers, sociologists and political scientists have been helpful to underline that social mix is considered in public discourses and policy agendas as a key factor to enhance individual and groups' opportunities for upward social mobility at least for three main reasons[2]:

- a "local development" perspective (from the "insiders point of view) – as social mix may be helpful to change the perception of deprived and problematic neighbourhoods "from outside[3]", counteracting stigmatisation, attracting new (less problematic) inhabitants, and stimulating new broader relationships and socio-economical opportunities for people living "inside" these places;
- a "social upgrading" perspective – related to the supposed "civilizing" influence of wealthier and middle-class residents, whose presence could motivate problematic individuals and groups, thanks to the contacts with role models from a different socio-economic background;
- a "social cohesion" perspective – as the exposure to "the other" can lead to mutual understanding, learning or, at least, tolerance.

3.3. Spatial proximity between "diverse" groups and socio-economic upgrading: critical views

Analysing the three perspectives listed above, one major objection is linked to the fact that considering social mix as a key factor for change in residents' behaviour thanks to the wealthier or middle-class residents' influence, means reducing these people's problems to "social pathology", neglecting that poverty and social exclusion depend also on structural social and economical

[2] Based on international planning, geographical and sociological literature on social mixing initiatives, this "classification" has been done directly (cfr. Briata, 2011a).

[3] The reference to "internal" and "external" descriptions and dynamics is proposed having in mind that what is "inside" or "outside" a place is never something "absolute": this is a strategic construction operated by the local and not-local actors (including the researcher that embraces these distinctions) to simplify complex situations, and to prefigure some course of research and actions, excluding others.

factors, and that the single persons or groups' know-how/will/exposure to "the other", as well as the local level initiatives may be not enough to reach socio-economic upgrading (Raco, 2003).
At the same time, based on the outcomes of anti-segregation policies, the assumption of a strong link between social mix and housing mix is far to be proofed. A lack of evidence for this link where housing mix was realised has been underlined by a number of studies carried out in different countries (Kearns, 2002; Whitehead, 2002; Musterd & Andersson, 2005). At the same time, tenure mix practices have demonstrated that these policies may result in spatial proximity between different socio-economic/ethnic groups, but that this condition doesn't necessarily translates into social interaction between people of different background in public spaces, schools, services and shops (Butler, 2003; Allen *et al*, 2005). In this direction, also the thesis that the exposure to "otherness" leads automatically to mutual understating and tolerance is far to be demonstrated. Moreover, *from the methodological point of view*, it has to be said that these researches have been useful to highlight how complex is understanding what kind of social mix is taking place in these neighbourhoods, due also to the *slippery nature of this concept*: all neighbourhoods are, in fact, "mixed", but from anti-segregation policies' point of view some seem not to possess the "right" mix (Cole & Goodchild, 2001). Is then social mix a way of intervention aimed at creating the "right" mix? What are then, in these policies rationales, the characters of a "balanced" conception of mix? May "social engineering" create it?

3.4. Development agendas, public-led gentrification, social control: critical views

Other studies have analyzed social mixing initiatives in the context of new development scenarios of the post-industrial cities. In this direction, anti-segregation policies may be seen as strategies to change the deprived neighbourhoods' role, image and population in the broader cities' contexts, putting them "on the map" of the urban territory. These dynamics may be more common in the inner city areas or in some European cities' historical centres, where the relationships between the real estate pressure and urban renewal may result much more clear (Diappi, 2009). For these reasons a growing body of literature has underlined how social mixing initiatives may be seen also as forms of state/municipality-led gentrification, that may carry with them significant threats of displacement for the weaker groups (Lees *et al*, 2008). Other perspectives have underlined that anti-segregation policies may be read also as a means for the states or local authorities to break up the "world apart" characters and territorialities of these neighbourhoods, having back the social control of places that seem to have only their own rules (Atkinson & Helms, 2007). In this vision, anti-segregation policies may be seen also as a "spatial declination" of security policies.

4. Why not ghettos?

A completely different point of view has been analysed by studies less interested in the "external" exclusion of "segregated" neighbourhoods and more focused on the internal dynamics among the inhabitants of these places. The debate on the limits and on the potentialities of segregated places has a long history that goes back at least at Park studies' (1925) in the context of the Chicago School of Urban Sociology. Despite this, the interesting aspects of the recent rediscovery of these issues is due on the one hand, to their connotation as "a reaction" to social mixing initiatives and, on the other hand, to the strong link that they establish with the current situation of the welfare state restructuring. These perspectives have tried to look at segregated neighbourhood not only as dangerous environments with their own rules, but also as places that could have a potential in stabilizing the cities (Cattacin, 2006). In this views, these places' function in contemporary societies

would be underestimated because here immigrants and people of low socio-economic status can find a warm and loyal surrounding and, considering the shrinking capacity of intervention of the welfare state, *self-regulated spaces of mutual-help and solidarity*. These relationships have a strong capacity to act and to solve concrete problems, and "mixing" policies may weaken or brake established networks, without giving any other kind of resource back. These perspectives do not suggest to consider the spaces of segregation in a positive way *tout court*: their potential "integrative role" in the cities is in fact strictly connected with the welfare state's financial crisis and the related difficulties in the implementation of redistributive policies. In this general context, combating these places may create more problems than solutions.

5. Concentration and public policies' role

Despite the vast amount of critical academic literature, social mixing initiatives still remain the main form of intervention in the immigrants' settlements, revealing a sort of disjunction between research and policy agendas. At the same time, this disjunction may be helpful to stimulate reflections on the weak aspects of research that has focused on these issues.
In particular, as underlined in paragraphs § 3 and 4:

- There are critical views of social mixing policies that, despite their criticism towards anti-segregation actions, seem still to be linked to a negative and problematic image of the immigrants' and weaker groups' spatial concentration. These negative views appear in some way embedded also in the researchers' analysis and narratives, and may condition the research point of view, not being useful to explore innovative approaches and ways of action;
- There are studies that underline the public hand's will to re-establish control on "problematic" neighbourhood, considering this issue mainly in a negative way. In these perspectives, social mixing initiatives have been seen mainly as place-focused declinations of security policies, implying forms of "repression". Due to the physical, economical and social conditions of decay that often characterizes these neighbourhoods, the public hand's will to establish forms of control is far to be illegitimated. A negative view *tout court* in this sense may not be helpful to explore innovative approaches related to the "control" issue, for example declined also in terms of care and not only in terms of repression;
- There are studies that suggest to reconsider the potentialities of "segregated places" with a particular attention to their self-regulating capacity, due to the shrinking redistributive capacity of the welfare state. The welfare restructuring is without any doubt a reality, but this does not mean that the public hand shouldn't and couldn't have any kind of role in these places, for example managing situations of conflict or integrating and/or sustaining existing networks. Underestimating the state's or the local authorities' possible role in these places may not be helpful to explore innovative paths of intervention.

Existing literature's gaps may create "open spaces" for further research and analysis based on two main families of problems related to:

- the connections between the *descriptions* of "problematic" neighbourhoods and the consequent *forms of intervention*;
- the *role that may be played by the public hand* in these kind of places.

In the next paragraphs the paper aims at pointing out how much the peculiarities of the Italian environments (a) may represent a good research field to observe the international literature's less explored aspects (b) may be useful consider them as "urban labs" to discover the "resources" of

multi-ethnic environments, and to develop new forms of research and action: challenging existing descriptions of multi-ethnic settlements, discussing innovative methodologies and intellectual approaches to these neighborhoods, and detecting alternative modes of interventions in such urban environments with a particular attention to the role – provider, enabler, conflicts' mediator, ruler – that the public hand may play in the face of the welfare restructuring.

6. Descriptions and "solutions"

A wide range of literature, studies and data have underlined that ethnic concentration is an uncommon phenomenon in the Italian context. Despite this, policy agendas did not invest in original and innovative spatial policies in these kind of environments: the main objective is contrasting concentration through social mixing initiatives as in other Western countries where this phenomenon is much more significant.
The very aggressive public debate on immigration in Italy (Rivera, 2009) could be the first reason for the administrations to act in this way. A public debate that seem to be able to influence even the more "progressive" policy agendas. "Based-on-fear" planning (Paba, 2010) is the other side of a dominant approach towards the newcomers, an approach fuelled by the media that, where the immigrants' presence becomes visible, label as *banlieues* historic and central areas or as *ethnic ghettos* places where the Italian born resident are still the majority.
These narratives of multi-ethnic environments seem able to affect policy agendas more than the "out of the mainstream" descriptions of academic literature and research when the immigrants' presence in a place is presented as an urban resource.
In this direction a core point in this paper is considering some core concepts and narratives that underpin analysis and forms of intervention in these places – in particular the problematic aspects of concentration – as "assumptions" (Raco, 2009) that, far to be proofed, play a large part in conditioning the public debate and policy agendas on this issue, but also in *orientating the researchers' ways of seeing.* For example, all the "distinctions" to look at the immigrants' presence as a resource or to see in the different typologies of ethnic economies a service for all the residents of a neighbourhood, are used to demonstrate that ethnic *concentration is not an issues* in those kind of places. The same could be said of the descriptions of the immigrants' presence in terms of share or percentages as it was introduced in this paper: we have to be aware that an "absolute" index con concentration does not exist. Concentration is defined both by perceptions and by relationships of the local with the global, the neighbourhoods with the rest of the city, a place with other places where the immigrants presence is in the policy agenda in Italy or in other countries.
This implies a reframing of the descriptions and of the forms of intervention in multi-ethnic settlements considering the "concentration/segregation" issue as a powerful "assumption" that is at once both descriptive and prescriptive.
As underlined by policy analysis and social sciences, analysis and problems' framing are strictly linked with existing tools that decision makers may mobilize to cope with them (Bobbio, 1996; Crosta, 1998). In this case it seems as if, as researchers, we try to frame problems in a way that cannot lead to existing tools and "solutions".
In this perspective, social mixing policies may be seen not as *one of the possible answers to concentration*, but as an *embedded answer* to descriptions based on concentration. This means that not only policy agendas should be reframed as literature has underlined until now, but that also our ways of looking at the immigrants' settlements – as researchers – should be subject to challenge and put under critical and auto-critical observation.

7. From immigration as a resource to the multi-ethnic neighbourhoods resources

Observing the immigrants' settlements in Italy, and concentrating on their multi-ethnic and multi-cultural aspects, may lead to some open aspects for further research and action. For example, the neighbourhoods' Italian born residents usually do not feel comfortable with the descriptions of the places where they live made by the media and policy makers. Descriptions made "from outside" are quite different from those made by people living "inside" these neighbourhoods (Briata, 2011b).
These differences may be related to different reasons:

- a multi-ethnic co-existence *de facto* – that of course may bring problems, mistrust and prejudices – but that in some circumstances may lead to consider the "outsiders" as "established";
- a vision of ethnic concentration as an opportunity for commercial development or other kind of business also for the Italian people;
- the consequences that Italian traders have to face in their everyday life due to the negative imagine of the place where they live and work built up from media and actors that see the problems from outside – a fact that generate forms of place stigmatization, rendering the areas less attractive, and weakening the position of the local economies. Be described from outside as "otherness" in the face of the rest of the city, risking to be put out of the maps of the city itself.

These are only some examples of the problematic issues to work on in the perceptions of the Italian residents, traders and workers of multi-ethnic settlements.
In the last years the Italian multi-ethnic settlements and their descriptions as ghettos or *banlieues*, have stimulate the insurgence of some literature that has tried to focus not only on the problematic aspects as they are perceived from outside, but on everyday life and coexistence problems as they are perceived and described by Italian and foreign residents – people, community groups, users of services in those particular neighbourhoods. This is the rationale that guides description such as those of Torpignattara (Rome) by Fioretti (2011) or for Via Padova (Milan) by Arrigoni (2011) and Gadda (2012).
This attempt to catch "the insiders point of view" may be seen also in a number of pioneer actions carried out by public administrations in a number of cities where the guides for the analyses of multi-ethnic environments were a number of associations and community groups rooted at the local level. Social realities that carry on everyday activities in these places, trying to cope with concrete problems. An example could be the "participated analysis" carried out in the Padua train station area by Mimosa – an association rooted at the local level that works on social exclusion issues. This action was carried out in cooperation with the Municipality and Confesercenti (the traders association), involving the local entrepreneurs (including a large number of foreigners), workers and residents. This work aimed at establishing some core points to be followed in the area regeneration. The project was characterised by different types of field analysis: ethnographic observation, interviews to relevant actors, discussion with community groups, interviews to different "categories" of people living in the area (young/old; workers/residents; Italian/foreign entrepreneurs; men/women). Among the more significant outputs:

- the differences between the perception of the place "from outside" and "from inside" (inside life seem to be better than how it is perceived and described from outside);
- the differences between the daytime and night time perception of the area;
- the differences between the women and men perceptions' (independently from the immigrant/not-immigrant origin);
- a vision of the immigrants' presence from the Italian residents' point of view that does not hide problems, but at the same time that is not a stereotypical one – there is not a negative

perception of immigration in general, but a number of deviant behaviours are associated with the foreigners;
- a vision of security that does not seem to be complacent with the narratives based on "emergencies" proposed by the media, but that claims for the restoring of a "lost normality" though initiatives able to bring regeneration, vitality, a different positive visibility of the area that "should be much more similar to the city centres" (Banca Etica, 2008).

This survey was the first step of a project that led to the opening of a "zero kilometre" market (based on the residents' proposal for a quite problematic square); the promotion of a number of events to bring people in the area also in the evening; the "adoption of an ethnic shop" from the Italian entrepreneurs to build up bridges between different economic realities.
The Aldermen for the trade in the Padua Municipality has decided to propose this approach also for another problematic area close to the train station, but not so close to the city centre as the previous one. This experience has been described not for the still weak outputs in the area, but for the unusual way to "build up the problem" that seem to individuate: describing a place that "from outside" is always considered a problematic one based on the insiders perceptions. A description made also of "voices": micro-stories that tell of concrete problems, and of the local capacity (or not) to cope with them; resistance by the local groups to the existing dynamics; tactics that render everyday multi-ethnic and multi-cultural coexistence possible; awareness of what kind of problems could be faced at the local level, and what kind of problems require a not local approach or/and the public hand intervention.
Such a way of looking – less focused on immigration as a resource, and more focused on the resources of multi-ethnic environments – may be helpful also to understand the role that the public hand may play in these kind of places.
Considering the welfare restructuring, the public hand may have a different role, less focused on breaking up ethnic/problematic groups concentration through social engineering, and more focused on managing the coexistence of people with different (and not only ethnic) backgrounds, potentially but not necessarily conflictual.
These ways of looking may be more helpful to understand some strengths and weaknesses of these places such as the capacity of some local association to strike root and cope with everyday life problems, or the level and nature of some conflicts. A comprehension of these aspects could be helpful also to understand what kind of role may be played by the public hand – provider, enabler, conflict mediator, regulatory. This does not mean that all the resources to cope with the problematic aspects of these neighbourhood could be found inside them, but that in the comparison between the insiders and the outsiders images some new paths of research and action may be explored.

Evaluation of Water Resource Carrying Capacity of Small Towns in the Rapid Urbanization Period in China

Nailu Tian[1]

Abstract

With the acceleration of the urbanization process of the small town in China, the problem of shortage of the water resource has become evident, as a result, it is urgent to set up a system for monitoring and evaluation the water resource carrying capacity (WRCC) of these small towns and predicting the trends of the change of the WRCC in this rapid urbanization period according to the master plan of the town. By analysis the progress and problems of the previous research of the WRCC, this paper proposed a method: per-land water consumption method for monitoring the WRCC of the small town in the rapid urbanization period which can be cooperated with the 3S technology (RS, GIS, GPS) by surveying and calculating the average per land water consumption data of each water consumption unit in the small town. And based on the features of the water supply and consumption in the small town, this paper also proposed the index system and model for WRCC evaluation which is adaptable to the monitoring system. In the end, this paper takes Dongsheng town as a case for testing the reliability of the monitoring, evaluation and prediction system of the WRCC. And according to the result of the evaluation and prediction of the WRCC in Dongsheng town, the rationality of the master plan for 2020 has been tested and solutions are given to improve the WRCC in Dongsheng town.

1 Introduction

The WRCC of small town in the rapid urbanization period refers to the maximum support capacity of the reasonable optimized water resource for the local social and economic development, which is within the administrative region of small town, in the historical stage of rapid urbanization period, on the base of foreseeable technical, economic and social development, for the principle of sustainable development, and in order to maintain the virtuous circle of ecological environment.

Thus, the study of WRCC of small town in the rapid urbanization period is different from the normal study of WRCC. Firstly, it takes the small town as the study area. Since the water circle in the small town has dual characteristic, the WRCC is also impacted by the nature and social factors. So in the study of the WRCC of small town in the rapid urbanization period, the impact of the human activities on water resource and the constraints of water resource on human activities should also be considered. Secondly, the WRCC is corresponding to the background of rapid

[1] The University of Tokyo, Japan, sweetmouse2000@hotmail.com

urbanization. China now is facing the rapid urbanization process which is firstly reflected on the changes of land use: with the continuous expansion of urban construction land, a large number of rural lands have been eroded. Meanwhile, this process of land use change, with the rural- urban agglomeration and rural industry structure upgrading, has brought significant impact to the social and economy in the rural area. So the WRCC in this period will also change dynamically according to the huge changes in social and economy. It is the features of WRCC of small town in the rapid urbanization period that makes the evaluation and monitoring of the WRCC much more difficult.

Since the 1970s, scholars have done a lot of researches on the WRCC of small town. These researches have mainly been conducted on in nature resource and environment region, focusing on the improvement of algorithm and the application of evaluation model. Although none unified method of calculation for the WRCC has been confined now, algorithms for these various models have become mature. Meanwhile, there are two deficiencies in these previous studies.

First, in these studies, the data for the evaluation of the WRCC come from the local water resource statistics. However, these data still have some questions as follows: firstly, these data are based on annual statistics. The period of statistics is too long to reflect the dynamically change of the WRCC in the urbanization process. It is impossible to get the monthly even daily data, since it will bring huge amount of work to the statistics department. Secondly, the data of water resource which take small town as the statistic area can hardly be found out in China, because there is mostly no water resource bulletin in the town level. Though we can find out the annual water consumption data from the statistical yearbook of the small town, these data are too general to reflect the water consumption situation. That means these data are not detail enough for the evaluation of the WRCC. Finally, these statistical data may be processed by the local department, so the reliability of the data is not very high.

Second, these studies are tent to focus on the relationship between the town scale and the WRCC. They often reflect the scarcity of the water resource by evaluation of WRCC, like Guo xuan's study on the WRCC in Yiwu [9], or predict the change of WRCC by Scenario analysis, like Teng Zhaoxia's study in Jinan [10]. These studies always consider the needs of water resource first and then find out some method to divert and save water in order to satisfy the needs. However, none of these studies proposed to make constrains to the population or the scale of the towns according to the result of the WRCC. From this point of view, these studies can do little things with the planning for the small town.

2 Evaluation based on per-land water consumption method

In order to evaluate the WRCC which will change dynamically with the urbanization process of the small town in the quickly urbanization period, it is urgent to get the water consumption amount which will change in pace with the change of land use.

Thus, the concept of per land water consumption has been proposed in this paper, which means the average water consumption in 1 m^2 and 1 day for different land use area in the certain level of social- economic development.

The water consumption per land value can reflect the level of water consumption in different land use units. And through the water consumption per land value, it is easy to achieve the conversion between the land use data which can be obtained from remote science technology (RS) and the water consumption data for the dynamic monitoring of the WRCC.

The method for survey of the water consumption per land value is as follows：Firstly, set up the GIS database and put the data of land use and height of the building from RS into the database to form the map of land use and building height separately. Secondly, overlap the maps together to form the map of water use units. These water use units which have different land use and intensity of development are considered to have different value of water consumption per land, and they become the base units for the survey of water consumption per land. Also, according to the features of different water use units, they can be divided into 4 types which have different ways for the survey of water consumption. Then, the total water consumption in small town will be calculated by the water consumption in every water use units. Finally, the total water consumption value will be tested by comparing to the water consumption in annual statistics. If the result is reasonable, the water consumption per land value can be used in the prediction and evaluation of WRCC.

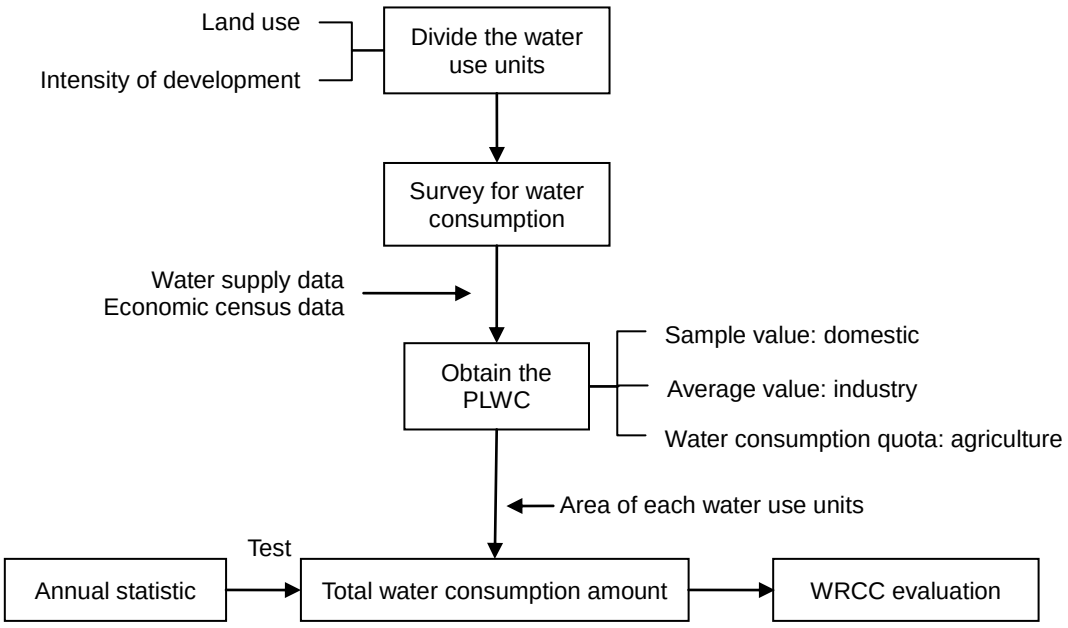

Figure 2.1: Structure of per-land water consumption method

Based on the water consumption per-land, the current system for WRCC evaluation would have to be improved, which means new index system will be set up, and the

data for the new index system will be obtained by calculation with the water consumption per land value and the land use data from RS or mast plan of the town. Also, current evaluation model has to be improved to adapt to the new index system. This new evaluation system for the WRCC can solve the problems in the current evaluation system which is too static to monitor the changeable WRCC in urbanization period. And the new evaluation system can apply better in urban planning. For example, in the process for making the master plan for small town, this new system can evaluate the WRCC in the future according to the population and land use data which has been decided in the master plan. And the result of the evaluation can also be one of the test tools for the rationality of the master plan.

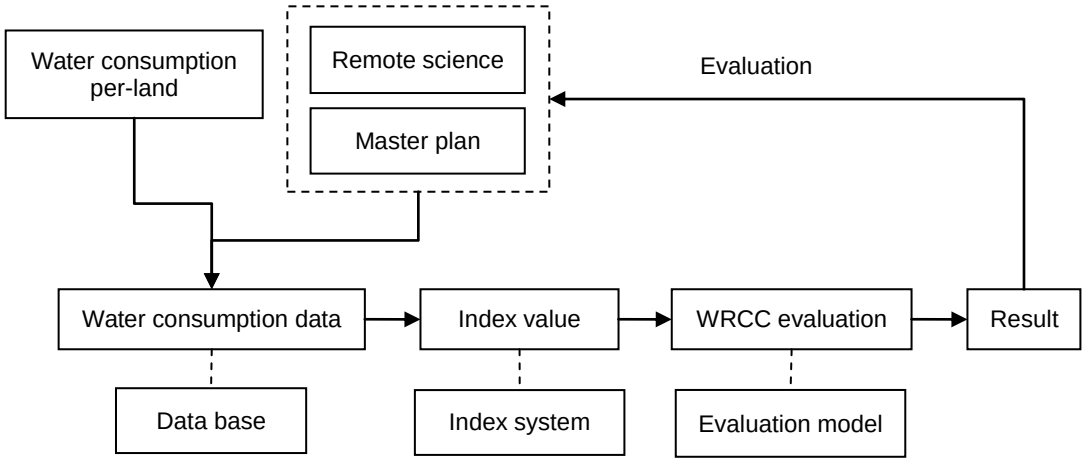

Figure 2.2: Evaluation of WRCC based on per-land water consumption

2.1 Divide the water consumption unit

Since the per-land water consumption is affected by the land use change greatly, the dividing of the water consumption unit is the key for surveying of the per-land water consumption. As the per-land water consumption is mostly affected by the land use and development intensity, these two elements are considered as the basis for dividing water consumption unit. The first thing to do is surveying for the land use and the height of buildings of the town and draw maps of them. The land use is divided into 12 types according to the "land use classification criterion" (GB/T 21010-2007). The heights of buildings are divided into 3 types: high rise buildings which have more than 10 floors, multi-storey buildings which have 4-6 floors and low-rise buildings which have less than 3 floors. Then, the two maps are imported into GIS to set up the spatial data set and overlaid to make the numbers of land units. These land units which have different land use and height information are confined as water consumption units. And these units are also the basic unit for the sample survey of the per-land water consumption.

2.2 Survey for per-land water consumption

On the basis of water consumption unit map, surveys are conducted in each unit. The

data of water consumption are got from the water company, according to the different use of the water, the water consumption units can be divided into following 4 conditions.

1. Domestic water consumption: related with residential and business area, including the water consumption of public service facilities and in daily life. As the water is supplied by the water company, the water supply data of different user can be got from the water company and the water consumption data in different water consumption units can be counted. Sample survey will be conducted for the per-land water consumption data in this condition.

2. Industry water consumption: related with industry area and also supplied by the water company. As there are many kinds of industries in one town, the difference in industry have significant impacts on water consumption. In this study, typical industry area which including almost all the industries in this town will be chosen as the research area, all the industries in the research area will be surveyed and the water consumption data will be got from “the second nation economic census”. As a result, the value of per-land water consumption of various industry enterprises can be got.

3. Agriculture water consumption: related with the agriculture area, the water directly comes from rain water and river. The per-land water consumption in this condition has already be studied and confined as water consumption quota for agriculture. So the water quota will also be used in this research as the per-land water consumption for agriculture.

4. Sanitation water consumption: related with road, green area and squares and the water mainly comes from rain water and river. As the water consumption in this condition is very low and relatively stable, annual data are used for this part of water consumption.

3 Establishment of evaluation system for WRCC

3.1 Index screening

The classification method and itemized method which are commonly used currently for screening of indexes are being combined together: the classification method is used first to list numbers of index exhaustively, and then itemized method is used to filter the index in order to get a small amount of itemized index for evaluation.

First, all of the index in current WRCC evaluation system were summarized and classified. And these indexes were sort by the frequency of occurrence. As a result, 50 indexes were listed. Since the number of indexes is too much for getting the data and determining the weight, these indexes need to be filter, and these indexes which have good representation and specification and easy to obtain are chosen for the index system. According to the data and standard value availability, initial screening

has been done. Then, refer to the features of the WRCC in the rapid urbanization period of small town and on the basis of expert consultation, finally, 12 indexes were chosen for the index system (Table3.1).

Moreover, the weight of the indicators is determined by AHP, Scores from 0 to 1 are given to these indicators according to their importance by 20 experts.

Table 3.1: Index system of WRCC evaluation in small towns

Target layer	Standard layers	Index layers	Units	Weight	Explanation	Function
WRCC in small town (A)	Water resource quantity (B1)	Water resource availability rate per capita (C1)	M^3	0.24505	Water resource available quantity/Total population	Water resource availability per capita
		Crossing water utilization rate (C_2)	%	0.076069	Crossing water consumption/ Total water consumption	Utilization of crossing water
		Ground water exploitation rate (C_3)	%	0.076069	Ground water exploitation yield/Total ground water quantity	Exploitation of ground water
		Water resource utilization rate (C_4)	%	0.141773	Water supply quantity/ Water resource available quantity	Development of water resource
	Supply and demand of water resource (B_2)	Leakage percentage (C_5)	%	0.019514		Water resource management efficiency
		Domestic water consumption per capita (C_6)	Liter	0.056341	Domestic water consumption/Total population*days	Domestic water consumption
		Water modulus (C_7)	Million m^3/km^2	0.108719	Water demand/ Land area	Water demand
		Agricultural water consumption per acre (C_8)	M^3	0.056341	Agriculture water consumption/ Farmland area	Agriculture water consumption
		Industrial output water consumption per million Yuan (C_9)	Million m^3	0.056341	Industrial water consumption/ Industrial output	Industrial water consumption
	Water resource quality (B_3)	Ecological and environmental water rate (C_{10})	%	0.088271	Ecological and environment water demand/ Gross amount of water resource	Ecological water and environment demand
		Urban sewage treatment rate (C_{11})	%	0.026824	Sewage treatment amount/ Total sewage amount	Sewage treatment efficiency
		Surface water level (C_{12})	Class (Ⅰ-Ⅴ)	0.048685		Surface water pollution

3.2 Evaluation model

Currently, the most common models for WRCC evaluation are System dynamics method, multi-objective decision-making method, the conventional trend, fuzzy comprehensive evaluation method. Due to the aim for WRCC evaluation in this research which in order to grading the WRCC into 3 levels for early warning of the lack of water resource on the basis of several indexes, the most suitable model is fuzzy comprehensive evaluation method. This method can not only use the mathematical definition of matrix multiplication to rationally combine the impact of various indicators on WRCC, but also through the fuzzy processing of each indicator to eliminate the jump between the various evaluation levels, thus making the function transit smoothly between the levels. As this algorithm is more accuracy, in this paper fuzzy comprehensive evaluation method are chosen for setting up evaluation model.

3.3 Index grading

The standard value of the 12 indexes which were determined as the factors for WRCC evaluation have 3 sources: the first one is the relevant standards in the national evaluation and supply and demand analysis system; and the second is the existed evaluation system for WRCC; and the last one is the average values instead when standard value can be hardly found.

Table 3.2: Grades of comprehensive evaluation

Index	Unit	v_1	v_2	v_3
Per capita water availability	M^3	>600	600-400	<400
cross-border water	%	<5	5-50	>50
Groundwater extraction rate	%	<30	30-70	>70
Water resource utilization rate	%	<30	30-80	>80
Pipeline leakage rate	%	<7	7-12	>12
Per capita daily water consumption	Liter	<70	70-220	>220
Water modulus	Million m^3	<1.5	1.5-3.9	>3.9
Agricultural per mu water consumption	M^3	<400	400-800	>800
Industrial per million yuan output water consumption	Million m^3	<0.08	0.08-0.2	>0.2
Ecological and environmental water rate	%	>5	5-2	<2
Urban sewage treatment rate	%	>70	70-45	<45
Surface water level	(Ⅰ-Ⅴ)	Ⅰ、Ⅱ	Ⅲ、Ⅳ	Ⅴ

According to the standard value of the index, the effect of these indexes which taken into the WRCC are divided into 3 grades. The grade v_3 indicates that the situation of WRCC is comparatively worse, the WRCC is close to saturation, will not carry in the near future, the potential of the further development of water resource in very small, water resource shortage is likely to occur and the development of economic will be restricted by water resource. So in this situation, an early warning should be given

and measures should be taken to improve the water demand and supply condition. The grade v_1 indicates that the situation of WRCC is good, the water resource still has carrying potential. So in this situation, water supply is guaranteed. The WRCC condition in grade v_2 is between grade v_1 and v_3, which indicates that the development and use of water resource has reached a certain scale, however, the potential of further development of water resource is still high and the water resource can support the economic development in the near future.

3.4 Evaluation matrix *R*

How to choose the evaluation matrix *R* plays a significant role in the fuzzy comprehensive evaluation. Since the value of evaluation grade is discrete, the final point of evaluation is discontinuous with respect to the value of some evaluation factor if we just assign some grade v_i to evaluation factors according to their values. In order to eliminate this kind of discontinuation, in this article we adopt some reasonable weight functions of evaluation grades *V*. These weight functions are characterized by piecewise linear and continuous with respect to the value of some evaluation factor.

4 Case study

In order to test the practicality and accuracy of the WRCC evaluation system which is proposed in this paper, Dongsheng town are chosen as the region for case study.

4.1 Test of the estimated value

Based on the survey methodology introduced before, surveys are conducted in different water consumption units and the per-land water consumption value of each water consumption unit has been obtained. Then, the total water consumption value of each unit is estimated according to the per-land value. Comparing the estimated value with the statistic value in statistical year book of 2008, it is easy to find out that in the first condition, the statistic value is 80% of the estimated value, while in the second and third condition the statistic value and estimated value are almost the same. The estimated annual water consumption of Dongsheng town is 62,250,000m^3, while the statistic value is 59,290,000 m^3, the error is 5%. This proves that the per-land water consumption method for predict the water consumption is relatively feasible.

4.2 Forecasting of water consumption

With the WRCC evaluation model and the estimated water consumption value by per-land water consumption method, not only the WRCC now but the WRCC in the future can also be evaluated. The land use, land scale and the development intensive data are obtained from the master plan, and the evaluation result itself will also become evaluation tools for the reasonability of the master plan.

Figure 4.1: Types of water consumption in different areas

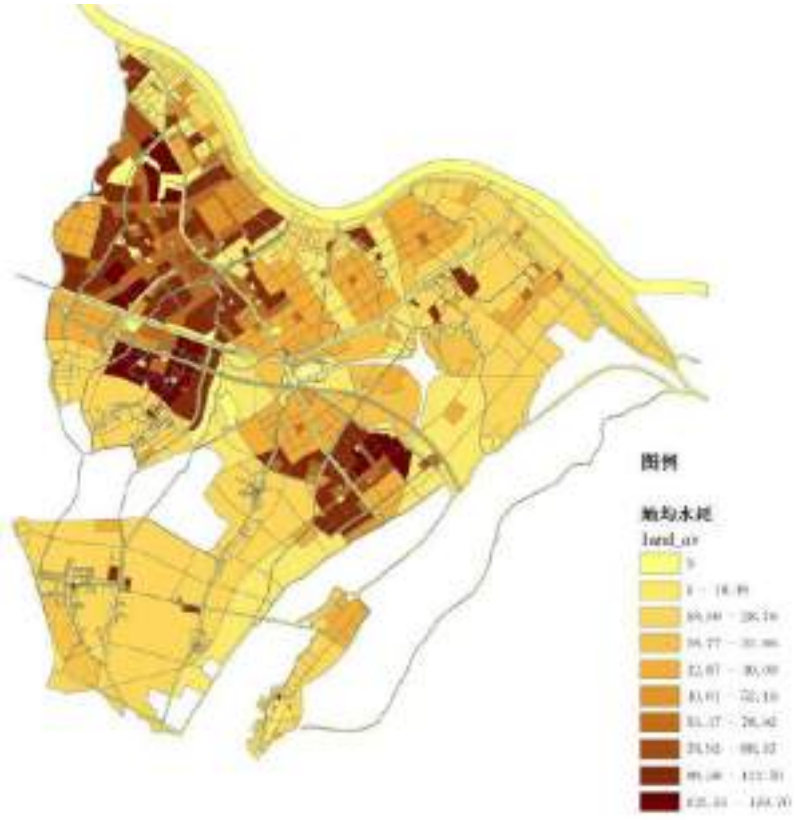

Figure 4.2: Average water consumption in different areas according to the master plan

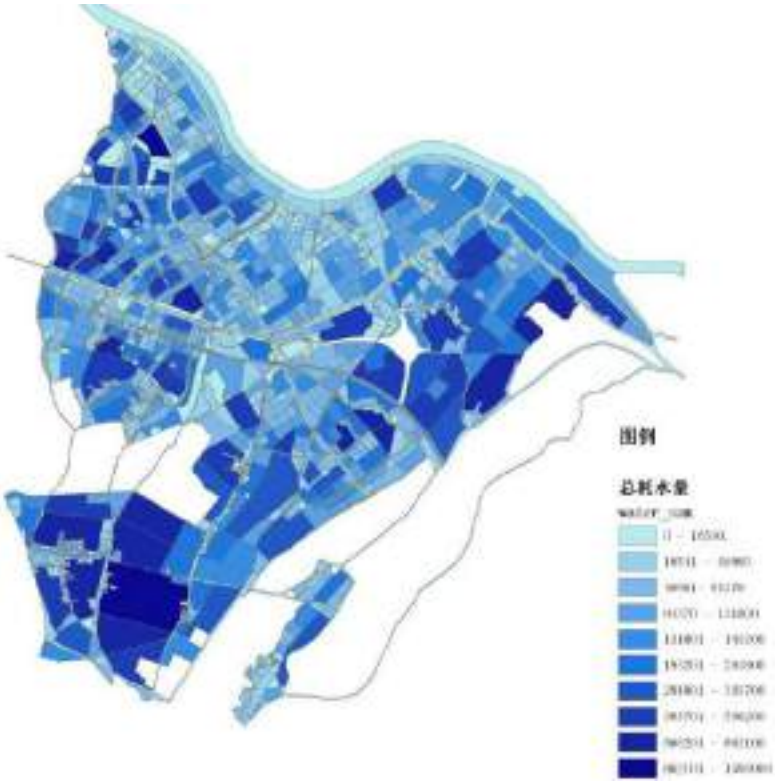

Figure 4.3: Water consumption in different areas according to the master plan

In this paper, the land use and height data are obtained from the master plan of Dongsheng town (2010-2020). 22 water consumption units are set up by overlaying the land use and the height data (Figure 4.1). Based on the per-land water consumption value which surveyed before (Figure 4.2), the water consumption of each unit can be calculated and maps are made (Figure 4.3). From these maps, it can be find out that the planned new town has relatively high per-land water consumption, due to the planning of high density of business and residential area.

Table 4.1 Predictive value of some indexes in Dongsheng, 2020

Index	Value
Per capita daily water consumption	196.91 Liter/person*day
Water modulus	20.22 Million m^3/km^2
Agricultural per mu water consumption	590m^3/acre
Industrial per million Yuan output water consumption	0.0027 Million m^3/million Yuan
Urban sewage treatment rate	100%

Based on the prediction of the water consumption data, the value of each index can also be predicted. It can be found out from the historical data that the amount of water resource stays stably in spite of the urbanization process. As a result, hypothesis can be proposed that the water resource amount in Dongsheng town will still stay stable in the future 20 years. According to the economic and population data

planned in the master plan in 2020, the value of all the index can be calculated (Table 4.1).

4.3 Evaluation of WRCC

Also, the evaluation of WRCC of Dongsheng town in 2020 can be conducted. According to the result of evaluation, in 2020 the critical point of WRCC in the grade v_1 is 0.1916, the critical point of WRCC in the grade v_2 is 0.6162, the critical point of WRCC in the grade v_3 is 0.1922, and the integrated score of the WRCC is 0.4997. It is evidently that according to the master plan of 2020, the WRCC of Dongsheng in 2020 is still belong to grade v_2, which means the exploitation of water resource has already reached a quite big scale, however, there is still some potentiality left for exploitation. As a result, the water resource condition can still support the scale of land and population planned in the master plan in 2020. It also means that the master plan of 2020 is within the carrying capacity of WRCC and it is reasonable from the aspect of water resource. However, the integrated grade of WRCC in 2020 dropped 0.02 comparing to the WRCC in 2008 which is 0.512. So it is also shows that in the process of rapid urbanization, WRCC is being threatened by expanding of land scale and rising of population, and should be pay special attention on.

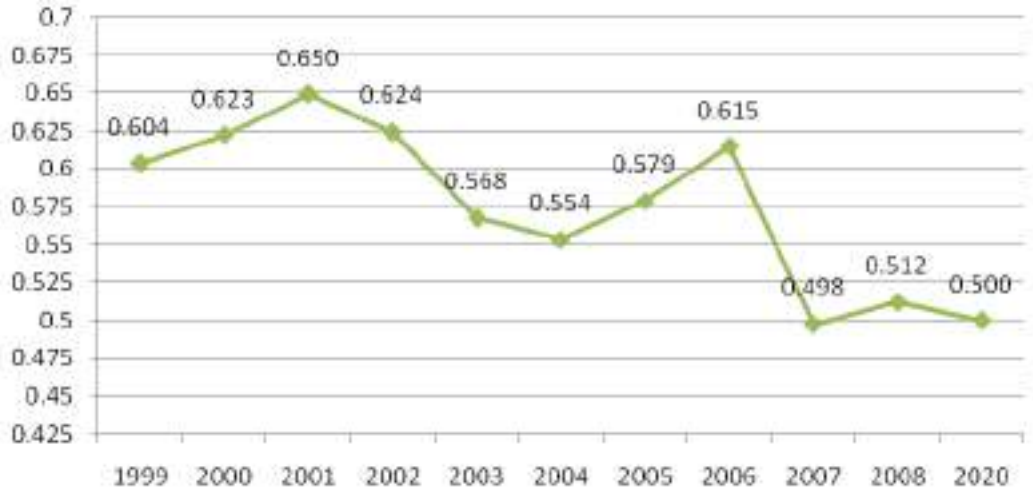

Figure 4.4: Annual integrate score of WRCC in Dongsheng

From the critical points, it is easy to find out that the critical points of 2 indexes: Daily per capita water consumption and water demand modulus in grade v_3 is rising constantly, especially the critical point of water demand modulus in grade v_3 which is 0.53 has exceeded the critical point in grade v_2, which is 0.47, that means this index is now in the warning state. It is the rise of the two indexes that induces the decline of the integrated score in 2020. In order to avoid the damage to the water resource caused by urbanization process, it is very urgent to take measures to improve the WRCC from the two aspects.

Table 4.2: Weights of index in the year 2020

Index	ri1	ri2	ri3
Per capita water availability	0	0.9345	0.0655
Cross-border water	0.5909	0.4091	0
Groundwater extraction rate	0.8	0.2	0
Water resource utilization rate	0.1420	0.8580	0
Pipeline leakage rate	0	0.93	0.07
Per capita daily water consumption	0	0.6539	0.3461
Water modulus	0	0.4739	0.5261
Agricultural per mu water consumption	0.025	0.975	0
Industrial per million Yuan output water consumption	0.7345	0.2655	0
Ecological and environmental water rate	0	0.3024	0.6976
Urban sewage treatment rate	0.8529	0.1471	0
Surface water level	0	0.25	0.75

5 Conclusion and outlook

The method for evaluation of WRCC of small town in the rapid urbanization period being proposed in this paper can be easily cooperated with 3S technology. By the land use and height data obtained by Remote Science (RS), with the spatial data base and calculation by GIS, the water consumption can be monitored dynamically. This method solves the problems in the current WRCC evaluation system which is static and difficult to obtain data, and can monitor and evaluate the WRCC in the rapid urbanization process conveniently. According to the application in the case Dongsheng, this method proved to be feasible, and the result of evaluation are turned out to be reasonable by experience judgment.

Since China has vast territory, and the climatic condition and economic development level are quite different from one region to another, as a result, the water resource condition and consumption amount are also have much difference. The per-land use water consumption value surveyed in this paper can only be representative of water consumption in economically developed small town in South China. In order to built a WRCC evaluation system which can be used in all the region in China, next it is urgent to divide China into several regions according to the climate condition and the habit of water use, and survey the per-land water consumption in all the regions, and set up the per-land water consumption system for the whole China.

KHARTOUM AND THE SUSTAINABLE URBAN RESTRUCTURING MARCH FOR ABSORPTION OF RAPID GROWTH AND URBAN CHANGES

Dr Sharaf Eldin Ibrahim Bannaga[1]

Abstract

The humanitarian priorities in development patterns has been an international concern, which makes environment and development issues cross-cutting and as a result of rapid urbanization phenomenon the concept of sustainable urban growth becomes urgent since cities are under constant physical and social changes. In addition, cities are made of different and often conflicting interests and landuses. They are therefore, in need of restructuring to contain these changes. Greater Khartoum is a typical example; it has been growing rapidly and is subjected to continual transformation. Khartoum started in the Independence Day(1/1/1956) by less than 3% of the total Sudanese population and this figure jumped to 16.8% in 2010 while the physical block grew beyond imagination.

This paper presents a comprehensive restructuring programme that Khartoum implemented to accommodate the changes, at first absorbed the huge influxes of the rural uprooted population and later improved the physical environment. This included treatment of squatter settlements to strengthen the urban fabric, reallocation of incompatible urban functions, revitalization of the CBDs and other urban renewal schemes. People mobility, a major objective of the restructuring programme received most attention. Transportation lines were extended for more coverage of the road network and higher population concentrations in congested settlements were diluted, particularly the filthy slums. Re-planning of old neighbourhoods, traditional villages, etc was performed and urban utilities were expanded. Popular physical development was encouraged to keep pace with the burgeoning demographic explosion.

Restructuring has also been employed for adoption of the appropriate local governance systems considering surplus population distribution, establishment of new local markets and other economic activities.

The restructuring programme made positive effects in protecting the environment, attaining socioeconomic benefits, particularly activation of the urban economy. The main difficulties encountered were the problems associated with the relocation processes but relocation made the regularization possible thus attaining social justice.

[1]Bannaga Consult, Khartoum – Sudan

1.0 Introduction

1.1 Evolution of the Concept of Sustainable Development

Many people had thought for a long time that environmental requirements were incompatible with the objectives of comprehensive development, but controversy about the environment as a key input to the developmental process has overcome the first stage which made the issues related to environment and development more obvious and evolved the concept of "sustainable development". This was officially born in Rio in 1992 during the UN Conference on Environment and Development and then confirmed by World Summit in Johannesburg in 2002. It becomes a new doctrine and all nations agreed to adopt a pattern of development that integrates production, protection and conservation of resources which brought about a shift from the demand for pure economic growth to the demand for balanced development based on the use of resources with maturity and wisdom, and a robust economy with safe environmental and social cohesion. This gave birth to alternative visions focus on the humanitarian priorities in the development patterns, known as the model of human development. The school of the new visions claims that the previous development model has not trickled down the development benefits to the poor.

1.2 Cities' Dynamics

The city reflects the arts, abilities, intelligence, genius, and temperament of humans and it also reflects their failures. Having to accommodate multiple urban functions and activities it provides a comprehensive life of a nation and represents the contents of its civilization, as reflected by the behaviour of society and its values, the life system and its various activities. Cities may witness throughout history, periods of prosperity, they may also be subject to periods of deterioration and the consequential changes in their physical structure. They may have different and often conflicting interests and landuses, and the larger the city the more complicated are these interests and their conflicts. As the city grows, so do the incompatibilities between landuses. Disparities exaggerate until time comes when conflicts cannot be resolved by any other way than reallocation; in urban forms it implies a start from scratch to make the required urban changes. This phenomenon of urban changes gives a city its dynamic and transformation nature. Experience shows that when a city is in a state of rapid urban transformation, its physical block expands fast and with different modes of growth activities dictated by the transitional characteristics of the city. Khartoum is a typical example of such growth, characterised by massive development of informal settlements and slums, inadequate coverage of public transport and other public goods, particularly employment opportunities, and the consequential increase in the percentage of the urban poor, environmental degradation, deterioration of city landscape, etc. To cope with the emerging situation infected cities are therefore in need to restructure and enhance their urban structures. There are a number of good examples that can be highlighted: Barcelona implemented a successful restructuring programme, the main focus of which was environmental improvement through dilution of development concentrations and

availing land for special uses. Tehran performed urban restructuring and absorbed huge influxes of migrants. Warsaw established a new city and adopted a new urban form creating a balanced spatial structure and evolving a pleasant townscape of a harmonized building form to attract investors. Some of the other restructuring successful stories are publicised by HABITAT and World Bank mainly on slum upgrading such as that undertaken by Dakar/Senegal UNCHS[8], Medellin/Colombia and Santo André municipality, São Paulo, UNCHS[6]. Khartoum massive restructuring programme is described below.

IGAD Map

2.0 Methodology and Objectives

This paper summarises a practical study which benefited from a primary data gathered by the author and his associates from a number of field surveys conducted for different purposes in Greater Khartoum and IGAD Sub-African Region cities, Bannaga[3,4], and a secondary data obtained from an in-depth literature review. The task of data collection was accomplished through different means: households surveys were carried out in selected Khartoum areas while visits were made to IGAD cities to gather the required data. The author observations and accumulated knowledge complement the discussions. He played a key role in the Khartoum restructuring programme when he was the responsible minister for 12 years.
This paper aims at:
(1) throwing light on the extremely huge magnitude of Khartoum growth and the consequential urban degradation which was thought to be beyond repair,
(2) documenting Khartoum successful experience and demonstrating how management reformation can be employed to correct urban distortions.

3.0 Khartoum and the Urban Transformation Process

3.1 Greater Khartoum Profile

Khartoum Capital, is a tri-city formation (Khartoum, Omdurman and Khartoum North), situated in central Sudan where the Blue Nile and White Nile meet and the River Nile originates. Its physical block is shaped by the three rivers; by creating the three distinct cities and an island in between; each city starts by the confluence of two of the three rivers. It exists at latitude 9-15 degrees and longitude 24-45 degrees and at altitude of 1353 feet in a hot and dry semi-desert climate with less than 150 mm, annual rainfall. Urban activities are clearly distributed between the three cities. Khartoum accommodates the business district, foreign trade and international economic activities. It is relatively young but surrounded by ancient villages providing it with agricultural products. Omdurman holds the Sudanese national and cultural heritage and local trade activities while Khartoum North accommodates the large industrial factories, the railway main station, the river transport facility and the government Mechanical Workshop.
Like many cites established by the European colonisers, old Khartoum is a Colonial-style city with a distinguished centre of a fortified core, surrounded by neglected indigenous native settlements. Its architectural style is mixed and the old colonial model of government and staff buildings gives the Nile Avenue its distinguished character. Omdurman's physical model highlights some of the Islamic traditions, such as Khaleefa's house and Mahdi's Dome. Khartoum North's old settlements are famous for their popular building forms exemplified by old tomb-like structures and traditional mud-brick dwelling units.
Unlike European colonisers' big cities, which centres undergo deterioration as their original owners move out to newer, more salubrious and more fashionable residential areas, Khartoum centre still suffers from low density development and it is nearly dead during off working hours. Now the majority of Khartoum new slums are found in the urban peripheries. Such slums provide cheap accommodation and

informal low-cost services, a place for essential economic contributions by lower income people, a reflection of unwanted aspects of urban life. Khartoum is overwhelmed by traditional settlements and villages in addition, to scattered expansions forming organic isolated blocks. The scattered expansions and similar urban formations are due to:
(1) the nature granted by the Nile rivers where the streams form the main border lines of the main physical blocks because villages and other urban areas have been historically founded along the streams of the three rivers,
(2) expansion encouraged by abundant and highly fertile land serviced with water,
(3) natural urban-village style growth, and
(4) viability of Khartoum for more development.
Thus, Khartoum faces the challenge of changing this prevalent village system of growth to a natural urban development system by integrating the villages into the city and forming a strong sequential urban fabric. This is why Khartoum always falls short of providing essential services, particularly extension of transportation networks.

3.2 Khartoum Urban Structure Development

Greater Khartoum urban borders were not delineated, its centres and their role within these borders are also not defined. Khartoum started as a small cohesive and intact town with a solid core forming the CBD. It enjoyed a lullaby of peace, stability and was exemplary in cleanliness, lushness of greenery and ease of life precision. Traffic was easy, while the population density was in proportion and residential reserve was abundant. Greater Khartoum grew with diversified congregation of diversities reflected by ethnic mixture of Arab and African bloods and a variety of African and Nubian cultures, overwhelmed by Islamic faith but this diversification enriched its social fabric when it was well maintained. Khartoum however, lost its physical cohesion and social strong netting when the rural uprooted population began to pour heavily in the city. Since then, Greater Khartoum has been growing rapidly and its scale of growth was beyond belief despite the fact that rapid urban growth is an international phenomenon. The annual population growth in most developing cities was about 4%, Habitat[7], but was about 6% in Greater Khartoum, the fastest developing metropolis where more than 50% of the total Sudanese urban population live. Greater Khartoum started in the Independence Day (1/1/1956) with 250000 inhabitants or less than 3% of the total Sudanese population and this figure jumped to 16.8% in 2010, totalling seven million, Table 1. This is primarily due to huge unexpected migration and the consequential uncalculated urban expansion through illegal encroachment upon lands. The accelerated growth evolved urban forms characterised by haphazard development of irregular endless expansions and sprawled growth lacking basic human services, refer to Fig 1. This is accompanied by changes in residents' traditions, behaviours and cultures. The Khartoum squatter population hurriedly built their adobes in open spaces and void areas inside the three cities and they indiscriminately occupied whatever vacant lands exist to the extent that nearly two thirds of the urban block had been turned into "makeshift shelters", creating huge subdivisions occupied by poor dwellers, the result was total urban

degradation, Bannaga[1-3]. Besides the dwellers' torrents, their shelters were subject to annihilation by rains which made the wet season a nightmare for them.
Khartoum development pattern is contrary to 'Compact City' model which retards urban sprawls and reduces energy and services cost. The table 1 shows a periodical population density decrease, primarily encouraged by lack of development control but reflects low-density traditional development. The sprawled paradigm disadvantage appears in the consumption of farmland, as reflected by Table 1, energy and loss of green space. The scattering of urban formations is due to the nature granted by the Nile Rivers, existence of natural village style that encourages urban-rural growth.
Khartoum Centre also deteriorated because it has not kept pace with the ongoing dramatic urban changes and continues to live in the past.

Fig 1 Stretch of Greater Khartoum Physical Block

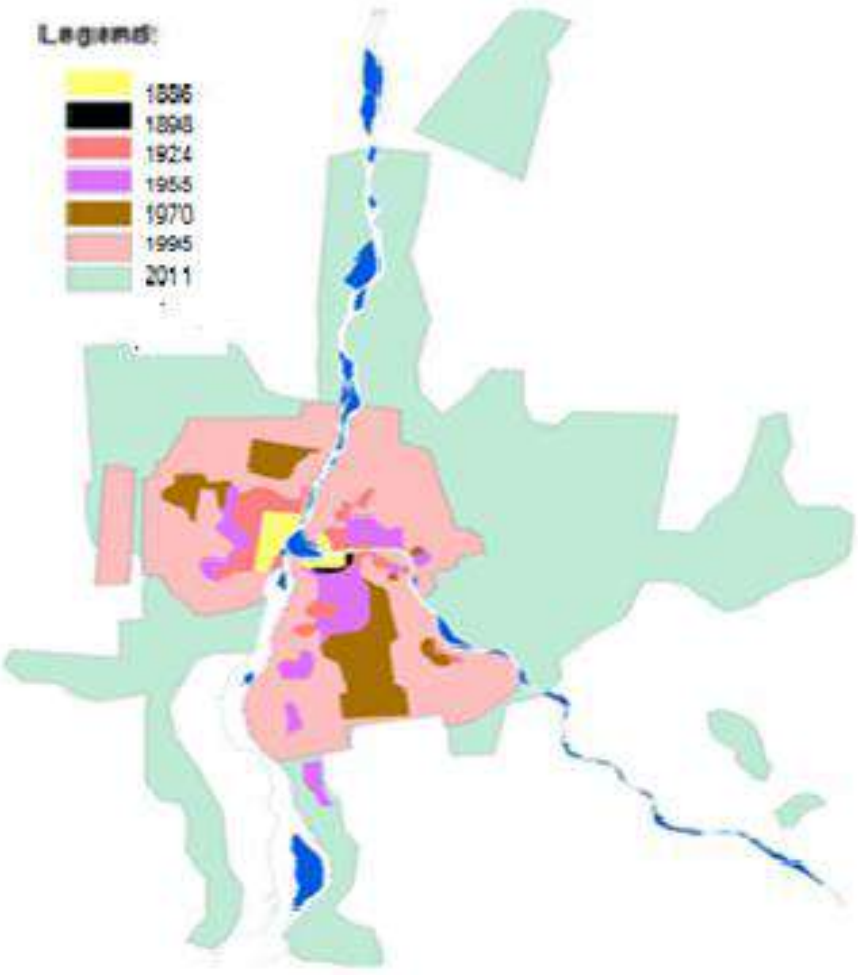

Table 1: Khartoum Physical Block Growth and Population Density

Year	1955	1970	1980	1998	2006	2010
Population in million	0.25	0.64	1.17	4.37	6.01	7.00
% of Sudan population	3.0	4.4	5.7	14.9	16.4	16.8
Total area in hectare	1680	3000	22840	80250	132300	165000
population density in person /ha	149	213	51	55	45	42

4.0 The Khartoum Urban Restructuring Programme

4.1 **Why Urban Restructuring?**

Urban restructuring adopted by Khartoum was not for reconstruction of dilapidated or ruined structures or building renovation, but for undertaking a complete urban reformation e.g. treating the deteriorated environment, correcting the distorted urban structures, maintaining the deplorable public utilities and generally enhancing the cityscape. These distortions led to loss of the urban entity and the citizens' civilized behaviours. Thus, restructuring must firstly, corrects the mistakes of the past and secondly accommodates the transformation needed to advance urban efficiency, build a sustainable city capacity and elevate the quality of urban life. This required installation of a better urban management scope to:

1. Bring justice between residents and reduce the physical forms variations between different settlements e.g. bridging the gap between two types of building patterns: full service regular neighbourhoods inhabited by affluent categories and dense, overcrowded shanties or slums, lacking basic services and mostly not recognized by authorities. This inequality feeling poses an barrier between the two distinct different groups and threatens the society, public security and social order. According to UNCHS[7], city status report, (62 %) of urban residents live in slums in African.
2. Setup a base for government resolve to address the squatting phenomenon which is encouraged by complete absence of effort in the sphere of urban planning, housing

and basic services provision. The neglected burgeoning population continued their squatter practices, justified by genuine demand for shelter.
3. Correct all previous mistakes e.g. abandoning the colonizers ' old urban model and containing change effects of rapid expansion.
4. Reorganise the urban space after re-evaluating all urban functions and activities to achieve environmental sustainability through landuse optimisation and to accommodate new desired functions that strengthens cohesion of the urban fabric.
5. Give urban residents the opportunity to rehabilitate the structures they live in.
6. Perform total urban reformation to accommodate the huge influxes of migrants, absorb the city surplus dwellers, improve the physical environment, strengthen the urban fabric and integrate all isolated scattered villages.

4.2 Urban Management Reformation

The first pivotal task for execution of the urban restructuring programme, reticulated above was installing a new effective management, equipped with knowledge and popular authorisation and able to pursue an integrated approach focussing on implementation of supportive legislations and polices and application of intensive sound spatial planning. Reformation was not difficult because Khartoum has great potentials. It is endowed with all kinds of natural resources encompassing land, water and energy and possesses vast stretches of fertile soils. Khartoum is a laboratory for education and training and it contains colourful inhabitants with different cultures, backgrounds and specialities thus, able to attract all kinds of investments and businesses but far away from adopting a knowledge-based economy.
As expected, the new management succeeded in replacing the prevailing legislations issued by central governments by legislations that belittled the role of the Federal State and weakened its grip on town planning and land management. The current Physical Planning and Land Disposal Act, 1994 was the first to be issued. The deficiency of the old acts was not primarily related to lack of accommodation to local requirements but the main aim of the legislation reform is to protect individual and group rights of the state residents, and to adhere to the principle of the local rule to solve conflicts that arise locally. The management then effectuated the Spatial Planning tool and performed wide-range planning processes. A change in the concept of planning paved the way for a shift from serving the rich minority to serving the poor which achieved justice among all urban society layers. A coordinated workable Ten Year Restructuring Plan was formulated in which treatment of the informal settlements and absorption of the surplus population were foremost tasks and spatial reorganisation was applied in a manner that strengthened urban fabric. This helped the poor to settle and become tools of development. And before embarking on remedial works, urban planning was employed to delineate new directions and areas for physical development to accommodate all populations whether new or original residents. Urban restructuring was also applied to balance landuse intensities to reduce the disparities among populations. The idea was to appropriate the use of space because Khartoum had large free spaces and some areas were less utilized compared to normal built-up area rates, Doxiades[5]. These vacant

areas were planned and certainly many benefits were harvested such as covering urgent needs of expansion but the main factor that necessitated free spaces planning was to control and protect the vacant lands from illicit use and invasion by squatters.
Khartoum management took a step further by applying informatics in all land allocations and development activities. Use of GIS and space and computer technologies, and internet enabled Khartoum management to benefit from the geo-spatial data technology for allocation, processing and registration of lands. The most beneficial work gained is computerisation of the "Housing Plan" which was based on allocation of land plots (site and service system) for citizens. The land administration role was to choose the eligible people who apply for land plots after making an evaluation in accordance with a criteria. Currently, the information system performs the job by automatically identifying and nominating the eligible persons without human intervention.
To better their performance, authorities implemented a wide-range of urban policy reforms, particularly those govern land tenure, transfer transactions, acquisition and expropriation dealings. Accessibility of shelter for all people(UNCHS Agenda) was also promoted through the legalization of the status of squatter and unauthorized settlers and by encouraging all kinds of regular residential development and by lifting restrictions imposed by government financial institutions on real estate's development and housing schemes. It was necessary firstly to apply prompt solutions to promote and encourage house development and return things to normal to prevent citizens from acting on an impromptu basis, which had previously led to the rolling of unauthorized settlements. However, by mobilising all people masses the processes of residential development was expedited and raised to a higher level and scarcely seeing a site without construction activities because popular construction was propagated. Upgrading of squatter and displaced settlements has also produced a development revolution and increased the housing stock allowing many marginal families to settle down. New towns have cropped up, dilapidated dwelling units were rebuilt and regular settlements have become overwhelming. Popular and official development proceeded to include construction of schools, water network, roads, etc and almost all urban activities .
To manage the city the management recognised the significance of being in close contact with the urban communities to effectuate a change of positive attitude that is necessary when seeking solutions for the urbanisation problems. Decentralisation of urban decisions, democratisation of local authorities and sharing of information were exercised and yielded positive results. Success was attained because the urban community was fully empowered and all stakeholders' efforts were mobilised, and a decentralized system was fully operational.

4.3 Surplus Population Absorption Schemes

Ambitious housing schemes, details of which are displayed in Table 2, were implemented but no option other than site and services model was at hand. They included huge housing plans, where 320,000 families received plots and other allocations through Alssalam townships(relocation sites) served 25000 families and allocations of built housing units benefited 40000 limited income families. Private

housing projects were also executed and a number of sites were allocated but were subjected to tight planning regulations to ensure validation of project by the authorities and as a result 30000 families were accommodated. Accordingly, new towns have been founded, becoming a real addition to the physical block. These included three Alssalam (Peace) townships, allocated for settlement of newly arrived homeless families. The described schemes availed large spaces for public utilities thus, releasing the pressure on open spaces, vacant lands and government reserves left for future expansion in old subdivisions. The new extensions, distributed evenly throughout the three cities, assimilated active and effective urban communities, refer to Fig 3. The total number of people served was 2.65 million and the number of plots allocated was 123% of the total number of the housing stock existed in Khartoum before programme commencement in 1990, which was 337400 units, as estimated by Doxides[5].To service these huge residential subdivisions land allocations for public utility development were made easy for all kinds of investments to provide services and employment opportunities for the population. The decentralisation system was reinforced by spatial redistribution to consolidate local rule, reduce traffic pressure and ease people mobility. Administrative districts, market centres and selected urban economic activities were redistributed to make them closer to dense population concentrations.

Table 2: Number of land Plots, Built Housing Units, Private Schemes and Alssalam Townships

City	Land plots (housing plans schemes)	Housing units (popular housing scheme)	Housing units (private investment schemes)	Land plots (Alssalam Townships)	Population served based on 6.4 P/family
Khartoum	95000		12577	10000	
Khartoum North	120000		15756	10000	
Omdurman	105000		1400	15000	
Total plots	320000	39400	29733	25000	
Grand total				414133 plots	2.65 million

4.4 Restructuring Operations

4.4.1. Aim

The aim of the restructuring operations programme was to transform Greater Khartoum into a metropolis of good urban style and dress while taking a life pattern

that adapts to the future and with special consideration to the presence of the Nile Rivers that give Khartoum its flavour and colour and its original urban form. Its implementation made sure of an inclusive involvement of city dwellers and their representative organizations while responding to local conditions and reducing the risks on poor people. Two of the important courses of actions pursued were clearance of worse physical distortions while the other was irregular settlements treatment.

4.4.2 Treatment Processes Applied

To regularise slums, villages, squatter and informal settlements, they were subjected to treatment processes to primarily improve their environments, correct their illegal status and improve their living conditions. Each irregular settlement was studied and three different approaches were considered for its treatment and this was accomplished either through settlement clearance/relocation or planning/replanning or incorporation into the urban fabric, accordingly Fig 2 was produced:

Clearance/Relocation: Worse physical distortions represented by filthy slums were cleared because they were insusceptible to improvement. Clearance of settlements was also applied to dilute the concentration of population in congested areas, as a prerequisite to environmental improvement. Relocation targeted recent settlements occupied by people who were not strongly attached to the land and their level of mobility was high so it was easier to relocate them to alternative sites. Other types of relocated settlements were those occupying areas which had been allocated for other uses as well as slums built in areas unsuitable for residential use or those which were a focus of human relegation.

Planning/Replanning: was applied in settlements more liable to improvement than relocation because e.g. their inhabitants constitute a permanent city population with strong attachment to the land they occupy though land ownership, level of permanency of buildings and planning requirements were major factors in deciding the planning option,

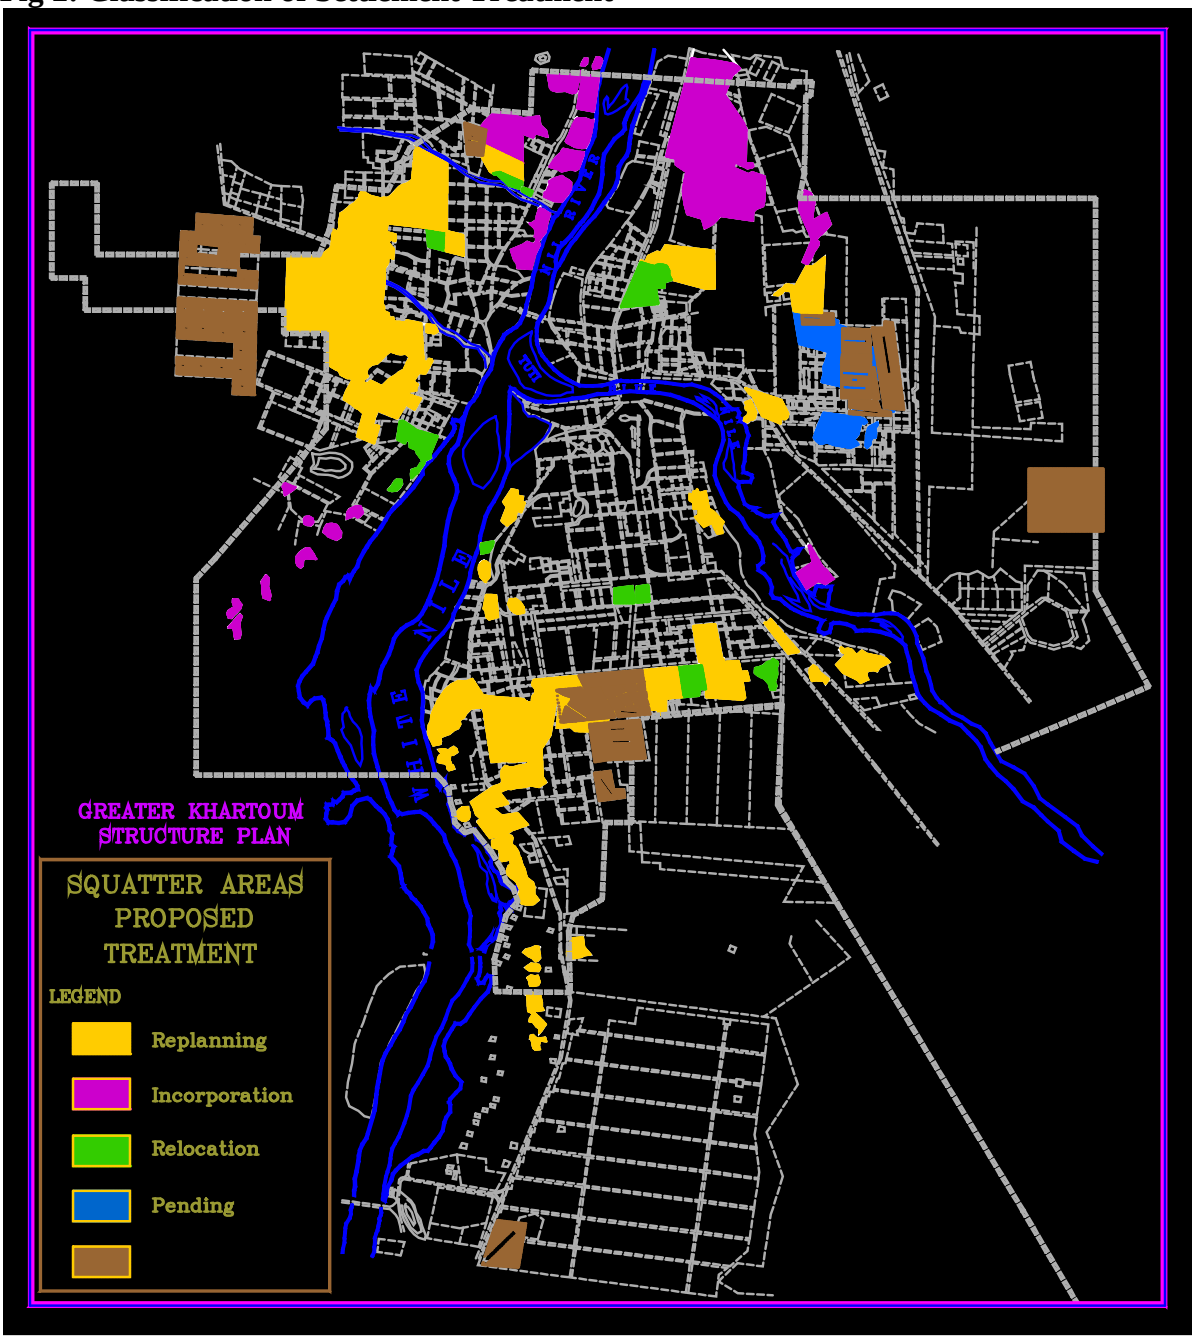
Incorporation: was applied in cases where the history of settlement/village establishment goes back several decades and their inhabitants lead a normal way of life i.e. settlements' planlayouts were acceptable and served with basic social services.

4.4.3 Clearance of Worse Physical Distortions

Though remediation means correcting thing but here correction can only be by returning to normal situation and clearing filthy settlements or those misplaced or their environments were seriously affected by awful malpractices, resulting into a drastic deterioration. Such settlements were highly unsecured and constituted real threats to public health. Some of them were built on natural water courses and were a principal cause of the 1988 flood catastrophe that devastated Khartoum and led to

collapse of tens of thousands of houses. More than fifty Filthy settlements of the kind were cleared.

Fig 2: Classification of Settlement Treatment



4.4.4 Treatment of Slums and Squatter and Informal Settlements

Slums are settlements that are densely populated and their environments are filthy and unhygienic but still function to provide cheap accommodation, informal low-cost services, and places for essential economic contributions by lower income people. It is recognised that many of the squatters are genuine cases of lack of shelter and this provision gap is filled by encroachment on whatever available urban land. Land mafias are also operating with huge financial resources and they know the ways and means that are available to organise their crimes. UN-HABITAT considers housing as" Informal Housing" when it does not conform to the laws and regulatory frameworks set up in the city in which it occurs. It is not likely to conform to the enforced planning and building regulations, a good example, is the traditional villages established in areas outside Khartoum previous boundaries. Numerous villages were built facing the River Nile forming historic residences of indigenous people of Khartoum suburbs. Some of these residences may include high quality housing, occupied by rich and influential people.

Fig 3 shows the huge scale of the treatment operations carried out targeting villages, squatter and other informal settlements(represented by single oblique lines ///), while Table 3 exhibits details of the legalised number of plots. More than 160 slums and squatter settlements were regularised, benefiting more than 280000 dwellers while IDPs settled in more than 70000 plots.

4.4.5 Village Organisation Programme

Villages are traditional informal settlements scattering throughout Greater Khartoum. They were incorporated in the physical block of the metropolis after they were subjected to planning/replanning or incorporation processes. They possess vacant areas which were used to accommodate some of the surplus population thus they provide enormous opportunities to address the squatting problem and help in absorbing rapid growth. Village organisation processes were therefore, promoted and the majority of villages was regularised and incorporated in the physical block. Their environments were improved and they were linked with the main transportation and metropolis networks. Most of squatter settlers and IDPs who managed to live in the core of villages were absorbed and the surplus was resettled in relocation sites.
The village organization programme paved the way for village physical forms improvement through streets opening and open spaces allocation and for registering villagers' plots in land registers. According to Table 3, more than eighty thousands villagers possessed proper titles.

Table 3: Number of Plots Targeted by Treatment of Squatter and IDPs' Settlements, Village Organization, and Old Neighbourhoods' Replanning Programmes

City	Number of plots treated (squatter programme)	Number of plots legalised (village programme)	Number of plots replanned (old neighborhoods programme)	IDPs settled through (IDPs Programme)	Population served based on 6.4 P/family
Khartoum	50250	32550	6500	15500	
Khartoum. North	50290	30250	5560		
Omdurman	181236	20400	14050	61000	
Total plots	281776	83200	26110	76500	
Grand total				467586	3.0 million

4.4.6 Replanning of Old Neighbourhoods Programme

Old traditional residential neighbourhoods underwent urban renewal to improve their quality of life and to facilitate the provision of services and public utilities and to ease traffic flows. These old quarters were developed at the time when man and motor were not separated. In this programme the number of families involved surpassed 26000.

In summary, the Khartoum Urban Restructuring Programme provided shelter through absorption and legalisation schemes for more than 5.5 million people or benefiting greater than 880000 families.

4.4.7 Restructuring and Development of the Khartoum Centre:

4.4.7.1 Development Authority:

It is known that management of capital cities always suffers from cross-cutting and conflicting forces exerted by all levels of governments especially if the central government is overruling and interfering in all aspects of local governance. Khartoum Capital is no exception.
Khartoum Centre Development Authority was established to supervise the execution of joint development projects between State and Federal governments in the Centre but has been given limited administrative authorities. Most importantly was the agreement on the Centre geographic boundaries. Two main issues were considered: (1) complete coordination between higher government executives(central-state-local) who possess constitutional authorities after identifying the role of each in the Centre management (2) resolving the professional conflicts between all levels of

government executive departments by formulating a workable procedure and specifying the tasks and responsibilities of each.

4.4.7.2 Restructuring and Developmental Projects:

To develop environmentally safe and prominent centre some reforms were made:

- Distortions were corrected targeted misplaced and substandard buildings but those of historical and cultural values and giving the Centre its Sudanese spirit and identity remained untouched while some of old government departments, including departments situated along the water frontage were reallocated for rearrangement of the Centre spaces.
- Some improvements in urban efficiency were made when:

(1) incompatible functions were replaced by desired economic activities

(2) reallocation of urban functions in central zones was inevitable due to strong functions expansion and urban dynamics particularly where functions consuming unnecessary large valuable spaces

(3) new social, civic, commercial and recreation activities cropped up forming modern features of urbanisation

- Open spaces in the Centre Heart witnessed expansion and if made green will enhance the landscape, allow fresh air movement and dilute the concentration of development. Once this becomes a reality the Centre will be vivid and full of life. Enlargement of the Centre Heart open space helped in creating new pedestrians routes and passages and gave people easy access to the Centre surrounding areas but what hoped for is the complete evacuation of all types of motors out of the inner central spot represented by the UN square. The pedestrians movement to and from the square could then follow four axes, two in the north-south direction and the other two in the east-west direction. These axes when freed from motor movement pedestrians commercial and recreational spines will lead into marketing and leisure zones. The void areas and the Army garrisons in the eastern part of the Centre, beyond the railway tract, if developed will cover future investment demands.
- Some transportation lines were extended out of the Centre but, the Centre still falls short of essential transportation and other networks. However, the Centre population density is extremely low necessitating adoption of compact city development model.

4.4.8 Reallocation of Selected Metropolis Functions

To follow are some of the reallocated functions:

1. Many incompatibility-based urban functions relocation schemes have been executed in the last two decades to sustain growth, optimize spatial utilisation and attain urban efficiency. They were carried out for (a) landuse revitalization (b) landuse compatibility(c) Central Markets decentralisation, etc
2. Restructuring of metropolis transportation lines, municipal and other engineering networks. They were essential for serving the huge urban expansions. Restructuring included almost all existing urban networking e.g. water systems, electricity supply and other municipal services considering that transportation and traffic systems restructuring often result in spatial rearrangement. New passages to facilitate traffic

movement were opened and extended to serve the vast urban subdivisions and markets in an unprecedented manner and the lengths newly constructed roads exceeded several times of those constructed since Independence Day.

5.0 Lessons Learned from Khartoum Experience

Urban restructuring is a fearful task to perform and the main difficulties encountered in executing the Khartoum restructuring programme is containing the problems associated with squatting and the consequential relocation processes.. The appropriate measure is to address its root causes together with lands distribution to the needy since use of force alone is a meaningless solution without strict controls and painful punishments of mafia land grabbers.

Relocation in its final form is uprooting and replanting in an alien and hostile environment. Therefore, it is a tough decision to make, justify, explain and carry out. On the face of it, looks like any other simple planning decision but most problems arise when relocation decisions involve the disadvantaged, the poor and the under privileged. Much resentment is precipitated if relocation is forced involuntarily. lnA fact some relocation are simple, popular and gratifying. Khartoum Experience show that patient grassroots action preceded by elaborate and comprehensive consultations can produce miraculous results. Haste and high handed approach especially if accompanied by indecision and hesitant actions produces irreversible damage and nasty unnecessary confrontation. To set the process in motion the first issue to be addressed is guaranteeing support of higher executives followed by an elaborate process for securing public approval and support. The second issue is the proper contact with the citizens involved. Most important is dissemination of information, and media monitoring. Popular committees were best forums to float such action and employment of the civil judges helps a lot. Their presence abates citizens' fears, moderates committees members squabbling and infighting and adds respect and credibility to the committee's actions.

6.0 A Concluding Assessment

Urban restructuring certainly satisfies the three pillars of sustainability; environmental protection, social elevation and economic growth. Khartoum gained real benefits from urban structure enhancement and provision of public goods, particularly housing and slum upgrading.

The socioeconomic benefits are evident when considering the large scale of house provision and the improvement of the poor's settlements conditions. Urban planning has forced social diffusion, effective stakeholders participation and created some sort of commercial and trade activities that sprout along the streets. The most important residue of urban restructuring is settlements regularisation which was exercised with fair and just procedures and all land allocations are completed mechanically and without human intervention. All stated benefits have been harvested by citizens and particularly the marginalised residents. In last visit made to one of the treated large settlements, namely Haj Yusuf East area, in April 2010 an enormous social and economic development was witnessed. To date, essential services such as, water,

health, education, electricity and other urban facilities have been completed. A number of Haj Yusuf dwellers who were subjected to the planning process and granted proper land titles together with those settled in absorptive cities were interviewed to know their opinion about their new living conditions. Their response was very positive and they were satisfied by the level of progress made. The interviewed people reacted by a warm welcome and recalled the days of their positive interaction with the planning process, and they are very pleased to harvest the fruits of the legalisation process. They remembered the previous awful conditions and their sufferings and the hardship they went through when residents were afraid to walk through their settlements in daylight, and when even police forces avoided chasing any criminal person who entered their slums for hide-out.

In conclusion, Khartoum deserves to be rewarded for the very useful work accomplished and other cities should learn from its experience because it is of a huge scale and unmet internationally. Khartoum has enormous urban potentials and can meet the future challenges without complications if it seizes these opportunities and continues to carry out more urban enhancement and developmental projects though it has not yet benefited from its unique site and genius loci. However, Khartoum would sustain its growth and move forward if the Restructuring Programme is accompanied landscape beautification and greenery programmes targeting the ample open spaces and void areas throughout the physical block. Intensive reforestation and trees plantation make the programme highly innovative and add a lot to Khartoum which is gifted by the three Nile Rivers.

THE COLLECTIVE MEMORY EFFECT ON CROSS-BORDER COOPERATION PRACTICES IN EUROPE

Beatrix Haselsberger[1]

Abstract

The main objective of this paper is to examine the significance of planning cultures under the lense of overcoming the dividing function of national borders. Doing so this papers seeks to analyse the collective memory effect on cross-border cooperation practices and more precisely to figure out to what extent subconscious collective memories influence formal planning decisions in general as well as the quality and success of cross-border cooperation processes in particular. However, rather than searching for the cultural nucleus of cross-border planning practice, I am proposing an analytical framework, capable of examining the question of how appropriate trans-cultural understanding can be built up in different cross-border regions. Absent such an understanding will tend to legitimise the stereotypes we hold of 'the others' and hamper the practice of cross-border cooperation.

1. Introduction: Setting the scene

European spatial planning has emerged in a way that has (mostly) ignored the complexities associated with national borders, tending to take a monochromatic view of them as either 'closed' (external borders of the EU) or 'open' (internal borders of the EU), often rooted in a singular view of either a 'space of places', or a 'space of flows' (after Castells 1996). But this view denies the much more complex, shaded reality of borders, which are ambiguous human constructions (*cf.* Paasi 2009; O'Dowd 2003). Unpacking the complex border phenomenon brings to the fore that borders are in fact comprised of an overlapping set of boundaries (including administrative, political, social, cultural, economic and mental), all of which have spatial and social impacts and influence spatial planning processes, decisions and outcomes (Haselsberger 2010). This understanding helps explain why properly working cross-border networks are rarely found throughout Europe despite the many financial support programmes and institutional frameworks set up by the European Union (*cf.* Dühr et al. 2010, de Vries 2008). Assuming that the planning systems mismatch is not the root-cause of the problem, as can be learned from successful cross-border cooperation projects (Fürst 2009), I am arguing that the lack of a trans-cultural understanding may be regarded as one of the reasons why, despite good intentions, long-lasting and effective cross-border cooperation turns out to be so difficult in planning practice.

As planning cultures are changing over time and the beliefs, perceptions, and feelings of different social groups, classes and entire societies are difficult to grasp

[1] Vienna University of Technology, Austria,
Department of Spatial Development, Infrastructure and Environmental Planning
Centre: Regional Planning and Regional Development – beatrix.haselsberger@tuwien.ac.at

(Friedmann 2005; Hofstede 2001, Knieling & Othengrafen 2009), it is not surprising that these complex aspects have so far been largely ignored in planning research debates. In this paper, I propose an analytical framework that will allow us to explore these mostly subconscious and all too often 'taken-for-granted' dimensions of cross-border planning. The innovative aspect of my approach lies in combining collective memory and planning culture theories and by unpacking 'taken-for-granted' generalisations about 'the others', which often take the form of negative stereotypes and misconceptions within a given planning culture. By doing so, I hope that this paper will contribute to a deeper trans-cultural understanding and thus help to overcome a critical aspect of the continuing, historically contingent, and divisive effects of (European) borders.

2. Cross-border cooperation: The significance of planning cultures

Overcoming national borders through spatial planning and, in particular, through various forms of cross-border cooperation is a very challenging task that requires much more than 'just' planning the physical space of the area under consideration. It has to deal with issues such as the figuring out of appropriate solutions for differing or even conflicting interests and intentions on both sides of the border. The situation becomes even more complicated when considering that human beings are not only part of their respective administrative and political systems, but behave according to their own cultural and societal backgrounds and experiences. Reeves (2001) alerts us that if planners, professionals and practitioners do not reflect upon these socio-cultural characteristics or do not consider them important enough in the planning process, this may compromise the effectiveness of planning.

But it is also the case that those directly involved in the planning process – planners, professionals and other practitioners – act according to their own social and cultural understandings as well as their value system, that is to say, according to their own planning culture(s). Fürst (2009) defines planning culture as a mental predisposition, encompassing specific values and orientations, which those involved in a given planning process share. These 'soft cultural factors', as Ernste (2012) calls them, are decisive for the success of any planning process. As part of their professional work, planners, professionals and practitioners, make or implement spatial plans or manage and coordinate development projects, in accordance to their *"ability to interpret and re-interpret rules and norms in the framework of their own personal motivations"* (Ernste 2012, p.88). Hence this group of people does not act in a detached and unemotional way, but according to what I call 'the collective planning ethos' of their country (representing the institutional and political settings in which they are embedded). On the other hand it has to be stressed that, in addition, very emotional individual, cultural and societal backgrounds – the 'habitus' (collective civilised dispositions) of a person, as Bourdieu (1979) calls them – are at play. They are characterised by gender, religion, race, ethnicity, language, politics, family background, education, dress-code, hobbies, interests, personal experience, professional qualification, views, beliefs and priorities.

In the scientific debate, it has been strongly emphasised that different planning cultures produce very different kinds of planning as well as that the underlying cultural differences may hamper cross-border cooperation and even risk the building up of negative or stereotypical judgments of 'the others' on the other side of the border (*cf.* Friedmann 1998, 2011; Sondercock 1998; Hofstede 2001; Healy & Upton 2010; Fürst 2009; Knieling & Othengrafen 2009; Haselsberger 2010). On the other hand it has also been demonstrated that trans-cultural understanding provides a means to grasp the way that *"planning tools and practices are being adjusted in different ways in response to common challenges and with what effect"* (Nadin 2012, p.2), and doing so furthers the spatial integration process. What is needed then is a truly trans-cultural understanding, where *"planners [on both side of the border] must identify what values they are taking into their work and whether they could provide betters services for their customers by seeking constructively to change some of their attitudes, values and ethics"* (Kitchen 2007, p.147).

This raises the question if planners, professionals and practitioners have the ability (or rather the political will and/or interest) to understand issues deriving from other frameworks and languages. Interestingly, *"similarities can be equally important as differences [when] looking at different perspectives and challenging one's own beliefs and attitudes towards people with which one is dealing."* (Reeves 2011, p.598-9) Dory Reeves further alerts us (by referring to the work of Susan Bryant 2001 on the building up of cross-cultural competences) that it could be very problematic if the planning culture within which a planner is embedded appears to be too similar to the institutionalised practices of his/her cooperation partner. This might easily lead to over-identification and moreover to inappropriate assumptions about the reality. Languages serve as a good example here. The meaning of the terms *Raumplanung* (Austria, Germany), *Urbanistica* (Italy), *Urbanisme et Aménagement du Territoire* (France, Belgium, Luxembourg), *Town and Country Planning* (UK), *Ruimtelijke Ordening* (the Netherlands), and *Land Use Planning* (Ireland) all evolved in their own particular legal, socio-economic, political and cultural contexts. Strictly speaking, the terms are not internationally transferable to other countries, except in the most general sense. This applies even in countries with the same language; *Raumplanung*, for instance, has different meanings in Austria and Germany (*cf.* Haselsberger 2009).

So what we can learn from current debates is that planning cultures:

- are very hard to grasp as they encompass various interests, beliefs and perceptions as well as different means of resources, such us power and money (Reimer & Blotevogel 2012) originating from different spatial scales (e.g., local, regional, national, supra-national, cross-border), which are not necessarily harmoniously aligned;
- are manifested in many different (symbolic and ideological) layers, such as values, traditions, attitudes, mind sets and habits, which are shared by those taking part in the respective planning process (Fürst 2009);

- vary from place to place as well as from context to context, but might gradually converge over the next few decades due to the ever-expanding worldwide net of professional contacts and the internet (Friedmann 2011); and that they
- are difficult to decode from non-native-language-speakers and cannot be transferred easily to any other context or situation (Haselsberger 2009).

Although it is often argued that the concept of planning culture is unclear and difficult to define within humanistic and social science research and that it is a big challenge to operationalise it as a scientific concept (Knieling & Othengrafen 2009), a first important theoretical-analytical roadmap has been provided by Gullestrup (2009). He distinguishes between a horizontal dimension of culture (those segments of culture, which are manifested on the same 'perceivable' level: e.g. immediately visible cultural traits) and a vertical one (those segments of culture, which provide an understanding for the perceivable cultural layers: e.g. hidden, taken-for-granted assumptions and fundamental legitimating cultural traits). For him culture consists of (a) meanings, attitudes and values – the emic perspective (according to Harris 1999) or the cultural specific aspects of communication (according to Reeves 2011) – as well as of (b) the visualised or manifested product of social interactions – the etic perspective (according to Harris 1999) or the generalised aspects of communication (according to Reeves 2011). Knieling & Othengrafen (2009) have further elaborated the model of Gullestrup (2009) by incorporating the three levels of culture as introduced by Schein (2004) into it. Doing so, they have introduced the 'cultural planning model', which consists of three levels, namely (a) 'planning artefacts' (visible planning products, structures and processes); (b) 'planning environment' (shared assumptions, values and cognitive frames that are taken-for-granted by members of the planning profession); and (c) 'societal environment' (underlying and unconscious, taken-for-granted beliefs, perceptions, thoughts and feelings which are affecting planning) (Knieling & Othengrafen 2009, p.57).

Although these models provide important insights for grasping the planning culture complexity, it is argued here that the dimension of time and change – although partly considered in the Gullestrup model – does not achieve the attention required. The model of Gullestrup only briefly introduces the 'culture dimension of time' and limits it to 'culture change-initiating factors'. He distinguishes between external ones, those deriving from nature e.g. climate change or from other cultures e.g. through European integration processes and internal ones, those which arise within a particular culture, due to political change, etc. But planning cultures are subject to change or as Friedmann (2011) describes it, they are "*in movement in the sense that they are continually being revamped to adapt to perceived changes both internal and external in origin*" (p.196). Hence the question arising is of how shared meanings and values are constructed and why which elements are passed over – or not – to the next generations and what impact this process has for the building of personal and social identities turns out to be a fundamental issue.

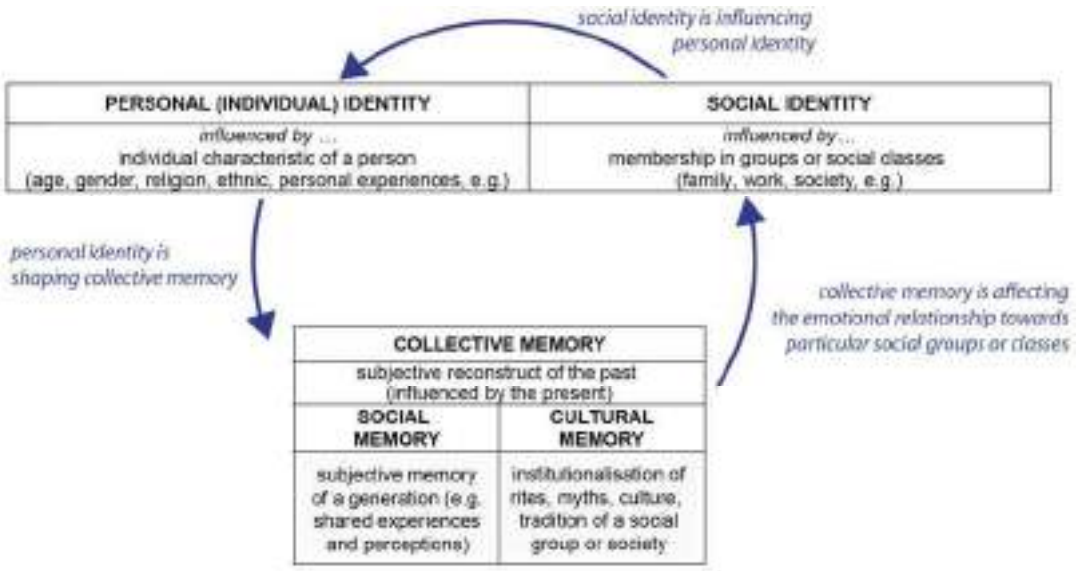
This is particular relevant in a cross-border planning context, where different kinds of boundaries are often deeply rooted in the minds of people, manifested through stereotypes and sometimes expressed through distrust and fear. Building on the hypothesis that spatial planning and consequently cross-border cooperation is strongly (but often unconsciously) influenced by identities, collective and cognitive (mental) pictures of a specific area, adapted from 'collective memories' of social groups (e.g. societies), which are only coherent in a relative sense, I'm arguing that it would be important to find out how far 'subconscious collective memories' affect the quality and success of 'formal cross-border cooperation processes and practices'. Interesting, however, is that while the awareness of the identity phenomenon is present in the 'sociologists' world' (e.g. Manuel Castells), little attention is paid to it in the 'planners' world'.

3. The subconscious dimension of planning: Collective memory matters

Collective memory offers useful insights into the 'cultural mismatch' understanding of problems in cross-border cooperation processes and practices and doing so help to better specify and conceptualise some of the still prevailing difficulties in cross-border network structures emerging from real interactions between partners who may occupy more or less coterminous juridical, organisational, cultural and cognitive planning spaces.

The added value of collective memory becomes even more evident for the planning culture discourse when considering that it provides a fundamental basis for the construction of social identity or to say it with Sandercock (1998) words *"to take away a person's memory is to steal a large part of their identity"* (p.208). Identity in turn is an essential segment of planning culture (Castells 2010). As introduced in Figure 1 the development of an individual's identity is partly influenced by the groups and social class (*cf.* Bourdieu 1979) to which a person belongs. Interesting in this context is that belonging to one social group may favour the interests and opinions of in-group members (inclusiveness) over out-group members (exclusiveness), which in a cross-border planning context can also result in the building up of generic stereotypes of 'the others' (Hofstede & Hofstede 2005). This also means that cross-border cooperation activities may fail simply because the social affiliation to their own group (or society) is much stronger and more developed than a desire for contact with some particular out-group, in particularly in those cases where there is a fundamental split in interests and perception between the cross-border cooperation partners (Haselsberger forthcoming 2012).

Figure 1: Interrelationship Identity – Collective Memory



Source: Haselsberger (forthcoming 2012)

The emotional relationship of groups and individuals' towards a particular group or even society as a whole depends on both collective memory and history, which are by no means synonyms (Halbwachs 1985). In contrast to history (more or less objective and static picture of the past), collective memory is a subjective reconstruction of a past that is shared, passed on and constructed permanently by a particular social group or class, through personal (individual) experiences and traditions, that may permit temporal and spatial distortions of past happenings. Hence, collective memory colours the present and is embodied in contemporary practices

According to Aleida Assmann (2006) collective memory can be divided into the more subjective social or communicative memory (for example the memory of a generation, which refers to a time-horizon of around 80-100 years) and the more objective cultural memory (institutionalisation of the rites and myths of a society). Social memory is the most subjective form of memory, which builds on the individual perspective of a single person and remains vital as long as this person is alive and/or part of the group. A personal (subjective) example may help to explain the significant role of knowledge building by this kind of (subjective) memory. My father served actively in the Second World War. Thus he personally experienced the moment when the Italians changed sides: at the beginning of the war, he had fought shoulder-to-shoulder with the Italians as allies, but by the end his former 'war colleagues' had become enemies. Luckily he survived the War, but what remained was his generalised picture of Italians, mainly characterised by distrust. Despite living next to the Italian border, travelling to Italy was not acceptable for him. This – of course personal and subjective – example helps to explain why in some cases it may be so difficult to work together across national borders and in particular to build up reciprocal trust. Cultural memory might thus be described as '*the culturally*

institutionalised heritage of a society' (Assmann J. 1995, p.130) insofar as it preserves the knowledge from which a society derives its identity, tradition and culture. The distribution and adjustment of the cultural memory is institutionally organised through expert bearers (such as scientists, academics, priests) and becomes reality through time-independent cultural patterns or *lieux de mémoire*[2] (texts, hymns, rites, monuments, signs, cultural emblems) as well as institutional communication (recitations, practices, observances). The work of Nora (1984) concerning the loci memoriae of France exemplified that the society itself creates identity through visible and non-visible cultural patterns. He argues that comprehensive time- and place-independent cultural patterns enable all to build on a collective identity, even if people sharing this identity are not personally acquainted. Important, but often underestimated, is the extent to which these *lieux de mémoire* are influencing and shaping peoples' opinions and viewpoints. Hymns serve as a very good example to underline this point: '*Wo man mit Blut die Grenze schrieb*' – where the border was drawn in blood (Carinthian hymn); *'heiss umfehdet, wild umstritten […] viel geprüftes Österreich'* – strongly fought for, fiercely contested […] much tested Austria (Austrian hymn); or *'Già l'Aquila d'Austria, le penne ha perdute. Il sangue d'Italia, il sangue Polacco, bevé, col cosacco, ma il cor le bruciò.'* – The Austrian Eagle has already been plucked. Italian blood, Polish blood, it drank, together with the Russians', but its heart was burned. (Italian hymn)

4. Collective memory & planning culture: An underestimated interrelationship

The planning culture discourse has strongly emphasised that cultural differences manifest themselves in several different ways or perspectives. Nonetheless the focus of the current debate has tended to be on the formal end of the spectrum, in an anecdotal way. The subconscious aspects of culture, those being referred to as underlying and unconscious, taken-for-granted beliefs, perceptions, thoughts and feelings in the planning culture debate although being recognised as important cultural dimensions have not received the attention required in the theoretical planning culture discourse so far.

Figure 2 depicts the prevalent cultural considerations emerging from sociology as well as planning theories and debates much as the layers of an onion. Doing so it provides the basis for a comprehensive overview of how collective memory is shaping and influencing planning-specific formal and informal discourses and practices. Social memory (the nucleus of culture) and societal environment (the nucleus of planning culture) build up the core of the onion. Representing the emic perspective of (planning) culture, these aspects are hard to grasp from an outsider perspective and as a consequence are often referred to as 'taken-for-granted' in the scientific debates. The situation becomes even more difficult when considering that both core dimensions are heavily interrelated and influence each other subconsciously. On the other hand cultural memory and the planning environment as well as the planning artefacts are introduced as the most superficial layer of the onion

[2] A *lieu de mémoire* is any significant entity, physical or non-physical, which has (the potential to) become a symbolic element of the memorial heritage of any community (monuments, hymns, e.g.) (*cf.* Nora 1984).

– the etic perspective of (planning) culture – which from an observer perspective is immediately visible. In addition the framework unpacks also the degree of objectivity of the different layers, with the core layer(s) characterised by different meanings, attitudes and values as the most subjective form of (planning) culture. The outer layers of the framework, on the other hand, represent the most objective aspects of (planning) culture, which could also be described as the visualised and manifested product of social interaction.

All layers of the comprehensive framework have a clear relationship to each other, in both a horizontal (within the respective layer) and vertical (cross-layer) way. On the one hand, the horizontal relationship assists the understanding of how the several layers of collective memory are influencing the layers of planning culture and consequently the planning profession as a whole. On the other hand, the vertical or cross-layer relationship – with individual preferences based on nurture and experience influencing and shaping the kinds of collective action – underlines the importance and relevance of subconscious and subjective aspects within formal structures, such as the planning system as a whole. Due to the cross-layer relationship, where the informal-subjective layer, which derives its evidence from the social memory, is recognised as a central anchor point towards the understanding of what impact socially produced culture has on planning, the dimension of time and change is fully considered and integrated in the framework introduced.

Figure 2: Collective Memory & Planning Culture's Framework

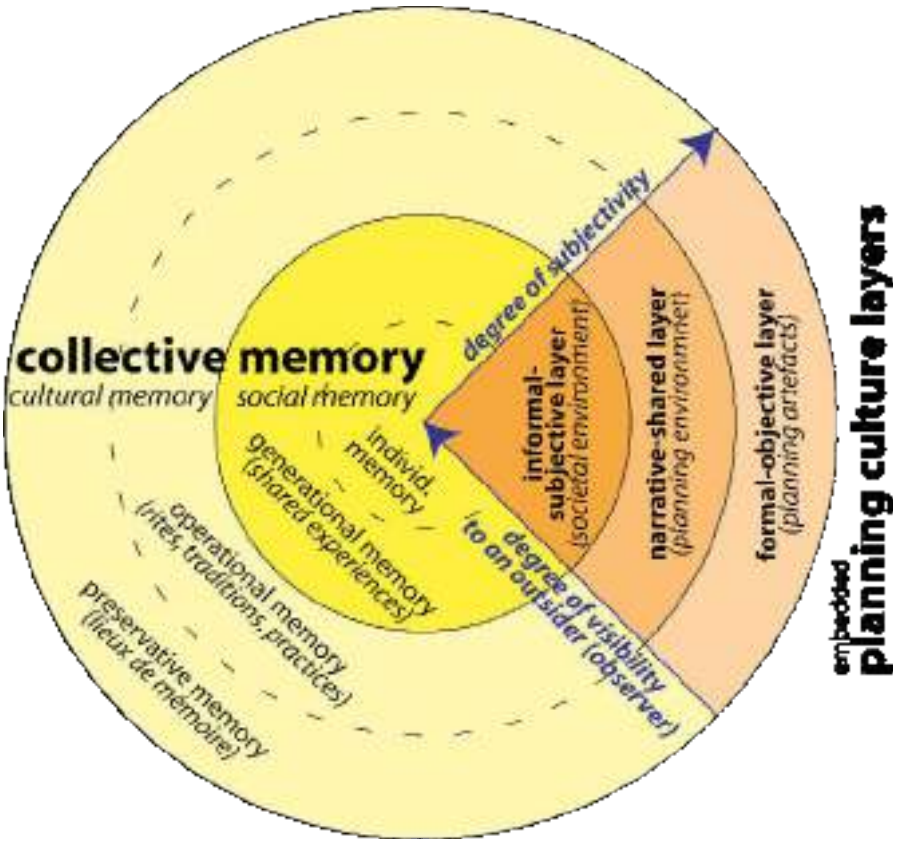


Table 1: Collective Memory Layers

Collective Memory Layers	***Social memory*** (conversational remembering): transmitted interactively; limited to a time-horizon of 80-100 years; intergenerational scope; consists of: (a) The ***individual memory*** might be described as a biographical remembering of own experiences and relationships based on which an individual derives his/her personal identity. (b) The ***generational memory*** emerges in a specific milieu of spatial proximity, where it gets shaped and transmitted through regular interactions, discourses and dialogues based on shared ways of life, experiences and perceptions.
	Cultural memory (institutionalised collective remembering): transmitted symbolically; unlimited time horizon; trans-generational scope; consists of: (a) The ***operational memory*** manifests the rules and attitudes of collective activities and practices a culture considers as socially essential, such as social and religious ceremonies, rites, actual behaviour or dress codes. (b) The ***preservative memory*** is the most symbolised layer and consequently the immediately perceivable cultural layer of a society. It becomes reality through time-independent cultural patterns or lieux de mémoire, such as artefacts, texts, monuments, national holidays, hymns.

(dimensions after Assmann A. 2006; Assmann J. 1995)

Table 2: Planning Culture Layers

Planning Culture Layers	***Informal-subjective layer*** The basic value layer influencing people's acceptance for plans, social justice, social efficiency, moral responsibility, etc. Core cultural layer (according to the Gullestrup model) Societal environment layer (according to the Knieling & Othengrafen model)
	Narrative-shared layer The formalised layers of norms and rules, planning practices, objectives and principles, shaping the contents of planning, such as considerations for ethnic minorities or handicapped persons. Manifested cultural layer (according to the Gullestrup model) Planning environment layer (according to the Knieling & Othengrafen model)
	Formal-objective layer The immediately perceivable layer and its resultant outcomes, such as planning systems, structures, institutions, instruments and products. Manifested cultural layer (according to the Gullestrup model) Planning artefacts layer (according to the Knieling & Othengrafen model)

Source: Authors' own elaboration
(dimensions after Gullestrup 2009; Knieling & Othengrafen 2009)

The framework suggested allows further the proposition that 'what planners do or consider important' is rooted in their individual concerns which are transmitted to wider social expectations and influence the way planning work takes place in a particular national, regional or local context. Because of these differences emerging from the different planning cultures, the exchange of planning ideas and practices, meaning when *"planning ideas and practices get to travel from one context to another"* (Healey 2010, p.XX), turn out to be a major challenge in particular in a cross-border context. Also Friedmann (2011) described this phenomenon very well on the case of the World Congress of Planning held in 2001 in Shanghai. *"The global discourse was far from unified, and […] planners often talked past each other, not quite knowing whether or not they made sense to their polyglot audiences."* (Friedmann 2011, p.164)

5. The significance of 'the others': Trans-cultural understanding has many dimensions

Considering that cross-border network and structures of cooperation evolve from social interactions between partners who may occupy more or less coterminous juridical, organisational, cultural and cognitive planning spaces, the added value of trans-cultural understanding becomes evident for any cross-border cooperative endeavour. But how can it be built up? Due to the fact that borders are ambiguous human constructions constituted by many different kinds of overlapping boundaries (Haselsberger 2010), I am hypothesising that it is not sufficient to *only* understand 'the others' planning approach, but in addition to unpack the taken-for-granted yet powerful generalisations about 'these others' which might have been yoked to negative stereotypes and prejudices over time. Ethnographers (such as Brown & Theodossopoulos 2004) have highlighted with a series of case studies that it is through the strategic use of stereotypes of 'the others' that social and political boundaries of inclusion and exclusion are drawn. By stabilising expectations concerning what lies beyond the 'self-constructed differentiating border of comfort' (van Houtum 2003), doubts, uncertainty and vulnerability are reduced within the bordered territory. This means, on the one hand, that it is through the awareness and perception of otherness, that social solidarity and membership is affirmed and hence a society is able to define itself (Paasi 2005). On the other hand, such certainty is generated by the distortions of collective memory in characterizing 'the other' (Herzfeld 1992), where (those in) power assert a positive meaning for their own identity while defining difference as 'otherness' (Sandercock 1998). Evidently these distortions impede cross-border cooperation. Brown & Theodossopoulos (2004), for example, have highlighted in their work, about the 'constructions of otherness in southeast Europe' that the contingent constructions of otherness is exhibiting the region's profound historicity, but 'history-as-interpreted' and not 'history-as-lived'. Furthermore it is important to acknowledge that the rhetoric about 'the others' (deriving from 'history-as-interpreted') reveals itself in everyday life through more or less subjective versions of collective memory (cartoons, aphorisms, jokes, proverbs, etc), where content is abstracted from context. Mainstream media but also politics play a significant role in the production but also transmission of the

(mis)perception about 'the others', as Arsenault & Castells (2006), have demonstrated on the example of how the Iraq War was justified in the USA.

As the picture of 'the others' is manifested in the minds of people and gets expressed through social behaviour and practices, I am arguing that the proper understanding of 'the others' and the way 'otherness' is produced builds up the basis for trans-cultural understanding and doing so assists the overcoming of mental barriers. In methodological terms the proper understanding of 'the others' requires a slightly adapting of the analytical framework (introduced before) regarding its focus of analysis towards a multilayered consideration of the different perceptions of 'otherness' (see Table 3).

Table 3: Understanding 'the others' (potential layers of analysis)

Unit of Analysis	Expected Evidence
Emotional Perception of 'the others': **Experiences & Feelings** *(informal-subjective layer)*	*How people think and feel about 'the others' in specific and general terms:* • *individually (personal experiences, stories, feelings, emotions, e.g.)* • *collectively (shared experiences, myths, stories, ways of life, events, e.g.)*
Popular Perception of 'the others': **Mainstream Media & Politics** (*narrative-shared layer)*	*How the picture of 'the others' is generated and communicated by:* • *mainstream media (newspaper, radio, television, e.g.) and* • *politics (e.g., political agendas)* *and how it is manifested within the popular 'place culture' (e.g., music, cuisine, education)*
Official Perception of 'the others': **Legal & Contractual Frameworks** (*formal-objective layer)*	*How 'the others' are represented in:* • *official documents (e.g., laws, government reports) and* • *planning documents (focus: national, regional, local and focus: cross-border)*

The interrelationship of the three layers of analysis introduced in Table 3 provides a mean to understand how 'the others' are represented in a particular planning culture and what impact this has on cross-border cooperation practices. Doing so, it is most likely that the collective memory effect on cross-border cooperation practices can be grasped. Unfortunately the story is not as simple as it looks like at first sight. As discussed earlier, human beings tend to interpret and re-interpret information according to their own socio-cultural backgrounds and experience. In order to not risk fudging the evidence gained from different planning cultures that would favour the investigator's own culture, a neutral 'interpretation scheme' has to be set up before the field work takes place. This 'interpretation scheme' may vary from situation to situation and context to context.

6. Conclusions: Overcoming borders through trans-cultural communication

The building up of more effective long-lasting cooperative structures, based on mutual trans-cultural understanding and reciprocal trust, not only requires the understanding of the involved planning cultures and the role 'the others' play within it. This is only the first step on a longer journey towards the overcoming of deeply embedded boundaries.

An equally important second step is the cultural exchange, the communication and dissemination of 'the others' planning culture in an adequate trans-cultural way. This is a step, which can be done effectively only if (a) 'the others' culture (including its language) and planning literacy skill as well as (b) the way how the professional's perception of 'the others' is affecting the situation are well understood (Reeve 2011, Friedmann 2011). Moreover, success relies on the planner's engagement as well as his/her capability to negotiate, mediate, advocate and facilitate between conflicting interests. It is important that people involved in this step respect the diversity and difference of cultural views and are able to interpret them in an unemotional way (Sandercock 1998). Unfortunately the issue of trans-cultural communication, which is a competence more than a technical skill, has not yet achieved the attention required in professional training and planning education curricula (Reeve 2011).

If trans-cultural communication is done properly, it will certainly favour the building up of cross-border identities, which is considered here as the third important step towards the overcoming of the borders' dividing function. Several authors (*cf.* Smith 1992; Eder 2005; Haselsberger 2012) have highlighted that collective cross-border identities are possible. They argue for example that there is no contradiction between progressive forms of identity or even multiple identities originating in different national identities, as observed in the case of migrants. Moreover it should be underlined that identification with and belonging to larger social circles does not imply that smaller circles such as the family or the local, regional and national space are automatically displaced. On the contrary, these circles are more like layers. In terms of constructing a cross-border identity *'the consequence for the individual is an increase in choice: between his national and cosmopolitan identification he has the additional choice of being European'* (Eder, 2005, p.212). It appears that cross-border identities provide a means to assist complex societies (as in the case of a cross-border context) to overcome conflicting interests. But how can they be built up? Eder (2005), for example, argues that what is required is *"to bring the past of different groups together and merge them into a new past, they need to be coordinated in light of a past that transcends the diverging and often conflicting pasts that might have separated the members of the new group so far"* (pp.200–201). Hence, a shared overcoming of e.g., the failures of history by placing emphasis on the different facets emerging from the different nation-states – in the sense different but equally important – is building up collective memory as the basis for a collective cross-border identity.

However, if trans-cultural communication is done improperly, it could either foster existing negative stereotypes or revitalise those which have already been overcome as Jedlicki (2005) exemplifies with the case of the Polish German relationship. *'I was*

too optimistic when I wrote that the trauma of Nazi crimes had been overcome and their memory did not burden the Polish relations with Germany any more. […] Unfortunately, in recent years there were disturbing signals coming from some segments of the German society that have stirred uneasy feelings in Poland. [These signals] *arouse fear, distrust, and the worst recollections of the wartime massive expulsions of the Polish population from the territories annexed to the Reich […]. The healed wounds opened again. This is fully understandable, even if sometimes oversensitive response.'* (p.46). The Polish-German example raises two important points in terms of building up a cross-border identity. The building up of a collective memory is a very sensitive issue, which needs to be reconstructed permanently, by a retelling of the common past. Accordingly also the building up of a collective (cross-border or even European) identity is an ongoing process, within which individuals reshape their own collective memory, in relation to that of other relevant groups.

Acknowledgement

The arguments made in this paper will be presented at the conference on the basis of some specific examples of cross-border planning projects in Europe.

The author wishes to thank Prof. John Friedmann of the University of British Columbia, Vancouver, Canada for his thorough and helpful comments.

A COMPARATIVE EVALUATION OF URBAN DEVELOPMENT MANAGEMENT: TALE OF VIRTUOUS PRACTICE VS. QUESTIONABLE PRACTICE

Ali Ustun[1]

Abstract

As a consequence of current economic dynamics it's undeniable that most of the contemporary urban development activity is more and more forced to take place by public-private partnership processes in many parts of the world. In consideration of these stiffening conditions suffered by local governments, this paper will provide an analysis on recent and current urban development practices based on two contrasting instances. In this context, the delivery of good practice in urban design will be questioned from a process-oriented perspective. In examining how to deliver good quality in urban development this study will make use of a comparative approach, principally confronting two analogous towns (in terms of size, population and peripheric position with respect to greater metropolitan area) namely, Sesto San Giovanni (Milan) and Chelmsford Town (London) in their approach to manage the urban development in two development projects of similar size, respectively Ex-Falck Area and Beaulieu Park. The significant aspect differentiating two projects, is that the Beaulieu Park is project of a recognized design quality (CABE, 2004), fruit of a development process, reasonably lasted 5 years mainly thanks to public administration's pro-active participation and virtuous negotiation with property developers for the quality places (Hall, 2011). Whereas Ex-Falck Area, despite covering a similar surface area, has witnessed a prolonged development process initiated in 1993 and development plan approval has been finally obtained in 2011. The process has encountered several refusals of various proposals and stagnations due to abandoning of the various developers.

The object of comparison will on the basis of the relation of planning policy to the development process and approach followed by two local governments. The paper will draw lessons concerning the promotion of quality design in urban development processes by comparing how the problem of concerting the urban development process is handled in different urban design cultures and planning policy contexts.

1. Introduction

Downgrading conditions in many urban realms as opposed to promotion of the cities to attract new investment, places a contradictory attention on the practice of urban development in the agendas of many local governments as well as on the agendas of

[11] Polytechnic of Milan, Milan, Italy – ali.ustun@mail.polimi.it

developers. (Madanipour, 2006). The diminishing economic resources available to today's local governments not allowing them to shape the urban development autonomously, propelled further by the global financial crisis of 2008, has certainly created noteworthy scarcity issues in financial resources for urban development both from public and private domains.

The above-portrayed concerns which force the urban development to take place within the available financial means, the delivery of good practice asks not only the recognition of what's good urban design but also guidance, negotiation and proactive engagement in urban development process. The key to deliver well-designed places also lies on construction of good partnership between the private and public sector and on the local governments' capacity in guiding the private sector into socially and environmentally sensitive place making. (Tiesdell & Adams, 2011). This paper acknowledges that the first aspect is dealt with by a number of resources and therefore it will examine local governments' behaviours in decision-making processes, in order to promote the good practice in urban design in different policy contexts, since today's local governments need to be more pragmatic in creating instruments which attract the participation of private sector in the development process (Alberini 2011; Tiesdell & Adams, 2011).

In the proceeding chapters, we will first deepen the insight in process approach in urban design and deepen the analysis on the decision-making environment of property developers. Then each of the case studies will be explained on the basis of the policy context and the development of the process. In the closing section the different approaches pursued in two examples will be compared.

2. Regarding the Interaction between the Urban design and Real Estate Development

2.1. Urban Design as a Process

It's important to note beforehand, the proceeding parts of the present study will take the term urban design into consideration as a process, which is aimed to create good quality. Accordingly, the urban design can be viewed as direct design and indirect design. George (1997) classifies these design activities as first order design and second order design. First order design relates to the designer as the direct author of a project whether it's a public space, a building or so. The second order design relates to the designer which does not directly design the physical characteristics of places but designs the decision-making environments, development processes or frames through which designers (of first order), financial promoters, real estate developers operate. Generally (yet not exclusively) the second order design is performed by public administrations making use of tools as plans, incentives/disincentives, infrastructure provision, economic land provision and etc. To note that in the development process, second order design occurs before the first order design. Second order design creates/forms places by creating directions for first order design mainly by set-

ting constraints and potentials. Thus carries a considerable potential for policy makers which can easily alter the physical features of future development.

Concerning the dynamics which call for a second order urban design in the context of urban development one shall principally state three principal driving factors (George, 1997): The first is about the velocity in which the decision environments may change in the contemporary era. The urban development processes incorporate dynamic factors such as economic, social and political, which may change during the development of a project. This may prove inefficiency in relying on first order design in the context of urban development which tends to be comprehensive rather than being strategic. Secondly, the number of different issues that urban design needs to address as owed to its multi-disciplinary character, urban development processes call for involvement a number of different types of actors in process. This creates fragmented decision-making environments, which first order design cannot effectively govern. Second order design however proves itself more effective in complex and fragmented decision-making environments as it produces more global and abstract objectives which can becomes more easily agreeable and more easily diffused in fragmented decision making environments. The third one relates to the number of different involved actors, which can be produced by the urban development projects. Unlike a traditional designer which produces a single plausible solution for a single client, the urban designer usually finds itself in front many different client with different expectations which cannot be collectively satisfied by a single traditional design. The second order design becomes more appropriate when faced with a multiple client as a range of acceptable solutions are more likely satisfy multiple interests.

Drawing on the distinction between the first order and second order design activity, we can consider the second order design activity similar to contemporary governmental practice, which is characterized by Salamon (2002) as public managers must create the incentive systems which obtains the cooperation of the actors over whom they have limited control. Yet, It's worthwhile to make a distinction between various government models as specified by Tiesdall & Adams (2011): The traditional hierarchical, top-down government systems where power flows downwards and outwards and consider that policy decisions can be implemented by a command & control systems are outdated government systems which seem to have very limited capacity and opportunity to make sound policy implementations in the contemporary conditions.

The contemporary process of governance is composed of interaction networks between governmental and non-governmental actors, power is diffuse, with all actors having specific resources with which they bargain to pursuit their own objectives. The contemporary governance model means that all actors need to operate in new ways to create mutually favourable conditions to have the cooperation of the other actors. Arguing that the contemporary network of governance shifts the importance in policy delivery from management to enablement, basing on three sets of competences listed by Salomon (2002,16): "Activation, orchestration and modulation skills" the urban designers must be able to create networks, create positive synergies

between the actors involved and make use of incentivation and disincentivation tools for the delivery of good practice.

2.2. Real Estate Development

Real estate development is the process, which creates the built environment and consequently transforms the forms and character of the urban settlements. As framed by Rowley (1998), the real estate sector has transformed the character and the form of the cities in most continents. The public policy is a means of managing the real estate development process ensuring a direction for what's publicly good. In weak public policy environments, real estate development tends to create marked-led outcomes which reflect developers' marketing strategy or perception of what sells better (Hall, 2011); whereas strong policy guidance can make real estate development create policy-led outcomes (Tiesdell & Adams, 2011) which are more compatible to societies needs rather than being market oriented products. In order to operate effectively policy makers certainly have to have a good understanding over the dynamics, risks associated with the real estate development processes and interests of the principal actors (designers, investors, developers, landowners etc.) in the real estate development process. In the context of a diminishing role for the public sector in the urban development, such an understanding by the operators in public sector, can modify the institutional incentives, barriers and the regulatory context for the delivery of what's public good (Carmona et al. 2002). The lacking of which will most probably result in an abundance of private-led development project with limited attention to public needs.

The real estate development sector operates in cycles and it has a volatile character. Likewise the governance term, also the real estate development has undergone several significant changes during the latest decades. The contemporary developers are highly consensual on the fact the what makes the development success is the offering of the quality product at the right timing and on the right location (Tiesdell & Adams, 2011).

The state – market relations in the context of the urban development has been subject to analysis by a number of studies. At the most profound level Barrett et al. (1978), pointed out the tasks and processes where state – developer contact took place and identified the forms of it. At a later stage, Doak & Karadimitriou (2007) identified the roles played by different actors in the development process and furthermore highlighted power relations between the actors and how these come together complex structures. Ball (1998) analyzed the structure of the networks of the actors in the development process which showed that the linkages between the actors do not solely occur from economic ends but also social historic, political and cultural ones. Moreover, the study asserted that the actors engage in the process as long as it contributes to achieve their basic objectives and classified them on a detailed table according to their role, functionality, timescale, external appearance and relation. His findings demonstrated that supply-side actors (being: Landowners, developers and funders) typically have short-term financial and economic motives to engage in the project

and tend to see the development as a financial commodity. Demand side actors (investors, occupiers and community) typically have long term, and design objectives and see the development as an environment to be used. One significant key finding of the study has been the design quality globally wasn't an objective shared by the whole of the actors and objectives are also subject to internal trade-off. In his study Ball, views the debate on the development quality as a 'gap' between the conflicting objectives of supply side and demand side actors. The remediation of this gap can be performed by three means, which are regulative means, remunerative means and normative means. It's worthwhile to keep in mind that the first means is coercive and the latter two are foresee encouraging of developers via financial and normative facilitation. Given the variety of possible interventions, public sector can make use of a number of resources in order to guide the urban design practice and formation of urban development. More specific tools are explained by a number of studies (Carmona 1999, Bentley, 1999, Carmona 1998, Carmona 2002, Punter & Carmona 1997, Punter 2007).

3. The Questionable Case: Ex- Falck Area in Sesto San Giovanni

Sesto San Giovanni, located on the northern border of Milan municipality, has registered a surprising fast growth due to the industrial settlements, i.e. Pirelli, Breda, Marelli, Falck etc., which occupied a relevant size in the city since the beginning of the 20th. century. Given the intensity of the industrial activity in the city, Sesto San Giovanni pursued the role of the "industrial pole" of the Milan metropolitan area in this period and became considered as one of the principal productive centres in Italy. After 1970'ies, the period which characterized the closing up and moving out of many industrial settlements throughout the world, as well as the ending production of the Falck Factories which have left a dismissing area with large industrial structures for a city like Sesto with modest settled dimension and relatively low economic capabilities.

By the beginning of '90'ies, the owner of the area the steel production company Falck has already closed down the production and completed the dismantling of industrial structures formerly housed the production. However, the PRG[2] approved by the municipality in 1993, has confirmed the industrial land-use of the area (even though the industrial productions had already stopped for some years by then), which made any re-use hypothesis quite irrelevant. Furthermore, the industrial land-use attributed by PRG has also undermined the property value of the area, which rendered economically unfeasible if not unreasonable the potential sale of the area. Under these consequences, the property owner, Falck decides to propose to the Municipality an alternative transformation plan for the Falck area and for this purpose Falck commissions the architect Kenzo Tange for drawing up a masterplan covering and area of 160 ha. (Goldstein, Bonfantini, 2007) The plan proposed a linear theme park which tributes the industrial past of the area. However, the large green area (covering about 40 ha.) becomes the only feature, which receives an attention in the project of Tange.

[2] PRG: Piano Regolatore Generale: Stands for the general zoning plan in the Italian Planning System

Given the area owner's apparent willingness in transforming the area and the scarce quality in Tange's proposal, the municipal administration contacts the Falck group in order to reach at an agreement on the characteristics of a possible transformation. In 1997, an agreement document is signed between the owner group, local administration and Agenzia Sviluppo del Nord Milano in which establishes requisites and modality of transformation of the area. In 1998, an international idea competition is organized for the design of an Urban Park for the area. The winning project by Arch. Viganò, which proposes residential, commercial and productive uses inside an urban park, is not put into action though.

At the end of 90'ies the Falck Group sells the area to another operator Cascina Rubina Immobiliare, Gruppo Pasini, which commissions two architects (Lugli and Goggi) for preparing the new PII[3] for the area, in 2001. The project proposes a series of interconnected areas with a major residential development. The proposal faces a resistance by the local administration because of the incompatibility between the proposed uses and those foreseen by the PRG of 2000. After the refusal of the proposal, the area owner decides to change the approach and commissions a group of experts from several disciplines in order to prepare the guidelines for the transformation and a new project proposal by Arch. M. Botta. In 2002, on the basis of the guidelines prepared by the commission, the Gruppo Pasini prepares a new PII proposal which contains residential, productive new uses as well as the conservation of the historic buildings.

Given the necessity to define a unitary and strategic development plan, which can be shared both by the public and private sector, the Sesto San Giovanni municipality creates a work-group Aree Falck Work Group which is composed of the municipal technical officers and various external consultants regarding the specific themes. In 2005, the technical office of the municipality by collaboration with the Aree Falck workgroup, publishes a document "organic framework reference" which aims to define a unitary urban development project which ensures an architectural quality of buildings, and of the street furniture in the entire site. This document becomes integrated part of the guidelines prepared in 2000.

In 2005, The Zunino Group acquires the Falck area from the Pasini group, at a distance of three months, the Zunino Group commissions Renzo Piano Building Workshop for the preparation of the masterplan for the area. In 2006, a preliminary proposal of PII to the municipality council, the discussions of administration and a public consulting which takes place at a period of one year. In 2008, the updated PII, revised based on the observations of the commission and work group, is once again presented. However, by the raising voices of global crisis and by the Zunino Group

[3] PII: Programmi Integrati d'Intervento (Translation: Integrated Intervention Programs). Italian Law 179, 17/2/1992 (Bossetti & Gatti, 2011). A recent implementation tool in Lombardy Region which disciplines requalification of the urban fabric by the intervention of a mix of uses and building typologies to be promoted as a private (or public-private consortium) initiative.

decides to sell the Falck area. After two years of negotiation with several real estate operators, finally in 2010, the Sesto Immobiliare acquires the area and 2011, a new preliminary plan of PII is proposed by the same project author. After 2 revisions as requested by the municipal administration, in the septemeber 2011, the proposed PII becomes finally approved.

4. The Virtuous Case: Beaulieu Park in Chelmsford Town

Chelmsford town is a small borough with a population around 150.000 and it's situated on the north - east of London, and it's the center of the county Essex. The town has achieved to grow continuously as a part of County policies, even after the decline in the manufacturing sector, which is compensated by the expansion in the service sectors. In order to sustain it's growth the town has faced a substantial and ongoing house-building programmes. However, as noted by Hall (2011, 75) the physical features of the development which has been formed during 1960 – 1970'ies was has been mediocre so far, uninspiring and far from satisfactory.

The "reversing" of the town's ordinary history in town planning, the first move was made by the new administration by the adoption of a new local plan in 1997, which structured the whole town's future development. Moreover, the county of Essex has also emanated a revised design guide to supplement planning guidance on the county level. As asserted by Hall (2011): These two elements have been the legislative foundation for a progress in a town-wide the design control. Though the breaking point in the town's planning history has actually been the change of the philosophy pursued by the new local administration, which attributes an important role to urban design in the development process, accepting urban design as an integral part of the planning activity and created a significant difference in the ongoing practice, because urban design is not a statutorily required function of planning authority in the English planning system rather it has a promotional standing.

The overall goal adapted by the Chelmsford local government was to make places by envisaging, shaping and managing change. This implied reasoning in different scales (town, neighbourhood and street); taking account of different information, using the density as the context for design and using the quality term as a glue which holds the whole together.

Still the progress cannot be made solely by definition of global goals yet they needed to be translated into site – specific guidelines. The overall global spatial strategy was translated into a development plan employing a long-term vision. The new plan prepared in 1997, emphasized policies encouraging intensity of the development and accessibility which put a significant attention on the brownfield land. In the translation of the generic design goals into operative guidelines the town Chelmsford used the county-wide design guide as a basis which applied on generic aspects of the future design.

The most crucial aspect of having a clear spatial policy translated into specific design guidelines from the development point of view is the bridging role it sets up between the authority and the developer. This way, all the relevant aspects that the planning authority expects, are clearly transmitted to a potential developer.

In the aim to provide the quality in urban development the local administration made use of another planning tool in order to take a more active role in the project development process. The planning brief – a synthetic site-specific document addressing the physical and design features of an eventual future development – acted as the principal vehicle in taking a proactive approach in the development process. The council prepared planning briefs for the sites available for development or for those whose development it promoted. By doing this, the design principles and guidelines for a site were being set-out beforehand. The essential role of this tool played is asserted by Hall (2011, 76) as: "They often helped to unlock complex urban sites, if done quickly they influences value, increased certainty and established a design approach before negotiations took place."

In the practice all the site specific types of guidance normally contained a review of purpose of the guidance; site appraisal; policy context; design principles to be applied to the site. In addition a proactive engagement enriched this document by diagrams of the desired building blocks, frontages access and uses and guidance on implementation.

The distinctive character of these design briefs were their significant detail in which they address the physical structure of the new development. Block sizes, active facades, location of open spaces were all defined in the brief in order to leave less room to move if the all design guides is to be followed. Hall (2011), claims that this level of detail received a positive reaction by the developers in Chelmsford on the basis that, developer knew right from the beginning the position and the idea of public administration which saved them time in the process of planning approval.

Even though a having a clear policy and guidance of future development and a proactive role in the process the local administration has also engaged in ongoing negotiation with developers and their professional agents. In some instances the proposals were handled by a group of professionals from different disciplines. Despite being time consuming negotiation also proved useful when done in positive and constructive manner in order to reach the desired results.

The Beaulieu park project site lies on the north-east margin of the Chelmsford town and covers about 370.000sqm of green land (CABE, 2004). It's a project carried out in two phases, to be realized by multiple developers. The initial planning brief, approved by the council in 1996, hadn't foresee any detail on the physical form further than pedestrian and vehicle access and location of playgrounds. The local government at that time had the expectation that the initiative on design can be left to housebuilders (Hall, 2011). Therefore in the first phase of the project the developers proceeded by producing their own masterplan, which set out a spine of road network,

unable to form building blocks, defining the overall development scheme of the whole area. Later on a variant of the masterplan has divided the land into parcels to enable the construction. More specifically, the first two stages of the development consisted principally of large detached housing aligned by main roads and placing the smaller-sized housing as well as social housing to the marginal portions of the site. Thus, the initial phase of the development reflected an urban development scheme from the developers' perspective. As in Hall's words (2011,80): "this followed the desire of house builders at the time to 'front' their schemes with what they considered to be the most impressive houses, relegating the smaller properties, including the social housing to the rear of the site."
In 2000, when the development of the northern part of the Beaulieu Park was brought into agenda, the urban design team of town's planning council has taken advantage of this opportunity and prepared a design brief for the site in the form of masterplan. The design brief consisted of a site appraisal, a prescriptive masterplan diagram addressing the location of blocks, facades, pedestrian routes and open spaces. The result achieved by the latest stage was clearly distinguishable from the precedent stages. Larger detached houses were replaced by smaller, with different styles, more façade continuity and higher density were achieved. Furthermore the social housing was seamlessly integrated to the rest of the built fabric and it was indistinguishable. The new scheme adopted a range of architectural styles which provided a deliberate diversity and gave a distinct character to the development at the most intimate scale.

According to CABE (2006, 32) the developers of Beaulieu Park scheme expressed that the masterplan has been very useful in making clear the expectations of local authority. As affirmed by CABE (2004), the developers haven't objected to these as they recognized the higher quality in the scheme proposed by council and furthermore satisfaction of those requests speed the process up considerably. The cooperation between the planning council and developers produced a final settlement scheme which is detailed loyally to the initial masterplan.

5. Conclusions

A narrative based comparison between two public administrations of similar sizes essentially demonstrates how the problem of concerting the urban development process is handled in different planning cultures and policy contexts. In order to concretize further the dependability of the outcomes of this comparison was made between two development projects of similar sizes.

For an understanding of how urban design policy could impact developers' decision-making with positive outcomes the Beaulieu Park at Chelmsford is accepted to be a reliable example where public administration succeeds in making realize what is publicly desired by a proactive engagement and negotiation. On the contrary, in case of the ex-Falck Area in Sesto San Giovanni poses an equally important example where the public inertia unable to provide a shared vision for the future of the area, forces the private sector to take a pivotal position in visioning the probable future scenarios for the area and public administration remains as passive actor which relies

solely on its legislative powers in managing a highly complex development process. More specifically, perhaps the principal inadequate move made by the government was in the contents of the zoning plan approved in 1993. A simple short sightedness in grasping the potential of the area by approving a land-use which had already chosen to abandon the area, not only decreased the market value of the land but also forced the private sector (the land-owner in this case) to generate a new scenario principally in order to keep the value of its assets. Consequently, the private sector became the promoter of the future urban development in the area as the option of cession of the land has become economically unfeasible by the new zoning regulation.

The development of the rest of the project which sustains 28 years between the initial development proposal and undersigning of development plan for the area, takes place in the form of highly recursive process composed of four cycles starting by the proposal of a new masterplan (by different designers commissioned by different private operators) and concludes by refusal of the masterplan proposal by local government which also causes the private to abandon the project. It's important to underline what's criticized here is not the refusal itself; but the inefficiency caused by the passive role played by local government which doesn't go beyond an "officer" who approves or refuses the private proposals rather than taking a proactive role in development of an area with certain potentials.

During all four cycles, we witness a project development majorly in line with property developers' philosophy indeed the all of the four owners of the area choose to commission renowned architects or except the first owner which also organizes a international ideas competition for the development of the area. It seems plausible that in an ambiguous decision-making environment, property developers make use of important architect names as a proof of the validity or the quality of their development proposal in order to convince the local government to grant approval. Moreover, the fact that the third private developer which had to sell the area in 2010, as majorly affected by the downturn of the real estate market, is a further sign of the prolonged development process being incompatible with the property markets character of cyclical functioning.

The development of the Beaulieu park on the other hand, demonstrates a more successful approach in the management of the urban development processes which goes beyond the usual management via proposal-refusal-revision cycle. The proactive approach shown by the public administration ensures the delivery of the expected results by the public administration. This became the principal breaking point which makes the Chelmsford case distinct from the Sesto San Giovanni's approach to the development process and which marks a distinction in the planning history of the Chelmsford town as well. The planning council, aware of the crucial need to transmit their own opinion regarding the spatial features of good quality development, made use of a tool which already existed in the system with an adequate operational rapidity. Preparing the design brief's on development areas has given the privileged position to public administration to act as the pivotal actor in the development process.

Moreover, it also clearly transmitted the public administrations expectations on an area well before the development begins. From the developers' point of view this has already been a major progress because the developers were able to understand clearly what was expected from a certain land (Hall, 2011, CABE 2004), which proved to be time saving in obtaining the planning permissions. Further to the successful pivotal position pursued by the government which enabled them to put their second order design skills effectively on the table. However, the proactive engagement in the process, which is open to constructive negotiation, has become the substantial drivers of the success in the delivery of the good quality in future development.

The comparative approach attained in this study not only demonstrates how the large-scale urban development is managed in different policy contexts by similar sized local governments. The outcomes show the inefficiency of conventional proposal-refusal planning system in managing complex development processes and its incompatibility with property market cycles. Furthermore, the study evidences the only possible way in overcoming the development plans shaped from the private perspective is taking proactive approach and bridging the public expertise and know-how to developers who otherwise tend to form the development according to what sells better as noted by Hall (2011,81).

TERRITORIAL COHESION OF A METROPOLITAN AREA IN THE LIGHT OF IMPLEMENTATION OF SPATIAL POLICY – THE CASE OF LODZ METROPOLITAN AREA

Iwona Pielesiak[1], Bartosz Bartosiewicz[2], Joanna Ulańska[3]

Abstract

In Polish legislation there are no relevant provisions allowing for institutionalisation of metropolitan areas. This means that the biggest cities and their directly surroundings, strongly related to each other and experiencing dynamic transformation of the socio-spatial structure, are deprived of joint coordination of spatial policy. According to the administrative division of the country, the main responsibilities for shaping and implementing the objectives of spatial policy are assigned to a municipality – a territorial unit of the lowest level. Municipalities are equipped with a local spatial development plan, which is the only instrument having the status of a local legal act. It only must be consistent with the provisions in regional and national plans, which are assumed as general documents, relating to the major development directions but not to the particular land use.

Metropolitan areas in Poland are mostly consisting of several dozen of municipalities. Unfortunately, each territorial unit usually implements its individual spatial policy, considered as the most profitable only by the local authorities. This situation is potentially most dangerous in the territories of strong internal linkages, such as metropolitan areas definitely are. It would be a truism to say that long-lasting effective functioning of the metropolitan area is not possible without the common spatial policy.

The authors' main objective is the analysis of relations determined by the local spatial policies in the metropolitan area. The analysis is conducted on the example of Lodz Metropolitan Area (LMA) – a territorial unit located in Central Poland, consisting of Lodz and its 27 neighbouring municipalities. Choosing LMA for analysis is not accidental. For two years the authors have been conducting a wide research project in this area, which should result in elaborating a method of measuring territorial cohesion of the metropolitan areas.

The analysis described in the article is based on the obligatory spatial planning documents and takes under consideration future land development along the municipal borders (directly neighbouring land use forms and subsequent ones, in case the first land use form was a linear object). The key element of the procedure is the identification of conflicts in the borderline zones. First, each

[1] University of Lodz, Lodz, Poland, i.pielesiak@interia.pl
[2] University of Lodz, Lodz, Poland, b.bartosiewicz@geo.uni.lodz.pl
[3] University of Lodz, Lodz, Poland, joanna_2@wp.pl

place where any kind of discrepancy is observed is being marked on a map. The discrepancy means that the land use on the sides of the municipal border has a different form eg. agricultural and residential areas. Furthermore, more detailed discrepancy criteria are established (combinations of land use that may be classified as spatial conflicts), the length of the border with discrepancies is measured and its share in the total length of the border is calculated.

The final step of the analysis is supposed to reveal the impact of the identified conflicts on LMA's functioning, which is followed by formulating recommendations for unified spatial policy in the metropolitan area.

1. Introduction

In common parlance, cohesion is mostly understood as a close contact or union, a result of separate elements forming a new whole. In academic research, the term applies to various domains – economy, social relations, ecology, and infrastructure – and especially to transportation, spatial planning, etc. The common point for all these is the territory which forms a reference point for their analysis. Therefore, when trying to present the internal integration of a territory in a holistic perspective, the term territorial cohesion should be used (Bartosiewicz, Pielesiak 2010b, 2011)**.**

Territorial cohesion is a multidimensional, ambiguous and controversial term. In the past few years, it has frequently appeared in debates over the European Union's future development. The Polish government assumed in its proposal that territorial cohesion should be explained in both its static and dynamic aspect. In the first sense, it is presented as the optimal state, a result of efficient economic exchange and flow which ensure economically and socially effective resource allocation. This state, which assumes a certain minimal development level of selected domains (access to public services, accessibility by various transport modes, etc.) instead of their standardisation, is a consequence of an adequate spatial planning, which creates the optimal circumstances for the development of individual territories. It is emphasised that the process of reinforcing territorial cohesion is an extremely complex one, hence its implementation should take place not only on the EU level, but also on the national, regional and local one. In turn, the dynamic aspect of the term "territorial cohesion" places emphasis on the simultaneous stimulation of socio-economic cohesion (stimulating management efficiency and the effectiveness of addressing social disparities) in the framework of integrated management of EU development (Bartosiewicz, Pielesiak 2010b, 2011).

At present, research on territorial cohesion is focused on the macro scale (the national or international level). At this stage, there are a number of concepts and instruments which serve to measure territorial cohesion. (Dutkowski, 2009; Farugia, Gallina, 2008). This branch of research is an inherent part of the EU cohesion policy.

Research on territorial cohesion on the subregional stage is less common, although this dimension seems to be equally important. Creating cohesion policy on a national or international scale without including the lower levels poses significant difficulties. There have been several studies on subregional territorial

cohesion but it still remains a poorly researched area, especially where the methodological aspect is concerned. Researching territorial cohesion on the subregional level requires a wholly different approach.

The territorial unit analysed by the authors is a metropolitan area. It is understood as the area of a large city and its functionally related direct neighbourhood. In a number of international classifications, the terms "metropolis" and "metropolitan area" apply not only to large cities but also to urban settlements which contribute significantly to the economic structure of metropolitan functions, that is exogenic service and administrative functions on a global, continental or national scale. In Poland, the term is commonly applied to the largest cities and their neighbouring areas. As a result, not all metropolitan areas distinguished in Polish studies meet the international criteria. In any case, they are areas with strong internal linkages, which require particular attention and unified coordinated management.

In Poland, the subjects of metropolises and their surrounding areas is gaining the recognition of the academic world as well as local authorities of various tiers. Although legal acts regulating the functioning of metropolitan areas have not yet been passed, a few municipalities have already carried out detailed analyses of the current socioeconomic situation and have prepared and started to implement concepts for future development. However, in most cases, apart from a delimitation and a very general idea of the area's future functioning included in provincial spatial development plans, no detailed, multifaceted analyses have been carried out. In particular, the municipalities' territorial cohesion, which should form the basic standard for the possible creation of institutionalised municipal areas, has not been researched.

In case of a metropolitan area, it is impossible to apply most of the indices used in international and interregional comparisons. Notwithstanding the fact that assuming the municipality as the basic unit of research calculating some of them would be pointless, many data are aggregated at least on the regional level, and therefore the researchers may encounter a lack of input information.

In a situation like this, accepting various kinds of internal linkages within a metropolitan area as the benchmark for territorial cohesion seems to be the most reasonable solution. This approach is consistent with the authors' theoretical framework. For two years, they have been implementing a large-scale research project under the title Territorial Cohesion of Lodz Metropolitan Area, which aims to develop a comprehensive and universal method of measuring territorial cohesion on the subregional level based on a number of internal linkages (cf. Fig. 1) (Bartosiewicz, Pielesiak, 2010b).

In this set of linkages shaping territorial cohesion, relations resulting from the implementation of spatial policy are of vital importance. When there is no common policy for a large city and its surrounding areas, and each municipality in fact implements its own one (for further details see subchapter 2), such relations may be investigated by analysing spatial planning documents valid in individual municipalities which specify the guidelines for spatial planning.

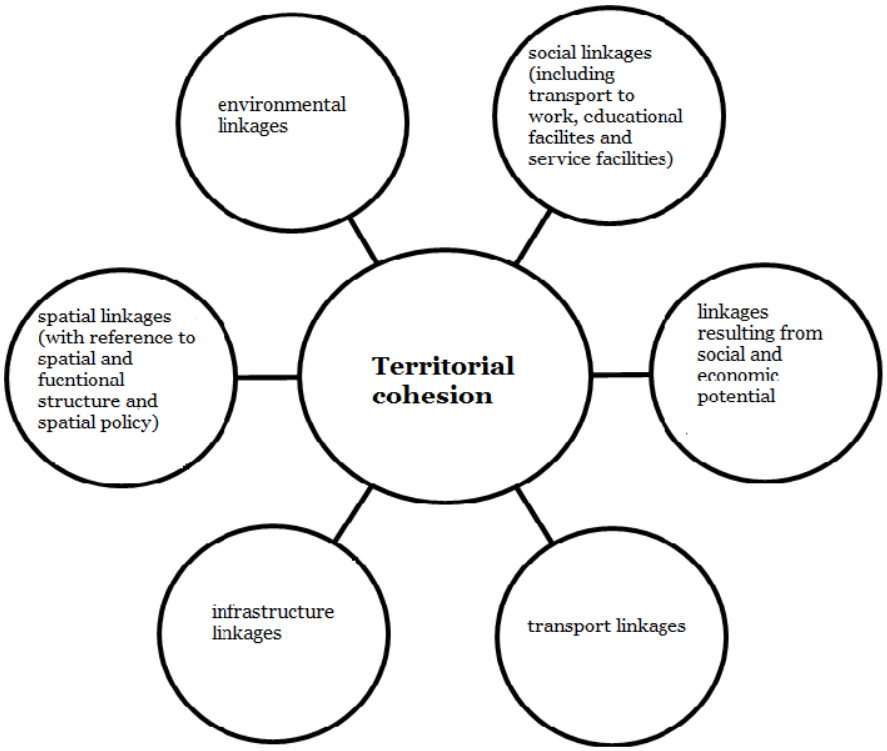

Figure 1. Linkages creating territorial cohesion

The authors' observations prior to the research suggest that the guidelines for spatial development of areas along municipality borders are often divergent and lead or may lead to functional and spatial conflicts. Such situations are particularly dangerous in metropolitan areas, which are subject to intensive urbanisation processes, and may result in irreversible negative alterations which disrupt the proper spatial development of the territory. This means that the borderline zones are crucial from the perspective of spatial policy cohesion of metropolitan areas. Therefore, it is these zones that should be selected for analysis when assessing spatial development policy, taking into account the intended use of the adjacent areas (for further reference see subchapter 3).

Based on these assumptions, the primary aim of this article is to develop a universal method of measuring the cohesion of metropolitan areas in light of spatial policy, based on the identification of spatial conflicts (according to the spatial planning documents in force), and to present the conclusions following its implementation in Lodz Metropolitan Area.

2. Spatial functional conflicts in Lodz Metropolitan Area

Spatial functional conflicts are analysed in Lodz Metropolitan Area – an urban region located in Central Poland. It consists of Lodz and its 27 adjacent municipalities (area of 2.5 thousand km^2) and is populated by 1.1 million people. As far as the demographic potential is concerned, it is the fourth largest metropolitan area in Poland.

2. 1. Spatial policy and the metropolitan areas in Poland

The Polish three-tier spatial planning system is regulated by the 2003 Spatial Planning and Land Development Act. According to its provisions, the individual levels – the national, regional, and local one – should complement one another, forming together a consistent spatial policy system. The first two tiers aim to specify the main guidelines for spatial development throughout the country and in individual regions. Documents passed on these levels do not constitute law; they are instructions designed to broadly name the guidelines for development and secure the implementation of national or regional sector policies (e.g. transportation policy or public security policy).

On the national scale/nationwide, these functions are fulfilled by *The National Spatial Development Concept*. Legislated at the national level, it is a binding legal document, whose provisions should be taken into consideration when preparing sector policies and documents specifying the guidelines for spatial policy on a regional or local level. It is an obligatory document whose primary aim is to identify the main guidelines for regional spatial development, while taking into consideration supralocal needs.

The lowest but most important from the standpoint of spatial planning is the local tier. Municipalities, which are the basic administrative units in Poland, have the widest possibilities to influence spatial development. It is a consequence of their legal character. In light of existing regulations, municipalities are autonomous and independent units. Municipal authorities are responsible for providing the residents with conditions necessary for their proper functioning and for the management of the municipality's development. Municipalities have their own financial resources and may undertake independent actions.

In light of the 2003 act mentioned above, Polish municipalities have at their disposal two basic instruments of spatial development. The superior one is the *local spatial development plan*. Of the two documents, it is the only local legal act, which means that its provisions are legally binding and determine the intended use of a particular area. It may encompass the municipality as a whole, but due to its detailed nature it is usually designed only for its particular areas. The spatial development plan specifies the details of the intended use of the land, takes into consideration the existing and planned infrastructure and transportation facilities, and specifies the regulations for land development.

The other obligatory document for every municipality is a *study of conditions and directions of spatial development*. It encompasses the whole local administrative unit. It does not constitute local law but its provisions must be taken into consideration when preparing local spatial development plans.

Although the aim of this article is not to assess the spatial planning system in Poland, it should be emphasised that it does not function properly, especially at the local level. Local spatial development plans are not obligatory for municipalities and although the act has been in force for almost ten years, they encompass only somewhat less than 50% of the area of Poland. Unfortunately, in

the case of the largest cities and their surrounding areas, this number is even smaller. This is not only the result of high costs of preparing spatial development documents but also, and especially, the consequence of a very complicated and lengthy procedure. Decisions based on purely political motives hamper the process to a considerable extent and also contribute to the problem. Lack of binding local spatial development plans results in inconsistent spatial development, spatial chaos, mixture of conflicting forms of spatial development. These problems are particularly common in metropolitan areas, which are the most attractive lands for investors. The situation is exacerbated by municipalities which compete with one another to attract as many investors as possible, often disregarding the individual residents' interests.

The best solution seems to be the introduction of legal provisions which would oblige the authorities to pass common regulations specifying the spatial policy in a metropolitan area. Unfortunately, although there have been many debates in Poland about the need to institutionalise metropolitan areas, little has been done is this respect. Current legislation imposes only the obligation to delimitate the metropolitan areas in provincial spatial development plans, but it does not oblige the authorities to take any specific actions to coordinate the development.

While the legislators notice the problem of metropolitan areas, they have not yet stipulated any instruments for implementing a common spatial policy. In 2008, a government initiative emerged, proposing passing legal provisions leading to coordinated management of metropolitan areas. The need for a common/unified spatial policy, as well as transportation or housing policy, was strongly emphasised. However, no consequences followed; the issue of so-called metropolitan act has been suspended and has not been discussed for a long time. Meanwhile, many studies conclude that the changes to public space are irreversible, especially the ones conducted in Warsaw Metropolitan Area, where the problem is at its most extreme (Jakóbczyk-Gryszkiewicz, 1998, Lisowski, 2010).

In this situation, seeing the need for cooperation, local governments in large cities and surrounding municipalities started a grassroots movement of forming associations for cooperation in the development of metropolitan areas. In a few regions of Poland such associations have been functioning for years, sometimes with moderate successes (mainly with respect to the common organisation of public transportation), but the lack of necessary legal provisions significantly hampers the effective functioning of these authorities. Sometimes not all municipalities are interested in joining metropolitan associations, which also limits their efficiency.

To sum up, the Polish spatial planning system is not ready for the processes which take place in metropolitan areas, and independent initiatives of individual municipalities increase significantly the risk of spatial conflicts. The problem is exacerbated by the procedure of enacting spatial planning documents. If the documents are obligatorily consulted with the governments of adjacent municipalities, their comments do not need to be taken into consideration. This means that there in fact no legal obstacles to pass documents which allow for potentially conflicting provisions.

2. 2. Identification of spatial functional conflicts in a metropolitan area

Spatial conflicts take on/appear under various names – land-use conflict, locational conflict, environmental conflict, prohibited location, nuisance property, LULU – Locally Unwanted Land Use, NIMBY – Not In My Back Yard, etc. Their appearance is related to various combinations of social and economic factors, such as the increase in environmentally damaging activities, the growing range of public and private investment projects, increasing ecological and social awareness in society, the improvement in the residents' education and living conditions, the decline of public trust in authorities and social institutions as well as greater mobility (Meyer, 1995). The locations which prompt objections are commercial facilities perceived as a nuisance (industrial sites, certain service facilities such as petrol stations, large animal-raising farms) or a threat to local businesses (shopping malls), construction and development of existing technical infrastructure facilities (motorways, sewage treatment and solid waste utilisation facilities, power plants), but also objects which were designed to serve the community (council housing, alcohol and drug rehabilitation centres, youth correctional facilities, and even hospitals).

Identifying and defining the conflict from the standpoint of spatial planning is not an easy task. One viable solution would be to assume that the conflict stems from the incompatible intended use of adjacent lands, which is related to negative external effects (environmental degradation, nuisance affecting neighbours due to noise, electromagnetic radiation and odour pollution, landscape defacement, etc.), and results in a decrease in their effective functioning. Spatial conflicts may take on different forms, depending on the local socioeconomic and environmental circumstances. In tourist resort, they manifest through an expansion of hotel, boarding and recreational facilities, which often damages the neighbouring lands of natural value. The development of natural resources extraction projects may lead similar consequences, together with an extreme environmental degradation and a considerable nuisance to the neighbours. Actions considered conflict-provoking include planning economic centres without taking into consideration the existing buildings (frequent in case of greenfield projects), locating nuisance manufacturing and service facilities in the immediate vicinity of residential areas, introducing multi-family housing into single-family or homestead housing areas, dividing green corridors (river valleys, forest areas) with anthropogenic development. Spatial conflicts are triggered by the presence of relatively environmentally non-degraded areas, legally protected to secure the local ecosystems from increasing human pressure. These areas, which should be left undeveloped, are gradually surrounded by residential areas and subject to a wide range of negative phenomena, such as land enclosing, increased tourist traffic, lack of sewerage and solid waste treatment policy, etc. An extensive set of legal provisions for environment protection tends to be perceived as a source of conflict by the local authorities and investors, who prioritise the economic and social sphere instead of environmental protection. The local governments' negative attitude is exacerbated by a lack of financial compensations for lost growth potential (Gołąb-Korzeniowska, 2008).

Spatial conflicts arise very often in suburban zones of major cities, which are at risk of intensive suburbanisation processes. Unwanted alterations to the suburban zones in Poland are possible partly due to their insufficient coverage by spatial development plans, which paves way for accidental development. This allows for placing typically urban or residential single-family houses among homestead housing. Spatial chaos is becoming more intense in suburban areas, the more so because according to the public opinion lotting and selling the existing agricultural areas is a very lucrative business. In that case, landowners and investors have more say in the matter of long-term permanent spatial planning than spatial management authorities. On the other hand, often the local authorities themselves are interested in attracting new residents, considering them a positive influence which increases the municipality's income. This results in numerous problems, among them environmental degradation, poorly developed infrastructure, increased costs of its development and maintenance, conflicts between the local agricultural producers and the newcomers from highly urbanised areas (Henderson, 2003; Lisowski, Grochowski, 2008; Tokajuk, 2011). The last situation is particularly problematic when the area in question is incorporated into the sprawling city. In these circumstances it is advised to avoid ostensibly reconciling the conflicting functions in local spatial development plans by specifying mixed-use locations. A plan should explicitly determine the intended use of the land. Where a conflict of functions appears, a transition period should be introduced to gradually eliminate the unwanted ones.

The starting point for the authors' methodology of investigating spatial conflicts in metropolitan areas is the assumption that they tend to arise in the borderline zones along municipality borders. This assumption is a consequence of the Polish spatial planning system described above, where municipal authorities establish spatial policy guidelines on their territory and are not obliged to take into account the situation in the neighbouring areas. Such a system may trigger spatial conflicts.

The basis for the identification of spatial conflicts is a planning document obligatory for every Polish municipality, that is the *study of conditions and directions of spatial development*. It specifies the target model of the administrative unit's spatial and functional structure, which is the basic spatial planning document.

The first step in the analysis is the identification of the existing forms of intended land use along every municipality border within the metropolitan area (see Fig. 2). The scope of the analysis depends on the type and area of the land in question. If it is of a small size or linear character (e.g. a road), an adjacent area is included in the analysis.

The next step is to determine the compatibilities or discrepancies in the intended land use on each side of a municipality border. Discrepancy is described as every situation when the intended land uses differ, even if it does not create a conflict (e.g. a forest and a meadow). This step requires to specify the length of the border where the discrepancies occur (in proportion to the overall border length) and analyse their type, that is characterise each pair of discrepancies

which can be observed in the borderline zones. This method of analysis allows the researchers to determine some details of the discrepancies in question (cf. Fig. 2).

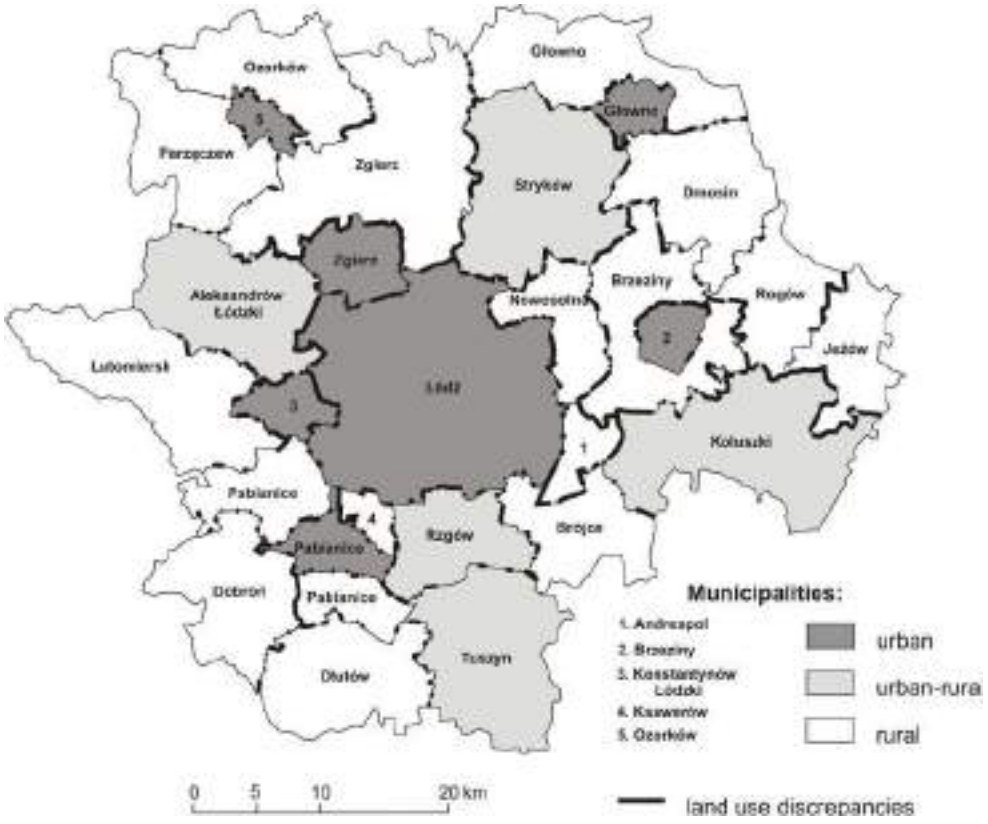

Figure 2. Identification of potential land use discrepancies in Lodz Metropolitan Area

The outcome of this part of the analysis is a map showing the outlines of the municipal borders subject to the analysis, highlighting the sections where discrepancies occur, and a table depicting the length and type of discrepancies for each borderline zone.

The next stage, based on identification of the discrepancies, is selecting the sections of the borders where conflicting development is intended. Conflicting development arises when following intended land uses occur on adjacent lands:

- residential areas – industrial areas;
- residential areas – nuisance service facilities (e.g. large-format stores, logistics terminals, etc.);
- residential areas – land of natural value subjected to legal protection;
- residential areas– nuisance properties (e.g. sewerage treatment plant, garbage dumping ground);
- industrial areas – land of natural value subjected to legal protection.

The selection is based on analysing all discrepancies and subjecting the selected areas to a detailed analysis. It consists of studying local spatial development plans, if any exist, then air photographs and topographic maps, in

order to exclude areas where the conflicts are a result of permanent development and the potential to change the situation within the existing spatial policy is limited.

The spatial conflicts identified in this way are then characterised in detail and form a basis for guidelines for local governments which outline the ways to eliminate the conflicts.

2. 3. Results

In the area of the authors' research, the subjects of analysis was the intended land use of 62 borderline zones of total length of over 600 km. Out of these, 52 types of sections characterised by discrepancies in the intended land use on either side of the border were identified. Their total length amounts to almost 330 km, which is 54% of the total length of municipality borders. Out of the 52 sections, 25 ones (total length of 165 km) which could cause potential conflicts were subject to a detailed analysis. These were adjacent residential areas and forest areas; residential areas and industrial, commercial and storage areas; multifunctional areas and open spaces; recreational areas and industrial, commercial and storage areas; residential areas and resource exploitation areas. Land uses indentified as not being potential sources of conflicts were adjacent additional afforestation and forest areas, forest areas and open areas, residential areas and cultivated green areas, industrial, commercial and storage areas and commercial areas.

In case of 14 borders, conflicting types of land use appear along over 70% of their length. Spatial correlations among the analysed conflicts are difficult to observe. They appear both in close vicinity to the central city, influenced by intensive urbanisation processes, and in rural areas, located in peripheries and consisting mostly of open spaces. However, it should be emphasised that most conflicts appear in borderline zones, where urbanisation processes are at their most dynamic (cf. Fig. 3 and Fig. 4).

During the course of a further detailed analysis, nine of the original 25 potentially conflict-provoking relations were identified as non-conflicting. These were holiday housing areas – sport, tourism and leisure (recreation) areas; single-family housing areas – multifunctional areas; open spaces – industrial and residential areas; open spaces – agricultural areas; open spaces – multifunctional areas, multi-family housing areas – commercial areas, holiday housing – industrial, commercial and storage areas, commercial areas – recreation areas, open spaces – special use areas.

Currently and, according to spatial planning documents, in the long-term perspective, spatial conflicts in Lodz Metropolitan Area appear along 44 km of municipal borders (almost 14% of the total analysed border length). Most of the identified 16 types of conflicts are connected to residential areas adjacent to forest areas or open space which are legally protected or planned to be placed under such protection. They make up respectively 28% and 15% of the length of potentially conflict-provoking borderline zones. These observations confirm the paradoxical effects of legal protection for areas of high natural value, which attract residential and holiday housing.

Along 10 km of borders, residential areas are located adjacent to industrial, commercial and storage areas (most of them are located in the borderline zones of municipalities situated the immediate vicinity of the central city). Borderline zones where residential areas are located adjacent to commercial areas, or holiday housing is situated next to forest areas, are scarce.

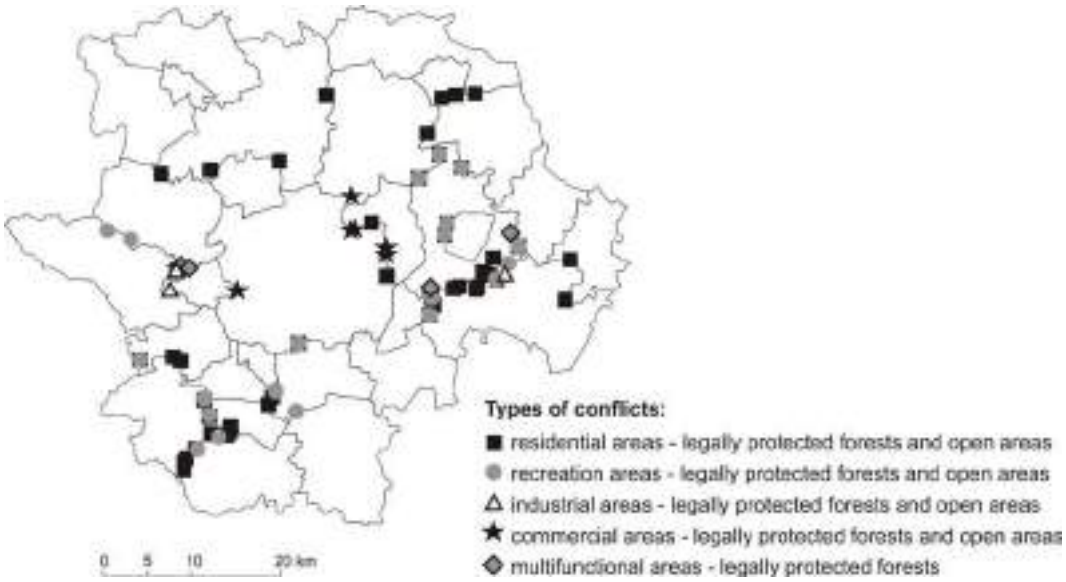

Figure 3. Potential land use conflicts concerning legally protected forests and open areas in Lodz Metropolitan Area

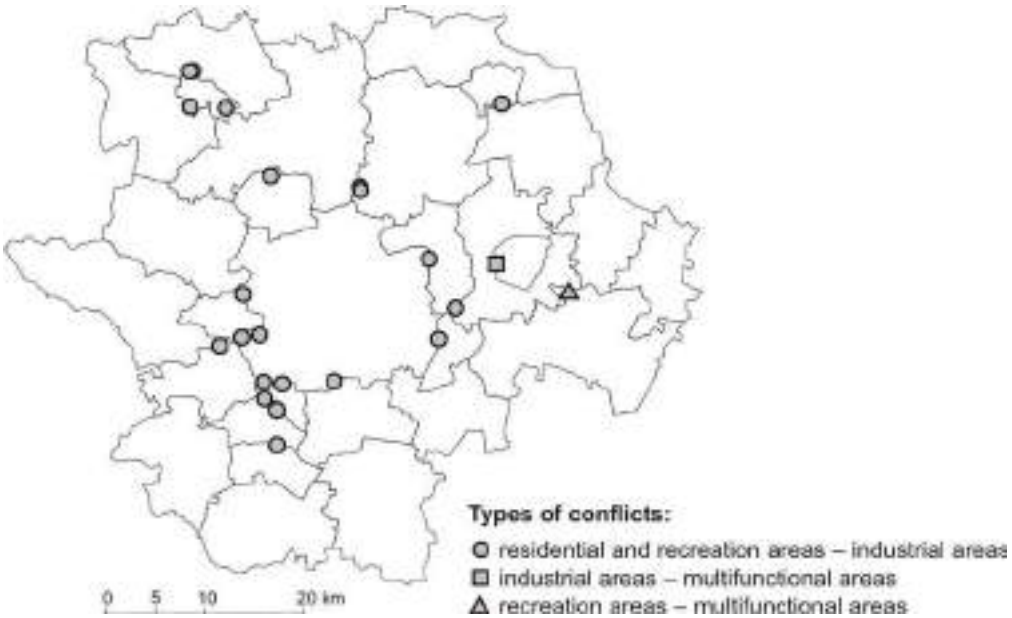

Figure 4. Potential land use conflicts concerning industrial and multifunctional areas in Lodz Metropolitan Area

Apart from the areas mentioned above, multifunctional areas located adjacent to residential areas, recreation areas, and industrial, commercial and storage areas were identified as potential sources of spatial conflicts. This results from the fact that multi-purpose designation is very imprecise and in fact does not specify the intended land use. Therefore, residential areas adjacent to industrial, commercial and storage areas, as well as commercial areas, were also described as potential sources of conflicts.

3. Conclusions and guidelines for spatial policy coordination in Lodz Metropolitan Area

Based on the analysis of locations which may create potential spatial conflicts, the following general directions for the municipalities included in Lodz Metropolitan Area could be proposed to eliminate problematic issues:

- Developing a local spatial development plan for borderline zones should be preceded by an in-depth analysis of the state of and guidelines for spatial development of the adjacent land. The decision-making authorities (resolution-passing and executive organs) should be made aware of the potential consequences of negligence in this field. Simultaneously, implementing legal instruments with more power over local governments is a solution worth considering, since the current legislation does not oblige local authorities to take into consideration motions pertaining to the *Study of conditions and directions of spatial development* or the opinion of neighbouring municipalities on the solutions accepted in the draft of the study.
- For selected sections of municipalities, specified in the S*tudy*, where the intended land use is a source of spatial conflict, the S*tudy* should be changed or provided with more details in the local spatial development plans, in a way which would decrease the negative impact on adjacent areas. A positive change would be introducing buffer zones (e.g. green belts) separating residential areas from industrial, commercial and storage ones. A model for a detailed spatial development plan is the local spatial development plan for a part of Koluszki municipality, where forest areas were delimited to separate recreation areas from multifunctional areas on the other side of the municipality border, which formed a part of a legally protected area.
- Ambiguous land designation, that is ‘multifunctional areas’, should be eliminated from spatial development documents due to its imprecision and the fact that it allows to introduce unwanted functions, which increase the municipalities’ profits but contribute to a permanent destruction of spatial order.

To sum up, in light of the research method used by the authors, territorial cohesion in Lodz Metropolitan Area was evaluated positively. The number and severity of identified spatial conflicts are low, making the spatial policy of the municipalities relatively easily tolerable for the adjacent ones. It should be appreciated that when providing additional details to the *Studies* in local spatial development plans, solutions compatible with the generally accepted rules of

spatial planning are used when conflicts arise. However, it is to be noted that Lodz and adjacent areas, contrary to Warsaw or Poznan metropolises, are not marked by dynamic socio-economic development when compared to other regions. Therefore, it may be assumed that the positive conclusions are a result of relatively little investor pressure instead of adequate planning tools and awareness on the part of decision-making authorities.

THE GOLDEN HORN: HERITAGE INDUSTRY VS. INDUSTRIAL HERITAGE

Zeynep Günay[1]

Abstract

The aim of the research is to evaluate the role and the impact of heritage industry in the revitalisation of the post-industrial spaces of Istanbul, with a case study on the Golden Horn as empirical evidence. The results of the research are related to the questions: What role the industrial heritage play in the revitalisation of historic environments? What are the ways to turn such industrial heritage into sources of social and economic development? What are the likely impacts on the local economy and local community? The conclusion gives an overview of the extent of the impacts that industrial heritage has on the Golden Horn, and in turn relates this back to the wider idea of heritage industry being promoted for the wider urban policy-making in Istanbul.

Keywords: Heritage industry; industrial heritage; Golden Horn; Istanbul.

1. Introduction

The revitalisation of former industrial areas has been one of the crucial tasks facing the urban policy agenda throughout the world since the mid-1970s; whereas the "heritage industry" has become the new orthodoxy in the shift from production to consumption as means for the restructuring and reimaging of post-industrial economies in the global order. The increasing tendency to link heritage and conservation with economic development has brought new meanings to cultural assets, the value of which has started to become related solely to the economic value it sustains or generates. In particular, the commodification and instrumentalisation of industrial heritage by the heritage industry has turned out to be the determining factor in the creation of "opportunity spaces" in post-industrial economies. At the same time, many academics are critical of attempts to reform post-industrial spaces of consumption with privatised spaces and commodified cultures.

Within this context, the aim of the paper is to evaluate the role and impact of the heritage industry in the revitalisation of the post-industrial spaces of Istanbul, with a case study on the Golden Horn industrial heritage as empirical evidence. The results of the research are related to questions regarding the role industrial heritage plays in the revitalisation of historic environments as well as ways to turn such industrial heritage into sources of social and economic development, and the likely impacts on the local economy and local community. Regarding these questions, the first two

[1] Istanbul Technical University, Istanbul, Turkey – gunayz@itu.edu.tr

sections are devoted to the theoretical discussions to question the role of the instrumentalisation of industrial heritage in the revitalisation of post-industrial economies. The third section explores reflections of these theoretical discussions regarding the Golden Horn industrial heritage in relation to the Istanbul heritage industry. The conclusion gives an overview of the extent of the impacts that industrial heritage has on the Golden Horn, and in turn relates this back to the wider idea of heritage industry being promoted for the wider urban policy-making in Istanbul.

2. The Heritage Industry: Instrumentalisation of Cultural Heritage

In a world, where the value of a cultural asset depends on the economic value it generates, it is not surprising that heritage has become "the" industry itself. The revitalisation of former industrial areas has been one of the crucial tasks facing the urban policy agenda throughout the world since the mid-1970s; whereas the "heritage industry" has become the new orthodoxy in the shift from cultural production to consumption as means for the restructuring and reimaging of post-industrial economies in the global order. Since the mid-1970s, the industrialized world has experienced the effects of the deindustrialisation process through the restructuring of the global economy and its associated production and technology developments. While these deindustrialised areas have been turned into derelict and brownfield lands, communities have faced severe economic, social and spatial detoriation through the lack of economic development potential and reduced quality of life. The urban policies of the 1980s have put these derelict areas on the development agenda within the framework of socio-cultural and economic regeneration initiatives. In particular, deindustrialisation has given them the opportunity to attempt to reinvent themselves within a new role through the use of culture, and especially heritage, more broadly as part of place-marketing, the growing emphasis of which is stimulated by urban entrepreneurship, as well as urban competition.

The economic exploitation of heritage is not a new phenomenon, however the economic function has come more to the forefront in recent times as a result of the global urban agenda and economic imperatives in policy formulation. There is even an increasing amount of research that focuses on the necessity of evaluating cultural heritage as an instrument for economic development in response to the challenges brought by globalisation and neoliberalisation. According to Tiesdell et al. (1996), the rational economic and commercial choice starts with the desire to conserve historic landscapes. Similar to the governments' increasing focus on economic returns, the role of heritage in economic development has also become the primary policy agenda both for international and national conservation expert institutions (i.e., UNESCO, 2010; ICOMOS, 2011; English Heritage, 2005a; 2005b). The development of cultural sector as an industry has led to profound changes in urban policy through the utilisation of regeneration as a driving force to emphasize the role of heritage as an opportunity space. According to Hall (1998), cultural industries may provide the basis for economic regeneration; filling the gap left by vanished

factories and warehouses and creating a new image that would make them more attractive to mobile capital. The relationship between heritage and the rising tendency of heritage industry is well-defined by Rypkema (1992). According to him, conservation primarily involves buildings; historic buildings are real estate, and real estate is a commodity. For a commodity to attract investment capital, it must have an economic value; for an economic value, there is a need for scarcity, purchasing power, desire and utility. Thus, heritage has it all.

The growing articulation between heritage and industry is stimulated by a number of factors (OECD, 2009): First, there is an increased interest in culture, particularly as a source of identity and differentiation in the face of globalisation. Growing levels of cultural capital, stimulated by rising education levels, postmodern consumption styles, and increased mobility creates a high demand for culture. Secondly, the evidence for the economic contribution of culture reveals high supply potential which includes the development of cultural tourism to stimulate jobs and income, and which projects the external image of regions and nations. The OECD study (2009) on the economic importance of culture indicated that in several major economies, the value of the cultural industries is between 3% and 6% of the total economy. Similarly, WTO/ETC estimates that cultural tourism accounts for nearly 50% of international tourism (2005). In the USA, the surveys of cultural travellers indicate that 30% of domestic tourists are influenced in their choice of destination by a specific artistic, cultural or heritage event or activity. In Africa, Latin America and Asia, cultural tourism is often seen as a means of supporting heritage conservation as well as raising local incomes (Richards, 2007). In addition, the tourism industry is a sector that demands less costs in comparison to other industrial sectors (Urry, 1999). According to Urry, the cost of creating labour in tourism and leisure is only 1/8 of manufacturing. The heritage sector, which represents an important part of the cultural industries, provides jobs for 8.5 million people in the EU, and contributes 4.5% to Europe's GDP (OECD, 2009).

While culture has become the business of cities as evident from the figures above, one of the most important consequences of neoliberal policies on urban conservation is the transformation of cultural heritage into a "cultural product" with a marketing value under the name of cultural capital. In this way, it is possible to define the heritage industry as the management of historic environments and cultural heritage as consumption spaces that are rearranged and organised to promote consumption. The increasing tendency to link heritage and conservation with economic development has brought new meanings to cultural assets, the value of which has started to be related solely to the economic value it sustains or generates. According to Pendlebury (2009), there is a great tendency to perceive heritage as producing immediate and instrumental benefits, rather than conceptualizing it as important for its own sake. While cultural heritage has been turned into a concept that is related to present conditions as a result of interpretation of history, it also becomes an inseparable part of the global consumption models through the "packaging of history" (Walsh, 1992). This, according to Urry (1999), is the reconstruction of culture.

3. Reimaging Industrial Heritage as an Industry

> "*Holland in just one day!!: The Netherlands Open Air Museum uses authentic buildings, objects and true stories to bring the past to life. Come with us on a journey through the last two hundred years. The museum, with its farmyards, farmhouses, cottages and businesses, farmer's café and shops, is a hive of activity.*"

Industrial heritage is the witness of the industrialisation process of nations. It has affected and continues to affect all social, cultural, technological, and economic dynamics of life. It explains not only the past, but includes present and relates to the future (Alfrey and Putnam, 1992). As the material evidence of this industrial culture, it has become the new opportunity space in the revitalisation strategies of post-industrial economies by providing a unique chance of conversion in the shift of cities and countries from being centres of production to centres of consumption.

This significant role has been well documented by international conservation institutions. For example, 52 of the 936 UNESCO World Heritage areas listed in 2012 are industrial properties. The scope of industrial heritage consists of buildings and machinery, workshops, mills and factories, mines and sites for processing and refining, warehouses and stores, places where energy is generated, transmitted and used, transport and all its associated infrastructure, as well as places used for social activities related to industry such as housing, religious worship or education. According to the Nizhny Tagil Charter for Industrial Heritage (TICCIH, 2003), the values of industrial heritage consist of "universal values" as they are evidence of activities which had, and which continue to have, profound historical consequences; "social values" that provide an important sense of identity; "technological and scientific values" in the history of manufacturing, engineering, construction; "aesthetic values" for architectural quality, design or planning; "intrinsic values" contained in human memories and customs; and "rarity (scarcity)", in terms of the survival of particular processes, site typologies or landscapes. The fundamental that differentiates industrial heritage from other heritage is its nature, which is closely related to individual areas, as well as its social identity and history (Köksal and Ahunbay, 2006).

There has been not only an increased awareness of the importance of industrial history in understanding heritage in recent years, but also the growing tendency to use industrial heritage. This tendency has emphasised the importance of sustaining historic buildings and any remaining industrial uses, while attracting new investment and introducing high-quality new designs. There are important examples throughout the world that build conscience to restore and reuse existing industrial heritage stock in order to stimulate cultural and economic regeneration such as London Tate Modern Museum (former electric plant), Swansea National Waterfront Museum and Liverpool Merseyside Maritime Museum (former entrepots), Big Pit National Coal Museum in Blaenavon (former coal mine), Gar D'orsay in Paris (former train station), World Heritage Site Zollverein in Essen (former colliery and coking plant), Notthingham Lace Market and Birmingham Jewellery Quarter (former lace and jewellery manufacturing sites), Shanghai M52 (former warehouses) or Birmingham

Back to Backs (former worker lodgements).

The reason for this increasing interest in industrial heritage is that they are stated to be more interesting than regular office spaces (Zukin, 1989). According to Zukin (1989) their structure has both a solidity and a gracefulness that suggests a time when form still identified place rather than function. Moreover, the scarcity factor highlights the fact that the process of deindustrialisation after a process of rapid industrialisation has left many places that are in need of reuse; and the value of converted industrial buildings have held their value and remained saleable in depressed housing markets (Tiesdell et al., 1996). Reusing existing buildings is also a simple way of achieving sustainability by saving waste and reducing the need for new building materials (English Heritage, 2005b). Finally, there is the governmental desire that the heritage industry creates attraction zones not only for visitors but also for enterprises and workers. Industrial heritage may provide opportunity spaces to increase the competitive advantage of cities through the deployment of tourism investments and the branding of space. Even the industrial landscape is emphasized as a strategy to reclaim and validate a post-industrial site in order to turn it into a multifunctional landscape. For instance, UNESCO (2010) states that the Tate Modern is estimated to bring in revenues of over €125 million to London every year. The Birmingham Jewellery Quarter has introduced the role of industrial heritage as an instrument in local economic development. English Heritage (2005a) states that the Quarter has turned out to be one of the most important tourist nodes of Birmingham, creating 1500 businesses and 6000 jobs. In the Nottingham Lace Market, moreover, 80% of the 450 firms located there are still in the cultural production and consumption sector, while the property values have risen by 28%.

However, many academics are critical towards attempts to reform post-industrial spaces of consumption with privatised spaces and commodified cultures which focus on conservation and social consequences. The commodification and instrumentalisation of industrial heritage by the heritage industry, in particular, has turned out to be the determining factor in creating opportunity spaces in post-industrial areas. It has increasingly been threatened with the loss of its functional values due to technological, economical and social changes. The industrial heritage has even become too industrial. This is related to the debates on history versus heritage, which underlines the fundamentals of authenticity values (Alfrey and Putnam, 1992). The process, which started with the model of Disneyland, finds new arenas of use. Examples for the modification of heritage for heritage museums or parks include the change of the Manchester Castlefield Heritage Park, Netherlands Open-Air Museum in Arnhem, or Abu Dhabi Heritage Park. Today, the similar pattern is evident even in shopping malls such as Forum Shops of Ceasar's Palace in Las Vegas. Thus, heritage industry commodifies the past and its architecture into new forms, and stylizes historic areas through abstract and artificial forms. Unless industrial heritage can retain some of its original functions, its intrinsic qualities are lost. According to Lowenthal (1985), even conservation practice has turned into an artificial modification of the past, while ripping away the connection between the conserved and the past. Hewison (1987) emphasizes the examples like the Wigan

Pier Heritage Centre as the promotion of British rural life as a romanticized and exaggerated industrial past. According to him, the heritage industry is regarded as responsible for devaluing the cultural worth of cultural objects as they are repackaged for mass consumption. This is romanticisation and commodification of the past which shows itself in Laura Ashley shops, vintage clothing, façadism in urban centres, heritage parks and the souvenir industry. In particular, Urry (1999) states that if we are interested in history, we should protect it from the preservationists. Similarly, Ashworth and Tunbridge (2000) state that the more conservation, the less locally distinctive identities. Although culture and heritage-led approaches search for distinctiveness/uniqueness, standardisation is perceived, such as in the case of thematic parks, thematic housing projects, shopping malls, and archistar museums. Boyer (1996) states that the city as spectacle is a commodified location for consumption. On the other side of all these developments, the main problems of citizens are ignored, local cultures and identities become lost. For instance, the examples of the Lace Market and the Birmingham Jewellery Quarter, which are stated as good practice examples, are criticized for the fact that the attractiveness of physical buildings has contributed to higher value users wanting to colonise the area and displace the existing buildings. This has brought a threat of gentrification and even the loss of industrial heritage to the area (Pendlebury, 2009). With regard to the reuse of industrial heritage, it is therefore important to maintain the links that areas have with their own history.

4. The Golden Horn Industrial [Heritage] Industry

Industrial heritage has always played an important role in the revitalisation process of the Golden Horn. In the 19th century Ottoman Empire, Istanbul and its environs was the place where industrialisation was the most dense. Due to increasing foreign investment, labour and technology in particular, the number of industrial facilities increased after the 1850s. At the beginning of the 20th century, Istanbul had 55% of the total 256 industrial complexes of the Ottoman Empire (Köksal and Ahunbay, 2006). Among these, the Golden Horn has always had an importance by virtue of its being a major natural port for economic, cultural, social and military development. Since the Byzantine period, the Golden Horn has been surrounded by shipyards, merchant houses and warehouses. In the Ottoman and Republican periods, it became one of the major industrial zones, as was especially proven by the Prost Plan of 1936. The industrial development in the Golden Horn, which continued in the 1970s and early 1980s, had profound environmental and socio-economic effects on the surrounding neighbourhoods including the deterioration of the historical urban layout, water pollution and change in the social layout. The 1980s marked another turning point in the transformation of the Golden Horn into a heritage industry. Starting with the Golden Horn Waterfront Revitalisation Project in 1986, several interventions have taken place to clean-up this very valuable area to provide a global city image. These include the reclamation and the beautification of the shores of the Golden Horn and the clearance of industries under the leadership of Bedrettin Dalan - the first Mayor of the Greater Istanbul Municipality between 1984 and 1989. As a result, 600 small manufacturing establishments were evicted, and 30.000 buildings,

100 of which were historic examples which reflected the industrialisation of the Ottoman Empire, were demolished (Bezmez, 2008, p. 821). In the period starting from the mid-1990s, the Golden Horn has once more become the central focus for city governments in need of creating a world city image for Istanbul and increasing their competitive advantage in the new global order. This was the same period when the Golden Horn was declared a "cultural valley" by Ali Mufit Gurtuna, Mayor of the Greater Istanbul Municipality between 1999-2004. Considering culture as the growing value of global economy, the goal was to reintegrate the Golden Horn with the rest of the city by providing a new culture-led attraction zone to represent Istanbul globally. The role of the Golden Horn as a culture-led attraction zone was once more mentioned in the 1/100.000 Scale Istanbul Environmental Master Plan (2009) and the Istanbul Strategic Plan 2010-2014 (2010).

The Golden Horn Cultural Valley Project plays an important role in the turning of industrial heritage into sources of social and economic development. It has different dimensions including the conservation of historical waterfront neighbourhoods, the transformation and refunctioning of historic industrial facilities, and the utilisation of cultural amenities and landscape design. This paper especially focuses on the transformation and refunctioning of industrial heritage.

The number of industrial facilities in Istanbul, which was 256 in the 19th century, decreased to 43 (Köksal and Ahunbay, 2006). Today, 15 of the remaining 43 industrial complexes are in the Golden Horn (see Fig. 1). Three of these are now used as museum complexes (Şirket-i Hayriye and Lengerhane / Rahmi Koc Industrial Museum, Silahtaraga Electric Plant / Santral Istanbul Energy Museum), three as congress and exhibition centres (Feshane Textile Factory / Feshane Exhibition Centre, Tophane-i Amire: Imperial Armory / Mimar Sinan Fine Arts University Exhibition Centre, Darphane-i Amire: Imperial Mint and Printing Office / Exhibition Centre), and one is now used as a university campus (Cibali Tobacco Factory / Kadir Has University). Silataraga Electric Plant is also accomodated by Istanbul Bilgi University. The Golden Horn Dockyards (Tersane-i Amire) are still in their original usage, which makes them the oldest dockyards still operating. On one hand, adaptation and re-use is an appropriate and a cost-effective way of ensuring the survival of industrial heritage; on the other hand, the use of original patterns and the utilization of new uses that respect the historical identity of industrial heritage contributes to the sustainability of the industrial heritage of the Golden Horn.

In economic terms, the transformation and refunctioning of historical industrial facilities has resulted in increasing economic vitality, especially by means of new retail investments and land and real estate prices (Günay and Dökmeci, 2012). In Sütlüce, where the Sütlüce Congress Hall is located, the abandoned sites have started to be transformed into offices along with new real-estate investment projects including shopping malls and hotels such as the Arçelik Company Headquarters, the Enyapı Shopping Centre, the Hilton Garden Hill, and large-scale housing projects such as the Polisan Residence, the AG Plaza and waterside residences. In particular, the location choice of the Hilton Garden Hill, as the first luxury hotel investment, is

very important for the future envisioning of the Golden Horn. Many domestic and foreign business groups such as Koç Holding, Demirören and Ulusoy are also attempting to purchase the remaining land in the area (Hürriyet, 2010). Considering the land market values declared in the official websites of the Beyoğlu, Fatih and Eyüp Municipalities, it may be seen that the value per square metre in Karaağaç Street reached €1560 in 2011 (it was €140 in 2009 and €85 in 2004). The value per square metre in the residential areas toward the slope of the hill has increased to €570 in 2011 from €35 in 2009. In commercial areas, the prices begin at €4600 per square metre. A similar increase in the land values can be seen in the areas surrounding Kadir Has University and the Rahmi Koc Industrial Museum. In the Halıcıoğlu neighbourhood of the Rahmi Koç Industrial Museum, for instance, the price per square metre of residential area land is between €640 - €1560, while it was between €35 - €65 in 2005. This has also had an effect on the spread of arts and museum facilities along the Hasköy manufacturing zones in the environs of the Rahmi Koc Industrial Museum. While the number of visitors to the Rahmi Koc Industrial Museum reached 134,000, the Feshane Exhibition Centre receives 2 million visitors per year (Günay and Dökmeci, 2012).

Figure 2. Adaptive Reuse: Rahmi Koc Industrial Museum (above); Santral Istanbul (below) (Source: Z. Günay)

Figure 3. Sutluce Slaughterhouse, after reconstruction (Source: Z. Günay)

Figure 4. Halic Dockyards (Source: Z. Günay)

Despite these economic impacts, the likely impacts on the industrial heritage and community are still under question. The most important reason for this is the fact that the Golden Horn Cultural Valley Project has not been integrated into policies for economic development or into regional planning. Moreover, there has been no comprehensive strategy for the conservation of industrial heritage. The interventions have had tendencies to compromise historical integrity or the authenticity of industrial heritage such as in the Sütlüce Slaughterhouse case. Once defined as "the gigantic ghost" (Radikal, 2002), it was demolished and reconstructed as a congress hall by the Municipality (Fig. 3). Recently, the proposals on the replacement and refunctioning of Tersane-i Amire (Fig. 4) as a privatised tourism facility have raised serious debates (Birgün, 2008). Moreover, there are still a considerable number of industrial sites to be registered and utilized such as the Kasımpaşa Flour Factory, the Cendere Pump Station or the Unkapanı Flour Factory. This shows the importance of private sector incentives in the conservation of industrial heritage, contrary to the general norms when the state is the primary enabler of conservation. In the Golden Horn case, the private sector has been able to refunction these industrial complexes by respecting their original uses, contrary to the incentives promoted by the Municipality such as the demolition of the Sütlüce Slaughterhouse.

Regarding the socio-economic consequences, one of the criticisms focuses on the fact that economic vitality is limited to specific locations. This is also related to the provision of the functional integrity of industrial heritage to the wider surrounding. For example, the opening of Kadir Has University has resulted in new functions being made available for utilization by new potential customers. The increasing number of students and visitors has increased the overall safety of the region and has encouraged further arrangements regarding transportation links in the Golden Horn. However, the local retailers complain that the closed structure of the university limits expenditures. However, the privatisation of public spaces, such as in the case of the Rahmi Koc Industrial Museum or Kadir Has University, has prevented public use and public service. These even include the changing of the name and the closing of the street in front of the University. In addition to public spaces, the emphasis on building the infrastructure for attracting visitors such as convention centres, prestige hotels or thematic parks results in the transformation of residential areas into business districts and the isolation of the community. Considering cultural participation, most of the visitors are outsiders and the accessibility of the community is limited to participating in cultural activities in their neighbourhoods.

5. Conclusion: Heritage Industry vs. Industrial Heritage

The fundamental that differentiates industrial heritage from other types is the fact that it is about communities own lives, identities and histories. This makes industrial heritage an issue of social phenomenon along with its potential to be a catalyst for further cultural and economic development. The research has demonstrated that there have been important investments during the previous decades to encourage the transformation and re-functioning of industrial heritage in the world, including Istanbul. However, this growing interest could not prevent industrial heritage from

becoming deteriorated. While the general tendency is to demonstrate history "in just one day", there is still a misunderstanding of the value of industrial heritage, and the lack of community conscience. The research shows that the Golden Horn projects run the risk of commodification of industrial culture and heritage; although they have played a vital role not only in improving the image of the Golden Horn, but also in being part of the branding of Istanbul. The solution is more to do with the conservation of the "industrial landscape" through the preservation of the "spirit of place", as ICOMOS (2008) states. This necessitates programmes for the conservation of the industrial heritage to be integrated into planning processes and into policies for socio-economic development; the preservation of historical integrity and authenticity and the utilization of adaptive re-use and preservation of functional integrity by creating links between areas to their own history.

THE VISUAL LANGUAGE OF STRATEGIC SPATIAL PLANNING: HOW IT WORKS IN DIFFERENT PLANNING CONTEXTS

B. Gedikli[1]

I. Introduction

Visualization is a key concept for spatial planners since, after all, the very discipline is about territories[2]. Although a variety of media can be applied for visualization – such as 3D images, sketches, diagrams— the most suitable medium seems to be maps for the representation and visualization of territories.

Maps are powerful tools in that they can lead to consensus or conflict. The so-called consensus or conflict can be attributed to what maps represent: A map is *"...a cumulation of choices made among choices every one of which reveals a value"* (Wood 1993 cited in Jensen and Richardson 2003). Map-making, according to Jesen and Richardson, involves activities of selection, omission, simplification, classification, creation of hierarchies and symbolization. Their point can be linked to plan-making --as it also involves the very same activities--: The visual language of plans[3], too, can lead to consensus or contradictions among the relevant parties, namely central government; local government; property owners; land developers; professionals related to planning, design, conservation, engineering and the like. This implies the necessity of well-developed cartographic representation so as to transmit the very ideas of the plans as intended, and avoid conflicts.

Plans at city, metropolitan or regional scales are strategic ones. They aim at showing the general spatial organization for territories. Hence, they are *intentionally* selective (Mazza 2010, Friedmann 2005); i.e. their scope is limited to key issues, which decisively pave the way for further lower scale plans.

This paper aims at exploring the visual language of strategic spatial plans. In the face of the rapid changes that cities have had to tackle since the 1980s --thanks to ever globalizing socio-economic relations--, planning community has assumed that cities can attain a desired future state only through more flexible plans; i.e. strategic spatial plans. These plans, as mentioned above, simply and purposefully general, selective and comprehensive; implying a different way of representing the space than the

[1] Middle East Technical University, Ankara- gedikli@metu.edu.tr
[2] This study uses the terms territory, city, space, urban, etc. in place of one another.
[3] Obviously, contradictions or consensus on plans do not simply refer to the visual language selected; yet, the scope of this paper is limited to that.

traditional land-use plans. The study first portrays the intention of strategic plan-making and how this intention is represented visually through examples from different planning systems; and then elaborates its interpretation in the Turkish context.

II. Representation in Strategic Spatial Plans

Visualization of the territory is an inseparable component of spatial planning. Dühr (2003) mentions that images are used to either directly express the intention of an urban policy and/or support the policy. Kunzmann (1996 cited in Dühr 2003) suggests that visualized spatial presentation, despite its vagueness, can reduce complexity to a great extent.

Mazza identifies three typical characteristics of strategic spatial plans: **Generality, selectivity** and **comprehensiveness**: The strategic plan has to be **general**, because its frame has to be both precise and flexible at the very same time. The stability and durability of strategies should be secured in a way to provide a certain framework for the investors. Concurrently, they should allow margins for maneuvering (or flexibility) for the realization of policies and projects in the face of changing conditions. The plan should be simple in order to keep its strength over time, be easily understood and communicative. Meanwhile, the strategic plan should be **selective**. It should not face all the phenomena related to urban development; but should stabilize the priorities in time and space, and select a few primary spatial problems. Finally, the strategic plan should be **comprehensive** in a way to bring the solutions and selected problems together in a spatio-temporal framework. This framework should allow the assessment of opportunities and constraints, advantages and disadvantages (Assessorato allo Sviluppo del territorio, Comune di Milano, 2000).

Salet and Faludi (1999) talk about the "revival" of the strategic spatial planning rather than the birth of it. It is because the strategic approach in plan-making had already been experienced during the establishment of the welfare state after the Second World War and in the 1960s. How the contemporary strategic planning differentiates from the one experienced in those years lies in its **policy agendas** and **institutional relations**: Vis-a-vis the rapidly changing socio-economic conditions and the accompanying sustainable development discourse, the present policy agendas of strategic planning oscillate between two poles; namely competitiveness agenda and environmental agenda (Albrechts 2003). A multiplicity of aims, directly or indirectly related to spatial development, take place in between these two poles (Figure 1).

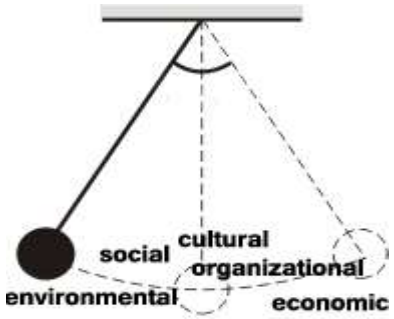

Figure 1-Multiple Aims of Strategic Spatial Planning

Under the impact of the global mode of capital accumulation, the aims of strategic spatial planning practices of the last two decades seem to go beyond physical development; including improvment of competitiveness capacity of localities while providing urban sustainability. These two new agendas have led to a new visual language for spatial planning which go beyond mere coloring of different land-uses.

I.1. A Metaphoric Imagery

Many practical cases around the world reveal that the generality, selectivity and comprehensiveness features of strategic plans are often associated with metaphoric visualizations. These metaphoric images are believed to increase the power of the spatial strategy. Dühr (2003) states the metaphor of "Blue Banana", representing a developed area from the south-east of England to the north of Italy (Figure 2). She notes it as a successful one in raising awareness and understanding about complex spatial development trends.

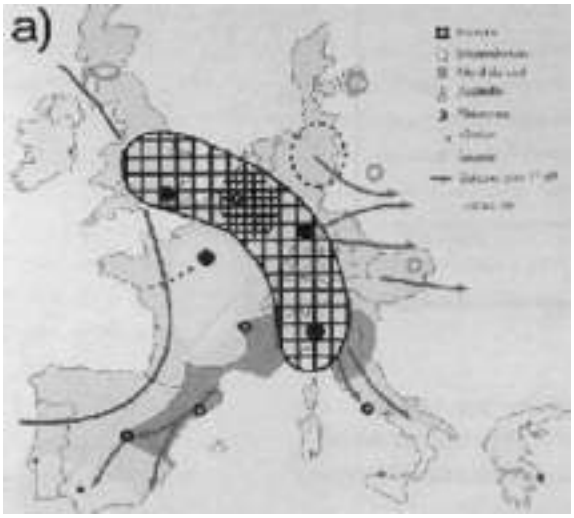

Figure 2- Blue Banana
(Dühr 2003)

Likewise, the metaphor of "Reversed T" (T rovesciata) in the Strategic Plan of Milan represents a spatial strategy based on a reversed T-shaped transport corridors (Figure

3). The "Reverse T" connects Milan's three airports; Malpensa, Linate and Orio al Serio. Part of the strategy is to locate private and public investment in these axes to improve the public infrastructure and transform the surrounding areas. These axes also aim at linking new developments in the periphery with the city centre, providing more green areas, improved services and accessibility across the City, and producing new alliances with the stakeholders across the urban area (Mazza 2007). Another example is that of Lyon's Schema Directeur: The territories in Lyon are represented by the petals of a flower including the centre. The petals show a balance between the different territories of the urban area (Figure 4).

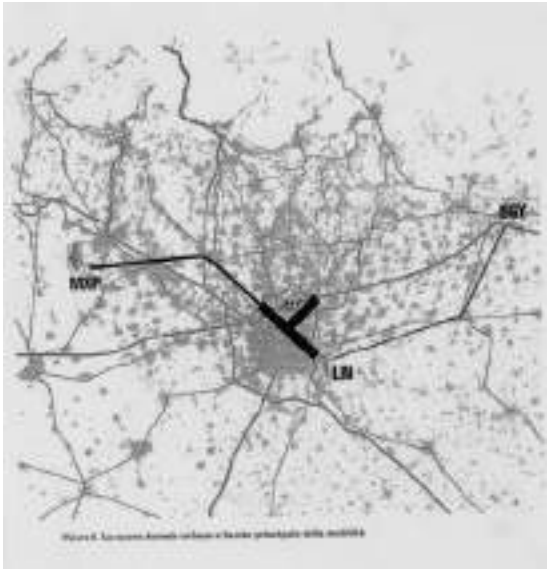

Figure 3- Reversed T
(The Framework Document of Milan)

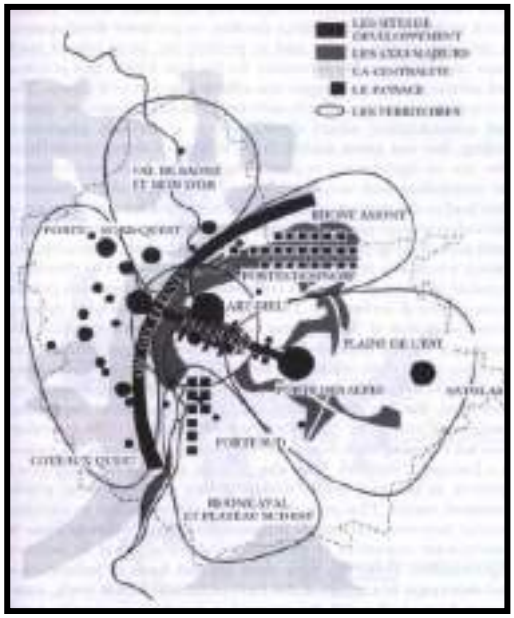

Figure 4- Five Petals
(Le Schéma directeur de l'agglomération Lyonnaise approved in 1992)

Many people, even without reading the plan reports, can capture the visions, core values and spatial relations which are embedded within such metaphors. They carry powerful messages about the organization of space within a certain locality (Jensen and Richardon 2003). Planning systems in many European countries, under the impact of the EU's common spatial development agenda[4], increasingly apply metaphoric imagery in strategic spatial plans.

Use of metaphors are often applied for strategic projects that are supposed to create brand new images for cities. The waterfront design competition held for Doha Waterfront guides to the competitors with the idea of "Three Corniches"; a metaphoric image for the waterfront development strategy (Figure 5).

[4] The efforts towards a European scale spatial policy in the EU promote the use of metaphors in spatial planning, since they describe the spatial structure of Europe in a way to be easily understood.

Figure 5- Doha Corniche
(Design Brief for Doha Corniche, 2003)

The metaphoric language, in fact, improves the communicative capacity of the strategic plan: It is through the metaphors that the major concern of the plan is transmitted to decision-makers, investors and general public. The use of metaphors comply with the generality, selectivity and comrehensiveness principles of the strategic spatial plan. A metaphor reflects the general idea of spatial development; it is selective only focusing on certain issues; and it is comprehensive in that problems/potentials of the territory can be grasped within it. Obviously, metaphoric imagery is not an obligation in strategic plan-making. However, practical cases prove that they are very powerful instruments to transmit the aims of a plan to interested parties.

II.2. Use of Logos and Slogans

Likewise the metaphoric representation of space through catchy images, use of logos with sloganlike statements is also common in strategic spatial plan-making. As extensively discussed in the planning literature (eg. Harvey 1989, Brenner 1999, Hall and Hubbard 1996, Gordon 1999, Williams 2000, Vanolo 2008, Zimmerman 2008), one major impact of globalizing socio-economic relationships is the rise of interurban competition. Localities compete with one another in order to attract the globally wandering capital (Şengül 2003). The logos accompanied with slogans are supposed to disseminate "how the city should be perceived" as proposed in the strategic plan. Figure 6 shows the logo of the Strategic Plan of the Bologna Province, which is in fact an abstraction of the strategic plan itself.

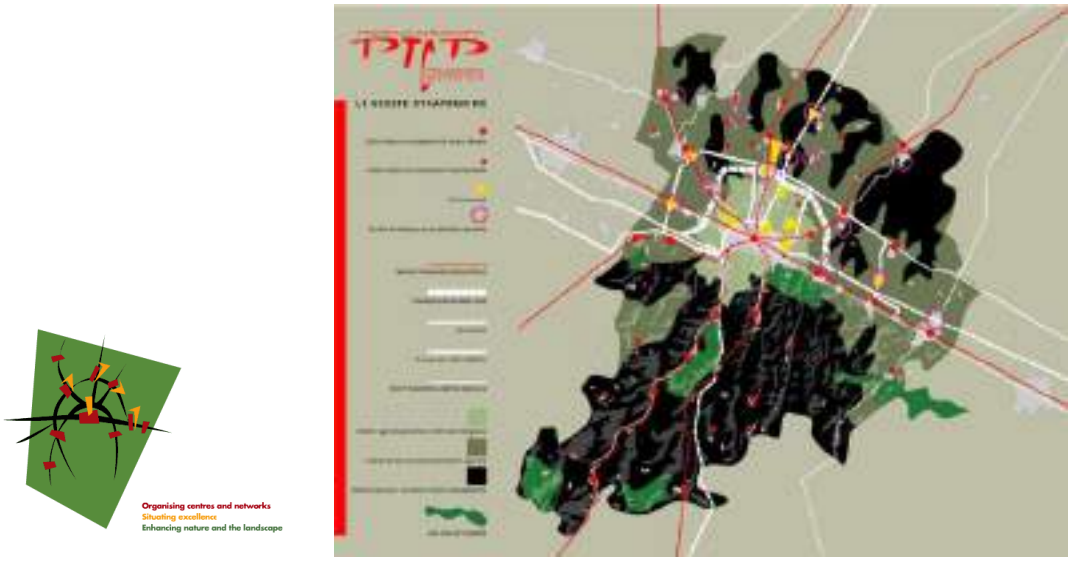

Figure 6- The logo for the Bologna Province Strategic Plan (left) is an abstraction of the plan itself (right). (URL: www.provincia.bologna.it)

Figure 7 and 8 show the logos for the strategic plans of Rio de Janerio and La Spezia. Both logos are accompanied by slogans; "Rio forever Rio" and "Verso la citta nuove" (Towards a new city), which are easy to remember by the general public.

Figure 7-The Logo for the Strategic Plan of Rio de Janerio
(The Strategic Plan of Rio de Janeiro 1996)

Figure 8-The Logo for the Strategic Plan of La Spezia
(The Strategic Plan of La Spezia 2011-http://pianostrategico.spezianet.it/Documenti/visioni_ottobre_2001.pdf)

II.3. Representation of Strategy

The second step, after the metaphoric imagery, is the representation of the spatial strategies on maps. It should be noted that some plans demonstrate both the metaphor and strategies on the very same scheme, while some others show them in successive schemes. As mentioned before, the strategic spatial plan --while providing a definite framework—should be flexible enough in the face of the rapidly changing socio-spatial conditions. Salet and Faludi (1999) makes an analogy between the "territorial space" and "war space": The role of strategy in a military plan is to never lose sight

of the final objective despite the ever-changing conditions of the battlefield. The troops have to adopt to the changing conditions, but should not leave the main strategies of military action. Similary, a territorial strategic plan has definite strategies, which are flexible enough to respond and adopt to the changing socio-spatial conditions without losing sight of the desired future goal; namely the **vision**.

What does the strategic plan aim at with the strategies it possesses? A strategic plan basically demonstrates **1) no-go areas** (natural and archaeological heritage sites, valuable agricultural land, immediate coastal areas, etc. are under this group), **2) areas for development** (obviously the way and degree of development are differentiated in different areas) **3) major hubs and corridors** (showing the interflows among territories). The strategic plan, with its vision and strategies, guides the preparation of lower-scale land-use plans (with precise forms, widths, heights, densities, and coordinates of land-uses). In other words, it is not an alternative to the land-use plan; rather, it provides a framework for the preparation of land-use plans.

As it is not the alternative of the land-use plan, the strategic plan should have a language of its own. Examples around the world show that the three strategic groups mentioned above mostly represented via symbols, icons, signs, geometric forms (triangles, circles, etc.), lines with arrows. The illustration does not have to fit the geographic space, some significant functions can be exaggeratedly drawn. Within the EU countries, there are attempts towards developing some iconographies to represent common spatial policies; eg. Figure 9 shows the polycentric and balanced development of European territories, while Figure 10 represents the policy of urban-rural partnership (European Commission 1999).

Figure 9-Polycentric and balanced urban development

Figure 10-Urban-Rural Partnership

Obviously, there are national differences in the application of iconographic language, because of cultural differences and long-established planning traditions (Dühr 2003). Still, as the below examples indicate, it is possible to talk about a common tendency towards the use of this style.

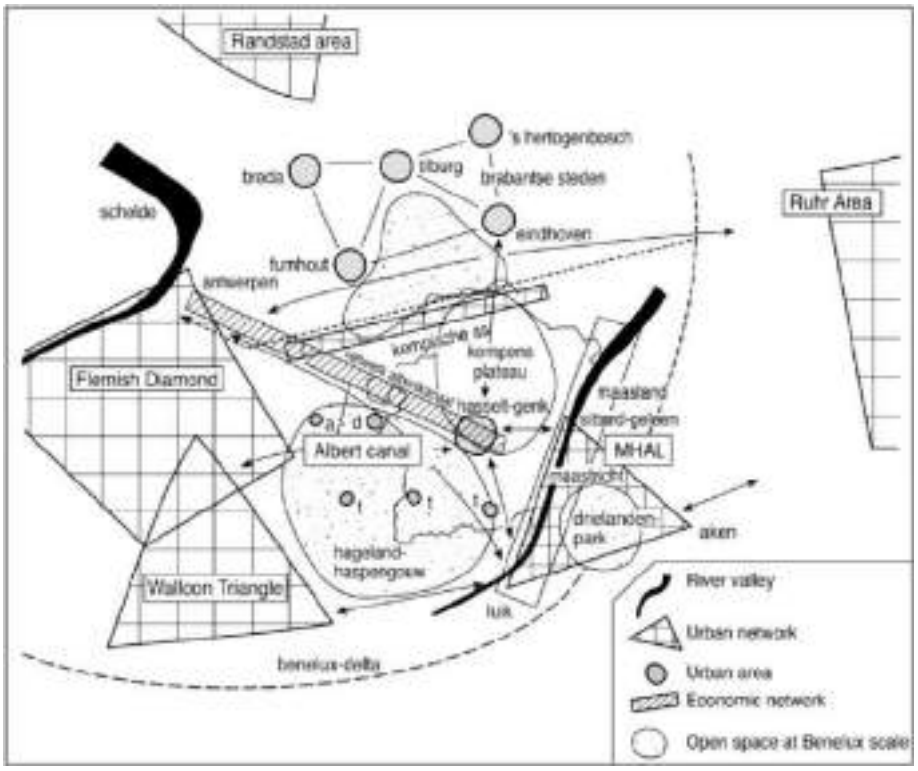

Figure 11-"Flemish Diamond"
(Albrechts and Lievois 2007)

Figure 11 illustrates the application of the "diamond" metaphor in spatial planning. The plan adopts a simple iconography to demonstrate the spatial strategies, which are supposed to have strong impacts on territories like creating economic networks, urban networks, etc. The legend items imply the two basic agendas of the current era: Both economic and environmental aims are strongly included in the aims of strategic spatial planning of the Flemish Diamond.

Two other recents example are that of Northern Ireland (Figure 12) and London (Figure 13). Likewise the above example, their strategic plans show important hubs and corridors, protection and development areas with reference to specific locations. The legend of the London plan also includes some policy issues in parantheses, which can be referred for detailed explanations of illustrations.

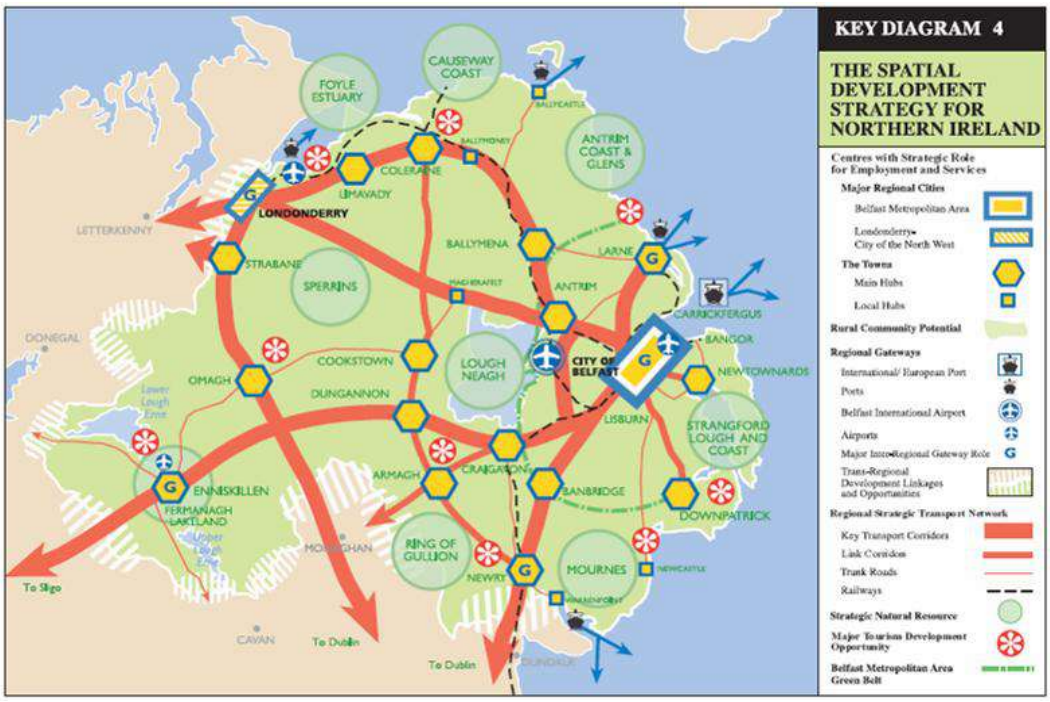

Figure 12-Northern Ireland's Spatial Development Strategy
(Shaping Our Future-
URL: http://www.drdni.gov.uk/rds_adjustments.pdf)

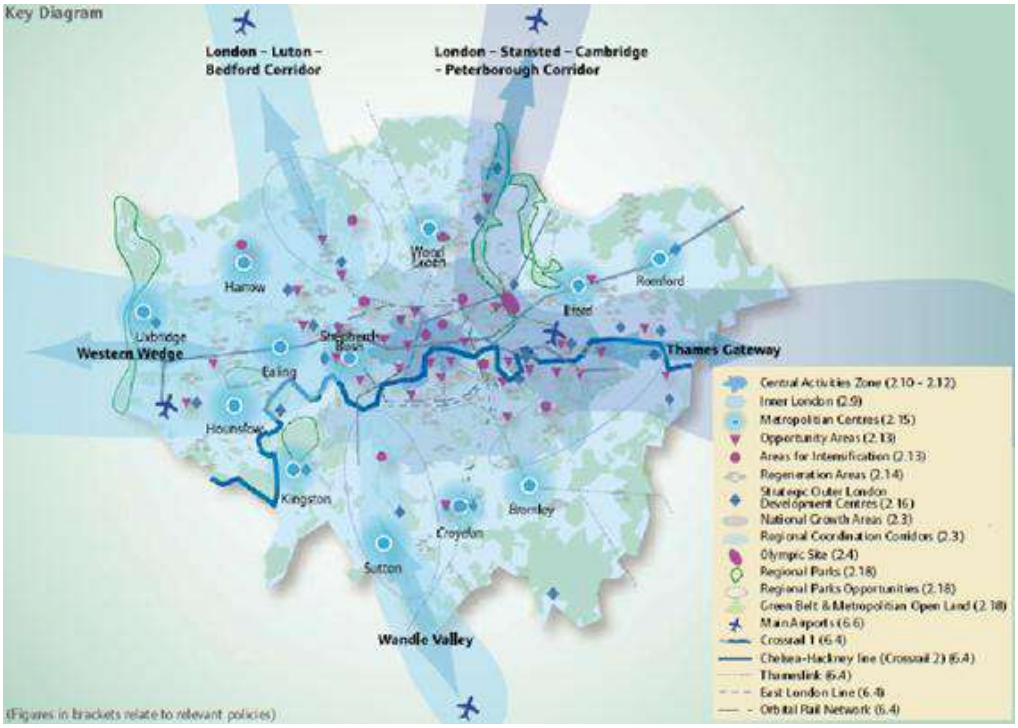

Figure 13-London's Spatial Strategy
(The London Plan-
URL: http://www.london.gov.uk/sites/default/files/The%20London%20Plan%202011.pdf)

The examples above show the general spatial strategy in a selective way. Actually their very language also proves why they cannot be the alternatives of land-use or urban design plans. They do not indicate any spatial form, any coordinates, any code for urban development. With the simple iconographic language they have, what they do is to guide the lower scale plans.

III. Strategic Planning in the Turkish Context

Until the beginning of the 2000s, strategic plan-making did not take place in the Turkish planning legislation. Therefore, there was not a nation-wide recognition of this approach, except for the attempts of a few local governments. It was in the early 2000s that the strategic planning has been declared in national official documents and legislation. In 2004, a series of laws were enacted related to public administrations, obliging them (including local governments) to prepare strategic plans and performance-based budgeting with reference to the plans (Gedikli 2009).

This paper is not to elaborate the above-mentioned strategic plans, since they may or may not be related to the spatial development; therefore may or may not have physical schemes with them. Another plan type in the Turkish planning hierarchy – the subregional land-use plan[5]-- is intended to carry the message of a strategic spatial plan as described in literature. Over 15 years ago, this plan type was introduced between regional and urban development plans within the spatial planning hierarchy. The authority for preparing it changed hands several times; now belongs to the Ministry of Environment and Urbanism.

The new law on Provincial Special Administrations (2005) introduced a new type of Subregional Land-Use Plan – namely the Provincial Land-Use Plan[6], without a clear explanation of its content and scale, therefore conflicting with the existing Subregional Land-Use Plans (Ersoy, 2006). The Urban Development Law defines the "subregional land-use plan" as *"the plan that determines housing, industry, agriculture, tourism, transportation, etc with respect to national and regional planning decisions".* It is problematic that it does not tell anything for heritage conservation, and leaves its consideration to regulations. Moreover, the multiplicity of upper level plans (subregional, provincial land use plans not much differentiating from one another) leads contradictions and inefficiencies in practice.

Leaving the authority conflict aside, the visual language adopted in subregional plan-making also leads to confusions. These plans are prepared at the scales of 1/100000, 1/50000 and 1/25000, i.e. they are upper level structure plans. Examining the plans, they (maybe not all) seem to adopt some new legend items in line with the contemporary strategic spatial planning practices around the world; eg. *"special project area", "innovative industrial zone", "R&D area", "ecologic impact boundary"*. Moreover, they do comprise symbols for some functions, perhaps not as

[5] Çevre Düzeni Planı
[6] İl Çevre Düzeni Planı

strong or exaggerated geometric images, therefore not holding a strong visual message.

However, most of them are still prepared with the logic of comprehensive land use plans, covering everything related to the territory under concern. Because of the language they adopt, general public tend to comprehend them as physical land use plans with accurate coordinates and forms; and plans can occasionally be the subject matter of court cases.

A plan at the mentioned scales can only be a *structure (or strategic) plan* guiding to urban development plans. Although the related legislation mentions the guidance role of subregional land-use plans, they are drawn with a visual language not much differentiated than that of urban development plans, which, first of all, causes conflicts in practice; and second of all, creates a chaotic situation in the planning hierarchy.

Although the present paper points out the obstacles related to representation of space in upper level plans, it does not propose an immediate modification of the existing visual language. If the visual language problem of these plans is not handled together with a review of the language of urban development plans, the problem will remain, even get worse. Therefore, a careful review and revision of their language, too, should go together, so that they could adequately interpret the decisions of strategic plans at settlement scales.

IV. Conclusion

Map making (or plan making as the subject matter of this study), as Jesen and Richardson (2003) mention, is about *selection, omission, simplification, classification and symbolization*. They can lead to consensus or conflict. This implies the necessity of well-developed cartographic representation so as to transmit the ideas of the plans as intended, and avoid conflicts.

This study has focused on the strategic plan-making, which has become widespread in the face of the ever globalizing socio-economic relations. These plans, prepared as general, selective and comprehensive ones, adopt a different visual language than that of the traditional land-use plans.

Strategic spatial plans are in fact upper scale structure plans, aiming at demonstrating the general spatial strategy in a strong way. Many recent strategic planning examples reveal the increasing use of metaphors, logos and catchwords in order to raise awareness about complex spatial issues. Meanwhile, since they are not alternatives to physical land use plans, practical examples show a variety of iconographic language adopted in strategic plan making. Obviously the iconographic languages adopted change from one planning system to another due to cultural differences.

Upper level plans have been comprised in the Turkish planning system, too, with the name "subregional land-use plans" and "provincial land use plans". They are supposed to guide to the preparation of lower scale land use plans. Nevertheless, they seem to adopt a very similar language to that of urban development plans. Moreover, they do not seem to carry powerful and creative spatial messages that would highlight the distinctive qualities of settlements. This is not to say that the role of strategic planning is simply to improve the competitive capacity of territories va highlighting their distinctive features. Rather, an emphasis on the distinctive qualities and combining them in a strongly constructed spatial image give the territory *a direction for future*.

This study does not indicate the foreign examples as benchmarks to adopt in the Turkish context; nor proposes an immediate modification of the existing visual language in upper level plan making. The cultural specifities, as mentioned before, should show themselves in different planning systems. Moreover, the visual language problem of these plans should be handled together with a review of the language of urban development plans. Clearly, this would be a careful and collaborative work of many relevant institutions, also involving other topics of plan making.

Collective Housing and How It Effects Contemporary Planning – Learning From the Danish Bofælleskaber From a Complexity Perspective

Abstract for AESOP 26th Annual Congress, Ankara 11-15 July 2012

** The Netherlands Organisation for Applied Scientific Research (TNO), Delft, The Netherlands and Department of Human Geography and Urban and Regional Planning, Utrecht University, Utrecht, The Netherlands*

Track:

11 – Housing, regeneration and community development

Key words:

Co-housing, Self-organization, Actor-networks, Planning Strategies

Abstract

In the light of current emergence and promotion of collective private commissioning for housing (co-housing) in the Netherlands, this paper explores the encounters such civic initiatives have with spatial planning practice. Co-housing is a challenge for conventional planning practices since it moves beyond the well-know concept of (governmental-led) participatory planning, and side-lines conventional public-private partnerships. Instead, planners are confronted with the capriciousness and diversity of civil actor-groups, and civic groups are challenged by a rigour planning system – both of them working within their own logic. In order to study how co-housing initiatives and practices of spatial planning interrelate and effect each other, three recent planning experiences in the establishment of 'Bofælleskaber' in Denmark are explored. The comparison between Denmark and the Netherlands is made because both countries have similar planning systems, while communal housing is such a strong(er) cultural element in Danish society. Defining the actor groups initiating co-housing schemes as 'self-organized' (the emergence of new structure out of fairly unstructured beginnings), (*Cilliers 1989*) and the process towards realisation of their projects as 'translation towards actor-networks' (*Callon 1986, Latour 2005*), brings together elements from both actor-network theory and complexity theory into one analytical framework. Using this analytical approach, the trajectories the initiatives took towards realization are studied, with an emphasize on how they engage in planning and what controversies and associations arise from these interactions. This framework not so much focusses on the mergence of perspectives into a coherent whole, but rather on the multiple trajectories that run through a process of establishing a co-housing initiative. (*cf. Massey 2005, Hillier 2007*). From these cases, lessons can be learned how planning systems can be made more adaptive to self-organization by community-based networks.

1. Dutch Housing: moving towards private commissioning

Since the 1990s already, the role of citizens as commissioner for the development of housing in the Netherlands is a subject of debate. Coming from a post-war tradition of large-scale reconstruction and urban lay outs, with its last episode the construction of the VINEX-neighborhoods in the 1990s, the Netherlands has been known and celebrated for its efficient, large-scale and institutionalized building sector. However, this practice is also criticized for the strong uniformity in the Dutch housing stock it caused, turning the Dutch citizen into a dependent consumer of houses, and reducing the once common practice of private commissioning into nothing more than a niche of the Dutch housing market. (SEV 2010). Subsequent interventions from national governments through resolutions (such as the Resolutions Duivesteijn in 1998 and 2000) and policy documents (such as the Memorandum Mensen, Wensen, Wonen in 2000), subsidies provided by regional and local governments, and the execution of numerous experiments with different forms of private commissioning (such as by the SEV – the Housing Experiments Steering Group) have attempted to bring the Dutch resident back on the stage of commissioning. Figures on commissioning, kept by the Central Statistical Office of the Netherlands (CBS) however show, that over the last thirteen years (1998-2011) there has not been any increase – on the contrary: rather a decrease of private commissioning (see figure 1). In 2006, the Housing Experiments Group (SEV) explained this lagging behind by some of the barriers they encountered while executing experiments with private commissioning: the Dutch building customs and (planning) regulations, leading to high (financial) risks and extensive planning processes. Their recommendations in order to further stimulate private commissioning were: 1) to designate land in the land use plan as intended for private commissioning, 2) to establish a pre-funding-scheme for private commissioners in order to reduce financial risks and 3) a 'knowledge campaign'. (SEV 2006).

Recent figures on commissioning – up to 2011 – however still show no significant increase. Although the financial crisis has led to quite a downfall of overall housing production (82.932 houses were realized in 2009, compared to 57.703 in 2011, a decrease of 30%), and a slow retreat of commercial developers, this has not been compensated or replaced by more private commissioning. That this might change in the near future, is argued in a final evaluation of the experiments executed by the SEV in 2010. Chances for private commissioning are seen in a more relaxed land- and housing market, a demand for more sustainable and social forms of living and a less task-setting, more facilitative government. The recommendations coming from this final evaluation are: 1) reconsider the distribution of risks – both financially and institutionally, 2) less regulatory frameworks and 3) more reasoning from the perspective and interest of self-organized initiatives for collective private commissioning. This latter aspect was also recently advocated by Adri Duivesteijn in the leading debate TV-show 'Buitenhof' (dated 02/26/2012). Duivesteijn – once the initiator of the Resolutions Duivesteijn – is now alderman for Housing in Almere, where he is making private commissioning possible on a large-scale. During the TV-show, which main topic was the current stagnation of the Dutch housing market – he argued on the urge to bring 'housing' closer to people themselves again, to have people act collectively in taking responsibility for their maintenance of their living environments, or realizing their houses, not only as individuals but in small self-organized building groups. If people themselves are the initiator, he argues, it is surprising to see what quality is realized, according to the Almere experience. However, Duivesteijn argues, in the Netherlands,

people still tend to think too much that government needs to take care of citizens. The citizen, on the contrary, has since long been able to act for himself, only being obstructed by a system in which the building sector has been monopolized by developers, housing associations and housing policies.

Figure 1: Newly build houses according to commissioning (source: CBS)

	1998	1999	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011
Public	22,5	22,5	20,6	18,8	19,6	22,4	22,4	25,4	26,2	26,1	27,1	29,1	32,7	35,5
Commercial	63,2	62,3	62,0	67,1	65,4	63,3	64,7	63,5	62,4	63,4	62,2	60,7	56,2	53,3
Private	**14,3**	**15,2**	**17,3**	**14,1**	**15,0**	**14,3**	**13,0**	**11,2**	**11,4**	**10,4**	**10,7**	**10,2**	**11,1**	**11,2**

This last recommendations by the SEV and the remarks made by Adri Duivesteijn, triggered me to consider a specific branch of private commissioning – that of *collective* private commissioning ('collectief particulier opdrachtgeverschap') – in more detail in this paper. Collective private commissioning – or: co-housing in more international terms – concerns people who collectively commission, develop and maintain their living environments, sometimes paired with collective ownership of (parts of the) estate and communal living. (SEV 2010). This form of development is even more of a challenge within the Dutch context, because it does not only sideline the conventional building institutions and practices by the direct acquisition and development of plots by individual citizens, like regular private commissioning. The collective element of such projects, turns it into a spatial planning process as well: common facilities, common (or even public) spaces, several houses instead of one, make it necessary to asses which program is allowed and best on what location – both from the municipal planning perspective as from the initiating citizens perspective. Therefore, this form of collective private commissioning is not only a challenge for developers and housing corporations, but also to municipalities and its spatial planners. Moreover, the initiative no longer lies with the municipality providing plots, but with the self-organized building groups themselves – leading to a civic-public interaction that is very unusual within the Netherlands. In Dutch planning, civic-public interaction is foremost structured by participative planning procedures, that are predominantly governmental-led. In participatory planning procedures, citizens are merely invited to 'think along' the planning objectives set out. Collective private commissioning, or co-housing, on the contrary, refers to initiatives that originate in civil society itself. (Boonstra and Boelens 2011). As such, planners are confronted with the capriciousness and diversity of civil actor-groups, and civic groups are challenged by a rigour planning system – both of them working within their own logic.

It is in this light, and through this paper, that I want to explore the conditions that are needed to better facilitate such civic initiatives from a spatial planning perspective. In order to study how co-housing initiatives and practices of spatial planning interrelate and effect each other, in this paper I make an international comparison of the housing schemes and planning systems in the Netherlands and Denmark. These countries show many similarities in planning and housing, but differ on some

specific aspects that relate to the barriers that were observed in the Netherlands concerning collective private commissioning, as I will argue in the second paragraph. After discussing these contextual differences between Danish and Dutch planning and housing schemes, I theoretically frame initiatives for co-housing as self-organization in the third paragraph. Defining the actor groups initiating co-housing schemes as 'self-organized' (the emergence of new structure out of fairly unstructured beginnings) and the process towards realisation of their projects as 'translation towards actor-networks', brings together elements from both actor-network theory and complexity theory into one analytical framework, providing me a vocabulary the express the particularities in the establishment of a co-housing initiative in more detail. Using this analytical approach, in the fourth paragraph, I explore three cases of co-housing in the Copenhagen-area, in order to learn what trajectories the initiatives took towards realization, with an emphasize on how they engage in planning and what controversies and associations arise from these interactions. From these cases, lessons can be learned how planning systems can be made more adaptive to self-organization by community-based networks in general, thus redefining the contemporary relevance of planning in theoretical and practical terms, to a more discretionary practice of shared responsibilities.

2. A Dutch-Danish comparison

2.1 Some methodological notions on international comparisons

Before I take off in making an international comparison between the Netherlands and Denmark, some notes need to be made concerning the minefield one walks into when conducting international comparative research. International comparative research is often set up in order to borrow from policy and planning practices elsewhere for problems found in one's own planning environment, or to strive towards convergence of planning practices (for instance done in the context of European Union cohesion policies). (Booth 2011). This is considered to be a minefield because planning as a practice is the outcome of very specific local and national cultures; planning systems are deeply embedded in their socio-economic, political and cultural context, and there exist path-dependencies such as persistence of institutions and cultures. (Booth 2011, Nadin and Stead 2008). These path-dependencies should be taken in consideration when conducting comparative research. Following Mahoney (2000), Booth describes these path-dependencies as: historical sequences of contingent events that set institutional patterns or event chains in motion that have deterministic properties, causing an unwillingness to change. (Booth 2011). Overlooking the path-dependencies that shape planning practices, can cause serious difficulties when one tries to borrow and transfer or to converge practices over national (and thus institutional) boundaries. However, the reason I conduct this comparative research is not so much to converge practices or to borrow Danish concepts to translate these to the Dutch context, but rather to study the particularities of both Danish and Dutch practice, in order to understand and question the path-dependencies that exist and determine the Dutch interaction between how co-housing initiatives and practices of spatial planning. Therefore, taking in consideration the path-dependencies that exist within the Danish and

the Dutch planning system, are not so much a problem to overcome, but rather the reason for doing a comparative research in the first place. To take this into full consideration, I use a mix of comparative research strategies (conform Booth 2011, following Tilly 1984). First, in the comparison of the national planning system and housing policies I use an individualising comparison, in order to grasp the particularities that exist within each system. In the later part of this paper, I analyse four recent planning experiences in the establishment of 'Bofælleskaber' in the Copenhagen-area and Sjælland, Denmark. The comparative strategy that I use in this part of my research is twofold. On one hand I use a 'finding variation' strategy: to 'establish a principle of variation in the character and intensity of a phenomenon by examining systematic differences among instances' (Tilly 1984, 82–3) and on the other hand I use a 'encompassing' strategy: to find 'different instances at various locations within the same system, on the way to explaining their characteristics as a function of their varying relations to the system as a whole' (Tilly 1984, 82–3). Or in other words: on one hand I look into the variations between and particularities of the cases, and on the other hand I look into recurring characteristics between the cases that can be traced back to what is called the 'planning system'.

2.2 Comparing the planning systems

Planning systems in general

An international comparison of planning system is easiest to start off from previous studies on the different planning families that exist within the European Union, such as those conducted by Newman and Thornley in 1996, and the European Commission in 1997. These planning families make clear that – on a global scale– the Danish planning systems and housing scheme is perhaps one of the most comparable to the Dutch. Using the planning families as a starting point can however also be tricky, because these planning families have been defined in order to facilitate the convergence of planning practices among European Union member states (CEC). And my aim is to grasp the particularities of each system. But, as the following comparison will show, the particularities of the systems are nuanced, and thus of even greater value to the study of path-dependencies concerning co-housing and planning.

As planning systems are expressions of fundamental values in a society, there are parallels between models of society (that shape the relationships between state, market and citizens) and the spatial planning system (the ensemble of territorial governance arrangements that seek to shape patterns of spatial development in particular places). (Nadin and Stead 2008). Dividing the European planning systems into four families (Nordic, Germanic, Napoleontic and Anglo-Saxon), Nadin and Stead find it hard to qualify the Dutch planning system as part of one specific family, since it has characteristics of all. The Danish planning system is qualified as part of the Nordic tradition. (Nadin and Stead 2008). Newman and Thornley, who base their study of national planning systems on legal families, classify the Dutch planning system as part of the Napoleontic family – characterized among others by a division of regulation between central and local governmental control, and the Danish as part of the Scandinavian family – characterized among others by a strong emphasize on local self-government.

However, both planning systems do not work out that distinct. The Dutch system is one of the forms of the Napoleontic family that is a rather 'fused' system – in which the three – local, provincial and central – governmental layers are all involved in planning; fused between hierarchy, relative autonomy and co-government. The same workings between levels of government – a fuse between hierarchy, relative autonomy and co-government – is visible in the Danish planning system. (Newman and Thornley 1996). Both the Netherlands and Denmark are part of the 'continental legal systems' (Roman, Nordic, Germanic) – that seek to create a complete set of abstract rules and principles in advance of decision-making: making plans, regulate things in advance, drawing up rules and systematizing things. (Zweigert et al 1987).

According to the European Commission, both the planning systems in Denmark and the Netherlands belong to the Comprehensive Integrated family (other families are Land Use Regulation, Regional Economic and Urbanism). (CEC 1997). This stands for a spatial planning system that is conducted through a very systematic and formal hierarchy of plans, from national to local level, with its main focus on the coordination between public sector activities on various scales and spatial coordination in general, being plan-led, and strongly influenced and funded by national government. More specific similarities concern:

- A governmental system that can be classified as 'unitary', in which power resides with national government, although certain responsibilities may be delegated to government departments for specific territorial units of local government. Both planning systems are predominantly public sector driven, the public sector enacts land acquisition and land banking. (CEC 1997)

- Both planning systems use national instruments, strategic instruments, framework instruments and regulatory instruments. As national instruments, in both planning systems the national government provides perspectives, plans, sectoral and issue based guidance; in Denmark the national government also provides general policy guidance. Strategic instruments are in both planning systems used by regional groupings of local authorities, in the Netherlands by the provinces, and in Denmark by the regional administrations (provinces are absent in Denmark since a reform in 2007). Both framework and regulatory instruments are enacted by the municipality, the local planning level. Frameworks are set by Kommuneplan (DK) or Structuurplan (NL), and the regulatory instrument is the Lokal Plan (DK) or Bestemmingsplan (NL) . In both systems, only these last regulatory instruments set by local government are legally binding. (CEC 1997)

- Concerning discretion: the Netherlands provide just a little bit more discretion and flexibility in decision making in practice compared to the Danish system that is very committed and tolerates little formal discretion. However, in both planning systems the planning objectives and policies are relatively close to the development that actually takes place. (CEC 1997)

- In both planning systems permits for building are provided by the municipalities. In Denmark this is the 'byggetilladelse' (DK) or the 'bouwvergunning'(NL). Permits are needed in both planning systems for construction, building, change of use, sub-division and demolition, and applications must be in compliance with building plans and regulations. In Denmark there is

very limited flexibility to vary from the approved plan, in the Netherlands there is some departure allowed from the approved plan in specific circumstances.

Overall, the Danish and Dutch planning systems are comparable to a high degree. But by elaborating in more detail on the two systems, also some differences become explicit, making the comparison between the two countries interesting and relevant for my research. These differences concern civic involvement in plan procedures, and the development of legally binding plans.

Difference: civic involvement

The first difference concerns participation, the right to appeal to plans and public involvement. In both planning systems participation is legally embedded, but in slightly different ways. In Denmark there is more public involvement in advance of the approval of plans, but no possibilities to appeal to a plan after approval for other than procedural or legal grounds – compared to the Dutch system in which there is public involvement in advance of plan approval occurs is not legally embedded (though it does occur often through participatory planning processes), but there are more possibilities to appeal to once approves plans on content based issues. In Denmark, the lack of opportunity to appeal is argued because the extensive early consultation is generally thought adequate. Concerning the permits needed, in Denmark no consultation takes place. In the Netherlands a notification is mandatory, and interested parties have the right to object to the provision of permits[1].

Difference: the legally binding local plan

A second difference concerns the development of the only legally binding plan within the planning system – in the Netherlands the Bestemmingsplan and in Denmark the Lokal Plan. In the Netherlands, the Planning Act obliges all municipalities to develop and regularly update the Bestemmingsplan for its whole territory, and make sure that – through the Bestemmingsplan and its legally binding status – all developments within the municipality are in line with the Structuurplan (the strategic vision) made by the municipality. The Bestemmingsplan is developed by the municipality itself, and functions as a way to steer land acquisitions by developers, that come after the Bestemmingsplan is approved by the municipal council. In Denmark, the Lokal Plan has a similar

[1] The differences in civic involvement in more detail. 1) Before proposals are confirmed. DK (Kommuneplaner): the public are informed of the major issues and are encouraged to submit ideas and proposals. The 'pre-consultation' stage must last a minimum of eight weeks. NL (bestemmingsplan): public may be informed but this is not mandatory. 2) After publication of planning authority's firm proposals. DK: consultation for eight weeks with the public, opportunity is to object. Further consultation is undertaken if the plan is modified significantly. NL: consultation for four weeks on draft plan and opportunities to object. 3) The use of hearings and inquiries. DK: non. NL: objectors may request a hearing to explain their objection in person to the municipality. 4) Opportunity for challenge after the plan is formally adopted / approved. DK: challenge is possible on legal or procedural grounds only. NL: after the municipality has adopted the plan it is submitted to provincial executive and displayed for four weeks during which limited objections can be made. After approval it is displayed for a further four weeks when appeals to the Council of State are possible on matters originally subject to objection. NL: at the time of submission to province for approval, new objections may only be made to changes.

legally binding status, which becomes instated after approval from the municipal council. However, in Denmark it is by no means a legal obligation to provide such plans for all the municipal territory. Lokal Plans are only developed at the time a large or important development is proposed, or when the municipality wants to promote a certain area. Moreover, the Lokal Plan is often developed in close negotiations with the intended land-acquisitioners or developers, before the approval of the plan by the municipal council. (Newman and Thornley 1996).

New laws

The comparison of the two systems in CEC was made in 1997, based on spatial planning acts that have since then been changed in both countries. In Denmark the legal framework of the 1992 Planning Act has been replaced by a new planning act in 2008. In the Netherlands, the 1965 planning act has also been replaced in 2008 by a new planning act. In Denmark, the Ministry for the Environment revised and updated the Planning Act as a consequence of the reform of local government structures in Denmark, which was fully implemented by 1 January 2007, transforming most planning responsibilities to the new municipalities, and mandating the new administrative regions to prepare a regional perspective for future spatial development with the new municipalities. (Ministry of the Environment, 2007). In the Netherlands, the Parliament approved for a new law on spatial planning in 2008. The objective of this new law was to reform the Dutch planning system into a more decentrally organized system, distributing more responsibilities to the provinces and municipalities. According to this new law, national government only pinpoints general guidelines, and provinces and municipalities each make their own strategic visions for their respective territories, they themselves being responsible for a good synergy between these visions. (Staatsblad van het Koninkrijk der Nederlanden, 2008). Although these new laws might have provoked new working methods and a different practice in the respective countries, fundamental changes to the above comparison are not at stake.

When I summarize the above comparison, I come to the conclusion that although there are many similarities between the Dutch and Danish planning system, some fundamental differences occur as well, that might be of influence in the interaction between co-housing initiatives and planning practice. First, the Danish planning systems allows more civic involvement before plans are approved, and lesser opportunities to appeal afterwards, on which one can assume that Danish planners overall are more experienced with open civic-public negotiations than the Dutch planners. And second, because of the Danish flexibility in land acquisitions and the development of the legally binding land use plans through negotiations with the intended acquisitioners and end-users, one can assume that the Danish planning system suffers less from regulatory frameworks that obstruct co-housing than the Dutch planning system.

2.3 Comparing the housing schemes

Housing schemes in general

In a short overview of the historical development of the housing sectors in both countries, again some parallels become explicit. Even though the growth of population in the second half of the Twentieth century, when the current housing sector was institutionally shaped, shows some divergence between the two countries (In Denmark from 1945-2011 37,5%, in the Netherlands in the same period 80,7% - Source: Danmark Statistik; CBS) – the institutions that were shaped in this period do not diverge that much. First, both countries have very explicit policies on housing set by national government. (CEC 1997). This interference from national government, under influence of respective social-democratic and conservative-liberal governments, manifests itself mainly in a strong expansion of non-profit housing the second half of the Twentieth century, and a complex system of tax-reliefs to encourage home-ownership and economic growth (Boelhouwer and Van der Heijden 1993, Nielsen 2010). Second, and related, the countries have a very similar composition of the housing stock (see figure 2).

Figure 2: Composition of the total housing stock in ownership (2011) (Source: ABF Research and Statistics Denmark)

Ownership form	**Denmark**	**The Netherlands**
Private ownership	60%	60%
Social rent	20%	31%
Private rent / other	12%	9%
Andelsbolig (see page 12)	8%	-

Overall, also the housing sectors and related policies of the Netherlands and Denmark show a high degree of similarity. But of course, by elaborating on the similarities of the two systems, also the differences become more explicit, making the comparison between the two countries interesting and relevant for this research. These differences concern individual commissioning, and forms of collectiveness.

Difference: Individual commissioning

A first remarkable difference between the Dutch and the Danish housing sector is the way in which houses are developed. In contrast to the Dutch housing construction, in which from 2007-2009 70% of the newly built housing stock is the result of multi-dwelling programs, in Denmark only 7% of the newly housing stock is *not* individually commissioned – 93% of the newly built houses are developed as individual projects. Moreover, of the 7% multi-dwelling programs, 49% is 2-4 dwellings, 22% is 5-9 dwellings, 14% 10-19 dwellings, 2% 20-29 dwellings, and 13% 30+ dwellings in one project (McKinzey&Company 2010). With a total housing production of 87.899 new dwellings in the same period, this leaves around 80.000 new dwellings developed individually, against around 800 dwellings developed as part of a 30+ dwelling program. (Danmark Statistik). So, one can conclude that overall, building projects are small in Denmark. This is a direct result of the small land allocations that are usual in Denmark. In order to develop highly diverse residential areas, local

planning and tract housing[2] tendering procedures by municipalities are often regulated by tendering building plots individually, sometime even with a maximum limit to the number of building plots per buyer. Moreover, new buildings tend to have their own individual characteristics and it is rare for two projects to be exactly the same. The general conduct and tradition in the Danish construction industry is that projects are often designed with detailed specifications. Danish clients typically leave planning and design to advisors (engineers and architects) while construction companies are brought in late in the process to execute the plan, which leads to a highly fragmented building sector. (McKinzey&Company 2010). As the percentage of new dwellings constructed in the period 2005-2007 in owner occupied is 85% (Danmark Statistik), it can be assumed that in Denmark, the development of new owner-occupied dwellings is almost entirely done in private commissioning.

Difference: Forms of collectiveness

A second remarkable difference between the Dutch and the Danish housing sector is the collective character. This may sound remarkable in the light of the amount of small projects being developed, but the frequent occurrence of collective forms of ownership or collective maintenance of living environments does not necessarily overlap or conflict with the culture of small projects. In general, Danish society has strong collective features. In a research published in 2002 on power within Danish society by the university of Århus, it was argued that the strong presences of 'associations' within Danish everyday life forms a significant base for civic power, of importance for the development of networks and mutual trust among citizens. And although issues of individualization, professionalization and European unison are considered to be threats to this associational culture, the conductors of the research wondered whether perhaps the associational aspects of Danish everyday life where so common to Danes, that the awareness of the particularity of this collectiveness are beyond noticing. (Mikkelsen 2002: 13).

As part of the same research project, Andersen (2002: 207) found that in 2000, 93,6 % of all Danes is in one way or another associated to at least one 'forening' (association, or 'vereniging' in Dutch) and that the average Dane is involved in 3,7 different 'foreninger'. These 'foreninger' can concern any aspect of civic life. Andersen distinguishes four types of foreninger: 'gruppeinteresser' (organized around a shared responsibility), 'sagsorienterede forening' (organized around a political or societal goal), 'aktivitetsbestemte forening' (organized around a certain activity) and 'kooperative forening' (organized around cooperative ownership). (Andersen 2002: 207). As these 'foreninger' occur in every aspect of Danish everyday life, they are also present in the domain of housing and spatial issues. As 'gruppeinteresser' concerning spatial and housing issues, Andersen mentions bolig-, lejer-, grundejerforeninger (home, rental or landowners associations). What these foreninger have in common is that individuals living in an certain building or environment, associate with one another in order to maintain certain shared facilities. For instance in rental housing, residents are associated in lejerforeninger, small self-governed units where local tenants have a high degree of self-management. (Bengsston and Ruonavaara 2010, Jensen 1995). Or in a grundejerforening, people

[2] Housing developed with multiple identical homes and few design variations. (McKinzey&Company 2010).

privately own plots on which their house is located, but collectively take care of their shared environment (a road, a garden etc.).

As example of a 'kooperative forening' concerning housing, the 'andelsbolig' cannot remain unmentioned. Roots of associative home ownership are considered be found in the rural cooperative tradition, taken towards the Danish cities in the early twentieth century, when rapid urbanization took place as a result of industrialization, and new houses where urgently needed. Workers established building societies (byggeforeninger) and build terraced houses for themselves and their families. When the workers would have paid off the buildings, they turned into cooperative housing associations that owned the buildings collectively. (Bruun 2011: 67). Especially during the second half of the Twentieth century, this form of ownership has been promoted by legal measures and tax reliefs. Today, it forms a well-known and common form of housing in Denmark, amounting for 8% of the total housing stock in 2011 (Danmarks Statistik) and in the inner city of Copenhagen up to one-third of all housing. (Bruun 2011, Kristensen 2007). This form of associative of home ownership is some in-between form of private ownership and rent. The apartment building is owned by the association, and in order to obtain an apartment one has to become member of the association, by buying a 'share' – which is the apartment – and by paying a membership fee on a monthly base. If one moves, the 'share' is sold back to the association, that is responsible for the maintenance of the building and is democratically governed through a board and regular meetings.

A third aspect of collective forms that characterize the Danish housing sector that is of interest to mention here are the 'bofælleskaber'. These are communities of people sharing residence (in one building or in separate entities) with a high degree of shared facilities, such as a shared kitchen, common rooms, gardens etc. Often, these communities are organized around an intentional life style, such as eco-communities, but they can be pragmatic as well, such as senior- bofælleskaber. Two forms of 'bofælleskaber' can be distinguished: the 'collectives' (communities with a common economy) and 'co-housing' (that pay a fixed amount for common expenses but not sharing an economy). (Marckmann 2009). Real statistics on this form of housing are lacking, but estimations illustrate that this form of living is not such a uncommon thing in Denmark. In the late 1970s, around 3% of the Danish population lived in 'bofælleskaber'. (Skardhamar 2010). Today, estimations are that there are at least between 50-150 'bofælleskaber' in Denmark, housing around 1% of the Danish population (estimations based on memberships of 'bofælleskaber'-organizations such as www.bofælleskaber.dk and LØS for ecocommunities). But, as 'bofælleskaber' are not administrated as such, there is no organization for senior 'bofælleskaber' (for elderly) and membership of an organization is not obligatory, these estimations can be rather low. (www.bofælleskaber.dk; www.losnet.dk; Marckmann 2009)

When summarizing the above comparison, I come to the conclusion that again similarities between the Dutch and Danish schemes exist in general terms, but some fundamental differences occur as well, that might be of influence in the interaction between co-housing initiatives and planning practice. First, the private commissioning in the development of houses is not just a niche like in the Netherlands, but in Denmark this is the common practice. Therefore, one can assume that the institutions that are believed to obstruct the private commissioning in the Netherlands –developers and housing corporations – play a lesser role in the Danish housing sector. This accounts not so much for the housing corporations respecting the size of the Danish social housing sector, but it does account for the developers. The McKinzey&Company study of 2010 indeed does problematize the

absence of professional and efficient developers-building sector in Denmark because of the amount of private commissioning. But overall, it can be assumed that in the Danish practice of developing houses, both professionals as citizens are much more accustomed to the idea of private commissioning in general. (McKinzey&Company 2010). Second, the Danish housing sector and habits show many more forms of collectiveness than the Dutch housing sector. These forms of collectiveness concern common maintenance of living environments, cooperative ownership and common social lives in communities. These forms of collectiveness do not necessarily overlap, but the extend to which these forms of collectiveness penetrate society, makes it possible to assume that Danes in general are quite accustomed to collective living environments. Therefore, I assume that in Denmark, co-housing is much less of a niche than in the Dutch housing sector.

2.3 Resumé

I started off this comparison from the hypothesis that Denmark and the Netherlands have very comparable planning systems and housing sectors. Indeed, from an international perspective, Denmark can be considered to be one of the most comparable countries for the Netherlands with respect to planning system and housing schemes. The comparison however, becomes more relevant because of the differences.

As major obstructions for private commissioning in the Netherlands, and more specifically collective private commissioning, I mentioned several aspects in the first paragraph. First, I mentioned the Dutch building customs that retain the monopoly of the development of new housing with developers and housing corporations, making it difficult for private individuals or groups to enter the stage of commissioning. Second, I mentioned the lack of financial and institutional frameworks to support co-housing initiatives. And third I mentioned the regulatory frameworks in planning practice that make it difficult for self-organized initiatives to find a match between their own objectives and the ways of spatial planning. It seems, as I learned from the international comparison between Denmark and the Netherlands, that some of the institutional aspects that obstruct the Dutch situation are quite different in the Danish situation. This makes it possible to assume that collective private commissioning is a far more common thing in Denmark. There are simply more path-dependencies that can be followed in the Danish situation when one takes the initiative for developing a co-housing project, or a self-organized building group than in the Dutch situation. These path-dependencies are: forms of collective living that are more common in Denmark than in the Netherlands, the common practice of private commissioning in Denmark, the flexibility and negotiated character of the legally binding Lokal Planer, and the habituation of civic-public deliberations over plans.

But this is only speculative so far. Does collective private commissioning indeed take place on a more frequent base in Denmark than it does in the Netherlands? And if so, do the Danish initiatives encounter significantly less barriers in the realization of their initiative than their Dutch counterparts? The first question is difficult to answer, because it demands good statistical data and a well defined demarcation of what co-housing or collective private commissioning exactly comprises. Does one only look at the 50-150 bofælleskaber that are listed as members of the various overarching organizations, such as LØS and www.bofælleskaber.dk? Or does one include the senior-

bofælleskaber as well? Does one look only at the newly established initiatives, or does one include the older ones – some dating back from the 1960-1970s – as well? And does one or does one not include the Andelsboligforeningen – making up such a significant part of the Danish housing sector, but most often established in already existent estates, and not newly built as such. With all these different demarcations in mind, I come to the estimation starting at 1% of the Danish population that can be considered as collective private commissioner (which is probably not a whole lot different from the Dutch situation), up to 10% (which is significant). And then I have not even taken into account that real statistics are lacking on collective private commissioning in both the Netherlands and in Denmark – leaving me really only guessing whether these percentages are realistic estimations or far, far below the actual Danish situation.

Therefore, this is a question I willingly leave for the more statistical scientists – be it economic or demographic researchers – and instead limit myself to the second, more planning-related question. Do the Danish initiatives for co-housing and collective private commissioning encounter significantly less barriers in the realization of their initiatives than their Dutch counterparts, because of the many path-dependencies that already exist within Danish planning and housing schemes? This is the question I will deliberate on in the following sections of this paper. In order to answer this question, I will take a closer look into four recently established co-housing examples in the Copenhagen-area. But before that, I will first introduce a theoretical framework that gives me the vocabulary and analytical tools to frame such initiatives as self-organization.

3. Framing co-housing as self-organization

3.1 Self-organization of actor-networks

In the introduction of this paper, I already framed collective private commissioning, or co-housing, as initiatives that originate in civil society, autonomous community-based networks of citizens. They get organized outside government control and develop their living environments out of their own interest, in self-governance and with their own means – a definition earlier developed as self-organization in urban development. (Boonstra and Boelens 2011). This definition however, deserves some further theoretical elaboration, which I will give below.

Self-organization

Developed in the physical sciences, self-organization is generally defined as the appearance of structure or patterns where before no structure or pattern existed: a process of autonomous development and the spontaneous emergence of order out of chaos, whereby a system can develop a complex structure from fairly unstructured beginnings, or the spontaneous emergence of global coherence. Key feature of self-organization is that the intention for emergence of new order comes from (elements within) the system itself: spontaneous, autonomous, out of local interactions,

without external agents imposing anything. (Heylighen 2001, Teisman et al. 2009, Cilliers 1998). However, a system never stands entirely on itself, it has both a history and an environment, and movements of and inside the system can never be explained to a single origin. (Cilliers 1998). As Cilliers puts it: a system "*can develop a distributed form of internal structure that is neither a passive reflection of the outside, nor a result of active, pre-programmes internal factors, but the result of a complex interaction between the environment, the present state of the system and the history of the system*." (Cilliers 1998: 89). As systems emerge, it is important to note that in complexity theory it is generally understood that emergence is not heading for a certain form of optimization, equilibrium and order, but rather towards higher forms of complexity. The newly emerged order from self-organization is not so much a solution to the chaos or the unstructured beginnings that existed before, but rather an addition of extra complexity. The emergence of new structure happens because or despite of already existing structure, and thus is increasing multiplicity. (Prigogine and Stengers 1984).

Currently, complexity theory and the notion of self-organization are entering the domains planning and governance as well. When applied to governance structures, self-organization is understood as the internal dynamics of an existing governance systems developing organized structure, but also as the steering limits of one singular actor due to the autonomy of other actors and their ability to behave and organize in a self-chosen way. (Klijn and Snellen 2009, Boons et al. 2009). Understanding co-housing as a form of self-organization makes two things explicit. First, in puts the emphasize on the internal drivers of the initiative: the idea to establish a co-housing project does not come from one actor summoning others to start co-housing, but is a complex constitution of various actors sharing the same internal drivers and ideas. The incentive for movements comes from (elements of) the system, the actors and intended end users themselves. The drivers come from within the group itself, and are based on self-interest and self-motivation. Second, it puts emphasize on the emergence of the system, and on the emergence of new order, understanding co-housing as a process that starts with a person having an idea but no co-initiators, resources, location, etc. towards a realised co-housing project in which a number of people live their everyday life – the newly emerged order. Despite the internal drivers of those involved in the co-housing group, the importance of an environment (both physical as institutional) should not be forgotten. As the system emerges further, elements of this environment are constantly dealt with and boundaries of the system can shift: elements in the environment can become either included or excluded from the system during the process. Moreover, the eventually newly emerged order – the realized co-housing project – is not replacing any pre-existing chaos, but as a realized project is rather adds another layer to the existing planning and housing schemes.

Actor-network theory

However, though such abstract interpretation of a co-housing project make explicit the difference between internal drivers, the environment and emergence of new order, they do not explain the behaviour of actors and their interests and motivation to act to the conditions that surround them, or to decide to change something. In order to understand the behaviour of actors in less abstract terms, I make use of the strong resonances that exist between complexity theory and actor-network theory. (Hillier 2007). This relates to a baroque interpretation of complexity, in which the discovery

of more detail, interconnectivities, heterogeneity and specificity are leading in the study of a system. (Law 2004). Systems can be understood as networks – networks that are not defined by theorists standing outside the system, but networks (and its boundaries) that are performed, operated or constructed by the actors that make up the network (or system). Moreover, individuals act in multiple networks simultaneously, who are themselves in turbulent, unstable motion, connected entities moving in folds and infinitely varied patterns. (Hillier 2007: 47). What is interesting in using actor-network theory as an addition to co-housing projects as self-organization, is the non-distinction it makes between human and nonhuman entities. (Latour 2005). Actor-network theory not only focusses on the behaviour of human actors involved in the process of network-making, but adds a material thinking. Space is seen as part of the sum of relations, connections, embodiments and practice that make up networks. Things relate because of (in)voluntary encounters in space (Thrift 2006: 139). Moreover, networks can also be constituted around places and things, and places and things play a crucial role in the maintenance of the networks. Thus actor-network theory enables to consider the importance of the spatial objects in the process of establishing a co-housing project, such as location, architecture, plans etc.

Translation

Moreover, what complexity theory abstractly terms as 'emergence', has a more developed equivalent in actor-network theory, which is 'translation'. Translation is the movement of an actor in the construction of his network. The process of translation consists of several phases in which the "*identity of the actors, the possibility of interaction and the margins of manoeuvre are negotiated and delineated*". (Callon 1986: 203). Translation is also characterized as the sociology of ordering, and how this ordering is done in practice. (Thrift 1996: 25). In spatial planning, translation is understood as organizing the resources to make certain spatial transformations possible. The process of network-building is "*the translation of the objectives, limitations and opportunities of other actors so that these can start 'behaving' according to their own requirements, but in line with the wishes / characteristics of the dominant actor*" (Boelens 2009: 190). This refers to both the group formation a co-housing project has to do, the collection of resources needed for the realization of the project, and the constant maintenance of the homogeneity and coherence within the system or network. All this can be characterized as a process of translation. (Thrift 1996, Hillier 2007).

The combination of self-organization, actor-network theory and translation, enables me to do three things that I consider to be important in studying co-housing projects and their interaction with existing planning and housing schemes. First, self-organization enables me to put the emphasize on the internal drivers a group has. Second, actor-network theory enables me to consider the importance of the spatial objects in the process of establishment, such as location, architecture, plans etc. Third, translation enables me to focus on the process of becoming, the way a network forms itself and develops towards realization. However, the mutual benefit of this combination goes deeper, as I will illustrate in the following paragraph.

3.2 Self-organizing behavior

In the literature on self-organization, different forms of self-organized behavior are described, more or less opposites that exist simultaneously within a self-organizing system. These are bifurcations versus equilibria, and dissipative versus autopoietic behaviour. (Heylighen 2001, Cillier 1998, Van Meerkerk et al. 2012). However, there is little literature on how these different types of behaviour interact with each other, or how these kinds of behavior can be used in analyzing the formation of networks or systems. In the literature on translation four sequential 'steps' are presented - Problematization, Interessement, Enrollment and Mobilization. (Callon 1986). These steps, or moments that are presented as phases a network moves through, are however in practice not at all so sequential, and in reality overlap. As I will argue, the four types of self-organized behaviour are equivalent to the four phases of translation. By combining the two in one analytical framework, I transform the four sequential steps of translation into four types of behaviour that are simultaneously present in the constitution of a system or network, and I transform the four types of self-organized behaviour into interrelated moments a systems moved through.

Bifurcations and Problematization

The problematization phase in the establishment of an actor-network is often presented as the first start-off. In this phase, the leading or initiating actor starts with a disassociation from the existing situation, making others (and one selves) see there is a problem that needs to be addressed by new ways of doing. The actor renders him- or herself indispensable in finding this new way of doing, and defines obligatory passage points that need to be taken into consideration in finding new kinds of behaviour. (Callon 1986). This phase corresponds with the type of self-organized behaviour that is named 'bifurcations'. According to complexity theorists, bifurcations are moments in time and place on which elements in a system suddenly 'decide' to break with existing path-dependencies and start behaving in a new, unforeseen and unexpected way. These bifurcations spontaneously set in motion and emergence of new order. (Heylighen 2001, Cillier 1998). Bifurcations are therefore both a starting point for new behaviour, like the problematization phase, but they are as much a reaction to that what is already in existence – that what was considered to be in equilibrium. The notion of bifurcation therefore adds the notions of iterative movement and the notion of 'event' to the definition of problematization) – the 'lightning strike' that misses to the rather passive description issued by Callon (1986). (Thrift 2000).

Dissipative behaviour and Interessement

The second phase presented by Callon is that of interessement. In this phase, the initiating actor starts looking for allies, and tries to tie them to the network. In doing this, he is in competition with other evolving associations and identities, and severe work is needed in order to 'interest' other actors to the emerging actor-network. (Callon 1986). This phase is therefore very much about dealing with the outside, with the others. It has to be considered what is taken into account, and what new propositions need to be found and accounted for. (Latour 2004). This phase therefore

corresponds with the type of self-organized behaviour that is indicated as 'dissipative'. Dissipative behaviour also concerns to external orientation of a system: increasing interactions between various systems, a sensitivity to external influences but also affecting the environment (so both way interaction) and wide(ning) boundary judgements. In this process, the production of new structures and processes takes place, in which variety and redundancy of ideas (plans, content) and actors is aimed for. This often happens at the expense (in terms of attention, time, energy, resources) of existing structures and processes leading to tensions between 'new' and 'existing'. (Van Meerkerk et al. 2012).

Autopoietic behaviour and Enrolment

The third phase presented by Callon is that of enrolment. In this phase, the specific role of the actors that become interested in the actor-network are negotiated, and a common identity is determined and set. (Callon 1986). This phase is characterized by an internal orientation: propositions are instituted or otherwise rejected, hierarchies are set, and both the inside and the outside of the collective are stabilized. (Latour 2004). This phase therefore corresponds with the type of self-organized behaviour that is indicated as 'autopoietic'. This type of behaviour also concerns an inward orientation, as it concerns the process of reproduction, confirmation and self-(re)creation, highlighting the essential of the system, stabilizing internal structure and intensifying boundaries. In this phase, the identity of the system is formed and set, and a variety and redundancy of plans and ideas is countered. (Van Meerkerk et al. 2012).

Equilibriums and Mobilization

The last phase of translation, according to Callon, is that of mobilization. In this phase, the actor-network has evolved into a coherent whole, and only a small number of individuals speak in the name of all others in the network. Thus, a new type of equilibrium, a new type of order has emerged, in which certain entities within the network control the others. (Callon 1986). In this phase, the maintenance of the network as a collective becomes important, but also the constant evaluation whether the network is able to still follow through. (Latour 2004). The terms equilibrium and emergence of order already make explicit the kinship to self-organization. Mobilization, or the new equilibrium can both be seen as the outcome of translation as the outcome of self-organization. But, following Prigogine and Stengers, this new order does not necessarily go at the expense of other – already existing order (this competition being a concern of dissipative behaviour), but rather exists on top of the already existent order – bringing things into an even higher order of complexity. (Prigogine and Stengers 1984).

Adding different types of self-organized behaviour to the process of translation enables me to emphasize the difference that can occur between the various actors involved in the process – in this case the initiative as a group, the individuals that acted as leading actors or initiators in the process, and the planning officials involved – because, as becomes clear in the cases, different processes of translation take place simultaneously. Translation therefore is not a linear process towards

optimization, but rather different types of behaviour that should all be simultaneously present within a process in order to succeed – and be a success for all actors involved. In the perspective of co-housing projects, these four types of behaviour relate to the following aspects. Bifurcation and problematization refers to the willingness or urgency of the involved actors to step out of the usual way of working, to disassociate from existing planning and housing schemes and try something new. Equilibrium and mobilization refers to the elements or schemes that are used in order to turn the initiative into something familiar, something obvious, something that does fit existing planning and housing schemes; the initiative becomes something identifiable, it gets a name that represents the initiative as a coherent whole. Dissipative behaviour and interessement refers to the encounters the initiative has with the outside environment – trying to be as broad, informed and open for new and different options and actors as possible, in order to choose – once in the selective modus of autopoietic behaviour and enrolment – in the best interest for the initiative, and excluding those thing unnecessary. In the autopoietic and enrolment modus, the initiative deals with the internal dynamics, including those elements from the outside that are necessary for the initiative to survive, and selected and choosing in the best interest.

3.3 Associations and Controversies

This brings me to the core question I put forward in this part of the paper, namely the interaction between an initiative for co-housing and the existing planning and housing schemes. What problems and barriers, and what changes and opportunities become visible between these two worlds? What encounters take place? Therefore, as a last step in setting out the theoretical framework for analysing co-housing initiatives, I introduce the notions of controversies and associations, notions that are also derived from actor-network theory. (Latour 2005). In actor-network theory, enquiries should always focus on tracing the associations that have made the system happen. In doing so, the researcher is re-assembling: mapping those actors and elements that have actually made something happen and bringing them together again. This mapping is done by studying the formation of networks by "*deploy controversies and trace associations*" (Latour 2005: 16), because the moments of controversy and association are usually surrounded by activity and thus well documented. Controversies roughly means when things break down, when people disagree, when innovations or new unexpected situations happen. Deploying controversies means to open, unfold, and arrange these controversies in order to make use of them. Associations roughly means when people and/or things join, when they line up, when things start functioning as a whole, when the network (that was visible at the controversy) become invisible or 'normal'. A system or network proofs its existence by its associations. For this reason, it is not possible to determine a system beforehand. Defining a system is only possible if actors, associations and influences become clear through the actions of actors, "*we have to follow the actors themselves*" (Latour 2005: 12, see also Callon & Latour 1981, Law 1986, Law 1992). When mapping the actions by the various actors involved, the associations and controversies between the self-organized group or co-housing initiative and existing housing and planning schemes become visible.

4. Case analyses

Using this analytical approach, the conditions that gave rise to the initiatives and the trajectories the initiatives took towards realization are studied, with an emphasize on how they engage in planning and what controversies and associations arise from these interactions. In this paper, I explore three present-day cases in Sjælland, Denmark. All of them are newly developed projects. Two are examples of ideological living, one has a more everyday-life cohabitation scheme. They are all different in the planning process they underwent. Below I give an overview of some of the key characteristics of each initiative.

	Lange Eng	***Fri og Fro***	***Hallinge Lille***
Location	Albertslund	Egebjerg, Odsherred	Valsømagle, Haraldsted

4.1 Lange Eng

(Sources: Interview Albertslund Kommune 2011, Interview resident Lange Eng, www.langeeng.dk, Vaerdigrundlag for Bofællesskabtanken 2006)

Lange Eng is a co-housing initiative in the municipality of Albertslund, close to Copenhagen. It consists of 54 individual households. It is a bofælleskab organized in a grundejerforening, not based on any ideology but quite pragmatically organized around a shared everyday life, such as common dinners six nights a week, and a variety of social activities. The houses are in individual ownership. Lange Eng is one of the six other projects in the development of Herstedlund, which was developed simultaneously – but the only co-housing project. The whole of Herstedlund is organized in a forening as well, but the inhabitants of Lange Eng do not participate too actively in this neighborhood-community. Lange Eng was established in 2008, after two years of ideation and two years of building activities. The realization process consists of four phases: 1) ideation and shaping

the core values, starting with four friends sharing an idea and ending with finding the location in Albertslund, 2004-2005; 2) designing and planning: starting with finding the location and ending with the purchase of the ground, 2006; 3) building: starting with the ground purchase and ending with moving in and the bankruptcy of the developer, 2006-2008; 4) living in Lange Eng: ever since moving in in 2008.

Bifurcations and mobilization

The reason to start the initiative was that there were no houses available that fit the demands of the initiators. The developer involved was willing to experiment with a co-housing project this scale, and the municipality was also willing to work with such a new group of people. During the process, some justifications to the original idea had to be made, but none of the actors considered this problematic. When setbacks occurred as the developer went bankrupt, the community took over easily, even though this was new for all. The main controversy related to these bifurcations was the tens housing market and high demands for a nice and social living environment forced some people to start developing their own houses. The main association was that all actors involved were willing to experiment and try something new.

Dissipative behaviour and interessement

Contacts to find more allies were laid in the personal network of the initiators, other initiatives were visited, and consultant were hired. Various locations were considered, as are various forms of ownership, the architectural design is discussed, a bank is contacted for loans. During the process, people leave to initiative because they disagree with the location in Albertslund. After realisation of the project this kind of behaviour stops except for open house-days that are sometimes organized. Main controversy in the dissipative and interessement modus is that so many things have to be taken into consideration, that the network of allies is remains still fluent and elusive for some time. The main association is that between the people that become resident in Lange Eng, as this one becomes durable, while all other associations are temporary, and function more or less 'helpers' on the way of the process.

Autopoietic behaviour and enrolment

Core values are defined right from the beginning. Meetings are held on a frequent base. Soon, a plot of land is found that fit the demands of the initiators. Many people leave because of the choice for the location in Albertslund, but soon a new group forms around the initiators and the location and a forening is established. Choices are made on loans, ownership, design and the land is purchased. The meetings are still frequent once the community is established, but now organized around a common social life. The group is in the end quite homogeneous in age, and socio-economic backgrounds. Main controversy in the autopoietic and enrolment modus is that some choices concerning the initiative shut out interested people, but attracts new people on the other hand. Main association is

that a match is found between the demands of the initiators and the local planning conditions. The forening is established after the decision for the location was made.

Equilibrium and mobilization

The four initiators are the leading actors and spokespersons for the group and remain so during the whole process. Use is made of the concepts bofælleskab, forening, grundejerforening. The development, planning and design process are considered to be quite regular by all actors involved; in the end Lange Eng is not seen as something new, but rather part of a long tradition – only the size of the project is considered to be rather unconventional, but as a logical thing because of the tens housing market when the project was initiated. Main controversy in the mobilization and equilibrium modus is that, after realization, Lange Eng does not have any interactions with the other housing estates in Herstedlund, as was hoped for in the planning of the area. Main association is that even though most actors in the beginning were willing to experiment, they eventually did follow all the path dependencies concerning planning and housing schemes, and a satisfactory match between the demands of the group, the plan, and housing scheme was found.

4.2 Fri og Fro

(Sources: Elm and Dilling-Hansen 2003, Martinussen 2010, Interview resident Fri og Fro 2011, Interview Odsherred Kommune 2011, www.losnet.dk, www.friogfro.dk)

Fri og Fro is an eco village in the municipality of Odsherred, north west Sjælland. It consists of 17 individual households. The core values of the community are based on sustainability, both socially, economically and environmentally. The individual houses are all self built, using natural and re-used materials. The idea of Fri og Fro is inspired by the Danish eco Village Friland, which was the subject of a TV show in 2001-2002. It is a bofælleskab organized in an andelsforeningen, which owns the land, but the individual houses are not part of that forening. In 2005 the people of Fri og Fro moved to the area, after three years of ideation and planning, but the building of the individual houses, the common facilities and landscaping is still taking place in 2011. The realization process consists of three phases: 1) ideation and drawing out the first ideas for an eco village, starting with initiating and ending with finding the location in Trundholm (now part of the municipality of Odsherred), 2001-2003; 2) designing and planning: starting with finding the location in Trundholm and ending with moving to the area, 2003-2004; 3) building and living, a phase that is still current.

Bifurcations and mobilization

The initiators were inspired by the TV show about Friland and wanted to take such an initiative themselves too. What they tried to do new is to apply the legal form of andelsboligforening to the eco village concept. Also unconventional was that the Lokal Plan was written by the initiators themselves, both new for them, as for the municipality. The willow-based sewage system they applied was unconventional. Adjustments to the planning of the area were a shift from the 60 houses the area was 'planned for' to 17 houses by Fri og Fro, the adjustments of rural and urban

zoning, and the allowance of temporary houses. People in the group were all inexperienced with building ones own houses, especially with the natural and re-used materials. Architecturally the eco village is very distinctive. Main controversy related to bifurcations and mobilization is the whole 'doing-everything-by-themselves': the ideation, planning, designing, building is considered to be something very unconventional by the actors involved. Main association is between the municipality that was very willing to step out of conventional ways of working in order to get the land developed, and the initiators that were well prepared and educated for the do-it-yourself process.

Dissipative behaviour and interessement

From the beginning, a website to inform and attract people is made and maintained during the whole development process. Many municipalities are contacted in order to find a location. A legal advisor, constructors and a bank are consulted during the process, and a contractor is hired to make the area ready to be built. The relation between the initiative and the local community in the existing village is considered important and several events are created to establish good relationships between these two worlds, that gradually become more intertwined, and conflicts on nuisances are solved informally. Some people leave the initiative along the way, but soon new people join, some couples divorce during the demanding building process and several houses are for sale in 2011. The materials for the houses are mostly local and natural or re-used, so some group members go around the area in order to 'pick up' left over materials from building sites and the like. Fri og Fro has many visitors and organizes frequent tours. The goals for sustainability are generally felt to have been too broad and are not considered to 'bind' the group together, as the building process on the individual houses has been demanding, the focus of the group has been less on living together as was intended. Moreover, there are disagreements on the prices for the houses that are put to sale and whether this is an individual matter or a concern for the community. In the end, an andelsboligforening is not established because the houses are considered to be too different. Main controversy related to the dissipative and interessement modus is that the focus of Fri og Fro has been more on the individual building processes than on living together as a community, there are disagreements on the prices for the houses that are for sale – said to be fixed prices for economic sustainability, but now felt too be a more individual matter by some members, the core values on sustainability are considered to be not focused and defined enough to bind the community into a coherent whole, no andelsboligforening. Main associations are the temporary associations between consultants and contractors during the development process, and a more durable association between Fri og Fro and the local residents of Egebjerg: due to the constant outwards orientation of Fri og Fro the two communities have grown quite intertwined.

Autopoietic behaviour and enrolment

At the very start of the idea, the initiating couple sets out the core values and ideas for the eco village. Very soon the location in Trundholm is picked because it fits the demands of the initiators, and the municipality is willing to cooperate because having a community like Fri og Fro settle in Egebjerg means the local school and supermarket can survive. The core values and design and planning for the eco village are discussed among members during frequent meetings in Copenhagen.

It is felt that living in a group makes a sustainable life easier to realize. The members of the group agree on the fixed prices for the houses in order to prevent speculation. A collective loan is made in order to purchase the land as an andelsforening. Since the people moved to the area, common meetings, occasional parties and working weekends are held, but these are voluntary and not all members join. Main controversy related to the autopoietic and enrolment modus is that the core values on sustainability are not felt to be strong and focused enough to bind the community, the agreement on fixed prices is now dividing the community, focus has been on individual work, not on common activities. Main association is that between the interest of Fri og Fro and the municipality, and with the local community in maintaining the amenities.

Equilibrium and mobilization

The initiating couple is spokesperson for the whole group during the development process. A byggeforeningen is established during the planning process, an andelsforening is established to purchase the plot, and an forening is established to maintain the sewage system. In adjusting the Lokal Plan, conventional planning procedures can be used. Landownership as an andelsforening is unconventional, but in practice not so distinct from other forms of private ownership, since it is quite common that publicly accessible land or nature conservation areas are privately owned. Main controversy related to the equilibria and mobilization is that small adjustments to the land use zoning are made, and the specificity of the Lokal Plan due to the demands of the eco village makes it a very unconventional plan. The decision not to apply the concept of andelsboligforening because this legal form does eventually not fit with the architectural lay out of the eco village is a controversy as well. Main associations are between the demands of the community and the Lokal Plan, that are merged into one legally binding document, and several forms of forening are used in order to realize the project.

4.3 Hallinge Lille

(Sources: Elm and Dilling-Hansen 2003, www.hallingelille.dk)

Hallinge Lille is a co-housing project in the municipality of Ringsted, mid Sjælland. It consists of 18 individual households. The core values of the community are on sustainability and permaculture. The houses and buildings are individually designed, using natural and re-used materials. It is a bofælleskab organized in a grundejerforening. The first people move to the plot in 2002, to live in the already existent farm in the area, but the whole community gets established in 2005. The development of Hallinge Lille is characterized by a long and problematic planning process. The realization process consists of four phases: 1) ideation and drawing out the first ideas for a whole village, starting with initiating and ending with finding a location in Skjoldnæsholm, 1998-1999; 2) designing and planning (1): starting with the location in Skjoldnæsholm and ending with a different location in Ringsted 1999-2001; 3) designing and planning (2), working on the location in Ringsted and ending with an adjustment of the demands of the community to the existing land use plan; 4) building and living, from 2005 onwards.

Bifurcations and mobilization

The idea for a community as Hallinge Lille was a long cherished dream of the eventual founder of the community – a place where one could live 'from cradle to grave', with facilities for both children and elderly. She was motivated to have this dream due to personal circumstances in her family, and started realizing her dream after following a course on 'taking life in ones own hands'. A new community for 100 dwellings in the open, rural land is however an unconventional thing in Danish planning, so the planning process showed to be problematic – until the county decides to open a pilot on developing adjacent to small villages in the rural areas. Main controversy related to bifurcations and mobilization is a lack of places – both in urban as in rural areas – where one can live in a small social community but with all sorts of facilities for children and elderly motivated the founder to develop herself. Main association is that it proved difficult to find a location to settle, but the county pilot opened the final possibility.

Dissipative behaviour and interessement

By putting up notes, the initiator finds the first interested people that join the initiative. Various municipalities and landowners are contacted for locations. However, the first and second locations found are both subject to a local planning conflict between residents and county, and long negotiations are held between the initiative and local residents, but eventually the landowner refuses to sell. This setback makes that the group of initiators starts to fall apart. New locations are taken into consideration, but the eventually found location is again subject to disagreement on the plan, and again negotiations are held between the initiative, local residents and the municipality of Ringsted. Landscape architects and architects design the buildings and area. During the whole process, various consultants on legal, organizational and financial matters are contracted. Now Hallinge Lille is established, a website is maintained, and there are various possibility to visit the community, and villagers are invited to join festivities in the community. Main controversy related to the dissipative and interessement modus is the divergence between the initial ideas and the local planning conditions, which makes negotiations and reframing of the initial idea necessary, but almost leading to disintegration of the whole initiative. Main association is between the demands of the initiative and the local planning conditions, but at the costs of the first.

Autopoietic behaviour and enrolment

First meetings are quickly followed by the establishment of a forening, and a strategy and statutes are made. The outlines of the initiative are: a location in mid Sjælland, approximately 50 hectares, 100 dwellings and various facilities. Twice, a location is found but not developed because of local planning disputes and disagreements with landowners. Several meetings are held among the initiators to agree on the goals of the initiative, permaculture and a eco-spiritual community is the main binding idea. The initial ideas are scaled down in order to make a fit with local planning

schemes more feasible. After the first setbacks, the general meeting decides in 2001 to give it one other try. A new site is found in Ringsted, the farm and land are bought, but again concessions have to be made to the demands of the initiative and local planning conditions. Architecturally, in size and use of colour, the houses are made to fit to the architecture of the local village. Paths running through the area make sure the existing village remains connected to the forests. Main controversy related to the autopoietic and enrolment modus is that the group or community ends up being considerably smaller (18) than originally intended (100) and hardly any of the intended facilities are realised in order to fit the initiative in local planning conditions. Main association is that the founder, group and initiative is determined enough to continue to make efforts to realise – at least parts of – the original idea. The ideas on permaculture, consensus democracy, and eco-spiritual community appear to be strong binding elements for the group.

Equilibrium and mobilization

Soon after the first people come together, a forening is established. During the process, various plans – municipal, regional and national – appear to be dominant over the initiative. An adjustment of zoning is needed, and thus consultation with local residents, eventually the municipal council disagrees with adjustment of the zoning boundaries and the initiative has to be realized within the boundaries of the existing land use plan. When the houses are built, a grundejerforening is established. Main controversy related to equilibria and mobilization is the dominance of existing land use plans prevents new order to emerge. Main association is between various concepts of forening and bofælleskab and the ideas of the initial founder.

5. Conclusions

Reviewing these cases with this analytical framework makes several things apparent that are interesting to mention, before diving deeper into the conclusions that relate to the research question. In each phase, almost all types of behaviour are visible. These are not only performed by the leading actors, but by all involved in the process. Actors and interests move in and out the initiative and the process, and persuaded end goals can be different for each. Both the project, the location, the actors involved act in multiple networks simultaneously, who are themselves in turbulent and unstable motion. (Hillier 2007). Interlocking interests in one phase, can continue in another phase, but might as well unlock or change during the process. This framework makes apparent that co-housing is not so much on merging perspectives into a coherent, agreed whole, but rather on the multiple trajectories that run through a process of establishing a co-housing initiative (cf. Massey 2005). Of course the initiative self-organizes towards realization, and this can be seen as a coherent whole. However, actors involved other than the initiators and intended end-users, can have different end goals than the realization of a co-housing project per se. Therefore, not the merge into a coherent whole is what is important, but rather the emergence to a higher form of complexity, that is the existing situation *and* the realized co-housing project. Focus is not on

changing a situation, but rather on adding something new, something extra to the already existing situation. A higher form of complexity that is satisfactory for all involved.

5.1 Case encounters

The main research question for this second half of the paper concerned the encounters between Danish co-housing initiatives and the existing planning and housing schemes. In order to investigate this question, I identified different types of self-organized behavior, four kinds of attitudes between a co-housing initiative and existing planning and housing schemes. Bifurcations are jumps away from the usual path-dependencies in the housing schemes and planning system, and the decision to take matters in ones own hand and to develop something new on ones own behalf. New equilibria stand for becoming part of the usual scheme of things, a new thing but part of a coherent whole. Path-dependencies are deployed for ones own sake – elements of the existing housing and planning schemes are used in order to establish 'the new'. Dissipative and autopoietic behaviour are reactions of the evolving network to the internal dynamics and the external environment. Internal means who is and who becomes part of the system or group. External means who is kept outside but still needs to be considered or encountered. As these types of behavior all show different attitudes between the initiative and planning and housing schemes, each type of behavior concerns different associations and controversies between the initiative and the planning and housing schemes. Reviewing these associations and controversies makes clear what the exact encounters between co-housing, housing schemes and planning are.

Associations between the co-housing initiative and planning and housing schemes appear to have been strongly colored by various actors who are willing to experiment, open to try something new. In Lange Eng this concerned the initiators, the municipality and the developer, in Fri og Fro the initiators and the municipality, and in Hallinge Lille the initiators and the county. Surprisingly, in all cases, the eventual divergence from the usual ways of working has not been as big as might have been expected. In Lange Eng, conventional planning procedures were followed, and a satisfactory match between the demands of the group, the plan, and housing scheme was soon found. In Fri og Fro, the content of the Lokal Plan is unconventional, but since the municipality was open to the ideas of the community (out of self interest!) and the initiators were well educated in what was expected from them, the demands of the initiators and planning schemes of the municipality did satisfactorily merge into the legal document of the Lokal Plan, and eventually all obligatory planning procedures were followed as usual. In Hallinge Lille eventually there was hardly any divergence from the usual planning procedures. Local conditions obstructed the original ideas of the initiators, which in the end were adjusted to fit the local planning conditions after all. Concerning the collective housing schemes that exist in Denmark, all three initiatives used various forms of forening during the process. In Lange Eng the forening was established after the decision for the location was made, and eventually it turned into a grundejerforening. In Fri og Fro the byggeforening was established soon as the location was found, and an andelsforening was established to purchase the plot. In Hallinge Lille the forening was founded even before a location was selected, and eventually the group got organised in an grundejerforening. All three projects are bofælleskaber.

Other associations that occur during the development of the co-housing initiatives that have been important for the realization, concern three aspects. First, the temporary associations between the initiative and various consultants and constructors. The initiators of the cases appoint that the more these external actors are acquainted with co-housing initiatives, the better and fruitful these temporary associations are. Second, the association between the various members of the co-housing initiative is important. In all initiatives this is organized around sharing a certain life style, pointed down in the statutes of the forening. In Lange Eng and Hallinge Lille, this proved to be strong binding elements for the community. In Fri og Fro, the work on the individual houses proved to be more dominant than the communal aspects of the initiative. The third association concerns the relation between the co-housing projects and its surroundings. In Lange Eng, no significant association appears to exist between the residents of Lange Eng and their neighbors. When Lange Eng was built, the whole area of Herstedlund was developed, so no negotiations with local residents had to take place, and the social activities within Lange Eng itself appear to be sufficient for the residents but closed to outsiders. In Fri og Fro, deliberations and activities between local residents and residents of Fri og Fro take place from the very start of the project, and gradually, the two communities become socially intertwined, because both communities use the same amenities in the village. In Hallinge Lille deliberations between the local residents and the initiators take place, but these are not on all aspects positive. As the project is realized, social activities do take place in which both local residents and the residents of Hallinge Lille participate.

Controversies between the co-housing initiative and planning and housing schemes apply firstly to the lack of available houses that meet the demand of the individuals, making them eventual decide to develop for themselves. This was especially the case in Lange Eng, where the initiators were confronted with a tense housing market, and Hallinge Lille, where the initiators whished for a rural community with facilities for both children and elderly. The initiators of Fri og Fro were mostly driven away from the conventional housing market by ecological and self-building aspirations. Secondly, concerning the local planning schemes, in Lange Eng no controversies happened. In Fri og Fro, small adjustments to the land use zoning were necessary, and the specificity of the demands of the eco village makes the Lokal Plan into a very unconventional document. In Hallinge Lille a controversy occurred between the original ideas of the initiator in order to fit the local planning conditions. Negotiations with local residents and the municipality and a reframing of the initial idea proved necessary, almost leading to disintegration of the whole initiative. The group or community ends up being considerably smaller (18) than originally intended (100) and hardly any of the intended facilities are realised in order to fit the initiative in local planning conditions. The dominance of existing land use plans prevents new order to emerge. Thirdly, concerning collective housing schemes, the only controversy happened in Fri og Fro, was that the initial idea to become an andelsboligforening was abandoned, because the architecture of the project proved to be incompatible with this legal form of ownership. Fourthly, architectonically, all three projects turn out to be rather distinctive from their surroundings. Lange Eng is a considerably larger structure than the other projects in the surroundings. Fri og Fro is completely different with the houses built out of straw, clay, and re-used materials. In Hallinge Lille, the architecture of the houses is adjusted to the surroundings in use of colour and building heights, but still the houses built on ecological principles look very distinct.

Other controversies that occur during the development of the co-housing initiatives that have been threatening the realization, mostly concern the choices that have to be made concerning location,

ownership and financing of the initiative. As long as these choices remain open, the network of allies remains fluent and elusive. Soon as choices on these aspects are made, people leave the initiative but others join. In Lange Eng this concerned the location in Albertslund. In Fri og Fro this concerned the choice of having fixed housing prices. In Hallinge Lille it concerned the lack of location. Core values defined in the beginning do not always turn out strong enough to keep the community together, or vibrant. In Fri og Fro, the project has individualised because the building process of the individual houses has proven to be too demanding for some, and moreover, the discussion on the housing prices for those houses on sale, has been dividing the community. In Hallinge Lille, the community is seriously threatened by the setbacks in the planning process, and ends up considerably smaller than originally intended.

5.2 Learning from the Danes?

Having said all this, it is now time to move to the final conclusion of this paper, concerning the Dutch-Danish comparison. In the first part of this paper, I mentioned various aspects that are presumed to be obstructing the emergence of collective private commissioning in the Netherlands. Among these obstructions are Dutch building customs that are accustomed to large scale development by professional developers and housing corporations, and regulatory planning frameworks that are governmental-led and leave little room for the civic-public negotiations that are part of collective private commissioning. In order to understand how the Dutch planning system can become more adaptive to self-organization by co-housing initiatives, in the second part of the paper I argued it might be beneficial to take a closer look into the Danish planning and co-housing practice. Danish and Dutch planning systems and housing schemes have many similarities, but differ on some crucial aspects concerning the obstruction for co-housing in the Netherlands. I mentioned four major differences: first, the Danish custom of consensus-based civic-public negotiations before plans are approved; second, the Danish custom of negotiations between municipalities and (future) landowners before the legal plan is defined; third, the Danish custom of small projects, small plots, making private commissioning a common practice and the building sector fragmented; and fourth, the many forms of collectiveness in taking responsibility for maintenance, ownership and everyday life, make the Danes much accustomed to collective living environments. For these reasons, I assumed that in the Danish situation, co-housing initiatives suffer far less barriers – or at least different ones – than their Dutch counterparts.

So let's see. In the third and fourth part of this paper I used an analytical framework for self-organization to study three co-housing initiatives recently developed in Sjælland, Denmark, and their encounters with the planning and housing schemes. This leaves me with the question whether the binding and conflicting elements that the Danish initiatives face, are the same, or different ones than the Dutch initiatives. First, concerning public-civic negotiations. The cases show that the Danish custom to have extensive deliberations between citizens and municipality before plans are approved, do not concern the co-housing initiative itself, but rather a desired consensus between the new co-housing initiative and already existent local community. Whether these deliberations are obstructive to an initiative or not, depends much more on local planning conditions than on systemic elements. For Lange Eng, no negotiations were necessary since there was not local community yet when Lange Eng was developed. In Fri og Fro, the initiative took much consideration in getting to be

wanted by the local community itself. In the Hallinge Lille case, the negotiations between the initiative and local residents remained problematic for all locations they applied for, but these disputes were rather the result of disagreeing residents and planning authorities than between the residents and the initiative itself. Second, concerning the negotiated legal plan. In the cases, it shows that the negotiated legal plan was enabling for both the initiative and the municipalities in finding a fit between the various demands and the eventual legal plan. There was no beforehand allocation of the plots to become home to a co-housing initiative. Rather did the initiatives suit the general planning intentions of the municipality (for Fri og Fro and Lange Eng the resourceful people it would bring to the municipality), giving the municipality the arguments to prefer these initiatives over others. The negotiated legal plan also enabled the initiative to have their specific (ecological or other) demands legally framed and secured. Third, concerning the practice of private commissioning. In the cases, indeed no problematic encounters took place between the initiative and contractors based on individual commissioning. Rather, the more difficult encounter between Lange Eng and its contractor was due to the large scale of the project (52 houses in one architectural structure) than to the non-professional commissioning. And for both Fri og Fro and Hallinge Lille, the challenges to get loans, contractors and legal advise had more to do with the communal and ecological character of the initiative than with the private commissioning. Fourth, concerning the collective forms of living. All three cases have taken benefit from the collective schemes Danish law provides. These were supportive on various aspects: they helped in finding loans and purchasing the ground, they helped to define common goals and rules-of-living for the people in the initiative and to define these in self-written statutes, and they helped in appointing spokespersons for the initiative that could deal with all negotiations and deliberations with planning officials.

These examples show indeed, that in the Danish system, a co-housing initiatives suffers less barriers in relation to the existing planning system and housing schemes. This does not mean however, that the Danish co-housing initiatives are without turbulence or challenges. Their starting point has been provoked by a tens housing market or general lack of houses that meet the demands of certain individuals. Finding allies, resources, a location to settle, are all hurdles all initiatives face. Some general lessons can therefore be learned from the cases I studied in this paper. First, it is important to find like minded people and people and parties that are willing to try something new, and not focus too much or too long in convincing or deliberating with those that regard the initiative as something threatening. Second, it is important to acknowledge that the networks around an initiative can remain fluent and elusive for a long time, and it is perhaps more fruitful to accept the temporality of some associations than to focus too soon and too strict on membership and commitment. Moreover, it is important for the initiators to stay close to their initial goals, and to find a location, framework, plan that fits their idea – if no allies are there yet, they will come eventually when most choices are made. All actors involved in the initiative are subject to different and multiple trajectories, and acceptance and acknowledgement of these differences can make deliberations more easy-going and changes less disappointing.

For the Dutch system specifically, some recommendations can be made on how planning can become more adaptive to self-organization by community-based networks in general – without wanting to merge the two planning systems or the bluntly copy Danish practice to the Netherlands. But learning from the Danish cases, I would like to make the following recommendations. First: try not to change too much in the planning system, since local planning conditions seem to be more relevant chances or obstructions to a co-housing initiative than the planning system in general.

However, the negotiated legal plan is for sure a form of adaptiveness that could be beneficial for the Dutch planning practice as well. Second: the building sector based on large scale development in the Netherlands is the opposite of the Danish small scale and fragmented building sector. As the latter is critiqued for its lack of economic efficiency, it might be a challenge to think of ways in which the building sector in the Netherlands can become more small scaled and thus more open to private commissioning, without losing its economic efficiency (perhaps through the application of ICT in order to efficiently connect demand and supply in materials, concepts, contractors etc.) And third, it might be worth exploring how forms of collectiveness can become more promoted and legally supported in the Netherlands, in order to help initiatives to get organized, become and remain robust and to gain the resources they need in the realization of their dreams.

REGIONAL DISPARITIES IN THE EUROPEAN UNION. WHAT ARE THE FACTORS THAT COULD INFLUENCE THE SUCCES OF SINGLE REGIONS IN DEPLOYING EUROPEAN AID?

Federica Leone [1]

Abstract

The concepts of solidarity and cohesion represent the principal aims of European Union (EU) regional policy. Indeed, promoting economic and social cohesion can mitigate the structural disparities among European regions, having positive effects on all Community territories. EU encourages these objectives through financial funds and instruments in aid of less developed regions. However, despite these financial efforts, disparities in the European context and within the same national boundaries persist. The reasons for this phenomenon are partially ascribed to the capacity of Member States and regions to manage financial resources, identifying priority projects and sectors, where investments should be directed.

Moreover, regional disparities are quantified by means of symptoms and driving forces. The former represents the effects of inequalities, such as GDP per capita, unemployment and youth unemployment. The latter concerns the reasons of spatial imbalances, such as R&D and human capital, infrastructure, environment, governance, social, natural, and human capital. On the other hand, only by tackling these problems could economic and social development be encouraged and promoted. In addition, single Member States have a directive role in deciding how the financial instruments should be used and in bearing the responsibility for managing it properly. From this perspective, the driving forces represent causes of spatial disparities and at the same time the key factors of regional success in deploying EU aid. However, some of these elements, such as R&D, human and social capital, and governance, can influence the strategies and policy to manage European funds in a direct way. Indeed, for example, innovative projects in the R&D field and forms of governance, characterized by transparency and efficiency, can represent the distinction between more and less developed regions. On the other hand, although infrastructure, environment and natural capital do not have a direct impact in deploying EU regional policy aid, their analysis is necessary in order to understand the invariable aspects, such as geographical position, and how these immutable factors should be handled, acting to other elements.

[1] University of Cagliari, Cagliari, Italy - federicaleone@unica.it

The main disparities in terms of GDP persist at regional level. From this perspective, Italy represents a significant case study due to historical divide between northern and southern regions. Indeed, Italy represents an emblematic case of coexistence of a rich area, which is typified by the central and northern regions, and the south, characterized by widespread economic and social deprivation. From this perspective, this paper aims to identify and examine driving forces that influence and encourage the regions' success in deploying EU regional aid, analyzing the specific case study of Italy.

1. Introduction

The formal birth of regional policy within the European Union (EU) dated back to the adoption of the Single European Act in 1986. The principal aim of EU regional policy concerns solidarity and cohesion concepts. The former is based on the reduction of structural disparities; meanwhile the second intends to promote economic and social cohesion owing to the positive effects that the mitigation of economic and social gap among European regions could have on all territories (European Union, 2011).

This purpose is achieved through three main objectives: Convergence, Regional Competitiveness and Employment, and European Territorial Cooperation. The Convergence goal promotes conditions and factors in order to foster growth and real convergence for the least developed Member States and regions. The Regional Competitiveness and Employment objective intends strengthening regional attractiveness, competitiveness and employment throughout EU. Meanwhile, the third goal aims at promoting cross-border, trans-national and interregional cooperation in order to achieve an integrated territorial development (European Union, 2009). In practical terms, the EU uses Structural Funds and instruments for the purpose of achieving these three objectives. Moreover, the principal fields of investment are: knowledge and innovation, transport, environmental protection and risk prevention, and human resources (European Commission, 2008, pp. 2-3). For the 2007-2013 programming period, the three fundamental financial instruments are: the European Regional Development Fund (ERDF), the European Social Fund (ESF) and the Cohesion Fund (European Union, 2009).

The ERDF focuses on regional development, economic challenges, competitiveness and territorial cooperation; meanwhile the ESF supports actions in order to promote employment and social integration in the labour market, and reforms in the education system. The third financial instrument, the Cohesion Fund, concerns different issues such as transport and environment infrastructure, energy efficiency and renewable energy (European Commission, 2008, pp. 2-3).

Although the EU defines the priority goals by means of the Community strategic guidelines on cohesion, National and regional governments manage European regional policy in a decentralized way. Indeed, the single Member States and regions have the task of choosing the principal objectives for each territory through a

collaborative process among European, regional and local authorities, social partners, and civil organizations (European Commission, 2008). Indeed each Member States drafts a National Strategic Reference Framework (NSRF), which defines strategies and the operational programmes (OP) that it intends to implement. The latter identifies criteria and priorities in order to select the single projects (European Union. 2010).

However, in recent decades, the European regions have tackled new challenges deriving from globalization and opening up of its economies. Indeed, the competition among new and old European countries but also between Member States and South-east Asian countries has increasingly extended. These phenomena have caused a redistribution of activities due to production dispersion and an increase of intra-sectional and intra-firm trades. These aspects represent some of the causes of the recent economic crisis that has hit both less and most developed regions in Europe (European Commission, 2006).

From this perspective, in the European context, two levels of disparities can be recognized: national and regional. The first concerns the national level, where Luxembourg represents the richest Member State in terms of per-capita income; meanwhile the poorest is Romania. The latter is around seven times poorest than Luxembourg. This gap becomes wider at regional level, where Inner London, the richest region, has a gross domestic product (GDP) that is 290% of EU-27' average. On the other hand, Nord-East Romania region, the poorest, has a GDP which is 23% of the EU average. From the international perspective, these disparities are really significant. Indeed in China and India the regional gap has a value of 7 times, in US only 2.5 times and in Japan 2 times. This difference between European Union and the international scenario reflects the fact that the EU is not based on a common market but on community values and policies, which are underwritten and accepted by all Member States (European Commission, 2008).

From this perspective, it is easy to understand what the real importance of EU regional policy is. However, single funds and financial instruments are not sufficient to achieve the social, economic and territorial cohesion. Indeed, only if Member States and regions are able to manage the funds and to identify priority projects, they can benefit from these financial instruments in order to encourage and promote the economic, social and territorial cohesion.

From this conceptual framework, this paper aims at identifying factors that influence and encourage the regions' success in deploying European Union regional aid. In particular, the Italian case study is analyzed in order to understand the direct and indirect issues that have entailed the historic disparity between northern and southern areas.

2. Disparities and factors of success in the EU

The main territorial disparities at European level are between the core and the periphery. Indeed, the European Spatial Development Perspective (ESDP) identifies only a big economically integrated area, named “pentagon” that is composed by London, Paris, Milan, Munich and Hamburg. This zone provides global economic services and functions that guarantee high incomes and well developed infrastructures. On the other hand, at national level it is possible to recognize different inequalities, such as those between rural and metropolitan areas. Indeed, in the capital city region, there are the most favorable business conditions, such as accessibility, IT usage, transport, infrastructure, and education level. This unbalanced phenomenon reduces the possibility to have an aggregated economic growth (European Communities, 2004).

From this viewpoint, it is possible to recognize two different types of disparities: symptoms and driving forces. The former represents the effects of disparities in the EU, such as GDP per capita, unemployment and youth unemployment. Meanwhile, the latest, which are R&D and human capital, infrastructure, governance and social capital, constitutes on one hand the causes of spatial inequalities, and on the other hand, key aspects that can promote and encourage an appropriate and efficient management of the European financial instruments. Indeed, single Member States have a directive role in deciding how the funds should be used, and in bearing the responsibility for handling them properly. Therefore, the driving forces represent the factors that influence the regional success in deploying EU’s aid. However, their clout can be either direct, such as R&D, human capital, governance, and social capital, or indirect, such as infrastructure, environment, and natural capital.

In the following paragraphs, the European context in terms of direct and indirect aspects is analyzed in order to define the conceptual framework in which the Italian case study is included.

2.1 Direct factors

The success of regions in relation to European financial aids is closely connected to their capacity to change and innovate. From this perspective, encouraging research, development and innovation represents a key issue in order to promote a sustainable economic growth. In this paragraph, the different direct factor are analyzed for the purpose of defining the current situation within the European borders and in order to clarify in what way they could promote an efficient handling of financial instruments.

First of all, an important and significant disparity exists among Member States and single regions in terms of research, development and innovation. Indeed, at European level, the better standards in relation to research are achieved in Sweden, Finland, Netherlands, Germany, France and some areas of United Kingdom. This phenomenon reflects the geographical distribution of disparities in EU. Indeed, in the

Convergence regions people with a tertiary education represent only 18% of total amount of human being aged 25-64. Meanwhile, in other regions this percentage achieves 26-27%. Moreover, different studies and analysis show that higher education and training improves and increases labour productivity, people's income and life satisfaction. In addition, people with a tertiary education, and in particular researchers, exercise a key role in terms of production and exploitation of new knowledge. Indeed, in 2007 the average relationship between productivity and the amount of people aged 25-64 with a tertiary education showed that productivity was 780 PPS higher for every percentage point in regions where the share of tertiary educated was above average. From this perspective, a high percentage of tertiary educated people represents a factor that can promote and encourage the economic growth (European Commission, 2010, pp. 32-37).

On the other hand, the tertiary education does not represent the only source of highly skilled workers. Indeed, retraining of people in every level of skills can improve and increase the number of highly skilled workers in particular if it is connected to labour market needs. In addition, skills and highly skilled workers allow regions remaining competitive in a global, knowledge-based economy. Indeed, the globalization and the recent economic crisis have increased intra-sectional and intra-firm trades. This phenomenon has caused some problems and at the same time some advantages. On one side, it has provoked a dispersion of the production, which has been located outside European borders by the main companies. From this perspective, some vulnerable sectors, such as textile, metal and electric equipment, have registered a decline in employment. In particular, this trend has concerned less specialized zones that have to compete with no European emerging economies, which are characterized by low-cost and low-quality products. Meanwhile, the specialized regions have moved up their economies towards high-end production, niche markets and high-tech goods. As a consequence, this market behavior has increased the production, maintaining the same level of employment. On the other hand, the globalization has produced an increase in the demand for logistic, monitoring and management systems. Indeed, the regions, where the economy is characterized by employment in financial, business and logistic sectors, have registered an improvement in terms of production and employment. It is the example of Luxembourg and Ireland, where in 2008 the trade surpluses in services thanks to financial sector were respectively 31.6% and 13.3% of its GDP (European Commission, 2010). From this perspective, the investments in human capital, entrepreneurship and improvement of business environment are essential in order to reduce economic loss, in terms of employment and production. Moreover, the integration of global trades, the introduction of new technologies and more skills could improve the economic situation of all regions. In other words investments on research, development and innovation as well as an appropriate and effective business venture can help State Members and regions to administrate EU regional policy's financial instruments.

Moreover, the quality of institutions and governance in general can have significant effects on economic growth in terms of efficacy of regional development strategies. Indeed, not only does an effective governance system entail guaranteeing that funds

are spent in proper ways but also it ensures and encourages a coherent and efficient strategy, the involvement of all stakeholders, the selection of good quality projects, and the monitoring, and the assessment of results. According to European Commission (2001), good governance is composed by five principles: openness, participation, accountability, effectiveness, and coherence. The first principle refers to a more open cooperation between local, regional and national government. It is important in order to encourage the participation and the involvement of all community. Participation is a prerequisite of development strategies' success. Indeed, first of all, coordination of all the stakeholders who participate in the planning processes is fundamental since the impacts of their actions could be completely out-of-control otherwise. This would possibly cause ineffectiveness and/or inefficiency of the planning processes. Secondly, the management of public participation processes provides information about local planning contexts and allows implementing more effective action strategies. Therefore, it promotes a better understanding of a community's needs, and as a consequence, planning decisions could meet population demands in the most proper way. From this point of view, participation could give a solid foundation to planning strategies and narrow local conflicts. The concept of accountability concerns the clarity of defining and identifying the roles and the responsibilities in the legislative and executive processes. The fourth principle refers to the effectiveness and timeliness of policies and strategies in order to identify clear objectives and an evaluation of future impacts. Coherence regards the complex problems that are not possible to be tackled individually because they need a political leadership, a strong responsibility, and a cooperation beyond national boundaries.

Form this point of view, an efficient governance system should be multi-level in order to identify the multiple and complex needs and preferences of people (Gore and Wells, 2009). Moreover, the multi-level governance has to be composed by horizontal and vertical collaboration. The first refers to central government; meanwhile the second concerns the cooperation across different governmental levels. This could represent a way to implement coordinated strategies of public investments. However, a multi-level governance needs a good training of municipal staff that should have skills in project management and budgetary practices. From this perspective, the partnership represents a key principle in order to achieve the economic, social and territorial cohesion, because the sharing of skills and knowledge can make planning and implementation more effective. For instance in France, a partnership between regional and central governments has been introduced in order to share responsibilities in terms of strategy design, monitoring, reporting and managing. On the other hand, only if the administration and the other different authorities are competent, efficient, impartial and client oriented could a multi-level governance be effective. (European Commission, 2010).

2.2 Indirect factors

Encouraging the economic, social and territorial cohesion represents the main objective of EU regional policy. From this perspective, the investments in specific

fields such as infrastructure, environmental, and natural capital can promote the economic and social growth. However, although little do they have a direct impact in deploying EU regional policy aid, their analysis allows a more complete and exhaustive comprehension of investment channels, which are the key issues in the identification of strategies and policies to manage European funds.

Moreover, the opportunities of regional success in terms of competitiveness and economic development are connected to availability of infrastructure, such as transport and telecommunication networks. Indeed, the provision of effective infrastructures can have positive effects on productivity and growth. For instance, a well-planned transport system can encourage the regional development in terms of productive costs reduction, and improvement of competitiveness. From this perspective, a better access to labour market represents a key factor in order to attract investments and to promote economic and social cohesion (European Commission, 2010). In general, the major motorway networks in terms of density are located in Netherlands, Belgium, in the western German regions, and in United Kingdom. Moreover, high accessibility for goods and passengers represents an important aspect for regional economic performance that can be achieved by means of efficient road or motorway but also thanks to railways and airports (EUROSTAT, 2010). In addition, high –speed ICT networks represent another significant element because it improves the capacity to compete in the global market. From this perspective, the access to this kind of technology is essential in order to develop public and private on-line activities, such as communicating, selling and buying goods and services. Therefore, the crucial issue is the lack of bonders. Indeed, these activities are not linked to a specific place, and as a result, it allows people to take part in economic, social and political life. In addition, ICT networks make market more flexible (EUROSTAT, 2010).

On the other hand, environment and natural capital are two significant factors in order to achieve the EU regional policy objectives. However, some environmental aspects such as the geographical position represent an invariant factor. Indeed, for example regions with geographic handicaps, such as mountain and insular regions, show physical characteristics relating to their positions that inhibit their development. Therefore, the main problems concern the population decline, and high levels of unemployment. Moreover, the low density population goes with low level of infrastructure and services (European Communities, 2004). In addition, climate change has negative impacts on economic, social and environmental systems in terms of environmental degradation, biodiversity loss, unsustainable use of natural resources, food supply, health, industry, and transport. In particular, the regions, which are mainly exposed to these problems, have to face important challenges to agriculture, forestry, fisheries, energy production, and tourism industry. Moreover, the intensity of these impacts depends on different issues, such as the physical vulnerability, the economic development and growth, the natural and human adaptive capacity, and the disaster monitoring mechanisms. From this perspective, the use of renewable energy and the measures to mitigate the impacts and causes of climate

change can create an economically and environmentally “win-win” situation (European Communities, 2004).

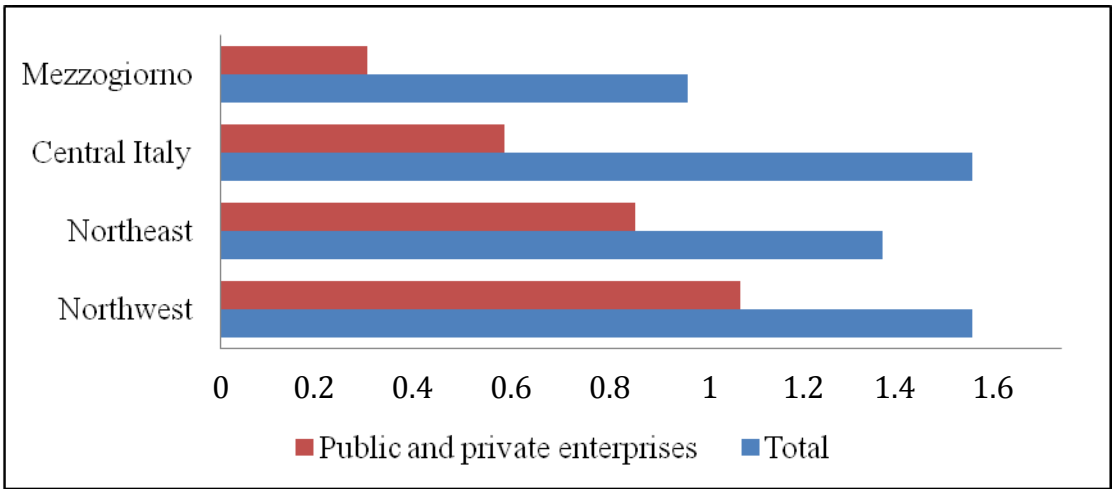
In conclusion, the regional success could be indirectly influenced and promoted by a better management and development of infrastructures, and by the investments on environment. Indeed, the latter can promote the economic development in three ways: ensuring a long-term sustainability of economic growth, reducing external environmental costs and promoting innovation and new jobs (The Council of the European Union, 2006).

3. The Italian case study

Despite in recent years, disparities in terms of GDP has been reduced, significant regional differences within the same nations persist. Although these disparities are marked in different Member States such as Germany, France and United Kingdom, Italy represents an emblematic case due to coexistence of a rich area, which is composed by centre-northern regions, and the Mezzogiorno, which is characterized by an economic backwardness. However, the significance of Italian example in this context is not related to intensity of these imbalances but to their persistence in the course of time. Indeed, this divide depends on historical factors that date back to Italian unification. This phenomenon has led to a dualistic framework that represents a distinctive aspect of Italian development model (Aiello and Pupo, 2009). In this paragraph, the direct and indirect factors in relation to the Italian case study are analyzed in order to understand their impacts on the historical disparities between northern and southern regions.

3.1 R&D and human capital

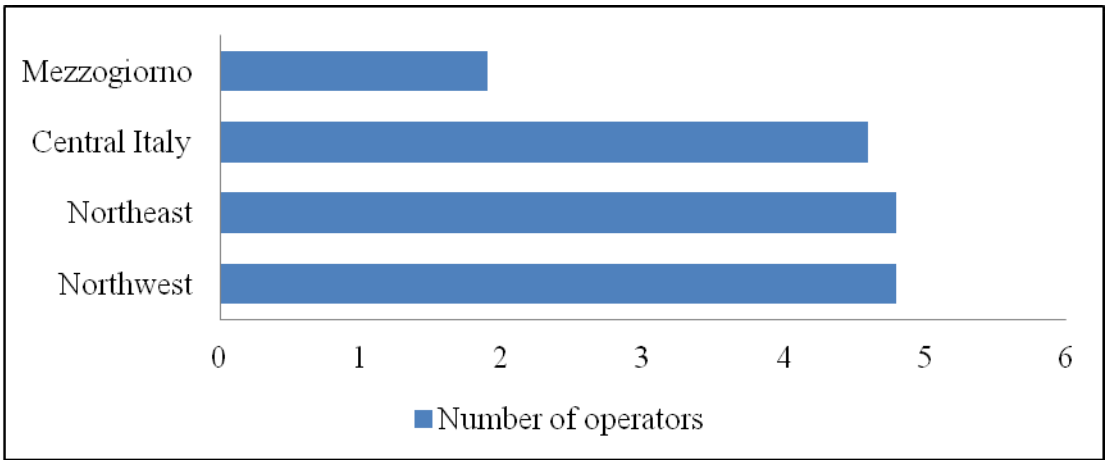
In relation to R&D, in 2009 the main total expenditure on this field, in terms of GDP percentage, is located in the north and central Italy (Bar chart 1). In particular, the worthiest regions are Piedmont (1.83%), Latium (1.78%), and Trent (2.09%). However, in the latter the significant percentage is due to both public and private institutions. In Piedmont is prevalent the role of private enterprises; meanwhile in Latium, universities and public research bodies represent the main investors. Moreover, the expenditure of private enterprises in the Mezzogiorno is below the national average owing to medium-low dimensions and the sectional compositions of companies (Istat, 2009).



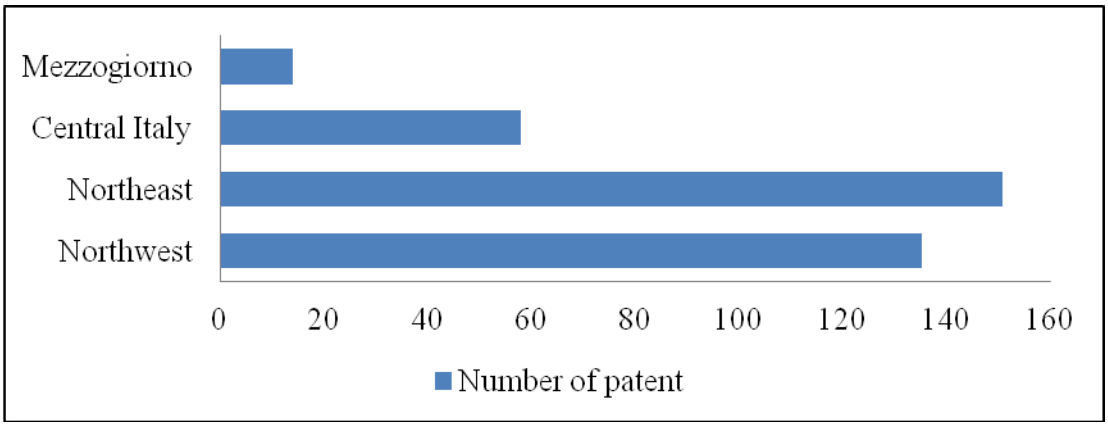
Bar chart 1 Expenditure (expressed in percentage of GDP) on Intramural R&D in 2009 (Istat, 2009)

In addition, the companies that invest in R&D are concentrated in the northern Italy, where regional governments support small-medium enterprises by means of tax reliefs. In particular, the most amounts of funds come from Lombardy, Lazio, Piedmont, Emilia-Romagna and Veneto. For example in Lombardy two different kinds of funds exist: FRIM and FESR. The former finances industrial and development research projects that are oriented to innovation in terms of products and processes. The second support investments that are linked to industrial application of research results (Pagamici, 2011).

The divide between Northern and Southern regions is confirmed also by the number of operators (for 1000 inhabitants) on the R&D field (Bar chart 2) and by the number of patent for millions of inhabitants (Bar chart 3). Indeed, the higher percentages are linked to the northwest and northeast areas, where there is the combined action of private enterprises, which absorb the 60% of R&D operators, and universities. However, in the central and southern regions, the supremacy concerns the universities and public research institutes (Istat, 2009).



Bar chart 2. Number of operators (for 1000 inhabitants) on the R&D field in 2009 (Istat, 2009)

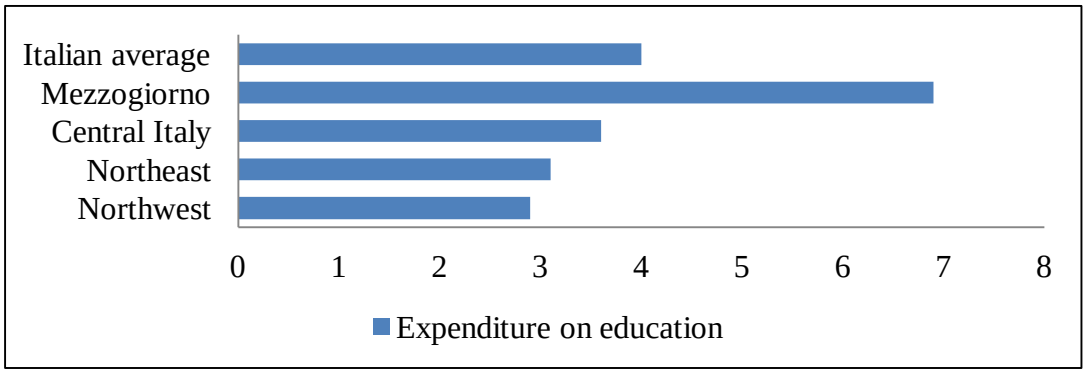


Bar chart 3. Number of patent per millions inhabitants in 2007 (Istat, 2009)

In relation to the second indicator, the territorial distribution of patents shows a low level in the Mezzogiorno, where the value is similar to the less European State Members. Meanwhile, the situation is different in the North due to the sectional productive structure (Istat, 2009). From this perspective, the success of northern regions is assignable to a strong presence of industry and a polycentric spatial organization, where productive services are distributed around a number of local centers.

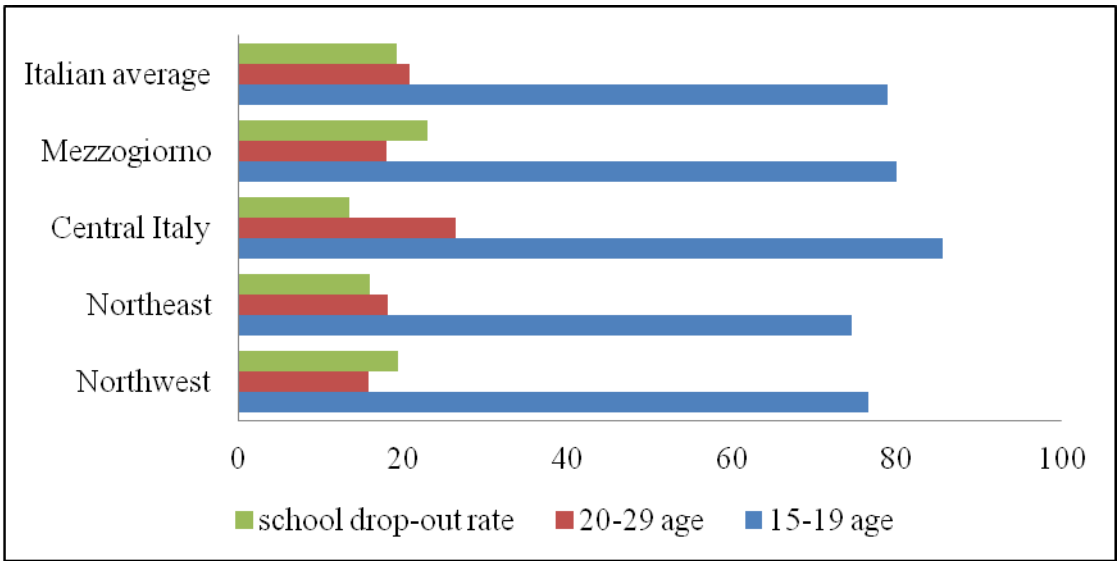
Moreover, the gap between northern and southern regions in terms of human capital is analyzed in relation to six indicators: public expenditure on education, expressed in percentage of GDP, rate of participation to education in relation to 15-29 age population, the school drop-out rate, the percentage of population with a tertiary education, and the rate of young people outside the productive and the educational process.

In 2007, the rate of expenditure in relation to GDP on education was 4.0% in Italy (Bar chart 4). However, the situation is different between northern and southern regions. Indeed, the main percentage of investments concerns the Mezzogiorno regions, such as Calabria, Sicily, Basilicata, Apulia, and Campania, owing to a larger school age population (35.1% of total Italian school age population).



Bar chart 4 Rate of expenditure in education, expressed in percentage of GDP in 2007 (Istat, 2009).

On the other hand, the percentage of participation of 15-19 and 20-29 age population to education (Bar chart 5) shows the same data in the entire Italian territory. Little is the percentage in relation to 20-29 ages. However, this phenomenon suffers from the mobility of tertiary educated people. Although the percentage of participation is regularly distributed, the school drop-out rate is particularly relevant in the Mezzogiorno. Indeed, for example in Sicily the trend reaches nearly a 25 percent.



Bar chart 5 Rate of participation to education in relation to 15-19 and 20-29 age population and the percentage of school drop-out in 2009 (Istat, 2009)

In addition, it is significant the percentage of 30-34 age population with a tertiary education. Indeed, the rate is particularly low in the Mezzogiorno, where the percentage assumes a value of 15.2% that is below the national average (19%). Moreover, in the south of Italy the rate of 15-19 age population outside the productive and educational processes assumes a value of 29.7% that is 9.7 point lower of Italian average. These data are confirmed by the statistics on unemployment. Indeed, the rate of youth unemployment (15-29 ages) was about 36% in 2009; meanwhile the Italian average was about 25.4% (Istat, 2009).

From these perspectives, despite the higher expenditure in the education field, the Mezzogiorno shows a lower percentage of tertiary educated population and a higher school drop-out rate. Therefore, it appears that the backwardness of southern Italy is imputable to other reasons, such as quality of education process, and social issues in relation to family composition. On the other hand, the efforts of private enterprises on the R&D field represent the distinctive aspects that have positively influenced the success of northern regions.

3.2 Governance and social capital

Until 1990s, the national strategies of development reflected the top-down approach in Italy. As a consequence, the role of public administration has increasingly become central in the Mezzogiorno, exacerbating the historical divide between Northern and Southern regions.

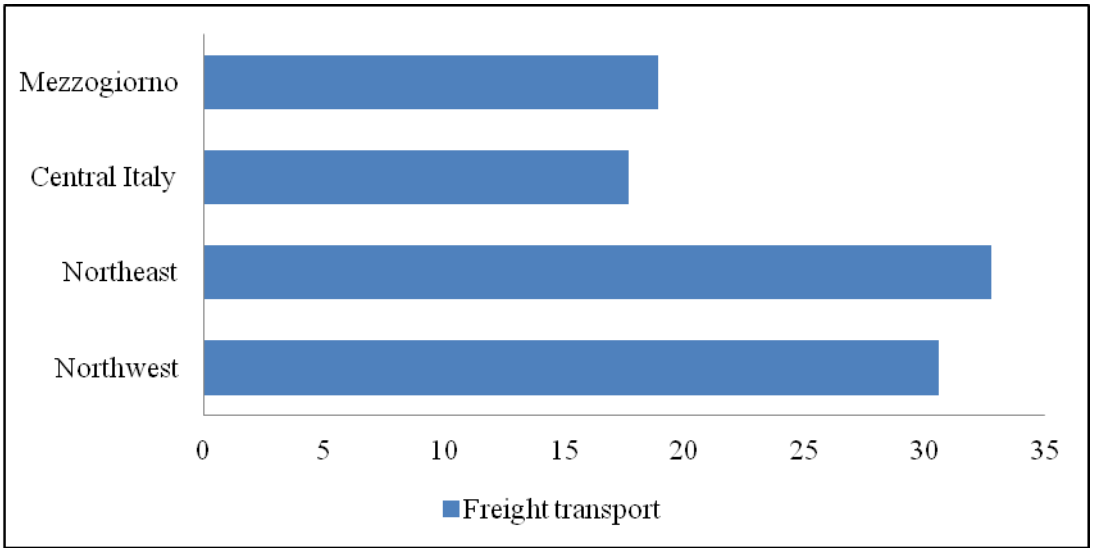
However, although it appears (Calamai, 2009) that the devolution in conjunction with the liberalization of key sectors have decreased the Italian disparities, strengthening the capacity of self-financing, the Mezzogiorno is still characterized by

an existence of criminal organizations, which undermine the effectiveness and transparence of economic, social and political strategies as well as the integrity of public administrations. One example is the incapacity to manage the emergency state relating to solid waste disposal in Campania. Indeed, this emergency state represents an economically profitable situation for the organized crime, which collects more profits from the illegal waste management rather than from drugs deal and extortions. Moreover, this situation is made worse by legal entrepreneurial sectors, which on one hand, take advantages to illegal waste disposal systems in order to reduce costs and on the other hand, this context allows them taking an active part in crisis management (Lacuelli, 2008).

From this perspective, despite the new progress of Mezzogiorno, the historical disparities between northern and southern regions are partially ascribed to a scarcity and a negative typology of social capital, based on political patronage and characterized by dishonest governance.

3.3 Infrastructure, environment and natural capital

The road transport represents the favorite modality of freight movement, provoking consequent phenomena of congestion. Moreover, four fifths of total freight transport originates in the central-north regions, meanwhile one fifths in the Mezzogiorno (Bar chart 6).



Bar chart 6 Percentage of freight transport in 2008 (Istat, 2009).

Indeed, the economy of northern regions is based on an export oriented system and it is strongly dependent on international markets. In addition, the main industrial productions are located in Lombardy, Piedmont, Veneto and Emilia-Romagna. Moreover, northern producers do not have interest in the southern market due to single market and currency and globalization. This situation has led an increasingly demand for federalism forms by northern regions. The principal airports in relation

to tonnes of freight, and number of passengers are Milan-Malpensa, and Rome-Fiumicino. Another important aspect is represented by ICT networks. In the central-north regions the 50% of families possesses a broadband connection. However, the percentage is lower in the Mezzogiorno, where the rate reaches the 38.6%. On the other hand, the gap in relation to the access of broadband connection is lower for the category of enterprises. Indeed, the rate of companies that use this typology of ICT networks is 77.8% in the Mezzogiorno, and 84.5% in the central-north regions.

Moreover, the geographical position represents an important factor that can promote and encourage the economic and social cohesion. Indeed, northern regions are obviously advantaged owing to their proximity to the more economically integrated areas. In addition, this situation reflects the disparities between core and periphery zones of Europe. In addition, the percentage (gross domestic consumption) of electricity production from renewable energy sources is 20.5% in Italy in 2009. However, the situation is different between the Norths, where the rate reaches the 22,3%, and the Mezzogiorno, where the percentage represents the 16.1% of total electricity production in 2009.

From this perspective, the success of northern regions is represented by facility of commercial trades beyond their boundaries thanks to their geographical position but also to their infrastructure effectiveness, the production of hydroelectric power thanks to their proximity to the Alps and a wide flat territory.

4. Conclusions

The EU regional policy promotes economic, social and territorial cohesion and innovation among its Member States by means of financial funds and instruments. However, despite EU efforts, disparities among different territories continue to exist at international and national scale. In addition, globalization and economic growth has affected more and less developed regions, representing one of the main challenges for European regions. Moreover, within the national boundaries regional disparities are significant. From this perspective, Italy represents an emblematic example owing to the historical divide between economically stronger northern regions, and the Mezzogiorno. The latter is affected by economic backwardness, which is made worse by criminal organizations, corruption and political patronage.

However, in no way does the only role of European Union guarantee a stable growth across all European territory. From this perspective, the EU regional policy represents a tool in order to influence and promote the regional success but at the same time it is not sufficient to promote economic, social and political growth. Therefore, more efforts and skills from single Member State and regions are necessary to achieve EU regional policy’s objectives. For this reason, direct and indirect factors are analyzed in order to understand the aspects that can promote the regional success.

The first group of aspects, concerning R&D, human capital, governance, and social capital, promotes the important principle of innovation. Moreover, governance and strong institution represent a prerequisite in order to achieve the EU regional policy aims. Indeed, the capacity to allocate funds within the regional territory is one of the most important issues of the European strategies. Therefore, only if governments and public administrations have skills and competence to identify the most appropriate investment sectors, can funds help the economic, social and political cohesion. The indirect factors, such as infrastructure, environment, and natural capital, allow regions to produce new surplus value goods and services, improving the local competitiveness in the international market. From this perspective, Northern Italian regions are famous for "made in Italy" products. They are linked to continuous innovations in terms of materials, marketing and quality. The small-medium enterprises are oriented towards a specialized market of exclusive products that are expression of quality. The "made in Italy" products allow to compete with the emerging economies, which are characterized by low costs of production and low quality. In addition, although the traditional successes in the fashion industry, which are represented by famous brands, such as Gucci, Prada, D&G, Armani, Versace and Valentino, Italy is characterized by production of famous gastronomical products such as "parmigiano reggiano" and "prosciutto di Parma". They are Protected Designation Origin (PDO) products. PDO is a regime within the framework of Protected Geographical Status (PGS) defined in European Union Law. PDO products are entirely produced and manufactured within the specific region and for this reason, they acquire unique properties. From this perspective, the capacity to orient the economy towards specialized sectors together with innovation efforts represents a key success of northern Italian regions (Onida, 2004). Therefore, innovation needs experimentations in all knowledge fields.

Moreover, the necessary infrastructure has changed since the possibility to buy and to distribute services online exists. Despite the increasingly importance of digital networks transport, infrastructures remain important due to its capacity to move people and goods across the EU and the world. In addition, some regions are more successful thanks to their geographical position and their natural resources. On the other hand, problems such as climate change need coordinated and integrated actions at all scale and level, because they have negative impacts on economic, social and environmental systems.

In conclusion, the scenario of northern Italian regions shows different factors that have promoted and encouraged the success in terms of economic, social and territorial cohesion. Some of these are connected to efficiency of public administration and institutions, others to capacity to orient the market towards specialized sectors that represents the Italian products in the world. From this perspective, more efforts in terms of R&D, innovation, infrastructure, governance and social capital are necessary in order to achieve the success in deploying the EU regional policy aid.

Hypocritical transitions?
The challenge of urban sustainable mobility transition.

Nina Vogel [1]

Abstract

This paper addresses the issue of sustainable urban mobility and the still persisting problems of implementing this objective, illuminated by current planning practice in the municipality of Fredericia in the so called Triangle Region of southern Denmark. The core questions are whether any imprints of a sustainable mobility discourse can be traced in the policy documents, how mobility is framed, and which arguments are used to legitimate or envision strategies and planning practices. Is Fredericia performing a transition towards low-carbon mobility? The paper will draw on concepts from transition theory in order to provide a framework to structure the analysis and to illuminate its contribution to explain possible path dependencies blocking more radical changes as well as identifying indicators for paths taken for the future development of the city. The paper aims to contribute to the discussions around urban complexity within transition processes. Transitions are always taking place, but the question is which direction they take and if these directions are in line with a planning approach for sustainable mobility.

Key words: Sustainable mobility, Ambivalence in planning, Complex city, Transition theory, Multi-level perspective

1. Cities' challenges of sustainable transitions

This paper analysis the challenge of cities to fulfill their aspiration for sustainable urban development with a focus on urban mobility planning in the case of Fredericia and the Triangle Region in southern Denmark. Identifying the transitions actually taking place and linking these to the main drivers behind current development will contribute to the discussion of ambivalent planning practice, the given gap between policy and planning practice, and creates more clarity for opportunities and necessity of intervention for more sustainable urban mobility. Dynamics and interrelation of general trends of growth and climate change pressure (landscape) and what generates and is translated into hegemonic practices and norms in urban mobility development (regime) as well as possibly opponent or supportive niches are discussed and will shed light on opportunities for change.

There is a general increase in the awareness about climate change and its consequences and the role of cities being prime generators of pollution and

[1] Aalborg University, Aalborg, Denmark – nvogel@plan.aau.dk

responsible as well as having opportunity for facilitating transitions towards more sustainable futures (Newman, 1999; Bulkeley et al., 2011; Graham et al., 2001; Hodson et al., 2010). Sustainability concepts are common in a lot of current planning policies and probably an obligatory 'section' to legitimate today's planning documents in general. However, questions arise if such concepts hold true or if they become 'empty, green promises' that are rarely fulfilled. "Our common future" - the Brundtland Report of 1987 - was path-breaking for many further formulations and understandings of sustainable development. Two main concepts are characteristic for the concept of sustainable development used in this report, such as: 1) the *concept of 'needs';* especially concerned with the world's poor and 2) the *concept of limitation*; regarding the state of technologically and socially conditions. These concepts should help to organize life here and now without compromising possibilities for future generations to meet their needs. This global contextualization of sustainability has to be scaled down to local contexts and explicit actions have to be taken.

In this paper, some possibilities and constraints in pursuing a transition of urban development into a more sustainable direction will be illuminated, using the Danish town of Fredericia as an illustrative example. The transition-theoretical concept of the multi-level perspective (MLP) will be used as a framework for analyzing the complex dynamics and diverse factors that affect urban development and (ambivalent) planning practice to map the transitions actually going on, and to identify drivers behind these transitions and possible interventions that may evoke changes in development paths (Geels & Schot, 2007; Rotmans & Loorbach, 2009, Geels, 2011). However, being interested in more radical changes to reach desirable futures of sustainable mobility, this paper will include a normative standpoint of transition from a sustainability perspective based on planning theory for sustainable urban development and political economy literature (Næss, 2012; Harvey, 2010). Hence the paper includes also the identification of directions of transition and the aspect of change versus reproduction or continuing of business as usual. Moreover the context within which one uses the analytical understanding or methodology of transition is crucial. The urban and its complexity will define transition in this analysis (Næss & Vogel, 2012).

The next section (2) introduces the theoretical and methodological context (transition theory), some challenges when investigating urban complexities of transition, and the analytical use of the multi-level perspective. In Section 3, the case of Fredericia will be introduced and key traits of its spatial development will be analyzed using the multi-level perspective, including a discussion of the main dynamics of the niche, regime and landscape levels. In the final section (4), main lessons drawn from the study will be presented.

2. Theory and methods

Generally speaking transition theory is considered to be of interest comprising issues of complexity and attempts to explain systemic change. For the research of transitions towards sustainable mobility the understanding of dependencies of socio-

technical processes and artefacts, such as the building stock, its utilization and the transport systems and especially how automobility is influencing and influenced by urban land use and transport infrastructure provision, will be essential. Moreover, transition theory can help to identify possible drivers for sustainable transitions such as key actors, resources available or pressure to for creating regime change.

Bertolini (2011) for example describes transition as *transformative change in complex systems*. Others define transition as "*a long-term process of change during which society or an important sub-system of society fundamentally changes*" (Rotmans & Loorbach, 2000: 2). Both of these definitions describe rather incremental change processes even though they sound quite profound being structural system changes. Nevertheless, to adapt to new conditions with e.g. optimizing through replacing or adding new components to a system can keep the basic system structure intact. The electrification of the car would be such an example, continuing on the main system infrastructure with maybe more efficient and less polluting artifacts. Moreover pace plays a role too especially when we are experiences a pressure to act now to avoid even worse climate disaster as already occurring. Other authors point towards the embedded contexts of technological change when describing: "*Transitions […] as shifts or 'system innovations' between distinctive socio-technical configurations encompassing not only new technologies but also corresponding changes in markets, user practices, policy & cultural discourses and governing institutions*" (Geels & Schot, 2007).

However it remains a challenge to define the urban mobility regime. Multiple causes and factors affect the given conditions and direction for urban development and its mobility patterns and systems, including e.g. different sectors of land use and transport planning, contested political structures, contemporary mobility culture as well as locally bounded socio-economic circumstances (Næss & Vogel, 2012).

2.1 Urban transitions

Gullberg and Kaijser are not explicit transition research scholars, but are interested in the urban and its transitions. They relate more to e.g. theories around the network and the complex city such as Marvin and Graham introduced these concepts in *Splintering Urbanism (2001)*. Moreover the spatial conditions of the urban (the building sites) and the network activities of actors are explicitly included. These elements are repeatedly criticized of being insufficiently included in transition theories of socio-technical regime change. Gullberg and Kaijser developed an own approach, called the City Building Regime Approach (CBR Approach), to analyze and define urban transition with its stabilization and change phases. "*By a city-building regime (CBR) we mean the set of actors and the configuration of coordinating mechanism among them, which produce the major changes in the landscapes of buildings and networks in a specific region at a given time*" (Gullberg & Kaijser, 2004: 18). They underline the institutional legacy of the city and describe the design of coordination mechanisms such as consensus, hierarchy, networks, trust and cooperation. The latter is interesting regarding responsibilities and political

action being formed and reproduced in cities and reflects a necessary discussion around legitimacy and normative dimensions in transitions.

The spatial dimension, its physical mass and inertia of the urban built environment, is crucial when dealing with cities' transitions. The ways in which cities grow reveal the type and potential of sustainable transition. Urban structures (e.g. infrastructure, housing) have a relative permanence and persistence to fast change. To analyze the geography of transitions helps to contextualize transition more concretely, to be able to compare different cases with varying transition pathways, different pace and direction of transitions (Coenen et al., 2010). Central questions are concerned with the explicit physical condition that creates and limits mobility patterns and also about relational space of cities that points towards the strategic interventions of transition actors and action. This represents exertion of power and possible influence on transitions from a niche level perspective.

The previous authors all relate to processes of change when defining transitions and some are more precise with their references than others. The normative dimension or question of legitimacy is relatively faint, but should be more in the forefront when aiming at steering transitions (e.g. Transition Management, backcasting as normative scenario tool). Moreover the complexity of transition processes and the difficulty to define and identify the explicit transition points and loci based on multi-causalities could be counteracted with a normative standpoint. Such an approach would help to filter and direct actors' goal setting, strategy formation, explicit planning practice and might be even able to estimate interaction mechanism of different systems.

To give an example from the field of planning: multiple actors can agree on the strategies and visions formulated for cities' potential development to describe desirable futures. They may fulfill the necessary 'sustainability agenda' in their goal formulations, but they often do not translate these overall goals into explicit, integrative and sensible measures. Planning goals and planning practice contradict each other, as exemplified in the case of Fredericia. This can be related to simultaneous growth approaches, which lead to a liberalization of planning and are reluctant to regulative measures that would help to develop towards their desirable futures (seen from a sustainability point of view), but might reduce the chance of fast profit. A more regulative as well as integrative policy arrangement would limit planning practice such as location and zoning in land use decisions and could thereby also reduce the amount of transport infrastructure needed for accessing new development sites as well as the distances actually traveled in daily life. Conversely transport infrastructure could be oriented more towards reducing individual motorized traffic, which would correspond with more dense development with different demand structures (Næss, 2011; Holden, 2007). However, based on a development away from formal planning to more informal planning practice, often ad hoc and developer led planning, these forms of regulation do not take place. Therefore the defined futures in form of vision or strategy documents as well as policy papers have little coherence with planning practices, they are missing an anchoring or outset in given challenges and become of a hypocritical character.

2.2 The multi-level perspective (MLP)

The multi-level perspective (MLP) is a theoretical transition concept that aims at describing transition pathways on three main analytical levels, socio-technical niches, socio-technical regime and socio-technical landscape, which reflect micro, meso and macro level respectively. Main transition pathways are 1) transformation, 2) de- and re-alignment, 3) reconfiguration and 4) technological substitution (Geels & Schot, 2007). The pathways differ in their intensity of the regime change and if the force is more internally or externally driven. The MLP is primarily concerned with reconstructing transitions around technologies, their interrelated, historical-evolutionary development within society and is often quite sector oriented.

The socio-technical regime is central and comprises the dynamically stable, established and hegemonic practices, discourses, institutions and artifacts. Or according to Rip and Kemp (1998: 338) a regime is defined as "*the coherent complex of scientific knowledge, engineering practices, production process technologies, product characteristics, skills and procedures, established user needs, regulatory requirements, institutions and infrastructures*".

Niches are relatively similar in their basic characteristics to regimes, but do not have the same pervasiveness and power in societal systems. Niches can support regimes or can be opponent in their approaches. Many transition scholars believe that niches are the main loci for transition or innovative development, being able to 'think outside the box', to use other resources and maybe having the ability to react more easily on pressure and change than the regime, which is considered to be more path dependent and locked in.

The landscape level could be described with: *"Developments [that] […] include largely exogenous processes that neither regime or niche actors can influence, or just very partially, such as broader developments in the demographic sphere (e.g. the transformation of family relationships, aging of society), social sphere (e.g. the growth of travel mobility and virtual networking), economic sphere (e.g. the globalization of production and consumption), cultural sphere (e.g. the surge of individualism), or environmental sphere (e.g. the depletion of natural resources)."* (Bertolini, 2011: 6)

Especially the landscape level includes crucial factors and developments to arrive at moments and processes of change. However, the MLP describes the interplay of niches, regimes and landscapes with main interest in opportunities for regime change. The analysis will be used for identifying important dynamics between these levels and to arrive at a better picture of crucial parameters for change in the case of Fredericia's urban mobility development.

3. Analysis

Based on an interest in understanding current development and its deviation from sustainability goals set, transition theory can be useful to explain possible path dependencies, which deny more radical changes as well as identifying indicators for paths taken for the future development of the city. The case study of Fredericia builds on document studies such as municipal planning documents, policies, visions and strategy papers of the Triangle Region, an interview with the director of the Triangle Region in 2011 and further relevant reports and sources of references illuminating case related circumstances.

3.1 Planning context

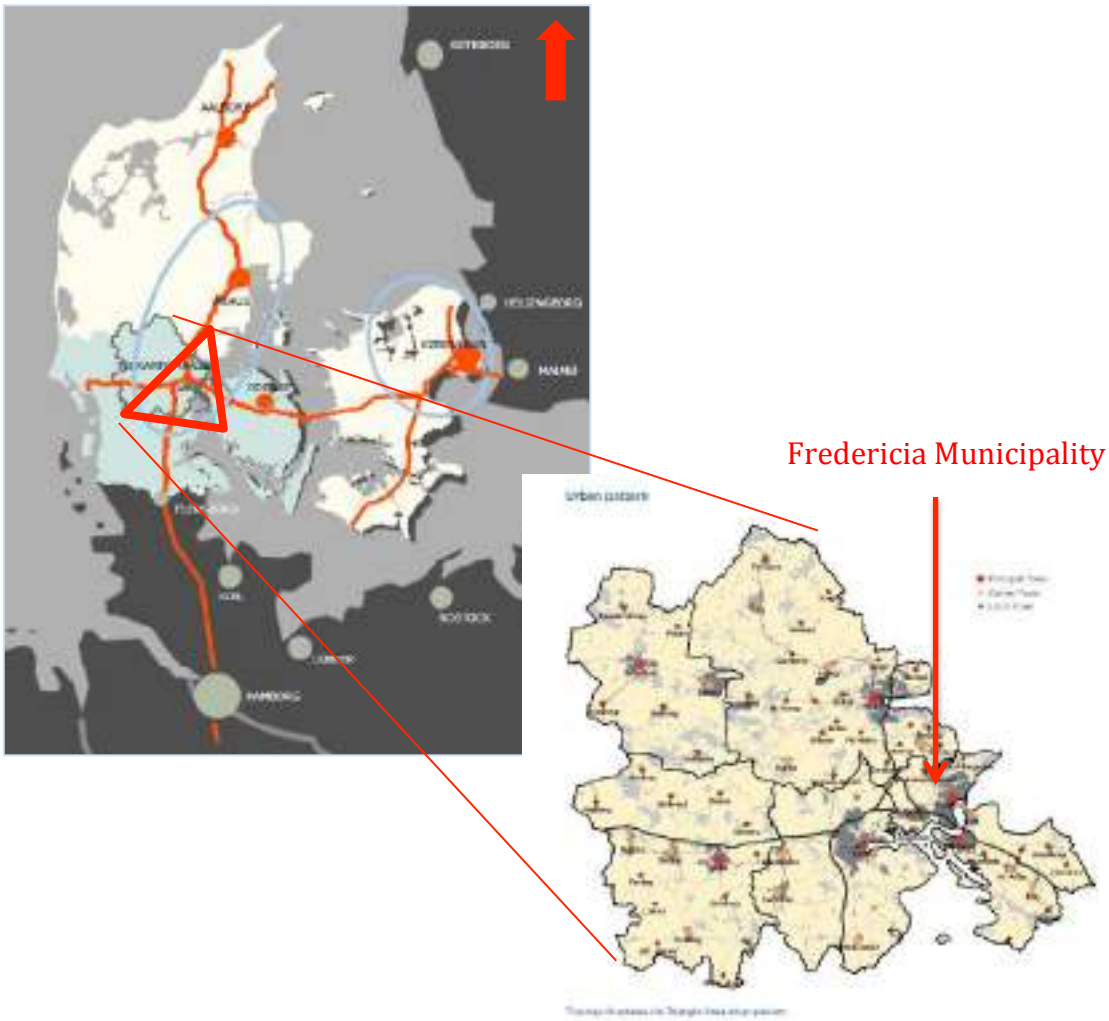

Figure 1: Location of the Triangle Region in Denmark and urban pattern of the Triangle Region (based on: Trekantområdet Danmark, 2007; Fredericia C, 2011)

The municipality of Fredericia has a population of approximately 50,000 (of which 40,000 in the continuous urbanized area of Fredericia) and is a part of the so called

Triangle Region. This polycentric region is a network of six municipalities, which account together for around 350,000 residents. The name *Triangle Region* originates from the three bigger cities Vejle, Fredericia and Kolding, which form a triangle when connecting these. In this network Fredericia is one of the most urban municipalities, covering a relatively small area and with less rural land within the municipal borders than what is the case for the other municipalities of the Triangle Region (see figure 1 above).

The Triangle Region is part of the so called East Jutland Growth-Corridor, stretching from Randers in the north over Aarhus to the Triangle Region in the south, including 17 municipalities. Since the national planning report 'The New Map of Denmark' (Ministry of the Environment, Denmark, 2006) this corridor has been given attention for investment and development strategies to be a growth center along with Copenhagen Metropolitan Area. Such belonging reinforces the general strive of municipalities for inward investment and they do compete with each other for attracting business and people. Consequently land use and transport planning practices appear to be of rather liberal character with less emphasis on objectives to e.g. reduce transport emissions and expansion of the built-up areas.

Nevertheless, there is a general increase in the awareness about climate change and its consequences and many Danish cities are aiming to take responsibility to tackle causes and adapt to conditions and so is Fredericia. Fredericia wants to be *one of the leading climate municipalities in Denmark* and is expressing its endeavor with plans to reduce its CO_2 emission by 25% in 2015 (with reference to 2006). Especially within the Triangle Region's network climate initiatives were launched. Fredericia participates in the following projects that can influence its urban mobility:

a) a partnership agreement with the DONG energy company, which addresses the high ambition of becoming also energy producer,
b) a pilot project introducing electric cars, which is part of a nation wide project, where in cooperation with Designskole Kolding a report with key parameters to introduce electric vehicles was developed (Etrans, Designskolen Kolding, 2011), and
c) buses running on alternative fuel are introduced (Triangle Region Denmark, 2009).
d) The so-called Formel M mobility management project is approaching the critical fact of the high amount of personal car travel to work within the municipal boundaries concentrating on the industrial park Danmark C (www.formelm.dk). This appears to be a necessary approach, as the Triangle Region is one of the Danish regions with an outstanding high automobility and highly car-depended land use structures (Krawack, 2011).

As an example, Figure 2 represents one of the most important arguments of travel time and distance within transport planning discussions as well as personal mobility decisions. The region-wide accessibility by car is clearly demonstrated in this comparison of areas accessible from Fredericia by car and public transport within certain time limits.

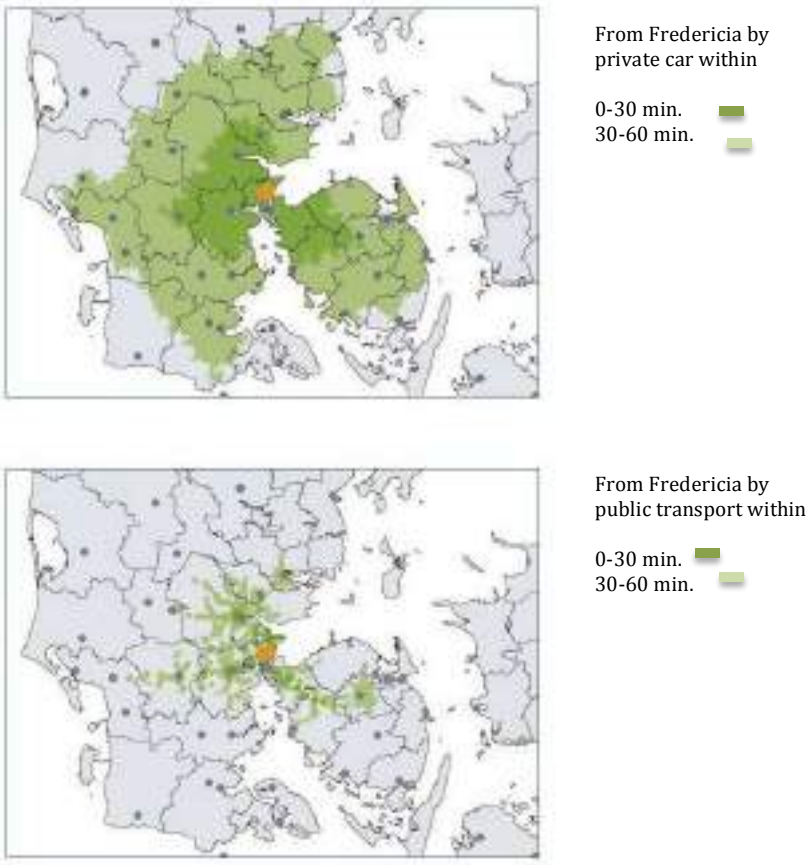

Figure 2: Travel time and distance by private car versus public transport (Region Syddanmark, 2010: 8)

However, the land use and infrastructure plans of Fredericia reflect no clear development strategy. The urban development is kind of two-fold, continuing a trend of sprawling development with expansion of the urban area demarcation, while simultaneously planning for inner-city densification, notably the new 'sustainability flagship' city district 'Fredericia C' (see illustration in figure 3).

Figure 3 represents the current land use in Fredericia municipality. As introduced above, Fredericia does have a relatively urbanized spatial structure with reference to other municipalities in the Triangle Region. However, this map illustrates the quite high amount of space available in-between the built-up areas such as green spaces and derelict as well as current low-density industrial zones. The map also illustrates the planned urban expansion, which seems to be spread rather randomly within the municipal borders. Danmark C as the biggest Danish industrial park with 600 ha, Fredericia C as new (sustainable) development project of 20 ha and the 140 ha sized new development site towards the west will be dealt with more in depth in Section 3.2). Moreover the relatively high amount of industrial space reflects the city's historical identity and it may evoke the impression of an industrial city even today. The representation in the municipal plan though is somewhat indistinct and might

give the impression of a need for expansion of the mapped demarcation. There is a gap between the actual used areas and the visualization in the planning document.

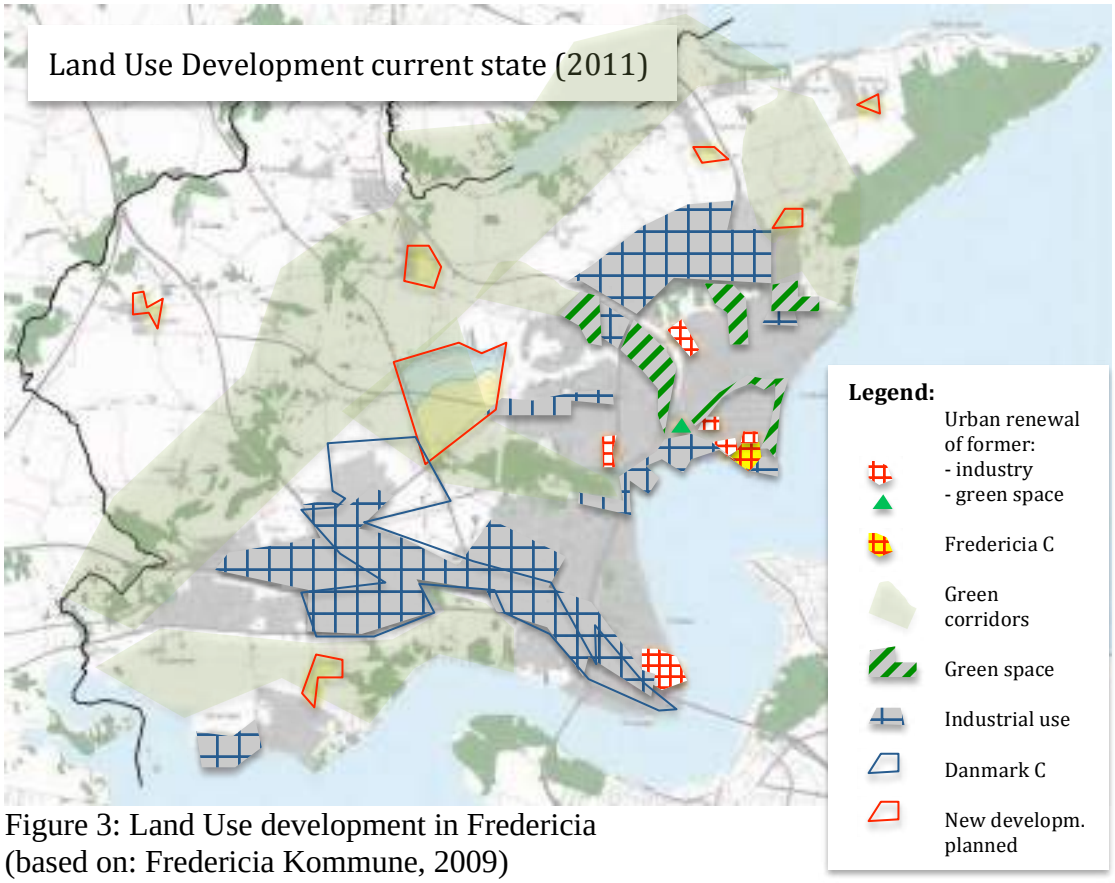

Figure 3: Land Use development in Fredericia (based on: Fredericia Kommune, 2009)

3.2 Chances for transition?

Applied to the context of urban and mobility planning in Fredericia, the landscape level comprises dominant trends and pressures that are more omnipresent such as the broad discourse about climate change and the need for cities to meet given and evolving challenges. Also a prevalent high level of competition within the polycentric region and between cities in general, accompanied by a liberalization of planning practice and strong promotion of growth strategies and couplings of growth to transport as well as a general need for a high mobility demand would account to this analytical level.

Ecological modernization is one of the most dominant paradigms around climate change and attempts to counteract the negative environmental impacts of higher consumption. Trends of individualism and mobility as freedom, materialistic lifestyles, continuation of a high exploitation of resources, however, are not as such altered, but rather adjusted to meet the numbers e.g. appointed in visionary documents. That also means there is a strong belief in technological solutions and innovations that will reduce emissions in transport for example to continue a level of

consumption and production patterns compatible with continuation of or increase in the present high amount of transport. A closer examination of demand, lifestyle and moral questioning tends to be excluded in such discussions.

Another important landscape-level feature is the general trend of increasing competition between cities, which may be even more pronounced in a polycentric region such as the Triangle Region. The notion of competition between urban areas internationally, nation-wide (the East Jutland Growth Corridor versus Copenhagen Metropolitan Area) as well as the inter-municipal competition in the Triangle Region (especially between Fredericia, Kolding and Vejle) exercise pressure.
The Triangle Region as a municipal network has no authority power on municipal planning practice. Relevant though are the mediations of planning approaches for the overall region and what is understood as valuable and necessary development.

One of the consequences is the municipal planning practice in the western part of Fredericia with an over-dimensioned zoning plan for urban expansion of 140 ha assuming the need for around 850 new housing units and retail development. Beyond a strong cultural value in Denmark of living in one-family houses influences such planning preferences. General reluctance to regulative measures of the spatial consumption of land prevails as with land for the industrial park Danmark C. Next to expanding the urban demarcated area infrastructural concerns are crucial. The highway infrastructure is understood as a logistic necessity for the industrial park and more generally as a major growth-generating asset of the region. The geographical context of the case municipality is used as argument for being an important Danish transport hub legitimating the expansion and construction of transport infrastructure (Fredericia Kommune, 2011).

The regime level comprises dominant modes of transportation, main infrastructures and actual spatial development, leading professional and institutional discourses around planning practice and its main tasks, prevailing political agendas as well as the dwelling types and locations, transport modes, shop designs etc. preferred by broad population groups. This comprehensive list of issues assign to different segments that are approached by planning practices and influence mobility developments. Especially the heterogeneity is crucial, which is favored by liberal political landscapes and reflected in regime structures. Market economy fosters such conditions to increase competition (Harvey, 2010). There is interplay between a multitude of actors, practices and structures, which are under constant formation and reformation and which have formed prevalent *multi-segmented regimes* within land use as well as within transport infrastructure development (Næss & Vogel, 2012).

The city authority is conscious about the need to transform towards more sustainable urban futures. Currently a main focus is directed toward the urban transformation project Fredericia C, where a former industrial area at the harbor is redeveloped into a dense and multi-functional city district. Fredericia C is a redevelopment project that started already in 2009 and was among other things initiated with an international idea competition on how to develop the former harbor area into a

economically, socially and environmentally sustainable city district. Connectivity to the given city was an important aspects as well as historical values and overall a distinct focus on multi-functional and dense development with 50% housing, 40% retail and 10% cultural use. Noticeable is a so-called *sustainability process tool* intended to lead and ensure the project's sustainable character throughout the competition as well as in further formal development phases. This appears to be a positive transition towards more sustainable structures in urban spatial planning. Additionally, local mobility management projects concerned with travel to work, parking policies or pilot projects introducing electric vehicles try to address a change in travel patterns towards more sustainable conditions. However, it is questionable how powerful these developments are in a long term and structural perspective. I would, initially, locate them on the niche level in a MLP perspective. They do not yet show any pronounced regime characteristics and it is questionable if a checklist with sustainability indicators can shift a political primary goal of growth.

Certainly the ambition is there to develop these niches to be part of the future regime in Fredericia but this is seen as challenge under current conditions of a general lack of an integrated approach of land use and transport planning towards more sustainable mobility. The inertia of the existing built environment is a different complexity and severity for transitions, which has to be accounted for when planning new development. The given planning practices do not reflect a clear awareness to the latter fact of relative permanence and path dependency. For example, the workplaces already located in the large sprawling industrial and commercial districts in the western part of the municipality will for a long time ahead make up a strong incentive to car commuting even if urban development in the next decades takes place mainly as densification. Besides, Fredericia has set aside an area of 140 hectares as a future development site for new dwellings and retail development. For one thing, this is an over-dimensioned expansion of the urban demarcated land that is unreasonable, judged against current needs. Secondly, this rezoning of land takes place in the outskirts of the city with poor access to public transport facilities, which will most likely create more car-dependency for its future dwellers and visitors (Fredericia Kommune, 2009).

The above descriptions point towards certain attempts by the regime to include some niche developments in the regime structures. Niches though can be of different character seen from a sustainable mobility perspective. Niches can support given regime formations or act in the regime's shadow without necessarily pushing for change, such as businesses favoring location in Danmark C as logistically central industrial park with direct highway connection and little regulations. Then there are niches that oppose the regime structures and practices and even try to tackle these. In this case, Fredericia C as a development project reflecting an integrative planning approach (at least as it is promised by the current documentation of the idea competition and plans), general densification plans for the inner city, promotion of bicycling as well as the attempt to introduce forms of mobility management could be considered as niche initiatives pointing towards a sustainable transition. On the other hand: unless these niche approaches are being backed up sufficiently, they risk to be

inefficient or outweighed by more dominant practices of daily mobility patterns, car-lobbies or businesses in general that would lose profit through major changes. Finally, the underlying driver for municipalities to support such niche projects is inherently the same, namely attracting people and businesses to the municipal territory. Sustainability initiatives thus run the risk of being subordinated to or coopted by a dominating strategy of increasing the city's economic competitiveness (Fredericia C, 2011).

3.3 Dynamics and barriers preventing sustainable transition

One of the key conditions preventing Fredericia and also other cities' from developing towards more sustainable mobility is the overall lack of an integrated land use and transport planning approach. The Triangle Region is addressing this gap in their agenda for the plan strategy currently being developed. Nevertheless, actors are struggling to approach this challenge and there are barriers that hinder the value and awareness for better land use planning as well as an integrated approach in planning. The above mapping of the different levels and their dynamic interaction reflects this basic problem. The landscape pressure or trends do affect the regime's segments differently. Taking into account the relative stability of the regime, which supports and facilitates multiple lifestyles and subsequent housing types and transport patterns, this leads to disconnected responses, which then in turn also explains the ambivalence in planning practice due to trying to satisfy 'everybody's needs' or performing rather hypocritical practices to reduce pressure. The regime seems to be ruled by the landscape trends and there is limited focus and support of challenging niche development.

One of the barriers is the missing political willingness to really deal with land use planning. The land use plan has developed into a massive list of regulative procedures, exceeding its limits of being able to cover all the issues stated and has ended up being neither read nor followed up and finally having no impact in planning practice (Krawack, 2011). This reflects a relative vulnerability of the regime, meaning it is sensitive towards general landscape trends of e.g. growth and attempts to offer prospects for urban development, but does this, however, with limited steering ability. Keeping the two main concepts of *needs* and *limitations* in mind, introduced by the Brundtland Report, the policy documents (e.g. land use plan, municipal plan) should, from a sustainability perspective, translate these concepts into locally anchored measures and aims. It could be questioned though to what extend these concepts are understood or used profoundly. Often short and superficial definitions are to be found in policy documents, which do relate mostly to the so called 'triple bottom line' introduced by the World Bank, namely the economic, social and environmental dimension of sustainability. However, this dominant concept of sustainability does not ensure a balance of these dimensions. Instead the economic sustainability often outweighs the other two.

This is tightly connected to another barrier, the planning system itself and has more of a structural character. Institutional responsibilities and organization hinder each

other in progressing towards more sustainable and integrative planning practice. Again, this is mainly a regime representation. A regime that is arranging its dynamic stability due to different structural segments with different practices, actors, discourses, values and norms. Also the region's strong external focus, rather than on improving internal conditions, determines to a high degree the planning discourse. The region's affiliation to the so called East-Jutland-Growth-Corridor as new national growth area is reinforcing competition in the regime from the landscape level.

Additionally the physical planning alone is questioned to have any impact as long as no explicit improvement in providing better public transportation infrastructure is given. Only an interaction of different measures can offer a development towards more low-carbon and generally more sustainable mobility patterns. So in MLP-terms it would translate into a more pronounced interplay of niche and regime to strengthen the niches to prosper, to network and to exercise power in an integrative approach. Furthermore the strategic relation between niche and landscape could exercise more specific pressure on the regime, such as creating a counter discourse to the coupling of growth and transport, frictionless mobility or general to reveal contradictions of the regime practices.

4. Main lessons drawn

The fuzzy transition processes taking place in Fredericia represent some first cracks in the regime structure and the beginnings of desirable niches that could by and large be up-scaled to the regime level. However, the power of rather unsustainable landscape trends on the regime dominates. The initiating and promoting of niches pointing towards more sustainable urban development is not enough and might loses momentum if no general landscape trends change as well.

In this context both opportunities and obstacles for Fredericia's sustainable transition in urban development and mobility can be seen. I will point out three main obstacles on landscape level as being crucial for the urban transition prospects:

1. Dominant discourse of ecological modernization, which translates and is accompanied by technological fixes in approaching solutions,
2. Spatial conditions in the municipal and regional area that create challenges for transport infrastructure and land use zoning,
3. Liberal political arena that is willing and compelled to create growth, which most likely impedes regulative planning approaches.

These landscape trends and paradigms are again translated into structures and practices on the regime and niche level and are used as legitimate arguments for rather unsustainable development.

Responses of the regime in form of expanding infrastructure and urban built environment or initiating competition processes around new sustainable city districts

are reflections of the regime ability to keep ‘in place’. The transitions taking place may slightly adapt the regime structure to an increasing pressure to act more sustainable, but in the main the regime prevails. This means that planning policies for sustainable mobility reflect a general acceptance of the region’s car-dependent structure, focusing on car-pooling, mobility management and zero-emission vehicles rather than aiming to reduce the amount of transport, which would integrate also land use planning into the policy measures. To influence the ‘mobility culture’ of the Triangle Region would definitely call for greater transitions on the landscape level including regional-scale land use planning and changed priorities in transport infrastructure development.

Nevertheless, opportunities on niche level can also be identified, such as:

1. A relatively transparent and participatory process of the redevelopment project Fredericia C that created a discourse around the sustainability of this flagship project
2. Nation-wide mobility management projects that take a closer look at the local circumstances in the Triangle Region or
3. Public transport and non-motorized forms of transportation get more attention (bus system in Fredericia, promotion of bicycling).

However, these niche initiatives will not have any bearing on environmentally sustainable and low-carbon urban mobility if a planning discourse is dominant that credits spacious areas for commercial and housing development due to a consideration of these elements as being competitive advantages or necessary to meet cultural needs. The same applies to a planning discourse depicting expansion of (road) infrastructure and also increases in the amount of transport as inevitable trends.

FRINGE: CHANGING CONTEXT OF THE URBAN PERIPHERAL AND 'NEAR-RURAL' AREAS IN A PROCESS OF STABILITY AND DEGROWTH

Ozan Hovardaoğlu[1]

Abstract

The dominance of the growth based theories over the planning literature and implications has once seemed to be unyielding and indomitable. For decades, growth has overwhelmingly been on the focal point of development strategies influencing both economic and spatial interventions in a wider range from national and regional level policies to land use planning. This picture, however, is itself receding in the past. Demographic structure changes having begun to be much more apparent especially after the 2000s in many countries represent a real challenge to almost all of the urban growth based strategies. These demographic structure changes seem to lead at least two vital questions. The first question deals with the need to find new strategies for efficient, suitable and so also 'smart' ways to entrench a certain level of economic success with possible near future labor market bottlenecks and without the existence of fast urbanization and rapid urban growth. The second question seems to be about the main 'problem' of the planning profession. The existence of population stability – or even decline – intertwined with the absence of rapid urban growth paves the way for taking quality based problems into the focal point of planning instead of growth based ones. The attention of the literature in relation to these two questions is directed toward new strategies which attempt to cope with controlling the economic consequences on the one hand and seeking problem based planning processes focused on qualitative issues of urban areas rather than just intending to manage growth problems on the other. In tune with this tendency in the literature, this study aims preliminarily at asking a third question having regard to the formerly identified two questions. This question takes urban peripheral areas wherein the 'urban' touches the 'rural', and near-rural areas wherein the accessibility to the amenities of urban life qualities and the proximity to the regional towns are minimally influenced by the friction of distance into consideration. This study aims secondly at contributing to the conceptual framework of urban fringe studies. To anticipate the direction, two major new industrial districts of Turkey, Gaziantep and Kayseri are examined in this research.

1. Introduction

Whatsoever might have been the reason, the Total Fertility Rates (TFRs) have begun to be dwindled after the baby boomers especially in the industrialized world. Although the total population of the globe still draws an upward tendency, many

[1] Erciyes University, Faculty of Architecture, Department of City and Regional Planning, Kayseri, Turkey – ozanhovardaoglu@erciyes.edu.tr

countries have already faced stability or even decline trends. The decreases in the TFRs intertwined with influential increases in the average life expectancies in these countries have provoked attention to the economic consequences of demographic changes. While the dependency ratios of younger cohorts have steadily been decreasing, an exact opposite tendency of the elderly dependency ratios have resulted economic impacts in a wide range from labor market bottlenecks to total efficiency losses. This kind of demographic structure change has influences on national level social security policies and so also on immigration policies which somehow find opposite reflections within the rise of right wing politics in some countries.

A similar demographic change tendency has begun to be apparent in Turkey especially after the 2000s. 'A young and dynamic population' component of the Turkish economy has already begun to lose its influences. The increase in the legal retirement age, revisions in the social security policies, preparations of ageing action plans seem to be the indicators of national politics awareness about what Turkey may face in terms of demographic change in the near future.

Fast population increases and rapid urban growth do not seem to be the fundamental components of the towns in Turkey as once they had been especially in the period between 1950s and 1980s. In tune with the prevalent demographic boom in this period, the main concern of planning had been the management of rapid urban growth. But beginning from the 1990s, the 'rapid' and 'fast' aspects of Turkey's population have gradually disappeared. The demographic indicators of the 2000s are becoming more like the ones in the European Union countries. Asking to what extent it is possible to maintain a certain level of economic growth without the population dynamism, therefore, indicates real challenging economic consequences of the demographic change. Both the national and local economies in Turkey have enjoyed the externalities of rapid urban growth and population increases, not only in terms of labor market but also in terms of industrialization. Until the 2000s, a somehow disguised interdependency between urban growth and industrial sectors has paved a way for remarkable local development success stories. A careful examination of these stories will certainly indicate the great merit of rapid urban growth and high amounts of urban population increases in these local development experiences, no matter if these success stories were planned or uneven.

This relation between economic development and urban growth seems to be one good reason explaining why urban growth is – and always have been for decades – so central in planning. Any forthcoming demographic structure change tendencies, in which the population draws stability or even decline trend, will presumably entail reconsidering urban growth based development politics. This shift in the focal point of planning indicates another challenge for the planning education, planning professionals and for the profession itself in Turkey.

The national planning agenda has already started to suffer from stridently brought up debates about what planning should deal with. A wide range of other professions from architects to engineers, sociologists, economists, geographers etc. take part

within these debates. These travails of the Turkish planning agenda, however, seem to give birth to new dimensions in planning in Turkey. These new dimensions are identified altogether as Turkey's new urbanization process in this study and in tune with these two questions mentioned above, this study aims preliminarily at asking a third one. This question takes urban peripheral areas wherein the 'urban' touches the 'rural', and near-rural areas (Hovardaoğlu, Çalışır-Hovardaoğlu and Sınacı, 2011) wherein the accessibility to the amenities of urban life qualities and the proximity especially to the regional towns are minimally influenced by the friction of distance into consideration. This study aims secondly at contributing to the conceptual framework of urban fringe studies.

The impacts of national level demographic structure change, perhaps, will not simultaneously be effective on local levels. Regional towns may face these problems in mid-term thanks to their central positions both in economic and urban terms. But the validity of these three questions depends on and requires empirical data from a case study. Examining the urbanization experiences of two major new industrial districts of Turkey, Gaziantep and Kayseri can give plausible evidence on the subject. Four main indicators are used in order to understand the direction of demographic change in these two towns that are the temporal changes of (a) TFRs, (b) population increase rates, (c) dependency ratios, and (d) cohort populations. Besides, the changes in the urban macro forms, urban growth and land use decisions of the towns of Kayseri and Gaziantep are researched in order to understand the rural urban fringes.

2. The Demographic Change Trends of the Global, National and Local Levels

2.1. The Demographic Change Trends of the Global Level

The term demographic transition was first used by the American demographer Warren Thompson in 1929 to label the changes — or transitions — he observed in birth and death rates in industrialized societies. The relation between demographic structure and development can preliminarily anticipate creating links between workforce or labor force demographics and productivity. This is why the effect of demography on economic performance has been the subject of intense debate in economics for decades. Actually, the demographic dynamics of nations, regions, and cities are thought to have vital importance in terms of general economic performance. However, the demographic structure is dynamic. It is easily possible to observe population fluctuations throughout the history in almost every scale, from settlements to regions, nations and even transnational levels.

The problem of population ageing is one of the most pronounced demographic change problems recently, particularly in the developed countries. The second problem is the fertility decline. The most common indicator for fertility is the Total Fertility Rate (TFR). It gives the average number of children per woman. Researchers show that TFR below 2.1 means a low fertility and decline in the total population. However, it is important to underline that, little fluctuations in this rate

result big influences. McDonald (2000), for instance, stresses that in a population with a fertility rate of 1.3, the population falls at the rate of 1.5 % per annum and such a population, in 100 years would fall to less than a quarter of its original size. He also shows that with a fertility rate of 1.9, the rate of decline in this population is only 0.2 % per annum which at the end of 100 years would result a population that is 82 % of its original size (McDonald, 2000). Despite the continuing increase tendency of the total world population, the increase amount is – owing to a decline in the TFR – gradually dwindling.

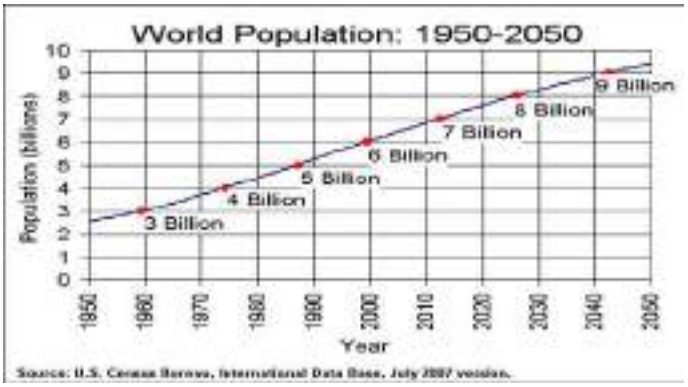

Figure 1. World population: 1950 – 2050 (Source: US Census Bureau, International Database, 2010)

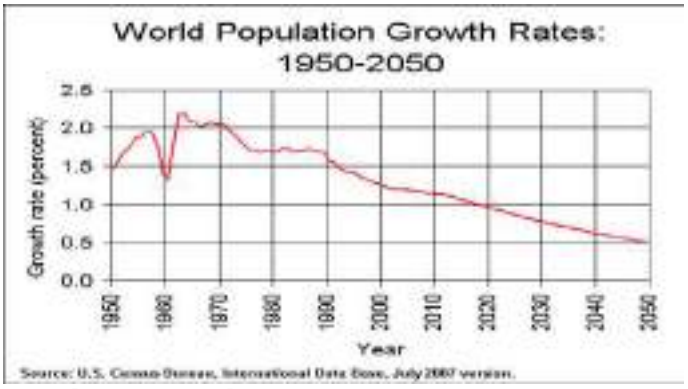

Figure 2. World population growth rates: 1950 – 2050. (Source: US Census Bureau, International Database, 2010)

An influential research example analyzes the possible near future influences of the recent demographic structure of the European Union (EU). At the 2nd Organization for Economic Cooperation and Development (OECD) world forum, Rainer Muenz was trying to draw attention to the rapidly ageing demographic structure of Europe by stressing that Europe is facing the lowest fertility rates ever recorded in the history of mankind (Muenz, 2007). Almost all countries in Europe have a downward trend of total population, a fertility decline, and an ageing demographic structure, he expresses.

Table 1. Total (Period) Fertility Rates in the EU Region

	1960/64	1970/74	1980/84	1990/94	2000/03	2004/05	2050

United Kingdom	2.86	2.20	1.81	1.78	1.66	1.74	1.75
Turkey	6.18	5.68	4.36	2.99	2.42	2.20	1.85

Source: Eurostat from Europe's Demographic Future: Facts and Figures, 2007, p.17

2.2. The Demographic Change Trends of the National Level in Turkey

The TFR in Turkey in 2005 was 2.20 while it was 6.18 in the period between 1960 and 1964. In a forty-five-year period, therefore, the TFR has declined approximately 65 %. Having regard to this decline in TFR, the total national population in Turkey seems to stabilize and seems to decline in near future if this latest forty-five-year trajectory remains the same.

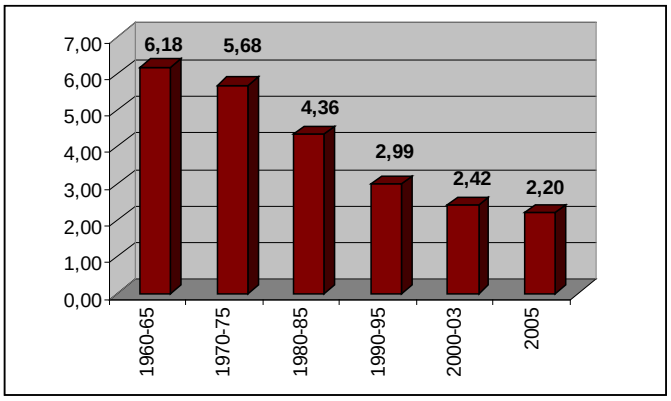

Figure 4. The national level TFR changes in Turkey in the period between 1960 and 2005 (Compiled from Europe's Demographic Future: Facts and Figures, 2007, p.17).

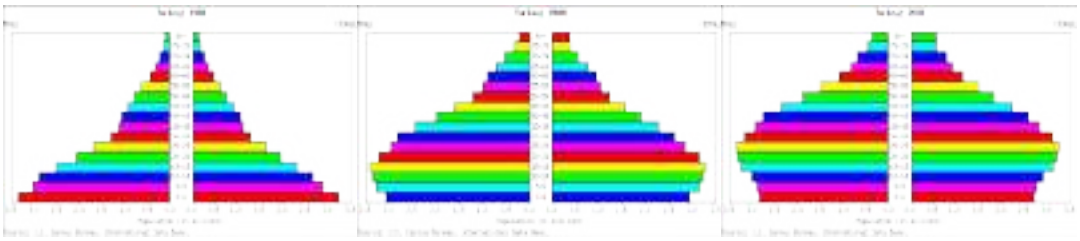

Figure 5. The national population pyramid of Turkey in 1980, 2000 and 2010 (Source: US Census Bureau, International Database, 2010).

In addition to the TFR decline trend shown in Figure 1, the population trajectory becoming much more apparent in the latest national population pyramid indicates the decline in the population increase ratios on the one hand and the shrinking proportion of the population of younger cohorts on the other. This trajectory, moreover, refers to a mid-term decline in the work force cohorts and to an increase in the population of the elder cohorts which indicates an increase in the elderly dependency ratios.

2.3. Contemporary Demographic Change Trajectories in Two New Industrial Districts of Turkey: The Towns of Gaziantep and Kayseri

Certain recent researches stress that the national level TFR change tendencies show some regional and geographical distinctions (Işık and Pınarcıoğlu, 2006). Despite some minor distinctions from one another, two new industrial districts of Turkey; the towns of Gaziantep and Kayseri, however, represent a similar trajectory to the national level changes. According to TURKSTAT data, the provincial TFRs in the year 2008 were as in the following: Gaziantep: 3.30 and Kayseri 2.56; thel TFRs in 2000 were: Gaziantep: 3.39 and Kayseri 2.51; and the TFRs in 1990 were: Gaziantep: 4.09 and Kayseri 3.64. There is a minor increase in the provincial TFR of Kayseri in 2008; however, the decline in the period between 1990 and 2008 is 29.68 %. Similarly, the decline in the same period in Gaziantep is 19.32 %. In the same period, the national level decline corresponds to 26.42 %. The rate of decline, therefore, in Kayseri is more than the national level, while the rate of decline in Gaziantep is less than the national level. All trajectories represent a decrease in TFR contrary to the trajectories of the period before 1980s. The population pyramids also represent a similar tendency.

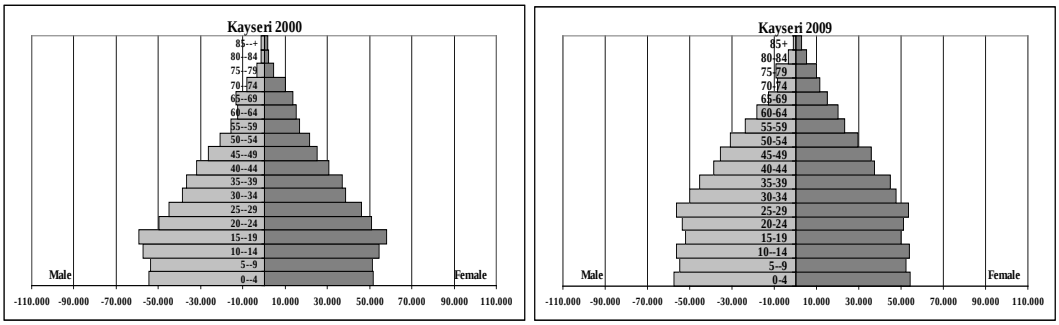

Figure 6. The population pyramid of Kayseri in 2000 and 2009 (Compiled from TURKSTAT census data).

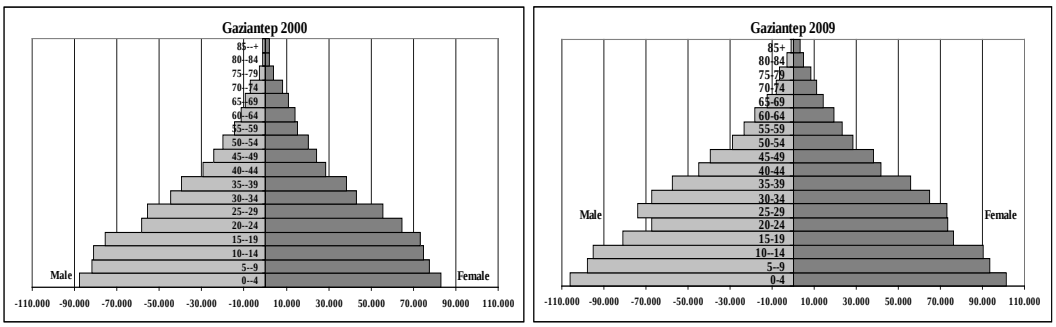

Figure 7. The population pyramids of Gaziantep in 2000 and 2009 (Compiled from TURKSTAT census data).

The change in the population ratios of working force and non-working cohorts in Gaziantep in the period between 2000 and 2009, however, seem to represent a coming decline particularly in the population of work force cohorts. In both towns, the population rates of younger cohorts have declined in this period while the population rates of elderly cohorts have increased. Table 2 apparently indicates the increase in the elderly dependency ratios and thus the population aging and the decline in the population rates of younger cohorts and thus the renewal rate of total population. In mid-term, both of these towns seem to represent similar demographic change trends to the national level trajectories and therefore, population aging, decline in the TFR and the dwindling proportion of population renewal rate seem to be the main determinants of the demographic structure of these towns.

Table 2. The population changes in Gaziantep and Kayseri in the period between 2000 and 2009 (Compiled from TURKSTAT census data)

Gaziantep	**2000**		**0-14**	**15-64**	**65+**	**Total**

3. The Rural-Urban Fringe

3.1. Theoretical Attitude toward the Rural-Urban Fringes

The post-war period after 1945 represents a major restructuring process both in economic and urban terms for almost all of the countries no matter if they joined the war or stayed as neutral countries. It is possible to distinguish between three significant realities of this period. Presumably, the most apparent one is the dominance of the Keynesian economics. In tune with the rise of welfare state and Keynesian economics, planned economy and planning profession itself had gained a central importance. The rapid population increase can be identified as the second clearly distinguishable realities of this period. It is not surprising that the short period after 1945 was called the 'baby boom' period in many countries. This generation is called the baby boomers. Rapid urban growth, fast urbanization and a higher amount of increase in the number of urban population than the total population can be identified as the most apparent consequences of this baby boom period.

This period also represents a beginning for an extremely high increase in urbanization in relation not only to the rapid population growth, but also to the industrialization based development strategies. Everything about 'urban' had become a focal point since development has been thought to be depended merely on urbanization; and thus industrialization. Even the indicators of development had been organized to measure the industrialization levels. The policies and strategies of this period have, therefore, focused on urbanization and industrialization. The dominance of welfare state policies and thus planned economy has paved the way of planning profession for a central importance. And central issues in planning were all related to 'growth' one way or another.

Drawing a brief perspective about how planning theoretically conceptualized the rural-urban fringe in a period in which 'growth' played the leading role seems to have a vital importance. The fringe has not been discovered recently, it has always been there in theoretical foundations of planning. It is possible to identify the first theoretical footprints of the fringe in von Thünen's influential work "The Isolated State in Relation to Agriculture and Political Economy" (von Thünen, 2009 [1863]) in a form of a dialectic between the core and periphery especially in 'Thünen's Rings'.

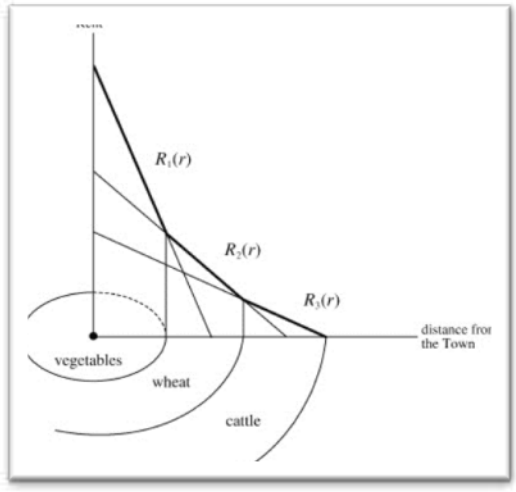

Figure 8: Thünen's Rings (Fujita, M., 2012).

Another influential study sharing a similar approach to the fringe with von Thünen's work is Walter Christaller's "Central Places in Southern Germany" (Christaller, 1966 [1933]). He identified the hierarchical relationship between the central places and 'hinterlands' wherein a dialectic between core and periphery results a hexagonal pattern of urban and regional services. In addition, McLoughlin (1969) draws attention to Charles Colby's (1933) study on 'centrifugal' and 'centripetal' forces in urban geography and puts that centrifugal and centripetal forces in cities have "the effect of concentrating certain activities and dispersing others respectively" (p. 62).

Besides, both in Burgess' (1968, [1925]) studies on concentric rings and later, Harris and Ullman's (1957, [1945]) influential conception on multiple-nuclei, it is possible to identify the core-periphery type of relations between the urban and fringe. The common point of all these fundamental theoretical studies of planning is that they all focused on center and central; and explain the peripheral within a context of core-periphery relations.

Adding the concept "land-use" within all these conceptions will pave a seminal way for the attempts of this study to understand the theoretical position of the fringe. According to those theoretical studies in which the land-uses occupy the focal point, the rural-urban fringe is a valuable part of urban wherein the land-uses which entails huge amounts of area usage and which should not be 'located' within the urban area are 'located'. Or it is the location for inter-urban and / or inter-regional heavy transportation. Especially in land-use based theories, as Gallent, Andersson and Bianconi (2006) put, "fringe is often seen as a degraded area, fit only for locating sewage works, essential service functions and other less than neighborly uses" (p. xv). Stuart Chapin, Jr. (1972) most remarkably puts the attitude of land-use based theories toward the fringe as in the following:

> *General principles relating to the location of land uses customarily identify three major functional areas in the urban complex: the work areas, the living areas, and the leisure-time*

> *areas. (…) The leisure-time areas are generally considered to include the major educational, cultural, and recreational facilities of the urban center consisting of colleges, museums, concert halls, libraries, colosseums, golf courses, large public parks and wildlife reserves for hiking, picnics and outings of all kinds, and similar facilities* (Chapin, Jr., p. 371).

> *(…)Intensive manufacturing: variety of site sizes for modern one-story or multiple-story buildings and accessory storage, loading and parking areas in close-in and fringe locations…* (Chapin, Jr., p. 372).

> *(…) Wholesale and related use areas: #2: range of choice in close-in and fringe locations, site sizes…* (Chapin, Jr., p. 373).

> *(…) Region-Serving recreation, education and cultural facilities: Major parks, public reservations and golf courses: acreage sites in fringe and outlying areas…* (Chapin, Jr., p. 374).

Finally, the attitude of growth-based approaches toward the fringe is tried to be shown. One of the basic methods of urban-growth based approaches is the threshold analysis. In their seminal work on threshold analysis, Kozlowski, Hughes and Brown (1972) define the thresholds as obstacles blocking minimum cost expansion opportunities of the urban areas.

> *(…) from which the most suitable physical growth directions for a town can be deduced. By estimating the threshold costs, indispensable for opening up new land for urban development, and by calculating the capacity of threshold areas (…) important data for determining the most viable possibilities for urban expansion taking into account existing physical conditions can be obtained. From this sequence in which adjacent areas should be developed can also be indicate (...)* (Kozlowski, Hughes and Brown, 1972, p.25-26).

According to their statements above, rural-urban fringes are considered to be the thresholds for urban expansion. To put in a nutshell, even though the fringe has not been discovered lately and it has always been there with the urban areas, many of the theoretical studies, owing mostly to somehow reasonable grounds, tend not to take care with the rural-urban fringes. The fringe has sometimes represented thresholds, sometimes been thought to be a ‘rational’ location for ‘less than neighborly’ land-uses and so on. In certain cases, the roles and usages of the fringe has not even been considered theoretically. The rural-urban fringe of the towns in Turkey stands for a remarkable example of these roles and usages.

3.2. The Rural-Urban Fringes in Turkey

To put it briefly, it is possible to observe similar notions of the rural-urban fringes of the towns in Turkey. But in addition to them, the urbanization process of Turkey entails identifying two important and, to a degree, peculiar characteristics of the rural-urban fringes which are, in turn, the slum house (gecekondu) areas and economically influential amounts of speculative investment on urban land. Every urban settlement, but especially the big towns, in Turkey has experienced rapid population increases and thus rapid urban growth for more than 50 years. During the

1970s, the increase rates of urban population reached a level way higher than the total population increase, and this 50-year-long period represents incredible amounts of population flows from rural areas to urban. Even the population projections of those plans which predicted the most reasonable increase and growth rates have become insufficient owing to population boom.

Slum house areas and urban land speculations have been two of the main agendas of both urbanization and planning profession in Turkey. And the basic spatial component of these two agendas was – and to a degree still is – the rural-urban fringes. Any attempt to consider the rural-urban fringe in Turkey in those times, therefore, seemed to be sentenced to become useless owing to the growth rates of towns. In some cases like Ankara, İstanbul and İzmir, and so also like Adana, Bursa, Gaziantep, Kayseri etc., urban expansion rates would have defied all attempts even to define a rural-urban fringe in a period when one year's rural has become the urban of another.

It seems totally reasonable for planning, both in practical and educational terms, to focus on dealing with urban growth and other related problems. But as underlined in the foregoing sections, the national demographic dynamics of Turkey has already begun to change and the influences of this demographic shift have started to be much more apparent. Urban transformation related issues and debates seem to capture the planning agenda in Turkey recently and urban growth and urban expansion seem to lose their central importance at least on popular grounds. Even though the urban transformation and renewal implications result an unnecessary density increase type urban growth (Hovardaoğlu, 2010b), the growth itself now seems to fail in attracting direct attention.

In tune with this shift, certain new usages seem to appear in the rural-urban fringes. Gated community type low density and high priced housing areas and big malls are the most popular ones located in the fringes. However, in many towns, the fringe has already occupied by slum house areas, industrial zones, certain public services and institutions which need big areas etc. In these towns, those popular uses need to jump over the 'traditional' land-uses of the fringe and they create new circles sprawling beyond the existing edges of the towns which of course results the existence of the speculative expectations. However, owing on the one hand to the jam within the urban area and on the other to the old habitual attitude toward the fringes, these areas have not been considered sufficiently enough to be components of neither the total quality of life nor the local development efforts especially in terms of professional and urban agriculture. Examining real examples from case studies can clear the ambiguity.

3.3. Some Key Evidences from two Major New Industrial Districts of Turkey

The towns of Gaziantep and Kayseri have experienced rapid population increases and rapid urban growth in the period especially between 1950s and 1980s. Even though the demographic indicators shown in the foregoing sections draw a similar

trend with the national tendencies, and the recent population increase rates have dwindled more than twice since the 1960s, urban growth still seems to be a dominant variable in their planning processes. Since 2005, particularly after the acceptance of new Metropolitan Municipality Law (Law no: 5216), the municipal area of these two towns have grown approximately ten times in hectares which results an inclusion of a huge amount of rural areas within the municipal borders. Although a contemporary law arrangement discusses to enlarge the metropolitan area into the provincial borders, this first 'municipal growth' paves the way for officially perceiving these rural areas as if they were the fringes of metropolitan towns.

Actually, many of these rural settlements, in a somehow commonsensical way, fit a definition of 'neither rural nor urban'. However, neither these settlements are from those places where 'urban' touches 'rural', nor do they fit a prevalent contemporary definition of rural-urban fringes if they are defined as "*that zone of transition which begins with the edge of the fully built up urban area and becomes progressively more rural whilst still remaining a clear mix of urban and rural land uses and influences before giving way to the wider countryside*" (Countryside Agency, 2002, in Gallent, Andersson and Bianconi, 2006, p.5). They seem more likely to fit a definition of 'near-rural' attempted to be explained in this study. And those areas, those zones of transition as defined above still seem to be left unconsidered. A brief look toward the rural-urban fringes of these two towns will ease to understand the actual relationship of these areas between the fully built up urban areas.

Figure 9. The current land-use pattern of the town of Kayseri (Archives of Metropolitan Municipality of Kayseri)

The traditional growth directions of the town draw a linear form begin from the city center to the west in one direction and to the north-east in another. The main land-uses have been located toward these directions but there has been a traditional bulb-

like growth direction towards north owing to the Sumerbank Textile Factory. On the opposite edges of the town, on the west and north-east edges, two industrial areas are located and one of them is already unified with another industrial area and shares a border with the free zone. The north and south edges of the town are surrounded by hills and mountains, and these edges can be characterized mostly by housing areas. It is possible to identify certain slum house areas especially on the northern parts of the west edge and southern edges. But these areas are not as prevalent as the ones in other major towns in Turkey.

Until recently the characteristics of the rural-urban fringes of the town did not have peculiar features when compared with most of the other towns in Turkey except those areas of orchard houses and Mountain Erciyes. But three important land-use types have begun to be apparent on the fringes of the town currently. The first one can be characterized by regional health services. On the northern part of the west edge of the city, a huge regional health campus with complex health facilities has planned to be located. The second one can be characterized by regional transportation services. On the west edge of the town, the construction of a freight village has been considered for some time. And finally, the third one is characterized by prestigious housing areas. On the south eastern part edge, the construction of this kind of houses has started. The local administration, however, does not have a special policy neither for rural-urban fringes, nor for the near-rural areas yet; although the administrators seem to be highly aware of a possible new type of competitiveness based on attracting especially qualified population (Hovardaoğlu, 2010a). The local administration of the town of Gaziantep also seems to be aware of this type of competitiveness and spent certain efforts to improve the total quality of life in the town. However, their policies have not considered special strategies for the rural-urban fringes yet.

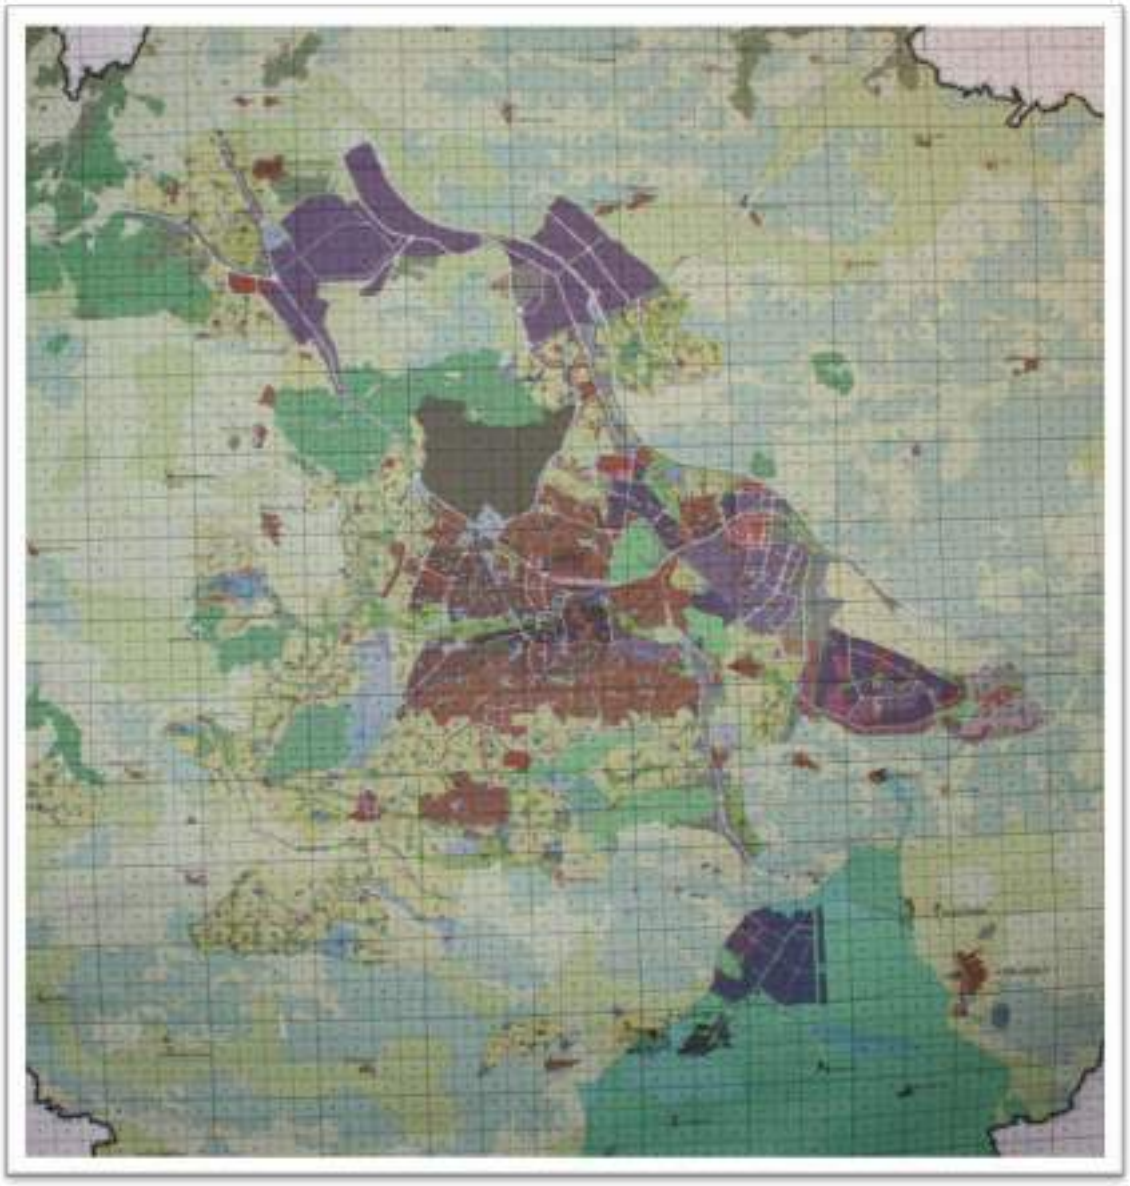

Figure 10. The current land-use pattern of the town of Gaziantep (Archives of Metropolitan Municipality of Gaziantep)

The industrial land-uses can easily be identified on the northern, eastern and southern edges of the town. But the actual distance and locations of these land-uses make it very difficult to relate the transition areas to the town, and especially on these parts, the transition seems to be ceased abruptly. There is a wide opening for the city, however, for such a transition especially on those parts begin from north-west edges and ends at south-west. This opening seems to give an opportunity for the town for a plausible rural-urban transition. In fact, it is already possible to identify some prestigious housing areas sprawling towards this opening which seem to be supported by the latest urban mass transportation investments. But still, the town does not have peculiar policies neither for fringes nor for near-rural areas.

4. Conclusion: Changing Context of the Rural-Urban Fringes and Near-Rural Areas

It is clearly possible to put that not considering the rural-urban fringes in conventional ways which tend to identify these areas in peripheral and rather passive terms can be much more helpful for those strategies attempting to improve the total quality of life with problem solving-based approaches on the one hand, ad to find alternative ways of development in an era of deindustrialization on the other. The fringe, today, represents greater amount of opportunities than anticipated in the traditional conceptions of planning. Not only do prevalent contemporary discussions in the planning suggest, but also the current demographic dynamics entail reconsidering a change in goals and tools of planning implementations. In fact, after an era dominated by the frantic increases in urban population and thus by advocacy of urban growth and growth management comes a time when these goals and tools once seemed solid and unshakable foundations of planning implementations turn into inefficient repetitiveness of routine blocking the way for seeking problem solving-based and quality-based approaches.

In this new era, if agricultural production – in professional and multifunctional terms – and urban life quality will be the two of the leading variables of development equation, then it is possible to put an obvious need of reconsidering rural-urban fringes and near-rural areas. Again, in this new era, if planning theoretically tends to reconsider or reimagine the urban in terms of mixed spatialities which are open and cross-cut by many different kinds of mobilities, from flows of people to commodities and information as, for instance, Massey, Allen and Pile (1999), Urry (2000), and Amin and Thrift (2002) put, then there will be an obvious need of reconsidering and reimagining the rural-urban fringes and near-rural areas as certain spatialities which convey much more than just being the opposite of urban.

Table 3. A Brief Look towards the Conceptions and Uses of the Rural-Urban Fringes.

	Traditional Conceptions of Planning	Conventional practical uses	Contemporary practical uses
Rural-urban fringes	- Thresholds which block alternative growth directions - Areas for specific land-uses which ***cannot*** be located within urban areas - Areas for specific land-uses which ***should not*** be located within urban areas - Low-priced peripheral areas - A tangent for certain uses which need to touch but do not	- Slum house areas - Waste-lands waiting desperately to transform into urban - Farmlands also waiting desperately to transform into urban	- Freight villages - Prestigious housing areas - Great malls & out-of-town retails - Areas for decentralized office space - Green energy production

	cut into urban areas like heavy transportation - Reserve areas for future expansion - Conservation areas like green belts - A hinterland piece connected to urban with dependency bonds - Areas for 'other' or 'excluded' less than neighborly uses - Areas for locating leisure facilities		- Conservation areas like green belts

To put in a nutshell, planning, especially in Turkey ad especially due to the current demographic dynamics, has a great opportunity to reconsider the rural-urban fringes and near-rural areas as vital components of both the development efforts and urban quality of life. In fact, these places seem to become the mıst valuable areas of urban agriculture and rural development.

NEIGHBOURHOOD DESIGN AND VMT: IS MALAYSIA PLANNING TO ACHIEVE THE SPIRIT OF NEW URBANISM?

M. Rafee Majid, Foziah Johar & Alia N. Nordin

Abstract

Urban population currently represents sixty eight percents of the total population of Malaysia, doubling its value of thirty three percents in 1970. By the year 2020, when Malaysia plans to achieve industrialised-nation status, about two thirds of the population will be in urban areas living in mass-produced housing schemes first constructed in the 1970s. Although travel modes have changed significantly in Malaysia along with the changes in the physical design of these housing areas, very little is known about how the changes influence household vehicle-mile-travelled or VMT. The effects of neighbourhood design on VMT are an important aspect to consider in our effort to reduce greenhouse gas emission. Thus, this paper presents the findings of a study carried out in the City of Johor Bahru, within the designated economic growth area of Iskandar Malaysia, to understand how the change in neighbourhood designs over the decades due to policies and lifestyles influences VMT. Fifty two residential neighbourhoods representing several decades from 1970s to the 2000s were selected and travel diaries of their randomly selected households were recorded. While the results obtained confirm the prevalent theory on the relationship between neighborhood design and VMT, unfortunately for the study area the average VMT has been increasing with the newly-designed neighborhoods. Increasing wealth and mobility apparently has seen increasing demand for neighborhood designs that are not as compact as the traditional ones and not as 'mixed uses' either. While the rest of the world is going for 'new urbanism', Malaysia which embraced its form of 'new urbanism' called 'mixed development' since 1970s is doing the opposite. As population of Johor Bahru is rapidly growing due to its location in the economic growth area of Iskandar Malaysia, serious rethinking of the current development policies is in order.

Keywords: Vehicle Miles Travelled (VMT), Sustainable Neighborhood, Neighbourhood Design

1. Introduction

Urban population currently represents sixty eight percents of the total population of Malaysia, doubling its value of thirty three percents in 1970. By the year 2020, when Malaysia plans to achieve industrialized-nation status, about two thirds of the population will be in urban areas living in mass-produced housing schemes first constructed in the 1970s. Over the decades, due to the economic and population growth as well as rapid urban development has been resulting in a tremendous increase of private vehicle ownership in Malaysia. Inadequate public transport availability and services worsen the situation. According to Malaysian Road and Transport Department (2011), the total numbers of privately-owned vehicles (POV) in Malaysia have reached 19,144,262 units. Among the units in 2011, Johor State with a population of 3.5 millions holds the second largest POV rate among the states in Malaysia with a total of 2,649,657 units. This POV rate is set to further increase as the population of

[1] Dept. of Urban & Regional Planning, Universiti Teknologi Malaysia, 81310 Johor Bahru, Johor, Malaysia. Email: rafee@utm.my

Johor is estimated to increase to 5 millions in 2025, with the biggest share of the increment will take place in the Iskandar Malaysia region.

Higher POV will increase the total number of travel trips which lead to higher vehicle-mile-travelled (VMT), thus resulting in traffic congestion and increased air pollution. Transportation, together with electricity and heat generation; manufacturing and construction; and residential have been identified as four main sectors that contributed to the greenhouse gas emission in Malaysia. However, research on VMT in Malaysia was barely heard off. Back in 2003 and 2007, it was used once as an indicator to measure road safety performance and as an indicator for international traffic safety comparison purposes. The parameter provides additional information about crash risk in terms of exposure for certain groups of road users. For instance, drivers who travel long distances are more at risk to be involved in an accident than those who make shorter trips (MIROS, 2011).

Therefore, it is the main objective of this study to investigate how changing designs of neighbourhoods in Iskandar Malaysia over the decades have influenced household VMT. The changing designs are described in terms of quantifiable characteristics including neighbourhood size, location of commercial zone, density, land use diversity, etc. The effects of neighbourhood design on VMT are an important aspect to consider in our effort to reduce greenhouse gas emission.

2. Residential development in Johor Bahru

After the 1997 monetary crisis, together with announcement of several physical and national plans, urbanisation of Malaysian cities intensified which saw a surge in the number of new housing projects or neighbourhoods that sprawled into rural area. Urban sprawling hit many cities in Malaysia, including Johor Bahru (Majid, 2011). Historically, residential development has been constantly happening in Johor Bahru since the 1980s (Table 1). Housing areas or neighbourhoods of many sizes were being developed each year with each new one was moving away from the city centre, encroaching into the rural area. This rapid urbanisation resulted in higher dependency on automobile as the preferred mode of travelling. Most of these developments are offered as mixed-used development where a diversity of land uses present ranging from residential to commercial and also industrial facilities in some cases. This is especially so for big development but some small ones offer only residential units, relying on the neighbouring developments for other facilities. Recent trend however has seen more and more exclusively-zoned developments offering only residential and recreational land uses which are not entirely a good idea if the city is trying to reduce household VMT.

Table 1. Development of Neighbourhoods in Johor Bahru over the years.

Year	No. of Neighbourhoods	Individual Size (acres)
Pre 1980s	7	From 35 to 251 acres
1980s	99	From 4 to 2000 acres
1990s	96	From 4 to 4800 acres
2000s	100	From 3 to 3200 acres

3. Neighbourhood Designs and Household VMT

Considerable amount of research has been carried out at varying depth trying to understand how built environment influences travel behaviour. Travel research by Cervero and

Kockelman (1997) has identified “three Ds” that influence travel demand and behaviour. They are density, diversity and design. Meanwhile, Ewing & Cervero (2001) and Ewing et al. (2009), next identified another “two Ds” which are destination accessibility and distance to transit.

Density refers to the variables of interest per unit area. The area can be gross or net, and the variable of interest can be population, dwelling units, employment, building floor area, etc. Ewing (1997) concludes that “doubling urban densities results in a 25-30% reduction in VMT or a slightly smaller reduction when the effects of other variables are controlled”. By other means, doubling urban density refer to compact neighbourhood. Compact neighbourhoods can degenerate vehicle trips and encourage non-motorized travel in several ways (Cervero & Kockelman, 1997). Furthermore, Cervero and Kockelman mention that by bringing origins and destinations closer together, the opportunity for resident to leave their car at home and walking or cycling to a destination will increase. In addition, compact neighbourhoods tend to have less parking, better quality transit services, wider mixes of land uses, and larger shares of low-income households, all factors that reduce car usage. In Johor, high density development can reach maximum of 60 units per acre (for apartments). However, high demand on landed houses, which particularly comprise of 8 to 40 units per acres, makes compact development not a development choice.

A simulation study by Kulash et al., (1990) and McNally and Ryan (1993) found that a connected or grid street design reduces VMT as well as slower average travel speeds. These support Calthorpe (1993)’s conclusions about the transportation benefits of neotraditional design, which connected street patterns reduces the distance of trip (with assumption trip frequencies are fixed). Research by Cervero and Kockelman (1997), found that neighbourhood with good design especially street pattern design and diversity will encourage people to commute by non-motorized modes. Their research result suggest “ a neighbourhood with all rectangular or square blocks could be expected to average nine more daily personal VMT per household than one with no quadrilateral blocks”. This is because rectangular or quadrilateral blocks (grid-like street pattern) will encourage walking since the interconnectivity between destination is higher. From the research, number of intersection (more intersection) helps fewer personal VMT per household.

Higher density is expected to reduce the need to travel long distances, thus lower the VMT. However, argument against this hypothesis by some scholar had made the literature on this hypothesis became ambiguous. Steiner (1994), in her review of literature on the link between residential density and travel distances conclude that resident of high density areas will travel shorter compared to resident of lower density areas. Differ with Steiner, Levinson and Kumar (1997), on the basis of their study across cities in the US with more than 1 million inhabitants, state the opposite. In their paper, they suggest that metropolitan residential density is principally a surrogate for city size. Large settlements offer more services and facilities, which could reduce travel distances and favour the use of slower transport modes and public transport. On the other hand, the dispersion of urban land use over a large area may lead to longer distances, which lead residents to use their cars. In addition, research conducted by Banister (1997) showed that average trip distances were shorter in larger settlement than in smaller settlement. This is because, inadequate or few public transport facilities require the resident to use their own car to get to the services and facilities that were also not provided in a smaller settlement. In Malaysia, neighbourhood size varied according to the land owner who developed the area. Thus, it may also associate with the changes of VMT in Iskandar Malaysia.

Using cross sectional data, Handy & Clifton (2001) and Bagley & Mokhtarian (2002) observed association between travel behaviour and neighbourhood characteristic are largely explained by the self selection of residents with certain attitudes into certain kinds of neighbourhoods. Residents will basically have their own preferences in choosing a neighbourhood. Those who are exposed with environmental friendly and low carbon programme may end up choosing a neighbourhood that promotes sustainable development (i.e. neighbourhood that provides special track for walking and cycling). Dieleman et al. (2002) who examined the issue with use of the Netherlands National Travel Survey, confirmed that both personal attributes and the characteristics of residential environments are determinants of travel mode choice and trip distance. However, home buyer with preferences to live near to their workplace, might not take neighbourhood design factors into consideration in buying a house.

New urbanism and transit-oriented development are some of urban design philosophies that have gained popularity in recent years as ways of shaping travel demand and lower the VMT. These urban design philosophies shared three common transportation objectives, which are to reduce the number of motorized trips, to increase non motorized trip (by foot or bicycle) and to reduce travel distances and increase vehicle occupancy levels (i.e. encourage shorter trips and more travel by transit, and ride-sharing) (Cervero & Kockelman, 1997). The New Urbanism principles synthesize a whole range of spatial patterns that are not only good urban design, but also fit in well with many other important planning goals including growth management, environmental protection and urban revitalization (Ellis, 2002). It promotes the creation and restoration of diverse, walkable, compact, vibrant, mixed-use communities composed of the same components as conventional development, but assembled in a more integrated fashion, in the form of complete communities (http://www.newurbanism.org/).

4. Materials and Method

4.1 Study area

The study area comprised of 52 neighbourhoods located within Iskandar Malaysia with irregular spatial shapes and has different land areas between 10 acre (minimum) and 3000 acre (maximum) (Figure 1). The average land area of neighbourhoods is about 1000 acres. Spatial data, including distance and area were obtained from Iskandar Region Development Authority, IRDA.

4.2 Data Collection

To understand the changing of VMT in Iskandar Malaysia, we conducted a survey of resident in fifty two selected neighbourhood located inner and outer from Johor Bahru City Centre. The selection of these neighbourhoods was mainly based on the time-periods during which they were developed (from 1960 till present).

The survey was conducted by means of distribution of travel diary and questionnaire among a school's students, with assumption that these students come from the neighbourhoods that their schools are in. Travel diary is a crucial method in order to obtain respondent vehicle miles travel data (see Cervero & Kockelman, 1997; Ewing & Cervero, 2001; Ewing et al, 2009). In this research, school student was asked to record their father or family vehicle odometer reading for one week. In addition, household data and travel data was obtained

using a questionnaire that was distributed together with the travel diary. The questionnaire consists of two sections, which are Household Demographic Data in section A, while section B gathers the Household Travel Information which includes: work trip, non-work trip, provision of public transportation, neighbourhood self-selection, travel frequency and travel attitude. Different with travel diary, in order to collect fair data, school students were asked to pass the questionnaire to their parent to be filled.

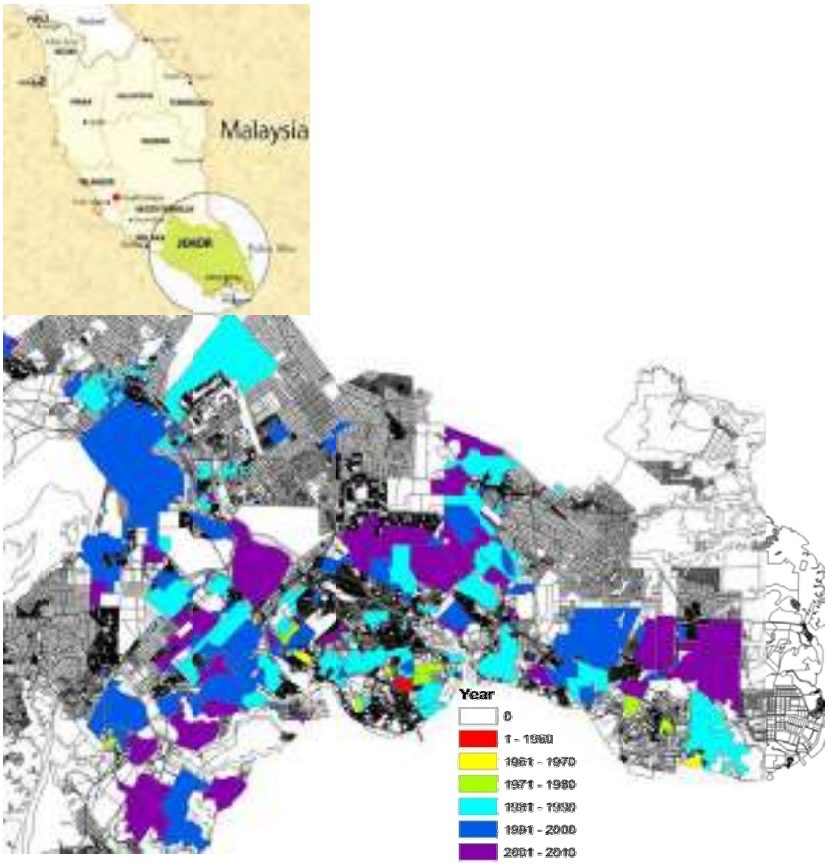

Figure 1. Residential neighbourhoods of Iskandar Malaysia by year of development.

5. Analysis and Discussion

Table 2 displays briefly the demographic characteristic of the respondents. From the survey, 69.44% respondent own at least one car, and 21.69% respondent own two cars. Respondent with more than two cars hold the lowest percent of car ownership with only 3.8%.

Table 2. Descriptive statistic travel data of neighbourhood by years

Building Decade of Neighbourhood	No. of Neighbourhood	Travel Distance (KM)	Household income (RM)	Household member	Car Ownership per house	License ownership per house
		Mean	Mean	Mean	Mean	Mean
Pre1980s	3	48.88	2722.22	4.44	0.8	1.67

The results of the VMT survey indicate that average daily travel per household increases against age of the neighbourhoods (Figure 2). Recently-approved neighbourhoods, i.e. new designs, tend to generate higher VMT compared to old ones. On average, daily travels range from 50 km/day for neighbourhoods built in the 1980s to about 100 km/day for those built in the 2000s.

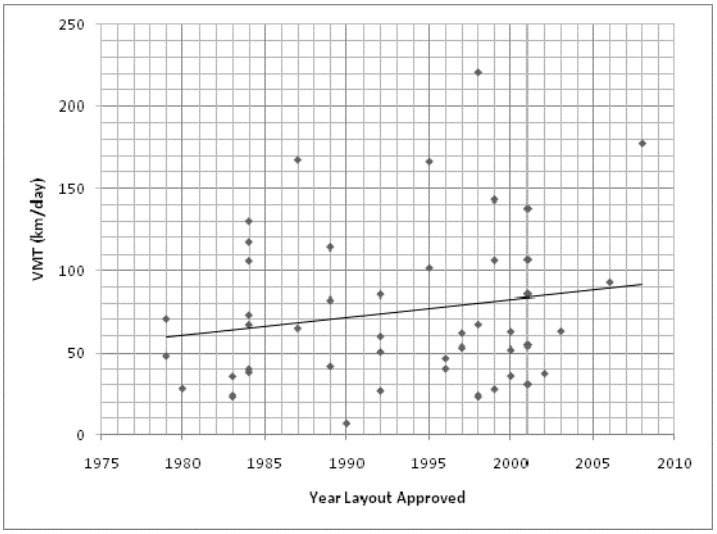

Figure 2: Higher VMT (km/day) are generated in recently approved neighbourhoods.

The values obtained have been controlled against the average household age and also against distance of neighbourhoods from the Central Business District (CBD) where most jobs are located. In this study, the distance of neighbourhoods to the CBD does not influence the total VMT generated by residents in respected neighbourhoods (Figure 3). This finding is opposite to that of Nasri (2012) which reported that neighbourhood distance to CBD is positively linked to VMT. Nasri (2012) concludes that longer distance from the CBD results in longer travel distance to reach various destinations. This, however, is only true if all those destinations are located in the CBD. In our case, only sixteen percents of the respondents work in the CBD. Besides, non-work travels are kept close to the respective neighbourhood and away from the CBD with all the services available nearby such as shopping malls, hypermarkets, linked shops and even offices above these shops. Thus, majority of the people no longer need to travel all the way to Johor Bahru City Centre to do their shopping or for work.

One factor that has been identified to have contributed to the increase of VMTs in those neighbourhoods is the diversity index. A study by Kassim (2012) has highlighted a progressive decrease of land use diversity in neighbourhoods in Iskandar Malaysia, including the neighbourhoods in this study. For plot of diversity index against age of neighbourhood, please refer to Kassim (2012). Figure 4 plots the VMTs obtained from this study against the diversity index from Kassim (2012) study for the neighbourhoods shared by both studies. The plot indicates that VMT increases as neighbourhood land use diversity decreases. Residents

of low land-use diversity neighbourhood will need to travel far in order to get to the facilities or services that are not provided within their neighbourhoods.

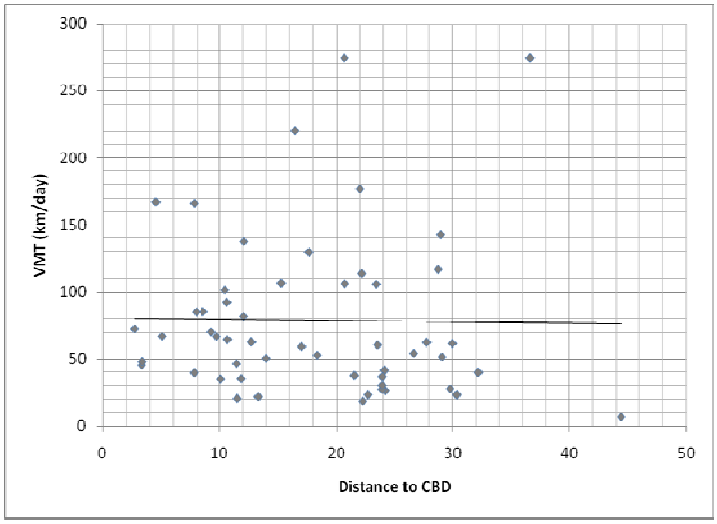

Figure 3: Distance from CBD has no effects on household VMT (km/day) for the study area.

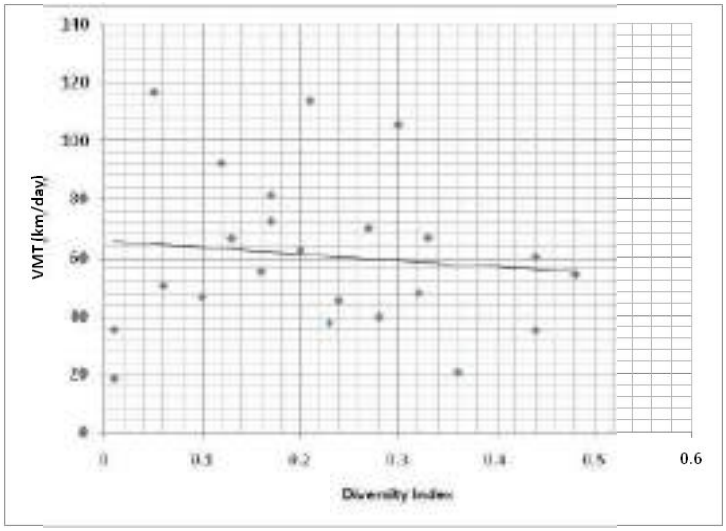

Figure 4: VMT (km/day) increases in neighbourhoods with low land use diversity.

Size of the neighbourhood and the location of the commercial area within a neighbourhood also influence VMT per household. Analysis of travel dairy against these two variables indicates that VMT is directly proportional to neighbourhood size but inversely proportional to the centrality of commercial area location (Figures 5 & 6). Centrality of commercial area location is crudely represented by the distance between the centroids of each neighbourhood area and its commercial area.

Currently Malaysia has no restrictions on where the commercial area should be located within a neighbourhood development. There are neighbourhoods with commercial area located at the centre which is alright but there are also commercial areas located at the

entrance or along the side of a neighbourhood development for various other reasons. There are some, due to their larger size, with more than one commercial area that are scattered over the neighbourhood. Locating facilities and services, i.e. commercial area, at the front and at the back of the neighbourhood, far from the residential area, forces residents to travel by car and over a longer distance. This situation is as explained by Levinson and Kumar (1997) that dispersion of urban land uses over a large area may lead to longer distances, which lead residents to use their cars.

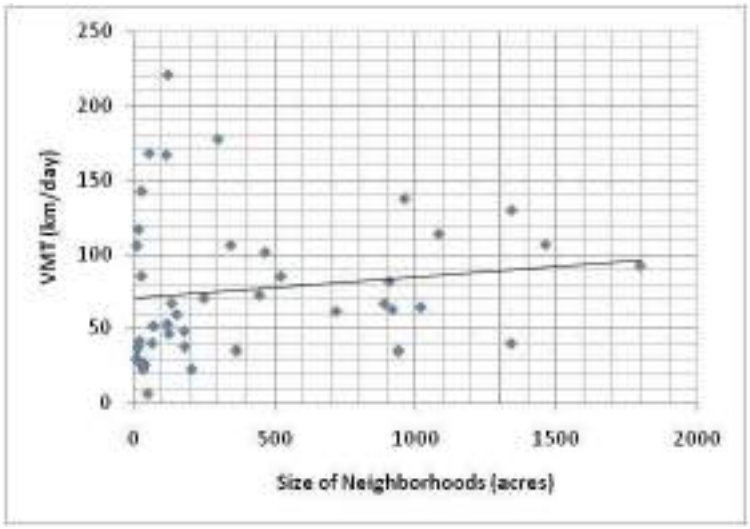

Figure 5. Vehicle Miles Travelled by Neighbourhood Size

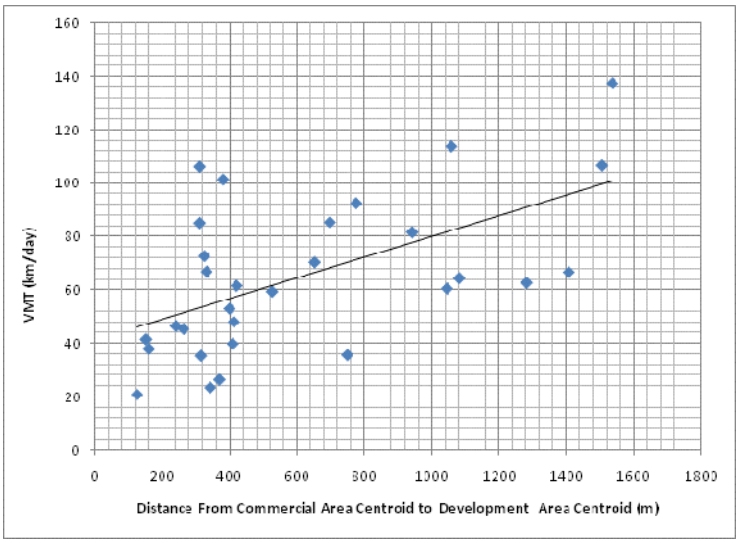

Figure 6. VMT (km/day) is also influenced by the location of the commercial area within the neighbourhoods.

Studies also show that density plays an important role in determining the size of VMT and higher density would normally result in lower VMT. It is however not true with the neighbourhoods studied in this research. It was found that VMT increases slightly with density. This is due to the fact that neighbourhood density is influenced by the size of the

neighbourhood. Smaller neighbourhood size will lead to higher neighbourhood density but with lower land use diversity. As a result, the VMT will not decreased even though the neighbourhood density is higher since the resident have to travel far to get to the facilities and services needed.

Finally, the last factor identified to influence VMT is neighbourhood intersection density. Theoretically, higher intersection density lowers VMT in the neighbourhood (Cervero and Kockelman, 1997) and grid-like street pattern encourages walking since the inter connectivity between destination is higher. The neighbourhoods in Iskandar Malaysia has, over the years, gone through a lot of changes with the street pattern from grid to cul-de-sac, loops as well as curvilinear, thus resulting in lower intersection density and finally lower connectivity index (Rusman, 2012). VMT analysis done in this study shows that VMT increases with the decrease in connectivity index which happens to keep decreasing as more recent neighbourhoods are shying away from the grid pattern into more aesthetic curvilinear pattern or more private cul-de-sac-dominated pattern.

6. Conclusion

The most important finding from the study in terms of effort to minimize greenhouse gas emission is that household VMT in Iskandar Malaysia is on the increase. More recent designs of neighbourhood seem to contribute negatively towards this, i.e. higher household VMT coming out from neighbourhoods developed the last couple of years than decades before.

Among the factors that contribute towards the increase in VMT are changes in lifestyles and preferences in housing that help shape the current neighbourhood designs. Neighbourhoods now are becoming bigger with less density and, unfortunately, less diversity of land uses. Those high density neighbourhoods are normally small ones exclusively zoned for housing, forcing the residents to travel beyond the neighbourhoods for amenities and facilities. Preference for curvilinear design rather than the higher connectivity grid design also increases household VMT.

While many cities are talking about reduction of VMT through better and compact designs, unfortunately for Iskandar Malaysia the average VMT has been increasing with the newly-designed neighborhoods. Increasing wealth and mobility apparently has seen increasing demand for neighborhood designs that are not as compact as the traditional ones and not as ‘mixed uses’ either. Thus, Malaysia in general and Iskandar Malaysia in particular are taking its mixed development concept, which has been initiated since the late 1970s, further away from the New Urbanism concept while the rest of the world are embracing New Urbanism. This is cause for alarm as Iskandar Malaysia is targeting to increase its population from the current 1.5 million to 3.0 millions in 2025.

REJUVENATION OF HOUSING DEVELOPMENT THROUGH COLLECTIVE SALES LEGISLATION

by

Dr Lim Lan Yuan

National University of Singapore

Abstract

Real estate goes through a life cycle from the predevelopment to the redevelopment stages. However, with the building of more multi-owner residential communities in the form of strata-titled developments, it is difficult to consider redevelopment as it is necessary to secure the consent of all owners to proceed with the redevelopment exercise. This paper discusses the planning strategy adopted in Singapore to undertake the rejuvenation efforts to ensure that the city-state would continue to be built with vibrant and modern residential developments. The pros and cons of such a strategy using the collective sales legislation are discussed. The collective sales law allows a majority of residents rather than all the residents to agree to the sale and redevelopment of the existing old developments. The legislation has been a subject of much criticism the main of which are the uprooting of existing owners, and the waste of building resources because of the demolition of fairly new buildings. This paper puts forth some recommendations for a modified strategy to ensure a more orderly and productive use of resources. The rejuvenation strategy, however, has useful relevance for speeding up urban development in a densely populated city.

Keywords: collective sale, rejuvenation, residential development, Singapore

1. Introduction

Land is generally developed to satisfy a particular function, typically by the building of a structure. There is a distinct cycle in the demand for developed land and in the ability of a built-up property to satisfy the market needs. An important concept in understanding urban planning and development is the life cycle of a property. This concept explains the evolution of the property from the beginning as an undeveloped land through the completion of the building to the end when the structure is demolished and the site re-developed.

This rhythm of obsolescence and renewal in a property over its life is known as the theory of property life cycle (Thorncroft, 1969). The planning and design of the development signifies the first stage of a property life. It carries on through its construction and completion. And finally, with the passage of time, a building becomes obsolete when it is physically exhausted or when it is no longer economically worthwhile to keep it in use, and a decision may be made to redevelop the property.

The redevelopment initiative is easily undertaken when the land belongs to a single owner. In the context of multi-owner residential developments in the form of strata-titled development, it is difficult to consider redevelopment as it is necessary to secure the consent of all owners to proceed with the redevelopment exercise. This impediment is serious in a country which is highly urbanised and subject to rapid changes in the environment. The purpose of this paper is to discuss the planning strategy adopted in Singapore to undertake the rejuvenation efforts to ensure that the city-state would continue to be built with vibrant and modern residential developments to meet the needs of the new environment.

2. High density and strata developments

High residential densities have become an increasingly important feature of compact urban environments like Singapore and Hong Kong. While there have been arguments against high density living such as congestion (Mitchell 1971), overcrowding (Baum and Davis 1980), and difficulties of maintenance (Dredge and Coiacetto, 2011), there are positive reasons for encouraging high rise developments. Some of the advantages of high residential densities include equitable access to a range of key services within walking distance and the development of a strong local identity. However, in view of the urban planning challenges in most capital city cities, the trend is towards higher and not lower densities. These challenges include reduced availability of land, the need to accommodate growing urban populations and the need to ensure economic viability of public transport systems and other community infrastructure.

There is considerable consensus nowadays that medium-density and high-density development will provide the major source of urban housing in the future and is a key response to urban planning challenges in most capital city cities (Randolph and Easthope, 2007). Indeed, increasing density through the adoption of median-density and high-density residential development is thought to improve the efficiency of urban settlement patterns and achieve more sustainable urban forms (Randolph, 2006).

Strata title provides a key property rights mechanism to deliver medium-density and high-density development. A strata scheme is a development or collection of buildings where individuals have title to, or can own, a small portion known as a lot, and share access to and responsibility for the maintenance of common property which is jointly owned by all the owners. In an apartment building, a buyer purchasing a unit would receive title to a lot comprising a private apartment and a share in the common property that includes areas such as lifts, stairwells, car parks, recreation facilities such as pools or tennis courts. Most compact cities have legislations providing for the building of such multi-owner developments. Similarly Singapore introduced the Land Titles (Strata) Act in 1967 to provide for such developments.

3. Studies on rejuvenation and reurbanisation

In a modern urbanised city, several medium and high density structures are a common feature of these cities. However, when high-density developments reach their old age and become functionally obsolete, rejuvenation and renewal would have to be considered in order to retain the vibrancy of the urban city.

Urban decay is an inevitable result of growth of a city based on the property life cycle (Thorncroft, 1969). However, urban regeneration is not a "slash and burn" process (Planning and Lands Bureau, 2001). It is a process by which dilapidated structures and deteriorated buildings are improved through various means, ranging from upgrading, modernisation, rehabilitation, and redevelopment (Prasad, 1989).

Urban regeneration has been defined as "….comprehensive and integrated vision and action which leads to the resolution of urban problems and which seeks to bring about a lasting improvement in the economic, physical, social and environmental condition of an area that has been subject to change" (Roberts 2000 p17). The primary aim of urban regeneration is to upgrade a whole neighbourhood through improving blighted areas, ameliorating traffic situation and providing open space and better urban infrastructure (Couch, 1990; Zielenback, 2000).

Most of the previous studies discussed the challenges encountered in the urban regeneration process. Poor institutional arrangements (Adams and Hastings, 2001), non-people-centred policy (Ng et al, 2001), and dislocation of people (Sigsworth and Wilkinson, 1967) are some of the difficulties encountered. In some counties, governments are blamed for their ad hoc and patchy efforts in urban regeneration (Yung and Ho 2008).

Over the past decade there is evidence suggesting that many countries such as many English cities are experiencing a degree of reurbanisation with the emergence of city centre living after numerous years of counter-urbanisation (Couch et al, 2009).

Private housing investment in these areas has re-emerged during the 1990s and has become an established trend during the 2000s. The process of reurbanisation involves the movement of people back into the cities, and the repopulation of the city centre and inner ring. It has been argued that reurbanisation represents a phase of urban development in the urban lifecycle model (van den Berg and Klassen, 1987).

However, the redevelopment of a site with existing old structures, and the repopulation of the site require much efforts. Very often they could only be undertaken with the support of legislative powers. In the context of housing developments which are owned by multiple owners such as strata titled developments, the decision of each of the owners has been to be obtained before a redevelopment initiative can be undertaken. To overcome the difficulty, Singapore's government introduced an amendment to the strata title legislation in 1999 allowing a majority rather than all residents to agree to the sale and redevelopment of the existing old developments. This has facilitated the rejuvenation process as a few minority owners cannot now upset the initiative. The legislation has, however, been a subject of much debate and criticism the main of which are the uprooting of existing owners, and the waste of building resources because of the demolition of fairly new buildings. The following provides a detailed description of the approach to rejuvenation planning in Singapore.

4. Collective sales legislation

In Singapore, a strata title development may consist of purely residential, commercial or industrial premises or any combination of these properties. The nature of these developments is typically high-rise and high-density. The residential developments, mainly condominiums, must have a minimum plot size of 0.4 hectare. The larger condominiums are provided with the full range of amenities and facilities such as car parks, swimming pools, saunas, gymnasium, squash and tennis courts, putting green, clubhouse, a multi-purpose hall, barbecue pits, supermarkets and shops. The smaller condominiums may only be able to provide a small swimming pool. A 24-hour security system is a common feature in many condominiums.

The body corporate which is known as management corporation comprises all owners of the strata development. To enable the management corporation to obtain the necessary funds to carry out its duties and functions, it is empowered to levy contributions determined by it at a general meeting. Each subsidiary proprietor or owner is required to contribute an amount proportional to the share value of his respective lot. The share value is commonly allotted based on the floor area groupings of 100m2 (or 50m2 for newer properties). A larger unit with a higher share value would therefore contribute a higher levy.

An enbloc sale or a collective sale refers to the sale of the properties owned by individual owners in a strata titled development undertaken collectively to a purchaser who is usually a developer. In other words, the sales of these properties are undertaken together at one go simultaneously. The process for an enbloc sale is provided by an amendment in 1999 of the Land Titles (Strata) Act (Cap. 158), which is explained as follows:

- For developments less than ten years old, the owners with at least 90 per cent of the total share values and at least 90 percent of the total strata areas must agree to the enbloc sale. For developments ten years or more, the owners with at least 80 per cent of the total share values and at least 80 percent of the total strata areas must agree to the enbloc sale.
- The sale committee comprising up to 14 members must be elected at a general meeting of the management corporation by an ordinary resolution.
- General meetings must be called to consider the appointment of lawyer, property consultant and marketing agent, the apportionment of sales proceeds, the terms and conditions of the collective sale agreement, and the terms and conditions of the sale and purchase agreement.
- A lawyer must be present to witness the signing of the collective sale agreement to sell the properties.
- Owners are given a five-day cooling-off period after signing the collective sale agreement but they can change their mind only once.
- The sale must be by public tender or auction, after which negotiation is possible if the reserved price is not obtained but the negotiation must be concluded within ten weeks.
- A four-weekly report must be given by the sale committee to keep the owners updated of the progress of support by the majority.
- A valuation report on the worth of the site as at the date of the close of the tender is required to be carried out (Lim, 2010).

5. Impact of legislation on development

The amendment to the strata title legislation enabling collective sales has the following impacts on urban planning and development.

- Enbloc sales are undertaken because a greater potential is possible when there is a higher plot ratio is allowed on the site. The existing site may be under-utilised, that is, not fully developed or the existing building is already physically obsolete, and need to be re-developed.

- Enbloc sales provide an important source of vacant lands which will hasten the redevelopment process in a highly built-up city.

- The redevelopment of older buildings will yield modern and vibrant projects with up to date features, amenities and design. A necessary element in a rejuvenation project is physical improvement (Jeffrey and Pounder, 2000).

- Investments in development projects will contribute to the economy. As new investments are always larger than the value of existing developments, they would promote economic activities.

These positive impacts are beneficial for a compact city like Singapore which provided private owners the opportunity to redevelop their existing old buildings and rejuvenate the environment, and for the planning authority to better plan the overall physical landscape and infrastructure of the city.

Despite the various positive impacts, there are also negative influences of the collective sale law on planning and development. They include possible social disturbance and the destruction of social networks of existing residents and communities (Needleman, 1966), the displacement of businesses (Thomas, 1977) and the waste of building stocks if the existing developments are fairly recent. These are some of the reasons why rehabilitation rather than redevelopment is preferred. There is therefore the need to consider the balance between retaining existing social communities with a strong sense of belonging, and redeveloping an old site to a modern, vibrant neighbourhood in line with the changing trend and developments of the surrounding environment.

6. Recommendations

The two key criticisms of the rejuvenation approach adopted in Singapore are that building resources are wasted, and the untimely dismantling of existing homes and neighbourhoods. The following are proposed solutions that may help reduce the objections raised.

In order to overcome the demolition of fairly new buildings and the uprooting of existing communities, a longer period may be mandated before a collective sale is being considered. In other words, no collective sale should be undertaken unless the buildings are say, at least 20 years old. An exception can be allowed for buildings which are in a poor state of repairs. To identify such buildings, a government or an independent professional review panel can be established whose function is to assess the state of repairs of the building. Developments which are in a good state of repairs and functional would not be approved for collective sales.

Alternatively, a higher percentage of owners' approval may be considered for collective sales. In other words, for developments less than ten years old, the law may provide for owners with at least 95 per cent of the total share values and at least 95 percent of the total strata areas must agree to the enbloc sale. For developments ten years or more, the owners with at least 85 per cent of the total share values and at least 85 percent of the total strata areas must agree to the enbloc sale. A higher majority level of owners required for the approval of collective sale will certainly help to prevent strong existing communities from undertaking collective sales.

Whatever new proposals are introduced or imposed to overcome some of the negative influences of the collective sale law, there is a need to strike a balance between retaining existing development and undertaking redevelopment. In a situation where the building maintenance has not been properly taken care of, the city would be filled with old and dilapidated buildings. The benefit of a redeveloped neighbourhood would certainly outweigh that of retaining the identity of the existing communities located in an unpleasant environment.

7. Conclusion

In a highly compact city and where housing developments are jointly owned by multiple owners, opportunities should be provided to allow these property owners to decide on issues governing the retention, upgrading and redevelopment of their developments. With rapid changes in the environment and the advancement in building technology, property developments can easily become both functionally and economically obsolete. In addition, for residential developments, the changing lifestyles and rising living standards will exert a greater need for change for such developments to improve their facilities and services. All these developments affect the vibrancy and rejuvenation of an urban city.

The Singapore's approach to rejuvenating housing developments in the urban city is one useful planning strategy which can be adopted. This paper makes recommendations for ensuring a more orderly and productive use of resources to speed up the urban development process in a densely populated city.

Abstract

Urban public spaces are one of the fundamental elements in the structures of cities and these spaces play an important role in the social life of communities, and one aspect of social life is social values so there is a relationship between public spaces and social capital of communities. And this relationship is question of this research. This paper is assessing the relationship between neighborhood public spaces and social capital of one community, in doing so it investigate 2 neighborhood of Tehran, as Iran's capital and one sample of cites with rapid urbanization, both with same inhabitant period to eliminate its affect on the result, one of them with variety of public spaces and one without it, at the same time it investigate social capital in both neighborhoods according to residents point of view. Because of nature of this research mixed approach (quantity and quality method)are chosen and resident's point of view is obtained through interview and observation and questionnaire, the result shows that in the neighborhood with public urban spaces these values are stronger, but most of the Tehran's neighborhood suffer from this shortage so finally this paper provides a map of Tehran's neighborhood to show how are their condition in having this kind of spaces the results show that most of the neighborhood in Tehran lack this fundamentals as a basis for formation of community.

Key word: social capital, public space, neighborhood, Tehran City.

1- Introduction

Increasingly, national and local planning policies have supported the development of more sustainable communities in recent decades. Thus, governments require that 'livable communities' are created and new neighborhoods are designed to encourage social interaction.

This arises from the need to encourage more vibrant communities, it helps rebuilding local social capital. Local social capital is the 'glue' which binds people together in a neighborhood and encourages them to cooperate with each other. It is the local networks together with shared norms, values and understandings that facilitate cooperation within or among groups in a neighborhood. Individuals feel isolated and are untrusting without social capital and levels of cooperation in the neighborhood are reduced. In this sense public space as one the fundamental elements of neighborhood play a vital role in the shaping & promoting social capital as a fruit of social relationship. They act as a 'self-organizing public service', a shared resource in which experiences and value are created (Mean and Tims, 2005). The social capital of public space is wide ranging and lies in the contribution it makes to 'people's attachment to their locality and opportunities for mixing with others, and in people's memory of places' (Dines and Cattell et al., 2006). Although paying attention to concept of public spaces is becoming enhance in the urbanism literature these days but in Iran it seems this spaces have been reduced in the compare with last decades. Moreover, public space in Iranian cities promoted social interaction in the past. Before 1920, inside each "Mahalle" (urban neighborhood in Iran) we could find a variety of neighborhood public space. Some spaces were shared between some neighbors while others belonged to all residents of a Mahalle. Therefore, a basis was formed for different levels of social interaction between the inhabitants which consequently caused the local social capital to shape and improve. In Pahlavi dynasty that started since 1925 until 1979, significant interests in Modernization and tendencies to imitate Western urban planning were emerged. After 1960s, Iran led itself to a more rapid rate in its urbanization process urbanization. This transformation occurred because of brisk changes in social life, political structure and economic formations. As a result, a high level of rural-urban migration occurred. This process has intensified since 1976(The IRANIAN revolution and the war between Iran and Iraq). These rapid changes were the cause of great transformation in the form, function and meaning of neighborhoods. Evident shifts in the spatial organization and reduction of public spaces were the most significant signs of this change. Moreover, the recent Master plan of Tehran demonstrates the lack of urban public spaces designed for the purpose of people's social gatherings in the neighborhood (The Ministry of Housing and Urban Development, 2008).

So, this article aims to explain the relationship between public spaces and the concept of social capital and show how these spaces can shape and promote this concept in the neighborhoods.

Thus, this article surveys two neighborhoods that both of them have plan but they are different in distribution of public spaces.

2- The Social capital's definition

For the first time, the term of social capital was used in 1916 in an article[4] by "HanIfan" and it was raised in West Virginia University (Yaghoubzadeh, N and Amiri,P. 2011). The term to describe the tangible things that people used in everyday life is often used. This term later in the book "Death and Life of American Cities," Jane Jacobs were cited. Jane Jacobs stated that the impact of social networks within the old and historical contexts, urban and mixed urban uses a form of social capital and can maintain the cleanliness and safety and urban quality of life in the urban structure of the efficient role of urban life in the public arena are (Jacobs, j.1996). This term has little background in sociology and political management and training of the 1990s by scholars such as James Coleman, Bourdieu, Robert Putnam and Fukuyama were used (Navid,Y and Parviz ,A. 2011). Moreover, there isn't any agreement about social capital definition and it depends on the discipline. Because of the difficulties in defining social capital, authors tend to discuss the concept, its intellectual origin, and its diversity of applications and some of its unresolved issues before adopting a school of thought and adding their own definition (Adam and Roncevic 2003).

In this paper we survey different definitions and theories about it and finally determine some variable for measuring it. Dekker and Uslaner convey that Social capital is about the value of social networks, bonding similar people and bridging between diverse people, with norms of reciprocity (Dekker and Uslaner 2001; Uslaner 2001). Dekker and Uslaner (2001) posited that social capital is fundamentally about how people interact with each other. Knoke (1999) said that 'the process by which social actors create and mobilize their network connections within and between organizations to gain access to other social actors' resources' (Knoke 1999, p. 18). Portes (1998) defines it as 'the ability of actors to secure benefits by virtue of membership in social networks or other social structures' (Portes 1998, p. 6). Brehm and Rahn (1997) said that it is 'the web of cooperative relationships between citizens that facilitate resolution of collective action problems' (Brehm and Rahn 1997, p. 999). Moreover, 'Social capital can be defined simply as the existence of a certain set of informal values or norms shared among members of a group that permit cooperation among them' (Fukuyama 1997). Putnam defined it as 'features of social organization such as networks, norms, and social trust that facilitate coordination and cooperation for mutual benefit' (Putnam 1995, p. 67) and as the extent to which people in communities engage with one another and outside agencies that affect the quality of their lives (plamer, 2001). The social exclusion unit (2000) defines social capital as 'the contact, trust and solidarity that enables residents to help, rather than fear, each other' with vital resources such as community spirit. Whereas in the past, social networks were commonly based on proximity, they are now based more on work and interest groups. The strength of networks based on proximity has decreased because people know few of their neighbors, particularly in medium to high density areas and where there is high residential mobility. Pantoja (1999) identified a different set again, including: family and kinship connections; wider social networks of

[4] "The rural school community center" by Hanifan, LJ

associational life covers the full range of formal and informal horizontal arrangements; networks; political society; institutional and policy framework which includes the formal rules and norms that regulate public life; and social norms and values.

We know that there are approaches against of our idea. Critics of the social capital approach include RICHARD FLORIDA. In the rise of the creative class florida writes: 'A number of serious social commentators in recent years have urged us to recultivate and rebuild the old form of 'social capital' found in these communities. Such efforts are fruitless. Since they fly in the face of today's economic realities, a central task ahead is developing new forms of social cohesion appropriate to the creative age. All in all, we agree with FLORIDE and mentioned that social capital is made base on level, type, and strength of current relationship and public spaces promote the social capital that we want to extend them. Although there are critics such as mentioned, we can't ignore vital role of public space in the social and economic life of communities (Cowan, Rabert, 2005).

3- The Role of public space on promoting social capital

Public space (including street, street market, community center and park) is a vital part of everyday urban life. Public space is open to all, regardless of ethnic origin, age or gender and there isn't limited time for using it. Different age groups tend to use public spaces at different times of day and for different reasons. People spend time in the public space without spending money. Public space can promote neighborliness and social inclusion. The open spaces near our homes give us a valuable place to socialize with our neighbor, whether chatting over the garden fence or meeting in the local park. On the large scale, community gardens and city farms bring people together from different ages and cultures, and thus help to create a real sense of neighborhood. Another benefit of Public space is its potential as a venue for social event and shared resource in which experiences and value are created (Mean and Time, 2005).

In fact, we can't conceive space without social content and society without a spatial milieu. So, there is two-way relationship between them. Because people create and modify spaces while at the same time being influenced in various ways by those spaces. According to Gehl (2004), today, urban designers and planners focused mainly on human aspects of public spaces, and people response positively to be in such places (Daneshpour and Charkhchian, 2007). Urban design as knowledge that deals with the public realm- both physical and sociocultural- and the making of places for people to enjoy and use (Carmona et al, 2003), is able to encourage people to be present in urban spaces through promoting spatial qualities of public spaces within the urban areas. This will be led to social interactions in such spaces. Hence, it is clear that cities need sociopetal spaces in order to achieve the healthy, active and livable societies. Hence, by shaping that built environment, urban designers influence patterns of human activity and social life (Carmona et al, 2003) and Jane Jacobs as one of the adherents of the social usage tradition, emphasized their role as containers of human activity and places of social interaction and about replacing "art" by "life" pointed out that: The city could not

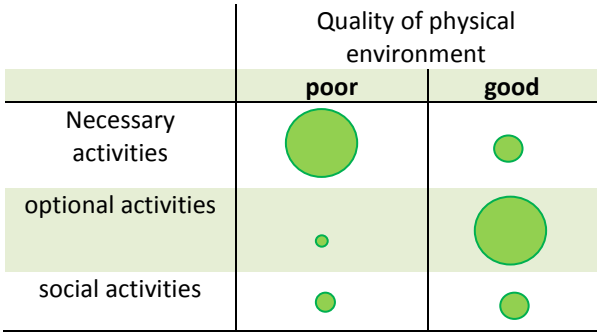
be a work of art because art was made 'selection from life', while a city was 'life at its most vital' complex and intense (Jacobs, 1961). The same kind of detailed observation informed subsequent work in this tradition such as Jan Gehl's studies of public space in Scandinavia (1971) and William H. Whyte's(1980) The Social Life of Small Urban Spaces (Carmona et al, 2003). The Important work on the role of space in the accumulation or building of social capital has also been produced Henri Lefebvre[5]. Lefebvre (1991) argues that city plans exist as representations of space while at the same time urban space itself is constituted by special practices of everyday life. Urban space must become the place where speech becomes a catalyst to reshape social relationships. Designing urban spaces that encourage social activity establishes an image of collective social life (M. Ijla, 2012).

The social space contains a great diversity of social objects which facilitate the exchange of material things and information (Lefebvre, 1996). So, urban space has to become a place where people enjoy spending their free time and sharing their common interests with others in that space. This interaction gives these public spaces the ethical and aesthetic power to build the social capital that underscores the stability of society, its common threads and interests, without destroying the uniqueness of any group.

With this background, we discuss Gehl's idea about public space. Gehl illustrates how the environmental quality of public spaces affects the intensity of their use. He argued that outdoor activities in public spaces can be divided into three categories – 'necessary' activities; 'optional' activities and 'social' activities. *Necessary activities (such as going to school or work or shoping, waiting for a bus or person, running errands and describing mail, etc)*include those that are more or less compulsory. *Optional activities (such as taking or walk to get a breath of fresh air, standing around enjoying life, sitting and sunbathing, etc)* are which activities that people participate in if they wish or have enough time to do. *Social activities (such as greetings and conversations, communal activities of various kinds, passive contacts, etc)* are all activities that depend on the presence of others in public spaces. Social activities occur spontaneously, as a direct consequence of people moving about and being in the same spaces. This implies that social activities are indirectly supported whenever necessary and optional activities are given better conditions in public spaces (Carmona, Tiesdell, 2007). The crux of Gehl's argument is that when public spaces are of poor quality, only strictly necessary activities occur. When public spaces are of higher quality, necessary activities take place with approximately the same frequency – although people choose to spend longer doing them – but, more importantly, a wide range of optional (social) activities also tend to occur (Carmona, Tiesdell, 2007).

[5] Lefebvre, Henri. *The Production of Space*. (Oxford: Basil Blackwell, 1991),34.

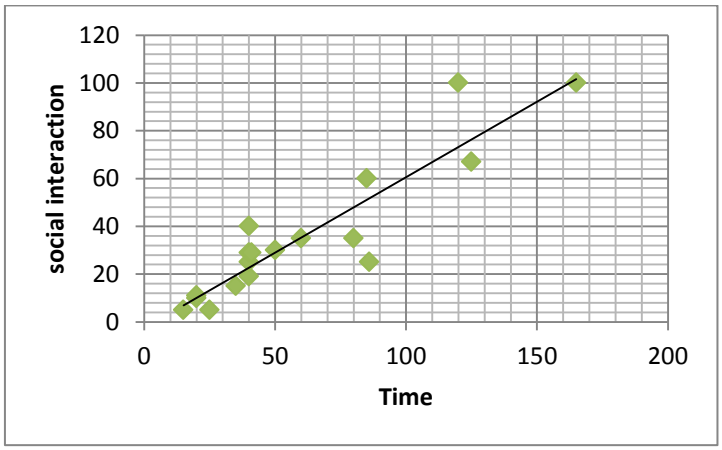
Figure 1: relationship between the quality of public spaces and the rate of occurrence of activities



(Carmona, Tiesdell, 2007).

This figure presents the relationship between the quality of public spaces and the rate of occurrence of activities. When the quality of public space is good, optional activities occur with increasing frequency. Furthermore, as levels of optional activity rise, the number of social activities usually increases substantially.

Chart 1: relationship between the number of public space and frequency of social relationship



(Carmona, Tiesdell, 2007).

This chart shows the relationship between the number of public space and frequency of social relationship. So the more time people spend public space, the more frequently they meet and the more they talk.

Another point is the use of semi-private space between private and public (or communal) space that can increase the threshold, as can good social relations between neighbors (Williams, J 2005). Semi-private space is very important in terms of social interaction. They provide a gentle transition between public and private space (Williams, J 2005). Increasing proximity through design increases repeated passive contacts between residents, which helps to form social relations (Williams, J 2005). Of course,

the importance of design in influencing social interaction but there are many other factors that many also influence social interaction, including: personal factors, informal social factors, formal social factors. But this paper just aims to figure out the issues involved in public spaces as representational spaces, and it also shed the light on the role of public spaces in creating social capital. Therefore social capital as a fruit of social relationship was shaped and improved by public spaces.

It has long been acknowledged that different housing neighborhoods acquire different social Relationship, meaning and identity (Douglas.R, et al.2008).There is a clearly related between neighborhood's physical and social dimensions. Among this, public spaces can affect both of two aspects – social dimension and physical dimension- Many commentators have discussed how spaces affect people, their feelings, behaviors and identity. (Ralph, Rappaport, Montgomery, Gehl, lynch…) but in this paper, we focus on social aspect of public space that shows in the bellow diagram. So bellow diagram shows the relationship between social and physical and perceptual dimension of public space and social capital. The quality of public space can influence on the type of activity and activity kind is related with social relationship so it promotes social capital. On the other hands, social capital can affect on the quality of public space, because there is two-way relationship between them.

Chart 2: the role of public space on promoting social capital

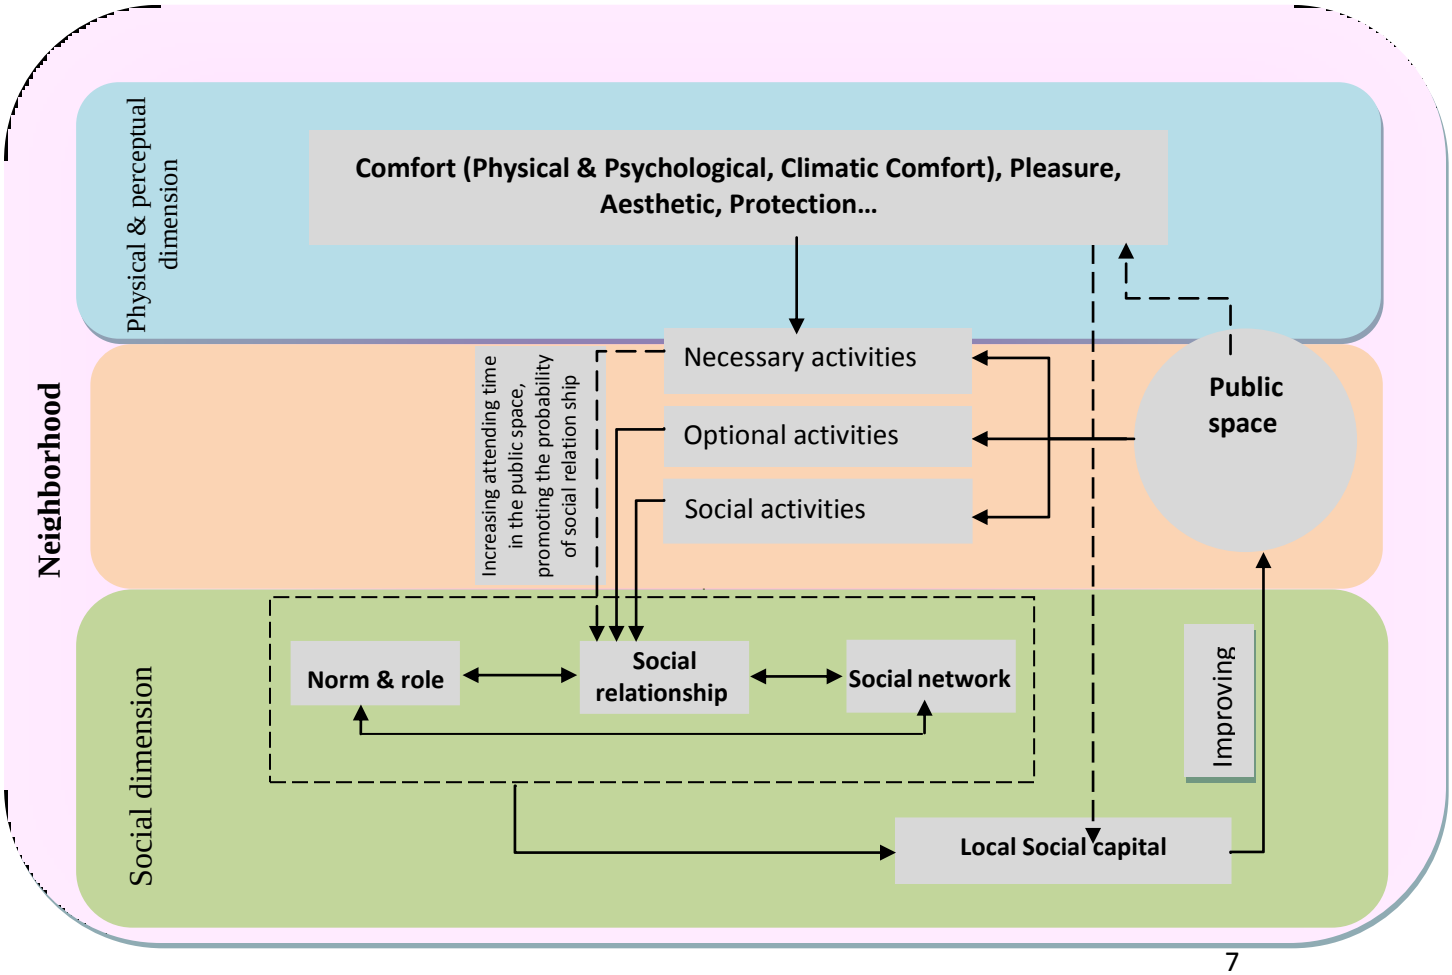


Table 1: Factors and Indexes of Social Capital and Related Theoretician

Factor	Index	According to who recognize
Rule & norms	1. Helping neighbor (care children or sick person) 2. Trust (the most people can be trust/ the most people are honest/borrow sth…) 3. Pride to neighbor 4. Level of integration & segregation	1. Jane Jacobs 2. Robert D. Putnam
Social relationship	1. Informal (family- friend- neighbor) 2. Formal (organization- association- colleagues) 3. Level of social relationship	1.Gehl 2. Whyte
Social network	1. Membership in some groups 2. Frequency of attending in public meeting 3. Frequency of participation in group or in election or in doing something in neighborhood as volunteer	1. Robert D. Putnam 2. Robert A. Hanneman

Some indexes aren't mentioned because they have multidimensional essence, they are made indirectly and with much relationship.

4- Research approach and methodology

This study draws on an exploratory research undertaken in the role of public spaces on shaping and promoting local social capital within two urban neighborhoods in Tehran: **"Nazi abad"** in the south west and **"Mehran"** in the west of Tehran. These two neighborhoods were selected based on a great difference between their spatial organizations. Both of them are middle class neighborhoods which have existed for more than 40 years, and at least two generations have lived there through this period.
Because of study nature, a mixed-methods approach was adopted, which have two parts: first part consisted primarily of first-person observation by the authors. The purpose of this study part was examining how, when, where, why the urban spaces are used. In other words, the difference of public life was tried to understand– public space in two neighborhoods. Many of the best commentaries on the use of public spaces and the function of these spaces in the public realm framework are based on first-person

observation: Death and life of great American cities[6], life between buildings[7] and the social life of small urban spaces[8].

The second part evaluates the role of public spaces on shaping and promoting of "social capital" in these two neighborhoods by quantitative approach (**questionnaire)**. Whereas In each of the two different neighborhoods studied, **norms and rules, social relationship** and **social network** as social capital's factors.

According to this structure, the questionnaire was designed to find out the role of public spaces on shaping and promoting social capital's indexes.

Table 2: The Related Question of Each Index

Index	Question
Rule & norms	- Interest in living in the neighborhood - Conveying that the character of neighborhood is good - Dislike to go to another neighborhood - Sense of supporting neighborhood and neighbor - The length of residence
Social relationship	- What do they do with friends/ family/ neighbors? - When/ where do they go? - Level of relationship - Like to have relationship with other neighbors
Social network	- Membership in some group (for example group of neighbors) - Frequency of attending in public meeting or memorial meeting - How many your friends live in the neighborhood?

Information presented in this report is the result of a survey done in four times; first on spring days in May 2010, second time winter days in February 2011, tertiary time summer days in august 2011and last time was autumn days in November 2011. In each neighborhood 100 inhabitants took part in the survey. As people's relation with public spaces differs according to their age and gender, therefore quota–a sampling method was selected for this survey. Samples were chosen based on the age pyramid of Tehran (according to national surveying 2007.)

[7] Jan Gehl,1971
[8] William H whyte,1980

5- **Case – study neighborhood**

Both neighborhoods that were selected for detailed investigation was officially started at the beginning of the 6th decade of 20th century, When Tehran as a capital of Iran are faced rapid urbanization. “Mehran” is located at the west of Tehran; in close proximity to the CBD whilst “Nazi Abad” located at the south of Tehran where so is far from city center and suffers from accessibility.

The communities contrast in terms of social, personal and design characteristic. The layout of the neighborhoods is different: “Mehran” uses a row layout and “Nazi Abad” uses clustering. The division of communal, semi-private and private space within the neighborhoods is also rather different. “Mehran” has no semi-private space and thus no buffer between communal and private space, whilst “Nazi Abad” has buffer zones (semi-private space) between private and public (or communal) space into the layout. Overall, “Nazi Abad” has more verity of public space than “Mehran”. There are more families that were lived in “Nazi Abad” than in “Mehran”, where are more couples and singles. But conversely “Mehran” has higher social status than “Nazi Abad” (Majid Mansoor Rezai, Shabnam Esmaeily, 2010).

Spatial organization of Nazi Abad *Reference: Author,2012*

Spatial organization of Mehran Reference: Author,2012

Table 3: Comparison of the Case Study Neighborhoods

	Nazi Abad	Mehran
Location	South of Tehran	West of Tehran
Being development	1960	1960
Area	248 H	257H
Residential Area	76.7 H	116.2H
Mean Residential Unit	118m	398m
Population	42874	22443
Density	591	193
Per capita Residential	16.9	51.77

Function	Residential/commercial /cultural	Residential
Current configuration	Perimeter block enclosing an open space	Terraced pattern (traditional street layout)
Block scale	Short	long
Transition from public to private space	Gradual	Rapid
Household types	Diverse—majority families but also couples and singles	Mainly a newly married couples and singles

6- Result

1-6- Observation

The purpose of this part of the paper is to examine how the urban spaces are used. It provides information on where neighbors walk and stay either as part of their daily activities and public life. Author's observation from Distribution of public spaces shows a major difference between two neighborhoods (Table.4).

Table 4: Distribution of public spaces in two neighborhoods

Nazi Abad	Mehran
There are various layers and types of public spaces, such as: parks, local public squares, leisure axis, a cultural center and wide and green pedestrian paths. "Nazi Abad" has a powerful centrality in providing a community center for the neighborhood Like any other neighborhood center for each "Mahalle" (Iranian old neighborhood), Nazi Abad's comprises a mosque, a public square and a Bazaar. The Central Public Square in "Nazi Abad" is "Bazaar Dovvom" and "Mada'en" street is defined version of Iranian traditional Bazaar. Due to successful pedestrianization and a vast range of activities, these spaces have become dynamic and vital locations.	Mehran neighborhood has two typologies of public spaces: Parks and a shopping Centre. The shopping center that named "Pardis Zendegi" is situated front of the most important neighborhood's park to the edge of "Abozar Street". Shopping Centre is a complex On four floors; it is based around a large covered square with seating areas, cinema, cafes, kiosks and ornamental features. In fact This complex has mutual relationship with park. Thus, community center was shaped in this part.The other outdoor spaces are car oriented and do not firm public realms.

Observations of the **"Nazi Abad"** showed that most social interactions tended to occur in communal or semi-private spaces. These interactions were classified as being: formal or informal; frequent or infrequent; and sustained or brief. Thus, sustained, formal social interactions are more likely to occur in communal spaces, whilst brief informal interactions are more likely to occur in semi-private spaces. Public spaces are

distributed all over the neighborhood and there are pedestrian accesses to all of them. Wide and green pedestrians, accessibility, street front and level activity encourage walking in the neighborhood.

In "**Mehran"** can't be found an impressive increase in the volumes of walking and other neighbor's activities in the public spaces in the compare with Nazi Abad. Most streets of this neighborhood were empty of people and social interaction, but parks are meeting places as the most important public space of neighborhood for old people in the morning and for young people in the evening. Moreover, these parks and Pardis complex are used by different age and sex. But in these spaces are done only optional activities. Another meeting place of the neighborhood is a fast food restaurant that even people in other neighborhood go there and young sons and girls go there with their friends. Although this restaurant attract a lot of people, it can't help reinforcing public milieu in the neighborhood. So the public life in Mehran is lower than Nazi abad. The variations in the types of activities within different spaces are summarized in Table 3.

Table.5: observation public life through public spaces

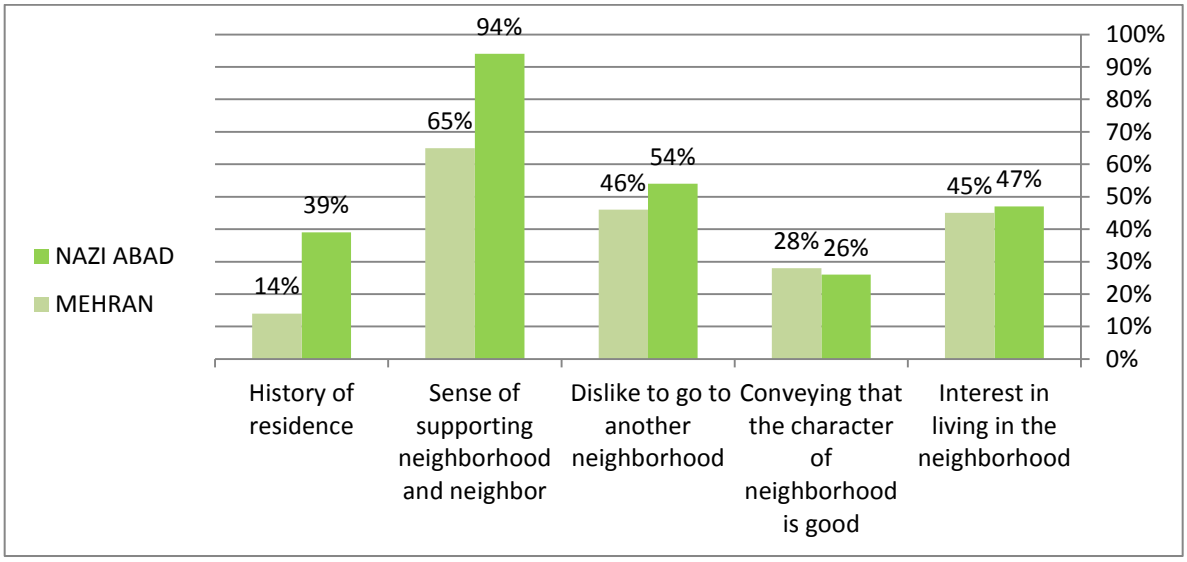
	Nazi Abad	Mehran
Interesting facades, window displays and exhibits		
Good walking rhythm with few interruptions in wide and green pedestrian		
Widespread secondary seating such as steps and edges of planter boxes		

pedestrian traffic in the evening		
neighborhood center		
semi-private space shared between neighbors		

2-6- The role of public space on social capital index according to inhabitant's approach

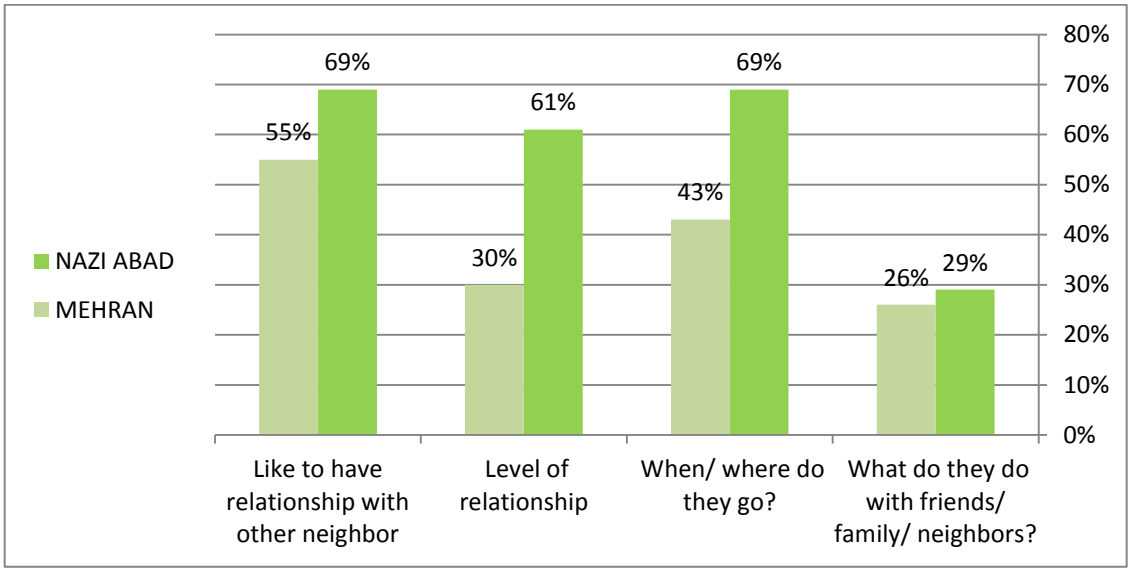
According to the theories, the social capital has three factors (role & norm, social relationship, social network). For measuring each factor, some questions are used that are presented in the bellow charts. The aim of the questionnaire is surveying the role of public space on social capital index based on inhabitant's approach. First, role and norm are surveyed. The average length of residence in Nazi abad is 28 years but it is 11 years in Mehran. Nazi abad inhabitants convey some good character for their neighborhood such as comfort (14%), good physical character of neighborhood (30%), capability of providing daily needs (30%), social cohesion (30%) and having social network (17%), but in Mehran this factors are comfort (37%), capability of providing daily needs (29%), good physical character of neighborhood (21%),good social character (23%). Thus, the average length of residence, sense of supporting neighborhood and neighbor, disliking going to another neighborhood, interesting in living in the neighborhood in Nazi Abad is more than Mehran, but considering good character for neighborhood in Mehran is more than Nazi Abad although the difference of them is miner. Finally, all questions are computed for measuring role & norm. It shows that role & norm in Nazi abad is stronger than Mehran.

Chart 3: The Related Question with Role & Norm



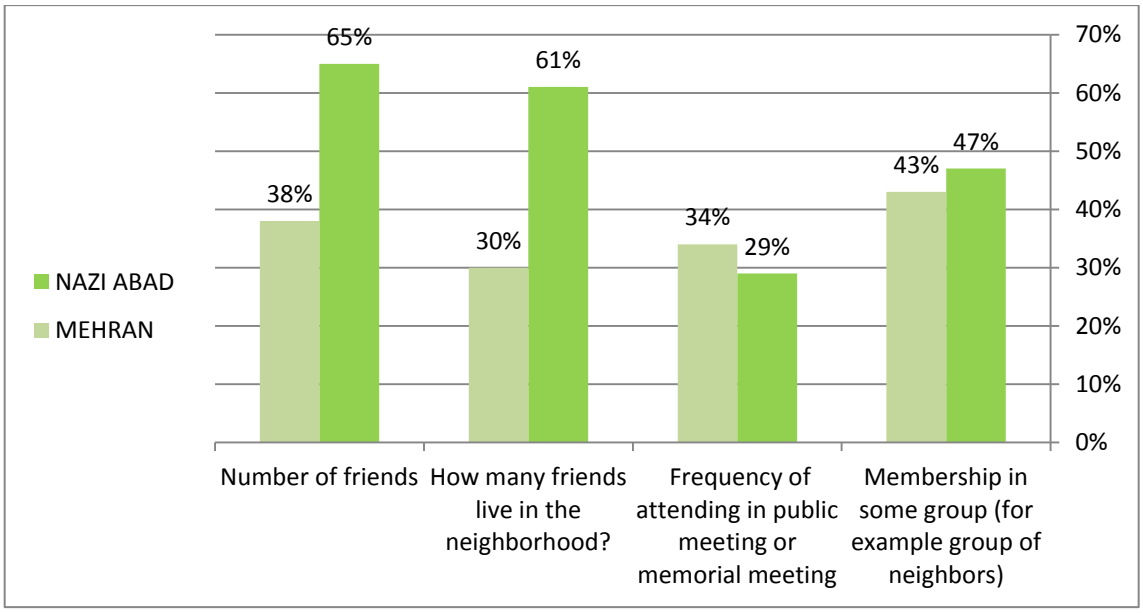
Nazi abad Inhabitants go to the public space for necessary activities (18%), optional activities (68%) and social activities (28%) and Nazi abad Inhabitants go there for necessary activities (4%), optional activities (57%) and social activities (26%). So according to the Gehl's approach they show that quality of public space in Nazi abad is better than Mehran. In Nazi abad resident go to park (34%), educational & cultural places (22%) and go to recreational & marketing places (34%) but in Mehran they go to park (67%), educational & cultural places (25%) and go to recreational & marketing places (2%). So bellow chart shows that all questions that are used for measuring social relationship in the neighborhood confirm that social relationship in Nazi Abad is more than Mehran.

Chart 4: The Related Question with Social Relationship



In Nazi abad they convey that they (57%) have many friends in the neighborhood and only some of them (5%) don't have any friend in the neighborhood but in Mehran they (29%) have many friends in the neighborhood and only some of them (14%) don't have any friend in the neighborhood. In Nazi abad they (68%) meet their friend in the neighborhood and only 23% of them meet their friend out of neighborhood, but in the Mehran they (42%) meet their friend in the neighborhood and only 37% of them meet their friend out of neighborhood. In the Nazi abad they meet friend in the known memorial meeting in the iran such as CHAHAR SHANBE SORY (18%), NIME SHANBAN (21%) and MOHARAM (46%), but in the Mehran they are CHAHAR SHANBE SORY (37%), NIME SHANBAN (22%) and MOHARAM (23%). So all questions except of frequency attending time in the public space or memorial meeting shows that social network in Nazi abad is stronger than Mehran.

Chart 5: The Related Question with Social Network



The analysis of social capital factors in two neighborhoods (Nazi abad & Mehran) shows that social capital in Nazi abad is stronger than Mehran. Because all indexes of social capital have higher rank than Mehran.

7- Conclusion

According to obtained Information from two neighborhoods, it is recognized that local social capital in "Nazi Abad" (neighborhood with verity of public space) is stronger than "Mehran". Also this paper result show how public spaces as a catalyst enable neighbors to build communities; to commit themselves to each other; and to knit the social fabric.

Based on this article's results, social capital and the representational space provide crucial insight in the role for urban planners in building social capital and stability for a society. Public space gives the opportunity for people to interact within the spatial environment they belong.

Whereas, recent Tehran development (after 1960) isn't paid attention to make new neighborhoods and redefine old neighborhoods according to require public spaces.

Tehran's urban management because of more income allocate more ground for residential land use and eliminate public and open spaces in neighborhoods. In fact they couldn't be called neighborhoods and merely they are residential districts like "Mehran". If we accept "Mehran" as a residential districts that doesn't have Variety of public spaces and suffer from lack of social relationship, participation, trust, social network and so social capital.

Most neighborhoods in Tehran are like Mehran according to low variety, distribution and accessing of public space. We don't convey in which of them social capital is low or strong because a lot of factors influence on it, but public space have fundamental role on it.

Social contacts are enhanced in a community when residents have opportunities for contact, live in close proximity to others and have appropriate space for interaction. Authors based on their knowledge about Tehran try to show that spread and development of Tehran neighborhood are like Mehran. So the convey that Tehran tend to be a city with non spaces. Bellow figure shows this reality in the Tehran's map.

Figure 2: Neighborhood Pattern in Tehran

PLANNING LOCAL RESPONSES TO THE ECONOMIC DOWNTURN: RHETORIC AND PRACTICE IN A SMALL PORTUGUESE MUNICIPALITY

Carlos Rodrigues[1]

Abstract

This paper analyses the planning of the local responses to the global crisis, giving particular emphasis to the relationship between rhetoric and practice. As such, it pays particular attention to the ways the planning process and outcomes are being affected by a planning-inspiring discourse that imports and, enthusiastically in the case of Águeda, uses the whole set of buzzwords wrapping up European development policy. The analytical focus is placed on the discursive line based on the Triple Helix Model. The paper argues that, despite the mismatch between the local conditions and the requirements of a true THM-based development path, the associated discourse and rhetoric is contribution to positively transform the territory.

Introduction

Águeda is a small municipality located in the Centro region of Portugal. The local economy, heavily dependent on an industrial basis made of SMEs operating in the so- called traditional, low technological content sectors, is suffering the effects of the current period of economic downturn. The local government is playing a prominent role in the attempt to mitigate those effects and the inherent planning effort is being directed at the design and delivery of a broad range of economic, environmental, cultural and social initiatives, which, in a way or another, are aimed at contributing to alleviating or even reverting the situation. This paper analyses the planning of the local responses to the global crisis, giving particular emphasis to the relationship between rhetoric and practice. As such, it pays particular attention to the ways the planning process and outcomes are being affected by a planning-inspiring discourse that imports and, enthusiastically in the case of Águeda, uses the whole set of buzzwords wrapping up European development policy – e.g., the green economy, smart growth, sustainable and inclusive development, energy efficiency, and climate change.

The paper draws heavily on experience, as the author has been actively involved in the planning effort that is taking place in Águeda. The views resulting from a (privileged) observation point are considered against the theoretical developments that are tackling the role discourse and rhetoric play in the design and delivery of territorial development policies. In this sense, by offering insights on how a globally-defined prevalent discourse influences the way a small municipality of a Southern

[1] University of Aveiro, Department of Social, Political and Territorial Sciences and GOVCOPP-Governance, Public Policy, Competitiveness Research Unit, Aveiro, Portugal – cjose@ua.pt

European country is responding to the crisis, the paper is an attempt to give a contribution to empirically enrich that burgeoning planning theory literature.

The state of the art (briefly taken...)

The use of language and communication in planning has been the subject of a prolific and controversial scholar work in the last decades (e.g. Tett and Wolfe, 1991; Throgmorton, 1993; Richardson, 1996; Jessop, 1997; Innes, 1998; Gunder and Hillier, 2009). Discourse, rhetoric, argumentation and so forth, have been placed under the spotlight by planning theorists, mirroring, in a way, the linguistic turn occurred within the social sciences (Rydin, 1998). Even planning *technical* tools, such as computer modelling, forecasting and survey research were studied as "*rhetorical tropes*" (Throgmorton, 1993, p. 334). However, the recognition that language and communication has a role in the planning endeavour can be regarded as a major reason for that interest, namely after the so-called argumentative turn (Fischer and Forester, 1993) and the rise of communicative (Sager, 1994; Innes, 1995) and collaborative (Healey, 1997, 2003) planning paradigms. As emblematic as it can be, Judith Innes's suggestion that "w*hat planners do most of the time is talk and interact*" (Innes, 1998, p. 52).

In this context, the emphasis placed by planning theory on language can be associated to the motivations underpinning the rising of the argumentative turn. Using the words of Fischer and Gottweis (2012, pp. 7/8), that emphasis stems from, on the one hand, "*the realization that public policy, constructed through language, is the product of argumentation*" and, on the other hand, "*the recognition that language does more than reflect what we take to be reality, [...] it is constituent of reality, shaping –and at times literally determining – what we understand to be reality*". This equates Maarten Hajer's idea that language can *create* the world, besides describing it (Hajer, 1993). Accordingly, language can be regarded as endowed with transformative power. The basic argument here is that it may change material conditions and even power relations (Khakee, 2000). Moreover, the argumentative turn in planning theory wrecked the positivist tradition according to which discourse was as a neutral means for describing the world (Hajer, 1993). In fact, the Habermasian communicative rationality empowering action, at the core of the new planning paradigms, turns language into a political, thus non-neutral, system of meaning which, in the words of Healey (1997, p. 277), is "*embodied in a strategy for action*". This political nature accommodates the claim for democratic, value-laden planning (Healey, 1997; Innes, 1998). Language, as such, emerges as a means to democratize the policy making process (Torgerson, 2003).

Several intellectual drivers guide the language related research in the planning field: from post-structuralism, such as the Foucault inspired studies (e.g., Richardson, 1996) or the Lacanian approaches (e.g., Gunder and Hillier, 2009), to neo-Gramscian appreciation of hegemonic discourses (e.g., Jessop, 1997). Within these approaches, many assume a critical stance towards what Khakee (2000, p. 122) would call the "*postmodernism´s requirement of a multitude of discourses that form the future*". In

fact, planning language is full of buzzwords, many more than the ten contestable words that make the "*game of buzzword bingo*" placed under the spotlight by Gunder and Hillier (2009).

Buzzwords pullulating in planning hegemonic discourses often shape the formulation and bear the legitimacy of ideas about what developmental action should be. They provide ammunition to the rhetorical devices (Throgmorton, 1993) that ground an arguably apparent mitigation of uncertainty about the future and the expression of desirable states of well-being (Gunder and Hillier, 2009). This can be associated with the deployment of an unquestionable '*truth*' about what should be aimed and done. Empty signifiers (Laclau, 1996) are instrumental here, since they have the power to lift buzzwords up to a state beyond question and critical enquiry (Swyngedouw, 2007).

Sustainability, as it would be revealed by a broad-brush literature survey (e.g., Gunder, 2006; Gunder and Hillier, 2009; Davidson, 2010; Swingedouw, 2010), stands out as illustration of something that, as a praiseworthy planning final goal, is beyond dispute and, above all, disallows dissensus or disagreement (Swyngedouw, 2010). Krueger and Gibbs (2007, p. 1) make the quantitative account: "[...] *over 6,000 local governments from 113 countries have adopted sustainability initiatives since the early 1990s*". Gunder and Hillier (2009, p. 20) associate this dominant planning narrative to the empty signifiers ability to act as a "*foil to give the appearance of doing something about global warming and the environment, when in effect it is largely deployed to maintain the priority on economic growth for achievement of global competitiveness*". This gives ground to the assertion that buzzwords like sustainability enter a hegemonic discourse meant to perpetuate the neoliberal *status quo* (Swyngedouw, 2007), in which market forces and concomitant focus on growth override a broader approach to societal development (ironically at the core of the sustainability '*triangular*' conceptualization).

To this argumentative line follows a critical stance towards communicative planning and its democratic ideal based on consensus building processes leading to collective action (e.g. Bengs, 2005; Purcell, 2009). The argument that the communicative planning paradigm favours the neo-liberal '*plan*' is attached to the ways academic ideas are traded on the intellectual marketplace, where they are subjected, in the words of Bengs (2005, p. 9), "*to the laws of rhetoric as are all other kinds of discourses*". The problem of unequal power distribution is also brought over (Purcell, 2009), originating the labelling of communicative planning as naïve, due to the impossibility of neutralizing power imbalances, i.e., of establishing the "*ideal speech situation*" (Habermas, 2001, p.102, cited in Purcell 2009). Allmendiger and Haughton (2012, p. 90) add to the critical ground by averring that the planning system "*gives the superficial appearance of engagement and legitimacy, whilst focusing on delivering growth*". This manipulative stance, according the same authors (ibid.), bears on "*some carefully choreographed processes for participation which minimise the potential for those with conflicting views to be given a meaningful hearing*". Language, obviously, is a central piece in the choreography...

This debate, though nurturing a burgeoning academic literature, is still poor in what concerns the *praxis* effects of the widespread planning language, that is, what is happening in the terrain[2]. This paper aims to humbly contribute to fill in this gap and, in a way, to know more about the power of discourse and rhetoric to brighten the dark side of planning that can be knitted together with the popular saying that *the hell is full of good intentions*.

The method and the research context

Following Winton (2012, p. 4), rhetorical analysis provides a method for knowing "*how arguments are constructed to persuade audiences to accept and support particular constructions of reality, truth, and courses of action*". In the context of this paper, the focus was placed on the construction of reality, truth and courses of action that took place at Águeda, a small Portuguese city of approximately 50 thousand inhabitants. Rather than using a formal method of discourse and/or rhetorical analysis, the research was heavily based on direct observation, made possible by the active participation of the author in the local policy making and delivery process, combined with the analysis of documental sources, namely policy documents, institutional WWW sites and newspaper reports.

The information gathered from these sources was analysed against the perception that discourse, namely if marked by incompletion, ambiguity, and contradiction, has the power, as put by Phillips and Hardy (2002, p. 1), '*to produce a reality that we experience as solid and real*'. The subsequent research step drew on an approximation to the three elements which, following Leach (2000), need to be considered when dealing with rhetorical analysis: exigency, audience and persuasive discourse. The final research stage was dedicated to appreciate the results of the discursive and rhetorical framework for action developed in the city under scrutiny.

Located in the Centro Region of Portugal, in between the two major national cities, Porto, up North (70km), and Lisbon, down South (250 km) Águeda presents as distinctive mark a long industrial tradition. Its economic structure is dominated by manufacturing industries (ca. 56% of total employment). The metal processing industry is the most important sector of activity, representing 41% of the total number of manufacturing firms and 33% of industrial employment. In addition, the sectors of ceramics for construction and articles of stoneware and earthenware, the manufacture of components and accessories for motor vehicles, and the production of furniture (mainly metallic) are significant for Águeda in terms of the employment structure.

The weight of SMEs is overwhelming. In fact, the number of firms with more than 250 workers is marginal and more than 92% of the total firms have less than 10 workers. Most of these firms are family-owned, with a business model centred on the

[2] Though, for instance, Raco (2005).

supply of standard products with a relatively low technological content. However, the capacity of these companies to compete in both national and international markets is fairly high (e.g. the municipality ranks third in the Baixo Vouga sub-region in terms of exports, being only superseded by Aveiro, the main city in the region, and Ovar, where several large multinationals operate), taking advantage from a variety of competitive factors, which range from low-skilled, low-cost labour force, to more innovation-related factors.

Águeda's endogenous entrepreneurial capability has highly contributed to the local economic success during the last century. A number of firms in various sectors of activity have been able to swiftly adapting to changes of international market demand. For instance, the metal furniture sector found a competitive advantage in developing areas such as design and marketing, and the lighting industry evolved towards more sophisticated products based on innovative design and technologies. This explains why Águeda was able to maintain a high employment level until the turn of the century. In fact, after decades of almost full employment, from 2001 onwards, the unemployment rate has substantially increased, trend that has been strengthened by the economic crisis. Manufacturing was the major responsible for this development. Between 2000 and 2009, for instance, there was a reduction of approximately 7000 jobs in manufacturing firms. According to the most recent data, the unemployment rate amounts to ca. 9% (against the national 15% mark).

Going beyond good intentions...

These recent developments in unemployment, as well as the crisis effects on firms' performance, as one could expect, have drawn the local government attention. They configure what can be regarded as the *exigency*, that is, the *defective* situation to be addressed (Leach, 2000). Local development policy has gained a new perspective, the one of fighting the impacts of the downturn. Nevertheless, the changing dynamics had already started with the election of a new political leadership in 2005. At the time, SMEs' competitiveness and innovation capacity were lifted up to the policy (discursive) core. Since then, as reported by Rodrigues and Melo (2012), a process of '*Europeanization*' of Águeda's policy environment held ground. In other words, the competitiveness and innovation discourse found shelter in the *plentiful* basket of buzzwords that wrap up the European policy context and started serving as inspiration for the local policy response to the economic downturn: the omnipresent concept of sustainable development, the green economy, the zero carbon goals, climate change mitigation, and, with the recent Europe 2020 framework, the hegemonic '*smart*' qualifier (CEC, 2010).

> "*Águeda assumes itself as an emerging smart city, because by developing triple helix partnerships aimed at looking at the territory in intelligent manners and placing ICT at the service of governance, mobility, economy and the environment, it is contributing to improve the quality of life of its citizens*".

This statement[3], taken from a speech made by Águeda's Mayor in 2011, provides a good illustration of the ways the local approach to development policy is being influenced by the hegemonic discourse emanated from Brussels, in which empty signifiers abound. To the Mayor's words one can add up a diversity of initiatives ranging from the association to international organizations and events with sustainability at their core (e.g., ICLEI- Local Governments for Sustainability and Energycities), to the Local Agenda 21. In sum, the green colour of the green-yellow city flag gained a new meaning, the one of a quest for sustainability in every government sphere, recurrently mirrored by the political discourse as the (only) way to fight and even revert the downturn effects.

It is at the level of industrial development through innovation that the aims pursued by the research reported by this paper find the most effective ground for evidence collection. Having the vast *audience* of local and regional actors determinant of and/or affected by economic development, the rhetoric adopted the deployment of triple helix partnerships, heralded by the Mayor's speech reproduced above, as a major reason for Águeda's '*smartness*'. The triple helix model (THM) (e.g., Etzkowitz and Leydesdorff, 1998), in brief, depicts the development of innovation systems with basis on relationships between and functional overlapping of university, industry and government. The THM discourse gained ground in Águeda through a EU project financed from 2008 to 2011 by the URBACT programme[4]. It was specifically aimed at generating several triple helices based on local clusters of economic activity and thus developing university-government-industry relations.
The local government states as major development objective the promotion of a strong local economy through entrepreneurship and the renewing and strengthening of the existing productive fabric (CMA, 2010). The government reserves for itself a leadership role in serving as a "*development agent*" contributing to develop new technology and innovation-based industries, create jobs and better future prospects for university graduates, and retain and attract population. Still, sound collaborative dynamics between the local political and production worlds and between these and academia is regarded as a crucial development.

In this context, the THM was rapidly looked at as the tool that would nourish success. This was mirrored by the official discourse, in which the model gained prominence and a persistent presence in the local policy design and in the local development debate. This can be illustrated with basis on a diversity of pieces of evidence. For instance, the THM is being utilized by the political forces opposing to the Mayor's party as a means to give argumentative power to criticisms. In fact, a member of the local City Council, criticizing the allegedly excessive focus of public investment in the city centre in detriment of the rural surroundings, averred: "*the triple helix model states that in order to keep the competitiveness of a region, its different parts should be equally developed*" (AMA, 2010, p. 52[5]). For those familiar

[5] Translated from the original in Portuguese.

with the THM, this statement lacks accuracy because the model does not make explicit any requirement related to equal development levels among different parts of a given region.
Meanwhile, the discursive focus on the THM has permeated industry-related organizations. For example, in an international seminar on innovation held in Águeda, industry representatives pointed out "*the importance of the theme of triple helix and the fundamental role of the university to stimulate innovation and entrepreneurship within this time of knowledge*"[6]. One can argue that the official discourse had the *persuasive* power needed to spread an enthusiastic perception towards the THM.

The use of the THM as policy inspiration can be regarded as problematic in the context of a small, traditional, and peripheral economy. In fact, significant barriers challenging the aim of putting in motion the kind of organizational and interactive arrangements predicted by the THM can be identified in Águeda (Rodrigues and Melo, 2012). Rather than analysing these barriers, it is seemingly more productive to shed light over the way the model permeates the policy making process and influences action. Nevertheless, a previous point should be made: local firms do not rely on academia or other formal knowledge centres to develop their innovation capabilities; the most important inputs are found in the chain of suppliers and customers that they integrate. As such, one can argue that the prospects for a full deployment of '*true*' (i.e., as described and/or predicted by the THM) and systematic triple helix based arrangements are far from brilliant. In fact, the THM- related objective of "*convergence of methodological and epistemological aims and norms between academy (industrialization of science) and industry (scientification of industry)*" (Viale and Etzkowitz, 2005, p. 9). The argument could, indeed, feed the frequent suggestion that, using the words of Edwards and Nicoll (2001, p. 104), "*the rhetoric, particularly that of policy, is not reflected in the reality*". Taking into account the mismatch between the model and the framework conditions, there is scope for an attempt to find out an explanation for the uncritical acceptance of the official rhetoric. Rodrigues and Melo (2012) provide an answer, suggesting that the plasticity characterising the fashion the THM is being used, because implying its conceptual emptying, offer local government officers the ideal basis sustaining an approach to local development susceptible of easier social legitimacy. In other words, the model assumed the status of an empty signifier and, as such, became a subject of consensus.

The local consensus on the THM-based path leading to enhanced innovation capacity and competitiveness can be seen as an example of how rhetoric, though established upon an unrealistic basis, may be instrumental in influencing an *audience* in its way of thinking. In addition, the research made in Águeda allows for an additional argument, configuring a perlocutionary act as in Austin (1962): the new ways of thinking have a nourishing effect on the willingness of local agents to act, or, maybe

[6] See **http://urbact.eu/en/projects/innovation-creativity/runup/the-role-of-universities-for-economic-development-in-urban-poles/**

more accurately, to act differently, that is, in innovative ways. In fact, there is evidence showing that the official discourse and rhetoric has been instrumental in the deployment of important initiatives marked by their **real** contribution to innovation and competitiveness of a number of local firms and to attract new businesses, thus creating jobs. This is the case of the recent prize-winning "*Águeda concept: from local to global*" initiative[7], based on a Municipality-led partnership including ca. 20 local firms and several other public and private organizations (ironically, despite the THM discourse, higher education, at least directly, does not participate). The partnership developed an innovative house model based on modular architecture which gathered the competences of a diversity of industrial sectors operating in the region and made appeal to the mobilization of innovation resources that, in isolation, would remain latent. In a traditionally unfavourable terrain as far as cooperation among firms is concerned, the successful effort underpinning the collaborative platform cannot be dissociated from the rhetoric-induced new ways of thinking. The Mayor himself helps to consolidate this view. In a recent speech about the '*Águeda concept*', he averred that the initiative was placed under the more encompassing will of transforming Águeda into "*an internationally recognised smart city*".

Additional evidence is provided by the Lighting Living Lab[8] that has been the most tangible result of an innovation and competitiveness network financed by a regional innovation strategy developed by the Centro region authority. This network, actually, was a kind of launching ramp of the THM-centred discourse which today wraps up the local policy endeavour. The project aims at promoting R&D and innovation in the lighting industry sector, in which Águeda has a prominent position in the country, focussing on the concepts of smart and eco-sustainable lighting. Adding to the advantages ripped by the participating firms, there are strong indications that the community will also benefit from the initiative, namely from such developments as the public lighting master plan aiming energy efficiency.

The benefits accrued by the THM rhetoric go beyond enhanced firms' competitiveness and efficiency gains in public services. It has also brought over improvements to the policy-making process, which changed from a traditionally fragmented and atomistic approach into a more coherent fashion of designing development strategies and policies. In this sense, one can argue that the use of the THM as referential contributed to enable Águeda to better organize itself and start to create more favourable framework conditions to enhance the innovation capacity of the local productive fabric. Eventually, these improved framework conditions would also contribute to strengthen the ability of local firms to make use of the knowledge produced within academia, or, in other words, to diminish the gap between discourse and reality (Rodrigues and Melo, 2012).

Moreover, benefits can be extended to the enlistment of new resources to fight the crisis, namely financial ones, tapped from external sources. This is true both at the

[7] http://www.aguedaconcept.com
[8] http://www.lighting-living-lab.pt/

national and European levels. The THM ideal driving the policy-making process has, in fact, fostered new communication patterns between the local and the central government[9], facilitating the local access to national funding streams directed at industry development. It has also created the opportunity to internalise the discursive *spirit* of European programmes, very much focussed on such things like collaborative innovation, smartness and sustainability, thus placing the municipality, because perfectly tuned with the EU language, in a better position to access financial resources otherwise overwhelmingly reserved for larger cities. The participation in EU programmes like URBACT and INTERREG, supporting the argument above, put Águeda working together and learning from much bigger urban agglomerations such as, among others, Potsdam, Gateshead, Patras, Montpellier, Almeria, A Coruña and Lugo.

The unrealistic discursive line craving for emulating in Águeda innovation practices taking place in more advanced economies endowed with the critical mass to deploy THM-driven development strategies, is underpinning new forms of policy design and delivery. New and old ways of acting and deciding together with new and old development coalitions are being combined in ways that are provoking positive transformations in the territory. The THM, unfeasible to be put in motion in its true meaning and institutional structure, has endowed Águeda with better ability to enter what Sotarauta (2010) calls the *spirit of times*, that is a general atmosphere emerging from the general societal communication upon which development opportunities and paths are open and consolidated.

Concluding remarks

This paper shed light over the effects discourse and rhetoric can exert on planning and policy making and thus on the transformation of territories. By studying the case of a small Southern European city, it has shown that new ways of thinking and thus new forms of policy design and delivery can spring from discursive and rhetorical devices, even when these are made of buzzwords and '*buzzmodels*' many times inspired by events going on in specific places (e.g., the widespread techvalley syndrome ignited by the Silicon Valley) of impossible or at least very hard replication elsewhere. The analytical focus was placed on the discursive line based on the THM, which can easily enter the category of 'buzzmodel' of unfeasible materialisation in the specific case of a small peripheral economy like the one characterising Águeda. The THM as local development inspiring source incorporated a mismatch with local reality and a match with the global *spirit of times*. The former is being left for the satisfaction of those who, like Albert Einstein, think that imagination will take you everywhere (as opposed to logic which takes you only from A to B). The latter, though, can be associated to real processes of change that are making Águeda a *smarter* city, though not in the sense of the dominant discourse. In fact, Águeda is accumulating *smartness* because, under the inspiration of such

[9] This approximates the argument of Rydin (1998), who looks at rhetoric as a way to nourish new communicative patterns between local and central governments.

rhetorical devices like the THM, it is, firstly, forming new development coalitions where cooperative traditions were hard to find – a good example are the double helix configurations bringing together the local government and industry -, and, secondly, improving its capacity to access both national and European funding sources. In addition, the evolving change dynamics may produce benefits that go beyond the generation of increased profits in a number of local firms and thus are extended to the local society as a whole. Hitherto, the mitigation of an eventual Janus-faced effect (Swyngedouw, 2005) subjugating the collective good to segments of interest defined by market forces is being ensured by the clear positioning of the local government as the institutional sphere leading the change process.

first draft – please do not quote without permission

Abstract

There has been a renewed interest and planning-theoretical underpinning recently for the idea of urban development projects as instruments for strategic urban transformation as well as for reflexive governance (e.g. Pinson 2004; Van den Broek et al. 2010; Oosterlynk et al. 2011). In many respects, however, the normative perspective envisioned by such contributions appears to stand in a counter-factual relationship to real-world scenarios. Empirical evidence and scholarly critique (e.g. Moulaert et al. 2003; Altshuler and Luberoff 2003; Salet and Gualini 2007) in fact highlight the fact that urban projects very often fall short of their strategic or integrative intentions: on the contrary, they often are occasions for untreatable controversies over urban development. As such, they express a peculiar a vocation for enhancing potentials for local conflict and often provide the scene for their very enactment.

Understanding the reasons and dynamics of conflict around urban projects still represents therefore a crucial precondition for arguing about the potentials for strategic reflexivity of project-based urban development initiatives. In this perspective, we need not only acknowledge agonism and conflict as constructive and constitutive elements of social relations, as sources of its strength and ability to innovate, but also inquire into the conditions under which agonism and conflict can be turned away from producing disrupting social outcomes and towards realising potentials for innovative transformative dynamics.

The paper proposes an empirically informed reflection on such conditions. Based on selected cases of conflict around urban development projects in Germany, it focuses in particular on a dual aspect which often characteristically defines the dynamic of

planning conflicts: the contradictory rationales and temporalities taken, on the one hand, by (institutionalized) policy development and planning practices and, on the other hand, by social mobilisation practices within the extended timeframe of the process. It argues that more awareness and consideration of the way an agonistic moment may develop and of the dynamics and forms of social mobilization (Melucci 1988) in the course of policy development and planning is crucial for addressing a process design that may enhance the potential for reflexive outcomes.

1. Introduction: on the 'strategic' potentials and challenges of urban development projects

Urban policy and planning research literature has shown recently a distinctive interest – with variable critical depth – for urban development projects as instruments for strategic spatial transformation (Pinson 2004, 2009; Van den Broek, Albrechts and Segers 2010; Oosterlynck et al. 2011; see also: Carmona and Burgess 2001; Carmona, Burgess and Badenhorst 2009).

Following a season of studies more explicitly targeted at inquiring critically into the contradictions of projects as the expression of 'neoliberal' practices of urban development policy (Altshuler and Luberoff 2003; Flyvbjerg, Bruzelius and Rothengatter 2003; Moulaert, Rodríguez and Swyngedouw 2003; Salet and Gualini 2007a; Majoor 2008; Diaz Orueta and Fainstein 2008), these contributions signal a distinctive interest in re-assessing and re-defining (in critical but overtly normatively-oriented perspective) the potential meaning of spatial projects, within an alleged movement of 'revival' of strategic spatial planning as evoked, among others, by authors like Healey (1997, 2007, 2010; et al. 1997), Albrechts (2004, 2011), or Salet and Faludi (2000).

According to a meanwhile diffused commonsense understanding, the 'strategic' nature of planning is identified with a "long time perspective" which "does not specify a fixed end state but operates as a flexible framework for sustainable spatial development", by this combining "a strong 'action orientation' and an increased sensitivity to the multiplicity of actors involved in strategic spatial planning" and to the need for introducing forms of social innovation into the planning and policy process (Oosterlynck, Albrechts, and Van Den Broek 2011: 3).

What is particular interest for us here is the way a strategic orientation of planning is tied to the potential roles of projects as instruments and measures of spatial transformation. Key in this respect are the notions of action-orientation and co-production. In the words of Oosterlynck et al., "action orientation implies an interest in planning instruments [that may realise] the *governing of land-use conflicts*, ways of *integrating various spatial claims* and the *operationalization of spatial quality and sustainability*, whereas social innovation draws attention to *the coupling of the transformation of space and the transformation of social relations in space* and to the

satisfaction of local needs" (Oosterlynck, Albrechts, and Van Den Broek 2011: 3, italics added).

This understanding resonates of Healey's concerns for the potential and challenges that urban projects – in light of her conception of "place-governance with a planning orientation" (Healey 2010: xiii) – bear for practices of strategy formation in place development. Major urban projects are seen as new interpretations of urbanity through complex mixes of interests and resources mobilised, and raise the question of how to create new places that are not elite enclaves, but "long-term public realm resources", with "attributes of inclusive urbanity" (Healey 2010: 126-7). Urban economies, policy processes, public and private entrepreneurship and management models, mobilisation patterns, strategic imagination and framing visions, as well as positioning in translocal development trends, are discussed as elements that need to be understood on the background of the ongoing struggle for "safeguarding the public realm" in urban projects (Healey 2010: 159): a struggle which involves conditions like energetic agency and a proactive governance mode, skilled and committed guidance, critical monitoring by the political and civic community, plus a strategic view of trans-local connections.

Similarly, authors like Salet and Gualini (2007b; Salet 2008) have argued in favor of a joint critical consideration of aspects of conceptual, strategic and democratic integration across scales in the framing of urban projects as a condition for their capacity to introduce sustainable socio-spatial innovation.

Compared with a more critically-minded literature, however, recent discourse on 'strategic spatial projects' has often gained a distinctive normative orientation. Recent work by Oosterlynck et al. is, again, a significant example. Projects as the instruments for the "structural transformation of socio-spatial reality", in this respect, are seen as necessarily capable of exerting (strategic) 'selectivity' while pursuing an 'integrative' framework of goals, which in turn implies fostering horizontal and vertical forms of cooperation. In sum, projects constitute an instance of 'co-production' which implies "a specific focus on how spatial transformation may facilitate social innovation both in the substantive sense of improving the satisfaction of local needs and in the process sense of involving non-conventional, grassroots and disadvantaged actors and groups" (Oosterlynck, Albrechts, and Van Den Broek 2011: 3). Again, what is of particular interest here is however the convition that "[t]he *place focus* of strategic planning and design […] provides a promising basis for public-public cooperation as well as between the government and civil society and private sector actors (a 'government-led-but-negotiated form of governance' […]" (Oosterlynck, Albrechts, and Van Den Broek 2011: 3-4, italics added). This conception leans upon the 'four-track' model of strategic spatial planning elaborated by Albrechts (2004, 2011; see also Van den Broeck 2011), based on the combination of different action trajectories, "one for the vision, a second for the short-term and long-term actions, a third for the involvement of the key actors, and finally a fourth track for a more permanent process (mainly at the local level) involving the broader public in major decisions" (Albrechts 2004: 752).

In a similar vein, Pinson (2004, 2009) has argued about re-assessing urban development projects and their role in public policy. His reading is in line with an attention for the governance of urban projects as the specific focus of analysis, as expressed by approaches to the inquiry of projects as 'policy instruments' (Lascoumes and Le Galès 2004) as a way to get insights into the nature of a policy. This amounts to assuming 'projects' as the object, rather than as merely a unit, of analysis (Pinson 2004: 200). In this respect, projects can be analysed as a specific mode of policy action: rather than simply a context, arena, or sequence of actions that unveils a set of power relations and interests in the city, it represents a constitutive dimension of their enactment. Projects are a specific mode by which the urban policy arena is constituted.

In this perspective, "in as far as it adopts the instrument of projects, public intervention does not consist anymore in imposing the supremacy of public regulation, but primarily in organising the combination of different types of regulation" (Pinson 2004: 228 - my translations from French). This justifies an attention for projects that points at changing sources for legitimacy and effectiveness of public action, implying new 'reflexive' attitudes such as capacity of anticipation, integration of uncertainty, openness to context, decentralisation of action, and sensitiveness to actors (Pinson 2004: 220).

Interpreting projects as expressions of a reflexive and innovative process- and action-orientation of urban policy, however, remains problematic, and normative applications of this ideal deserve critical scrutiny. In fact, assumptions of projects as 'open' frames of public action, allowing reflexive responses to emergent outcomes and turning unintended consequences into collective resources, remains largely counterfactual if not merely ideal. Analysing their logic is hence crucial for a critique of the strategic nature of urban projects and of their potential as innovate instruments of public policy. This paper is a step towards such a critique.

2. 'Strategic urban projects' as object of theorization and object of research: insights from a social movement perspective

The brief, and certainly partial review of current scholarly discourse on 'strategic spatial projects' represents an outstanding critical background – as well as a critical object – for our assessment of urban development projects based on empirical evidence from some case-studies. It is based on an on-going critical concern, on the one hand, for a domain of urban policy and planning practices in which urban development projects constitute specific strategic-relational constructs (Gualini 2008, 2010, forthc.) and, on the other hand, for contentious character of urban policies and for the role urban development projects often play in this respect as factor of social contention – to the point, in some instances, of even becoming catalyzers of social movements and major foci of local political conflicts (Gualini 2011a, 2011b).

The perspective chosen in this paper, against this background of interests, is a quite specific one: it is an attempt to gain new sources of reflexivity from an engagement with the nature of social contention around urban development projects, and to do so based on hypotheses drawn from the literature on the dynamics of contentious politics and social movements.

Besides specific interest in this literature and in the issues it raises for critical-interpretive urban policy analysis, this approach is motivated by the conviction that the development of the 'strategic' features and the effective pursuit of the 'strategic' aims of urban development projects – as briefly sketched above – are only to a limited extent amenable to be subject to a 'design' intentionality, and that they rather highly depend upon the capacity for reflexive co-evolution in relation to insurgent social inputs along the life-span and dynamics of the policy and planning process. In this respect, the task of this paper constitutes a limited step in this direction of analysis, based on case-studies of the actual reality of what are all-too-often 'strategically dumb' projects. Along a critical reconstruction of their policy and planning processes and of related dynamics of contention, the paper aims at gaining elements of understanding of what the logic of social protest and mobilization can specifically teach us about how and under which conditions such a strategic reflexivity can emerge and be exerted.

2.1. Contentious politics and social mobilization

In this section, we first define the key assumptions drawn from research on social movements, and then formulate the hypotheses that inform the two case studies that follow.

In adopting a social movement perspective on conflicts around urban development projects, we move from the basic observation (Tilly 2004) that the dynamics of contention and social protest are tied to their political-institutional, social and economic context, and that this context significantly defines conditions under which they may take place. In this context, however, social movements must be understood as a distinct form of social protest and contention by virtue of three features that characterize them as collective action and as a collective construct (Tilly 2004: 53):

- they are sustained organized public efforts to raise collective claims, combining claimants, objects of claims and a public in a 'campaign';
- they combine forms of political action, which form over time context specific, standard-operating modes by which collective action is enacted: the social movement 'repertoire';
- they are public representations of unity, worthiness, collectivity and commitment, involving significant processes of identification and collective identity building.

The sorts of claims, forms of action, and collective identification mobilized and their combinations differ according to the time-space specificity of social movements and the contingent situations in which they emerge. Their relative salience may vary

among social movements, among claimants within movements, and even among phases of movements (Tilly 2004, 184). The origin and features of social movement claims, repertoires and identities, moreover, are rooted in the regime within which they operate. In this sense, as pointed out by Tilly (2006), contentious actions are shaped by regimes in several ways:

- by regulatory control on possible claim-making repertoires;
- by the power of policy practices and discourses to selectively constitute potential claimants and potential objects of claim;
- by producing streams of issues, events, and governmental actions around which movements may rise and fall.

The forms and dynamics of contention are hence a function of the specific political-institutional, social and economic conditions under which they emerge: it is in their shadow that a 'political opportunity structure' (Tarrow 1998) for collective action may emerge: "contentious politics is triggered when changing political opportunities and constraints create incentives for social actors who lack resources of their own. They contend through known repertoires of contention and expand them by creating innovations at their margin. When backed by dense social networks and galvanized by culturally resonant, action-oriented symbols, contentious politics leads to sustained interaction with opponents. The result is the social movement." (Tarrow 1998: 2).

In our perspective, this observation is important in a twofold way. First, it leads us to consider planning practices as being defined as a 'policy regime', i.e. as an action situation which is not only shaped by political-institutional, social and economic framework conditions, but by the specific policy rationale that defines its course of action and by its potential for selective regulation of modes of collective action. Second, the selectivity of forms of social-political regulation and discipline expressed by planning as a 'policy regime' may precisely become the occasion for forms of identification, leading to the emergence of a 'political opportunity structure' for collective mobilization.

This observation is important in relationship with the insurgent, constructed and anything but 'natural' features of social movements – an aspect which has led scholars to warn against the 'ontologisation' of social movements (Melucci 1988: 330). Against approaches to social movements that emphasize factors for individual mobilization – material interests and resources as well as subjective and voluntaristic variables – over the symbolic-cognitive and interpretive aspects of social experience, authors like Melucci (1988, 1989, 1996), Snow (et al. 1980, 1986), Tarrow (1998) and Tilly (2004; and Tarrow 2006) emphasize the emergent and constructed character of social movements as forms of collective action.

As these author show, a motivation to adhere to a context of interaction – like a form of collective mobilization – *per se, i.e. a priori* of interaction itself, is rarely found; conversely, with the varying of activities and modes of involvement, interests for participation and modes of participation also tend to vary: "the 'motives' for joining

or continued participation are generally emergent and interactional rather than pre-structured" (Snow *et al.* 1980: 795). Motivation to participation can neither be seen exclusively as an individual nor as a discrete variable: it is rather constructed and consolidated through interactions and in the framework of their process-like dimension (Melucci 1988), whereas "rationales for participation are both collective and ongoing phenomena" (Snow *et al.* 1986: 467).

Actors 'produce' collective action because they are able to define themselves and to define their relationships with the environment (other actors, available resources, opportunities and obstacles) in terms that involve a collective and shared identification of issues and issue-boundaries, in relation to which they feel their interests to be involved and they might consider to mobilize their resources in that direction. The identities that are thus strengthened are 'social products' of the events that occurred in a particular time-space conjuncture (Melucci 1988, 1996).

Contrary to conceptions which see the outcomes of social movements as functions of the definition of objectives and of the group's ideology - thus binding them to the sharing of defined 'values' –, this conception understands processes of collective mobilization as phenomena subject to significant variability according to differences in relational structures. In this sense, the relational settings of interaction constitute at least as important factors in defining paths of participation and cooperation as dispositions or value assumptions do.

2.2. Social movements and planning processes: research hypotheses

This aspect is of relevance in relationship with fragmentation that characterizes contemporary societies in late modernity (Melucci, 1989, 1996) and the way this affects social movement in the urban context. It hints at a recognizable change in features in contemporary urban movements, whereby 'neoliberal' and globalized urban development policies and practices have contributed to a progressive erosion of cycles of urban movements based on established local groupings and interests based on traditional forms of affiliation and mutual identification – be they corporatist, class, or community based – and on their social movement infrastructure (Mayer 2007). While moving away from conflicts grounded on basic social cleavages, however, urban conflicts have pointed to the emergence of "a variety, a multiplicity of conflicts, revealing the untreatable diversity of local societies and the emerging need to build shared identities" (Pacchi and Pasqui 2011: 4). To this obviously contribute the new cross-sectional social impact and visibility taken by the 'neoliberal project' in cities, as well as an unprecedented local as well as trans-local mediatization of urban struggles.

This is in line with the observation that contemporary social movements take often the form of 'multiform movements' (Tarrow 1998: 103), flexibly, syncretically and pluralistically combining different forms of collective action and tactics. This accounts for the fact that often, in contemporary social movements, "heterogeneity

and interdependence are greater spurs to collective action than homogeneity and discipline" (ibid.: 137), and that mobilization often takes the form of democratically decentralized movements (ibid.: 129), that is, of 'decentralized, segmented, and reticulated' groups that capitalize on variety and pluralism.

Two interrelated conditions are crucial for collective mobilization to occur under such conditions. The first is the enactment of opportunities for involvement through the development of a repertoire of actions: "contentious collective action demonstrates the possibilities of collective action to others and offers even resource-poor groups the opportunity that their lack of resources would deny them", and thus "it can pry open institutional barriers through which the demands of others can pour" (Tarrow 1998: 87). This aspect points to the importance of the 'public performance' of contention and of the development of itineraries of repertoire change in response to changing opportunity structures.

The second is the importance of symbolic mobilization in order to define alternative belief systems that may constitute interfaces for mutual identification and support collective action. In fact, "it is participants' recognition of their common interests that translates the potential for a movement into action" (Tarrow 1998: 6), but this recognition is an interpretive endeavor that implies developing frames of identification that allow to bridge differences in positions and preferences and to create new symbolic-cognitive bonds. This explains the importance of collective action frames and of dynamic and co-evolutive processes of framing in the development of social movements

'Framing' results from practices of consensus mobilization intended as a practice that involves constructing symbols of consensus: these however are not only drawn from 'categorical identity' (Tarrow 1998: 119-120) but increasingly involve mobilizing emotional commitments that may contrite bridging categorical differences. Thus, "most of the work of 'framing' is cognitive and evaluative – that is, it identifies grievances and translates them into broader claims against significant others" but, to a significant extent, it involves "tapping or creating emotional energy" (Tarrow 1998: 111). This can occur through different processes of framing – like frame bridging, frame amplification and frame extension – and ultimately lead to *frame alignment*, i.e. of the alignment between individuals' or groups' frames along *collective frames*. As such, "frame alignment [...] is a necessary condition for movement participation, whatever its nature or intensity, and that is typically an interaction accomplishment" (Snow *et al.* 1986: 467).

'Framing' is anything but a purely intentional process: it is an interactional outcome, as part of what Tarrow (1998: 121) calls 'framing through contention' – and, at the same time, it is a condition for reproduction and co-evolution of interaction.

This leads us to discussing two last interrelated aspects that are key for assessing social movements in the framework of planning processes: the nature of frames dominating social movements, and their intertemporal dimension in terms of their

possible trajectories of evolution. They bear a combined relevance to the question of the social-political outcomes of contentious movements in the context of public policy and, in particular, their prospects of their co-evolution towards integrative rather than polarizing and ultimately disruptive outcomes.

The first aspect can be usefully discussed combining the typologies of conflicts and related forms of social movements advanced by Pizzorno (1993) and Melucci (1996), as Pacchi and Pasqui (2011) have recently proposed. In their view, even if their peculiar combinations are frequently observable, distinguishing these types analytically is important in order to recognize the different consequences that different kind of urban conflicts based on them can have for planning and policy practices.

Pizzorno (1993) proposes a threefold typology in which he distinguishes 'recognition', 'interest' and 'ideological (or value)' conflicts. 'Interest conflicts' are typical for parties which share the same values and the same systems of relations in a pluralistic environment in which they struggle for their relative distribution of benefits. Obviously, conflicts of interest can be radical and can entail radical opposition, but they usually are framed as a distributive game, in which what is at stake is typically a comparative benefit gain.[1]

'Recognition conflicts' are conflicts that are promoted around a group's or actor's claim for recognition of its identity. As Pizzorno underlines, 'identity' in this case is anything but a given, being rather often defined in opposition to other parties, and involves therefore struggle for mutual identification in which a new identity is a possible outcomes of the conflicts itself.[2]

'Ideological (or value) conflicts', finally, involve clashes among (ontological) world-views and among systems of values and beliefs which claim for universal validity. The relation to concrete interests is therefore often not transparent if not irrelevant, and different interests can be bridged and conveyed.[3]

[1] In the characterization by Pacchi and Pasqui (2011: 4): "Interest conflicts take place when scarce resources (and firstly land and its possible uses) are distributed through planning decision. Often these kinds of conflicts have an economic and financial dimension: for example the competition between different uses of transformation areas is often a competition between developers and landowners, or between different promoters, or between financial operators and developers, and so on. If we consider also the public administration an economic actor producing resources through planning permissions, also the bargaining between institutional bodies and the private sector can be considered an interest conflict."

[2] In the characterization by Pacchi and Pasqui (2011: 4): "Recognition conflicts take place when social groups (often local) want to be recognized through planning decisions that contribute to their identification. Often these kinds of conflicts are connected with the defense of 'local' (environmental, cultural, community) values, or with the claim for exclusive uses of a public space, against uses considered inconvenient."

[3] In the characterization by Pacchi and Pasqui (2011: 4): "Ideological conflicts take place when the beliefs themselves (the very ontological frameworks) are a contentious object. In this kind of planning conflicts there is not a shared framework between the parts: the framework is the object of conflict. Radical ecological conflicts, for example, can be considered ideological, because the parts

If we combine Pizzorno's typology of conflicts with the emergence of specific kinds of social movements which give expression to them, as in Melucci's typology, we gain elements for interpreting the potential evolution trajectories involved. As Melucci (1996) underlines, new social movements increasingly involve practices of mutual identification and recognition that tend to stress the limits of social representation within which traditional class or corporatist struggles were played out. Melucci's distinction between 'claimant', 'political' and 'antagonistic' movements resembles the one proposed by Pizzorno in that, moving from one to the other, it stresses the increasing importance of alternative framings both as a factor of external positioning and of internal cohesion of the movement – with an increasing availability to systemic conflict as factor of identification and mobilization. In the words of Pacchi and Pasqui (2011: 5), "[m]oving from a claimant to a political and to an antagonist movement, the symbolic content tends to increase, while the divisibility and negotiability of goals tends to decrease, and so does the reversibility of conflicts; in the end, such conflicts tend to become zero sum rather than positive sum games."

The second aspect concerns the intertemporal dimension of social movements, that is, the development of cycles of contention and of the evolution they may take – through phases of mobilization, processes of diffusion, extension, imitation and reaction, and possibly demobilization and decline (Tarrow 1998: 142 ff.). The issue is relevant in view of the outcomes of contentious planning processes. The trajectories taken by social movements around contentious plans and projects, as pointed out earlier, are the result of the strategic selectivity of 'policy regimes' and of the way opportunity structures are defined and appropriated by collective actors.

The hypothesis that can be inferred from these observations and that we want to explore is threefold:

- firstly, as they contribute to defining the political opportunity structures for contentious actions and for collective mobilization, and ultimately for the nature of social movements, planning processes and the 'policy regimes' in which they are embedded are also determinant for shaping their evolutive trajectories;
- secondly, the co-evolution of planning processes and social movements in a defined contentious situation depends upon the way forms of strategic reflexivity either side are developed on either side and on how these mutually interact;
- thirdly, a more developed awareness of dynamics of contention and social mobilization in planning processes is essential for developing a strategic reflexivity of public policy that may make co-evolution towards integrative outcomes possible.

The question is, ultimately, how far awareness of the nature and meaning of social mobilization processes is can be developed within the context of planning processes and how far this may lead to responses and realignments that may develop a form of strategic reflexivity and favor the emergence of integrative outcomes.

---

want to produce (different) universal systems of values and meanings. Often, in this kind of conflicts scientific information and technical knowledge are at stake."

3. Planning processes and cycles of contention: two case studies

In this section, we present two case-studies of actual conflicts around urban development projects in Germany. The case-studies neither claim to be exhaustive overall assessments of these conflicts nor to draw conclusions on grounds of direct comparability. However, they share a common interpretive framework based on the *joint analysis of planning processes and of related cycles of contention*. The focus of interpretation is therefore the pattern of co-evolution of planning and contention, as can be interpreted through an analysis of the social mobilization developed around each project.

3.1. The case of MediaSpree, Berlin, 1992-2012

Introduction

The urban development project known as 'MediaSpree' – extending over 180 ha. for an originally expected built space of 1.3 mio. sqm. and an investment volume of ca. 2.6 billion Euros – is basically a marketing construct. MediaSpree does not actually exist as a unitary, let alone publicly initiated project. It is basically the result of a marketing initiative, characterized from the outset by an incremental approach to place-making. As a unitary project, it is identifiable mainly by a strategic frame of a mainly symbolic branding- and marketing-oriented nature. This is reflected in the nature of public-private relationships developed around the project.

Phase one: indicative strategic framing

The public career of the project has developed in a distinctively incremental way. Its origins date back to the early post-reunification years, in the early 1990s. Despite its regained centrality, the area's development potential was rather neglected in the immediate aftermath of Berlin's unification, being sidelined by a focus on development along the so-called *Zentrenband* connecting the eastern and western city and on the 'critical reconstruction' of the historic city pursued by the *Planwerk Innenstadt* (Senatsverwaltung 1997). Nevertheless, this planning background proved to be determinant in framing its prospects as attention extended to the area of the Ostbahnhof, leading to an urban design contest in 1992 and to the first formally binding plans in the mid-1990s. Extending the design rationale of the *Planwerk Innenstadt*, plans foresaw a new skyline made of a 'chain of architectural pearls' along the eastern waterfront.

The fusion of the boroughs of Kreuzberg and Friedrichshain in 2001 introduced the opportunity for a unitary development scheme. The planning document devised by the Berlin Senate – as a complement of the *Planwerk Innenstadt* – in coordination with the boroughs, the *Leitbild Spreeraum Friedrichshain-Kreuzberg* (Senatsverwaltung 2001) is a spatial-functional vision which redefines the

Spreeraum as a unitary area and attempts at a coordination of the heterogeneous developments taking place. The focus was on tertiary development along a livable waterfront environment for a mix of leisure and working activities. Subsequently, the vision was strategically targeted towards creating an attractive urban environment in particular for 'creative' and media enterprises to locate, prospectively contributing to clustering and specialization in key sectors for the city's economy. Nevertheless, the strategy was clearly functional to a maximization of development potentials. This was backed by provisions for a 10-meter public waterfront integrated with a new open space along remains of the Berlin wall, the East-Side-Park.

The resulting planning approach relied on a flexible steering mode with minimal regulating inputs from the public. Despite its identification as strategic development zone, the city's direct commitment – besides the provision of incentive structures mainly through public subsidies – was from the outset significantly restrained. As the strategic frame was made of an indicative system of objectives implying incremental market-based mechanism of implementation, the relational frame adopted was a relatively stable but loose, disjointed structure of relationships.

Phase two: market-oriented strategic-relational framing

MediaSpree's planning objectives were mainly pursued through joint marketing efforts. This in fact amounted to a substantial delegation by the city to a private interest coalition to define a development strategy for the area. The result was a flat hierarchy behind which, however, lies an apparent dominance of behaviours and attitudes framed by market-oriented visions and behaviors clearly dominated, which made the future of the area primary dependent on the demand-side and on investors' preferences. This aspect, as we will see, bore important consequences for the project's reception in public debate in the first phases of contention.

Accordingly, MediaSpree gained the status of a strategic project *de facto* more by marketing and branding than by formal political commitment. A crucial role was played in this by the initiative taken by the area's landowners – in large part public- or semi-public corporations – shortly after the adoption of the *Leitbild* to join a local marketing agency. Originally founded as Spreemedia GmbH, the agency was turned a few years later into an association known as Mediaspree e.V., financed with the contribution of the Federal scheme for regional development and by members' contributions.

Change from the original form of a limited liability company to an association, introduced in 2004 and politically supported by the Berlin Senate, conferred the agency a semi-public character strongly contrasting with the original set-up. This transformation however did not change its mission as an agent of property interests, entrusted with marketing properties, attracting investors, networking and counseling members, and building an image for the purpose of an effective overall development of the area. Following the successful location of the headquarters of firms like MTV

Europe and Universal, Mediaspree e.V. consistently focussed its image-building and marketing efforts on media-related industries.

Mediaspree e.V. represented an attempt at contrasting a weak market situation by channeling investors' attention on a unitarily marketed area. Its associative form suggests transparency as an expression of non-self-interested conduct.

Despite this carefully constructed public image, Mediaspree e.V. was neither an open forum for public consultation nor a true interest coalition. On the one hand, an extended range of local stakeholders was never involved, the public being represented by local authorities – the Berlin Senate and the borough – in the advisory board along with the Chamber of Commerce and the local Agency for Labour. On the other hand, while the agency acted as collective representative of property owners, negotiations about concrete investment deals were kept strictly individual.

Another significant feature that emerged along with this relational setting is that MediaSpree was never formally declared as a priority project of the city. In line with its rather non-committal attitude, in overall terms the Berlin Senate adopted a delegation strategy which – next to a key role for Mediaspree e.V. – implied leaving formal planning authority with the local borough. The borough acted mainly as controlling instance in enforcing planning laws, regulations and development contracts. At this level of the planning procedure, the borough was thus entitled to formulate its own goals and to exert influence on developers. The key instrument for this was the development contracts attached to each building plan and reflecting the degree of cooperation between the public and the private investors. The Senate however kept planning authority over some areas – e.g. Anschutz and some others – as well as significant influence over areas of state-owned enterprises. The presence of land property of significant public-owned companies in fact the Berlin Senate a stake in development in the area. It was to become, however, also a potential source for conflicts of interest between the Senate and the borough – particularly, as we shall see, as the project became contentious.

Phase three: awareness raising and antagonistic mobilization

The project's strategic and relational framing briefly described constitutes the framework within which MediaSpree turned, within a few years, into one of Berlin's hotspots of overt antagonism. Despite all this, it took relatively long for citizens groups to raise their voice – in particular, participatory process having been kept strictly formal. This is in part certainly due to the practices of Mediaspree e.V., which have remained largely unaccountable as well as unaccessible to the general public. Moreover, in first instance, its branding approach constructed an artificial image that was little targeted to as well as little felt by local citizens. In addition, given the nature of the area and the significant physical and symbolic separation from its Kreuzberg side, developments on MediaSpree's core areas did not

necessarily raise expectations of typical neighborhood conflicts. For long, all these factors contributed to the rather limited public visibility of the project.

This however was rapidly bound to change in the mid-2000s. A variety of development contributed to introduce the first phase of mobilization. For one, the pervasive marketing and branding activity of the agency – with its symbolic co-optation inclusion of local 'grassroots' activities in image building – increasingly raised awareness on the factual consequences of planned developments for the alternative milieux that had been making the area famous – and a major tourist attraction – after Berlin's reunification. Moreover, some key initiatives dramatically contributed to rise local as well as supralocal awareness.

In fact, dependence on market forces led development of MediaSpree to be in part defined by single disjointed development initiatives, for which ad-hoc negotiation frameworks were defined. These were clustered in particular in a section called Oberbaum-City as well as in a large-scale project by the American investor Anschutz Group – now known as O2-World Arena – for which development contracts were signed with the borough in 2000.

The initiative by Anschutz – one of the first major foreign investors in the area – to build a large multifunctional event arena bound to exert a huge impact on the area. Development contracts – by which Anschutz agreed pay-offs for road improvements and contributions to the realization of a playing field and the East-Side-Park along the Spree – were defined directly with the Senate at a time in which the overall concept for MediaSpree was still in the making, and were decisively influenced by Anschutz negotiating power vis-à-vis the boroughs' compelling need for facilitating investments under public zero-cost development conditions. This led to obtaining a prominent and intrusive position in the area. One paradoxical result was that the planned East-Side-Park appeared to be degraded to a facility dependent on the investor's will – keeping an unhindered riverside view and waterfront access – to which even part of the former Berlin wall monument has been sacrificed. This had a tremendous impact on public perception on the threats to an area that had turned over years into one of the city's most dynamic and creative hotspots of informal development.

This rise of visibility went along with the progressive emergence of antagonistic action, drawing in particular from autonomous-anarchist circles related to a mixed milieu of squatters and extending to insurgent anti-capitalist and anti-gentrification groupings, which had increasingly been pointing to the segregation and polarization effects of east-Berlin's revitalization processes.

A crucial role as an 'early riser' and as a broker of citizens' mobilization was to be exerted by the formation of the association *MediaSpree Versenken!* ('Sink MediaSpree!'), as it proved capable of directing attention to the specific local development challenges involved in the project while tying them to a broader, city-

wide system-critical movement. In a few years, MediaSpree Versenken! managed to develop reference to the Spree waterfront area into a cohesive and bridging symbol.

On the one hand, the contentious practices it promoted – like demonstrations, occupations and flash-mob inspired performances – were capable of appealing to actors and groups attached to specific local development issues, like the public nature of the waterfront and the nature of its uses and appropriation, as well as to tie-in to the pragmatic interests of a variety of local actors, particularly of 'pioneers' of temporary creative-cultural and leisure-oriented uses of space. By this, its actions also contributed to turning the image-building campaigns of Mediaspree e.V. upside-down, and to introducing a symbolic re-appropriation of the image of the area. On the other hand, MediaSpree Versenken! proved capable of connecting local and supra-local interests and perspectives and in bridging scales of protest. Accordingly, while slogans like 'Spree waterfront for all!' rapidly became carriers of broader forms of protest and mobilization and gained local as well supra-local attention – beyond the ideological origins of the promoters – as rooted in an alternative vision of local development, MediaSpree itself become an overarching symbol of opposition to the 'selling-out' of the city.

Not surprisingly, the features of the relational setting also turned into a significant matter of contention at a point in time in which first antagonistic actions raised attention on the contentious potential of the project, as the marketing agency and the actors they represented lent themselves to becoming an amenable symbolic target for movements critical of neo-liberal urban developments – not necessarily with direct local ties.

Phase four: institutionalized dissent and diffused contention

MediaSpree Versenken! became a significant actor in the project's arena by raising attention on the exclusionary character of planned development and on the marginalization of local interests. In organizational terms, MediaSpree Versenken! represented anything but a decentralized-networked movement in the strict sense (Tarrow 1998: 129), and actually kept a radical ideological core throughout the cycle of contention. Its actions, however, developed on the background of a significant resurgence diffusion of urban antagonism in Berlin, with significant forms of 'localizing protests' (Mayer 2007), like the actions promoted by the Berlin Social Forum founded in 2003, but also the emergence of contentious urban policy issues leading to direct actions like the storming and subsequent public appropriation of the Tempelhof area in 2009. In this respect, the resonance of its actions was amplificated by the network-like diffusion of urban policy related contention in the late 2000s.

MediaSpree Versenken! contributed thus to conferring visibility and symbolic unity to contentious forces around a project. What is also notable, however, is that it managed to develop elements of a counter-project which – even more than the symbolically powerful, but techno-politically unviable alternative to Stuttgart 21 –

could introduce a wedge in local planning. By this, it eventually gained an active role in the policy process as it managed to channel a diffuse public distress towards recognizable planning counter-proposals.

Success in mobilizing citizens – under the slogan 'Spree waterfront for all!' – towards a local consultative referendum, which was ultimately held in July 2008, led to overwhelming support for a development alternative to the official plans. This was expressed in the form of concrete physical requirements – a 50-meters clearing along the whole of the eastern Spree-side in order to realize a consistent public waterfront, a unitary 22 m. building height, and a pedestrian-only use of the planned bridge – which were easily identifiable beyond more or less ideological divides, but would in practice imply a moratorium and a substantial revision of formally and in part legally binding agreed developments.

In the aftermath of the referendum, these requirements and their implications for political action temporarily became the main focus of contention for current local politics. Crucial for the dynamics of contention around MediaSpree was the fact the referendum had forcefully altered the relational setting of the project, introducing new constraints and resources for policy actors. This implied not only new opportunities for representatives of the movement to influence policy agendas, but also the emergence of hidden intergovernmental tensions as it put the project's main public actors – the Berlin Senate and the borough of Friedrichshain-Kreuzberg – in a rather awkward position.

While formally directed to the borough – statutorily mandated to give a formal response to the consultation – the referendum clearly was primarily directed against the 'neoliberal' practices of Berlin's governing coalition and of its business partners. While the joint marketing agency was liquidated in late 2008 – formally because of expiration of federal funding, but factually as a sign of the weakness of its coalition of interests face to the political challenge ahead – the Berlin Senate and its decided unwillingness to revise strategies for the area became the political target of contention – with developments around Anschutz's O2-Arena as the main symbolic marker.

The borough's potential to influence development, on the contrary, was reinforced, even if controversial. Following the referendum, the borough was forced to balance between dual political commitments. Its official position was – in line with formal planning developments – that, while demanding consideration for citizens' orientations, the referendum could possibly alter the state of things. In fact, established or progressing development contracts negotiated with developers define a difficult balance of public and private interests which – so went the argument – would have required amendments involving often dramatic compensations. On the other hand, the borough was asked to play a mediatory role which could only be possible if significant if partial recognition of citizens' requests could impact on the redefinition of the project.

The resulting situation was conflictual. The Senate at several occasions threated with withdrawing the borough's planning authority over the area in case decisions should be enforced that would imply devaluation and/or compensation measures. Subsequently, the Senate confirmed the borough's authority, as well as these threats, upholding the original planning goals (Abgeordnetenhaus 2008a) and pursuing a strategy of sidelining the referendum's result.

Moreover, after the liquidation of Mediaspree e.V. no unitary representation of land owners is presently in place. In July 2008, in reaction to the referendum, twelve major land owners have constituted an informal agreement based on the demonstrative rejection of any public dialogue. Nevertheless, controversy continued on whether existing formal agreements really constituted a binding legal obligation – as the Senate argued – since not all areas actually had defined building contracts, while several areas still lacked concrete commitments by developers.

The emergence of social antagonism thus also created new political opportunities for the borough. While subaltern in terms of power relations, its new position introduced possibilities for refining its own role by exerting a more proactive and ad-hoc mediation between public and private interests.

Following the referendum, the borough first promoted a discussion forum, and then established a public commission – the *Sonderausschuss Spreeraum* (Bezirksamt Friedrichshain-Kreuzberg 2007, 2009), including all political groupings of the council as four citizens' representatives – called to deliberate on the planning amendments demanded by popular vote. The commission was an attempt at bridging interests and opening-up participation in response to increasing unease with the shortcomings of formal decision-making processes. As such, it asserted the legitimacy of stakes beyond those represented by Mediaspree e.V. and the need to articulate consensus at a broader scale of involvement. While the results reached by the commission were disappointing and ineffectual – as well as contested by opponents (Initiativkreis Mediaspree Versenken 2009) – in upholding the formal prerogatives of the project against demands for change, it actually contributed to creating a structured arena of exchange to a range of actors, leading to some significant is partial and ad hoc change in plan provisions on specific lots. It was an expression of an insurgent dynamics of informal deliberation practices which, far from capable of revising the overall strategy for the area, nonetheless contributed to a significant if piecemeal shift in attitudes and practices.

A first notable example was readiness shown by the Berlin Senate in late 2008 to rethink its land-use policy along the Spree (Abgeordnetenhaus Berlin 2008b) introducing measures for safeguarding non-commercial, social and experimental activities and to adopt according up-dates of the *Leitbild*.

This involved a revision of criteria for land assignment adopted by the Berlin public land agency, the *Liegenschaftsfonds*, introducing new possibilities for the promotion

of alternative socially oriented projects in strategic (re-)development areas (Abgeordnetenhaus Berlin 2010).

Significantly, this partial reorientation of public policy developed within a broader public debate on the rationale of urban development (Stadtforum Berlin 2009) – of which a project like MediaSpree had been a major catalyzer.

Thus, while revision from rent maximization goals towards a more socially oriented (and more effective) land policy agenda was formally included – in the wake of an insurgent housing policy issue – in Berlin's new coalition agreement (SPD – CDU 2011), the issue also became a stake for broader forms of mobilization. In 2011, the civic initiative *Stadt Neu Denken* brought together a coalition of representatives from academia, professions, arts and civic associations and groups around the idea of an alternative approach to urban development. Soon around 500 individuals and civic organizations were involved in activities centered on developing ideas and requesting public policies allowing for socially attentive and flexible forms of urban development capable of reflecting the social creativity and pluralism of local urban contexts.

A further development which clearly reflects issues and demands raised in the framework of MediaSpree and other contemporary planning controversies – and which can be seen as a clear albeit partial response to shifting public moods on urban issues – is Berlin's Senate initiative of launching an IBA Berlin 2020 as a policy framework for a more experimental and participated approach to urban development in the inner-city fringes (Senatsverwaltung 2011).

3.2. The case of Stuttgart 21, 1988-2012

Introduction

Stuttgart 21 is a project which has become the center of a complex and still on-going social and political controversy, bearing different conflict potentials and developing along several significant social and political dimensions. As such, it has already acquired a significant position in public as well as scholarly attention. The intensity and diffusion of antagonism developed around the project are uncommon to public policy processes in Germany, and have prompted attention e.g. on the 'new' sociological features of urban protest and citizens mobilization around contentious urban development initiatives – their peculiar cross-sectional and inter-generational features being one of main aspects addressed by social researchers.

Above all, Stuttgart 21 has triggered a large public debate on issues concerning local policy and the apparent legitimacy deficit of public decision-making procedures incapable of incorporating a truly agonistic dimension of politics. Accordingly, the features taken by citizens' mobilization against this project have turned Stuttgart 21 into a catalyst for a broader public debate on the 'renewal' of local democracy.

First phase: techno-political conception

The beginnings of the project's political career are marked by what will be experienced as a key feature throughout the protest mobilization, a significant lack of transparency and of public openness. The marking event was the press conference in which, on April 18, 1994, the project called 'Stuttgart 21' was officially presented as a partnership project of the German federal government, the Land Baden-Württemberg, the City of Stuttgart and Deutsche Bahn AG (DB), involving a new underground station on the location of the extant, urban redevelopment dismissed railway grounds, and an improved railway connection to Stuttgart airport. What was presented by the protagonists themselves as a 'coup' (Heinz Dürr, CEO of DB, *Stuttgarter Nachrichten* 14 February 1995, quoted in: http://www.leben-in-stuttgart.de/geschichte.htm) marked a style of policy-making which was characteristic for a phase of techno-political conception carried out 'behind closed doors'. In fact, a first concept by Stuttgart-based transportation expert Gerhard Heimerl for a transit station connected to a new railway line to Ulm had been developed by DB since 1988, and was backed in September 1992 by a first crucial intergovernmental agreement on a solution combining a new station to a specific railway development option.

Significantly, in this phase, the way the project was managed in the public domain does not allow it to arise above a threshold of attention amenable to turning it into a significant issue in political campaigns. This happened despite the fact that critique had been voiced early: the alliance *Umkehr Stuttgart*, composed of seven environmental and transportation advocacy groups, had expressed dismissal of the project, backed by the Greens which advocated the 'lean' alternative (Bündnis 90/Die Grünen 1995) – with arguments later by and large taken over by the movement. This was certainly due to the peculiar inter-institutional and inter-party support which backed the project, but also to the form of political communication adopted. In both the elections of the state parliament of Baden-Württemberg in April 1992 and the elections for Stuttgart city council in June 1994, Stuttgart 21 did not play any significant role. Even more significantly, the issue was almost completely absent from official parties' election campaigns for the Baden-Württemberg parliament in March 1996.

Second phase: formal planning

The latter elections took place at the outset of the *second phase* of the process, which marks the beginning of formal planning. From 1995 (first feasibility study presented in January, first exposition of plans in Stuttgart) (DB 1994) to early 1997 (decision on the design competition for the station), the foundations were laid for the start of the legal planning procedure, the *Raumordnungsverfahren*.

Meanwhile, a framework agreement among the institutional partners reached in November 1995 established mutual responsibilities in the development and financing

of the project, based on fixed costs forecasts – with a ceiling on public expenditure – and defined performance benchmarks. Both provisions, and in particular the former, were to become major issues of contention as for the cost-benefit ratio of the project and, above all, the transparency of expenditure forecasts.

The inter-institutional agreement of November 1995 was a landmark event in the development of the project. After only two years from the launch of the project, with formal planning procedures still pending, a contractual foundation for the project was laid down binding all partners (DB, Federal government, State government and the City of Stuttgart) to realizing the project under defined financial and operational conditions. The agreement provided for a timeframe and a building costs ceiling of 4,893 billion DM to be covered according to defined share rules by DB, the Federal state, the State Baden-Württemberg, the Region and the City of Stuttgart.

The double-bind realized between the parties in 1995 – to be later strengthened by agreement between DB and the City of Stuttgart by which 'fixed' the former's gains from the sale of the released railway tracks areas for urban development – was to become a major political factor and a key argument for the allegedly 'irreversible' character of the choice to build Stuttgart 21. By this, a contradictory situation was defined: on the one hand, a techno-political solution in a relatively advanced and concrete decision-making stadium, backed by a binding long-term financial and operational agreement; on the other hand, a still running formal planning procedure which, while formally providing for them, in fact ruled out any public consideration of techno-political alternatives of development.

A key defining element for the ensuing controversy since the *Raumordnungsverfahren* was the practical impossibility for any significant alternative concept to be analysed and discussed in public. In fact, the subsequent formal planning procedure, the *Planfeststellungsverfahren*, contemplated an alternative infrastructure and urban-regional transportation concept based on a rationalization of the existing node, which however was dismissed as not capable of realizing the objectives of the project. The strategic aim of Stuttgart 21 was since that moment held as identical with the techno-political adopted – by which, any possibility for public debate to influence the nature and features of the project was effectively ruled out. Accordingly, during the formal planning procedure and the consultation process involved, no real interface for dialogue with instances based on rejection of key tenets of the concept or on requests for alternatives was in any way made available. Rather, a political-institutional logic made of presumptive consensus formation and procedural legitimation consistently became dominant in framing the context in which contention could develop.

Third phase: institutionally-framed contention

Mounting civic protest notwithstanding, the planning process proceeded swiftly. In February 1997, a first phase of formal public insight and consultation – as required

by the *Raumordnungsverfahren* – was opened: the objections submitted – mostly referring to environmental and local impacts and on property rights – manifested the project's potential for conflict. Nevertheless, in November 1997, the *Raumordnungsverfahren* was positively concluded and the operational planning phase, the *Planfeststellungsverfahren*, introduced. During the *Planfeststellungs-verfahren*, 11,500 objections were presented by about 2,700 citizens, local communities and environmental groups, which were mostly dismissed as not relevant.

In this phase, contention around the project arose significantly, gaining a significant role in political campaigns, for the first time, on occasion of local elections in Stuttgart – involving choice of a new mayor – in October 1996.

Despite significant elements of polarization and even personification of the issue in party-political spheres, the dynamics of contention was still strongly framed by the institutional and procedural logic of the formal planning process. This occurred in two different, apparently contradictory, but intertwined ways.

On the one hand, the formal planning process offered a framework for expressing dissent on the project which – despite increasing contestation – still proved capable of framing and 'disciplining' protest. In fact, this framing capacity was to endure until the mid-2000s, when the last judicial procedures ensuing from the formal planning process were finally decided against the projects' opponents. A contribution to or, at least, an attempt at 'disciplining' protest was also given by an institutional strategy of 'displacing' dissent by opening spaces for participation on significant local side-aspects of the overall project. A significant moment in this strategy was the public participation procedure initiated by the City of Stuttgart in 1997 on the basis of the urban development framework concept for the railway areas to be dismissed, drafted by the city's planning department (Stadtplanungsamt Stuttgart 1997). Attended by an average 200 citizens and developing in a highly contested atmosphere between March 1997 and mid-1998, the public participation procedure increasingly manifested the limits of an approach systematically devised to exclude debate on the strategic conditions for development in the area and, in particular, on the feature of the infrastructural project on which it is premised. This rapidly led to radicalization and to petitions of principle concerning a truly democratic assessment of the effectiveness and legitimacy of Stuttgart 21 as a whole. As a matter of fact, as a side-effect of opponents' disappointment about public consultation, the first significant judicial initiatives against the city's decisions concerning the project were launched by representatives of the movement.

On the other hand, the first significant organized civic initiatives started addressing institutional possibilities for democratically rejecting the project. This is in particular the case of *Leben in Stuttgart - kein Stuttgart 21*, a civic initiative founded in 1995, which in July 1996 managed to gather 13,000 signatures in support of a local petition to change the city's statute in order to allow holding a local referendum on Stuttgart 21. Demands for a democratic opening of decision-making procedures, however,

were doomed meet on deaf ears on side of political party coalitions in power. Until 2007 – and before regaining significance in 2011, under completely changed political conditions – requests for a referendum remained a constant strategic focus of opponents, and their recurrent dismissal the marker of an political-cultural hegemonic elite and of its supporting interests coalition.

Between 1997 and 2001, Stuttgart was the scene of constant but scattered and often minor protest activities against the project developing within this dual frame. The experiences made by contentious forces on both these levels – the establishment of an effective interface for debate and strategic interaction, and the employment of institutional resources – however, proved to were key to the shift in protest and to the formation of a true an unprecedented social movement against the project during 2000s.

Fourth phase: extended and decentralized mobilization

Despite procedural successes and resulting claimed legitimation, the project's prospects become increasingly problematic in the late 1990s-early 2000s in connection with inter-institutional issues (not least, because of the self-deceiving timeframes and financial conditions defined for its realization, face to the need to complete the framework of agreements on matter of transaction involved) and, furthermore, with significant change in the nature and forms of civic protest.

In order to understand the reasons for this shift, three aspects must be considered. The first concerns the increasingly problematic commitment of the city's government to co-financing agreements with long-term political and administrative consequences. After a crucial a covenant between the Bund and DB was signed March 2001 – securing federal support to a project the financial viability of which appeared increasingly questionable –, in December 2001 the City of Stuttgart purchased from DB – for an amount of 459 million Euros which, according to opponents, clearly exceeds any reasonable profitability – the areas on which it committed itself to realising 17,000 new jobs and 11,000 residential units, thus significantly contributing to securing financing for the project.

The second aspect concerns the increasing symbolic visibility of the project and of its consequences as its realization approached. Controversies on the demolition of parts of the listed station hall building – designed by Paul Bonatz in the late 1920s – and on the destruction of parts of the popular historic park space, the Schlossgarten, in the city center, in particular, contributed to heating discussions and spreading civic mistrust, and marked the last stages of approval of the project, which was finally reached in 2007.

The third aspect is, as previously mentioned, the progressive expiration of procedural-juridical resources for effective opposition and the exhaustion of related strategies of contention by civic initiatives against the project.

As a matter of fact, between 2005 – when the *Planfestellungsbeschluss* was adopted – and April 2006 – when the last pending lawsuits against Stuttgart 21 were dismissed in favour of the project by the Land court of justice, rendering the *Planfestellungsbeschluss* legally binding – not only the last formal hurdles for the project, but also the last factors for strategic restraint to contention were removed, and a new structure of opportunity for new direct antagonistic actions emerged.

This was further reinforced when, in the following years, the latest attempts at adjudicating the right for popular expression were exploited. A significant escalation in readiness to public protest was reached with the mobilization in favor of a local referendum on the project, which was backed by about 67,000 signatures, but again dismissed by a majority of the Stuttgart city council in December 2007. In July 2009, also the Land court of justice – on grounds of the extant contractual agreements among the parties reached in 1995 and 2001 – rejected popular requests for a referendum on the project.

Meanwhile, the landscape of contentious practices against the project was significantly developing. Already during mobilization for the referendum, random demonstrations had been held demanding a stop to the project, with an estimate average of 5,000 participants. In July 2007, the various streams of opposition expressed by actors, initiatives and groups in and around Stuttgart were bundled in an umbrella organization called *Aktionsbündnis gegen S21*. The *Aktionsbündnis* brought together most 'historic' protest groups along with insurgent initiatives developed along the way. The *Aktionsbündnis* included local citizens' associations (Leben in Stuttgart e.V., SÖS Stuttgart Ökologisch Sozial), associations for ecologic protection and heritage at state and local level (*BUND, Stiftung Architekturforum BW*, *Aktive Parkschützer*, *Schutzgemeinschaft-Filder e.V.*), political parties of the centre-left spectrum (*Grüne, die Linke, SPD-Mitglieder gegen S21*), unions' representatives (*GewerkschafterInnen gegen Stuttgart 21*), and specific issue-related associations (*Pro Bahn e.V.*, *Verkehrsclub Deutschland*). The model was later imitated by similar associations dealing with the issue in other regional contexts (e.g. *Aktionsbündnis Heilbronner gegen S21).* The focus of mutual identification was support for the concept known as K21, which had definitely gained a key role as an alternative to the official project after it was presented in 2000 under the name 'optimised terminal station' (*Kopfbahnhof*) and subsequently fine-tuned in terms of both technical and financial terms. The concept showed on grounds of technical performance and of its comparative cost-benefit ratio the futility of 'megalomanic' structural interventions, while still allowing for 75 ha, i.e. about three-quarters of land-use gain through improvements on the railway tracks.

The *Aktionsbündnis* was led by a coordination team of about twenty representatives, which devised basic strategies concerning the repertoire of actions and the communication and negotiation strategies to be adopted. The pattern of protest initiatives however remained decentralized. It represented, in this respect, a typical example of a democratically decentralized movement (Tarrow 1998: 129), i.e. of an organizational setting drawing its strength from representing a decentralized,

segmented, and reticulated coalition of groups which allowed for multifarious and pluralist expressions of contention while providing an 'master frame' for mutual identification and recognition.

The new constellation formed an important condition for the development of a true social movement in opposition to the project, as it extended not only the basis for representation, but also opportunities for identification with and participation in contentious practices.

Under the umbrella of the *Aktionsbündnis*, the movement soon promoted a broadly accessible and appropriable repertoire of actions. Most remarkable of all was the start of the weekly *Montagsdemonstration*en against the project held in front of the station in Stuttgart's city center. The career of Stuttgart's *Montagsdemonstrationen* – started almost spontaneously on October 26, 2009, with five participants – was to become as remarkable as was the symbolic reference chosen: the public Monday's demonstrations held by citizens of Leipzig, Dresden and other cities in the doomsdays of the German Democratic Republic in 1989, as a public expression of a withdrawal of trust and legitimation. The extent reached by such statement of distress towards politics and institutions by an increasingly broad range of participants – held for the one-hundredth time in November 2011 and attended by a steadily rising number of participants – was a powerful attractor of statewide media and public attention for the Stuttgart 21 controversy. It also constituted a new structure of opportunity for broadening mobilization, in that it laid the conditions for the emergence of a repertoire of forms of contention made of peaceful direct actions performed in public, like the weekly demonstrations, the tatzebaos and public 'wall-of-complaints' postings, and other performances like sit-ins, human chains, the occupation of endangered trees, monuments and public places, as well as the mobilization of creative and suggestive symbols (such as the recurrent Swiss national flag waived during demonstrations: a symbol for both a referendum-based democratic culture and for an integrated railway network planning approach opposed to the criticized DB planning philosophy).

Success by the Greens in June 2009 local elections – replacing for the first time the Christian-Democrats as the largest party in city council – and the start of the *Montagsdemonstrationen* later that year introduced a new public mobilization phase, further fuelled by the ongoing unveiling of contradictions in the financial basis of the project.

Under these changed social and political conditions, events around Stuttgart 21 rapidly precipitated. On February 2, 2010, the first tree cuts marked the actual beginning of construction works, which were readily countered by mass demonstrations: on July 10, attendance reached 20,000. On August 25, under police protection after demonstrators had occupied the roof, demolition of the north wing of the old station terminal began. Two days later, over 30,000 participants demonstrated against the project forming a human chain around the station. The

Montagsdemonstrationen gained a new salience and went on throughout the year, with participants constantly rising and reaching up to 60,000 in late 2010.[4]

Meanwhile, with politics at the federal, state and city level becoming fully involved with the issue – with the Greens as the party-political wing of the project's opposition, the Social Democrats in Stuttgart finally accepting requests for a referendum, and the federal and Land government coalitions rejecting any claim for political or legal revision – citizens' protest extended to the occupation of public spaces in central Stuttgart. As a consequence of its insurgent politicization – in view of state election to be held in early 2011 – first attempts at mediation were initiated on September 24, 2010, but failed. This phase culminated in the dramatic events of 'black Thursday' when, on September 30, 2010, ruthless attacks of armed police forces on protesters during a demonstration against the cutting of trees in the Schlosspark left about four-hundred citizens hurt – among which 50 school children – and one seriously injured. At this point in time – and with the determinant contributions of these scenes of violence – Stuttgart 21 had definitely become the most mediatized event in recent history of German politics and society.

Fifth phase: mediatized re-politicization and mediated negotiation

Under the pressure of September 2010 events, and under the threat of a significant regime change after the 2011 Land government elections, the main actors on both opponents and supporters agreed in October 2010 to the need for an extraordinary measure of mediation. Remarkably, this new phase combined a distinctive re-politicization of Stuttgart 21 with a condition of radical uncertainty among the involved actors. This historic conjuncture may explain the peculiar mutual interdependence that led political actors to agree to a moratorium of regular procedures and to initiate a mediated negotiation experiment in order to deal with the conflict. Under unprecedented nation-wide public attention and media coverage, what was originally a 'local' issue became the occasion for experimenting and debating a new form of public scrutiny and deliberation around a major project – and an occasion for renewal of democratic practices.

This is not the place for discussing details of the mediated negotiation procedure conducted in Stuttgart along eight sessions between October 22 and November 30, known in Germany as the *Schlichtung Stuttgart 21*. The features and outcomes of this highly significant but contradictory experiment are worth an analysis of its own (see: Gualini 2011a, 2011b). Here we highlight aspects crucial for understanding the impact the *Schlichtung* had on the social movement against Stuttgart 21. As a crucial

[4] As is usually the case, figures on attendance of demonstrations obviously differ according to sources: e.g. a demonstration on October 4, right after 'black Thursday' – as reported by *Der Stern* (2012) – was attended by 54,000 according to the organizers and by 25,000 according to police. It is also worth noting that the rise of public opposition fostered emulatory reaction like the organization of counter-demonstrations in favor of the project, backed by advocacy groups like *Wir sind Stuttgart 21* and *Für Stuttgart 21*, often tied to governing coalition parties.

result, the parties agreed that a 'stress-test' assessing the expected performance of the project would decide about its prospects of realization. This key provision from the mediation, albeit agreed upon by all the parties – including DB – to be binding, was marred by two contradictions, which soon proved of major political relevance. Firstly, the solution was basically technical and, moreover, it was technical in a non-neutral way, being strongly framed as a technical test of the proposed solution – the official Stuttgart 21 project – and by no means as way of testing alternatives that may express a different view on the problem to be addressed. In this sense, even if allegedly binding, the stress-test represented no opening whatsoever to alternative views on Stuttgart 21. Secondly, all possible exit strategies following from the stress-test were subject to the contractual bonds extant among the project partners. This amounted *de facto* to a black-mailing factor for DB towards both the Land Baden-Württemberg and the City of Stuttgart, as it implied substantial and politically unbearable claims for financial compensation in any instance – from the extension of moratoria on construction works to the demise of the project – that contravened scheduled realization. In addition – as turned out after the mediation sessions and in particular after conduct of the stress-test – granting independence and transparency in conduct and dissemination of results of the assessment proved impossible under such conditions, lending DB in many respects an unreasonable vantage position.

It is significant that, after a highly contested presentation of the result of the stress-test on July 29, 2011 (SMA 2011), allegedly confirming the DB's expectations of technical performance and thus giving way to the project, its validity was broadly contested by representatives of the *Aktionsbündnis*, while attempts by the mediator, Heiner Geißler, to bring into play a new 'integrative' solution based on the K21 concept (SMA and Geißler 2011), was readily dismissed as already negatively assessed in the *Planfeststellungsverfahren*. Paradoxically, at this point in time, arguments about the project's 'legitimation by procedures' seemed to have won it.

Sixth phase: mediation breakdown, institutional pacification – and demobilization?

It is impossible to understand the shift in the cycle of contention following the *Schlichtung* without emphasizing change in political conditions introduced by the 2011 Land elections and how they transformed opportunity structures for mobilization. As a matter of fact, the March 2011 elections had already exerted their influence long before being held, favoring the actors' willingness to enter a procedure of mediated negotiation. Much more disruptive was however their effect as they led to an historic change in government regime – with the Green party becoming the second largest fraction in the Baden-Württemberg parliament behind CDU and ahead of SPD, and ultimately leading to an unprecedented Greens-SPD governing coalition which made Winfried Kretschmann the new prime minister of Baden-Württemberg and the first Green prime minister in German history, and which relegated the Christian-Democrats to opposition for the first time in 40 years.

As a result, the Land government had become the institutional, but internally divided, representative of a diverse constituency of project opponents: on the one hand, it was to be held accountable for its electoral promises and, in particular, for promoting a state-wide referendum in case the *Schlichtung* would not effectively stop the project: on the other hand, however, it was now also accountable managing institutional agreements concerning the project.

Of this complex double-bind, the Greens-led governing coalition of Baden-Württemberg was soon to experience the consequences – in first place, after the referendum – held on a state-wide level on November 27, 2011, after a complex institutional procedure to make it possible – failed to reach majority for the rejection of the project.

Under these conditions, the movement had since experienced first instances of 'de-mobilization': remarkably persistent, but declining participation to the demonstrations in front of the station, as well as so-far isolated, but significant instances of polarization and radicalization. Of great public significance was, for instance, not only overt denial of legitimation to the referendum by several opposition groups, including some of the key representatives of opponents, but also the occasional outbrake of violence, originated by the splitting of strategies of groups which had joined the Aktionsbündnis, but had denied legitimation to the mediated negotiation process. As construction works at the station resumed on June 20, 2012, the first violent clashes with police occurred – probably due to the actions of a splitting group, the *Parkschützer* – resulting in 15 arrests and in charges against unknown for attempted manslaughter, within what had been until then – and with the exception of 'black Thursday' – a peaceful movement.

4. Provisional conclusions: social mobilization, cycles of contention, and the reflexive capacity of planning

It is obviously unwarranted to draw comparisons from two case-studies as diverse – and still ongoing – as Stuttgart 21 and MediaSpree. Nevertheless, the focus we have placed on the co-evolution of planning processes and cycles of contention makes it possible to recognize significant differences and to advance a few conclusions with regard to our hypothesis.

In general terms, we can characterize the key difference between the two cases in the following terms.

In the case of MediaSpree, the cycle of contention, moving from an essentially antagonistic mobilization with strong political-ideological tones, developed around an opportunity structure which made it possible to establish a ground for a broad symbolic identification (the fusion of local and supra-local urban policy issues around MediaSpree as a 'neoliberal' symbol) as well as to develop elements of a concrete alternative (an 'other' vision of urbanity for the area) which created

opportunities for activating interest based claims. This led to complex combination of diffusion and differentiation of social mobilization which, however, realized a relative shift from ideologically based antagonism towards more interest based claims for recognition. Apparently, this was key to the development of an interface with the statutory planning process and their actors and, ultimately, for the inclusion of elements of the repertoire of contention into the strategic response of actors.

The opportunity structure for social mobilization in the case of MediaSpree was therefore increasingly shifting towards an alteration of the strategic-relational setting of the project itself, and this – at least potentially – introduced significant factors affecting its evolution.

As of today, contestation and antagonistic action appear to have been playing a key role in altering the relational framing of the project and, more significantly, in possibly fostering reflexive strategic responses. They have generated significant public attention and capacity of local mobilization as well as opportunities for redefining the role of public actors and for partially reframing their priorities. Far from being settled, the controversy around MediaSpree appears to have at least generated conditions for a significant reflexive evolution of the project.

Very much to the contrary, Stuttgart 21 seems to delineate a paradigmatic example of a planning process reinforcing an opportunity structure for enhanced ideological radicalization of protest.

This is not to say, of course, that opposition to Stuttgart 21 was itself 'ideological' or not grounded on concrete alternatives. It means to say however, that the capacity to develop alternatives within the strategic framework of the project – a role meant to be played by arguments and proposals clustering around to the counter-project K21 – was progressively marginalized by the early closure of the planning process to any significant form of reflexivity with regard to the nature of the insurgent contestation. As a matter of fact, the modes of regulation and disciplining embedded in the statutory planning procedures – the legalization of dissent and its dispersion through singular compensation measures – in this case did not realize a dilution of protest, but rather its reinforcement across highly diverse interests and social groups. What has therefore characterized Stuttgart 21 as a unique case of extensively cross-sectional as well as intensively emotional social mobilization in opposition to a public project is that it has become symbolic for the unresponsiveness of politics and institutions and, for this reasons, increasingly political-ideological and antagonistic in nature – despite its diffuse 'bourgeois' character.

Such a reading would contrast, of course, with one underlining the 'post-' or 'anti-political' nature of Stuttgart 21 protest since, on the contrary, it underlines the political salience of a situation incapable of providing for adequate arenas for dealing with interest based claims. In this respect, the ideological and antagonistic nature of social mobilization is probably attributable in large part precisely to claims for recognition by citizens feeling excluded and estranged from public policy.

This is not the place for a thorough analysis of the reasons for this – which are in large part recognizable in the institutional and procedural rationale of planning for strategic development projects, in Germany as elsewhere. What we want to point out here is that, according to the features of the planning process, social mobilization around Stuttgart 21 gained momentum precisely in connection to the emergence of an opportunity structure that may appear surprising in relation to the 'concrete' nature of the object of opposition: an opportunity structure sustained by – but also increasingly 'stuck' into – a complex frame dominated by symbolic and identity-related recognition claims, with a distinctive antagonistic political-ideological profile. This frame made it possible for a broad cross-section of local society to identify and mobilize against the project, but its reverse was the progressive limitation and marginalization of opportunity structures for creative-integrative influence. As a matter of fact, the attempt to develop margins for integrative solutions thorough a procedure of mediated negotiation produced almost farcical results (Gualini 2011a, 2011b).

It is remarkable, in this respect, that even a dramatic change in the relational setting of local politics and institutions could not effectively alter the pattern of decision that had clustered over time along the project, consolidating it as an un-reflexive – object almost beyond the wish of the involved actors. It is hence only tragic that today – after a generous, but highly belated, and ultimately ineffective attempt at mediation, marred by problematic framework conditions, as well as after a long sought-after but ultimately failed referendum – the only possible alternatives (bot not unlikely) to realization of the contested project appear to be either its financial-operational break-down and abandonment, or a polarization and radicalization of protest. At any rate, Stuttgart 21 appears as of today as the ultimate example of planning failure to develop a capacity of strategic reflexivity and integration vis-à-vis the dynamics of social mobilization in a local context.

POTENTIAL IMPACTS OF CLIMATE CHANGE IN RAPIDLY URBANIZING REGIONS-A CASE STUDY IN HANGZHOU (CHINA) REGION

Liu Dan[1], Allaert Georges[2], Hua Chen[3]

Abstract

Climate change is expected to be a major driving force of landscape in the coming decades. It will have a multitude of potential impacts that vary in intensity and effect according to region and sector. In the context of global warming, the climate of China has changed significantly in the recent 100 years. According to "China's National Climate Changes Programme", there are mainly five aspects about the fact of climate changes in China: Firstly, the annual average temperature increases; Secondly, regional precipitations fluctuate somehow largely; Thirdly, the frequency of extreme weather events increase in speed and in intensity; Fourthly, sea level rises; Fifthly, mountain glaciers retreat rapidly, and the trend accelerates. The reason of climate change in China caused by human activities is mainly the irrational land use, which chiefly results in the rapid industrialization and urbanization process. This paper explores the potential impacts of climate change for the Hangzhou region. The aim of this paper is to conclude on the one hand some of Hangzhou sensitivities in relation to the expected primary effects of climate change. On the other hand a reflection is made on methodology to formulate preconditions as a scientific basis for further research by design on integrated adaptation options for the future spatial developments in function to upgrade Hangzhou resilience in relation to climate change challenges.

Keywords

Climate change, Impact, Exposure, Adaptation, Resilience

1. Introduction

Since the 1980s, global climate change, characterized by global warming, has a great deal of attention from governments, international societies and scientific researchers. Climate change will have a multitude of potential impacts that vary in intensity and effect according to region and sector (e.g. EEA, 2008). In the context of global warming, the climate of China has changed significantly in the recent 100 years. The reason of climate change in China caused by human activities is mainly the irrational land use, which chiefly results in the rapid industrialization and urbanization process (Zhang et al., 2009).

2 Ghent University, Ghent, Belgium –georges.allaert@ugent.be
3 Zhejiang University, Hangzhou, China – huachen1212@zju.edu.cn

This paper examines the impacts of climate change in China through a study of Hangzhou region, with a focus on an integrated and comprehensive assessment. The object of the regional analysis and assessments is to provide the basis for understanding where, how, and why certain regions are affected by climate change. The following sections apply the indicator-based assessment method to explore impacts of climate change relevant for spatial development in Hangzhou region.

The framework for this impact assessment was built upon the concept suggested by the Intergovernmental Panel on Climate Change (IPCC) (2007), Fussel and Klein (2006) and Rannow et al., (2010). Impacts of climate change are a product of exposure and sensitivity to climate stimuli. In this context exposure describes the nature and degree to which a system is exposed to significant climatic variations, while sensitivity is the degree to which a system can be affected, either adversely or beneficially, by climate variability or change (IPCC, 2007).

2. Study area

Hangzhou locates along the southeast coast of China. The prefecture-level region of Hangzhou extends from the border with the hilly-country Anhui Province in the west, to the flat-land near Hangzhou Bay in the east. As a core city of the Yangtze River Delta, Hangzhou has a position on the Hangzhou Bay 180 kilometres southwest of Shanghai that gives it economic power. It has been one of the most renowned and prosperous cities of China for much of the last 1,000 years. The total area of Hangzhou region is 16,596 km^2 with a population of 8.70 million. The urban area of Hangzhou (Hangzhou city) and five counties (county-level cities)—Fuyang, Lin'an, Jiande, Tonglu, and Chun'an are under the jurisdiction of Hangzhou (Figure 1, Table 1).

Figure 1. Location of Hangzhou Region

Table 1. Population and Land Areas of Six Districts in Hangzhou Region, 2010 (Source: Hangzhou Statistical Yearbook, 2011; the sixth China's National Population Census, 2010)

	Hangzhou city	**Lin'an city**	**Fuyang city**	**Tonglu county**	**Chun'an county**	**Jiande city**
Land area(km^2)	3068	3124	1808	1780	4452	2364
Total population(1000)	6242	566.7	717.7	406.4	336.8	430.8

The recent research show that the main tendencies of climate changes in Hangzhou are as follows: (a) significant warming of the winter; (b) extreme heat during the summer and the autumn; (c) an increase of precipitation; (d) more frequent typhoons (Hangzhou Meteorological Bureau, 2011). In terms of the urbanization impact on local climate change, the average surface temperature has increased by about 0.26℃ per decade from the 1960s to now in Hangzhou. Since the 1990s, when Hangzhou phased into the high-speed urbanization process, the degree of increase in temperature was higher. A historical reference is listed for each impact, substantiating it (Table 2).

The projections of climate change for the 21st century using the regional climate models indicate that, in 2071-2100, the surface air temperature in Hangzhou region will continue to increase (Figure 2).

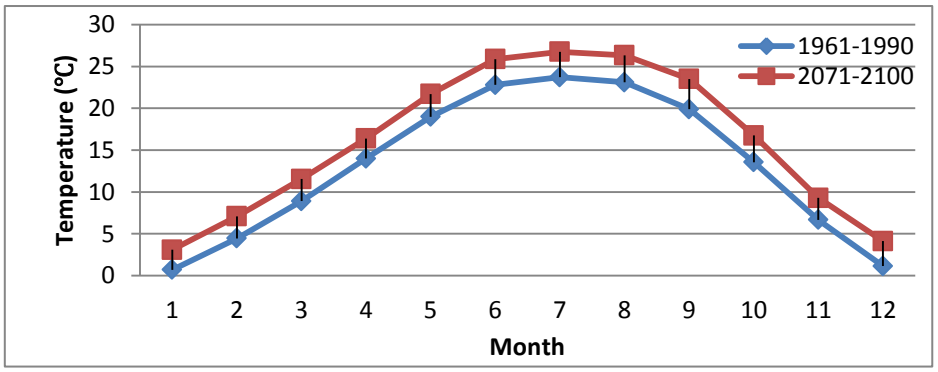

Figure 2. Comparison of Average Monthly Temperatures between 1961-1990 and 2071-2100 by the Regional Climate Model RegCM3 (Source: China's National Climate Centre)

Table 2. Climate Change Impact Table for Hangzhou Region (Source: own processing according to Hangzhou Meteorological Annals, Hangzhou Municipal Annals and Zhu et al., 2008)

exposure	Impact	Historical Reference	Adaptive Capacity in place
	Caused by extreme event:		
Temperature	Fluvial floods	Abundant rainfall events in summer (e.g. July 2002, June 1999, June 1996, May 1995, June 1994, June and July 1993,…, June 1901) induced several severe floods from rivers through history	Floods forecaster system in place
Precipitation			
Evaporation			
Storminess	Pluvial floods	Local floods in cities as a consequence of heavy showers in combination with an inadequate sewage system and no room for water(e.g. July 1997,Sept 1989,…, 1931)	
Drought			
Frost	Drought	Abundant drought events in summer, autumn and winter (e.g. July 2004, July-Oct 2003, March-Sept 2000, Dec 1996-June 1997, July 1994, Sept 1990, July-Dec 1988, Jan-June 1986, May-Oct 1967)	Drought forecaster system in place
Snow			
	Typhoon	Several typhoons are documented through history (e.g. Oct 2007, August 1997, August 1988, …, 1910)	Disaster weather forecaster system
	Heat waves	Several heat waves are documented through history in the summer (June-Sept 2003, Sept 1995, July 1995)	Awareness-warnings broadcasted on radio and television
	Cold waves	Several cold waves are documented through history in the winter (e.g. Feb 2008, March 1998, Jan 1996, Jan-Feb 1984, Jan 1977,…, 1916)	Awareness-warnings broadcasted on radio and television
	Hail and storm	Abundant hails and storms (e.g. June 2006, May 1991, April 1986, April 1977, April 1972, April 1962)	Disaster weather forecaster system
	Urban heat island effects	It is assumed that the historical cores and nucleuses are potential hotspots for UHIe.	Research in progress
	Not included effects caused by extreme event:		
	Summer smog Winter smog Ozone Forest fires	Several warming per year	Monitor system in place and broadcastings to raise awareness
	Caused by slow changes:		
	Water scarcity groundwater; surface water; rainwater; production water	Measurements show that Hangzhou region has yearly 2601m3 of water per person. This is a little less than national average level.	Monitor system in place and awareness raised.
	Loss of species and biodiversity	Rare species are being endangered in Hangzhou region.	Systematically monitored and awareness raised
	Increased Erosion (loss of soil)	Each year 5 million tons of soil erodes by water from 1980's.	Systematically monitored and awareness raised
	Other not included effects		
	Increased Energy demand (…)		

3. Materials and Method

3.1 Identification of climate change impacts relevant for spatial analysis

To focus on the spatial analysis a multitude of impacts of climate change were examined. The impacts were analyses in terms of their relevance for spatial development. Eight types of climate change impact of primary relevance for spatial development on a regional level in Hangzhou (large river floods, heavy rain and flash floods, heat waves, mass movement, forest fires, destruction of infrastructure, loss of soil by water erosion and loss of species and biodiversity) were identified. They are grouped into impacts caused by extreme weather events and impacts caused by slow climatic changes.

3.2 Assessment framework

The assessment framework defined the way the assessment procedure for every impact is organised (Figure 3). Each indicator provides useful information about single aspects of climate change impacts, but absolute numbers provided by indicators are only of limited value for an integrated assessment of impacts (Metzger et al., 2008). Three assessment classes (or categorical values) were used. Every indicator was classified to represent low (1), medium (2) and high (3) risks or low (1), medium (2) and high (3) sensitivity status. Assessment matrices were used to join and reclassify the indicators and provide a common index. This procedure provides comparable results for every impact regardless of the number of indicators used for the assessment. This classification remains coarse and thus emphasises the qualitative character of the assessment results. For the reclassification of exposure and sensitivity indicators the assessment matrix shown in Figure 3 was used.

The application of this framework for every impact allowed a comprehensive evaluation and comparison of the results. Figure 3 presents a scheme of the applied approach. In Table 4 and Table 6 the indicators and input data for the assessment are listed.

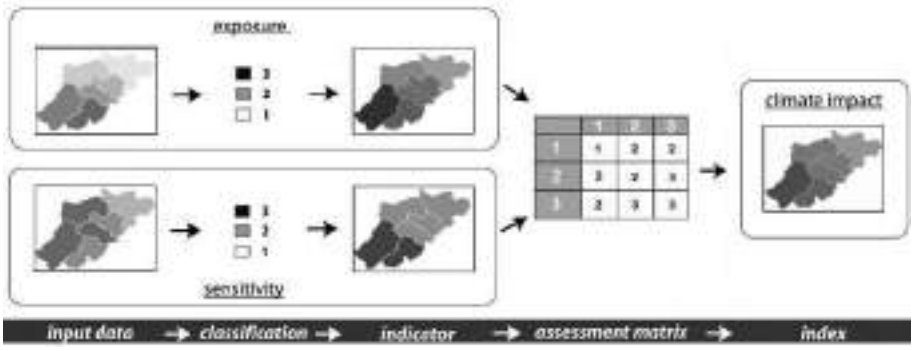

Figure 3. Assessment Framework for the Indicator Based Assessment of Climate Change Impacts (Source: in accordance with Rannow et al., 2010)

3.2.1 Assessing exposure

In order to calculate and assess indicators for regional exposure to climate stimuli the data sets from Hangzhou Meteorological Annals were extracted. Climatic parameters included information on precipitation (mm/month) in rainy season, days/year with heavy rain (Daily precipitation>50mm), hot days/year (T_{max} >37℃), percentage of summer months with low precipitation, Precipitation in month with erosion and yearly mean temperature (Table 3).

Table 3. Available Input Data of Six Districts in Hangzhou Region, 1986-2005 (Source: own processing according to Hangzhou Meteorological Annals)

	Hangzhou city	**Lin'an city**	**Fuyang city**	**Tonglu county**	**Chun'an county**	**Jiande city**
Precipitation in rainy season	277.4	283.2	284.6	299.5	332.9	332.4
Days/year with heavy rain (Daily precipitation>50mm)	3.70d	3.75d	4.00d	3.65d	5.20d	4.75d
Hot days/year (T_{max} >37℃)	8.2d	13.55d	10.8d	14.8d	14.65d	9.3d
Percentage of summer months with low precipitation	45%	35%	40%	65%	65%	55%
Precipitation in month with erosion	303.5mm	293.0mm	315.0mm	328.5mm	375.1mm	355.8mm
Yearly mean temperature	16.45℃	15.8℃	16.3℃	16.0℃	17.4℃	17.0℃

The results were averaged for each administrative district in Hangzhou region. The results are stored as a database with each administrative region referring to a database record. The records are referenced for further mapping and regional assessment.

Following the general framework in Figure 3 every climatic parameter that was used as an exposure indicator was classified into low, medium or high risks (Table 4).

Table 4. Input Data and Classification Used to Assess the Exposure to Climate Change Stimuli on the Base of the Information from 1986 to 2005. (Source: in accordance with Rannow et al., 2010)

Impact	**Available input data**	**classification**	
Caused by extreme events			
Large river floods	Precipitation in rainy season	<250mm 250-300mm >300mm	Low Medium High

	Days/year with heavy rain (Daily precipitation >50mm)	<4d 4-5d >5d	Low Medium High
Heavy rain and flash floods	Days/year with heavy rain (Daily precipitation>50mm)	<4d 4-5d >5d	Low Medium High
Heat waves	Hot days/year (T_{max} >37◦C)	<9d 9-12d >12d	Low Medium High
Mass movement	Days/year with heavy rain (Daily precipitation>50mm)	<4d 4-5d >5d	Low Medium High
Forest fires	Hot days/year (T_{max} >37℃) Summer months with low precipitation	<9d 9-12d >12d <40% 40-60% >60%	Low Medium High Low Medium High
Destruction of infrastructure	Days/year with heavy rain (Daily precipitation>50mm) Hot days/year (T_{max} >37℃)	<4d 4-5d >5d <9d 9-12d >12d	Low Medium High Low Medium High
Caused by slow changes			
Loss of soil by water erosion	Days/year with heavy rain (Daily precipitation>50mm) Precipitation in month with erosion	<4d 4-5d >5d <300mm 300-350mm >350mm	Low Medium High Low Medium High
Loss of species and biodiversity	Yearly mean temperature	<16℃ 16-17℃ >17℃	Low Medium High

3.2.2 Assessing sensitivity

Sensitivity to climate stimuli is determined by endogenous factors and main regional characteristics. The interdependencies (or the interplay) of these bio-physical, social and political factors and processes influence the degree of sensitivity (Rannow et al., 2010). Therefore, indicators for the main social and structural factors are needed to model sensitivity.

Most data were selected from the public databases of the Hangzhou Statistical Office (Table 5). The data cover aspects of (a) land use (e.g. percentage of water erosion area, forest or area protected by nature conservation law); (b) social issues (e.g. percentage of people older than 65 years); (c) built environment or technical infrastructure (e.g. percentage of area covered by streets, main roads, etc.) and (d) hazard risks (e.g. percentage of flood year, assessment of landslide hazards).

Following the general framework in Figure 3 all sensitivity indicators were classified using three classes (Table 6). The limits for each class were obtained by expert assessment of the available input data or based on the literature (e.g. Rannow et al., 2010; Yu et al., 2011).

Table 5. Available Input Data of Six Distracts in Hangzhou Region (Source: own calculation from Hangzhou Meteorological Annals 1986-2005, Zhejiang Construction Information Port, 2007; Hangzhou Statistical Yearbook, 2011; Hangzhou Forestry and Water Conservancy Bureau, 2001, 2010; Hangzhou Environmental Protection Bureau, 2004; Huang et al., 2008, Yu et al., 2011)

	Hangzhou city	**Lin'an city**	**Fuyang city**	**Tonglu county**	**Chun'an county**	**Jiande city**
Percentage of flood year	60%	64%	52%	57%	64%	67%
Percentage of built-up area	11.23%	0.37%	1.37%	0.82%	0.21%	0.33%
Percentage of people older than 65 years	17.5%	16.5%	15.5%	17%	15.8%	17.5%
Assessment of landslide hazard risk	Low	High	Medium	High	Medium	High
Percentage of forest	28.45%	77.76%	63.18%	71.43%	75.19%	75.25%
Percentage of area covered by streets and other infrastructure Fraction of highway	No data available	No data available	No data available	No data available	No data available	No data available
Percentage of water erosion area	6.37%	20.05%	24.48%	18.97%	32.92%	21.02%
Percentage of area protected by nature conservation law	6.05%	8.09%	1.07%	2.63%	21.35%	9.05%

Table 6. Input Data and Classification Used to Assess the Sensitivity to Climate Change Stimuli on the Basis of Different Data Sources (Source: in accordance with Rannow et al., 2010)

Impact	Optimal input data	Available input data	Data source	Classification	
Caused by extreme events					
Large river floods	Area impacted by dam failure	Percentage of flood year	Hangzhou Meteorological Annals,1986-2005	≤49.9% 50–59.9% ≥60%	Low Medium High
Heavy rain and flash floods	Percentage of paved surface	Percentage of built-up area	Zhejiang Construction Information Port, 2007	≤14.9% 15–29.9% ≥30%	Low Medium High
Heat waves	Percentage of population sensitive to heat waves Area sensitive due to urban heat island effects	Percentage of people older than 65 years Percentage of built-up area	Hangzhou Statistical Yearbook, 2011 Zhejiang Construction Information Port, 2007	≤18.9% 19–20.9% ≥21% ≤14.9% 15–29.9% ≥30%	Low Medium High Low Medium High
Mass movement	Area sensitive to mass movements	Assessment of landslide hazard risk	Bu et al.,2011	Low hazard Medium hazard Major hazard	Low Medium High
Forest fires	Area of forest cover sensitive to forest fire	Percentage of forest	Hangzhou Forestry and Water Conservancy Bureau, 2010	≤19.9% 20–39.9% ≥40%	Low Medium High
Destruction of infrastructure	Amount of infrastructure Importance of infrastructure	Percentage of area covered by streets and other infrastructure Fraction of highway	No data available No data available	≤4.9% 5–9.9% ≥10% ≤99.9m/km2 100–199.9m/km2 ≥200m/km2	Low Medium High Low Medium High
Caused by slow changes					
Loss of soil by water erosion	Area sensitive to water erosion	Percentage of water erosion area	Hangzhou Forestry and Water Conservancy Bureau, 2001	≤14.9% 15–24.9% ≥25%	Low Medium High
Loss of special and biodiversity	Number of species and habitats endangered by climate change	Percentage of area protected by nature conservation law	Hangzhou Environmental Protection Bureau, 2004	≤6.9% 7–13.9% ≥14%	Low Medium High

3.2.3 Assessing impacts

After exposure indices and sensitivity indices were quantified, they were merged to represent an index for each impact of climate change. The result was documented in maps showing the spatial distribution of every index for an impact of climate change at local level. In this way, maps of impacts of climate change in Hangzhou were created.

4. Results

The results from the impact assessment as well as the input data on exposure and sensitivity are presented below.

4.1 Exposure

Based on the data from Hangzhou Meteorological Annals, the map of local exposure to climate change risks in recently past is represented in Figure 4. The map shows that Chun'an county is the highest risk district. In addition, some hilly area like Jiangde city, Tonglu county and Fuyang city also show considerable exposure. And the analysis indicates most districts are exposed to heat waves. This is due to extreme heat of summer and a high grade of urbanisation aggravating heat wave events.

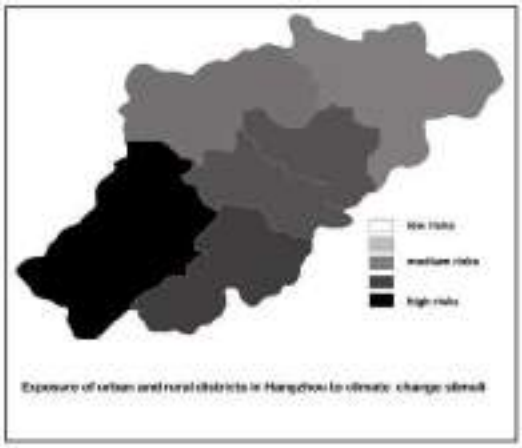

Figure 4. Local Exposure to Climate Change Risks

4.2 Sensitivity

Based on the indicators derived from social and economical statistics the sensitivity of six districts was analysed for all eight impacts. The results are documented in maps for every impact.

Most districts are sensitive to forest fires. This is due to the mountain region with abundance of forest resources. Also the sensitivity towards river floods is high.

This is related to the high frequency of flood year in all of districts of Hangzhou region. For destruction of infrastructure no sensitivity indicator could be obtained because of missing data.

After the assessment for each sensitivity index in isolation the results for each district were summarised. The map of the accumulated sensitivity indices for all impacts analysed is shown in Figure 5. Jiangde city, Lin'an city and Chun'an county are the most sensitive to the eight impacts analysed. The comparison of sensitivity indices gave a first indication of areas at risk of negative impacts of climate change. This status quo analysis provides information about areas where resilience to climate change needs to be enhanced.

Figure 5. Local Sensitivity to Impacts of Climate Change

4.3 Impacts

For the assessment and spatial analysis of each climate change induced impact the relevant indices of sensitivity and exposure were compared. Individual impacts show differing spatial distributions (Figure 6).

The analysis indicates a concentration of major impacts on Chun'an county, where a major climatic change stimulus meets high sensitivity. The impact of large river floods is concentrated on Chun'an county and Jiande city. The risk of forest fires is mostly relevant for Tonglu county and Chun'an county. The impact of heat waves is strongest in western hilly area, but north-eastern flatland is especially sensitive because of its high percentage of high urbanized areas.

The increase of temperature shows special relevance for the high value nature conservation areas and the highly urbanised centres. The risk of soil erosion by water is high to Chun'an county with abundance of water resources. The impact of heavy rain and flash floods is generally higher for hilly area than flatland. The potential mass movements are mostly relevant for all mountain ranges in central

and southern Hangzhou region. Lacking a qualified indicator for sensitivity, the destruction of infrastructure is solely influenced by heavy rain days and hot days. Nevertheless, Chun'an county is indicated as the location of major exposure.

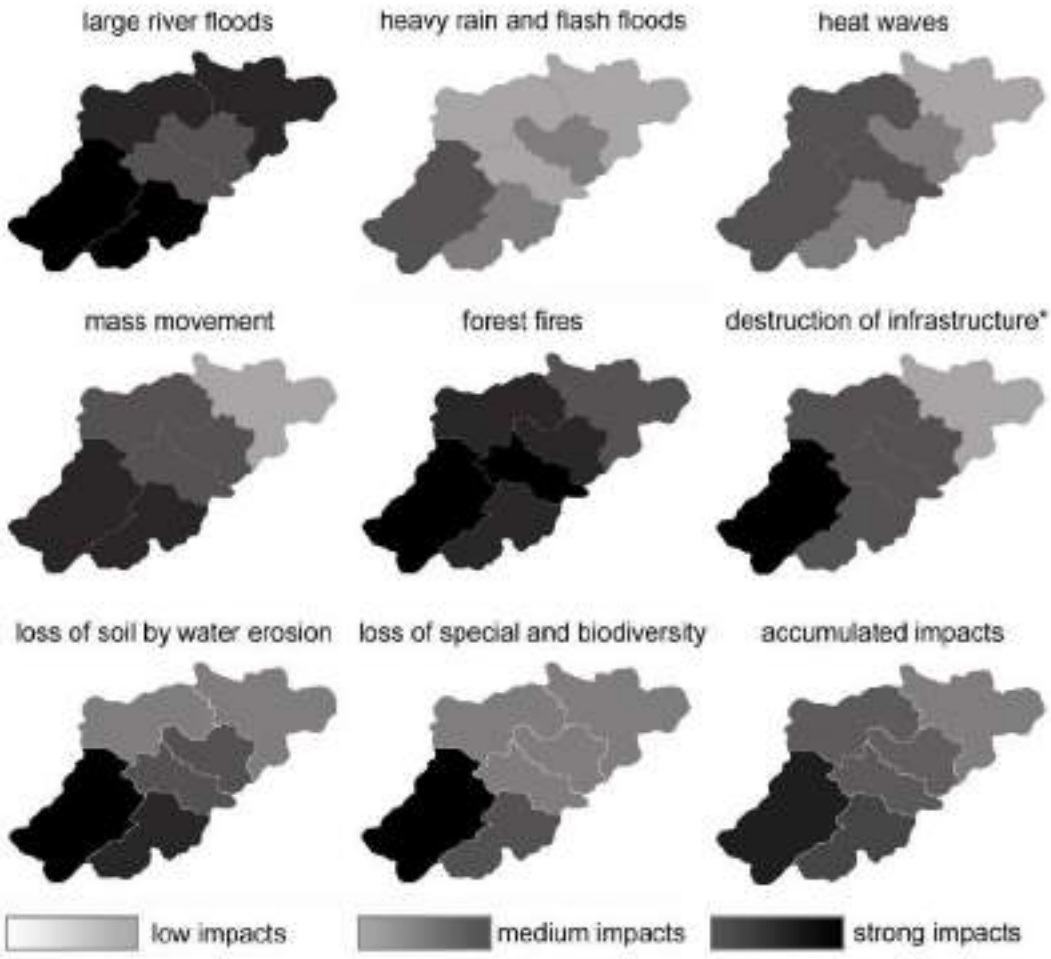

Figure 6. Results of the Indicator Based Assessment of Climate Change Induced Impacts.
*Lacking a qualified indicator for sensitivity, the destruction of infrastructure is solely influenced by changes in heavy rain days and hot days.

Based on assessing exposure and sensitivity, this research represents a picture of the impacts of climate change in six districts of Hangzhou region. In sum, the impacts of climate change from northeast to southwest had an increasing tendency. The hilly-country like Chun'an county, Jiangde city, and so on, is relative high risk.

4.4 Gaps and future research

It is very hard to describe the vulnerability without knowing which kinds of impacts are expected. In the case of Germany, Rannow et al. look in for available input data about potential impacts of climate change. However, there is not enough available data in Hangzhou/China. For example, based on the regional climate change model RegCM3[4], China's national climate centre only provides to date the data on temperature (T_{max}, T_{min}, T_{mean}) and average amount of precipitation from 2071 to 2100 for the IPCC scenarios A2[5]. But other data is still forthcoming, such as the information on the average number of summer or hot days, the average number of frost days and the average number of heavy precipitation days for the IPCC scenarios A2 and on the relative ones for the IPCC scenarios A1B[6] and B1[7]. In the present study, it is hard to assess and spatially analyse potential impacts of climate change without sufficient available input data to calculate and assess indicators for exposure to future climate stimuli.

Another gap which shall be required to be addressed is the urbanization stress on local climate change in Hangzhou region. Recently research shows that there is an objective dynamic coupling relationship between urbanization and regional climate change in China, which consists of the multi-level network effects of climate change on urban "social-economic-nature" complex ecosystems, the pressure of social-economic development, energy requirement and urban land sprawl in the process of urbanization on regional climate change (Fang, 1989; Huang, Fang, 2003; Wang, 2010). Reducing the negative impacts of climate change and increasing the resilience of physical and social structures within the rapidly urbanizing regions requires pro-active adaptation strategies. Understanding the impacts of climate change on land uses and the urbanization stress on local climate change is an essential basis for the development and application of adaptation strategies.

It is also necessary to enhance the database for the input data and provide more detailed information. In addition, further evaluation of the appropriate scale with regard to input data and assessment result is needed (Rannow et al., 2010).

---

4 RegCM3 is a 3-dimensional, sigma-coordinate, primitive equation regional climate model.

5 The IPCC scenario A2 describes a very heterogeneous world. The underlying theme is self-reliance and preservation of local identities. Fertility patterns across regions converge very slowly, which results in continuously increasing population. Economic development is primarily regionally oriented and per capita economic growth and technological change more fragmented and slower than other storylines.

6 The IPCC scenario A1B is one of the three A1 groups and its technological emphasis is a balance across all sources.

7 The IPCC scenario B1describes a convergent world with the same global population, that peaks in mid-century and declines thereafter, as in the A1 storyline, but with rapid change in economic structures toward a service and information economy, with reductions in material intensity and the introduction of clean and resource-efficient technologies.

Even though there are further improvements to be made, this study enables a primary understanding of where, how and why certain areas in Hangzhou region are effected by climate change. This information is essential for adaptation activities.

Furthermore, additional research will address the following issues about Hangzhou region in the near future: a) An assessment and spatial analysis for exposure to future climate stimuli; b) Identifying potential "hot-spots" of climate change by means of GIS-based overlay technique; c) Identification of interaction between urbanization and local change climate.

5. Discussion and conclusion

What is adaptation to climate change? Figure 7 shows vulnerability is determined by the exposure to primary effects of climate change, the sensitivity of structures of human activity and the adaptive capacity of systems under stress. Exposure and sensitivity determined the impacts of climate change; these are the secondary effects of climate change. As a reminder, the social ad spatial characteristics of the system are a function of the sensitivity, i.e. factors and driving forces. These are the socioeconomic, environmental, demographic and political factors, which are in turn controlled by drivers, such as the degree of economic diversification, the degree of education, etc. (Füssel and Klein, 2006) Mitigation enables us to adapt the exposure side, while adaptation enables us to adapt the sensitivity of a system.

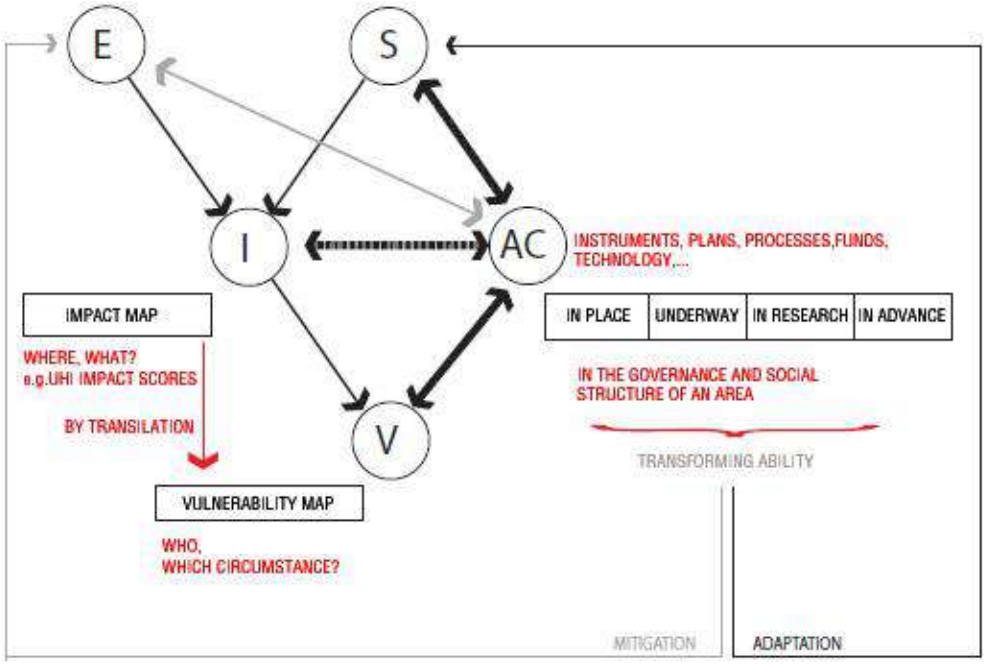

Figure 7. Integrated Vulnerability/Resilience Framework (Source: Verhofstede, 2012)

Hangzhou municipal government to date mainly focuses on mitigation of climate change by reducing greenhouse-gas emissions and enhancing sinks. According to "Hangzhou development planning of Low Carbon City", there are some strategies to meet the challenges of climate change. These strategies are: (a) to establish Low-carbon industries Agglomeration district; (b) to promote clean energy; (c) to build ecological zones and to enhance sinks; (d) to optimize the urban function; (e) to promote Low-carbon buildings; (f) to develop public transport. Furthermore, Hangzhou's adaptive capacity in place to climate change mainly emphasizes on forecaster system and monitor system in place. It has to date not been sufficiently considered to integrate adaptation options into planning procedures in Hangzhou. In face with both climate change pressure and population pressure, it is necessary to improve adaptive capacity of climate change in Chinese cities, Hangzhou included. Both adaptation and mitigation are now essential. There are researches which try to lead to the implementation of new planning strategies in Europe, while there is still a long way to go in China.

More Athenian sociospatial injustice in the works? Creating a metropolitan park at the former Hellinikon International Airport of Athens

Polina Prentou[1]

Abstract

Hellinikon is the largest, publicly-owned, urban, coastal area in Attica (626 Ha), as well as one of very few such areas left across the European urban coasts. It is the only remaining large-scale open space of Athens that can be used to address the shortage of green open public spaces, provide public access to 3.5 km of the urban waterfront, and supply an existing and extensive building stock for necessary social uses. By employing a variety of quantitative and qualitative methods with dross-disciplinary data at multiple scales, this paper has three objectives: a) to decodify the ways in which the current privatization processes spatialize not only intensifying inequalities and injustices, but also intensifying opposition by urban social movements; b) to document the importance of creating the Metropolitan Park of Hellinikon, by demonstrating why it is indispensable, feasible and inexpensive; and, c) to propose a basic strategy for the immediate protection of public ownership of the area and the creation of a Green, Culture & Recreation Park, by outlining a set of phases with short-and long-term concerted actions. Thus, in the midst of "no alternatives" discourses, it presents a realistic counterproposal to the privatization plans and mega-projects for Hellinikon and other public spaces across Athens and across other European cities.

[1] Postgraduate student in urban and regional planning, NTUA, Dipl. Arch. Eng. NTUA. Research coordinator of the research project "Basic planning & design principles for the creation of the Metropolitan Green Park at the Former International Airport of Athens," NTUA Urban Environment Lab.

Introduction[2]

Hellinikon, the area of the former international airport of Athens, is one of the last available, publicly owned, large-scale and prime urban coastal sites of Europe. It has been presented as "the largest planned real estate development project in Greece" (Hellenic Center for Investment, 2004) and it is currently promoted for privatization as the "largest urban development project of Europe" (Mitropoulos, as cited in HRADF, 2012, para 3). It s also an area with several unique assets of significant importance to the Greater Athens Area residents. It is 14 minutes away from the Syntagma square, 30 minutes far from Egaleo, Peristeri and Piraeus, and less than an hour far from almost the whole metropolitan area, by using the existing fixed rail, metro and light rail systems. Measuring a total area of 626 Ha, 528 Ha of the former airport along with 98 Ha of the coastal zone, it is the only remaining large-scale open space of the Greater Athens Area that can address the dramatic shortage of green, open and public spaces in Athens, albeit partially, being just 1/10 of the green area that the Greater Athens Area needs by domestic and European standards and laws. It is, also, the only remaining coastal zone of Athens that can provide public access to 3.5 km of the Athens waterfront, where more than 20 km are inaccessible or accessible only by paying user fees. Hellinikon is an area with a total stock of 480 buildings, many of them of technical, historic or architectural value. More than half of the area (56% or 250 Ha) can open to the public immediately, while the rest can open in phases after the necessary institutional arrangements.

The paper develops in three parts. First, it examines the history of the Hellinikon area since the closure of the airport in 2001, and especially the process towards its privatization since 2010. Second, it describes urban social residents' movements against the privatization of the area. Finally, it presents a counter-proposal for creating the

[2] This paper is based on the research project "Basic planning & design principles for the creation of the Metropolitan Green Park at the former Hellinikon International Airport of Athens", conducted in 2009-2010 by the National Technical University of Athens, Department of Urban and Regional Planning, Urban Environment Lab for the Local Union of Municipalities & Communities of Attica and the Cities of Alimos, Argyroupoli, Glyfada and Hellinikon. Research team: Dr. Nikos Belavilas, architect-planner, associate professor NTUA (head of the research), Konstantina Soureli, architect engineer AUTH, phd student in urban planning UCLA (research coordinator), Polina Prentou, architect engineer NTUA (research coordinator), Dr. Fereniki Vatavali, architect-planner NTUA, Maria Kalatzopoulou, civil engineer-transportation planner, researcher NTUA, Paschalis Samarinis, architect-planner, researcher NTUA, Evaggelia Hadjikonstantinou, architect-planner, researcher NTUA, Vasiliki Vallindra, architect engineer NTUA, Marina Theodorou, architect engineer NTUA, Theodora Hadji-Rodopoulou, architect engineer NTUA, Thomai Christopoulou, architect engineer UTH, and George Papathanasopoulos, civil engineer NTUA. Research advisory team: Vaso Trova, MSc architect engineer, associate professor UTH, Phaidon Georgiadis, urban and regional planner, and Dr. Yiannis Psycharis, economist, associate professor, Panteion University of Athens. The summary of the project (in English) is publicly available at: <http://courses.arch ntua.gr/fsr/135952/NTUA_2010_Hellinikon_Metropolitan_Park_Summary_En-1.pdf>.

Hellinikon Metropolitan Park, which is the concluding part of a research project conducted in 2009-2010 by the NTUA Urban Environment Lab.

1. Brief history of the area and of the current privatization processes

The area of Hellinikon was the International Airport of Athens until 2001, when the new airport at Spata started to operate. Law 2338/1995 specifies the terms and conditions for the relocation of the Athens International Airport. Further, regarding the future use of the former airport area, it outlines its conversion into mainly a Metropolitan Green Park. Former PM, Kostas Simitis, at the inauguration ceremony of the new airport emphasized that Hellinikon would become the largest metropolitan park of Europe. As Simitis (2009) mentioned, "It will become a metropolitan green area, a large park. I believe it will be the largest park of Europe" (Simitis, as cited in Kemanetzi, 2009). Despite the inaccuracy of this pledge, given the a number of existing larger parks in European cities, subsequent prime ministers also pledged for the creation of a metropolitan green park in Hellinikon (Papandreou, 2010).

However, about a third of the area was used for Athens Olympics infrastructure with *ad hoc* pre-Olympics regulation, in conflict with the regional plan of Athens and the aforementioned law. Law 2730/1999 permitted, without a regulatory plan, the development of Olympic games infrastructure inside the area. Many of the Olympic works were presented as temporary but they still exist in the area. After the closure of the airport, academic-research institutions, the state and the private sector presented projects and proposals regarding the future of the area. The proposals vary widely in terms of the social, environmental and economic priorities that dictate the potential development directions of the Hellinikon area.

Despite pledges by three subsequent prime-ministers to make Hellinikon a metropolitan green park with zero new construction, the efforts of the state have focused, since 2010, on the privatization of the former airport area (Table 1).

The current plans for the privatization of the area are officially launched in September 2010, when the Greek government started investigating possibilities of attracting funds from Qatar. The Memorandum of Understanding signed between the government of the Hellenic Republic and the government of the state of Qatar, acting by and through the Qatar Investment Authority, mentions the establishment of a joint committee of cooperation concerning joint investment activities. Despite these actions, the negotiations with the State of Qatar came to a halt a few months later, in spring 2011. While there are no official statements confirming or denying the end of negotiations, press articles note that the main reasons were the lack of a business plan for the area and disagreements on the terms of investment. Further, according to the European competition regulations, the Greek government had to make an open call for investments, and not to grant a single potential investor privileged status (Tsitsas 2011).

Table 1: Basic steps of the process towards the privatization of Hellinikon Area.

Process towards privatization	
2012 May	Four shortlisted. U.K.-based London & Regional Properties, Qatari Diar Real Estate Investment Co., Israel's Elbit Systems Ltd. (ESLT) and Greece's Lamda Development SA (LAMDA)
2012 April	New Regulatory Plan of Greater Athens under published for public consultation, did not pass as a state law End of the first phase of the expression of interest. Nine expressions of interest were submitted
2012 February	L. 4062/2012 for the development of the Hellinikon Area passed
2011 December	Invitation to submit an expression of interest for the acquisition of a majority of the share capital of HELLINIKON S.A. Eviction notices to public bodies and companies located in Hellinikon
2011 July	Hellinikon in the list of the state-owned assets of the privatization program (L. 3986/2011) Establishment of Hellenic Republic Asset Development Fund (L. 3986/2011)
2011 June	Presentation of Acebillo draft strategic urban model
2011 May	Establishment of Hellinikon S.A.
2010 September	Memorandum of Understanding between the government of the Hellenic Republic and the government of the State of Qatar

In May 2011, Hellinikon SA was established in order to manage the area of Hellinikon, to accelerate the development processes, to deal with technical and legal "obstacles" of the area and facilitate the negotiations between the Greek government and potential investors. As Hellinikon SA CEO Spiros Pollalis (2011) states: "We [Hellinikon SA] won't tell them [the investors] 'this is our plan, take it and implement it'. We will give them the guidelines and tell them that they will be judged according to the business plan and the development plan they will propose" (as cited in Papachlimintzos, 2011, para. 2-3).

A subsequent move towards the privatization process is the presentation of the Acebillo/Barcelona Urban Systems strategic urban model in June 2011. Former Greek PM, George Papandreou, invited Josep Acebillo in 2009 to make a proposal for Hellinikon area. Acebillo was involved in the negotiations with Qatar in 2010 and presented an outline of a strategic plan in 2011. According to Acebillo (2011), this is a first proposal, not a complete master plan, for the creation of a mixed-use area in Hellinikon. His proposal includes the construction of new building stock totalling

2.000.000-3.000.000 m^2 and the demolition of most of the existing buildings. It proposes the creation of 6.200-6.500 m^2 of housing units and 980.000 m^2 of residential areas on the coastal zone characterized as “mediterranean villages” and several “neo-tertiary” uses such as a financial and governmental district, a university and R&D district, live-work artists' dwellings, and one or more malls (Acebillo, 2011, p. 1).

A month later, in July 2011, Hellinikon was included in the list of the state-owned assets of the privatization program that was launched with law 3986/2011 of the Medium-term Fiscal Strategy established by the Greek government, the EU, the IMF and the ECB Also, with the same law, the Hellenic Republic Asset Development Fund (HRADF) was established, in order to manage the privatization programme. All state-owned assets that would be privatized are transferred to the Fund and the revenues of the privatization program will serve the stated primary goal of the fiscal strategy, to reduce state debt.

In December 2011, the Hellenic Republic Asset Development Fund announced the invitation for submissions of expressions of interest for the acquisition of a majority of the share capital of Hellinikon SA. The invitation includes the whole area, both the former airport and the coastal zone, and allows the investor to create a mixed-use development without any restrictions regarding land uses, with the exception of manufacturing. It allows for the development of up to 2,500,000 m^2 of new building construction. Further, it allows the complete demolition of the existing building stock of more than 470 buildings, including the Olympic games infrastructure and excluding just four designated buildings. At the same time, there is no specific plan for the creation of a park and public spaces. The first phase of the expression of interest ended in April 17, 2012 with proposals from investment and real-estate companies from the USA, the UK, Qatar, Israel, Spain, Cyprus and Greece. As the Hellenic Republic Asset Development Fund (2012) announced:

> Nine (9) expressions of Interest were submitted, indicating strong competition for this unique asset. The participation of 9 strong groups in this complex and long-term development project is particularly encouraging. Arguably this is currently the largest urban development project in Europe and it is strategically significant for Athens and Greece. (para. 3)

Out of the original nine who had expressed an interest, the Hellenic Republic Asset Development Fund chose four groups to participate in the second phase of the tender to buy Hellinikon SA. As *kathimerini* (2012) reported, “U.K.-based London & Regional Properties, Qatari Diar Real Estate Investment Co., Israel’s Elbit Systems Ltd. (ESLT) and Greece’s Lamda Development SA (LAMDA) are the four groups that will compete to buy Hellinikon” (*kathimerini*, as cited in Tugwell, 2012)

At the same time, in December 2011, all public bodies and private companies located in the Hellinikon area have received eviction notices by Hellinikon SA, and thus have been ordered to evacuate their facilities within one to five months, with no relocation

provisions (Lialios, 2011). Until May 2012, none of the total of more than 50 public bodies and private companies located in the area left their facilities.

In February 2012, L. 4062/2012 was passed for the development of Hellinikon area, after being in the phase of public consultation for only five days. The law provides a flexible plan for the investor of the area to create a mixed-use development that would include housing units, a research and educational centre, leisure and cultural activities, a business and administrative centre as well as recycling facilities and cemeteries. The park would be at least 200 Ha, including green and open spaces, leisure, sport, cultural and social activities, streets, as well as the open spaces of private developments urban infrastructure.

In February 2012, the new draft Regulatory Plan for the Greater Athens Area was also in the phase of public consultation for six days. Although the draft plan adopted some of the critical dictates of the Medium-term Fiscal Strategy regarding the privatization plans and real-estate development of the area, it did not eventually pass as a state law. Despite the fact that the plan lacked planning and economic documentation for the development directions, land use decisions, or local and regional costs and benefits of the Hellinikon development prescribed, it proposed a rather specific mixed-use development program for the Hellinikon area. This would include a metropolitan public space area, not less than half of the total area, of which 250 Ha would be a green park. In the rest of the area the plan proposed a mixed-use development that would include education, research, culture, tourism, sports and business activities, housing units and a business center.

The projects and laws presented so far on the privatization process of Hellinikon area indicate that a highly selective and step-by-step process of deregulation and re-regulation has been adopted. In order to attract investments, new laws are passed and new agencies are established, to ensure flexibility in land uses and building regulations. Also, well known architects, urban planners and experts, such as Acebillo and Pollalis, are mobilised to promote the project and devise the privatization strategy in collaboration with major financial institutions and law firms that serve as international advisers. What is common to all these proposals is that there are neither estimates, nor provisions for the long-term social, environmental and economic effects of the proposed urban development project on Greater Athens Area. Further, it should be noted that as of May 2012, there has been no accurate and detailed topographic plan of the area and no business plan for the proposed development and the viability of the various land uses in the current conjuncture. Similarly, there are neither analysis of immediate needs of the residents of Greater Athens Area, nor provisions for ways in which the proposed project is expected to address these needs.

2. Local and regional resistance movements, coalitions and initiatives against privatization

A coalition of residents, organizations and local and regional authorities have been opposing the privatization process of the area and demand the cancellation of plans for the privatization of the area, as well as the creation of a Metropolitan Green Park, with compatible social uses in the existing building stock. There is a long history of struggles of the residents for the protection of the public character of the area, starting with the closure of the airport in 2001 and the associated law. These struggles have culminated in a stable and growing regional coalition that has organized a series of initiatives, especially since 2007, when a rather milder privatization and development plan by the state had to be withdrawn (Table 2).

In 2007, residents of the City of Hellinikon and of the Greater Athens Area demolished illegal barriers and fences to reappropriate a part of the public coastal zone that was illegally occupied by nightclubs. The City of Hellinikon, which has responsibility to maintain and clean the beach, installed ADA infrastructure for the first time on public beaches of Greece (Antonopoulou, 2009). The mayor of the City of Hellinikon, Christos Kortzidis, supported the movement with a 24-day hunger strike. In January 2008, the coalition “Common action” was established by the four mayors from the cities that include the airport in their administrate boundaries. The coalition organised the three-day forum “Three days for a life” with discussion panels on the development of the area, with participation of academics, researchers, archaeologists, historians, engineers, architects and planners and a series of organizations and institutions. As part of the forum, local and regional authorities, institutions and residents from the Greater Athens Area, as well as students, planted 10,000 trees in the former airport area (City of Hellinikon, 2010). In June 2010, City of Hellinikon, organizations and residents demonstrated against the illegal occupation of the beach and illegal operation of nightclubs and other uses.

Facing the current privatization processes, the Initiative for Hellinikon Metropolitan Park was created in March 2011 by citizens and groups of people from the Greater Athens Area. Their initiative works aims at promoting a different direction for the development of Hellinikon area, addressing the needs of the residents of Athens. 76 local and regional initiatives, including the Initiative for Hellinikon Metropolitan Park, signed the “Open letter to the greek government, to the troika [IMF-EU-ECB], to the emirs and to whom it may concern: Hellinikon is not for sale!” declaring their opposition and mobilizations against the privatization of the Hellinikon area. The Initiative for Hellinikon Metropolitan Park launched the Festival of Resistance and Creativity for a Metropolitan Park in May-September 2011, with exhibition events, concerts and cultural activities. In May 2012, 20 greek artists gave a concert against the privatization plans of the area. In June 2012, social initiative “Iliosporoi” organised a picnic for ungrowth with the participation of Serge Latouche.

Table 2: Resistance movements against privatization (2007-2012)

Resistance movements, coalitions and initiatives	
2007 June	City of Hellinikon in collaboration with a variety of civil society organizations re-appropriate the illegally occupied Agios Cosmas beach by nightclubs, by dismantling the fences, restoring public access, and initiating a program of maintainance and cleaning, including ADA infrastructure for the first time on public beaches of Greece. Mayor Christos Kortsidis on a 24-day hunger strike supporting the re-appropriation of the illegally occupied beach.
2008 January	Coalition "Common action" established by the four mayors of the cities that include the airport area in their administrate boundaries. Coalition "Common action" organise three-day forum "Three days for a life" 10,000 trees planted by local and regional authorities, schools and institutions from across Athens
2010 June	City of Hellinikon, organizations and residents demonstrate against the illegal occupation of the beach and illegal operation of nightclubs and other uses.
2011 January	Autonomous Urban Farm established in 0,3 Ha lot, with residents and organizations starting planting of local vegetables and fruits, courses and networking with related initiatives in Greece and abroad
2011 March	Initiative for the Hellinikon Metropolitan Park established. 76 local and regional initiatives sign the "Open letter to the greek government, to the troika [IMF-EU-ECB], to the emirs, and to whom it may concern: Hellinikon is not for sale!" declaring their opposition and mobilizations against the privatization of the Hellinikon area.
2011 April	Former employees of state Olympic Airways create the Aviation Museum with Olympic Airways historic items at the former West Terminal.
2011 May-September	1st Annual Festival of Resistance and Creativity for the Metropolitan Park of Hellinikon: Concert by 20 Greek artists against the privatization plans of the area. Forum "Picnic for de-growth" with the participation of social initiative "Iliosporoi". Visit and talk by Serge Latouche "Full moon freedom beach party: Reclaim the beach 2 stages festival against the sell-out of ex-airport of Athens" by the Void Network, with more than 2,500 participants. 300 artists create visual and multi-media works of art for the protection of Hellinikon. One-month free exhibition in former Olympic Basketball building. Concert by Greek composer Mikis Theodorakis against the privatization of Hellinikon and for the creation of a Metropolitan Green Park. Four discussions and roundtables on the privatization of state assets and

	urban social movements and initiatives against it.
2011 December	Metropolitan Social Health-care and Social Pharmacy established serving patients from the region with limited or no access to the health care system. Psychological support services for people facing hardships and unemployment.
2012 March	1,100 olive trees planted by more than 3,000 residents and institutions from Athens, with the support of the Autonomous Farm. Regular gatherings for maintenance and irrigation by participants. Initiative for Hellinikon Metropolitan Park organises demonstration at Syntagma square against the law for the development of Hellinikon area
2012 April	1st Metropolitan Semi-Marathon organised by five runners clubs from the surroundings cities of Hellinikon and the region Initiative for Hellinikon Metropolitan Park organises demonstration at the HRADF offices against the privatization of the Hellinikon area 27 bodies and institutions located at Hellinikon sign petition against the privatization process and their displacement

In July 2012, the collective Void Network organised a full moon beach party and concerts with more than 2,500 participants. In September 2012, composer Mikis Theodorakis gave a concert against the privatization plans and for the creation of the Metropolitan Greek Park. Also, in September 2012, 300 artists participated in a month-long free art exhibition in the former Olympic Basketball building. As part of the festival, four discussions and round-tables were organised to discuss the privatization of public assets and the coordination of social movements and initiatives against it. The Initiative for Hellinikon Metropolitan Park also supported the initiative for an Autonomous Urban Farm inside the area that was created in January 2011. The farm measures an area of 0,3 Ha and produces local vegetables and fruits covering part of people's needs. As Totsikas (2012) notes: "From the first time, it is clear that our initiative is part of the protest against the privatization of Hellinikon area" (para. 16). The initiative has also connected with other initiatives and networks and has co-organised joint courses and workshops.

In April 2011, the former employees of the formerly state-owned Olympic Airlines run an Aviation Museum at West Terminal. They have collected items, as well as airplanes, from the history of Olympic Airlines and from the Hellinikon airport. In December 2011, an initiative of doctors, with the support of local authorities, established the Metropolitan Social Health-care Centre and Social Pharmacy, catering to patients from the region with limited or no access to the health care system, as part of emerging solidarity networks across Athens addressing pressing social needs. In March 2012, more than 3,000 residents and institutions from Greater Athens Area planted 1,100 olive trees inside the area of the former airport (Totsikas, 2012). In April 2012, five runners

clubs from the surrounding cities of Hellinikon area and the region organised the first semi-marathon inside the former airport area.

The Initiative for Hellinikon Metropolitan Park organised two demonstrations against the privatization process and the law for the development of the area, at Syntagma square and at the HRADF offices, in March 2012 and April 2012 respectively. Also, the Coalition of Architects issued a statement against the law for the development of Hellinikon area. What is more, 27 bodies and institutions located at Hellinikon signed petition against the privatization process.

The proposal for Hellinikon Metropolitan Park, as it is shaped by the NTUA Urban Environment Lab research team in collaboration with the Local Union of Municipalities & Communities of Attica and the Cities of Alimos, Argyroupoli, Glyfada and Hellinikon, was endorsed by local and regional movements, initiatives and coalitions, professional bodies and research institutions as a fact-based, feasible and inexpensive counter-proposal for the area. The basic approach of the research and its strategy is presented in the following section of the paper.

3. A counterproposal for creating Hellinikon Metropolitan Park

The discussion on the future of Hellinikon centers on critical issues facing cities and regions under conditions of cumulating crises, as articulated across spatial scales. The conflict over Hellinikon expresses variegated approaches regarding the functions of city space, urban development and more broadly the production of space, not only in intensifying or mediating various sociospatial inequalities and injustices but also in transcribing on the ground potential alternative sociospatial practices.

Hellinikon can be considered an exemplary case of how this discourse is set on the ground, especially because of the unique assets of the area for various actors, including the residents, the state system and domestic and international financial institutions and developers, the scale of the financial interests and states involved, and the symbolism embedded in the development of Hellinikon as a top priority and precedent-setting model of planning and privatization increasingly across Europe. In various debates on particular issues, what Hellinikon stands for, and for whom and what it is to be used, remains a defining difference of a range of approaches to space and justice. On the one side, Hellinikon is treated as a precious real estate asset for development, directly attached to objectives of debt and deficit reduction. On the other, Hellinikon is treated as a city space contributing to the city, which can partially address ongoing injustices and set a precedent for alternative development priorities and directions against the production and intensification of sociospatial injustices. While approaches that proclaimed to take a more in-between and nuanced stance were being occasionally presented over the past decade, the rapid developments and the continuous changes in the dominant discourses on the future of Hellinikon have tended to lead to a polarization

of various viewpoints. In addition, persistent demands for disclosure of the underlying priorities of various proposals are increasingly made in debates, critiques and public events.

In 2009-2010, given the shifting terms and means of the particular debates taking place regarding Hellinikon and facing the plans to address the intensifying crisis in Athens, the NTUA Urban Environment Lab was invited to collaborate with the four cities surrounding Hellinikon and was commissioned to conduct research on the area. This research seeks to answer the extent to which adopting alternative scenarios for Hellinikon is justified on sociospatial and economic grounds, to examine the feasibility of these alternative scenarios based on economic data, comparative analysis of case studies in various countries and documentation of the area along with an examination of its relations to the Greater Athens Area, and to propose feasible strategies forward. The rest of the paper provides a brief presentation of the specific questions addressed and the strategy proposed by the research team.

3.1. Hellinikon is indispensable for Greater Athens Area

Athens demonstrates a dramatic lack of urban public open and green spaces. Athens provides just 2-2.5 m^2 of green space per resident, and it has wasted 1.23 m^2 of publicly-owned open space per resident for the 2004 Olympic Games infrastructure and the subsequent private developments.

According to comparisons of indicators among 15 cities by the Hellenic Ministry for the Environment, Physical Planning and Public Works in 1994, Athens displayed the second lowest rate of green space per resident (2.55 m^2/resident), while Paris (8.5 m^2/resident), London and Rome (9 m^2/resident), Zurich (10 m^2/resident), Berlin (13 m^2/resident), Warsaw (18 m^2/resident), Wien (20 m^2/resident), Amsterdam and The Hague (27 m^2/resident), Rotterdam (28 m^2/resident), Bonn (35 m^2/resident) and Washington DC (50 m^2/resident), demonstrated 3 to nearly 20 times higher rates (MEPPPW, 1994).

This extraordinary lack of urban public open green spaces in Athens suggests, as an immediate action, the protection of all the existing spaces across the Greater Athens Area, as well as the conversion of other remaining open spaces at various scales into public open green spaces. The allocation of the whole area of the former international airport and the coastal zone and the creation of a green metropolitan park would add just 1.98 m^2 of green space per resident to the Greater Athens Area, resulting at best to nearly 4.5 m^2 of green space per resident.

Further, as it is prescribed by Greek planning standards and laws since the 1980s, it is not just the 626 Ha of Hellinikon Area that the city needs. About ten-times more green space is needed in order to acquire what might be called schematically “acceptable level of green space” in Athens i.e. green space approximating the levels prescribed by

planning standards and legislation.. Further, this standard does not take into account the current state of Greater Athens Area. It was established well before the successive expansions of the city with the production of urban sprawl across former forest and agricultural lands in Mesogeia, in Thriasio and on the slopes of the surrounding mountains. Also, it was established well before the accelerated loss of urban open spaces, either designated by law or potential green spaces, especially since 2004 for the Olympics infrastructure and the subsequent post-Olympics private developments. And, last, it was established well before the 2007 extensive and destructive wildfires of Attica. Therefore, even the adoption of such "acceptable level of green space" would remain significantly lower than the European mean.

What is more, the creation of Hellinikon Metropolitan Park will provide public access to 3.5 km of the Athenian coastline, while about 20 km are inaccessible or accessible only by paying entrance and user fees.

3.2. The park is an inexpensive project

The creation of Hellinikon Metropolitan Park is an affordable project, despite a series of statements to the contrary since 2003, by successive governments and planning authorities. The Hellinikon Metropolitan Park project has been continuously presented as an excessively expensive project, with a projected cost amounting to a range from €400 to €700 million, with respectively high operational and maintenance costs. During the period 2003-2007, the Greek state launched an international ideas competition, planning an extensive urban redevelopment project under the title "Hellinikon Metropolitan Park and Urban Development" and the creation within the park of a small luxurious city with floor areas ranging in the final 2007-2008 proposals between 1.300.000 m^2 and 1.450.000 m^2. This was an excessively expensive project both in terms of its building construction component and in terms of the infrastructure and design of open and green spaces. But although the projected costs were used to shape the justification of these development directions, there has never been a business plan or feasibility study to back these numbers.

Thus, the excessive estimated cost of the Hellinikon Metropolitan Park, as it has been presented over recent years, constitutes a choice rather than a documented necessity. This choice and position is problematic in three main respects. First, there is no justification for the need to construct a luxurious small city with high infrastructure costs on social, environmental or economic grounds, except for catering almost exclusively to a very limited subset of the economic sector of development, as well as a very limited set of consumers as beneficiaries, with potential adverse effects even on their counterparts. Second it presents impressively overestimated and overpriced construction and operation costs. There is no explanation for the construction cost of 76,000 euro/m^2 and its deviation up to 16 times from e.g., Maurice Rose Airfield project in Germany (4,500 euro/m^2). Last, it constitutes a choice to systematically display exorbitant costs as

unavoidable, in order to justify plans for privatization and concessions of the whole area or parts of it, the construction project or its subsequent management and commercial operation.

In contrast to the aforementioned estimates, the research indicates that the construction of a park with mild interventions and high quality construction is affordable, based on analysis and comparisons of construction costs in Greece and in Germany, taking for example the new parks at former airports of Berlin and Frankfurt. The estimated cost amounts to just €50 million for the area readily available today to begin major green works and restore building and technical monuments restoration and reuse – distributed in phases over a 10-year horizon. The total cost is just €100 million for the whole project – distributed in phases over a 20-year horizon. The estimated cost for annual operations, based on comparisons with the multi-year and detailed operation costs of parks such as the Royal Parks of London, amounts to €5 million annually upon completion of the first phase, and to €10-12 million for the completed park.

The cost needed for the construction and operation of the park could be covered by utilizing the revenues of less than a decade since the 2004 Olympics, from the existing infrastructure and leasing and concession contracts of the area. As our findings point out, according to economic data submitted to the Hellenic Parliament in 2010, the total revenues from leasing and concession contracts of the Olympic facilities of the area amount to €75.8 million, while the realised revenues amount to €35.7 million. That €40-million gap is due to the fact that the private companies which have signed mostly long-term concession contracts with the state-owned companies stopped their agreed-upon rent payments to the Greek state from 2008 onwards.

To conclude, the actual realised revenues of the Olympic facilities, if they had been used for the area, could have already financed more than the half of the construction of the park. If the total revenues were used, they could have financed about 75 percent of the park.

3.3. The park is feasible

For the creation of Hellinikon Metropolitan Park, the NTUA Urban Environment Lab research project proposes six immediate actions.

First, critical prerequisites for the creation of a Metropolitan Park are the cancellation of real estate development plans for the area. That is, the cancellation of sales, privatization, and concession plans for the entire area or parts of it; the abandonment of the questionable in many respects and excessively expensive plans to develop exclusive planning unit developments; and the cancellation of the environmentally detrimental, anti-urban and excessively expensive highway infrastructure construction projects along Poseidon and Alimos avenues.

Another critical prerequisite that has to take effect immediately is the removal of internal fences as well as the removal of the prefabricated exhibition pavilions in the surrounding area of the former East Terminal. This will help prevent a further fragmentation of the area, which would render future interventions even more difficult. It will also help reverse the image of abandonment and decay of the area.
In the coastal zone, it is necessary to implement the Presidential Decree on the coasts in effect since 2004, and control the permits and operations of businesses of sanitary interest, in addition to canceling administrative selective exceptions from the laws granted by the former Ministry of the Environment (e.g., Greek Church-owned cape along the coast with a concession contract for a nightclub).

Also, it is possible to immediately allocate 56 percent of the area to public uses and safeguard free public access. This could happen by the immediate opening to public access and use of 170 Ha of the southern part of the area, and of 180 Ha of the northern Olympic Pole, with the removal of fences. The remaining 44 percent of the area can open to the public gradually, by making the necessary institutional arrangements with the various public stakeholders (e.g., Ministry of National Defense, Aviation).

A relocation of the transportation facilities that occupy 19 Ha of the area is considered unrealistic and unjustified in planning and economic terms. This part, occupied by the Tram, ETHEL, KTEO and Attiko Metro, can be exempt from the public use of the park, as long as further construction or expansions are prohibited.

The gradual restoration and reuse of the existing building stock can provide a socially, environmentally and economically sound, as well as effective, solution to integral and complementary uses of the park that seek to address needs of the Greater Athens Area residents. Based on the documentation and evaluation of the building stock conducted in 2009-2010, out of the 480 existing buildings with a total floor area of over 490,000 m^2, 241 buildings with a total area of 366,160 m^2, or 75 percent of the existing stock, can be reused for low-intensity uses, mainly social in nature and scope, and with the exclusive use of all realized or expected revenues for the creation, operation and maintenance of the park.

Regarding new uses in the existing buildings across the park, the research project proposes the adoption of a strategy “from the ground up” based on the existing assets of the area, rather than the treatment of the space as an “empty lot for development.” Toward these ends, the aim must be the democratic and active involvement of society, its citizens, its organizations and local institutions in planning and implementation of what is socially beneficial, rather than the search for an investor who will implement a private development project. As noted above, a series of concrete examples along these lines have been developed in the area since 2010.

Following the aforementioned immediate actions that constitute prerequisites for devising a medium- and long-term strategy for the area as a whole, the NTUA Urban Environment Lab research project proposes a 5-axis strategy by area for Hellinikon Metropolitan Park (Figure 1).

It proposes the creation of an Open Metropolitan Sports & Recreation pole. This pole can be created by relocating the facilities of Agios Kosmas within the existing Olympic pole in the former airport. This relocation relieves the coastal zone from some of the recent construction. The creation of an Open Sailing Center in the Olympic Marina can cover the needs of local recreational, sports and sailing clubs, and further relieve the northern part of the coastal zone.

It proposes the full removal of the illegal mass entertainment uses from the coastal zone, the restoration of free unobstructed public access and the comprehensive redesign of the waterfront in compliance with the Presidential Decree on the coasts. The existing structures of the coastal zone have to be reduced significantly so that practically free public access and its natural features are restored immediately and for the long run. This objective requires demolishing the illegal entertainment structures, moving some of the sports facilities of the coastal zone as well as the complex of the Hellenic Center for Marine Research (HCMR) eastwards inside the former airport, and banning further construction in the Olympic Marina. In the open zones that will result from these actions, the research proposes the restoration and regeneration of the natural coastline, along with the protection of the archaeological sites, as well as the streams, the sandy beaches and the Agios Kosmas cape. Enhancing green spaces and creating an extensive pedestrian way and bike path network will improve the area and its public access, and will connect it to the rest of the Saronic Gulf coastline, north and south.

It proposes the creation of a Center for Culture, Education & Research in the area of the former West Terminal. The research proposes the development and integration in the park of the Hellenic Center for Marine Research along with the creation of a Scientific & Educational Aquarium, and, the restoration and protection of the coastal and marine antiquities, along with the restoration of the natural coastline. It also proposes the expansion of the existing archaeological storage spaces, the enhancement of the conservation and restoration laboratories, and the creation of an Archeological Museum exhibiting the large collections of the Saronic Gulf and Mesogeia, along with developing museological, educational and cultural programs. The historic civil and military aviation material that is preserved within the former airport can constitute the core of an Aviation Museum, housed in the historic hangars. It should be noted that the aforementioned proposals are already supported and promoted by related institutions and organizations. A small aviation museum already operates in the West Terminal building, with an exhibition curated by the former employees of state Olympic Airways.

Figure 1: General Master Plan of Hellinikon Metropolitan Park. Source: NTUA Urban Environment Lab research, 2010.

It proposes the creation of a Local Center with Social Uses, with the reuse of many of the existing buildings on the premises of the former USA base, with social welfare, education, culture, recreation and small-scale retail and entertainment uses. It is possible to also incorporate local administrative uses.

It proposes, finally, the restoration and reuse of the large designated building of the former East Terminal as a Metropolitan Node with compatible metropolitan uses (such as exhibitions, conferences, scientific and artistic events) under specific terms of operation. This large designated building, designed by architect Eero Saarinen, displays a metropolitan identity and through its size and symbolism can acquire a metropolitan role, if its uses and their scale are compatible with the preservation of the building and the operation of the park. Its proximity to the new metro station of Hellinikon can further enhance this possibility. Uses considered as compatible are uses with specific terms of operation that do not affect the building and the functions of the park, along with a ban on further construction, expansions or use of extensive areas for supporting

activities (such as outdoor parking). The term that the revenues from any operation within the park are allocated to the construction and operation of the park, namely the social, environmental and cultural uses and activities within it, applies to these uses and activities as well. By meeting these conditions, the aforementioned metropolitan uses can further enhance the social character of the park. Examples of incompatible uses are mass commercial and entertainment uses (e.g., malls and multiplex cinemas), because of their intensiveness and their incompatibility with the architectural complex and the overall role of the park. Large-scale administrative or educational uses (e.g., ministries or universities respectively) are also incompatible with the East Terminal building because of their architectural and functional requirements.

4. Conclusions

The discourse and debates for Hellinikon have focused, the past decade, on the creation of a metropolitan park. Despite the series of actions and initiatives to the opposite ends described herein, government proposals and pledges aimed at the maintenance of the open public character the area, or the largest part of it, by establishing free access and developing public uses in a metropolitan park it. The debates the area have revolved around practical issues, variegated theoretical and political assumptions about the city and, often, around scientifically unsubstantiated myths. The key issues of the debates have been the size of the park and its necessity to Greater Athens Area, its relation with Athens residents' needs, the construction and operational cost of creating a metropolitan park. Since 2010, the discourse on Hellinikon has focused on the unique characteristics of the area for attracting development projects. It is presented as a precious real estate asset for development, which could potentially serve the Medium-term Fiscal Strategy goal of debt and deficit reduction. The plans and state laws for the privatization of Hellinikon area allow for the construction of a new city inside the area, with no documented benefits on the social, environmental and economic conditions for the Greater Athens Area and its residents, and no estimates of costs, adverse effects and negative externalities.

This research seeks to address the key issues pointed out on the discourse and it proposes a feasible strategy, with short- and medium-term actions to create Hellinikon Metropolitan Park. Basic priorities of the strategy proposed is to maintain the public character of the area, to allow the public access to the coastline, to reutilize the building stock to cater for social needs, and to address the shortage of green spaces in Greater Athens Area. This counter-proposal has been endorsed and promoted by local authorities, local and regional coalitions, initiatives and movements reacting to the privatization process of the area. These initiatives and movements have already demonstrated how they protect their urban public space with concrete initiatives on the ground.

In conclusion, urban development appears to take center-stage in the proposed macro-economic remedies for the crisis regardless of its uses in the production and reproduction of crisis and restructuring, or its geographical diffusion across spaces and scales. A major approach focuses on mega-urban development as usual; asserting that it is through space again that macro-economic stability will prevail. At the same time, opposing approaches question its assumptions and premises for cities and regions and even for macro-economic stability per se, while exposing its potential effects in intensifying inequalities and injustices. Hellinikon can be considered as a prominent example through which to de-codify and analyse current debates and struggles over space, its production and its use across spatial scales and its effects over urban life, citizenship and justice. The directions and results of current developments on the future of cities and regions across Europe remain to be seen. But as the Hellinikon case appears to be increasingly demonstrating, a significant change of course in spatial development towards sociospatial justice, as every day process with concrete outcomes, is an idea whose time has come.

Acknowledgements

This paper could not be done without the systematic and comprehensive work of the NTUA Urban Environment Lab research project. Special thanks to Nikos Belavilas and Konstantina Soureli, members of NTUA Urban Enviroment Lab research team, for their generous support, useful comments and critical insights to drafts of this paper. Special thanks, also, to local municipalities around Hellinikon airport, local and regional coalitions, initiatives and movements that demonstrate in a stable way their reaction to the privatization and development plans for Hellinikon area with concrete actions from the ground. The responsibility for the opinions expressed in this paper and for mistakes and omissions is entirely mine.

URBAN CONSEQUENCES OF DIVISION IN 'DIVIDED CITIES': A COMPARATIVE PERSPECTIVE

Gizem Caner [1], Fulin Bölen [2]

Abstract

In the last three decades, there has been a growing body of literature concerned with a specific form of urban division, classified by its extremity. Whether the cities experiencing extreme division are called *partitioned* (Kliot and Mansfeld, 1999), *polarized* (Benvenisti, 1986; Bollens, 1998), *contested* (Hepburn, 2004, 2006), or generally *divided*, the main issues in these cities are agreed upon: disruptive circumstances of extreme tensions related to nationality, ethnicity, religion and culture. Well known examples of such cities are Belfast, Jerusalem, Nicosia, Sarajevo, Mostar, Beirut, and Berlin. Due to their distinctive attributes, these cities have an exclusive discourse differentiating them from other urban areas.

In this context, the central theme of this paper is to comparatively analyse urban consequences of division in selected case studies—Belfast, Beirut, Berlin, Jerusalem. Before starting the analysis, general definitions and concepts of the term 'divided city' will be briefly summarized. Then, each city will be analysed in terms of their divisive attributes. As each city has unique attributes of geography, history, and economic development, their division processes and outcomes differ substantially. Therefore, in each city, consequences of division are evaluated in concordance with their division processes.

In the conclusion part, it will be revealed that in spite of differences among cities, a common pattern of functional, structural, and social urban consequences will surface. These general outcomes will be illuminating for future studies that aim to generate planning models to tackle with the problems of divided cities.

1. Introduction

A general literature review on divided cities reveals a division between two separate discourses. The first one, mostly developed from 1950s to 1980s, referred to divided cities as common themes and conditions prevailing throughout the developed western world: divisions of capitalist production processes, urban segregation and increasing inequality between the affluent and deprived city districts (Safier, 1997). In the last three decades however, there has been a growing body of literature concerned about a more specific form of urban division, classified by its extremity. This limited sense indicated physical or political contestations in few special cases.

[1] PhD Candidate, Istanbul Technical University, Istanbul, Turkey – gizemcaner@gmail.com
[2] Prof. Dr., Istanbul Technical University, Istanbul, Turkey – bolen@itu.edu.tr

According to Anderson (2008) “mainstream urban studies in English-speaking academia have generally concentrated on 'normal', ‘undivided’ and more or less peaceful cities […] where these [ordinary] cities are considered 'divided', we have seen it is usually not by nationalism but by other divisions, such as ethnicity per se or social class”.

The above excerpt implies that reasons of division are determinant in identifying which group a city belongs to. Processes like globalization, decolonization and neo-liberal restructuring form socio-economic differences in cities, often layered with ethnic differences. Status, class, welfare, power, race and ethnicity are the lines of division, hence, pluralist disputes are emphasized (Gaffikin and Morrissey, 2011). These cities—New York, London, Paris etc.—are usually referred to as ‘multicultural’, ‘cosmopolite’ or ‘global’, and are believed to be easier to cope with since they are ‘merely’ divided (Benvenisti, 1986).

On the other hand, most prominent processes behind division in ‘extremely’ divided cities are political and ideological oppressions like wars, as well as divide-and-rule and exit strategies of the colonizers. In these cities, long-standing questions of identity, national sovereignty, territory, culture, language, and religion are to the fore, and they are usually layered with socio-economic differences. The presence of these undisputable aspects turns these cities into areas of challenge by all means.

This paper is mainly concerned with the latter type of divided cities. Four case studies have been chosen from this group: Belfast, Beirut, Berlin, and Jerusalem. Division in these cities can be perceived as an unwanted and unexpected intervention to the city ‘organism’. How this organism responds to this situation from within it, and how outside factors shape the development of the city during and after such an intervention is the main concern of this paper.

As conclusion, this paper aims to find a common pattern valid for all these cities by looking at the case studies’ urban development processes during their division phases. By doing so, it is expected that this paper will contribute to further studies regarding planning approaches and management means in divided cities.

2. Case Studies

Urban consequences of division in case studies are evaluated in a process-oriented manner. The process of division may be composed of following phases: pre-division, division, post-division or reunification (Kliot and Mansfeld, 1999). Each phase has a turning point marked by significant changes, and this is reflected on urban space.

Among case studies, Belfast is the only city that has not achieved reunification and remained in the post-division phase. On the other hand, Berlin and Beirut have both been reunified for almost twenty years. The case of Jerusalem stands discrete; even though reunification has been achieved, it was not recognized by the international

community since it was acquired by illegal annexation of West Bank territory. Moreover, latest developments point to a re-division phase in this city.

Within this study, division process and its urban consequences are examined in detail for each case. Each phase of division is analysed by giving specific reference to the changing nature of the physical setting of the city and its urban development patterns. Apart from the consequences of the imposed situation caused by division, other factors exerting force on the shaping of the city—such as planning approaches—are evaluated.

2.1 Belfast

[Pre-division] Ethnic conflict in Belfast has its roots in the 17th century when the British decided to establish a colony on the island by a process known as the *Ulster Plantation*. The newcomers—Protestants—walled themselves to form what the natives—Catholics—perceived to be "pockets of civilization" (Jones, 1960).

With the industrialization boom of Belfast in 19th century, labour demand was mainly met by the Catholics living in the hinterland (Boal, 1996). As a result, even though Catholics started to reside within the walls, they lived relatively clustered in their own residential environments (Jones, 1960), which were mainly located on the west side of the city. By clustering linearly on the axis of the Falls Road, they formed the Catholic working class area of Belfast. Similarly, working class Protestants started locating on the north, along the Shankill Road. These clusters are still visible in the city (Figure 1).

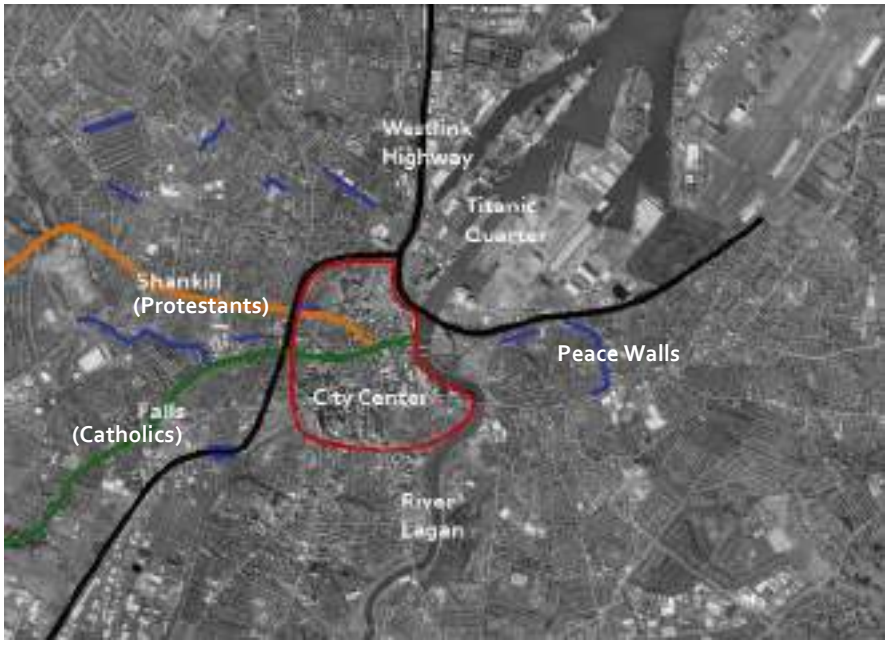

Figure 1. Belfast's Division (1974-2012)

The mainly ethnic and religious division took a nationalist form by the second half of the 19th century when Catholics started to voice their demand for Irish independence, and Protestants for reunion with Great Britain (Boal, 2002). Disturbances arose on the streets of Belfast. Catholics were from now on also referred to as Republicans and/or Nationalists, whereas Protestants as Loyalists and/or Unionists. As a result, in 1921, Ireland seceded from the United Kingdom, while only Belfast, which was predominantly British and Protestant, was granted regional autonomy. Consequently, segregation increased gradually during the 20th century.

[Division] As Catholics in Belfast became more alienated, they started to retreat into an institutionally self-sufficient world. By 1969, with the beginning of "The Troubles", spatial artefacts of division, the so-called "Peace Walls" started to appear on the face of the city.

As more Catholics and Protestants moved closer to their own ethnic groups, the boundaries of residential enclaves became more pronounced and symbolically significant (Calame and Charlesworth, 2009). Around 60.000 people moved as result of The Troubles (Brand, 2009).

Peace walls were constructed at 'interfaces' – boundaries where segregated Catholic and Protestant neighbourhoods collide with each other. When first constructed in 1969, it was hoped that they would be temporary. However not only are these walls still in place over 40 years later, but many others have subsequently been added to the urban fabric, adding up to a total of 88 up-to-date (Community Relations Council, 2008).

[Post-division] Even though Good Friday Agreement was signed in 1998, it did not bring solutions to the fractured structure of the city, or to everyday life within it. Urban arena of Belfast today, is a hyper-segregated one with strict sectarian territoriality (Bollens, 1998). In 2001, around half of the city's population lived in wards that are 90% Protestant or 90% Catholic community background (Gaffikin and Morrissey, 2011). As people moved to their homogeneous neighbourhoods, the city centre went through significant population decline. Today, major 'showcase' projects like Victoria Square, and other new apartment blocks for city-centre living has been built to overcome this disadvantage. But according to Gaffikin et al (2008), these developments are further dividing the two communities since the sectarian enclaves remain in place.

The ethno-religious clusters are particularly working class, suffering from a low quality of urban environment (Sterrett et al, 2011). In these clusters, social infrastructure, such as hospitals, schools, religious compounds and leisure services are duplicated. Each community builds their own institutions to meet the needs of their own community.

The contemporary urban structure of the inner and central city has been shaped by a comprehensive redevelopment process that emphasized major road infrastructure

projects (Hackett et al 2011). For instance, the new Westlink Motorway cut a path through working class housing areas and became a barrier between Catholics and Protestants. Further problems regarding transportation infrastructure are the increasing presence of cul-de-sacs since the 1980s (Figure 2) due to the eradication of peace walls.

Figure 2. The Layout of Inner City Belfast – 1960s, top; 2000, bottom (Forum for Alternative Belfast, 2006)

Figure-ground ratios of the city have changed drastically over recent years. Car-dominance in the city caused the emergence of spacious car parks, which further contributed to the increase of vacant and derelict land near the inner city. This situation, coupled with derelict buildings and poor pedestrian connections, bring about questions of safety. One measurement against these concerns is the caged houses. These houses are caged by individuals with bars and grills over gardens for protection against flying stones and the like.

Another important consequence of division in Belfast is the transformation of sectarian regions via the use of symbols. Murals are the most visible artefacts of territorial ownership usually displaying solidarity and grief. Curb stones are also transformed into territorial markers through red-white-blue or green-white-orange paint in many Unionist or Nationalist areas, respectively. Flags, being cheap and easy to display, are also used for strengthening groups' identity.

The bitterest artefacts of division without dispute are the 'Peace Walls'. 88 peace walls exist in Belfast today, some as high as ten meters and sometimes several kilometres long. Some have gates which can be closed at specific times of the day; some are operated by the police, some by adjacent communities (Brand, 2009). These walls are usually built upon request of the residents living near interface areas.

Recently, these walls have been painted by graffiti artists around the world to create tourist attraction (Figure 3), but as Brand (2009) implies, beautification legitimizes their existence. Peace walls are the scars of conflict on the urban form of the city, appearing suddenly and unpredictably, interrupting roads/parks, and shaping daily movement patterns of local residents drastically.

Figure 3. Peace Wall Painted with Graffiti, Cupar Way (Authors)

2.2 Beirut

[Pre-division] Beirut has always functioned as a multicultural city where religious groups coexisted, but lived in separate enclaves, with few mixed neighbourhoods (Silver, 2010). During 19th century, there was a 25% Christian community, living on the east side of the old city walls which constituted a boundary against Muslims living on the south and west of it. Mixed neighbourhoods existed near the commercial areas of the city (in the west), but even here, sectarian consciousness was strong among the residents (Davie, 1994).

As in Belfast, starting from the mid-19th century, Beirut witnessed rapid urbanization. From 1870s up to the First World War, Maronite peasants were coming from the rural areas and settling on the eastern quarters with the Greek Orthodox community, making Christians the majority in the city (Khalaf, 1993).

During the first years of the French Mandate (1920s), Beirut flourished as the "Paris of the Mediterranean" (Nagel, 2002). There was constant influx of immigrants from neighbouring countries, who preferred to reside with their own 'kind'. The city doubled in size. Consequently, 'Lebanism' of the Christians was pitted against 'Arabism' of the Sunni Muslims, and during 1930s there were violent clashes between Christian and Muslim gangs (Khalaf, 1993). After independence in 1943, due to the Arab-Israeli war in 1948, another influx of populations, this time

Palestinians, changed the face of Beirut's urban development. Dense shanty towns and refugee camps started to grow in Beirut's urban fringe. The main result was an increase in the Sunni Muslim population in the western part of Beirut.

The first civil war during 1956-1958 saw the first real demarcation line dividing the city along the former commercial axis; '*Rue de Damas*'- Damascus Road. Barricades were constructed across main roads; accentuating territorial identities of Beirut's West-Muslim and East-Christian residents. While Sunni Muslims and Greek-Orthodox communities lived near the city centre, the later coming population of Shiites and Maronites lived in the suburbs (Davie, 1994). When these suburbs carried on expanding, they started to meet; inevitably this lead to tensions along interface areas (Davie, 1994), which lead to another civil war.

[Division] The civil war started in 1975. Paramilitary organizations of the religious sects took power in their territory, and the line established during the first civil war was reactivated, which later became to be known as the Green Line (Figure 4). Permeability between two sectors of the city was entirely blocked.

Figure 4. Beirut's Division (1974-1990)

During the first phase of the war, Beirut experienced an outflow of people from its core, resulting in a process of 'ruralisation' (Tabet, 1993). These population movements escalated the slums and squatter settlements on the outskirts of the city. Ribbon developments appeared, beaches on the south of Beirut became slum areas, and whole coast on the north was ruined by high-rise complexes (Nagel, 2002).

Urban form of Beirut went through enormous changes during years of division; streets widened or narrowed according to exposure to snipers; buildings were classified according to how much they faced the battle zone; and, there was a

disjunction between intended function and effective use (Yahya, 1993). Former commercial and civic buildings, formerly the scene of inter-communal commerce and social interaction, were transformed into militia headquarters (Fricke, 2005). The built-up area, road and infrastructure systems sustained severe damage.

As further fractions into subgroups in East and West of Beirut started to appear the city became spatially fragmented into militia-controlled 'mini-states' (Silver 2010). The proliferation of territories, defined according to sub-national community or sectarian identities, fragmented the urban space into very small structural and functional parts (Makdisi, 1997; Nagel, 2002). Each of these subgroups marked their territory by setting up check-points, drawing graffiti, and building other visible or invisible boundaries (Davie, 1994). Yahya (1993) describes how Beirutis created self-sufficient neighbourhoods and apartment blocks, by generating electric power, providing housing, and safety for their inhabitants.

By the end of the civil war, one fourth of Beirut's buildings were damaged or demolished (Figures 5 and 6), some having been removed to allow movement of military vehicles, and half the population had temporarily or permanently left their homes. As a result, Beirut's primacy in Lebanon as the capital city was dismantled and its functions and services were decentralized to adjoining peri-urban or rural areas (Khalaf, 1993).

[Reunification] In October 1990, the civil war in Lebanon ended, "more from exhaustion than from the clear victory of any one group" (Nagel, 2002). Within a couple of months, the paramilitary organizations had been dissolved and the Green Line dismantled. However, the 19th century East-West divide is still there; neither of the two parts wants to pass to the other side (Davie, 1994). Davie (1994) explains this on-going division as follows: "having lived in two different geographies with two different cultural ways of living, each evolved into individual ways" and therefore developed their own social solidarity and self-sufficiency.

According to many authors (Makdisi, 1997; Kassab, 1994; Khalaf and Khoury 1993; Gavin and Maluf 1996; Höckel 2007) reconstruction developments since 1990s has contributed to the on-going division in the city. A master plan executed by a private reconstruction company, *Solidere*, is creating an ultra-modern global cityscape with futuristic urban landscaping (Larkin, 2010) concentrated in Beirut's Central District (BCD).

Critiques have raised many questions and concerns including; marginalization of the state from planning process and the monopoly of a single private company (Makdisi, 1997; Kassab, 1994); inadequacy of sole concentration on central district while the rest of the city remains divided (Nasr, 1996); the ultra-modern landscape appealing only to upper-class groups (Höckel, 1007); and discontinuity from historical bonds (Larkin 2010; Fricke 2005).

Figure 5. Photo of Martyr's Square from a Postcard in 1960s

Figure 6. Photo of Martyr's Square during the Civil War in 1978
(http://www.habeeb.com/beirut.war.lebanon.02.html)

Even though there have been efforts to address these critical discourses, the modern infrastructure of the downtown contrasts with the persistent poverty of the refugee camps and slums (Silver, 2010). Further, the city is still ethnically divided.

2.3 Berlin

[Pre-division] Berlin constituted one entity until it was divided in 1945.

[Division] After the Second World War, Berlin was forcibly separated into west (UK, USA, France) and east (Soviet Union-SU) sectors. West Berlin was an exclave in Soviet territory, with road, air and rail connections to West Germany.

After the *Berlin Blockade* of 1948-1949, quarrel between East and West Germany culminated in the setting up of two rival states; in Western Germany the *Federal Republic of Germany* (FRG), comprising the American, British, and French Zones, and in Eastern Germany the *German Democratic Republic* (GDR), comprising the Soviet Zone. GDR declared East Berlin as its capital, while FRG carried its capital city to Bonn.

The sealing off of the border was a gradual process which first appeared in 1952. GDR was approaching an economic collapse, and people of the East were trying to escape the negativities by fleeing to West Berlin (Elkins et al, 1988). In 1961, to restrict movement, *The Berlin Wall* was erected and armed by military and police forces of the GDR (Figure 7).

Immediately after 1961, roads were torn apart; rail systems were separated; and a full defence depth was erected with alarmed wires, dogs, watch towers etc. (Figure 8). In order to erect the wall, buildings were demolished along its route, usually involving a single street of structures, but sometimes, encompassing entire blocks (Loeb, 2006).

In West Berlin, urban development opportunities were restricted due to limited available land. Therefore, in the first phase of division, during 1950s, reconstruction projects were implemented in the built-up area. Even though the Eastern sector did not have an urban expansion problem, lack of funds and building material, combined with strict planning policies helped to contain the urban sprawl (Von Beyme, 1990). Consequently, both halves of the city evolved compactly. During the second phase of division, between 1960s and 1970s, the growing demand for housing was dealt with construction of massive, high density housing areas on the outskirts of the city in West Berlin. In the Eastern sector, there were also major urban extensions. Again, this caused the two sides of the city to develop in accordance with each other.

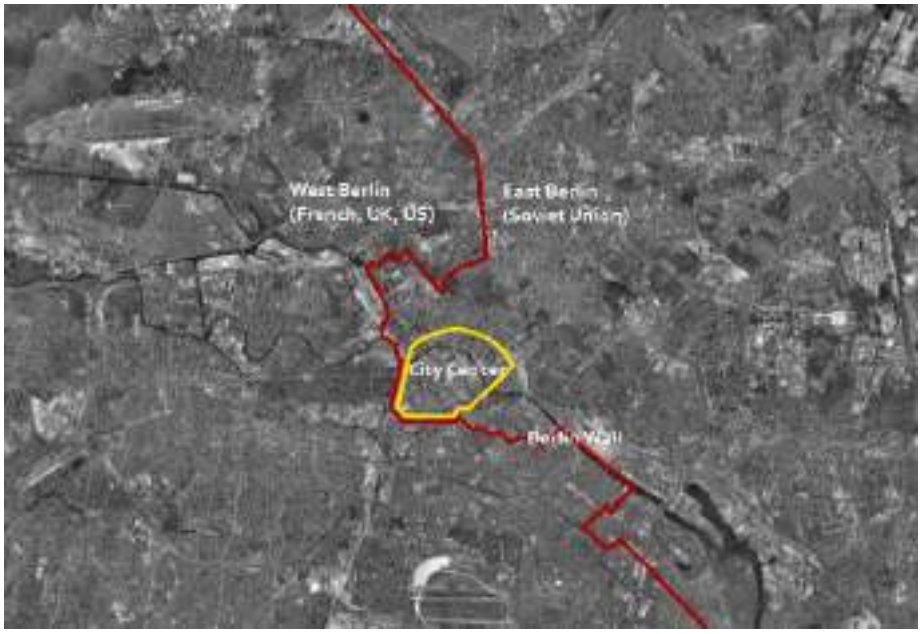

Figure 7. Berlin's Division (1961-1989)

Figure 8. Berlin Wall and its Defence Depth
(http://www.bbc.co.uk/schools/gcsebitesize/history/images/hist_berlin_wall.jpg)

The historical city centre (*Mitte*) and the Central Business District (CBD) on the north-east axis (*Friedriechstrasse*) remained in the East (Figure 7). But this commercial axis was treated as any other street in anti-market GDR, and the CBD was further developed in *Alexanderplatz*. West Berlin had to develop a new CBD around the Zoo rail station which was already a secondary commercial centre before division with shopping and entertainment functions. During the years of division a hierarchy of central places developed in West Berlin (Ellger, 1992), making this part of the city polycentric.

On the other hand, a concentric structure was taking shape on the East side (Schwedler, 2000). East Berlin had the advantages and central functions of a capital. It housed all government institutions, top party bureaucracies, headquarters of industrial conglomerates and embassies (Ellger, 1992). In FRG, the capital was moved to Bonn, giving a disadvantageous position to West Berlin in this respect.

The dual landscape of the city was accentuated by infrastructural dissociations. Only the sewage treatment plant in East Berlin served for both parts of the city. There was also collaboration in matters of water infrastructure. Solid waste disposal was also agreed upon after 1971. Most severely affected was the transportation network, which was split up and developed in different directions. Traffic played a smaller role in the GDR than the West; the huge magisterial roads were sufficient (Von Beyme, 1990).

In West Berlin, land use plans (FNP) developed during years of division were made as if no boundary existed. The context of the surrounding GDR was included in pale grey, and major routes that would be reconnected following reunification were indicated by dashes in a light tone (Figure 9). Construction that would impede a future reunification was not permitted. Contrarily, plans of the Eastern side showed no trace of West Berlin.

[Reunification] Almost 45 years of division finalized in 1989 with the end of Cold War. The destruction of the wall started rapidly and works to unite the city socially, physically, economically and politically has carried on up to date.

Since reunification, planning process of the city is shaped by a doctrine which became to be known as *Critical Reconstruction*. This approach to planning is; "a critical re-appropriation of the past's particular urban virtues" (Murray, 2003). The emphasis is given to pre-1914 history (Marcuse, 1998). There are some scholars who do not find this approach fulfilling (Nasr, 1996; Marcuse, 1998) since the urban environment after reunification did not shelter great historical artefacts. The most criticized development in this respect is the demolishment of GDR Palace of Republic in 2008 to restore the former *Hohenzollern Palace* which stood in this site before division.

Figure 9. Detail of the 1984 Land Use Plan (Loeb, 2006)

Berlin's planning activity has since been focused on three main themes: (1) Physical reunification; (2) Re-establishment of Berlin as the capital; and (3) Showcasing Berlin to create a global city. Specifically the final theme resulted in a number of large projects which are centred in the inner city. These projects have been criticized for creating a segmented city, and as in Beirut, being under the drive of solely the private market (Marcuse, 1998). A well-known example of these projects is the *Potsdamer Platz*.

On the other hand, presence of the Wall was acknowledged in all the plans that were created after reunification. Main consideration is to preserve the memory of the wall; by locating landmarks; leaving walkways and bicycle paths along the border strip; and preventing temporary uses along the border zone. A report developed in 2000 by the City Development Office elucidates the significance of the Wall and opportunities it offers for future development of the city as a unity (Loeb, 2006).

2.4 Jerusalem

[Pre-division] Due to its long history, a great variety of different populations lived in the city. Historically, Jerusalem was a city of quarters, where rigid separations were rare and customary (Pullan, 2009).

Between 1920 and 1948, Jerusalem was administered by the British, as the capital of British Mandate of Palestine, and its political and economic importance expanded. Population grew rapidly (due mostly to Jewish immigration). Although the city was always one entity until 1948, in mid-1930s both the Jewish and Palestinian communities had developed into cohesive and self-sustaining societies (Benvenisti, 1987).

For the purpose of municipal governance, the British designated twelve wards according to religious majorities. These were the first 'ethnic fault-lines' to be formally inscribed in Jerusalem during the twentieth century (Benvenisti, 1986). These were regarded as autonomous communities; enclaves, rather than quarters (Pullan, 2009).This approach fostered intergroup competition, deepening animosities between traditional rivals in Palestine.

[Division] After World War II, international support to build an Israeli state emerged and Israel declared independence in 1948 following a civil war (1947-1948). This resulted in division from 1949 to 1967. The *Green Line* marked the international armistice lines between East and West Jerusalem (Figure 10).

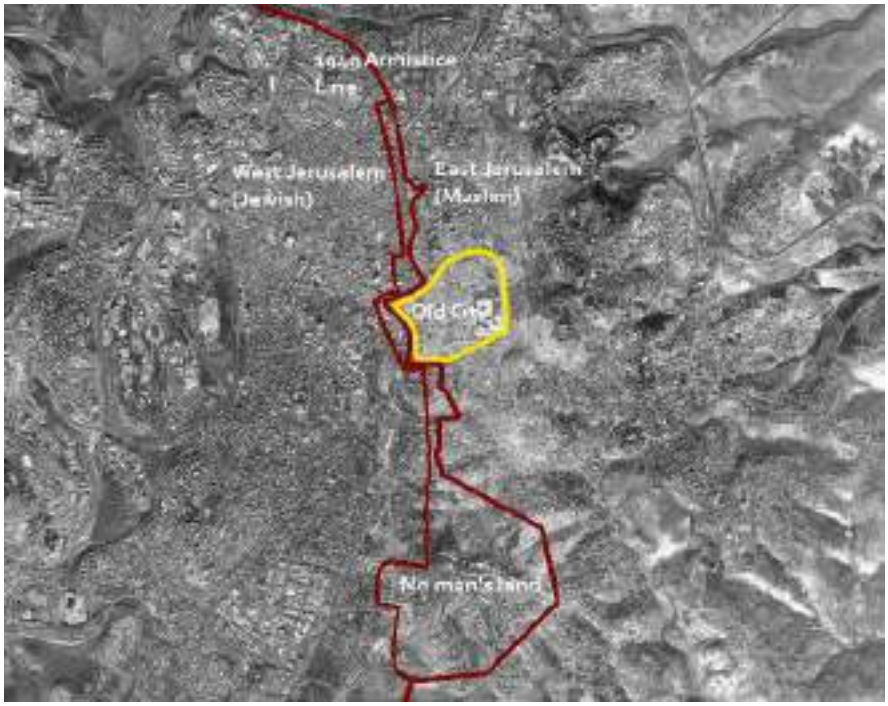

Figure 10. Jerusalem's Division (1949-1967)

During the 1949-67 period, armistice line between Israel and Jordan became an international border running 7 km north to south through the centre of the city. By 1962, the armistice line consisted of a physical barricade of barbed wire through a mined no man's land, with ramparts and blocked roads (Silver, 2010). The two countries each had their own institutions and jurisdiction over their own half of the city. Effectively, Jerusalem had two autonomous urban centres with UN supervision of the border and crossings closed to Arabs and Israelis (Pullan, 2009).

After division West Jerusalem became the capital of the state of Israel. The Israeli government was determined to secure and expand their holdings in West Jerusalem. Immigration was encouraged and government ministries were relocated from Tel Aviv to Jerusalem (Calame and Charlesworth, 2009). As the former commercial

centre of the city along *Jaffa Road* was bombed and deserted after the war, West Jerusalem shifted its business centre away from the Old City walls to the west, north and south. Physical infrastructure projects and housing construction flourished. The built-up area was expanded towards its hinterland, where possible–west and the south. These suburban settlements, over the years, transformed Jerusalem into a city of neighbourhoods, each with its own concentration of homogeneous, socio-economic, ethnic and religious populations (Kliot and Mansfeld, 1999).

The population and prosperity of East Jerusalem shrank because investments were focused in the capital, *Amman*. Palestinians preferred to live and work in Amman. Therefore, population growth in East Jerusalem lagged behind. Residential areas developed to the north, integrating rural communities within the urban area. Therefore, urban areas in East Jerusalem were segmented, lacking continuity, with separate population concentrations and lack of infrastructure. Unlike West Jerusalem, there was no organized planning or zoning process.

Residential quarters on both sides of the border became *cul-de-sacs*, so that nobody wanted to live in them. There was a reversal of traditional development patterns. Areas close to the city centre were occupied by frontier residents – immigrants, refugees or the destitute (Calame and Charlesworth, 2009). As might be expected, the two halves of the city shrank away from each other, trying to avoid the negative impacts of border areas: one side was oriented westward to Israel (*Tel-Aviv*) whilst the other focused east on Jordan (*Amman*).

Similar to every other divided city, Jerusalem was obliged to duplicate itself in every way. A dual landscape was visible through separate municipalities, CBDs, hospitals, schools, transportation networks and infrastructural systems.

[Reunification] Reunification of Jerusalem was not achieved by rapprochement, but instead by an occupation as a result of the 1967 Six-Day War. This incorporation of East Jerusalem into Israel was not recognized by the international community or the Palestinians. The two halves of the city were reunited by force; hence, two parts remained hostile even though the Green Line was dismantled.

All the barricades and partitions along the former Green Line were demolished and municipal services (water delivery, telephone services, electricity links etc.) unified. Roads were connected and paved, and new signs were posted: Jerusalem was physically re-united. However, there was a stark disparity of social conditions and opportunity between Israeli and Palestinian residents of Jerusalem, and this did not disappear with the barricades. This disparity was further deteriorated by urban planning policies of the Israeli government.

Israeli planning between 1948-67, and especially after 1967 has been shaped by objectives of national security and political control (Bollens, 1998). Many of the new suburbs are designed as individual enclaves, connected by primary road systems for the Jewish population and separated from Palestinians by open landscapes (Figure

11). The aim of urban policies; is to extend the Jewish city, demographically and geographically; to control hilltops for security reasons; to reconnect the formerly partitioned Jewish sites; and, to build scattered but interconnected Jewish neighbourhoods so that division of the city cannot occur again (Bollens, 1998).

Figure 11. View of a Palestinian Neighbourhood from an Israeli Neighbourhood and the Separation Wall in Between (Pullan, 2011)

This kind of planning is nominated as *partisan* planning (Benvenisti, 1986; Bollens, 1998) and establishes a radical form of *frontier urbanism* (Pullan, 2011), *forensic architecture* (Weizman et al, 2010), *conflict urbanism* (Misselwitz and Rienietz, 2009) and a *geometry of occupation* (Weizman, 2006). A local form of gated communities (Pullan, 2011) is the main form of urban development. Without a question, architecture and planning became tools in the conflict themselves.

[Re-division] In 2002, Israel began to build systems of physical and electronic separation—known as the *Security Fence*—between Israeli and Palestinian territories and within the Palestinian areas (beyond the internationally recognized Green Line) in northward and eastward directions. This wall is planned to be 570 km long and 6-8m high. The regional barrier passes through Jerusalem with 51 km segment separating Israeli Jerusalem from Palestinian suburbs to the east (Calame and Charlesworth 2009). Today a map of Jerusalem shows this complex patchwork of settlements and villages across the city, with its plethora of borders (Figure 12).

2.5 Results

Division process of each city is the main reason why different urban consequences are achieved. Belfast is particularly unique among case studies in that it was not divided by a war, but a colonization process. This caused internal cohesion in each group (colonized and the colonizer's representatives), and therefore the conflict grew from within the social organism. This is the main reason why Belfast's division process took longer than the rest, and why division still lingers.

Berlin, like Belfast, was divided in a long time-span, with more integrated borders, than those of Beirut and Jerusalem, where division was immediate and less penetrable. In Beirut and Jerusalem, it was during wars that the lines separating them were completely sealed, hence making them less permeable. In this respect, Berlin was also divided by an international war, but unlike Jerusalem, it was a relatively relaxed border where some interactions were possible from time to time.

All the case studies were divided through the heart of the city, except for Belfast, where division is scattered all around the city. Furthermore, peace walls in Belfast are not as armed as the others were. Since wars are the main reason of division in other cities, their borders carried a military presence. But all in all, the dividing lines turned streets into *cul-de-sacs* via walls, barbed wires, sandbags, wire meshes, steel and (in Jerusalem and Berlin) land mines.

When the city is divided from the middle, the two halves have restricted options for growth. The traditional pattern of urban sprawl is hindered where each side can only advance on available routes. For example, West Jerusalem could only develop towards the west. Different developmental patterns were observed; linear (Jeusalem), band (West Berlin) or ribbon typed (Beirut) developments. However, even though West Berlin had a hierarchy of centres, East Berlin continued to grow concentrically.

Deterioration of the buildings near the border was not only because of war damage, but also due to population exchanges. In Berlin, a further consequence has been derelict industrial buildings due to lack of finance (East Berlin) or incompetence (West Berlin). In war-torn cities of Berlin, Beirut and Jerusalem, buildings were demolished to give way to military border zones. This caused vacant lands to proliferate near border zones, especially after reunification. On the other hand, vacant lands in Belfast were mainly formed due to new road projects.

Especially in Belfast and reunified Jerusalem, urban fabric is dominated by roads. In Jerusalem, new road projects are used as tools to accentuate existing divisions, and in Belfast, although having the same effect, the aim is to attract new investments.

The most visual artefacts of division are territorial markers used to exert prominence on people's perception and behaviour. For example in Beirut, territorial zones of paramilitary organizations were marked by checkpoints and graffiti. Belfast and Jerusalem, which are not 'reunified', are fruitful areas for the study of artefacts of

division. Murals, flags, curb stones are only some elements reflecting territorial claims through the usage of urban artefacts.

A further consequence of division in war-torn cities has been the changing functions of urban space. The central functions of the urban core were lost; especially due to extensive war damage (in Beirut and Berlin). Once, these areas were the heart of the city with lively commercial and service activities, now they had become edges. Commercial areas moved away from the dividing line and bi-polarized. New CBDs were created, because either the old ones were right inside or partly occupied by the border zone. Bi-polarization of CBDs and reconnection of urban functions were essential problems encountered after reunification, particularly in Berlin.

All four cities were the capital of their respective countries before division. Administrative functions of the capitals remained in place in each, except for West Berlin, where it was carried to Bonn. However, the primacy of capital cities of Berlin, Beirut and Jerusalem faded away during years of division, in accordance with their political instability.

Residential zones in all the cities examined became ethnically homogenized due to population movements and displacements. Intersection points of residential zones were most vulnerable areas for conflict, and either barricades were erected (as in the case of Belfast peace lines), or they turned into derelict sites. People who had the opportunity moved out of these areas for safer havens, and low status immigrants, refugees or homeless people occupied the empty houses. As a result, residential segregation coincided with socio-economic cleavages, further breaching divisions.

The economies of all four cities suffered tremendously due to division. First, because all (except East Berlin and Belfast), lost their hinterland and became an ‘end city’. Second, even though West Jerusalem and East Berlin were improved as the capital city, duplication of public facilities, services, transport systems and infrastructure meant enormous waste of resources.

Reunification in Berlin, Beirut and Jerusalem showed that it was easy to re-connect the infrastructure, but hard to reinstate a city which will function as a whole. Among case studies, this is particularly prominent in Jerusalem; where East and West Jerusalem remain divided, and further, new divisions appear each day. Social realities, like chronic fear, contribute to this situation.

3. Conclusion

The results of the analysis show that in spite of differences among case studies, a common pattern of functional, structural and socio-economical urban consequences surface (Table 1). The fact that each city produces unique consequences according to their political, socio-economical and physical transformations should not be neglected. Hence, this list is preliminary and can be altered in consistence with the subject and the choice of case studies.

Table 1. Urban Consequences of Division

Functional consequences	* Declining central functions of the urban core * Segregated residential areas, 'ethnic enclaves' * Bi-polarization of commercial areas * Fading primacy of capital city administrative functions * Duplication of urban functions (transportation, services etc.) * Changing functions of urban space
Structural consequences	* Changing urban development patterns (linear, ribbon, concentric/polycentric etc.) * Road-dominated environment (Belfast, Jerusalem) * Proliferation of cul-de-sacs * Presence of frontier landscape * Proliferation of vacant land * Deterioration of buildings * Everyday artefacts of division
Socio-economic consequences	* Economic depression * Chronic fear * Population exchange, homogeneous zones * Socio-economic divisions parallel with ethnic divisions

All in all, it is expected that illustration of common developmental patterns of division will facilitate early recognition and management of this process. Further, this study can contribute to future studies which aim to construct effective planning approaches and management forms in divided cities.

ASSESING THE PUBLICNESS OF PUBLIC PLACES: TOWARDS A NEW MODEL

Dr. Georgiana Varna

University of Turku
Finland

Abstract

In an urban world greatly concerned with sustainable development (Human Development Report 2007/2008; UN Climate Change Conference Copenhagen 2009), building more socially cohesive, environmentally friendly and economic competitive cities appears as a key prerequisite. Through their multiple functions and various roles, public places are central to achieving urban sustainability. But public space has been a contentious term in the academic literature and a 'fuzzy concept' in the practice of city-making. This paper will present the findings of my doctoral thesis, clustered around three main points:

- a new way of conceptualising the publicness of public space, defined as the sum of characteristics that make a public space public;

- a new methodology for practically assessing public places and

- the testing of the new methodology on three new public place case studies, created in the past three decades on the post-industrial waterfront of the River Clyde in Glasgow, UK.

The research was based on a new understanding of publicness as having a dual nature: it can be grasped simultaneously as a cultural reality and as a historical reality. As a result, it was considered that assessing the publicness of a public place comprises two things: first, a measurement of the site as a snapshot against the existent standard of publicness and second, an explanation of that measurement though exploring its development process. This was applied in practice, on three new public places created on the regenerated waterfront of the Clyde, in Glasgow and conclusions were drawn regarding the robustness and usefulness of this approach.

1. Introduction – What is public space?

Public space is neither an uncontested nor an uncontroversial arena in the disciplines of urban design and planning (e.g. see Atkinson, 2003; Raco, 2003). Indeed debates on the "politics of space" (e.g. the tension between surveillance and access rights to public space) continue to capture academic and public attention (see Lefebvre, 1991; Flusty, 2001; Mitchell, 2003; Madanipour, 2003; Kohn, 2004), raising important questions of social justice, such as: "Who makes and controls public space?" and

"Who benefits from the development of new public space in the context of restructuring the city?" There are even more pessimistic voices arguing for the breakdown of society and „the fall of public man" (Sennett, 1977) due to a change in people's attitudes. From active participants in the life of the city, „the people" have become passive spectators to the display of neoliberal and market-driven forces (Foucault, 1986); the „public" has been „pacified by cappuccino" and lost its ability to fight for „social justice for all" (Zukin, 2000; Atkinson, 2003).

As a reflection of such concerns, a distinctive strand in recent urban design policy in the United Kingdom has been focused on urban design as making places for people (Urban Task Force, 1999 & 2005; DCLG, 2009; Carmona et al., 2003). As such, „the public" has been the subject of increasing policy attention over such matters as the commodification of space; cappuccino urbanism and a focus on affluent consumerism; the privatisation of public space; the militarising and securitising of space through CCTV and other express security measures; exclusion from public space; the emergence of gated communities; the Disney- fication of public spaces etc. In turn, public space is also the subject of a growing academic literature from the full range of social science and humanities disciplines (Carr et al., 1992; Sorkin, 1992; Mitchell, 1995; Zukin, 2000; Madanipour, 2003; Massey, 2005; Mensch, 2007). Each discipline sees public space through a different lens, and with particular interests and concerns to the fore. Political scientists, for example, focus on democratisation and on rights in public space; geographers on „sense-of-place" and „placelessness"; legal scholars on the ownership of and access in public places; sociologists on human interactions and social exclusion etc. The result is a diverse array of multi-disciplinary approaches towards understanding „public space" (Figure 1).

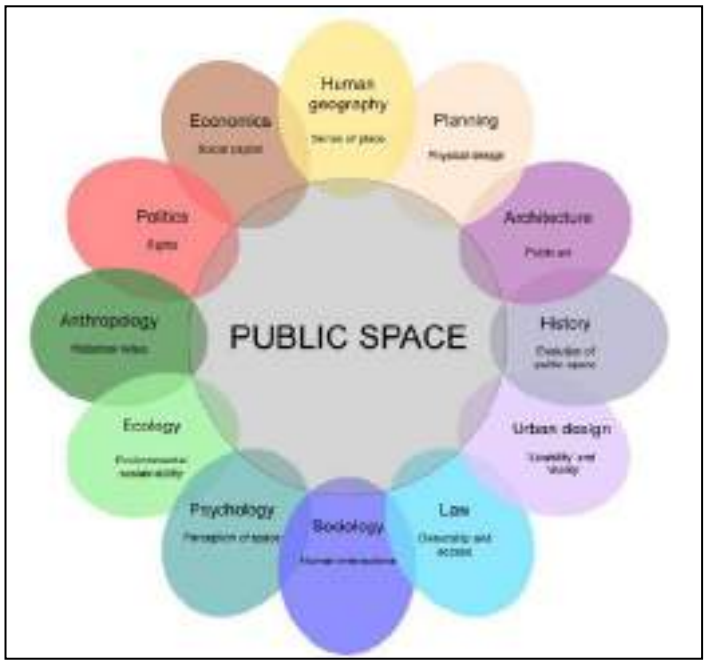

***Figure 1** Public space – a multidisciplinary approach*

What these various

disciplinary accounts seem to have in common though is a sense that something has been lost. It seems that a commonly accepted standard of publicness of public space has been tainted by the intrusion of economics and politics of fear and control (Sorkin, 1992; Mitchell, 1995; Davis, 1990; Zukin, 2000). The starting point of this research was to find out if there was a way to measure publicness and describe in a more rigorous way if and what has been lost.

The existence of these various understandings of public space from multi-disciplinary perspectives creates much confusion around the meaning of the terms „public space" and „publicness of space". During the research, it became apparent that the notion of public space is such a „slippery term" because first, on a theoretical level, there are so many conflicting and confusing multi-disciplinary views and definitions in the matter. Second, on a practical level, the real, built public places are complex socio-cultural, political and environmental products of a social group while on a third, individual level, public space is also a subjective, personal construct. A space can be public to me but not to you. The first aim of this inquiry was to try to shed some light into the meaning and the complicated nature of public space. Because of the existence of so many different disciplinary perspectives on public space and as it was felt that none of them clearly explained why public space is such a „slippery term" and defined it in a comprehensive manner, the research sought to approach the matter in a fresh way. The next paragraphs will present the theoretical foundations that anchor this study.

2.0 Theoretical considerations

2.1 The dual nature of public space and the Star Model of Publicness

As a distinctive part of the built environment, the main stage where the life of the community unfolds, public space is deeply intertwined with the beliefs, traditions, experiences, political views and so on, what is generally understood as the culture of a particular society.

> "The existence of some form of public life is a prerequisite for the development of public spaces. Although every society has some mixture of public and private, the emphasis given to each one and the values theyexpress help to explain the differences across settings, across cultures, and across times. The public spaces created by societies serve as a mirror of their public and private values as can be seen in the Greek agora, the Roman forum, the New England common, and the contemporary plaza, as well as Canaletto's scene of Venice" (Carr et al., 1992; p. 22).

In other words, on the background of larger political, economic and social structures, a certain society, at a certain point in time, holds a common understanding of what makes a public space, public, or otherwise said, what the ideal public space is and this is then translated in the various public places that are created. If one could grasp this general held view on the ideal public space and determine what key

characteristics are considered as giving a certain place its „quality of being public" or in a shorter phrase „its publicness", then this could be used as a standard for measuring different public places. But how to grasp this ideal? The approach taken here was to investigate the literature in the field, from as many disciplines as possible (with a focus on urban design and planning), in a deductive manner (see Figure 2).This is the understanding of a public place as a cultural artefact and its publicness as a *cultural reality*.

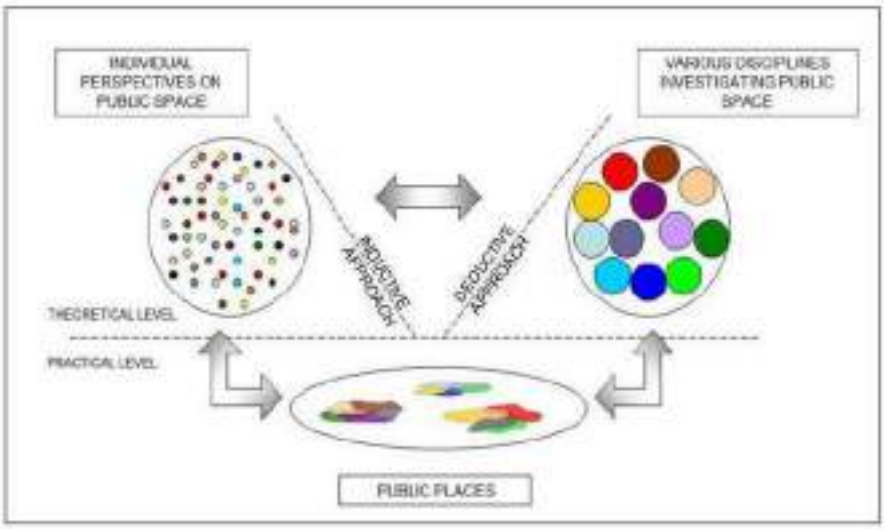

***Figure 2* Deductive and Inductive approaches to studying public space**

At the same time with being a cultural reality, the publicness of a public place is also a *historical reality*. As the western society changed in time, so did the conception and implicitly the physical representations of public space; a reflection on the history of public space in the western world shows that in different time periods, different public places were created according to different ideas and ideals of publicness. The ideal of publicness of the ancient Greeks reflected in the agora where women, foreigners and slaves were not allowed to take part (Mitchell, 1995) seems inappropriate for the contemporary western society. For the present inquiry, this means that an ideal public space and a standard for its publicness can only be defined for contemporary, newly built public places, in the UK and generally in the western world, in the last fifty years or so.

It needs to be stressed that publicness is seen here from a critical realist point of view, as something *out there*, something measurable, independent of the human consciousness. However, it is accepted that publicness can also be grasped from a subjectivist point of view. Each individual has a slightly different way of perceiving what a public space is (from one's experience of different public places and the personal meanings they are associated with). The subjective nature of publicness means that even though this ideal can be defined, it will not be shared by everyone. From this discussion, it results that on a conceptual level, public space is ever an

ideal, reflecting a general common view held at a certain point in time and in a certain socio-cultural setting; no reality can match it but by grasping this ideal and using it as a standard for publicness, public places can be measured, compared and as a result it can be known more clearly where they fail and how they can be improved. Therefore the research question anchoring this research was: *what makes a public space, public?* In other words, *how can one conceptualise and measure the 'publicness' of public space so that different public places can be graded and compared?*

In order to answer this, the dual nature of publicness theory was created. To analyse public space as a historical reality, there are available methods of research such as interviews, focus groups, document analysis and archival research. However, for analyzing the publicness of public space as a cultural reality, no actual method was found in the public space literature. Therefore, the Star Model of Publicness was developed to fill in this gap. Although the first of its kind, it is built upon several original and valuable attempts of analysing and quantifying different aspects related to the publicness of public places. The Dutch scholars Van Melik et al. (2007) looked at indicators related to one dimension of public space, management, and were concerned with comparing two opposed types of managed public places, "secured" and "themed" ones. On the other side of the Atlantic, the Americans Nemeth and Schmidt (2007) have also looked at the management aspect of public space and attempted to create a "methodology for measuring the security of publicly accessible spaces" (Nemeth and Schmidt, 2007).

When asking the quite deceptively straightforward question: "What is public space?" a web of closely related but loosely defined terms complicates the answer to this question greatly. As Orum (2010, p. 13) asserted "...the mystery and drama of public spaces begin with their very definition". When closely analysing the different ways of defining and conceptualising public space, it can be noticed that the literature can be grouped in five thematic clusters.

First, a key characteristic of public space appears to be related to **ownership**. Writers from North America such as Lofland (1980), Kohn (2004) or Staeheli and Mitchell (2008) identify as a crucial element for a place's publicness, its maintaining in public ownership. In addition to the above writers, there have been many voices arguing that a growing phenomenon of privatisation of urban space is responsible for much of the damage produced to the cities' public realm. These have come also from North American authors such as Sorkin (1992), Zukin (1995) or Banerjee (2001). Kohn's (2004) extensive study Brave *New Neighbourhoods: The Privatization of Public Space* is dedicated entirely to this phenomenon.

A second clearly defined cluster in public space research is concerned with the **physical configuration** of a public place. In several of the definitions and conceptualisations investigated, public space is associated with real physical urban places. For example Brown (2003) identifies urban public space as including "…formal squares, roads and streets, but also vacant land, verges and other 'edge-space'" (p. 10) while Tibbalds (1992) describes the extension of the public realm

from "… all the streets, parks and squares of a town or city into the buildings which enclose and line them" (p. 1). The bulk of this literature on the physical appearance of public places comes from the disciplines of urban design and architecture.

A third strand of research is framed by the sociological and anthropological public space literature and refers to the use of public space, or in other words, to their **animation**. Being the places of free assembly and interaction among the members of a community, public places are the physical stage where "…the functional and ritual activities that bind a community, whether in the normal routines of daily life or in periodic festivities" (Carr *et al*., 1992, p. xi) take place. Whether the case studies are the Latin American plazas (Low, 2000), the New York's redeveloped parks (Zukin, 1995) or "the third places" of the western culture (Oldenburg, 1989) these writings share a common preoccupation with people's behaviours and actions in public space and how these change over time. Two key studies that document the use of public space in relation to the above mentioned dimension of physical configuration are in the USA, Whyte's (1980) *The Social Life of Small Urban Spaces* and in Europe, Jan Gehl's (1996) *Life Between Buildings.*

A fourth strand of research is related to public space as the arena where the fragile relation between freedom and **control** unfolds. Many authors, among which Carr *et al*. (1992), Mitchell (2003) and Goodsell (2003) consider the quality of a public place of being a democratic arena for public life as fundamental for its publicness. They note that public places are historically the places that have served as the stage for the expression of the people's dissatisfaction with a certain state of affairs. As a result, they are the places where fundamental rights guaranteed by a democratic society, such as the right to speak freely and assemble, are manifested. What appears to have happened recently is an increase in the surveillance and control measures in public space, noted by scholars such as Koskela (2000), Atkinson (2003) or Raco (2003).

A fifth and last common theme is concerned with the maintenance of public places according to certain standards, so that they are clean, friendly and inviting areas. Although this meta-theme of **civility** is not as explicit as the others, many of the reviewed writings identify the presence of refuse and decay in urban public places as a cause and a mark of the broader decline of the urban public realm. One of the writings where the issue of public space maintenance is thoroughly addressed is Francis Tibbalds' *Making People Friendly Towns* (1992) where he states with concern:

> "… we are now witnessing a serious decline of this rich domain. Many of the world's towns and cities – especially their centres – have become threatening places – littered, piled with rotting rubbish, covered in graffiti, polluted, congested and chocked by traffic, full of mediocre and ugly poorly maintained buildings, unsafe, populated at night by homeless people living in cardboard boxes, doorways and subways and during the day by many of the same people begging on the streets." (Tibbalds, 1992; p. 1)

Five key dimensions of publicness have been presented, differentiated for the purpose of this theoretical endeavor into five meta-themes: ownership, physical configuration, animation, control and civility (Figure3).

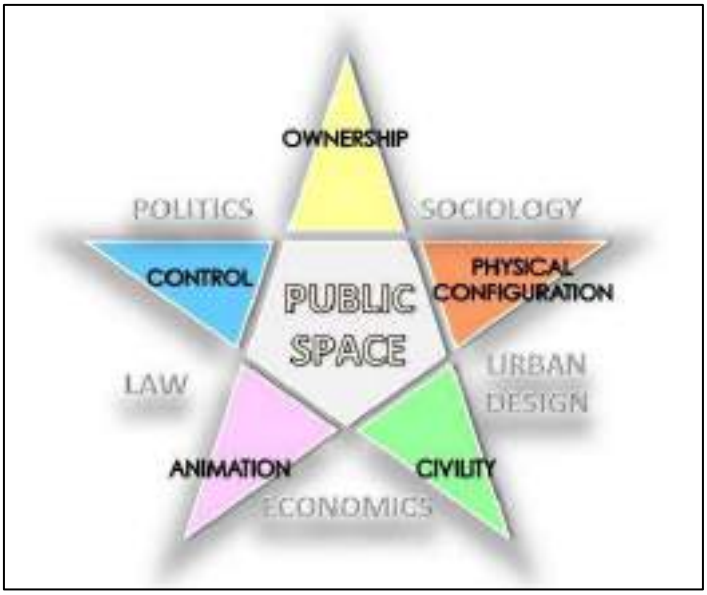

Figure 3The Star Model of Publicness

Through their synergic interaction, where the sum of all is greater than the parts added together, they create the publicness of public space. Public ownership of a site means that the place is owned, in a way, by all members of the society and is, in principle, open to all members of the public, no matter how one defines that public. It means that decisions about its use and accessibility are subject to some form of public accountability. High connectivity and visual permeability enable greater access into a public place, while specific elements of design support different activities, responding to different needs of people in public places. The absence of oppressive control allows for a freer and therefore more diverse use of a public place. A more civil place – one that is well lit, clean, green and inviting, will attract a greater number and diversity of users. A more animated place, where a variety of activities are performed by a large and diverse public will also designate a more public place. Therefore in this research public space is defined as:

> *the concept referring to all public areas, that are publicly owned by democratically elected bodies, well connected in the surrounding urban grid and designed according to principles that foster activity and social interaction, used by a large and diverse public in a variety of ways, controlled in an non oppressive manner and characterised by an inviting and tidy atmosphere.*

The definition illustrates the common understanding found by the researcher of what

constitutes a *very public* public place today in the UK and in the Western world generally, in relation to which existent public places can be measured. A key aspect is that these disciplines can be seen as varying from a *more public* to *less public* situation (Figure 4). This was the foundation for constructing a new tool for measuring public spaces.

More public	**-**	**Less public**
Publicly owned space with public use	**OWNERSHIP**	Privately owned space with public use
Well-connected/located within the movement system (i.e. on-the-beaten-track); strong visual connection to external public realm beyond space; without obvious entrances and thresholds; a wide range of supports for a wide range of activities	**PHYSICAL CONFIGURATION**	Poorly connected/located within the movement system (i.e. off-the-beaten-track); poor visual connection with external public realm; with explicit entrances and thresholds; narrow range of supports creating a limited potential for activities
A large and diverse public engaged in a variety of activities	**ANIMATION**	Dead public space: few people engaged in few activities
Free use and a comforting police presence	**CONTROL**	Overt and oppressive control presence - human and electronic surveillance; highly visible security presence
Cared-for; well-kempt; inviting	**CIVILITY**	Untidy, vandalised, dirty and uninviting

Figure 4 Descriptors of 'more public' and 'less public' for each meta-dimension

2.2. The Star Model – a practical tool for measuring public places

The thought process driving the translation of the Star Model from a theoretical construct into a practical tool to measure and represent publicness is shown in Figure 5. The challenge was to find elements for each meta-theme that could be measured easily and quickly so that anyone with an interest in a site could calculate its publicness. Bearing these in mind, a search was initiated for those elements that could bemeasured and that were influential for determining the five meta-themes (Annex 1).

Following this, the second stage was concerned with calibrating them. In this respect, a rating scale was decided upon for grading their variation from low to high publicness. In

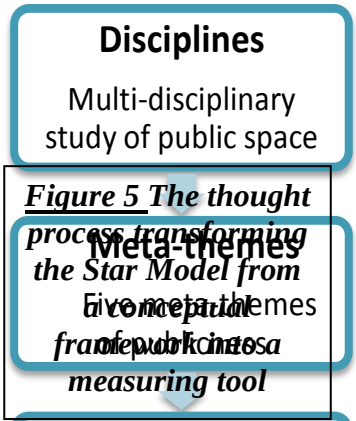

Figure 5 The thought process transforming the Star Model from

previous research, Nemeth and Schmidt (2007) have used 0, 1 and 2 values and created statistical modeling for a large number of public places in New York. This was considered as a too superficial way of observing and translating into measurements the different shades of publicness of particular public places. As a result, it was opted for a scale from 1 to 5, 1 being the lowest publicness and 5 the highest. A scale more than 5 would have complicated the model too much while a lower one would have not been sensitive enough for the different levels of variation. For each grade, the researcher tried to give a description as objective as possible for every indicator and create a scale ranging from „less public" to „more public" based on the theoretical decisions made during the literature review stage. Although it is acknowledged that the rankings have an inherent degree of subjectivity, the researcher tried to be as objective as possible and create a model as less arbitrary as feasible with the available time and resources.In relation to aggregating the results, it was decided to consider all indicators equal for each meta-theme, recognising that it is a task for future research to find out other more complex ways of calculating the measurements for each meta- theme.

To illustrate the results pictorially it was decided to translate the Star Model into a Star Diagram. The larger and better delineated the star, the highest the publicness of the public place would be while less well-delineated, even „negative" stars would reflect a site with a low value of publicness. In order to apply the model in practice, the majority of the indicators can be measured by using the method of structured observation. The only indicator that cannot be measured in this way is *Ownership status.* The rating for this indicator needs to be found out during the investigation of publicness as a historical reality, for which the methods of document analysis and semi-structured interviews were chosen. These made possible for the researcher to construct the development story of each site and understand how its publicness was influenced by different actors during this process. However, this will be not covered here due to the paper's limitations. Instead, only the results of applying the Star Model will be presented.

2.3 Applying the model in practice

The creation of new public places on the recent regenerated waterfront of the Clyde,

the central river in Glasgow, has not been adequately investigated. From a highly industrialised river that brought wealth into the city and made Glasgow the second city of the empire, in the second half of the 20th century, the waterfront underwent slow decay culminating to the city having turned its back to the river. The recent regeneration of the waterfront has been therefore a controversial process that captured the attention of the public, the media and the research community. In the process of urban regeneration, public space has been seen as a priority for changing the image of the city and for promoting Glasgow on the world stage. By assessing the publicness of new public places on Glasgow's post-industrial waterfront it was intended to apply and test the model, while investigating the recent transformation of the river as part of the broader background of the city's regeneration.

Regarding the number of case studies, a balance needed to be found between the advantage of investigating more case studies, which would help test the applicability of the model and the disadvantage regarding less time available for appropriately exploring the development process and historical background of each site. Consequently, three case study new public places created on the post-industrial waterfront of the River Clyde were selected. These were new public places, created in the last decades of waterfront regeneration, similar in purpose, in the sense that they should all have been created for the 'wide public', Glaswegians and tourists alike (and not for specific categories of users, such as a children's playground). Also, in order to introduce variation and see how the model works in slightly different circumstances, each case study was chosen as part of a different type of development that has been produced in a different period in the last thirty years or so. Based on these considerations, the following sites were chosen:

Pacific Quay, one of the first places where development started to happen on the derelict post-industrial landscape of the Clyde's waterfront, was the location for one of the first cultural regeneration events in the city – the Glasgow Garden Festival in 1988. It is an area dedicated to leisure and tourismbut also to the media industries, representing Glasgow's new „Media Quarter (the new headquarters of BBC Scotland have been relocated on site in 2007). The site is situated approximately one mile to the west of the City Centre, on the southern bank of the river. On the northern bank, opposite to the case study public place are the SECC (Scottish Exhibition and Conference Centre) and The Clyde Auditorium or 'The Armadillo' – two famous landmarks in the cultural and touristic life of the city.

Glasgow Harbour, developed mainly as a housing project, especially in its first stages, started in 2000 and it is one of the most controversial developments in Glasgow in the last decades. This is due primarily to the demolishing of the famous Meadowside Granaries, a significant landmark from Glasgow's rich shipping industrial past, to be replaced with luxury apartments and a new public place. It is situated to the West of the city centre, bordering the traditional working class neighborhood of Partick and was planned as an extension of the close by West End – the most affluent part of the city and the location of the University of Glasgow.

Broomielaw, the latest public space development on the Clyde waterfront, was

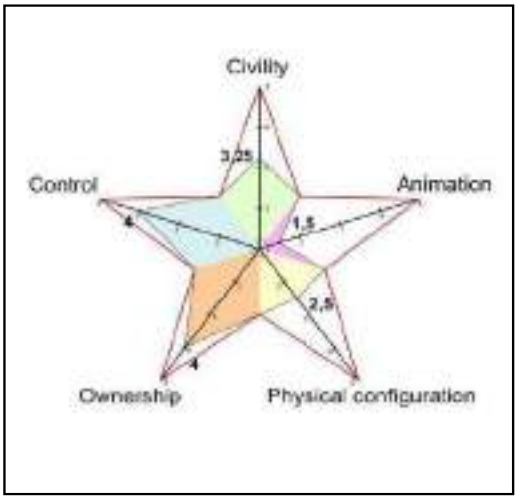
opened in 2009. It is part of a larger project consisting of two regenerated river walkways, one on the north side of the river at Broomielaw and one on the south side of the river at Tradeston, connected by a new pedestrian and cycle bridge, the Squiggly Bridge. Due to the current recession, the Tradeston development is not yet completed; the greatest progress has been made in the Boomielaw part and as such, the new public place here – the river walkway - was chosen as the case study. The site is in the City Centre of Glasgow, next to the International Financial Services District (IFSD) and has been a publicly led project by the Glasgow City Council.

Three days were spent in each location, from morning until evening and measure the indicators: Mondays to account for the week use, Fridays and Sundays for the weekend use pattern. It was considered that it was insufficient to record the animation of a place only for one day, because this would lead to a biased set of data. In that specific day, adverse weather conditions, a special event or celebration in the city or other similar factors could greatly influence the animation of a site. It was decided to perform the observations in the autumn of 2009, for approximately two months, from the end of September until the beginning of November.

3. Results

Applying the model was a successful attempt in the sense that the publicness of each public place could be graded and as such, comparisons were possible among them. The results show that the most public, public place is Broomielaw, with a value of **3.63** and the least public is Glasgow Harbour, with a value of **2.6** while Pacific Quay rates intermediary, with a value of **3.03** (Figure 6). The Star Diagrams allow for comparisons in terms of each meta-theme while the investigation of each site's development story allows for explanations of the obtained ratings.

Regarding the first meta-theme, each public place presents a different rating, illustrating a different 'shade' of ownership. Broomielaw is in public ownership, and as such it rates the highest. This is a result of the public place being in the ownership of the Glasgow City Council, the local democratically elected public authority, which led the regeneration process and kept its hold on the site.



Pacific Quay – overall rating of publicness **3.03**

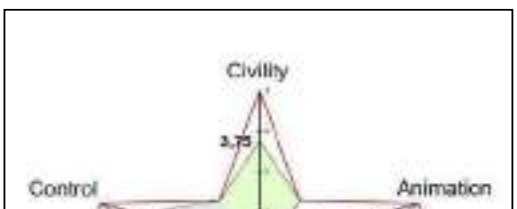


Figure 6**The results of the Star Model application in Glasgow, UK**

Pacific Quay has a mixed ownership, comprised by two owners, the BBC and the Science Centre. Glasgow Harbour is in the private ownership of Clydeport, the local port authority which has always owned the land and led the regeneration process. It cannot be concluded from these three case studies that a phenomenon of privatisation of public space is happening on the Clyde Waterfront. A larger study, involving more case studies would be required to establish this.

Related to physical configuration, the case studies can be discussed in terms of both macro-design and micro-design. Related to macro-design, none of the public places was found to be very well integrated in the surrounding urban grid. The best connected is Broomielaw, due to its proximity to the city centre, the creation of a

continuous walkway along the river in the 1970s and also to the desire of the Glasgow City Council to link the IFSD to the less developed south side of the river. Both Pacific Quay and Glasgow Harbour are very poorly connected to the surrounding urban grid, apart from the northern direction. In the case of Pacific Quay, this has resulted from a combination of factors: the lack of strong leadership and focus from the main actor, Scottish Enterprise, the continuous delay from the part of the private actors, who own the adjacent land and the lack of agreement among the public and private parties. In the case of Glasgow Harbour, there is a similar lack of development in the surrounding areas, a consequence of the recent economic crisis but also of the disagreements between the public and private actors to build a bridge over the Clyde.

In terms of micro-design, there is a good provision of walking opportunities in all the public places while sitting opportunities are better delivered in Glasgow Harbour and Broomielaw (although the focus was on robustness not comfort). In the case of Glasgow Harbour, the private owner and developer, Clydeport, wanted high quality materials in order to create an upscale housing development while in the case of Broomielaw, the aim of the Council was to create a postcard for the IFSD and Glasgow as a whole. In the case of Pacific Quay, there are very few and poor quality sitting opportunities, a reflection of the lack of emphasis on the development of this new public place. The Science Centre is an indoor venue, the BBC, a public office building and Scottish Enterprise focused mainly on bringing development on site and not creating a high quality public place. There are no active frontages bordering the new public places and very few opportunities toactively engage with and discover the environment. In other words, there is very little to make these places into destinations as they were intended.

All the public places rate fairly low regarding animation.This can be related to the lack of opportunities for active engagement and the poor connectivity with the surrounding environment, as discussed above. Pacific Quay and Glasgow Harbour rate the same and seem relatively empty places. Broomielaw is the most animated out of the three public places (with five activities performed in a short time interval), which can be related to a better connectivity of the site and its proximity to the City Centre. In terms of the number of people, although there could be no straightforward indicator devised, the indirect indicator, the Presence of Street vendors and/or entertainers reflects the number of users of the public places (448 people were recorded in Pacific Quay and 420 in Glasgow Harbour, with no street vendors and/or entertainers in either of them, with a much higher number of 1391 people recorded in Broomielaw, where there was only one street vendor present).

All three public places rate fairly high in relation to control. This is due to the overall absence of signs deterring behaviours and of sadistic street furniture. Also, a fairly low presence of guards was recorded. There were no private guards observed in any of the three sites and no public guards were observed in Glasgow Harbour and Pacific Quay. However, daily patrols were observed in Broomielaw. This is related to the existence for a long period of time of a negative image for the area (violence, drug abuse and prostitution) but also to recent incidents of childrenclimbing the

newly built bridge. All the public places have been found to be observed by CCTV cameras.

Related to civility, analogous, medium ratings have been obtained. None of the new public places have been provided with public toilets, a result of the Glasgow City Council's policy of closing them down on account of diminished public budgets. All of the public places have a fairly good provision and maintenance of greenery and lighting, Broomielaw rating marginally better. In terms of the tidiness of the area, the least clean site was Broomielaw. One of reasons is the fact that it is more animated and it seems that generally in Glasgow, the public does not respect the tidiness of the public places (littering, graffiti). Another reason is the lack of appropriate, high standard maintenance provided by the Glasgow City Council.

The three case studies investigated can be seen as representative for Glasgow's re-invention as a post-industrial city. The Pacific Quay site shows the focus of the city towards enhancing its media services, the Glasgow Harbour site is illustrative for the new trend of creating up market, luxury housing developments while the Broomielaw project is part of the new trend of establishing Glasgow as a financial and business centre. As part of this broader context, the average ratings of publicness obtained for the three new public places can be related to several factors. Among them is the relatively late regeneration of the waterfront, begun only at the end of the 1990s and the permanent empty purse of the Glasgow City Council, combined with a lack of funding from a national level (although the River Clyde is considered a Scottish national priority). Also, the divided ownership on the banks of the Clyde, the lack of a comprehensive vision for the river's regeneration from the part of the local authorities and the existence of a variety of public agencies and actors in charge with the public place provision and maintenance, frustrate the publicness of the new public places.

4. Conclusions

The following paragraphs will highlight the main ways in which this research project has addressed the existing literature, presenting both what this study challenges and what it confirms.

By initially reviewing multi-disciplinary literature, in which public space and publicness were conceptualised and defined in many different ways, this research gives a multidimensional definition of public space and proposes a unified theoretical model to describe the publicness of public places. Measuring publicness has proven to be a difficult task, and although a model has been created, and its first testing showed promising results, there remains plenty of scope for improvement. This is most evident in respect to the meta-theme of Animation, where more and better indicators need to be found. Also the possibility of measuring Animation in a similar way to the other four meta–themes needs to be reflected upon in more depth.

Through the application of the Star Model of Public Space, light was shed on the two overarching contemporary phenomena that have been identified recently as leading

to a loss in the publicness of new public places; privatisation of space and increased control of public places. Concerning the privatisation of public space, the results obtained by applying the model to the three new public places in Glasgow did not show conclusively that such a phenomenon is taking place in the Scottish city. However, they did show that indeed, increasingly, there is a blurring taking place between the boundaries of public and private as noticed by commentators such as Madanipour (2003), Kohn (2004) or Marcuse (2005). Concerning the control of public space, the results did show an increase in control measures especially electronic surveillance (i.e. CCTV).

Regarding the strengths of the model, first, on a theoretical level, the Star Model of Publicness brings together, for the first time, different key elements of publicness into one single entity. As such, the model clarifies the slippery concept of the publicness of public space and offers, at one glance, a comprehensive image of what makes a public space, public.Second, it measures publicness, quantifying in an objective way a concept previously considered mainly as a subjective construct. More, the publicness rating is not only encapsulated in one numerical value but it is also illustrated in a Star Diagram of Publicness. This is a new graphical representation that shows in a straightforward manner exactly where publicness is eroded or where it is enhanced. Third, the model offers a much-needed method to compare and contrast different new public places, created in the urban western world. The comparisons allow for understanding which public places are more public than others so that knowledge exchange is made possible and lessons are learned from the success and/or failure of different projects.

Apart from these theoretical strengths, the model is also deemed useful in the practical creation of public places.First, by giving one clear and comprehensive definition of what a standard public space is, the model facilitates information exchange in the development process, helping to overcome misinterpretations that cause many projects to be compromised in terms of quality. Moreover, by offering a standard for public places, the model functions as a decision support tool. In this respect, the different actors in the development process can strive to create not just a public place, but a public place with at least, for example, a publicness rating of **3**.Second, a chief advantage of the model is that it can be used as an audit method in the redevelopment of public places. Those in charge of such a project can assess where publicness fails, in a quick and informed way, so that interventions can be made towards the right areas and delays overcome.

Critically reflecting on the research undertaken and on the Star Model created, although this is deemed useful both in public space research and practice, several limitations should be highlighted.First, by applying a common standard and a common way of measurement to all public places, it can be argued that the particularities of a public place are lost when its publicness is translated into a number and respectively, a Star Diagram. Each public place has its own identity, its own atmosphere or *sense of place* resulting from the particular geographical location, the historical character of the area, the colours, the smells, the sounds, the specific layout and materials used, the type of greenery etc.

Second, although it is asserted that the Star Model measures publicness as objectively as possible, it has to be recognised that this is the subjective creation of the researcher. At any time, other researchers might find other key meta- themes or indicators to measure publicness. Nevertheless, it is hoped that thisinvestigation will open the way towards more rigorous and objective studies of public space and publicness.

Overall, this study can be seen as an experiment at the border between social and physical sciences, aiming to express in a formula, a complex social concept – the publicness of public space. It is felt that although a new conceptualisation of publicness was brought forward and an innovative way of measuring it was created, this is only the first, small step in a long journey towards more rigorous and more objective studies of the publicness of public space.

CULTURAL INDUSTRIES AND URBAN REGENERATION. PHYSICAL RENOVATION AND TERRITORIAL IDENTITY CREATION IN *ZONA TORTONA*

Ilaria Giuliani [1], Chiara Valli [2]

Abstract

The main subject of this paper is the relation between urban space and the agglomeration of economic activities tied to creativity and cultural production. The authors aim to contribute to understandings of this relation through a focus on the development of Milan as a creative city.
Urban issues such as identity redefinition, district regeneration, territorial branding and urban competitiveness are in this particular case closely bound to the production of culture and creativity. The co-localization of creative activities in a territory, it is argued, has important effects not only for the cultural industry itself, but is a potential engine for the broader development of an urban district and potentially whole cities. In our empirical example, we show how the gradual settlement of cultural economic activities in the *Zona Tortona* district of Milan has changed local space in terms of both the built environment and territorial identity.
The *Tortona area*, on the post-industrial periphery of Milan, has become a recognized territorial brand, "*Zona Tortona*", and one of the most dynamic zones and attractive areas in the city, used as a location for big events such as the *Furniture Fair* or the *Fashion Week*. The process through which this has been achieved began in the mid-1980s – with a pivotal intervention on a vacant industrial site by a photography company – and is still going on, in the form of a gradual and incremental series of creative settlements that continue to encourage other creative industry professionals to buy and renovate ex-industrial spaces.
As in *Zona Tortona*, all over Europe we see to an increasing number of examples of urban, economic and social regeneration led by private, bottom-up developments, very often connected to creative economic activities. This is why the *Zona Tortona* experience constitutes an interesting case study: enabling us to deepen our knowledge of contemporary processes of urban change.
In particular, two processes have intertwined in the Tortona area recent history: built environment renovation and territorial identity creation. The paper aims to throw light on these meaningful intersections.

1. Introduction

Milan is an international node for design and fashion production, in terms of trend setting and related manufacturing. Being known worldwide as a fashion and design capital, the city and the wider Lombardy Region are characterized by a spread distribution of small, medium and large businesses connected to this kind of production; furthermore, Milan is a major R&D and formation center for design and fashion subjects. Promotional events, like the design and furniture trade fair – *Salone del Mobile* - have literally changed large parts of the city (Jansson and Power, 2010). It is obvious, then, that a certain vocation and diffused knowledge about design and creativity is "in the air" in Milan.

All over the world, though, creativity and cultural production have been at the center of the discourse of Planning and urban renovation strategies. During the last 15 years, the importance of creativity seems to be emerged not only as a new, alternative, potential source for urban cultural development, but also as an essential resource to be competitive in the global market. Nowadays, creativity together with innovation and knowledge – the immaterial component of society – are differentiating factors that influence ideas, products, services and places, leading to competitive advantages in all fields of economy. As creativity, innovation and knowledge seem to become some of the main drivers of economic development of cities and regions, a new kind of economy is emerging, a new paradigm which embraces economic, cultural, technological and social aspects of development both at macro and micro levels. Indeed, many cities have recently recognized the value deriving from the presence of creative and cultural industries and have started to investigate how the mixture of culture and commerce, production and consumption, large and small businesses might work as a strategy to improve their image as global and dynamic nodes.

However, one of the major problems with creativity is its definition. Klausen (2010, pp.347) notes that "*the standard definition of creativity is problematic and maybe in an even worse state is generally acknowledged by creativity researchers themselves"*, and Scott (2010, pp.115) remarks that "*in view of its current vogue, the term calls urgently for substantive clarification"*. Kuntzmann (2005) defines creativity as a *fuzzy concept*, Landry (2000) indicates it as an alternative strategic approach to urban planning, and Florida (2002) describes it as the main source for cities to be competitive.
Furthermore in recent times, this new trajectory of the developmental perspective has raised a lot of uncertainties, conflicts and ambiguities. Central to this debate is the exploitation of cultural production for economic profit, in the service of the new emerging middle classes, leading to a destruction of original artistic values, instead or in the name of a genuine interest in stimulating cultural advancement. .
Regarding this, Zukin (2010) argues that creativity is arguably not just an end in itself, but also a means to develop distinction, economic spin-off and authenticity.

Indeed, all over the world we see an increasing number of examples of urban, economic and social regeneration, in which the conscious creation or nourishment of cultural and creative areas, districts, neighbourhoods has already been used as an instrument in the urban planning agenda.
In every major city, cultural and leisure functions are grouped together in a great variety of spatial forms and programs. They can be enclosed in stand-alone building or larger buildings complexes, or they may include entire quarters or networks of locations. Most of the time projects hosting cultural and creative functions are located in former industrial complexes but quite often they also imply the construction of new buildings. Some clustering strategies are simply linked to artistic/cultural activities, but many others also incorporate a great variety of leisure and entertainment elements such as bar, restaurants, cinemas, retail spaces, etc.
Sometimes such projects have started their career as innovative attempts in places left over after planning, by informal, private groups of cultural producers who turn them into new alternative cultural sites through bottom-up developments; in other examples, cultural clusters began their existence already in the minds of cultural managers searching for the ways to strengthen the market position of their amenities within a more competitive cultural and leisure market (Mommaas, 2004). In still other cases, projects come to life on the drawing board of urban planners through a top down approach, looking for ways to revitalize urban quarters or to strengthen the local creative economy improving the "global brands" of cities, through growth-oriented policies.

This seems to acquire more importance in a globalized world where places compete with each other and the image of a city plays a crucial role. In this contemporary global competition, cities become themselves products, trying as best as they can to attract investments, business residents, tourists, events and to improve citizens' satisfaction. In order to deal with this competition, which puts under pressure not only enterprises and public and private sectors, but also territorial areas, different typologies of tools are exploited, such as strategic plan adoption, place urban territorial marketing strategies, city branding actions, events and mega-events hosting that could produce and spread positive images of cities. So that when all these elements are well managed and promoted, the potentials to obtain good results are definitely higher and of success.

The case study we are presenting here explores some alternative urban patterns, that seem to be quite innovative in terms of features and factors involved in the process and which make this experience rather unique.
Indeed, it is a story of overlapping urban dimensions, equally giving their contributions to the redevelopment process: it is a story of industrial reuse and transformation, territorial promotion and urban marketing strategies linked with world known events taking place in Milan.
Thus built environment renovation and territorial identity creation are inextricable key factors of the regeneration process that need to be analysed together, with the same relevance, since they are continuing influence each other along the path (Giuliani, 2010). What links and supports these two material and immaterial

dimensions is exactly the territory, its spaces and its unused possibilities.

What makes this experience unique and worth to investigate is a combination of elements of interest: first of all, *Zona Tortona* is nowadays renown as one of the most influential fashion and design district in the world, accounting the location of top names in creative industries, beside being one of the most dynamic and attractive neighbourhood in Milan. Secondly, its uniqueness lays in the fact that it is able to grow and renovate itself thanks to its embeddedness in the territory, since it has developed not by top-down interventions, but rather from spontaneous triggering initiative from private creative companies. Thirdly, territorial image creation, still by private sector, has been the supporting infrastructure for the territorial transformation.

The paper is divided into four main parts. The first one reconstructs the historical context of this part of Milan, starting from its origin to narrow down to the urban, socio-economic situation the area was facing before the redevelopment process started. The second parts concerns the process from a physical point of view, considering the interventions on the ex productive sites and the actors were promoted by. The third one regards the immaterial dimension of the transformation, analyzing how different strategies of urban marketing have been applied. The last part tries to produce some final considerations about this urban spontaneous reindustrialization as an occasion to renovate and revitalize this part of the city, proposing possible future research issues. Maps, images and logos are provided for a better explanation of the case.

2. Research methods

The methodology adopted in this study is based on three different steps and on the assumption that it is always appropriate to use multiple methods and triangulation (Barnes, 2009). The first step consisted of a literature review to capture relevant background knowledge on creative and cultural projects within cities, and rehabilitation of traditional districts and old factories, which helped to develop a theoretical framework for the case study.
The second stage was a case study both with on-site interviews and review of some materials. Qualitative analysis of the social dimensions were carried out based on site direct observation and in-depth interviews, as well as review of both formal, published articles and informal documents led to events and activities such as brochures, magazines, websites, blogs about the case study. In depth ethnographic interviews were conducted in *Tortona area* and are intended to represent the common general perception and the evaluation about the zone; for this reason, interviews have been conducted with some people living in the traditional housing neighbourhoods, several creative workers based in the district, young people attending events in the area during some particular manifestations –like the Design Week, and the managing director of the first agency who founded the *Zona Tortona* brand. The third stage of the research methodology were in-depth surveys and drawing of thematic maps, intended to verify the extent of applicability of the list of

attributes collected from the literature review and to identify the underlying factors for urban and socially rehabilitation of this ex industrial periphery of Milan.

3. The story of *Zona Tortona*

The *Tortona area*, near *Porta Genova*, is a traditional neighbourhood of Milan which has become in recent years one of the most dynamic zones of the city in terms of cultural production, in particular in the fields of design, fashion and contemporary art. This area is known as the *Tortona area*, or *Zona Tortona*, following the name of one of its principal streets. This urban transformation has followed some uncommon paths, which have been partially influenced by the specific morphologies, histories, and geographical characteristics of the area, as we will explain in the following paragraphs.

3.1 Location

Located in the south–western part of Milan, the area is bound between the *Naviglio Grande* canal and the railway, and it is characterized by a huge variety of urban elements composing the landscape, belonging both to the productive and residential vocation of this area. Developing from the city-centre and involving several concentric strips, the area extends from the very central presence of *Naviglio* and *Darsena* canals, bordering with some more peripheral adjacent municipalities, producing different patterns of urban composition, both in terms of social and urban features.

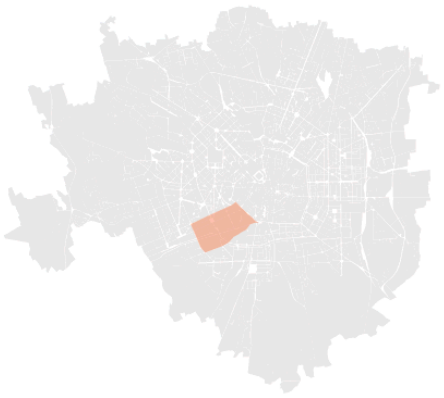

Figure 1: Location of Tortona Area in Milan

Tortona area was part of an old territory, the *Corpi Santi*, added to Milan in 1873, de facto a different municipality, mainly composed by some agricultural sites. This has been one of the main reasons why it has not been involved by the planning strategies and projects adopted by the Municipality of Milan during the last century.
This kind of unplanned character has led, through the years, to the coexistence within the same spaces of several heterogeneous functions, to a mixture of old and new

architectural typologies as well as to some different socio-cultural paths.

Thus differentiation from the city as a whole and non-homogeneity are two of the key features of this part of Milan, even in the perspective of becoming an interesting place of research, experimentation and production: the area preserves this kind of traditional and popular image and sense of belonging which is so deeply consolidated in the collective perception and at the same time, as place ever changing, it is spread to the introduction of new urban qualities, able to create a laboratory of contemporary city images.
Indeed the area seems somehow to go along with the contemporary trends in terms of urban regeneration, combining features of the past with patterns of the present and leading to an inclusive urban community where urban settlements are "*indicative of the way in which rooted cultures have evolved appropriate lifestyles in their physical environment"* (Guy, Farmer, 2001, pp.144).

3.2 Origins and urbanization process

After the annexation of the *Corpi Santi* to the Municipality of Milan, the localization of the *Porta Genova* Railway Station in 1865 and the construction of part of the railway, the urbanization process started within this urban portion of Milan. This was the chance for many industries of the metallurgical, mechanic and chemical sector to locate their plants there, in order to exploit the advantages coming from the presence both of the railway and of the *Naviglio* canal.
In shaping one of the most important productive sectors of Milan was, together with the location of vast industrial sites, a quite flourishing network of small and medium enterprises, handcrafts laboratories, workshops, garages, railway tracks, traditional architectural typologies as the *case di ringhiera*, eating houses and social housing neighbourhoods, located in-between mixed up spaces of working and living.
This functional mixitè of land uses laid the foundations for the urban morphology of a quite huge territory, included within the streets *Tortona, Solari, Savona*, up to *San Cristoforo* and *Giambellino*, designing a solid and heterogeneous urban continuum.
In a few years the agricultural vocation of this area had been converted into an industrial-productive one, changing the area's social composition and becoming one of the traditional working class neighbourhoods of the city.
At the same time this territory developed precisely as an enclave system due to the presence of two rigid layouts, the *Naviglio* canal and the railway, which, even being the key starting point of the industries settlements, have contained the urban sprawl towards the neighbouring areas, contributing to eventually shape a marginal, abandoned and pending environment.

The high concentration of industrial sites continued to evolve until the '60's, involving several famous companies, such as *CGE, Ansaldo, Nestlé, Riva Calzoni, Richard Ginori*, etc. At that point, because of the deep transformations affecting the whole productive system, most factories were dismantled to be moved farther from the expanding city center or have been closed due to the cessation of the production, leaving grand empty spaces behind.

Thus, in a 30 year period, all the industrial sites have been abandoned leading to a situation of urban blight and socio-economic depression, typical of the most post-industrial peripheries of Milan.
Before the starting of settlement of cultural and creative activities, these vacant disused spaces have been pending for quite a long time, without any kind of economic or social actor being interested in giving a new future to them – they seemed not to present any profitable patterns of transformation.

3.3 The process

The transformation of *Tortona area* is a story of a bottom-up preservation case, together with the promotion of a new vocation, started with some specific features that definitively could have not foreseen the result. It's a story of revitalization and re-industrialization in which the main infrastructures is cultural capital.
Tortona area regeneration is not a story regarding only the physical and functional transformation process and regeneration of historic spaces within an old productive neighbourhood; instead, it involves several and variegate aspects, such as local cultural and creative renaissance, new architectural typologies, and innovative strategies of territorial marketing.
Indeed one of the aspects that can be identified in retrospect is the necessity to apply different tools, both material and immaterial, in order to draw a new profile for this area creating a real new urban proposal. We argue that this process of urban regeneration has mainly involved two different patterns of transformation, recognizable because of the different intertwined competences: built environment renovation and territorial identity creation.
These two features mutually influenced each other, both in chronological and concrete terms. This interdisciplinary approach is considered here as a surplus value, as an ingredient that has been basic in the perspective of promoting this urban transformation along the time.

3.3.1 Built environment renovation by self organization[3]

As mentioned before, the two decades of urban blight with industrial settlements pending in hold for new potential uses let the economical values of the industrial properties went down, leading to a relative low price and to an immediate availability to be restored.
This new spatial and economic configuration transformed the neighbourhood in a fragmented territorial portion, without any precise vocations.
In that period the area was not involved in any kind of redevelopment process, both because of the lack of interest - at public administration's eyes it seemed that bigger and better shaped areas were more appetizing in terms of urban development for the whole city - and lack of adequate, less rigid tools to face such a neglected situation.
Nevertheless these ex-industrial sites were hiding a huge potential for the whole urban context, because of the proximity to the city centre and the particular

[3] For a chronological map of physical transformations, please see figure 5a and 5b, pp. 16-17

morphology of such kind of territory, made of a mixité of functions and spaces.

We will have to wait until the ’80s to face a new regeneration phase when, without introducing a large-scale redevelopment project - usually imposed from above and accompanying a relocation of the original inhabitants - the rebirth of *Tortona area* started, with what we’ll call the pivotal pioneer intervention, that afterwards led to an incremental series of interventions gradually transforming old buildings one after another. Thus the entire regeneration of *Tortona area* was achieved by a self-organizational process, launched by the aggregation of individual buildings renovations.

In 1983 the photographer and entrepreneur Fabio Lucchini, together with some other prestigious cultural professionals such Gisella Borioli and Fabrizio Ferri bought part of ex *CGE* company in *Tortona* area to settle their *Superstudio*. *Superstudio* is a poly-functional and versatile multi-location, a huge space (10,000sqm) created to meet the needs of operators and creative people working in the overlapping fields of fashion, art, design, communication, culture and entertainment.
The studio consists in wide and flexible spaces, which can be divided or combined, suitable for great events, exhibitions, conventions, fairs, fashion shows, performances. The variously-sized spaces are also suitable as studios for furniture, car, advertisement photo-shooting, for cinema/television sets.
Supertstudio soon became great attraction pole for international members of the creative class, such as photographers, journalists, artists, both in terms of temporary and stable permanence in the area, enhancing its fame within the district itself and also the whole city. Just two years later, in 1985, a second intervention took place with the settling the laboratory of the photographer *Carlo Orsi* inside an old complex of machine shops. What is important to point out here is that this is the case of already well established creative companies and big names in the cultural production field, who moved here and consequently attracted lots of smaller artists and creative producers.

In that time that ticking situation has been unlocked with the pioneer intervention initiative, it seemed that the risk of investment on such kind of properties has increasingly reduced because of the adequate location of cultural and creative functions in this urban territory. In this sense this first interventions triggered a gradual incremental process of revitalization of the area, encouraging other professionals, within the creative industry, to buy and renovate portions or entire industrial buildings and start their activities there.
This kind of perception was going to strengthen within all the private actors of the transformation along the years, leading to an inverse ratio for which the more high is the quantity of the settlements of creative and cultural activities inside disused productive properties, the less huge is the risk to invest in a regeneration process of such kind, exploiting the advantages deriving both from being inserted in a similar functions network and from the proximity and face to face relations.
Photographic sets, design and architectural studios, offices, universities, research centre, communication and marketing laboratories, are just some of the main cultural

and creative activities settled within *Tortona area*.

In 1999 the Municipality launched a bid for what was defined as the main intervention of cultural requalification in Milan in the last 50 years: the project of the "City of Cultures", for the realization of Center for Extra European Cultures, the Archeological Museum of Milan and the CASVA - Visual Arts High Studies Center. The competition was won by *David Chipperfield Architects*, but the work started just two years ago because of lack of funding. However, this shows the acknowledgement of the new identity of the area as the new cultural district of the city, even if so far this is the only intervention promoted by a public actor for the Tortona area.
Because of the increasing of activities and the consolidation of such kind of territorial connotation, at the beginning of the 2000's *Superstudio* decided to enlarge its spaces, establishing a new multipurpose laboratory, *Superstudio Più*, in the ex productive properties of the *CGE*, devoted to conventions, exhibitions, festivals and all kind of temporary events related to culture and creativity.
Going forward with the process, at different times and from different private entrepreneurs, several international "archistars" - such as David Chipperfield, Mario Cucinella, Tadao Ando, Antonio Citterio, Matteo Thun - were called for the renovation projects of big abandoned manufacture buildings and even several important fashion firms – Armani, Ermengildo Zegna, Hugo Boss, Kenzo – settled their headquarters occupying parts of these vacant properties.

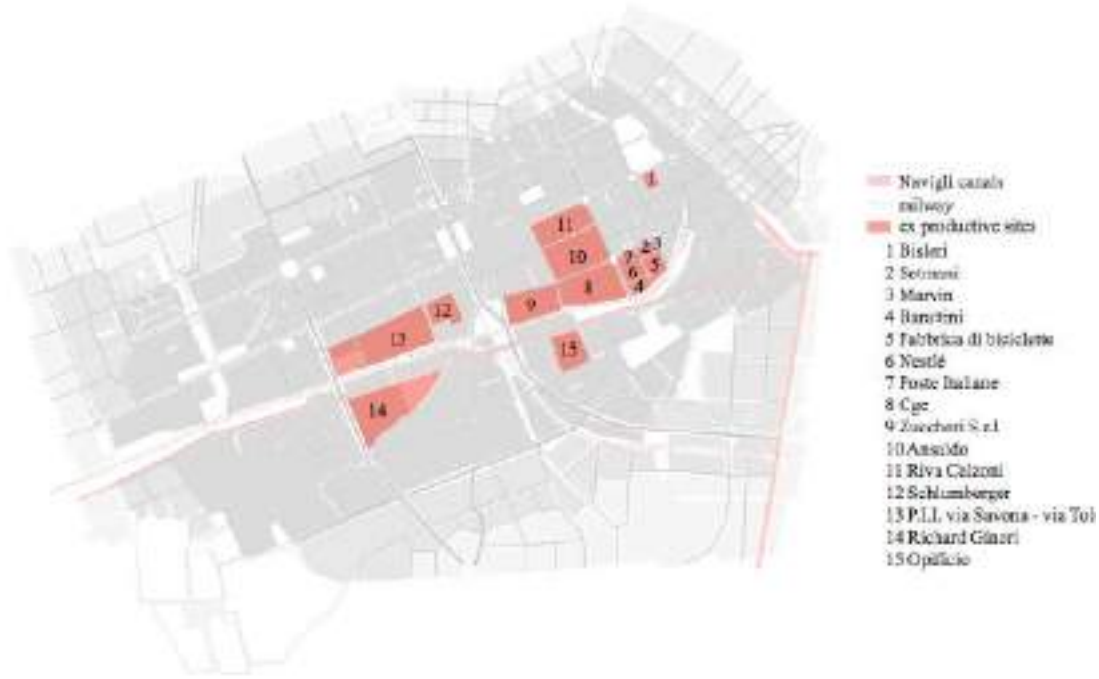

Figure 2: Map of the ex-productive sites

Running parallel with the physical transformation featured by diffused reuse of ex

industrial sites converted in new cultural functions, is a capillary soft movement to obtain new residences and services for the new established creative class.
Indeed as soon as the creative atmosphere infiltrated into the areas, some professionals moved there within new residential complexes and some others renovating old houses by themselves. These expansions added new values to the existing residential buildings and transformed the status of the devastated industrial communities, maintaining the traditional functional mixité and the restricting original neighbourhood community structure.

Figure 3: Map of actual creative and cultural activities

Under no circumstances the results and the reshaped identity were planned from the beginning by Milan Municipality, but were generated spontaneously by enterprises of private stakeholders to meet their own needs.
Indeed, what seems to play a crucial role in this reindustrialization case is also the typology of actors involved in the process. Both the pioneer intervention and many of the projects that came later one after the other, hade been promoted by actors of world renown, which are far from minor members of cultural industry. At least at the beginning their purposes was not dealing with the redevelopment of such kind of territory as a whole or with the possibility of taking advantages from being part of a cultural - creative network, but uniquely with the chances offered by this large scale ex productive spaces, perfectly easy-fitting and adaptable to their already wealthy activities. What emerged, thus, is not alike to other apparently seemingly examples of creative districts such as the Brooklyn's, East London's and Berlin's type examples of cultural industry SMEs moving into an area and transforming it.
Tortona story could be defined as a case of re-tasking abandoned large scale

industrial complex through new kind of production, i.e. cultural and creative industries, which had fundamental effects on the territory as a whole, both from architectural and immaterial dimensions.

Zona Tortona could be defined as an *informal* district (Chapple, Jackson and Martin, 2010) that maintains at the same time the well strengthened collective image of working class industrial periphery peculiar of the last century and the reshaped identity obtained through settlement of cultural and creative activities.

3.3.2 Territorial identity creation: *Zona Tortona* brand

The transformation process of the area has been deeply and inextricably sustained by the creation of a new image for this territory. The development and the relaunching of the area needs to be understood in connection to a more immaterial dimension made of identity promotion and communication strategies.
Zona Tortona is nowadays known as *FuoriSalone* area, the biggest satellite event zone of the annual international Furniture Fair (branded Milan Design Week) that now takes place at the fairground in Rho, just outside Milan. During Design Week and other great events like *Milan Art Week* and *Milan Fashion Week*, the entire Tortona street and its adjacent streets are filled with endless initiatives. Every industrial space, small or big, are temporarily occupied by showrooms, galleries, and fashion and design exhibitions.
One could unquestionably say that *FuoriSalone*, settling in *Zona Tortona*, was the spark that has triggered the promotion strategies and the branding process that constituted the inseparable binomial between *Zona Tortona* and *FuoriSalone*.
FuoriSalone event was launched and gradually expanded starting from the 80s as an alternative location for emerging designers to showcase their work contextually with the International Furniture Fair. The set of cultural and creative activities occurring at the same time but located outside the official International Furniture Fair was institutionalized in the early 90s, with the name of *FuoriSalone,* thanks to the initiative of *Interni* Magazine that published a volume entitled *Guide to FuoriSalone (in 1992)*. *Interni* started to handle the management and coordination of all the events and activities referred to *Fuori Salone*, with a great impact for the territorial promotion and international visibility of the area.

The typology of actor plays a crucial role even within the immaterial path of the redevelopment of the area. Both the Fair and the *Interni* Magazine are belonging to the private sector, and both of them are famous at the global scale. So that the initiative *FuoriSalone* developed and leaned on such powerful grassroots, and, thanks to those actors, it has been able to take on with a good probability of success, going beyond the traditional use of spaces for official fairs.
They had the capability to foresee potentialities, somehow hidden behind the merely entrepreneurial purposes of actors re-tasking abandoned large scale industrial complexes, making official that kind of cultural capital that was already in the air, coordinating events, giving new temporary images to locations, proposing new uses of spaces, and overall, involving people fully for one week per year.

That's how the strong liaison between *Tortona area* and the *FuoriSalone* has been created.

Along with the consolidation path of the event and the progressive renovation of spaces in *Tortona* area, more actors contributed to the development of the area.
Crucial for the formalization of the image of *Tortona* area has been a society for communication and event organization called *Recapito Milanese*. In 2002, *Recapito Milanese* promoted the creation of the brand *´Zona Tortona´* that institutionalized the emerging role and the creative vocation of this portion of Milan. The function of the brand was basically the one of gluing together all those initiatives that were already and independently well established, including them in an acknowledged symbol as part of the same entity. The red round logotype (figure 4) become unmistakable and was used in producing flags, pocket maps, guidebooks and road markings for the *Fuori Salone* week events. In 2005, the most important Milanese industrial realities in fashion, design, arts and cultural fields founded the association *Zona Tortona*, to further corroborate the district as a place of excellence for Milan at a national and international level.
Among the most relevant stakeholders, which created partnerships with *Zona Tortona*, we find: *Studio Labo* – which coordinates the relations between events and location through the portal *fuorisalone.it*, and *Esterni* Magazine – with sets up performances and stands all around the town. All these subjects collaborate and cooperate in a perspective of city marketing, which aims to launch the events in the area and the image of Milan as capital of Fashion and Design.
2011 marks another important step in the transformation of the image of *Zona Tortona*. At the beginning of the year *Design Partners srl* –the company that founded the brand of *Zona Tortona*, bankrupted following legal issues. A new name and a new logotype under the name of *Tortona Design Week* were created for the event by the *Tortona Area Lab* association, a no-profit organization set up in 2010 by the big names pioneer of the regeneration of the area, such as *Superstudio Group*, *Estate 4*, *Magna Pars* and *Tortona Locations*. *Tortona Area Lab* association works as a collector and selector of offers, a facilitator of creative processes and organiser of services for exhibitors and visitors.
The aim is to network the different talents of the area to enhance it in a wide perspective. Namely, the latest edition of *Fuori Salone* have pointed at attracting international creativity professionals and reaffirming the image of Tortona and Milano on the global panorama of quality creative economy. This is clear also from the new names of the brand and the association –*Tortona Design Week* and *Tortona Area Lab*, both formuated in english from the beginning.
The new logotype of *Tortona Design Week* was created by the internationally famous designer Stefano Giovannoni, it abandons the traditional red circle and assumes a squared shape with the representation of a black on white old shed-roof factory, typical of the Milanese industrial periphery.

Figure 4: Evolution of the logotype (2002, 2009, 2011)

As years go by, *FuoriSalone* has exponentially grown both for number of visitors and organized events: from 77 registered events and 25,000 visitors in 2003, to 772 events and 196,000 visitors in 2011[4].
Numbers are not the only thing that has deeply evolved during the last 20 years. We have seen how *FuoriSalone* was born as a complementary event of the official institutional *Design Week* in the Rho fairground. It used to be a not codified, spontaneous practice that aimed to promote young and unedited talents, together with the desire to animate not conventional spaces of the city through creativity. With the passing of the years, we saw how the event has been transformed in one of the most well organized and sponsored happenings of Milan, accompanying a meaningful physical transformation of the area. The lively chronicle of the creation of names, brands, associations and initiatives that have taken place in this area has represented a climax towards excellence and attraction of international creative insiders.
We argue that the strength of this event does not consist only in its innovative and creative contents; what makes *FuoriSalone* work is its authentic bond with the territory, in different ways. Firstly, on the pretext of *FuoriSalone,* parts of the Milan that are usually closed open the door to visitors, becoming public spaces for a week; showrooms and design studios are open until late, parties and social events are organized in spaces and modalities that have different functions during the rest of the year. In this sense, *FuoriSalone* proposes a different urbanity for Milan, even only for one week. Secondly, the territorial promotion strategies are not something that has been planned top-down by local governments or agencies; the self-organizational nature of all the initiative starts from talents and energies that are embedded in the territory, that unite their creativity from below. This aspect is quite different from other examples of territorial marketing strategies and creativity policies traceable in other European cities. The self-promotion through the brand "*Zona Tortona*" could be seen as a ´*a posteriori* vision´, it is a label to define a process that had started and developed organically.

3.4 Urban effects of an ongoing process

In the past century, Tortona area has rapidly changed its face, passing from suburban area, partly outside the city walls, to working class neighborhood, to postindustrial periphery and finally tertiary district with a strong connotation given by cultural and

[4] Data from the official website of *Fuori salone*, http://fuorisalone.it, accessed 21 april 2012.

creative industrial settlement.
All the phases of the transformation process were carried by micro scale changes deriving from socio-economic dynamics, without any overall coordinating planning actions.
Especially in the last two decades, as we saw, spontaneous economic dynamics were the occasion to renovate and revitalize parts of the city. The growth of the knowledge based economy went along with the progressive renovation of the city´s built form and the revitalization of entire neighborhoods.
Despite their relevant outcomes, the processes featured high levels of *informality*. To explain the meaning of formal/informal districts we refer to Chapple, Jackson and Martin (2010, p.226): "The term 'formal´ usually invokes a degree of intentionality, often involving a civic plan for redefining the identity of a neighborhood. The term 'informal´ invokes a degree of organicism and spontaneity; it usually refers to [arts] districts that have evolved through practices of local actors who have not been organized by a civic plan".

For what concerns *Tortona*, it is clear that we are talking about grassroots practices – at least at the beginning - which are connected by functional and localization economies´ patterns, but not by a planned general view.
The driving forces behind the regeneration of this neighborhood could be roughly described as the interests of professionals and companies who find convenient to establish their activities in the area. The factors concurring in making the area attractive for new professionals are of different natures: flexible and relatively low cost locations, but also geographical agglomeration advantages.
The spiral of image creation and physical renovation is an ongoing process that fosters its impacts every year.
Furthermore, we are talking about a culture-led transformation that is not traceable only in the physical buildings and open spaces, but lies greatly in the new ´creative' life styles and atmosphere, which belong to a more immaterial process of transformation.
Nevertheless, the presence of working class population is still strong, so that the social composition is still very mixed.
The result, then, is a vital and dynamic district, in continuous transformation and with a big potential due to the presence of still vacant real estate properties, together with a variegated social composition and a lively cultural atmosphere.

4 Conclusions and research agenda

As we saw along the analysis, there are several factors that make of this story quite a rare and unique case: the socio-economic and urban features of this traditional urban pheriphery of Milan as first support to the process trigger; the importance of world class and world city level cultural firms/corporations as factors increasing the success of the redevelopment; the two intertwined dimensions of physical renovation and identity creation as key factors of the transformation.
Since the spontaneous nature and the extremely dynamic and fast mutability of the transformation in *Tortona area* - exemplified also by the evolution of its image and brand, we argue it is interesting and important to keep on monitoring and researching

about this area and its vicissitudes.
Accordingly, after this first mainly descriptive framework, next steps in the future research should go more in depth into the following issues:

- the development of the private-led urban regeneration strategies and image creation in relation to the public governance vision
- the patterns of gentrification or soft-gentrification
- the positions and reactions of the historical population of the area
- the future of this part of Milan, in relation to the availability of further and still numerous formerly-productive sites
- Zona Tortona as a pivotal practice in relation to the new emerging cultural district promoted during the FuoriSalone (*Brera Design District, Porta Romana Design, Ventura Lambrate, Mecenate Area Design, Porta Venezia in Design*)

Notwithstanding the prevalent descriptive nature of this paper, we wish it can provide a glance of the complexity and significance of the integration of creativity in urban development, or in this case we could say: the integration of urban regeneration into the dynamic forces of creative industry.

The search for new forms of urban cultural governance seems more than ever necessary and urgent. Creative policies in Milan are not about boosting the creative image of the city. Indeed, the label of Milan as a capital of fashion and design has been present for centuries, nourished by the vivid and productive economy in these sectors. Unlike uncountable examples of city governments around the world setting up brands and improvised cultural vocations to compete in the global panorama, Milan can count on an authentic creative fervour of creative people, products, processes and places.
The challenge for the local government here is to match up these forces, dialogue with them and try to involve them in solving meaningful social, economic and environmental issues of the city and its metropolitan area. The risk, otherwise, is the one of an uncontrolled and deregulated development driven by private interests, which could irreversibly sharpen gentrification processes and social polarization.

Shrunk Hinterland and Swollen Seaboard: Regional Planning and Population Dynamic in Southern Brazil

Sergio Torres Moraes, PhD

sergiomoraes@arq.ufsc.br

Universidade Federal de Santa Catarina

Departamento de Arquitetura e Urbanismo

Campus Universitário – Trindade

Key words:

public policies, regional planning, de-growth, regional development

Abstract

The population dynamics in Brazil is strongly related to the increases in poverty, social exclusion and to a lack of a planning framework in a regional scale. In spite of its balanced net of cities, in Santa Catarina State the west high plains show a significant decrease of population in small and medium cities at the end of the last century and, at the same time, the swelling of costal cities. The State Government concerned to this issue, launched in 2003 a new decentralized administrative network, aiming to ease the development of the high plains region and avoid migration towards the seaboard. Last Census (2010) showed the plan failed. This paper's aim is to analyze the effectiveness of the regional planning actions to avoid the migratory flow from the interior to the coastal cities in State of Santa Catarina, Brazil.

Introduction

The State of Santa Catarina doesn't have metropolises, but it has the best level of income share in the country and count on with several well defined regional industrial and agro-industrial clusters (Siebert, 2008). The arrival of the neoliberals' economical policies in 1980 starts a migration flow from the interior plateau to the coast. The proximity of the ports and the improvement of the tourist infrastructure in the coastal area, besides to the lack of jobs in the hinterland, have also impelled this migratory flow (Bastos, 2011).

By 2000, this process of concentration of income and population in the seaboard was perceived as a barrier for development and for the regional

socioeconomic balance. Thereby, in 2003, the State Government establishes a new structure for an administrative decentralization whose objective was to strengthen the local policies, promoting an endogenous development. In spite of the establishment of several regional offices and programs in the last ten years, the migration process toward the seaboard continued and the population shrinkage already reaches medium cities like Lages (157 thousand inhabitants, 11st GDP of the state) (IBGE, 2011).

In spite of the fact that many scholars have been working on studies aimed to frame the problem of the population mobility, the recent data from the 2010 Census that shows the populational shrinkage in Lages, make the scientific community aware of the weight of the problem. For this reason, the study of Lages and surroundings is paradigmatic in this context to evaluate the effectiveness of the regional planning in Santa Catarina. Distant 200 kilometers from the coast, the Lages' region had its economy sustained by the wood extraction and Pinus reforestation for several decades. The monoculture, lack of positions in the industry and commerce are usually pointed as causes of the demographic decrease of 16,75% (IBGE, 2011) in the last decade that nor the administrative decentralization, nor the proposed regional planning were able to revert.

As the region is not economical stagnated we have looked for the possible causes of the failure of the government actions related to the regional endogenous development proposals.

Analysis

Economy and Migration

The increases in poverty and social exclusion that have resulted from urbanization in Brazil - and, more broadly, in Latin America - are key points to understand the population mobility that has led to the shrinkage of small towns and even some medium cities in Brazil. Actually, the concept of "urban shrinkage" in Brazil is complex and has to be linked to other issues as housing and jobs shortage and real estate market expansion rather than only urban environment decay.

In the second half of the twentieth century, a very intensive urbanization occurred, mainly due to a change in Brazilian economic base from agriculture to industry (as happened in several LA countries). Huge urban growth due the national economic policies (Import Substitution Industrialization-ISI) in the 1970's, further enlarged the industrial parks in the big southeastern cities (as São Paulo and Rio de Janeiro) and attracted additional millions of people from rural areas (by 1980, almost 43 million rural people had moved to cities) (Santos, 1996). As a consequence, at the middle of the century the city's periphery swelled and concentrated a huge number of poor people, previously spread in rural areas (Brito 2005; Maricato 2001).

The process of the liberalization of the Brazilian economy in the 1980's and the adoption of Foreign direct investment (FDI) economic policies certainly impacted some regions in the country with less-skilled population in a process that some authors have named "reverse polarization" (Rodrigues-Pose and Tomaney, 1999). In Brazil, FDI favored a relative dispersion of economic activity from the

metropolises outward into the hinterland and a migratory flow of capital and jobs toward south eastern states.

Notwithstanding, in Santa Catarina State such process did not occur with the same magnitude due its particular process of colonization that kept a balanced spatial distribution of the population. The successful pattern of development of the State is credited to the diversification of productive activities that embrace several successful local productive arrangements. Also, a significant agreement between social actors, good educational opportunities has pioneering in Brazil the creation of business incubators and technologic parks (Turnes, 2008).

Santa Catarina State

The landscape of Santa Catarina State, in southern Brazil, is characterized by two different regions: the coastal plain zone at East and high plains at West, separated by the mountain range called "Serra do Mar". This configuration helped to set up the development patterns for social and economic occupation of the territory. At West, huge proprieties for cattle rising and cook pines (Araucariaceae) extraction, later replaced by pinus wood (pinus elliottii) cultivation, boosted the development of cities like Lages (156,000 inhabitants in 2012) and Caçador (71,000 inhabitants in 2012).

At the Atlantic coastal zone (including major rivers basins and valleys) skilled European immigration at the beginning of 20th century favored industrialization and the ports helped the development of commerce. Somehow the coastal zone was also privileged with a mode of occupation conditioned by its fragmented physical and natural factors, allowing a balanced urban network, characterized by a rural small lots structure and by an absence of a strong regional pole. (Siebert, 2001). By 1950, the development of the road system in the state increased the connection between West and East, including in the State economic flows areas that previously were excluded, and also facilitated the population flows.

In spite of the increase of inter-municipal flows, the lack of roads infrastructure and the geo-economics fragmentation kept the Santa Catarina coastal cities isolated from the more dynamics centers of the country until the middle of the century. Between 1960 and 1970, the creation of a Federal University in the State Capital, Florianópolis and the roads improvements along the coast, changed the economic State trends, pushing cities development by the reinforcement of the tertiary economic sector (Pereira, 2003).

With the new road infrastructure, the tourist flow to the seaboard that have started slowly at the beginning of the 20th century increased, causing strong changes in cities morphology and impacting in the cultural and behavior local patterns. The development of the "tourism economy" is followed by decay on the small scale agriculture and by an expressive migration toward the seaboard, where the hope for a regular job was likely better. A significant parcel of the migrants was absorbed by the civil construction industry in cities that have been showing an accelerate growth since 1970. On the Santa Catarina´s seaboard, in spite of its socioeconomic

heterogeneity and good social index, a lack of basic infrastructure and urban planning characterize most of the cities (Pereira, 2003).

The cities development allowed by the tourism sector has act as a magnet for jobs. In the 1990 decade, many cities in the seaboard duplicated their population and reduced the poverty slower than the State medium. Data from IBGE (Brazilian Institute of Geography and Statistics) points out that among the ten faster growing cities in Santa Catarina between 1991 and 2000, eight are on the coast and also are on the coast the four where were observed the faster expansion (IBGE, 2004).

Notwithstanding, other factor have contributed to the faster development of the coastal areas in the State. The set up of industrial poles[1] closed to the coast also was crucial to the development of the Atlantic border (Seabra, 2011). In a deeper study Seabra (2011) found out that the distance to the coast is inversely proportional to the demographic expansion and the growth of the per capita income.

At the same time, the State hinterland at West show a significantly de-growth, mainly in cities where the economic base is the small agriculture business. Several crises in farming and cattle sector help to create a background favorable to pushing the population to the Atlantic coast cities (Turnes, 2008).

Administrative Structure

The power centralization is a major factor in the socio-political formation in Brazil. This administrative model, inherited from Portugal was reinforced by the military regime (1964-84), with serious consequences for the relationship between local, state and federal governments (Kraus, 1991). However, in the 50's, new territorial policies make municipalities and regions feel the need to combine efforts to meet their needs of planning and development.

In this context, by 1960 a municipal association process began in the State of Santa Catarina. With the State Constitution of 1989, the Santa Catarina Municipal Associations find their legal basis, consolidating the cooperation process started decades before. Today, all municipalities in the state are associated in 21 municipal associations, which have their activities coordinated by Fecam (Federation of Associations of Municipalities of Santa Catarina), based in the capital Florianópolis.

Conceptually, the Associations of Municipalities are organizations that aim to promote regional development through the intermunicipal planning and cooperation. In Santa Catarina, these associations are composed of micro-regions structured and bounded according to common political interests. The key aims of these associations are to join the municipalities associated in a permanent forum for discussions about common issues and provide specialized technical services (Moraes, 2005).

Besides the associations of municipalities it is observed in the 90´s a struggle to increase the participation of different actors in development processes. Several

[1] It refers to the textile complex in the Itajaí Valley, the metal-mechanic pole in Joinville and the coal industry in the Southeast.

initiatives in order to create links between civil society and local government were launched. Among these initiatives, we can highlight the formation of networks for development, as the Regional Development Boards, Hydrographic Basin Board and the Departments of Regional Development (SDRs) (Filippim and Rossetto, 2008).

In 2004, the new State Governator Luiz Henrique da Silveira (2003-2006) included in his government plan guidelines to promote an administrative decentralization in order to rebalance the State cities ´net and reinforce the local policies. In this context was created the Project My Place (Meu Lugar) that among its main aims are: formulation of 30 regional development plans focused in the social participation and identity reinforcement; formulation of programs for human resources capacitation in order to promote development and an implantation of a monitoring system to follow the regional and State development (Santos et alli, 2008).

To achieve its aims, the State Government strategy was the creation of 30 Department for Regional Developmente (SDR) establishing a new administrative structure for Santa Catarina State. The SDRs were created with the goal of representing the State Government within each respective region, coordinating government actions, promoting decentralization and regional integration of public administration, and coordination of development activities in their territory (Filippim and Rossetto, 2008).

Thus, at least three forms of joint development by are present in Santa Catarina nowadays: the Associations of Municipalities, boards/agencies and SDRs. They coexist and sometimes conflicted as they have very similar goals and act in the same territory. However, rather than integrated they are juxtaposed.

Lages Region - Amures

The study of the city of Lages and surroundings is important to the understanding of whether and how much the political and administrative structure is able to develop the region. Lages is the headquarter of a region with 18 municipalities, pooled in an association named Amures (Associação dos Municípios da Região Serrana) (Figures 01 and 02).

Figure 01: Santa Catarina State in Brazil and AMURES region in Santa Catarina State.
Source: Instituto Euvaldo Lodi de Santa Catarina.

Figure 02: The AMURES Region and Lages City.
Source: Instituto Euvaldo Lodi de Santa Catarina

Most Amures municipalities have extensive agricultural base characterized by large estates. From the 18 municipalities, 11 are among the 21 with lower Human Development Index (HDI) of Santa Catarina and have low investment in the productive sector and a large population concentration in urban areas. In relation to economic, political, social, educational and health differs from other regions of the State by high rates of illiteracy, unemployment, housing shortage and rural exodus. The Amures region is considered the poorest and most backward in Santa Catarina (Peixer in Filippim and Rossetto, 2008).

Lages emerges in the seventeenth century as a strategic point in the hinterland of Santa Catarina, right in the colonial arterial route for trade cattle and horses with the rest of the country. Livestock takes the lead role in the first economic cycle of the city and defines the structure of landholding in the region. Since 1850, the presence of skilled European immigrants facilitates industrialization and trade of Araucaria (araucaria angustifolia) timber, abundant in the region. Soon timber replaced livestock, giving the region a new rural and urban setting, with swelling of the headquarter city by migrants from rural areas seeking employment in the timber industry (Bastos, 2011).

From the first decades of the twentieth century, the exploitation of Araucaria allows the structuration of the entire urban complex and the economic and political structure. During this period, the region got a huge population growth, receiving a number of migrants from all social classes in search of personal opportunities.

In the Lages region, the timber industry was and remains until today basically the major source of income and investments. A shy diversification made for the pulp and paper industry has occurred in the years 1950 and 1960 did not change the economic perspectives. With the depletion of Araucaria timber, all Amures, region has entered a long period of economic regression just in years when the State economy grew more. Only in the 1990' s, with the trade of reflorested Pinus (Figure 03), the timber industry was again heated (Goularti Filho, 2007).

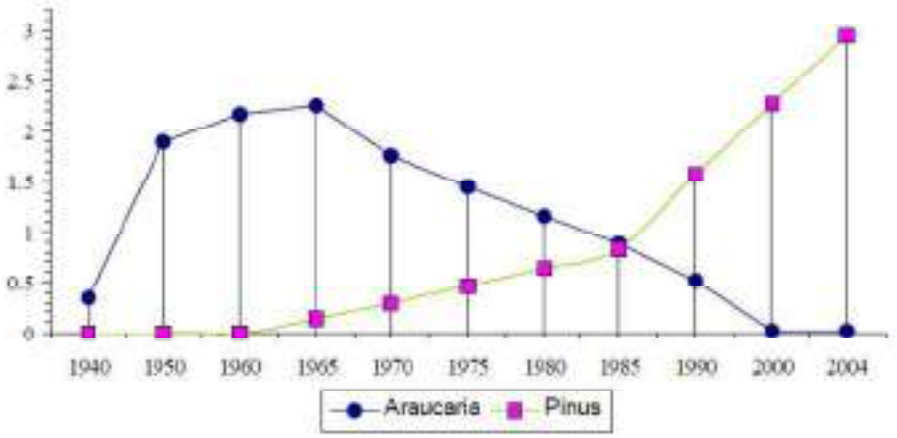

Figure 03 - *Pinnus elliottii* versus *araucaria angustifolia* production (millions of m^3)

Source: Sindicato das Indústrias de Serrarias, Carpintarias e Tanoarias de Lages (Sindimadeira), 2005, *apud* Hildebrando, 2009.

It is important to highlight that at the peak of the so-called Timber economic cycle circa 1950-60 - the region, and especially the city of Lages, became economically and politically strong enough to hold the title of chief state's economy (Goularti apud Hildebrand, 2009). Although the araucária depletion was blamed to the economic crisis, still in the early 1980s Lages had a prominent position in the state, occupying the third position among Santa Catarina counties, revealing that the social crisis and demographic decrease should be due to the process of income concentration and social inequality of Brazilian capitalism or due the administration inability to set up “Local Productive Arrangements”.

The nearby city Caçador (180 km north bound) should be taken as a counter example. It has a similar economic history related to the timber and was able to overcome the economic decay by economic diversification and investments setting up several other Local Productive Arrangements within the industrial timber sector, in agro industrial fruit complex and plastic material industry (Goularti Filho, 2007).

Final Discussion

In the contemporary world, the presence of multiple and complex economic activities generate the need for a set of political practices within a context of polarization and alliances between adjacent territorial units, which seek to aggregate and forming a unit - the region - which seeks to strengthen this union politically (Freestone, 2000).

This union, however, is not enough to unleash a process of "regionalization". So, the processes of "regionalization" we see today in Santa Catarina State appear from an attempt for leverage the political processes, many times without an understanding of how the different layers of different systems act - physical,

environmental, economic, social, cultural etc. ., as well how these systems are interconnected, what their interfaces and how these vital elements and especially how the community can manage the local systems.

In Brazil, as a rule, committees, associations or government institutes which intend to invest in regional planning, end up guided by political, technical and reflect a little off that real economic development and quality of life and environmental the territory. To reverse this common sense it is necessary to understand the key components in the constitution of a territory and think on the possible policies, planning and management within a given context. If on one hand the Brazilian public policies advanced significantly in recent years in relation to citizen`s participation in the process of social construction of urban territory, on the other hand has not yet materialized, in most of the country, effective plans for regional planning. (Moraes, 2005)

Despite the administrative dynamic of Santa Catarina State that intends to create a coherent structure to the regional development, the Municipalities Associations are still the most recognized agency when discussing regional policies in Santa Catarina. In spite of this, many authors (Kraus, 1991; Filippim and Rossetto, 2008) agree that the Municipal Associations do not perform adequately the role predicted in its statutes as planning, community discussions forums and services offer.

As a "discussion forum", the Municipal Associations work more as a space for exchange of information and experiences among the Mayors than as a mediator between the Administration and other social actors (Kraus, 1991). Also the financial applications despise the chances that could be offered by the Associations and the use of traditional channels through direct relationships with congressmen and senators always occur, characterizing what Kraus calls "favors'policy" which ends be replayed in the relationship between community and municipal power, obscuring the possibilities of increasing power to the organizing society (Moraes, 2005).

Kraus (1991) also shows that there are several obstacles to implement a structure for "micro-regional planning". Besides the lack of interest of the each associations (involved in different social actors as trade associations, unions, environmentalists, etc..), there are trends to act in the associated municipalities only as a service provider, bridging the gap of municipal technical frameworks.

Also the creation of the SDRs by the State Government is much criticized. As mentioned above, the SDRs are not integrated, but juxtapose to the other agencies. The passage of a proposed regional organization for development co-ordinated by civil society (forums / agencies) to another, coordinated by the government sphere (SDR) ends up to disorganize the local representations that refers its organization in different political edges. In fact, the SDRs disrupt the autonomy of the local organizations and have a strong negative effect on the local interactions and their claims (Filippim and Rossetto, 2008; Santos et alli, 2008).

The challenge for Lages' region is to set up integrate public policies and territorial actions that show more attention to the structural potentialities of the area and to promote an economic diversification and "Local Productive Arrangements" in

order to overcome the lack of pragmatic character, pointed (Goularti Filho, 2007) as a possible causes of the continued flow of people toward the seaboard. Turnes (2008) also give us a clue highlighting the need for a new model of development for rural regions, based on familiar agriculture, cooperatives, and strategies for generation of employment to young people.

The idea that a "Santa Catarina model of development", based on endogenous development and on a balanced network of cities with a homogeneous population distribution could promote a better quality of life, lasted for a long time. Notwithstanding, today this idea has been demystified (Santos et alli, 2008). The uneven growth of the coastal cities of Santa Catarina in relation to those of the interior and the impossibility of an integrated management due to the mismatch of the different regional administrations have been blocking opportunities for regions as Amures in the hinterland high plains of the State.

What can be seen through an analysis of the Amures region context is that even with the reduction in population and economic participation in the context of Santa Catarina, the region still has a potential industrial-economic dynamism. The use of this potential cannot be supported by Government administrative structure, but should be the result of a joint action between the public sector (municipal authorities and representative bodies of local government), the private sector and the organized society in developing programs and measures to attract new investments.

THE CHANGING ROLE OF URBAN HERITAGE AS DEFINED BY STAKEHOLDER ATTITUDES

Dr. Ege YILDIRIM
Heritage Planner, Abu Dhabi Tourism & Culture Authority

Abstract

This paper attempts to demonstrate the relationship between the changing role of urban cultural heritage and the attitudes held toward heritage by relevant stakeholders. The proposed framework is explored particularly through cities in Turkey, which the author has studied as part of her doctoral dissertation on 'Urban Conservation Projects and Governance', and cities in Abu Dhabi emirate, of the United Arab Emirates, where she has been working in the local heritage authority for several years. A comparative analysis is made to capture any enduring patterns shared across the different countries, and any specific situations particular to each. In an increasingly globalizing world and professional network, such comparisons can help to identify the scope of possible cross-pollination between the various cultural contexts of planning practice.

The conducted research and practical experience mentioned above suggest that the role which the urban heritage can assume within the planning, development and public life of cities is closely contingent on the attitudes held toward heritage by stakeholders involved in the preservation process, as well as the roles that these stakeholders play in the process. The degree to which the urban cultural heritage can effectively play a 'productive' role in the life of the city, or to which the preservation of its authenticity can be sustained in the face of development pressures and contemporary societal needs, are determined by the outcome of confrontations and negotiations among various stakeholders, each with their own particular interests and capacities. Some salient examples of factors affecting these negotiations are the maturity of public institutions and legislation, the awareness of and priority attributed by local governments to cultural heritage in their policies, the economic tools available to property owners and users to realize the economic potential of heritage assets, the lobbying capabilities of specialized civil society and community groups, and the level of involvement of experts and academics in actual urban conservation projects and processes.

Introduction

The **concept of 'heritage conservation'** has been constantly evolving since the birth of this modern notion in the 19th century. Around the middle of the 20th century, heritage began to be understood in an urbanistic sense and to feature in planning discourse, transcending the curatorial framework of single monuments and museums. This still remains an important and relevant conceptual milestone, as its implications

continue to be addressed today. The conflicts between the 'philosophical' aspects of urban heritage, related to the importance of heritage as a source of cultural identity, and the 'practical aspects', related to the realities of real estate economics, have as yet not been fully resolved. International principles and professional standards of heritage conservation have spread around the world, but their interpretation in each **cultural context** and the levels of practice that are attained still differ from country to country. This is both a challenge in terms of safeguarding the values that heritage presents, and an opportunity in terms of the multiple alternatives for preservation approaches offered by the diversity of the world's cultures. The understanding of how approaches can be customized also averts the dangers of importing foreign models to places far from their original source without regard for particular needs of local contexts.

Many of the underlying dynamics determining the level of understanding of, and thus the role attributed to heritage in the life of today's cities, are cultural, which implies they are contingent on the **value systems**, attitudes and behaviors of the **stakeholders** taking part in the urban discourse. This idea has been explored here within two cultural contexts, those of Turkey and the United Arab Emirates, where the author had a chance to observe these dynamics in action. In **Turkey**, these observations are based on the author's previous professional experience since 1998 and particularly on her doctoral dissertation on 'Urban Conservation Projects and Governance' completed in 2011, and in the **UAE**, on the author's experience in the heritage protection authority of Abu Dhabi Emirate since 2008. In both contexts, it has been possible to observe **certain recurring patterns** and also an **evolution** in the perceptions and roles of stakeholders regarding the urban heritage, albeit set in different social and political circumstances.

Evolving role of urban heritage

The **new understanding of heritage as an urbanistic force** that has a symbiotic relationship with development has been advocated by various researchers in the field, and increasingly gaining recognition in related industries. Some notable examples of this are seen in publications of the Getty Conservation Institute (2011) exploring 'Historic Cities', the Royal Institute of Chartered Surveyors (2011) dedicated to 'Heritage', and the Scientific Symposium of the International Council of Monuments and Sites (ICOMOS) themed 'Heritage as a Driver of Development' (2011). As highlighted in these publications, the notion of the built heritage now gathers cultural values and meanings in a broader context, and the 'need for heritage' is a signal of human societies trying to find themselves in a world dislocating under the effects of globalization. Heritage can move from a passive and aesthetic component, to a more active and assertive one, proposing visions and strategies for future development that combine conservation and 'modernity', providing lessons in reaching a more balanced, sustainable form of development that offers more cohesive social relationships, more human scales and more successful adaptation to the physical environment as demonstrated by vernacular buildings that use local materials and

techniques. Long considered a factor of additional cost, heritage is increasingly considered as a resource supporting economic development and social welfare. Investment in heritage produces attractive returns and positive impacts on land value, though methods to evaluate this are often still commercial and short-term-oriented. Cultural tourism can also be a form of sustainable development, as it is integrated within the local socio-economic context and cultural identity. Concepts and methods for the management of historic cities can make essential contributions to urban planning, as the analytical appreciation of the historic city reveals a repository of ideas that can provide continuity in city building. All these opportunities require a change of attitude, where we must question our expectations of buildings, and accept to modify our usage according to local environmental constraints (ICOMOS, 2011, pp. 9-11; Siravo, 2011, pp. 4-5).

A focused look at the **economic benefits of heritage conservation** is deserved, in light of its impact on shaping the role of urban heritage. Preservationists are increasingly being joined by other industries' professionals in defending that there is a strong economic case for regenerating historic buildings. Important historic buildings that may have been perceived as redundant for contemporary needs are often transformed, through adaptive reuse schemes, to a host of surprising uses that become very successful due to their unique character (Allies and Morrison & M&N, 2011). The inclusion of heritage assets in regeneration schemes provides a focus and catalyst for sustainable change. The impact of successful schemes is felt beyond the boundaries of the heritage asset itself and can boost the economy of the whole town. Historic buildings give a sense of place and a focal point that the community will rally around to support. The fabric and design can add a distinctive identity to the 'new build' part of a regeneration scheme, lifting the overall quality of the built environment. They may have interesting historical or cultural associations that can be developed through the wider regeneration area, and attract occupiers who would not be interested in a less distinctive building (Drivers Jonas, 2011, pp. 2-3). Economic benefits are further listed as increased and stabilized property values, which translate into increased property tax revenues; cultural tourism, which translates into increased jobs and increased sales tax revenues; and the building of strong communities and distinctive places where populations wish to live and work. Just the act of restoring one building can encourage others to do the same and improve the value of the entire block. Successful preservation programs foster community pride, learning, and creativity, which are critical to an educated workforce, as a strong economy and a strong community are inextricably linked (Anon, 2012).

The identification of heritage as catalyzing economic development is only just beginning to be supported by **robust and credible analyses**, through hard economic measurements, qualitative or environmental indicators (Rypkema & Cheong, 2011a). These measurements help to address not just the environmental but also the social and economic contibutions of heritage conservation to sustainable development, such as embodied energy, reduced infrastructure expenditure and reduced carbon footprint, and other energy savings of reusing existing built resources. Heritage

conservation may be, in fact, the single development strategy that simultaneously advances all aspects of sustainability (Rypkema & Cheong, 2011b).

The economic and social contributions of heritage to urban development are demonstrated to be possible, but depend on certain **conditions** being in place. Some schemes fail to deliver expected results, due to factors such as unforeseen costs, a beneficial use not being found for buildings, or visitor attractions failing to attract sufficient public interest. Working with heritage assets brings to the development process a special set of conservation, planning, funding and construction considerations, which often **require** specialist knowledge (Drivers Jonas, 2011, pp. 2-3). The special requirements are further elaborated in a study to assess the outcomes of the Townscape Heritage Initiative set up by the UK Heritage Lottery Fund, which identifies the importance of local knowledge, local capacity, appropriateness of scale, a permanent and stable local population, the presence of community groups, some local money existing in place, appropriate levels of housing market and demand, and a reasonable difference between the rehabilitation costs and the resulting property values of buildings (Shipley & Reeve, 2011). From a broader perspective, the sustainability of urban heritage preservation is contingent on its being part of a larger rehabilitation process that also addresses the issue of turning areas that contain the heritage into fully functional and developed portions of the city (Rojas, 2011, pp. 11-12), and integrated into the economic system of cities.

While it is critical to strengthen the **quantifiable aspect** of the economic role of heritage, this by no means means that **qualitative evaluations** are no longer as relevant or valid. On the contrary, these two aspects are mutually reinforcing, and integral to a full understanding of development. The **term 'development'** is defined in the UNESCO Declaration of Cultural Diversity, not simply in terms of economic growth, but also as a means to achieve a more satisfactory intellectual, emotional, moral and spiritual existence (ICOMOS, 2011, p. 9). As the concept gains new dimensions, the diversity of the types of values also increases, and more stakeholders become involved in the debate.

Stakeholder attitudes and roles

As our societies are becoming increasingly globalized due to advances in communication and mobility, global market economies fostering new trade and consumption patterns, and the spread of participatory democracies, so the policies of government intervention in the fields of planning and preservation are undergoing paradigm shifts. There is a new emphasis on **values-based conservation**, where the assessment of significance for heritage is made on a premise of the subjectivity of values, and the authority of expertise is questioned or tempered with a diversity of social narratives. This has the potential for a more holistic approach to conservation, integrating independent professional spheres with each other and with society at large, and broadening the audience for heritage. As such, cultural heritage acts as a medium of evolving social values, and its conservation can help manage rapid social

changes and mitigate their negative effects (Avrami et al, 2000, pp. 3-4). Conservation is thus required to engage more actively in cultural politics, to assess social and economic, or use and non-use values together, and to quantify the qualitative aspects of 'cultural capital' (Throsby, 2002, p. 103).

Upon examining the various types of values and their championing stakeholders, ones sees a basic pattern of **duality** manifested in different forms, such as scientific expertise versus social inclusivity, public benefit versus private rights, state intervention versus market forces, or indeed, conservation versus development. Expressed in another way, sociocultural values mobilize the cultural elite, philanthropists and community leaders, while the economic values attract consumers and real estate investors. Another pattern commonly mentioned is the shifting of values, e.g. how heritage is often perceived as a barrier to regeneration that too complicated to work with, or a symbol of decline and social deprivation, but how it is finally being recognized for its true range of cultural, social and economic values. For sustainable preservation programs, one needs to put all values embedded in urban heritage into play, as they are the drivers that mobilize a diverse set of stakeholders; the wider the variety of values, the better heritage can draw the support, financing and skills of diverse and capable stakeholders (Drivers Jonas, 2011, p. 2-3; Rojas, 2011, p. 11).

The **reconciliation of this duality** remains at the center of the debate regarding the role of values-based conservation and governance. Making heritage more accessible on a wider social level will also enable its acceptance as a valid option for the general public, politicians, decision-makers, contractors, developers and others. For this, an effort on both sides is needed, through bringing a more urbanistic approach to the heritage conservation agenda, while also improving the position of heritage values with the planning agenda. These can then be transformed from competing alternatives to mutually beneficial components of the same joint agenda (Yildirim, 2011, p. 28). Highlighting the social relevance of this proposition, Siravo (2011, p. 9) points out that conservation represents a minority position, but it is all the more relevant in times of environmental concern, and as it offers to overcome the divide between a powerful minority who are partisans of unrestrained destructive growth and a powerless minority who champion total conservation, to show how development can be channeled in the **interest of a vast majority of users**.

At this point, the question of whether or not the urban cultural heritage can effectively **play a 'productive' role** in the life of the city can be addressed in terms of reconciling the dualities related to value-based conservation through negotiations among stakeholders. A perhaps brutally simplistic assumption would place the answer given by the proponents of economic development as 'yes', while that given by the heritage conservation sector as 'no', with the former garnering larger support in society. However, a more consensual solution can be facilitated as more diverse types of 'value' (i.e. inherent, non-use values as opposed to use values measured strictly in terms of monetary profits) are adopted by members of industries such as real estate, economics and engineering, who are classically trained to undertake cost-

benefit analyses within purely financial parameters. The **definition of 'productivity'** in turn can be expanded to allow for new ways of measurement beyond the financial and quantitative.

Similarly for the question of whether promoting heritage as a driver of development inevitably leads to **gentrification**, a more predominant and immediate response would be 'yes', based on the premise that conserved and regenerated historic areas inevitably experience increase in their property value, which entails replacement of lower-income groups with higher-income ones. However, there are several points that show there is more complexity to this question. Gentrification can be considered part of the natural evolution and cycles of invasion and succession in places, where low-income populations are often themselves inheritors of their neighborhoods from earlier, wealthier occupants. Social change needs to take place, but the question can be modified to pursue its rate and manner, rather than its existence. Change can be softened, e.g. by reducing displacement, if not completely preventing it, through social housing policies that local governments adopt, such as subsidies and rent control. To give two examples to the risks of extreme approaches on both ends, full retention of low-income residents can lead to disrepair, as they cannot afford the maintenance costs of buildings, while full displacement of the resident population can cause mayors to lose their electorate and long-time partner in urban conservation efforts, as the new rich who move in can be unappreciative of the earlier efforts, in turn causing the disruption of projects (Getty Conservation Institute, 2011, pp. 19-22).

Further to the broad themes mentioned above, some **more specific factors related to stakeholders** can be acknowledged as influencing the role of heritage within urban development. The various social and economic characteristics of stakeholders that constitute important factors include the demographic profiles and the income levels of the communities residing in historic areas, the level of conservation culture that is internalized by these communities, the strength of the connection between users and the buildings they use, the approach of the local government toward heritage and the skills at managing funds for its conservation. The maturity of public institutions and legislation determines the level that economic incentives and aid can be offered to owners and users, conservation works on buildings can be facilitated, local governments are empowered to support owners and users, and how effective regulating mechanisms are.

To be elaborating on arguably the most important stakeholder in the debate, **local governments** are the only actors capable of ensuring coordination of other stakeholders, through a combination of legal enforcement powers, economic tools and social engagement and outreach abilities. They are increasingly required by communities to take responsibility for preserving the public-good component and the socio-cultural values of urban heritage (Rojas, 2011, p. 12). Economic tools made available to property owners and users to realize the economic potential of heritage assets, become more potent when local governments can channel the use of funds in a way that maximises the multiplier effect of incentives, e.g. by providing seed

money for privately owned buildings conditional to match funding. As another key tool at the hands of local governments, participatory governance has the potential to impact on historic environments through the devolution of land use planning and development control to local authorities. While this presents an opportunity to mediate between the competing interests of conservation and development, tensions also arise between localized decision-making, and national policy and international obligations to protect heritage (Landorf, 2011). To competently handle these sensitive dynamics, it is important to have good technical staff with heritage expertise in local authorities, consisting of well educated professionals of architecture and planning-related fields, as well as financial and real estate advisers (Getty Conservation Institute, 2011, pp. 19-22).

Beside individual characteristics of local governments and other stakeholders, the **methods of organization** between them present another essential factor in supporting the role of urban heritage. In the multi-actor settings that undeniably form the only viable governance system today, effective coordination and collaboration between all stakeholders that share responsibility, the ability for key actors to find enlightened partners with whom they can work together, and the presence of a stakeholder that assumes ownership of urban conservation projects and fosters the spirit and culture of collaboration are some of the basic requisites for the success of urban heritage conservation. Similar tenets have been outlined in the literature of site management for historic places. The principles adopted by UNESCO for managing World Heritage Sites, as explained by Feilden and Jokilehto (1993), include the conservation of all values present on the site, consultation with all stakeholders, regular monitoring and reporting done by appropriate experts, and periodic work programs and priorities defined within the strategic conservation plan framework.

The Turkish Context

Situated in a historical crossroads of civilizations, Turkey is home to a rich stock of built heritage, which endows almost every town with historic quarters to be protected. Legal and administrative systems to address the conservation of this legacy have been in development since the 19th century, and have generally followed worldwide trends in the field. However, the size of the population and the socio-economic and geographical dynamics of the country have rendered conservation a constant challenge. Influx of rural migrants into urban areas to form the new industrial workforce, in particular have made populist policies in local governments prevail at the expense of adequate protection of the urban heritage.

Traditionally, the conservation mandate has been burdened on the government and not fully integrated into the economic life of cities. In the face of the threats posed by these trends, conservation efforts have been undertaken with legislation that was strict, but weakly enforced and ill-equipped with implementation tools, and a centralized administrative structure, comprising the Cultural Ministry and its provincial branches, that had only meagre state resources at hand; these factors

confined conservation to the level of a bureaucratic and academic exercise that was marginalized from political decision-making processes, and not taken root as a community-wide culture. This 'top-down' approach can be understood in the context of the state-interventionist regime that was prevalent until the 1990s, but which has now given way to trends brought about by the evolving democracy of Turkey (Yıldırım 2009b).

Reflecting the wider trends discussed in the previous section, there have been important **new developments** over the last few years in the legislation regarding cultural heritage. Many are related to the accession for European Union membership and EU-compliance reform, entailing the devolution of government power and localization of preservation services, whereby increased roles, responsibilities and funding resources are given to local authorities, as well as incentives to private persons and bodies for cultural and natural heritage protection.

Since 2003, about ten **new laws and associated regulations** have been adopted, which have direct and indirect implications for historic preservation. These include new funding sources and responsibilities given to special provincial directorates and municipalities; the establishment of municipal Conservation Implementation and Regulation Bureaus (KUDEB) and provincial project and training bureaus, the streamlining of bureaucratic procedures; new tools for compensation of historic property owners such as transfer of development rights, and an expanded scope for urban regeneration and tourism-related investments. These changes, while deemed a remarkable legislative and administrative reform, have been received with some skepticism in terms of their effectiveness and consequences, which are yet to be fully realized.

This legislative reform coincides with **socio-economic trends,** such as an increased general interest in heritage preservation, fed by media coverage and the new awareness of economic value to be gained through cultural tourism, especially by local governments; a shift away from centralized, modernist planning toward strategic planning and the emergence of site management plans, particularly in the context of World Heritage Sites; the adoption of the new concepts of sustainability, livability, devolution and governance covered within the UN-based Local Agenda 21; increasing international sponsorship through programs of the European Union and funding bodies such as the World Monuments Fund and the World Bank; the increased interest of private companies in tourism investments in archaeological sites; and the strengthening of non-governmental organizations, including citizen groups and professional chambers. While these trends present opportunities supporting heritage conservation, they are accompanied by controversial project investments of international corporate capital in prime urban locations in Turkey, which draw the reactions from community groups through court battles and protest campaigns.

This all helps to produce an **increased number of actors** in the preservation sphere, coming together both in terms of their conflicting interests, such as in preservation battles, and in terms of collaborations, in terms of both international and public – private partnerships. In this new era of democratization, two important implications emerge that need to be monitored and managed for positive outcomes. Firstly, the relaxation of centralized government control will give way to more varied and contested views of preservation and to less strict applications of preservation principles. Secondly, the view of preservation as an economic revenue generator presents intensive initiatives for projects to preserve and reuse historic fabric on one hand, and potential abuse through misguided interventions on the other. In other words, it is possible to foresee a **quantitative rise and qualitative fall in** urban conservation projects and practices.

In response to these challenges and opportunities, some **basic measures** can be proposed, including staff and technical assistance to the highly underserved local authorities to provide guidance in interventions; the community sector to rise to the challenge of checking speculative interests in the private and government sectors empowered by the new laws; incentivizing good practices among private sector investors; and forming the 'right' type of partnerships in conservation projects that will achieve optimal results (Yildirim, 2011, p. 32-36).

Empirical research conducted during the author's recent **doctoral dissertation**, which explores the governance framework of actors in the urban conservation process, has provided some insights that elaborate on the propositions outlined above. The main **hypothesis** of the dissertation, explored through numerous case studies, states that 'for a successful project, the governance framework must include the active participation of four types of actors, i.e. Statutory Authorities, Investors, Users and Experts, to fulfill the respective requirements of legal, financial, social and scientific credibility of projects, as well as a fifth actor who will be the Project Owner. The focus case studies of the study have been the cities of Gaziantep, Kuşadası and Mudurnu, as well as about forty other towns of large, medium and small scale.

In the metropolitan municipality of **Gaziantep**, the 'Culture Trail Project', which is part of a wider initiative called 'Gaziantep: The City that Turns its Assets into Abundance', features a 5.5 km axis connecting the citadel with the historical commercial center, where street and building façade rehabilitation, infrastructure and landscape improvements, and restorations and adaptive reuse of historic buildings have been carrid out, aimed at revitalizing the historic center and integrating it into the social life of the city. Here, the urban heritage is clearly seen as a vital component of the vision for the city's future. The project has been initiated with the election of a new mayor with such a vision, and successfully implemented though strong municipal leadership and coordination, which revolves around the multi-actor 'Common Mind Platform'.

In the mid-sized tourist resort town **of Kuşadası,** the **'**Kaleiçi Quarter Street Rehabilitations Project', which is part of a wider initiative called 'Kuşadası Reclaims

its Natural and Cultural Identity', features street and building façade rehabilitation, infrastructure and landscape improvements. Kuşadası Municipality has formed a strong partnership with the Foundation for the Protection and Promotion of the Environment and Cultural Heritage (ÇEKÜL) and various universities' architectural faculties for the project.

In the small Silk Road town of **Mudurnu**, the 'Project for Tourism-based Revitalization of Traditional Architecture' involves efforts to revitalize the economy through cultural tourism, after the collapse of the poultry industry in the economic recession of 2001, through minor and comprehensive repairs in historic buildings, adaptive reuse for tourism, and visual improvements in the public realm. The special success of the Municipality, in coordination with the Provincial Directorate for Culture and Tourism, has been mobilizing funds provided by the new grant scheme of the Ministry of Culture and Tourism, for the design and execution of thirty restoration projects.

The examined projects have revealed some **successful outcomes,** such as transformation of the project areas- most of which had less development dynamics compared to the rest of the city- into more attractive destinations through physical improvement and increase in use and economic activity; enhancement of the city's identity; emergence of social and economic expectations from the local government and community toward the urban heritage; setting an example and providing impetus for other projects; actors sharing ownership of project, and development of a local preservation culture. Some **points of concern** also emerge, mostly related to interventions being superficial and lacking full technical and scientific competence. However, a general attitude full of optimism and a resolution to continue works is observed, as well as a tendency of implementation improving in quality, as lessons are drawn from mistakes in earlier phases of projects.

Some important points observed regarding the **processes** of projects are that partnerships are based on ease of implementation (e.g commercial districts being favored in initial phases over residential, as project co-funding by local traders is available), and a notable element of public participation, through information and consultation meetings with business owners, and multi-actor committees set up either for the specific project or operating city-wide.

The main stakeholders of urban conservation projects**,** in order of importance, emerge as Municipalities, with particular importance of individual mayors, Cultural and Natural Heritage Preservation Boards, and Governorships. projects. The role of Project Owner is played mostly by the metropolitan or district municipality, supported by the Ministry of Culture and Tourism and the Directorate of Foundations. A wide range of actors act as project partners, including the Directorate of Surveying and Monuments within the Ministry, the ÇEKÜL Foundation and its local branches, the Association of Historic Towns (TKB), the Chamber of Architects, private architectural practices. Project funding comes mainly from Municipalities, grants distributed by the Special Provincial Administrations based on the new real

estate tax co-payment scheme, international funding bodies and the Ministry of Culture and Tourism.

The case study findings suggest that the positive processes and outcomes of the examined projects are supported by the presence of the types of actors outlined in the main hypothesis, thus largely supporting the hypothesis (Yildirim, 2011, p. 322).

The key issue that needs to be addressed for success appears as maintaining the productive momentum of projects without compromising on scientific standards. From the governance perspective, this entails the **balance** between the 'Regulating' role of the 'Experts' and 'Users' and the 'Executive' role of the 'Investors' and 'Statutory Authorities'. To achieve this, an effective system of **coordination** and collaboration between these parties is required, harnessing as many channels of communication as possible. Other factors to consider include actors being involved in full capacity, whereby mandatory roles defined by legislation are supported by voluntary roles; technical capacity building for municipal staff through support from experts; project continuity being achieved, on a technical level by involvement of dedicated experts throughout design and implementation, and on an institutional level through long-term, lasting governance structures independent of electoral politics, being put in place. These measures also help to awareness for and reinforce the culture of preservation in the community.

As a concluding remark on these developments in urban conservation and their effect on the role of urban heritage in Turkey, one can note a **positive change** toward more social engagement, more opportunities to realize the economic potential, and heritage becoming a more visible component of the city image and the strategic visions for the cities' futures. For plans and projects that could not find the funds to be implemented before, the 'opportunity to implement' has arrived, being realized with varying degrees of success and competence, but nevertheless with great enthusiasm and a positive trajectory of improvement.

The Emirati Context

The urban heritage of the United Arab Emirates has been marked by the astoundingly **rapid transformation** of the country through its oil wealth, from a confederation of semi-nomadic tribes surviving on a basic subsistence economy into a futuristic post-modern landscape. The distinction of the post-Oil UAE from the pre-Oil period is clearly marked by the country's social and physical characteristics, but a continuum of **layers of urban growth** has still managed to form in this transition. Beside the survival of a short but vital urban layer attesting to the history of modernization, Emirati cultural heritage can be gleaned through traditions linked with a strong adherence to Islamic practices, enduring references to a nomadic, desert-bound lifestyle, and intangible heritage elements such as poetry, camel-herding and falconry. There are also important archaeological remains and ancient oases dating back to the Bronze and Iron Ages, which together form a cultural

landscape that have evolved and survived to the present day. The rapid development of the 20th century have caused major loss of the pre-Oil urban fabric, leaving behind only the monumental structures such as Qasr al Hosn in Abu Dhabi, and some traces of villages that can be found at the edges of oases in Al Ain. Although the heritage is not as strong in the built, urban sense, the intangible and rural elements find their references in the modern urban landscape, producing an unusual mixture of urban heritage. The country owes its modern-day achievements to the masses of expatriate workers and professionals taking up residence here, forming a highly multi-cultural population that has indirectly contributed to the urban culture.

The UAE is essentially a monarchy in terms of political regime, but it has some distinctive features that suggests a more democratic **governance structure** than one might presume. Firstly, the country is a federation of separate emirates, each with a certain amount of autonomy that includes a strong local mandate for culture; secondly, the **tribal governance** structure centered around the 'majlis' tradition of consultation enables a considerable degree of upward feedback of the communities' interests to the well-respected rulers to consider. With the advent of civic institutions, the government has adopted modern state organs such as the Federal National Council, but these have been superimposed on, coexisting with, and thus affected by local tribal structures. The urban development projects, which began with the flow of funds from oil exports in the 1960's, were initially directed from the Rulers' courts, but soon the realization of development plans required the establishment of government departments for specialized operations, which eventually led to the creation of federal ministries after unification as a nation-state in 1971. Today, local governments have a very high profile in the development of the physical world (Damluji, 2006, pp. 16, 36). Development budgets and projects are allocated by the Executive Councils representing the government of each emirate (Damluji, 2006).

More specifically for **heritage**, the development of **stakeholders** and activities can be traced back to archaeological excavations in the mid-20th century which started under the auspices of the late president Sheikh Zayed, and the establishment of the Center of Documentation and Research to record the emirate's history and resolve territorial issues. This was followed by the Department of Antiquities and the Al Ain Economic Development and Tourism Promotion Authority, which asked for UNESCO's support in preparing the Abu Dhabi Cultural Heritage Management Strategy. Completed in 2005, the Strategy promoted an integrated approach to the management of the emirate's cultural heritage, and recommended the establishment of the Abu Dhabi Authority for Culture and Heritage (ADACH) to implement this vision. The founding Law no. 28 of 2005 charged ADACH with a broad mandate for this end, and placed it among several new Abu Dhabi government agencies that have been expected to guide Abu Dhabi's ambitious future development (Yıldırım & El Masri, 2010). These agencies include the Abu Dhabi Urban Planning Council (UPC), Department of Municipal Affairs overseeing Abu Dhabi, Al Ain and Western Region Municipalities, the Department of Transport (DoT) and the Environment Agency. In 2011, ADACH was integrated with the Abu Dhabi Tourism Authority (ADTA), to form the Abu Dhabi Tourism & Culture Authority (TCA), this restructuring being

viewed by some as an indicator of a shift in the emirate government's policy toward engaging culture and heritage more actively in economic development.

The Abu Dhabi government has been showing strong initiative also in adopting the **Abu Dhabi 2030 Policy Agenda**, in development since the mid-2000s. Cultural heritage has been given an important role at policy level, as one of the main subject areas in the agenda; however, the level of implementation has revealed challenges, as it is often not clear how conflicts arising between the mandates of different agencies will be resolved and how the **government's priorities will be negotiated**. A recent example of this has been the Abu Dhabi Bus Station, an urban landmark of modern architectural heritage, which has been designated for protection by ADACH/ TCA but also scheduled for replacement with a new facility as part of the bus transportation development plans of the DoT. Negotiations between the two agencies are currently ongoing, and have recently taken a turn on the side of preservation, as the matter has been raised to the level of the Abu Dhabi Executive Council, and various briefings on the significance of the station have helped key officials re-consider the redevelopment scheme.

The policy agenda has been followed by sectoral versions, foremost among them the Abu Dhabi Economic Vision 2030, as well as the upcoming **Environment 2030** sustainability agenda. It has not been clearly defined how cultural heritage features within this agenda, i.e. in terms of the social, environmental and economic pillars of sustainability, but this may be a point that will be addressed among the agencies in future deliberations, as the EAD and former ADACH have many procedural and practical relations in effect.

The **emirate government's** predominant role also manifests itself as the primary **funding source** for both development and heritage conservation projects; the government's decision to cut the budgets of many agencies, which has been interpreted as a strategic move in the wake of the 2008 economic recession, has affected the heritage conservation work at TCA.

On a level below the emirate government, **municipalities** have exercised their **regulatory** capacity in a way that has shaped the formation of new urban layers. During the 1980s, bye-laws of the Department of Town Planning have required new buildings, particularly residential ones, to feature architectural elements of 'Arab/ Islamic' style on their elevations. Intended to reflect regionalism, the effect of this has been criticized by scholars to produce instead only superficial decorative features, often without consideration for the underlying principles of Islamic architecture (Damluji, 2006, p. 32).

Similarly, the misappropriation and literal application of features of traditional architecture such as wind towers and desert forts, have produced unintended consequences, misrepresenting the identity of the built heritage (Allies and Morrison & M&N, 2011). Here, the quality and role of design professionals becomes key as they **interpret and reproduce the regional cultural identity**. Damluji (2006)

provides some insights into this, such as the conventional architectural education in the region having been oriented towards structural engineering (p. 36), and the influx into the region of architects from different backgrounds and sense of aesthetics resulting in the experimental nature of the architectural profession (pp. 24 , 102-116). More recently, professionals recruited to the new public and private sector agencies are advocating context-sensitive design as the global best practice, instead of the conventional, narrower focus on operational and 'engineering' aspects of urban projects. This is a salient instance of the multi-cultural character of the stakeholder ecosystem in Abu Dhabi at work.

There are some examples of **architectural modernism** in Abu Dhabi, from the 1960s-80s, that has provided an appropriate response to local cultural and climatic conditions (Damluji, 2006). It is important to recognize this layer as part of the urban heritage, to complement and provide continuity to the more 'ancient', pre-Oil era sites and buildings, which are more readily recognized as 'heritage'. The scope for **adaptive reuse** of both types of heritage is as yet somewhat limited, due to factors such as the fragile physical nature of pre-Oil buildings and the substandard physical construction techniques of some early modern period buildings, not to mention the absence of a sufficient culture and industry supporting the idea. However, as more value is placed by the government, developers and the local community on the full range of heritage assets, it will be easier to develop methods of regenerating and integrating them within urban development.

Many illustrative issues related to stakeholders and the role of urban heritage can be observed in **Al Ain**. Considered the most 'authentic city' within the emirate, the modern city of Al Ain has developed in juxtaposition with an ancient oasis landscape, which was inscribed oas aUNESCO World Heritage Site (WHS) as the serial property of 'The Cultural Sites of Al Ain'. Al Ain Oasis, one of the components of the property, has been the subject of TCA's Al Ain Oasis Cultural Quarter Master Plan, aimed to connect the historic oasis with the surrounding urban fabric, and conserve it as a local environmental resource (Yıldırım & El Masri, 2010). The master planning efforts and the WHS nomination process have together been advanced through productive inter-agency coordination between TCA, UPC and Al Ain Municipality (AAM), to integrate the oasis master plan with the wider local plan, and to ensure coordination of the development control processes of each agency in and around the WHS areas. The AAM has supported some development restrictions by exercising the basic economic tool of plot reallocation. As additional restrictions arising from the WHS take effect in the property's buffer zones, reactions of local landowners and developers have also increased, revealing the need for more effective outreach to the local community to garner their support. The WHS designation also seems to have triggered a shift in the tourism marketing policy of the former ADTA, and the integration of the cultural heritage and tourims agencies forming TCA is likely to support work on cultural tourism promotion in Al Ain.

In conclusion, although the urban heritage has not been immediately explicit in cities within Abu Dhabi Emirate, it is nonetheless being recognized for its unique characteristics, created by a combination of factors special to this region and telling the particular story of the emirate's development. With the maturing of public organizations, legislation and capacity building with qualified local and expatriate professionals to support its conservation, the gradual development of its awareness among interested social groups, and perhaps most importantly its prioritization by emirate leadership, the urban heritage is slowly acquiring a more prominent role in the urban development context of Abu Dhabi.

Comparative Results

In evaluating the contexts of Turkey and the UAE, it is possible to conclude that while the two countries have quite different histories and socio-political situations, the developments occurring around the world, in terms of stakeholders and the role of urban heritage, have relevance in both of them.

The most important thread that one observes to tie the countries' experiences together is the general process of **modernization**, although each is at a different stage along this trajectory and have not necessarily followed the same sequence of steps to arrive where they are. In particular, both countries having predominantly Moslem and Middle Eastern societies, with elements of traditional and conservative cultures, the Emirati population can be said to be facing, since the late 20th century, some of the same key issues of modern life that the Turkish population was facing in the early 20th century with the establishment of the modern republic, or perhaps going back to the late Ottoman period. This has spatial dimensions such as the move from extended to nuclear family and household models that reflect in the move from traditional large houses to high-rise apartments, the development of participatory governance in planning and the establishment of civil institutions in regulating urban development.

In terms of shaping stakeholder values and attitudes toward the role of urban heritage, modernization overlaps largely with **democratization**, and the evolution from conservative to **progressive policy tools**. Referring to the range of policy tools for preserving the built heritage as formulated by Schuster et al (1997) in a sequence of most to least conservative, i.e. from ownership and operation, to regulation, incentives, property rights and information, Turkey's recent legislative and administrative reforms have enabled more advances along this line. However, tools such as plot reallocations to enable the transfer of development rights are also in use by Abu Dhabi's municipalities. In terms of the shift from top-down, government-controlled governance system toward multi-actor settings, Turkey has adopted more of these changes, although some multi-actor processes such as public-private partnerships can be found in the UAE as well. The federal government of the Emirates supports a decentralized governance structure more easily than in a unitary

state like Turkey, but local devolution in Turkey has also been in process, notably in relation to European Union accession.

In Turkey, concepts of urban heritage and its integration with the planning process have been a **long time in development**, resulting in more mature institutions and complex administrative systems. The much more substantial stock of built heritage to deal with, the economic dynamism in cities and the scarcity of financial resources in proportion to the size of the heritage stock, lend certain challenges to the effort of conservation. In the UAE, the drive to 'catch up' and excel on the global stage, and the exposure to international 'best practice' ideas brought by expatriate professionals, enables a potentially **faster adoption of progressive models**, though their true 'digestion' and internalizing by the local community naturally requires more time. Conversely for the UAE, time is short, but financial resources more ample. Also distinguishing the UAE are the multicultural collisions of professional and cultural practices, and the unusual, 'post-modern' combinations that result from it. In both countries, however, the fact that **promoting heritage** against development involves a **struggle,** is not so different. No matter how much wealth there may be, the action of engaging with urban heritage depends on the interest and will by those with the power to allocate and mobilize resources. Both countries thus prove themselves to be **part of the same global community**, where the future of urban conservation requires stakeholders to value and harbor a positive attitude toward the urban heritage.

The 'new' Metropolis as a post-political script? Re-reading a vision exercise for a metropolitan region

Peter Ache [1]

Abstract

Fritz Lang produced between 1925 and 1927 one of the most powerful 'allegories' (Fischer, 2003)regarding the 'Metropolis'. It was a futuristic as well as romantic script of the state of an urban society, which finds itself divided between the over ground managers and the underground workers, the latter caring for the 'm-machine', a mythical entity that keeps the society going. Metropolis is a story of salvation and betrayal, and the appearance of a first ever 'robot' that influenced all future images of an 'android'. The reception of Metropolis was diverse and mainly expressed huge levels of irritation. Siegfried Kracauer, the founding father of the sociology of film, called the movie 'a strange mixture of Wagner and Krupp' (Kracauer, (1984/1947)). In visual terms, it is safe to say that Metropolis set a standard, which was rarely met in later efforts. Despite being aged, Fritz Lang's personal vision of a metropolis still finds a link to current times, where the co-creation of metropolitan futures in group vision making processes has become very important, looking f.i. at Les Grand Paris exercise – or the exercise, which is under consideration here, the Greater Helsinki Vision 2050 (Ache, 2011). In fact, the metropolis continues to be 'the', though somewhat fuzzy, object of our times, where the globally acting research community discusses its existence (Sassen, 2001), the functions (Castells, 2010), or the way of operation (Taylor, Hoyler, & Verbruggen, 2010). The paper and presentation will reflect on the Greater Helsinki Vision 2050 process and will present a.o. the following findings: The vision exercise can be interpreted with the help of the institutional analysis and development framework (Ostrom, 2005) as an action situation with specific elements and structures. Furthermore, the GHV 2050 process shows characteristics that can be interpreted through new theoretical perspectives, like soft spaces (Haughton, Allmendinger, Counsell, & Vigar, 2010), (neo) pragmatism (Hillier & Healey, 2008), or planning in post-political times (Swyngedouw, 2009). And, returning to the outset, today the metropolis continues to be not just a new territorial form but the result of the preferences and intentions of actors, who create the metropolis in different variants. This includes the idealistic vision, that the metropolis itself is actually the 'm-machine', of unknown providence but with the capacity to mediate between 'hand and brain' (Lang).

1. Introduction

Fritz Lang produced between 1925 and 1927 one of the most powerful 'allegories' regarding the metropolis. It is a futuristic, dystopian but as well romantic script of the state of society. That society is definitely an urban society and it's most remarkable feature being a divide between over ground managers and underground workers, the latter caring for the 'm-machine', a mythical entity that keeps the urban society going. The romantic element comes as a story of betrayal and salvation, and the appearance of the first man-machine, an android built as the copy of the main female role/actor, an image that influenced all future perceptions of androids. This vision of a metropolis was influential in many ways. In visual terms, it is safe to say that Metropolis set a standard, which was rarely met in later efforts. Much of the scenery was designed by film-architects and can be found almost one-to-one in modern science fiction movies like 'Blade Runner' by Ridley Scott. The reception was, as one can read from historical comments, diverse and mainly a result of huge levels of irritation. Siegfried Kracauer, the founding father of the sociology of film, called the movie 'a strange mixture of Wagner and Krupp' (Kracauer, (1984/1947)), alluding to the combination of a deep mythical almost *Götterdämmerung* kind of layer with the steel juggernaut.

Film is of course not the main issue here, but urban futures are, though again, not in the futuristic terms of Fritz Lang. The creation and design of urban and in particular of metropolitan futures has become very important recently, looking for instance at the Les Grand Paris exercise, or looking at the exercise, which is under consideration here, the Greater Helsinki Vision 2050. For about a decade now, the metropolis or metropolitan region came into focus of such exercises of spatial and strategic thinking. In a EU context, the European Spatial Development Perspective (EC, 1999) could be named here first, sparking for instance in Germany a discussion about metropolitan spaces of a European importance, which many years later resulted in a debate about a new category to organize the national territory around metropolitan spaces (ARL, 2007; Knieling, 2009)[3]. In fact, the metropolis is the object of our times, albeit somewhat fuzzy, where the globally acting research community discusses its existence (from a global south perspective Robinson, 2006; starting obvioulsy with Sassen, 2001; UN Habitat, 2006), the function (Castells, 2010; Taylor, Hoyler, & Verbruggen, 2010), or the way of operation (Hall & Pain, 2006), and also its many variations (see the special issue of Regional Studies, Neuman & Hull, 2009), and the political or strategic dimensions (MacLeod & Jones, 2011).

[3] Which brought as well a new interesting interpretation, the communities of shared responsibility (in German *Verantwortungsgemeinschaft*), i.e. combinations of metropolitan cores with wider hinterlands with the core taking also responsibility for the surrounding hinterland [*(Peter Ache, 2008)*.]

The article uses for its reflection a metropolitan vision exercise that ran in Finland between 2007 and 2009, and continues as a strategy and planning process until today. The Greater Helsinki Vision 2050 exercise (hence GHV 2050) might irritate international readership right at the beginning. Finland and a metropolis sound like a mismatch, for instance due to a small overall population of five million inhabitants spread over a vast territory, with the largest city having just about six hundred thousand inhabitants in 2011. Compared with other metropolitan spaces (OECD, 2006b; UN Habitat, 2009; Wiechmann, 2009), we can speak about the lower end of the scale.

The exercise was also critically and with some irritation observed in the local context; until today a gross suspicion cannot be denied, expressing the fear that Helsinki as the capital city will be further developed on the expense of the hinterland. When looking into the constellations of that exercise, what can actually be seen is a strong link with a governmental agenda that drives territorial development into a specific, a 'metropolitan' direction. In a way, the metropolis becomes an object of intentions of the actors and the GHV 2050 Vision is the new script for that metropolis. This script, not least, is formulated as an agenda of creating the right spatial setting for a larger modernisation strategy. Finland's economy is heavily dependent on information and communication, on advanced technologies and services, operating at the technology frontier, that 'requires' so to say a metropolitan space with creative ingredients (Farole, Rodríguez-Pose, & Storper, 2009 (January)).

Terminology is important, as the reader has seen, and varies between greater region, metropolis, metropolitan space, or metropolitan region, capital city, and capital city region[4]. The spatial object of this article does not fit well the existing scientific terminology. It seems that our existing set of categories, theories or concepts is insufficient. The metropolis has probably much more of a transitional quality (P Ache, 2007) than anything else, as the current case study shows. It is a blurred definitional array, allowing for agreement or accordance, frequently operating on the basis of a 'perceived similarity' between collective actors[5]. A precise terminology is maybe not that necessary, if we accept the discursive construction of policy (Fischer, 2003). Then, the main element of the 'form', classically formulated (Benevolo, 2000 (8)) as an idea of density, morphology, mono or poly-centricity, is not that essential as an element. Seeing the metropolis from that perspective, it is not simply a new existing territorial form but the result of the preferences and intentions of actors who create the metropolis in different variants. And the 'vision' is the new script, no matter whether of or for the metropolis.

What will the paper do? This article will look into the outcomes of the GHV 2050 vision exercise, in particular the follow-up activities after the original

[4] Readers should be aware, that the notion of metropolis (and its variants) does not refer to a simple statistical area, like in the USA.
[5] So, one might wonder whether it is an 'empty signifier' (Swyngedouw and others?)

competition. The vision exercise can be read with the help of the institutional analysis and development framework (E. Ostrom, 2005) as an action situation with some specific elements (Part 1). The content side of the vision exercise presents interesting insights into actor's perceptions of what the metropolis should be. In particular the momentum of change is interesting to look into. The essential difficulty to cooperate over loose issues, the conflict filled opposition especially over budgets or economic items, shall be overcome by a strong but framed leadership, or in other words, by managers of change (Part 2). And finally, returning to the outset, GHV 2050 scripted a different future for the metropolis. In the reference case of the Metropolis movie, Fritz Lang, being an artist, developed an extreme and exclusive vision. He acted as an individual driven by the interest in the artistically enhanced *(but also 'poetic', see Hardy, 1998)* vision of a new life world. Lang's vision uses a conflict, not only dramaturgically, to elaborate a different future, calling for a race against the machine. Compared with that, the co-constructed future by a group of institutional actors has a different character, with one surprising aspect being, that in principle the vision is free of any conflict. In review of the process, the paper will reflect on this aspect and establish links with the discussion about soft spaces (Haughton, Allmendinger, Counsell, & Vigar, 2010), agnostic (neo)pragmatism (Hillier & Healey, 2008; following from Pløger, 2004) but also the post-political city (Swyngedouw, 2009) and the institutional void (Hajer, 2003). (Part 3)

2. Analysing a vision process in the metropolis

The metropolitan region of Greater Helsinki is an institution in the making and the Greater Helsinki Vision was and is instrumental in the creation of this new arena, addressing possible futures for the metropolitan space and creating a new action situation 6.

In 2006 the international ideas competition 'Greater Helsinki Vision 2050' (henceforth GHV 2050) was announced jointly by the region's fourteen municipalities, in cooperation with the Ministry of the Environment and the Finnish Association of Architects. The aim of GHV 2050 was to create a joint vision for the sustainable development of land use, housing and transport. The basic assumption of the brief was a rate of population growth similar to that in recent years, leading to an estimated 1.8 million inhabitants by 2050. Altogether 109 entries were submitted by the deadline in 2007. Out of these, nine entries received an award, which was presented in December 2007.

For the analysis of the GHV process, institutional theory provides a well-established conceptual framework for interpretation. Institutional theory has a

[6] The article works mainly with findings obtained in participant observation over a period of now five years. At several stages the author was invited to participate in the Greater Helsinki Vision and follow up process. During that period, a deeper insight into the operations and structures of the metropolitan region were obtained.

long standing tradition with at least three distinctive scientific branches, namely political sciences (Scharpf, 1993), social sciences (Berger & Luckmann, 1966) and economics (Samuels, 1988). The work by the Nobel Prize winner Elinor Ostrom belongs to the latter group, providing the institutional analysis and development framework (IAD) 7. Especially the work done by Elinor Ostrom (2005) will be used as the main source for an interpretation of the observations.

Much of Ostrom's work is interested in the management of common pool resources. One could argue that with the new spatial structure of a metropolis a very complex variant of a common pool resource problem is addressed, starting with the dimension of land-use and stretching to the complex resource climate 8. The most exemplary theme is probably urban sprawl (European Environment Agency, 2006) as a negative land-use phenomenon which brings arguments in favour of a better coordinated metropolitan space and calling for more effective planning institutions at the level of the functional urban region. The characteristics of common pool resources create conditions for cooperative action in distributed institutional settings.

The GHV 2050 exercise is essentially a spatial planning exercise, using the metropolis as it's object. Typically spatial planning is a public service produced in shared constellations, though increasingly using also private service producers (P Ache, 2010). The orientation for the service provision can be understood as guided by a preferred state of community affairs (V. Ostrom, Tiebout, & Warren, 1961), not least emphasising the political influence on the service provision. In such a context of preferred states of community affairs, preferences and intentions are more likely to be negotiated again, re-emphasising the common pool dimension of the metropolis. Overall, the metropolis in principle fits the common pool resource criteria quite well, though in the discussion at the end of the article we also point out an alternative view.

The framework of institutional analysis as outlined by Ostrom (2005) is multi-dimensional and complex. In the context of the current article, it is especially important to look into what is called the action arena. The GHV 2050 vision process can be seen similar to an action arena. There are several elements that institutional analysis applies to understand an action arena. Biophysical or material conditions, attributes of the community, and rules are the exogenous variables of an action arena. The action arena itself consists of a specific action situation, in our case the core of the GHV competition and follow-up process, and of participants. Participants interact in the specific external framework and create in an action situation the outcomes which are evaluated, therefore having an

[7] Which is compatible and partly integrates theories and concepts from game theory, microeconomic theory, transaction cost theory, social choice theory, public choice, constitutional theory, theory of public goods, concept of common pool resources (Ostrom 2005, 28).

[8] The World Meteorological Organization makes this claim of seeing climate as a resource. See http://www.wmo.int/pages/mediacentre/infonotes/info_17_en.html

impact on following rounds of action situations. The internal structure of an action situation focuses on the production of solutions or outcomes. Actors, assigned to positions which literally allow to act, are linked in the action situation. They have information about and a control over actions and are knowledgeable of potential outcomes, possibly including a view towards the costs and benefits of the potential outcomes. Using additions like potential or possibly denote an obvious element of uncertainty, which is that the probability of specific actions leading to certain outcomes is unknowable. Actors are restricted in that respect and cannot fully grasp all outcomes; in other words they are not fully rational in their behaviour and decision making. One essential element of institutional analysis are the rules which both, exist as exogenous variables but which are also applied or co-created in the problem solution. Rules order relationships in the action situation. Three categories are basically in use: operational, collective choice, and constitutional rules. If individuals voluntarily participate in an action situation they must share some general sense that most of the rules governing the situation are appropriate. However, as it says most, there is always an element of ambiguity, which brings another essential element, that of learning. Actors can learn in action situations, either from each other or from the achieved outcomes, and can adjust their behaviours accordingly.

Using above outlined basic principles, the Greater Helsinki vision competition and the continuation process can be understood as an action situation which is faced with many challenges: The external framework conditions over past years have developed a metropolitan policy angle, which partly pushes actors to think and act metropolitan. The national government created some external pressure on the discussion of a metropolitan concept, including management structures and processes.

The competition as such started as a one-off exercise and turned into a continuation process; meanwhile it shifted from the rather informal original setting to the more formal institutional arena of regional planning. Using the concepts of institutional analysis and development, the one-shot action situation turned into a flow of action situations, including a change of institutional composition. Within both action situations, actors from different institutions with different powers cooperated. That starts at the level of the municipality, which can be understood as as collective actors (Le Galès, 2002)9. Helsinki has primacy in the current action arena, being the economic, political, cultural capital. However, the basic situation is asymmetric not least in terms of the problem solution capacity, namely the provision of developable land, which is mainly provided by the surrounding municipalities. The vision, though highly complex, can be understood as a new collective choice rule, prescribing and invoking norms for future development. The vision intends to shape the behaviour of actors, though in its final form, it provides a rather loose framework of orientation and is not

[9] Le Galès quotes the Italian author Pichierri (1997) and his model of the collective actor: Common interests within the city, and those perceived as such; Collective decision-making; Internal and external representation; Integrating mechanisms, and; Capactiy for innovation.

strictly implemented. Sanctions cannot be given, unless the state steps in 10. A positive link is sought with a letter of intent, binding aims and objectives of the vision to investment programmes, partly financed by the state.

However, in the most common case participants bring back the vision into the individual institutional structures and will influence the activities there, as a script framing the mind-sets of actors. The process of taking the vision into institutions brings a separate element for consideration. If we turn away from an institutional actor perspective and bring the individual to the fore, what then can be said about the vision process and its importance?

The first perspective results from post-empiricist research and concepts in policy science, especially from an understanding of public policy as a discursive construct (Fischer, 2003). In a discursive setting, belief systems of policy makers do play an important role, not only in policy making as such but also in administrating decisions. Those believe systems shape facticity and are reflections of the myth of the given. From such a perspective, the metropolis can be interpreted in many ways: It is a metaphor, linking past experiences and perceptions in a comparative fashion to current times. As a synecdoche it stands as pars pro toto, resembling the nation state and its fate. It comes as a story, usually the story of globalization, which helps to accommodate the amorphous challenges resulting from global space of flows (Castells, 2010). It can also be understood as a model, a metaphor elaborated with further details, frequently using existing role models elsewhere (like the global cities London, New York, Tokyo). So, the metropolis is highly symbolic and therefore, as the interpretation of symbols says, it also has a high potential of ambiguity (Fischer, 2003). 11 The 'vision' of a metropolis covers before mentioned categories

Before-mentioned aspects all point out, that the metropolis as a new action arena is a very ambivalent structure and process; its main quality probably being a transitional object (Ache, 2008). On the other hand, in complex institutional settings like the ones posed by metropolitan spaces, the interactions in land-use are of such a magnitude, that a full rational control ultimately will fail 12. The solution might be found in the creation of a 'soft space' (Haughton et al. 2010), which bring in an element of vision making. In a stepwise approach, consider the following remarks:

"What has changed today is the complexity and scale of the mega-city region, and its multiple intersections with virtual spaces and flows of globalization. This complexity and scale not only has clouded our image of the city (even as it has

[10] Which is why the vision would not qualify as a rule 'proper', when for instance applying the IAD syntax (Basurto, Kingsley, McQueen, Smith, & Weible, 2010)

[11] And from a more radical perspective, it also has the quality of being an 'empty signifier'.

[12] In a sense, this argument is pointing back to the old debate about rational vs. incremental perspectives. The system maps on drivers of the land-use system, provided by the foresight exercise in the UK, are a good demonstration of that complexity (The Government Office for Science, 2010).

reinforced its centrality), but also has clouded our very ability to construct an image of the city region. This of course has direct consequences for the ability to govern one. If we cannot imagine, then we cannot manage." (Neuman & Hull, 2009, emphasis added)

An approach applying an 'incrementalism with perspective' might be more appropriate (Hutter, 2006) in such a situation. The incremental action is taken by various institutions. The perspective is provided by the vision, an imagination of the future. The article actually proposes to reverse the argument made by Neuman and Hull (2009): We can only manage if we can imagine!

3. Metropolis - creating a new script

Section will follow later

4. Re-reading the vision exercise – a new script for the Metropolis?

In terms of evolving planning practice, a number of dimensions become visible from the previous sections that result from such an exercise: the competition setting; the quality of an informal instrument; the intention to create ownership by experts; the attempt to create an accord on the basis of a vision; but also the coexistence of many visions, including that of planning experts and that of politicians. What more can be learned from such a vision process, in terms of the metropolis and its governance?

Figure 2 Metropolitan co-operation arrangements (see Annex)

The GHV 2050 competition and follow-up process attempted to create a vision to facilitate planning processes and cooperation at the level of the metropolitan region. Figure 2 (OECD, 2006a) provides an overview on metropolitan co-operation arrangements, using already existing examples from around the world. Besides organisational forms, for the current argument it is also interesting to see the row on long-term strategic vision in Figure 2. The element of having or not having a vision is a distinguishing moment. The academic discussion here takes an even stronger stance, as the presence or absence of a vision is considered as one binding if not essential element in the strategy formation process. We have already introduced the quote from Neumann/Hull alluding to the 'un-imaginable' metropolis, and it was also said, that in principle a reversed version of the argument is suggested here. The example of the GHV 2050 process has shown that developing a vision is resorting to a soft instrument to steer the otherwise distributed planning action in a setting of partly cooperating, partly competing institutional actors. The exercise of 'imagining' or 'en-visioning' had a boundary

spanning element, and at least attempted to change the course of events, not to speak of breaking path dependency. The material and normative aspects of the vision provided sufficient space for interpretation, due to the principal fuzziness of their character (de Roo & Porter, 2007). However, the fuzziness contributed to the communication function, in both the expert face-to-face communication settings but also beyond that in terms of a wider communicative or symbolic setting. Following system theory ("climate as a resource,") that communication function is very important to create autopoietic 13 self-adjusting systems. Following the argument made by Fischer (2003) on the discursive construction of public policy, the highly symbolic value of the metropolis can penetrate the institutions and change policy and action.

And, as it seems, such strategies can be found in many other places over the recent past and provide further prima facie evidence (P Ache, 2011): 'Milan 2030' attempted to create an 'open space as the main resource to act upon to ensure democracy'; 'Zaragoza 2014' wanted to keep momentum by using the ExPo Landscapes 2014 as an experimental continuation of ExPo 2008; 'Belgrade 2021' provides an 'open space for visions'; 'Turin 2011' applied a communication plan utilising amongst other elements 'images, stories, narratives'; 'Bologna 2015' works with 'seven cities' and focuses on habitability; and finally 'Paris 2100' is considered a general 'consultation' exercise. Actors in metropolitan spaces are obviously experimenting with many similar processes and try to utilise the various potentials or capacities provided by such vision exercises.

The motivation side of actors can be further explored using the idea, the metropolis resembles a common pool resource. On the basis of before findings and with a view to the specific set of actors, this statement needs to be adjusted; looking at the GHV 2050 example and for the time being, the metropolis has rather a 'club good' character. The set of actors, the addressees, even aspects of the wished for metropolitan society show aspects of 'exclusiveness'. The club good feature can also be seen as the main reason, why no conflicts became visible. Using concepts of 'agnostic pragmatism', no real antagonistic behaviour was obvious during the process. The absence of conflict relates not only to the chosen aims and objectives, the material sites of which seem to go together seamlessly, but also in terms of the processes. At the time of writing the paper, some form of antagonistic behaviour becomes visible. Mergers and other forms of joining up municipalities have been put up for discussion by central government, where cities assess their options by looking into the advantages or disadvantages of the proposed new institutional structures, and not all actors subscribe to the option of a metropolitan merger around Helsinki. The conflict finds here a different arena. The stakes are negotiated and rejected, mostly in or between different political bodies, not surprising with municipal elections at the end of 2012. Politicians fear a cut back of capability, especially in economic questions, which are overly understood as competitive situations; other regarding

[13] Applying the thoughts of H.R. Maturana and F. Varela, who developed this notion to describe self-adaptive systems.

preferences fall back behind a maximizing strategy in competition for exclusive investments. In other words, a club good perspective (if not even a private good perspective) takes over.

A critical comment made by Allmendinger and Haughton (2010) about soft-spaces and soft-planning and the post-political condition is evoked here:

"This body of literature emphasises how a consensual pluralist mainstream organised around loosely defined and hard to refute 'feel good' issues and labels such as sustainable development (and spatial planning) can in effect deny legitimacy and influence to more radical alternatives, in the process narrowing the search for creative approaches to planning". (Allmendinger & Haughton, 2010, p. 804)

On the basis of his analysis of UK developments and a critical comment on a debate of the city region, Harding (2007) emphasises that not all phenomena derive from a neo-liberal logic and nuances count; his claim is more positive in that "a much more fundamental rethink [is needed] of what it means to be progressive in an age characterized by perforated sovereignty and stretched urban hierarchies … but increased urban accessibility and more flexible work patterns …"; and further "(w)hat we currently lack are the conceptual frameworks and practical tools which might best facilitate such a balance", with balance referring to regional growth patterns combined with social and environmental benefits (Harding 2007, 456). The practice of the Greater Helsinki Vision process can be seen with a similar perspective. Although some institutional actors claim, that already the cooperation of the fourteen municipalities as such constitutes a creative approach, a more radical perspective was left out.

The lack of a radical perspective, in particular regarding issues of breaking up well-trodden paths, can be linked to the idea of a metropolitan identity. The metropolitan identity is not only an issue for workshop settings, the metropolis brings or requires as such a new 'civitas', a newly defined political subject. In the words of Agamben (2006):

"Going back to the metropolis, my idea is that we are not facing a process of development and growth of the old city, but the institution of a new paradigm whose character needs to be analysed. Undoubtedly one of its main traits is that there is a shift from the model of the polis founded on a centre, that is, a public centre or agora, to a new metropolitan spatialisation that is certainly invested in a process of de-politicisation, which results in a strange zone where it is impossible to decide what is private and what is public." (Agamben, 2006, 2)

The polis here is the city constituted by the subjects and by identity, both linked to the power to act, as Agamben continues at a later point. Citizens and their inclusion or exclusion gets into focus as a central actor in the entire system. Agamben claims, that the metropolitan *spatialisation* invests in processes of de-politicisation. In the view of the GHV 2050 jury decision, a contribution like City

2.0 that wants to establish a social silicon valley on the basis of city-cells and direct decision making by citizens, has been selected as a resourceful idea countervailing those perspectives. City 2.0 adds one dimension to the new governance setting by introducing basic democratic features. These are combined with strong positive leadership (open mayor) but also with regional citizen assemblies. At the core are the citizens and their communities. The local administration supports their ideas and motivations. This support is channelled through the "city-cells", neighbourhoods consisting of 10.000 to 25.000 inhabitants. The support can be money, expert services or space.

GHV 2050 and the other examples mentioned here are attempts to shape life worlds which are relevant for a very large population segment in Europe. In statistical approximation, geographical Europe has about five metropolitan regions of more than five million inhabitants, seventy larger than one million, and about 650 metropolitan regions with between 500,000 and one million inhabitants, though they are not equally distributed across the European space (Wiechmann, 2009). The latter group of metropolitan regions obviously accommodates a rather large sum of inhabitants. The hypothesis of the collective actor city (Le Galès, 2002) applies to the various citizens as actors, too. It is of importance to look into issues of identity or loyalty in an actually very open or porous situation, with reference to the transitional quality of the metropolis, and how the relationships between citizens and sovereign entities are constituted in negotiated and renegotiated processes (Paasi, 2003). With the help of a vision and matching symbols, we could build the metropolis as an imagined community (Anderson, 1991; Appadurai, 1996). There is of course the risk, as other authors critically claim (Swyngedouw, 2009), of empty signifiers and a post-political agenda in favour of a neo-liberalism (or elite socialism). That argument opens up our alertness to critically address the experiments and to make sure, that the 'wronged' parts of society can claim the rights they are entitled to. As is demonstrated in various European projects (Barreiro, 2010), without that aspect of forming a community and identity, the entire process will certainly be incomplete, and we will lack crucial elements of the futures which would otherwise not be.

And, how about the new-metropolis? The movie itself has received much critical acclaim, and Fritz Lang reportedly dissociated himself from the closing sentence, 'the mediator between hand and brain is the heart!' as a political motto. The motive remains though; the construction of a new metropolis with a new 'm-machine' of unknown providence but huge expectations is high up on the agenda. There is a new mediator between hand and brain, seen as the super-manager of change; looking at the requirements almost a super-natural being, maybe a new but definitely human android? Not only the current exercise of GHV 2050 demonstrates that there is still a prevalent idealistic vision; across all observations, in the end the metropolis becomes actually the 'm-machine', the highly symbolic '*Herz-Maschine'* (heart machine) in the German original of Lang's movie.

Annex

Table 3.4. **Main purposes of a selection of metropolitan co-operative arrangements**

	Informal co-operation networks (association/ platform/metropolitan conference)	Metropolitan authority/agency		Metropolitan government	Amalgamation	Tax-base sharing and redistributive grants
		Single-purpose	Multi-purpose			
Examples	Regio Randstad (Plateform) Lyon Urban Region, Council of Stockholm Mälar Region, Bilbao 3I – Metropolitana, Torino Internazionale (Associations) Regional conference (Rhine-Ruhr)	Many US cities Mexico City (large number of sectoral agencies) Athens transport agency	Montreal Metropolitan Community Greater Vancouver District Urban and Agglomeration Communities in France	Greater London Authority Stuggart Verband Association Portland Communidad de Madrid and Region Ile-de-France (Paris) as existing regional governments	Montreal, Toronto Busan/Seoul in the 1960s Madrid in the 1960s Melbourne in the 1990s	Minneapolis Saint-Paul Stockholm County Some municipalities within Paris Ile-de-France Busan/Seoul
Administrative boundaries	No change	Possible creation of a new layer		Building on a regional tier or creation of a new regional tier with an elected body	Disappearance of municipalities. Possible creation of sub-local units	No change
Economies of scale (cost saving)	No	For one public service only	For certain public services only	For certain public service only Expected (??)	Expected (??)	No
Sharing of public services	No	Yes, for one public service only	Yes, for certain public services only	Yes, for certain public services only	Common	In a limited way
Specific advantage	Great flexibility Might provide impetus for further co-operation	Cost saving for a particular service Better management of a metropolitan function	Idem to single-purpose + integration and co-ordination of sectoral policies	Integration and co-ordination of certain sectoral policies	No fiscal disparities Stronger political power One decision centre Better equalisation of costs	Reduce fiscal disparities Still allow some variety
Specific disadvantage	Does not tackle issues such as territorial spillover/negative externalities/equity Weak implementation capacity	Emergence of sectoral constituencies	Emergence of the funding and legitimacy issues	Democratic cost	Lack of creative diversity Democratic cost	Separate the costs and benefits of local public services
Long term strategic vision	Yes, in many cases	Yes, in many cases for economic development agency but risk of avoiding the multi-sectoral aspects of urban development	In some cases only	Yes, will depend on the administrative boundaries of the new structure	Yes, will depend on the administrative boundaries of the new structure	No

Note: This table provides a typology of metropolitan governance arrangements previously discussed according to the different objectives that calls for horizontal co-operation. This typology is not exhaustive. The selections of different options that it includes are not mutually exclusive, as some metropolitan regions combine several options (e.g., Montreal experienced an amalgamation of 27 municipalities whilst a multi-sectoral agency was created at the wider metropolitan level).

Form and Position：The Study of Building Capacity Distribution

——with discussion about the common problems in China's city development and urban planning

Shanshan Li , Qingniao Shen

Abstract

FAR (Floor Area Ratio) is an important index to understand and study the spatial development pattern of the city. In the condition of a given FAR, the spatial distribution of the capacity always represents the city form in particular place. A good design proposal is necessary to give a comprehensive treatment to the different contradictions in the site. The contradictions contain both external problems such like how to deal with the relationship between the site and surrounding area and internal problems such like how to deal with the contradiction between orientation and landscape. In the process of historical period, the distribution of FAR is highly explored by architects and urbanists such like Walter Gropius, Rem Koolhaas, MVRDV and so on.

In this paper, from a case study of urban design in Chongqing(China) , a methodology to create a understandable city form is present. This methodology is usually used at the beginning of a design proposal. Without considering the architectural style and material in advance, the urban form can have a visual assessment through the study on the distribution of FAR. Diverse spatial forms which come from different capacity distributions are explored, and then dealing with different contradictions, the urban designers need to give a contrast and assess between different forms, and finally conclude the optimize one.

Combined with the case study, the authors argue the complex relationship between FAR, site coverage and architecture height. And the general problems in China's city development and urban planning are also explored and discussed.

1. Density and FAR in city development

In the past ten years, China has a shocking urbanization process, with more building ,more car, more roads and so on.In this process , we can see hope of improving, which is different from many western countries. we should see the

advertage of the Chinese urbanization ,which takes along with more opportunity of working ,more goods. But on the other side it also have more problems such like high density of city environment , traffic jam and poor quality of building. It is well known that urban planning is a subject about how to distribute resources effectively, especially for land resources and a governmental decision on the goal of urban growth. At present, with the rapid urbanization and commercial development, the maximum economic that benefits from the given site is the main purpose of the city developer. So impose restrictions on density in urbanism becomes more and more important for the city developers. On the other side ,all the city governments have to face the basic contradiction between guaranteeing the continuous development of the city economic which means a narrow urban space with high density and avoiding the overdevelopment which meaning the damage to a livable city and a consummate image of the city. What is more , for the citizens, a city with high density is not suitable to live. As a result of all the city people paying attention to the density, FAR becomes an important index to deal with the urban spatial development mode, and it is also a kind of effective measures in the present urban planning and construction control of the city.

The concept of density in urbanism is frequently used to describe the relationship between a given area and the number of certain entities in that area. These entities might be people dwellings, services, or floor space. However, the simple fact that density is used in , for instance , design requirements, plan descriptions and communication between parties, does not mean that it is used correctly or to its full potential.①. In the book “farmax” ,density means the amount of available space per person. FAR (floor area ratio) means the total floor space of a built area to the total size of its lot. In the urban planning in China, every given area has a maximal FAR which is control by the local plan state.

For a given FAR of limited conditions, which is the basic premise of Chinese city planning and architectural design, different FAR means the space what can be built of local area ,also means distribution of urban form, while the same FAR can produce many different ways of space distribution, which lead to different space forms and architectural forms. In the condition of a given FAR, the spatial distribution of the capacity always represents the city form in particular place. A good design proposal is necessary to give a comprehensive treatment to the different contradictions in the site. The contradictions contain both external problems such like how to deal with the relationship between the site and surrounding area and internal problems such like how to deal with the contradiction between orientation and landscape.

In the process of historical period, the distribution of FAR is highly explored by

architects and urbanists such like Walter Gropius, Rem Koolhaas, MVRDV and so on.In this paper, from a case study of urban design in Chongqing(China) , a methodology to create a understandable city form is present. This methodology is usually used at the beginning of a design proposal. Without considering the architectural style and material in advance, the urban form can have a visual assessment through the study on the distribution of FAR. Diverse spatial forms which come from different capacity distributions are explored, and then dealing with different contradictions, the urban designers need to give a contrast and assess between different forms, and finally conclude the optimize one.Combined with the case study, the authors argue the complex relationship between FAR, site coverage and architecture height. And the general problems in China's city development and urban planning are also explored and discussed.

2. Historical research on density

During the last century, density has used to show the problems of the city. There are some arguments about the lack of relationship between density and form and some people think that the use of density in urban plan does not create a more livable city,
After a period of lacking the interest of the density, the research of Rem Koolhaas makes the concept get more attention in urban research fields.In the early research to Manhattan and New York, he used "crowded culture" to summarize the essence of Manhattan. "Crowded culture" can be analyzed as the skyscraper and high density of the city. What is more, its deep meaning is the crowd of the program in Manhattan. What he wants to show is the change of life style in the big modern city. The skyscraper changes cities culture, people can't gain a single function through a single plot. On the research of Rem Koolhaas, density is used to show the mixed culture of big city.

MVRDV does a research of the Netherlands and other states, seem to be filling up with a suburban "matter" of low cost housing, low rent offices, warehouses and other low density elements. The book "Farmax" examines the possibilities of how are we to cope with the matter that is turning our environments into a "sea of mediocrity", one vast "greyness", an education of difference and individualism and it is possible to reconsider this situation by carrying density to extremes and ruffling the texture with inserts or polarities.②. In addition, the light, the sunshine and related issues such as noise is also parts of the research content. In the study of MVRDV it clearly shows that in the extreme condition, any requirements, rules or logic are pure and unforeseen. They transcend the art intuition. In the research , the most important thing is how to change the restrict into possibilities.

Besides the mentioned arguments for a revaluation of density, there are two general

developments in the process of urbanization which can be identified that further legitimize the study of density. Firstly ,recent changes in how city building is organized have created a greater need to relate development programs to spatial qualities. Second, the trend in the increase in space consumption and the environmental, economic and social effects associated with this trend point to the need for research into the relationship between the quality and capacity of space.

Here we can see that the concern of density does not only focus on density as research method of a city, but also more and more urban researcher, urban planners and architects use creative ways. In the paper what is discussed is how to provide a planning and design method at the early stage of the design.

3. Form and position: a case study on FAR

Under a given FAR of the site, with no doubt, it means a fixed building capacity. But in such a fixed space size, urban design shapes as many as different possibilities, it just like putting certain capacity of water into different containers. So different containers show different forms and the different types of forms have different advantage and disadvantage. For example, a proposal with high level and low density of building-covered area and another proposal with low level and high density of building-covered area have many different impacts on the city.

In the numerous of design proposals, as the research of density in the works of MVRDV, they can have different qualities between the relation of a performance. So comparing with the different kinds of works, what the designers need to do is to choose the best one. If with a kind of design research to approach, in acme condition, the proposals can be measured with any demand, rules or logic in a pure form, which makes it to trend optimal design scheme through the assessment.

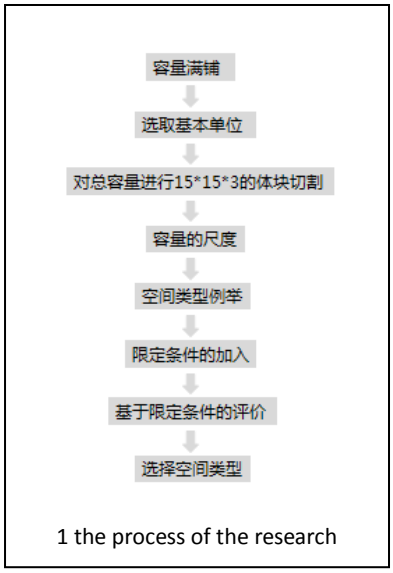
In this part, a specific case in Chongqing will be discussed to explore the planning and design method in a residential area planning project. What needs to be valued is the limiting condition which makes the design to be more logical in the project. What is more, the method is useful for the urban planners to optimize the space form in the urban design projects.

This methodology is usually used at the beginning of a design proposal. Without considering the architectural style and material in advance, the urban form can have a visual assessment through the study on the distribution of FAR. In the design process, firstly it puts forward different space forms which come from different distribution of density, then urban planners need to give a contrast and assess between different forms, and finally confirm one unique optimal space form. In the process, the

interaction condition will be appraised such like physical environment, behavior patterns, urban image and so on.

1) Background of the project

The project is located in stone pillars which is a small city in Sichuan province, China. It belongs to the new district. The main river of the city is close to the site which brings a realizable river view. The site is also along the main road which leads to convenience transportation. On surrounding environment there is a primary school near the site and some residential spaces.



1 the process of the research

The land use of the site contains green corridor, commercial and residential in the plan of government. Based on the space research of the elements on construction density and city's skyline control, the project tries to make it to be a new important area supporting residential, large-scale commercial, office services and so on. In the future it will become a new center area of the city.

For the urban planner, the most important thing is how to balance the public interest and the city development. In the project, the designer have to maximize the development scale in a given FAR, which is the main purpose of the developer. On the other side, the optimization urban spaces need to be created. So how to balance the two parts is the main question.

Before coming into a detail design, the logic of building space derivation method is discussed. The method can be separated into four steps. In the given FAR capacity calculation need to be discussed firstly. Secondly several typical space forms will have to be given under the certain FAR and certain capacity. Then contrast and assess between different forms. The interaction condition will be appraised such like physical environment, behavior patterns, urban image and so on. This process is the most important step. Finally using the chosen proposals (not only one proposal), the designers have to give more optimization and adjustment scheme.

Therefore, the logic of building space is discussed using a derived way in the early step of the design stage, but that does not means that the city design have the absolute most optimal solutions. In the selection of the evaluation, there was not the "correct" solution. This way just try to show a research attitude that in the design process there is a relatively rational way to cut into the study.

2) Four steps of the research

i. capacity calculation

In order to select the typical spatial types, the use of extreme conditions on the basic capacity can have a better effect in a fixed development capacity. So according to the given FAR and the land area, the biggest capacity of the project can be known. The biggest capacity means the maximal capacity calculation that can be built in the project.

2 capacity calculation

The Maximal Capacity Calculation= FAR * (Area of Fabric)

After that, the maximal of the construction spaces should be calculated. The maximal of the construction spaces means the rate of coverage which is given by the local government times the area of fabric. At the same time, without thinking about the possible existence of sunshine distance requirements, build capacity in the maximal of the construction spaces. The building should cover the construction spaces completely. After that the least layers and the lowest height can be known.

The Least Layers= The Maximal Capacity Calculation/ [(Area of Fabric)* (The Rate of Coverage)]

This limit layer (height) looks be like an unreachable situation and also can't start successfully in practical projects, but it can effectively delimit the boundary, making more intuitive understanding on the capacity size of this typical project for the urban planner.

Then the basic architectural dimension will be determined. There are two typical buildings (7 layer and 12 layer). According to each building there is a fixed construction area, the number of the building can be calculated.

ii. typical space forms

There are several factors to decide the forms of the space such like height, building forms, road density and so on. Also, the different combinations such like “I” “L” “U” can have different space visual experiences. So for different height, there are high-rise building and multistory building. According to different building layouts, there are different space type examples such like enclosed layout, half enclosed layout, linear

3 numbers of two typical building

layout and so on.

In order to improve the operation of the model, firstly the basic scale of one layer is used to cut the whole capacity. This process looks like cut the cake ,also when the whole capacity is cut into smaller and basic ones(15m*15m*3),the next thing is to group them and create a new form. On another word, it can be operated like playing the LEGO.

4 typical space forms

What should be noted is that in the process of taking examples of different space forms, there is not a result to put forward all the types. And the only thing that the designer need to do is trying to aim at different emphasis on the layout and give the typical and spatial types.

iii. contrast and assess

5 contrast and assess

In the whole process of the derivation of space form, contrast and assess the space performance is the most important step. The assessment is not a fixed standard measure. By contrast, in the different conditions and in different sites the factors that can influence the layout of the space are also different. These factors do not need a precise computation but the site investigation and the emotional thinking which are made by the designer.

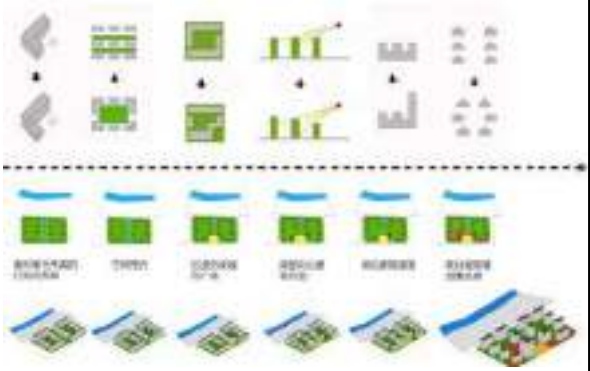
In this case, because of the functional requirement of the house, factors on light of the residential space and ventilated condition become the most important one to be considered first.

Secondly the public spaces are also play a positive role in social interaction. Also public space means more green plants and a more livable environment. What is more , considering the location of the site , there is a good river view which means the designer need to make more liver of the site to have the river view. Lastly the city environment also has important effect on the space forms. With the goal of becoming the a new center area of the city the space form need to create a impressive image of the city including the skyline and the public space of the city.

For the specific environment, a suitable standard is created to contrast and assess the

different proposals. After the urban designers give a contrast and assess between different forms, and finally the optimize ones are concluded. In the part, exclusive method is an effective way .

iv. Optimization and adjustment



6 optimization and adjustment

Based on the combination of limited conditions, many types of space layouts do not meet the requirements. So these space layouts will be deleted. Then the designer can choose one or two types to give more optimization and adjustment and finally choose the most suitable one. In the process of optimization and adjustment, considering the specific situation of the environment, more adjustments are added to the chosen proposal. The adjustments are more focused on the detail of the space forms. For example ,in the city environment ,a land mark is useful for the image of the site, so the designer improves the height of one building to 100m while other building can be more lower. The liner layout is a good way for the building to have enough sunlight, but considering the feeling in the site, some buildings turn to face east and west so that the whole space can have an enclosed feeling. Considering the sun light, the southern building should be lower than the northern ones. Al l the adjustments makes the proposal be more effective.

4. summary

In the China's urban development and planning, density is one of the essential fields of urban questions. The general problems in China’s city development and urban planning are lack of thinking on integrity. Most of the city developments only pay attention to the economic factor. Some others consider the sun light. But how to balance all the factors is the main problem. In this essay, a methodology to create a understandable city form is present. Used at the beginning of a design proposal, this methodology does not consider the architectural style and material in advance so that the urban form can have a visual assessment through the study on the distribution of FAR. During the process the urban designers give a contrast and assess between different forms, and the designer can have an integrity view which is the most valuable part of the methodology.

SYNAPTIC SPACES OF EUROPE: A CHALLENGE FOR SPATIAL PLANNING

Cecilia Scoppetta [1]

Abstract

On the background of contemporary rescaling process and of the current broad rethinking of some relevant concepts – such as "region", "territory", "locality", and "space" – the case of the Baltic Sea Macro-Region, and of the related place-based EU successful «experimentalist» strategies highlights the emerging of «soft spaces» as new forms of territorial organizations.
These clearly appear as a result of EU "soft" ("lateral") territorial approach outlining a really innovative multileveled spatial pattern.
By using a biological metaphor these soft spaces may be intended as «synaptic spaces» clearly claiming for a radical shift in planning approaches, by moving towards soft and synaptic planning practices involving «'soft process' of negoziation and learning».
Features of these spatial configurations drawing new continental geographies are explored by highlighting the role both of images/imaginaries and historical/geographical/cultural roots, to be used (re-interpreted) in the de-construction/re-construction of the contemporary European spatiality.
In this sense, we may say that, according to Faludi «geography still matters» (and also history!). In fact, Baltic Sea cooperative networks (that is: the basis of the new EU strategy) can be seen as a return to what once was an important communication channel for thousand of years and flourishing trade in the region. The model is that of the Hanse League, based on flexible not hierarchical (mainly economic) «weak ties» – or «loose coupling» – among autonomous cities (but not exclusively), which share a transnational unbounded Hanseatic "space" (not "territory") and which are periodically (not always) able to act as a collective actor to achieve local collective competition goods avoiding the «trap of joint decision».
It remains to be seen whether such a strategy – which has proved successful in the Baltic area – will be so effectively applied to other specific spatial and cultural contexts (with their differences in challenges and potentials), such as the Danube corridor, or to the much more "explosive" Mediterranean basin.

1. Introduction: on contemporary rescaling processes.

Since the end of the 70s, many scholars have focused on the emerging of metropolitan regions as dominant economic units in global society (Storper, 1997; Sassen, 2001; Scott, 2001) and as a key level supplanting national/regional/local

[1] Sapienza University, Rome, Italy – ceci62@libero.it

governments as the place of decision-making (Altshuler *et al*., 1999; Katz, 2000). Some of them have linked the rise of these entities to the shift from government to governance (March & Olsen, 1995), within which network forms are transforming, supplanting, or supplementing historical structures such as markets and hierarchies (Castells, 1996). Three main (often interrelated) paths have been explored: one is *networking*, encompassing processes and flows, actors and interest, organizations and structures, ideas and capitals. The second is *governance*, also claiming to engage a wider range of sectors and interests in governing, and the third is the *scale* of governance.

Governance research has pointed to the importance of processes of de-territorialisation and re-territorialisation in re-defining governmental boundaries and jurisdictional competences. Network analysis has inquired into emergent forms of interest intermediation that exceed or bypass established institution of territorial representation. Both emphasize the relativisation of geographical space – in particular of bounded space – as a determinant for policy action; both share an interest for phenomena of re-scaling of State action and for shifts in the meaning of territoriality for public policies.

Research traditions associated with scale (or scaling) – intended as the identification of the proper placement of governing responsibility – have a somewhat longer history than governance or network traditions. Antecedents include coordination among levels of government (Hambleton, 2003; Dijst *et al*., 2002), decentralization from higher to lower levels, devolution of functions among levels, and subsidiarity, which attempts to locate functions at the most appropriate level. But now there is something new: urban and regional studies have recently experienced a re-assessment of geographical notions – such as "region", "territory" and "locality" – in face of emergent socio-spatial phenomena that highlight an innovative concept of spatiality. In this sense, spatial re-scaling maybe represents one of the most significant contemporary changes in territorial interpretation and (consequently) planning.

Critical geographical studies have identified four geographical dimensions as co-constitutive of socio-spatiality: place, territory, scale and network. Among these, *territory* and territoriality entails the enclosure, bordering and fragmentation of social relations. Once established, these bounded territories constitute a «fixed, stable and immobile grid» and an «element of fixity on an otherwise changing geographical landscape» (Brenner, 2009), which it is difficult to modify.

Scale and scaling entails the vertical differentiation of social relations among, for example, global/State/regional/urban/local levels, as it is the assignment of responsibilities and the social construction of capacities of institutions (Miller, 2009): «the focal setting at which spatial boundaries are defined for a specific social claim, activity or behaviour» (Keil & Mahon, 2009). In this sense, scale-shifting refers to changing relationships, sets of participants, resources involved. Both scaling-up and scaling-down can produce a more favourable political opportunity structure for particular interests. Scale-shifting (or scale-jumping) also relates to the existence of extra-local and inter-scalar rules regimes that «constrain and channel the strategic options and tactical behaviour of local actors» (Miller, 2009): higher level institutions establish/limit the scope for policy and actions at lower levels,

enabling/preventing democratically-made decisions. In this sense, besides shifting responsibilities and capacities between levels of government, re-scaling also can involve the invention of new scale of actions: «scale is the actor's own achievement» (Keil & Mahon, 2009), because «we scale politics to our own purposes» (Magnusson, 2009).
But rescaling does not only mean the shift of responsibilities from *one* level to *another*: it also implies the emerging of multi-scalar interactions and of «a governance environment characterized by multiple constellations and multiple coalitions for development that define a geography of governance that is flexible, often overlapping, and increasingly autonomous from given territorial jurisdictions» (Gualini & Woltjer, 2004). This approach goes beyond rescaling in recent theoretical literature (Brenner 2003; Salet, 2003). By following part of the logic inherent in its predecessors (coordination, decentralization, devolution, and subsidiarity) aimed at responding to the breakdown of hierarchy, a principle behind rescaling was to find the most appropriate scale of governance for policy delivery. The evolution of terminology reflects two substantive facts. The first is the evolution of thought regarding institutional design and policy, which has recognized that hierarchical bureaucracies, command and control are not as effective in a flexible global economy and democratic institutions. The second is the emerging of governance alongside government.
But the main innovative feature of multi-scalar large institutional networks seems to be their learning dimension: they evolve and *learn* through complex processes in ways that are distinct from the ways that "mere" organizations or individual institutions. Grasping this peculiar way is essential to understand how they function/malfunction, how they create, decide on, and execute policies, strategies and plans, and how they exert power and influence to obtain outcomes, and how, in turn, they are affected by power and influence of their own members and by those outside them.

2. European soft synaptic spaces.

The interest on territorial changes due to globalization has inevitably led to a broad rediscovery of the spatial in policy disciplines (Le Galès, 1998; Salet & Faludi, 2000): the linkages among these emergent concepts – territory, governance, networking, rescaling – have been deeply investigated (Castells, 2001; Scott, 2001; World Bank, 2003) and spatial planning has become a fertile field for this analysis (Vigar *et al*., 2000; Albrechts *et al*., 2001; Salet *et al*., 2003).
Undoubtedly, the Europeanization process has highly contributed to this renewed interest. Reasons are firstly to be researched in the fact that European *space* – a borderless single market within which internal space mobility – coexists with national *territories*. But EU can no longer simply be viewed as a Europe of nation-states or a putative supra-state: it can rather be conceptualised – and this is its spatial novelty – as a multileveled or networked space of governance.
Further reasons can be find in the fact that, even if Brussels had never been granted a specific competence, interest in territorial issues are related to EU regional policy since the mid-70s, as it was conceived to balance development disparities between

countries focusing on the spatial impact of regional development within the framework of the Structural Funds and the objective of social cohesion. And, undoubtedly, both agricultural and regional policies (that is: the most of the European budget) presents striking territorial effects. In addition, during the '90s, EU policies started focusing on the role of cities as growth engine, in the light of the need of competitiveness to face the changes due to globalization. Cremaschi (2004) highlights four different tiers of the «wedding cake» of EU spatial policies: the basis of this "cake" consists of regional policies, the second tier is infrastructure networks and trans-European cooperation, the third is urban initiatives and the last – according to an idea originated in the Council of Europe as early as 1964 – corresponds to a spatial development perspective, that is a policy document aimed at guiding integrated strategies of territorial planning of member states. Cremaschi (2004) also underlines a somewhat double character of the concept of spatial development, a neologism which «combines the German practice of regulatory planning of physical and environmental factors with the British concern for local economic development». Thus, the European spatial logic has led to a sort of "light" Europeanization, which clearly refers to the three relevant contemporary issues of networking, governance and rescaling. In this sense, the spatial novelty of this soft and "lateral" approach can be clearly observed in the multi-fold terms and concepts that are used in EU territorial policies, since they have at the same time both a physical and not physical meaning. The term "polycentrism" (Davoudi, 2003) is the main example, because it refers to physical features, such as a multiple centres and diffused growth rather than core-periphery distinctions, but it is also connected with the idea of multi-level governance, which implies (not physical) partnerships between EU institutions/national governments/regional/local authorities. It is easy understanding why this flexible notion of polycentrism – which refers to forms of non-territorial politics which emanate from a multiplicity of (physical) *sites* and which cannot be reduced to a single centre – has become a useful way of thinking about the decentred, de-territorialized (and re-territorialized) dynamic nature of Europe, since this term has a much wider applicability to political and societal transformations under conditions of globalization (Scholte, 2004; Delanty & Rumford, 2006). Another useful neologism is "territorial cohesion" that link together both spatial and economic dimension.

This means that the «governance turn» in European studies (Marks *et al*., 1996; Jachtenfuchs & Kohler-Koch, 2004; Bache & Flinders, 2005) corresponds to a «spatial turn» (Berezin, 2003) because of the transformation of involved spaces. In fact, rather than being primarily concerned with state-building or the institutionalization of governance structures, the EU is centrally concerned with the construction of European space(s), and with the ways of understanding them, that is: a result of processes by which these governance spaces are constructed, showing the way space itself is constitutive of social and political relations.

These particular features of the (still ongoing) EU construction, on the background of the contemporary spatial re-scaling, have led to the emergence of the so-called "soft spaces" (Waterhout, 2009; Faludi, 2010b; Haughton *et al*., 2010): multi-area sub-regions in which regional strategies are being made between or alongside formal institutions and processes. These spaces are often overlapping and characterised by

fuzzy geographical boundaries. In a certain sense, we could also talk about "synaptic spaces", whose spatial dimension constantly changes as it is given by the lighting up and turning off of inter-relationships involving not only action potential, but also knowledge as a further learning value towards a co-evolution of places and planning approaches and styles (Faludi, 2008). Developing a new imagination of spatial phenomena may enable re-assessing their socio-political features, challenges and potentials. In fact, this innovative spatial concept means re-interpreting space as an open and dynamic multiplicity of relations through which power is being constantly re-shaped. This implies changes in powers across the existing tiers of decision-making, original scales of intervention, new actor constellations, and variable geometries of governance. According to Waterhout (2009) and Faludi (2010b) these emerging "soft spaces" seem to require a concept of soft rather than hard planning (for soft rather than hard spaces) to be used wherever challenges cut across boundaries demanding innovative joint action.

3. Using a biological metaphor to define the main features of synaptic planning approaches.

A fascinating suggestion is given by studies on self-organisation in the research field of biology and, more generally, on the topic of complexity and of artificial intelligence (Morin, 1983; Prigogine & Stengers, 1979, Anderson, 1999; Kauffman, 1995).

As it is known, the biological evolution implies that microscopic components, characterised by a simply structure and strong and relatively rigid ties, constitute – through their interaction – the constructive elements of more complex systems with weaker and more flexible ties, which allow the adaptation to unpredictable environmental changes. This highlights the relevance of resilience rather than stability: the latter is what allows a system to quickly come back to its original status after a temporary perturbation; differently, resilience allows a system to adapt itself to perturbations, especially if these are deeply different from those it already knows, and to absorb unforeseen shocks, continually adapting and evolving so as to resist collapse. In fact, the concept of resilience is defined as the «measure of persistence of systems and their ability to absorb change and disturbance and still maintain the same relationships between population or state variables» (Holling, 1973). In other words, a resilient system is formed by the dynamic interplay between deterministic forces and random events, structural factors and human agency, linear paths and contingency.

The example is the self-organization of living organisms (Bak, 1996): they are not a kind of automaton, directed from outside by a deterministic program, but systems whose state lies *between* the two extremes of a rigid, immovable order – which cannot change without being destroyed, as the order of crystals is – and a constant renewal without any stability. This state is clearly not static, but it allows reacting to random perturbations (Waldrop, 1992). In this way, transformations are not simple destructions of the already existing, but re-organizations enabling the emergence of new features, which can be a new structure or a new behaviour influenced by new structures (Holland, 1995). Every combination and renewal of a single part implies a

different functional organisation, that is: a different meaning of the relationships established among different parts. Therefore, the most relevant aspect of self-organization is the sense of self-creation (Atlan, 1983).
This means that the self-organisation of a system can be conceived as a «not banal machine» (van Foerster, 1981), which – differently from a "banal" one – does not work with a predictable input/output logic, by simply responding to the specific need for which it has been constructed. This is because a "not banal" machine is characterised by its own internal status that can generate multiple outputs.
A further feature of self-organization of living organisms obviously is its complexity: biological systems, in fact, are at the same time something more and something less than the simple sum of their parts. This allows the emerging of features deriving from accidental consequences and secondary products of interaction, and these, in turn, through a feedback mechanism, stimulate each single part of the system towards the expression of their specific potentialities. An example is given by the way in which culture or language – that is: features that exist at the level of the system as a whole – retroactively work onto the single components, by allowing the development of potentialities of each individuality. In fact, as well as spatial studies, contemporary sciences of complexity are marked by a crisis of traditional "boundaries": between concepts such as "producer" and "product", "cause" and "effect", "one" and "many", "organism" and "environment" (and also between "science" and "not science"). This leads to the concept of «recursive organisation» (Morin, 1977), in which effects and products are conceived in turn as necessary for the production itself.
Transferring the biological metaphor within the planning sphere means considering soft synaptic spaces as a collective *construct*, because they cannot be ascribed to a single definitive and deterministic project: in fact, the different actors involved constantly interpret it, take decision and act. This collective construct is a resilient experimental network based on weak ties shaping a not always predictable spatiality. But, in a certain sense, the by-products of this construct – the learning process given by the feedback mechanism – seem to be more relevant than the product itself, because they may allow further developments. As a "not banal" machine, the construct of a synaptic space is featured by its own internal status – and this means that it depends on history – but it is able to produce multiple outputs and different development trajectory.

4. The Baltic Sea EU Macro-Region as a synaptic space.

A significant example of synaptic spaces conceived as a construct is given by the recently introduced concept of EU Macro Regions (Stead, 2011). Macro-regions mean regions comprised of adjacent territories from several different countries that share a number of common challenges. While there may be many such functional regions in Europe, especially connected with geographical features, it is the development of a Macro-Regional Strategy (MRS) that establishes a macro-region from the EU's perspective. For example, the EU MRS for the Baltic Sea Region – published in the summer of 2009 and often presented as a blueprint for other possible

macro-regions – is defined as «an integrated *framework* to address the challenges and opportunities of a particular geographical area» (CEC, 2009).
Even though the concept has been used in International relations before, and even though the collaborative work between national and regional actors in the Baltic Sea area has been quite extensive, this EU MRS brings something new and concrete on methods and actions for sustainable territorial development, as it is aimed at creating a joint "platform" to enable all partner to act together in a transnational context.
During the last twenty years a paradigm shift has taken place in the Baltic Sea Region, as cooperation in all levels has changed from earlier bilateral to multi-level transnational cooperation in networks, such as city or thematic networks, the VASAB Long Term Perspective and the EU project South Baltic Arc. Networks and cooperation patterns between the local authorities are an existing and well funded resource, but their full potential has not been utilised so far. The EU Baltic Sea MRS should serve as a pilot case and good example on how the EU addresses challenges related to a specific region, from a transnational and cross-sectoral perspective. Further examples of EU MRS include the recent Danube Basin Strategy, and those for the Mediterranean, Alpine and North Sea regions (under discussion/consideration).
The need for an EU MRS for the Baltic countries has largely arisen from the fact that eight of the Baltic countries became members of the EU with the major eastern enlargement in 2004. But we may say that since the end of the Cold War the development and integration of this region has expanded and deepened. Much of the activity and integration has happened within and between cities and local authorities thanks to cooperative networks – such as the Union of Baltic Cities, the Alliance of Baltic Cities, the Council of Baltic Sea States – as a return to what once was with the Baltic Sea as an important communication channel for thousand of years and flourishing trade in the region.
An inclusive consultation process, aimed at identifying genuinely local concerns (and at building consensus from the bottom-up) constitutes the starting point of EU MRS. In the case of the Baltic Sea region, this process involved the submission of non-papers from governments and other official bodies, stakeholder events and a public consultation through the EU web site. This led to the establishment of three policy principles. The first is: *no institutions or laws*. In fact, before the establishment of the Baltic Sea EU MRS, a plethora of institutions already existed in this region (the Council of Baltic Sea States, the Helsinki Commission, the EU's Northern Dimension and the Nordic Council), but none of them took an integrated approach to coordinating all the sectoral policies. Nevertheless, it was felt that adding another administrative layer would not succeed in integrating this institutional network. Instead, it was decided to build the Baltic Sea MRS on existing institutions: notably the EU and, for cooperation with the external partners such as Russia or Norway, the Northern Dimension.
The second principle is: *no new funds*. In fact, it was felt that better coordination of the considerable existing resources – EU Structural Funds, research and IT EU programmes, Member State resources, funds from the EU Investment Bank and other international and regional financial institutions, such as the Nordic Investment Bank and the EU Bank for Reconstruction and Development – was more important.

Thus, we have no policy instrument or planning programme in the original sense, because the Baltic Sea MRS is rather defined – and this is the third principle – as an *action and place-based* strategy with a functional spatial approach. Four main "priority areas" for cooperation have been identified (environmental sustainability, competitiveness and prosperity, accessibility and attractiveness, safety and security), and fifteen goals to convert them into concrete policy action. In addition, eighty "flagship projects" are distributed over the fifteen "actions", in order to implement them, and a number of "horizontal actions" (including urban, rural and maritime issues, territorial cohesion and spatial planning) cut across priority areas.
Although discussions have already begun on the question about whether a specific EU budget line can be allocated to macro-regions in the programming period beginning in 2014, the premises of no new funding, no new legislation and no new institution currently set the frame for a coordinating strategy of already existing resources, instruments and networks of different legal status and tiers: MRS's key-words are creative implementation and coordination between programmes. This means that the macro-regional approach is place-based, inclusive and multi-sectoral (while many of the actions need coordination of sectoral policies). It also is multi-instrumental – since the wide scope of actions makes it impossible to fund them solely through one instrument – and it is based on multi-actor collaborations between different type of actors at various governance levels to reach consensus and to fine tune the actions. Thus, macro-regional approach requires imagination and lateral thinking rather than particular technical skills.
Another interesting novelty of MRS consists of its explicit experimentalism, since the EU Commission prepares periodical reports on the basis of coordinator reports and annual forums take place for partners and interested third parties, in order to review the strategy and to make recommendations on implementation.
But, in the light of the broader rescaling processes, the main relevant feature of MRS is related to the fact that the priorities do not necessarily have to be embraced by all actors, according to the principle of flexible membership: «the frontiers of a macro-region do not have to be precisely defined. Moreover, there is no requirement that any given territory be part of only one macro-region» (CEC, 2009). In fact, in the Baltic Sea region, some members focus on a select few, depending on their priorities and problems. This means that the physical boundaries of the target area may vary according to the relevance of the policy area in question: for some policies, all countries are involved; for others, policy might focus on a few regions, while some policies might be defined locally.

5. Explorative images towards a shift in planning imaginary.

If different countries of a macro-region share a number of common challenges, it is possible hypothesising that the latter derive from a shared "image" of their territories, which in turn constitutes a powerful and communicative instrument of territorial knowledge allowing further unpredictable development.
In this sense, a shared image of the Baltic Sea region is undoubtedly given by the landscape of the Baltic Sea coast, characterised by the formation of flat beaches, called "haffs", which are almost completely separated from the open sea by a narrow

ridge of land, the Nehrung (or “spit”). Such a narrow ridge of land is completely made up of shifting dunes, the securing of which is a constant problem for the population.
On the other hand, as macro-regions are proposed as a *framework*, we may say that also the latter is an “image” on the background of which all planning actions and policies can be oriented.
Generally speaking, on relationships between imagination (production/construction of images) and processes of knowledge a vast literature exists (Holton, 1978; Gruber, 1966; Kuhn, 1962; Starobinsky, 1970; Mills, 1959; Brown, 2003). The term “imagination” refers to activities of individual consciousness, through which each one, using images, represents to himself things, subjects or situations that, at that time, are not given to perception. Imagination can see elements concerning the problem and all significant relations between what it is known and what it is unknown, between what we know and what we want to know. Through imagination we put into inter-relation different knowledge so that they can be simultaneously used to interpret a situation. Imagination allows anticipating possible “scenarios” (frames) in which to place that problematic situation we are examining. Imagination, therefore, is not to be led back to “memory”, by confusing “image” with “recollection”, as a mere reproduction of sensitive things that are given to our mind through perception of senses: by recognizing its “creative” function, imagination is rather to be intended as «ability of possible» (Sartre, 1936, 1940). Within this perspective, “images” increase distance from “perception” and emerge with their own features. It leads to extend the term “representation” towards images that we recognize as «construction of the mind» (Jouvenel, 1964).
In fact, imagination first establishes a preference principle towards an idea, but also a different intensity among different representations, proposing an order between them. Furthermore, imagination allows transitions from an idea to another one through successive phases, by introducing to the mind simultaneous different representations and creating a convergence of many images within a single one (Kuhn, 1962).
Not by chance, a large sector of the vast bibliography on relationships between imagination and processes of knowledge regards “spatial” studies, both descriptive and operative, because of the use of representations (for example: cartographic representations) as main instrument. In the planning case imagination (production/construction of images) as interpretation (frame) means a way of analyzing, selecting, organizing and making sense of a complex reality, equipped with a spatial “appearance” (Rein & Schön, 1986). Planners use representations as comprehensive “narrations” (reflecting how a society has been arrived to the present through the past) on which constructing an agreement for the future among different and often conflicting social groups, so defining a practicable «negotiation space» (Secchi, 1989).
But images may also play a role as suggestive guide of collective imaginary (in the sense of an interactive learning) or as exploration/evaluation (Palermo, 1998) of social availability towards some proposed solutions (Gabellini, 1996). Among those focusing on the meaning of representations as “projection towards the future” (visions), many studies emphasize the role of images within identity’s (re)constructing processes. Anyway, the strategic meaning of images – in particular,

of images which are produced within planning processes (scenarios) – has been largely acknowledged (Faludi 1996; Secchi 2000). In this sense, a scenario is an image of a possible desirable future (Hirschorn, 1980).
Differently from "images" – which are produced by individuals – "imaginary" is instead a dimension of history and society. As well as "imagination", "imaginary" refers to images, that is to an articulated set of persistent representations (Starobinsky, 1970), which are equipped with powerful inertia, by opposing to their replacement. But, on the other hand, imaginary is not featured as something stiffened, but rather as something that is subject to a constant evolution and enrichment (Gramsci, 1977). In this sense, imaginary is a category to be led back to a predominantly collective dimension, with a unifying role of subjects (that is: a community), which are recognizable also in relation to the set of images they share.
On the other hand, these shared images are connected to a set of values, "figures", norms and rules (Hobsbawm & Ranger, 1987), cognitive and evaluative criteria, codes and languages, but also customs, beliefs, paradigms and «traditions» (Fleck, 1980), ritual practices, repetitions, frequent omissions and oversights (Soubeyran, 1988), "repertories", including what already exists (what is possible to describe and represent) and what, instead, does not exist yet (what is possible to imagine and prefigure). In a word, a system of relevant purposes through which a community recognizes what place within society it intend to hold in the future (that is: what is its own transformation project) and what it consider to have been in the past as well as the method of moral justification of its objectives.
Not only, therefore, each group (community) has its own imaginary (Baczko, 1978), but each recognizable level of a complex society refers to a specific imaginary (Patlagean, 1978). In this sense, it is possible to individuate some disciplinary imaginaries, that is: images (metaphors) which are shared by a scientific or academic community (Kuhn, 1962). It is also possible to individuate a "collective imaginary" based on the collective sharing of some particularly powerful metaphors (images): «perhaps universal history is the story of some metaphors» (Borges, 1963).
It is possible indeed to recognize some historical periods (Baczko, 1978) in which the broader collective imaginary appears as permeated by characters of one or more specific (disciplinary) imaginaries. In fact, boundaries among different imaginaries are not clearly defined, but fluid, discontinuous, sometimes overlapping and mutable over time (Bachelard, 1957) as well as the contribution of a certain specific imaginary to the construction of a larger collective one tends to change through stability/instability periods.
On the other hand, every specific disciplinary imaginary (for example: planning imaginary) has its own sedimentation and codification stages, and these could not always coincide with the pursuing transformations concretely acting in the realities (in "facts"). But this implies transferring them within the sphere of meanings (of collective imaginary). In this sense, it is possible to recognize reductions/expansion (Secchi, 1988) of "discursive" forms within «planning speech» (Secchi, 1984), which are associated with stability/instability periods. This means that the emerging of innovative "facts", characterizing instability periods, imposes the use of tentative (explorative) – necessarily indefinite, vague, often allusive – new categories (languages, images) towards the construction of innovative metaphors (utopias?).

Think of the different meanings that have been connected in different historical periods to the term "strategic planning" and to the need – in the mid-'70s and even more in the '80s, after the interruption of growth conditions, which had been assumed as the norm – to develop new planning theories and methods to face the emerging problems, by "assimilating" the new explicit role of the market (together with its rationality, its jargon and its specific imaginary). And think also of the further evolution of the term in the '90s that is: in the years of the rhetoric of competition among cities and territories and of the loss of authoritativeness of the old power and representation structures, demanding a wider inclusion of civil society in the sphere of planning. As a result, nowadays strategic spatial planning can be described as a social process through which local communities answer to endogenous and exogenous challenges connected to territorial governance (Healey, 1998; 2003a; 2003b).
In this sense, the concept of "synaptic spaces" may be conceived an explorative "image" towards a shift in planning imaginary.

6. Geography (and history) still matters: the Hanseatic model.

Not by chance the firstly experimented macro-regional strategy is that of Baltic Sea. In fact, the model is that of the Hanse League, based on flexible not hierarchical (mainly economic) «weak ties» (Granovetter, 1983) – or «loose coupling» (Weick, 1976) – among autonomous cities (but not exclusively), which share a transnational unbounded "Hanseatic space" (not "territory") and which are periodically (not always) able to act as a collective actor to achieve local collective competition goods avoiding the «trap of joint decision» (Scharpf, 1986).
In fact, the Hanse was an economic system – and a cultural universe – in which cities were the basic nodules for interaction (Dollinger, 1964; D'Haenens, 1984; Schildhauer, 1988). It was never *strictu senso* a political entity or even a city league, but an economic association which – even if it sometimes exercised political or military functions – was made of units with different levels of alliance. Strong and stable political links proved evil for Hanseatic commerce, as it happened, for instance, when conflicts arose between the fur-providing Russians and the only prince who was also a member of the Hanse, the Great Master of the Teutonic Order (Schildhauer, 1988). On the contrary, looser and more mobile groupings seemed to work better.
The general assemblies, which usually took place in Lübeck, were the only durable institution of an organization with no burocracy. While many minor towns were represented by the leading cities of their area, not even all the important cities were always present at the Hansetag, in spite of menaces and fines, so that it is difficult to know which cities belonged to the Hanse at a given time. The very way in which the Hanseatic cities grouped and the fact that some cities changed from one group to the other are also evidences of the laxitude of relationships within the Hanse. On the other hand, the Hanse surely produced a strong feeling of belonging far beyond commercial agreements. Even with so malleable organization and with so fluid and de-territorialized external or inner limits, the Hanse of cities was, in the late Middle Age, a redoubtable economic and cultural power. At times, it gathered more than two hundred cities throughout a territory stretching over a thousand miles. These strongly

interactive, decentralized but mutually coordinated small units developed a well-balanced urban self-organised system that survived for over three hundred years.
It is to be said that Marxist historiography has interpreted the Hanse as a colonial institution based on a class structure, which led to an economic domination against the pre-existent populations and against the opposition movement coming from the small bourgeoisie and the working classes (Fritze, 1984). According to such an outlook, the Hanse considerably retarded the development of autochthonous middle classes among non-Germans, while maintaining for centuries a noticeable unbalance between economic centres and peripheries, only capable of providing raw materials. Such an interpretation has led – especially in the Countries "on the other side" during the Cold War (and especially in the DDR, but also, in a certain way, in the DBR, because of the collective *mea culpa* sentiment) – to assimilate the medieval *Drang nach Osten* with Haushofer's *Lebensraum* theories and to a substantial erasing of history. But we can say that Slavic, Teutonic, Hanseatic, Jagellonian, Vasa, Prussian and Polish Danzig/Gdansk are all contained in the contemporary city, highlighting the Hanse's positive influence given by the network of stable communications between Eastern, Western and Northern Europe, based on a spirit of dialogue and compromise against warfare, which made technological and cultural development possible for very remote areas.
Especially about the worries (affecting the debate on EU macro regions) on the heterogeneity of the national, socio-economic situations, culture, political background, planning traditions and seniority as EU Member States, it is to be underlined that it was for only fifty years that the Countries of the Baltic Sea Macro Region were separated and isolated by the "Iron Curtain" and how the EU Strategy, in a certain sense, has allowed the re-emerging of deeply rooted historical links, leading back to the Vikings and the Hanseatic Period (the latter running from the XII to the beginning of the XVI century).
This means that, according to Faludi (2010a, b) we can say that geography (and history!) still matters and, therefore, place-based strategies are still needed: following Williams (1996), «spatial positioning» is still one of the key concepts to be considered, even though intended – according to the contemporary meanings of "space", "place" and "territory" – as geographic, historic or symbolic shared "images", which may be seen as a precondition for the development of innovative (imaginative) solutions.

7. Conclusions: the Baltic Sea Strategy in perspective.

It is too early to speak about the future of the Baltic Sea Strategy (BSS) and its implications on the economic, social and territorial cohesion of the region (and whether it fulfils the implementation of the Lisbon and Gothenburg Agendas, and not least the Territorial Agenda). What is already clear, is that the European Union will develop more of these "place-based" macro-regional strategies and approaches as «a tool of European integration and increased territorial cohesion» (Dubois et al, 2009). The elaboration of MRS makes it possible to promote the territorial dimension of EU policies and co-operation, because «the benefits of defining more "localised" policies are beyond dispute» (Salez, 2009).

Certainly, a one-size-fits-all approach does not work in a European Union of 27 Member States and 271 regions, but the question is whether it is possible to cover the whole European territory with this kind of macro-regional policies.
The reason for this increased interest is due to the awareness that all regions are different, and – as pointed out by the Territorial Agenda and the Green Paper on Territorial Cohesion – these differences should be turned into strengths. It is impossible to compare one region with another as the prerequisites are diverse, just like the opportunities and feasibilities. With a MRS the co-ordination of collaboration and financial means is facilitated by sharing the common challenges, goals and accomplishments. There will always be some features that cannot be solved only on local, regional or national levels, but which have to be faced with a transnational approach (such as transport corridors, energy and ICT networks, environmental issues and problems inflicted by climate change).
The debate whether the MRS is to be considered as part of the Cohesion Policy, or as independent beings with a more integrated and place-based policy approach, induces the BSS, according to Samecki (2009), to be summarised as an opportunity for transnational co-operation to constitute an excellent laboratory for multi-level governance on common development challenges and opportunities, and a means for an integrated and co-ordinated implementation of multi-sectoral EU policies, aiming at increased economic, social and territorial cohesion. In other words: the MRS is a new way of making Europe more effective.
There have been some criticisms of the BSS as well. According to Peter Schmitt (2010), the BSS is indeed a place-based strategy but it «suffers from a comprehensive territorial perspective». He states that the VASAB Long Term Perspective could «serve as a complement and explicit territorial strategy that takes into account the function and problems of different types of territories within the Baltic Sea Region». Peter Schmitt argues (and fears) that a macro-regional strategy, even if it is place-based, is not so clearly linked to territorial cohesion that it should be, because generally the latter focuses on better economic performance of different types of territories/regions, thus he sees a need for a co-ordination between the actions/policies and the location of the territory that they are supposed to have an impact on (Schmitt, 2010).
On the other hand, Faludi (2010a) argues that, if spatial planning is to be formulated as macro-regional strategies, then it becomes a vehicle, both for territorial cohesion and EU policymaking in general. If so, the interest in spatial planning is certain to increase.
Furthermore, understanding macro-region as “synaptic spaces” could allow us to imagine Europe in terms of cities, urban-systems, city-borne regions, and macro-regions: a more heterogeneous, complex and well-defined and coherent organism (in the biological sense), defined by deeper cultural layers (rather than those imposed by modern states).

REPRESENTATIONLESS URBAN IMAGES: CONTRASTING FORMAL PLANNING NARRATIVES AND INFORMAL REALITIES IN SARAJEVO

Mejrema Zatrić[1], Haris Piplaš[2]

Abstract

The level of urban competitiveness and positioning in the elusive global network/hierarchy of cities have in post-Fordist paradigm change, become crucial criteria for determining the successfulness of proper urban development. Following this logic, the strategies of representation of urban space have been, for some time now, the main focus of entrepreneurial urban governments. Indeed, the construction of the urban image, and such that is believed to be intrinsic to the successful global city, nowadays directs institution of urbanism in each of its practices – from crafting of planning narratives to design of the development projects. The ready-made contemporary urban representations, such as knowledge and creative districts, the landmark "starchitectural" commodities by famous authors or globalist commercial and leisure centers booming around the World thus gain symbolic primacy over plethora of small but significant symbolisms that surge daily in urban space as the result of its appropriation by the people of the city.

To reflect on the relation between appropriation and domination in the contemporary city, this investigation focuses on the city of Sarajevo where informal /illegal/ settlements built on the hilly urban periphery, mainly by war migrants and refugees, have gained strong visual presence in the urban image, and became a far-reaching symbol of sorts for the space-appropriation processes. Comparing the European city of Sarajevo to the urbanization boom in Latin American cities, such as Sao Paolo or Caracas, the similarities are becoming very visible as informal settlements are being systematically ignored and excluded from any development or upgrading plans.

By analyzing how this self-generated, informal urban reality of extreme appropriation contrasts with the recent planning narratives and strategies of the city's representation it will be demonstrated how contemporary urban governments fail to contain appropriation processes and the resulting symbols in their representational strategies, even when these constitute an imposing urban image. Keywords: urban representation, planning narratives, informal settlements, urban identity, appropriation of space

"Words are never 'only words'; they matter because they define the contours of what we can do." (Žižek, 2008)

1. Introduction

Ever since the 1960s, the issue of relation between representation and space-molding disciplines has been intensively addressed by the protagonists of (broadly defined) critical theory (Debord, 1995; Foucault, 1970; Baudrillard, 1995; Lefebvre, 1991; De Carteau, 1998). The identification of the rising primacy of the visual in the field of philosophy, sociology and critical cultural studies coincided with the abandonment of self-assured modernist doctrine in the field of urban planning. By the early 1980s, the struggling discipline of urban design liberated general planning theory from concern with the questions of form (Palermo and Ponzini, 2010), while the simultaneous rising importance of strategic spatial planning introduced myriad new media of representation – amongst them that of the text – as a way of giving shape to the intentions of the discipline regarding urban space and society as a whole (Healey, 2004). The political dimension of these texts cannot be overemphasized. Their mobilization by local authorities, along with those of culture and heritage, as a part of promotional activities, secured the emergence of urban branding – the ultimate representation of the urban reality in the global market of cities. Accordingly, the use of stories based on cultural content of places has been recognized as increasingly important for understanding the planning practice and political discourses on development. (Jensen, 2007; Sandercock, 2003)

Upon deliberate simplification, it could be argued that representational democracy implies, in its basic settings, even representation of all of urban existentialities in the workings of the public. However, under the auspice of selectivity implied by the notion of strategy, the agency of the institution of strategic spatial planning does not display this kind of balanced treatment – a praxis resulting in what theory un-ambiguously entitles: deprived urban neighborhoods. Another theoretical concern related to the same matter is distinguishing between that what is formal and that what is, in counter-position, informal in the contemporary city.

Present investigation seeks to deliberately ignore these kinds of theoretical naturalization of givens in planning and social sciences, trying to throw a fresh analytic glimpse at urban facts and their representation by using systems of categories developed through the cutting-edge work of scholars such as Michel De Carteau and Henry Lefebvre.

At stake here is the important notion of social appropriation of urban space that is always tightly related to the possibility of use. Appropriation of space has been conceptually applied by scholars to address questions of signification by users' spatial practices (Lefebvre, 1991), community empowerment and interactivity of identity production in terms of space-community relation (Feldman and Stall, 2004), ontological security, and familiarization of public space (Giddens, 1984).

The products of appropriation are dispersed and, often, hardly identifiable signs – either material traces, in the form of real changes in urban spaces, or the common stories strongly bounded to certain places in the city. In both cases, these are representations of

sorts, signs of civic life and activity, signals of existence of people in the city. They are weak, ephemeral, fleeting, and, precisely for these reasons, easily ignorable vital elements of urban existence. Appropriations of space and their clustered uses produce informal urban geographies and cultures.

Extensive research has been undertaken to address causes and consequences of planning practices and development projects in relation to their poor consideration of urban informality, often combined with practices of minority exclusion (Harvey, 1993; Hayden, 1995; Mele, 2000). While formal culture and its representations, such as national monuments, acquire unmistakable introduction to planning and political narratives, insured by the agency of the institution of heritage preservation, products of informal culture are largely ignored – with the exception made when they prove to be prone to commodification and branding (Vivant, 2010; Zukin, 2008).

Especially the recognition of the phenomenon of urban competitiveness and related branding practices had complicated the relation between scientific credibility of planning and issues of urban representation. The quest for the appropriate image that would compel investment and service sector workers has left little space for informal identities in the development agenda. The visual and the visibility play great role in this kind of a game, because, to exist in the city, means to be represented. (Hayden, 1995) In this research, two types of representation are addressed – the one of planning and branding texts; and the one generated by the 'city in itself', captured in the phenomenological concept of *place*.

The city of Sarajevo is studied as a valuable case providing for the possibility to vividly illustrate the discrepancy that often takes place between the two, but is rarely so obvious. In Sarajevo, the informal housing construction that had its first appearance already in the 1950s, dramatically increased in the second half of the 1990s, due to great demographic changes caused by post-war immigration. While in the majority of other cities the existence of zones of informality can be seamlessly 'over-written' through planning narratives and branding practices, in Sarajevo this kind of overwriting is unmistakably disclosed as a result of specific urban topography in the midst of which the 'informal' becomes an imposing part of the overall urban image, thus entering the collective representation of place.

This research will, accordingly, focus on the role of planning in the domain of representation by means of different types of texts /textual explanations of spatial plan, strategic plans, investors' guides, official city presentation /, and the ways in which they oppose the urban realities of extreme appropriation, namely, the informal settlements. In the next section the theoretical background of representation in critical studies and philosophy will be reviewed. By using the main extracted categories, a fresh insight will be offered into the dominant representational logic recognizable in contemporary planning and urban governance, in opposition to the production of informality through processes of appropriation. In the third chapter the clash of formal representational narratives and informal realities of Sarajevo will be exposed as a case study which demonstrates paradoxical confrontation between the city-text and the city-phenomenon.

Finally, the case will be put in a wider context by comparison to similar instances present in Latin-American cities where thriving informality gives rise to what we designate as the phantom-city syndrome.

2. Urban representation – the stakes in symbolism of urban form

2.1 The city, its representation and - the power

To imagine the future of the city means, firstly, to understand its present urban form and capture its ontology through the available media, and secondly, to use these media to project the ideas and intentions that would, hopefully, introduce change for the better. Both of these processes are, in the realm of space, matters of concern of the practice of spatial planning and both, thus, evolve around the sublime kernel of knowledge and expertise. The challenge to untouchability of this kernel and the deconstruction of its interwovenness with power regimes has been effectively and constantly undertaken by critical theoreticians and philosophers in the 1960s and 1970s, who supplied a range of conceptual tools to address this important issue.

In the work of Michel Foucault (Foucault, 1970), the underlying conditions of truth, inherent to the historical moment, decisively shape its related episteme. The question of representation of facts, or truth, through the scientific discourse is thereby put into focus and, with a gradual spatial turn in social sciences (Lefebvre, 1991; Allen et al, 1998; Massey, 2005) expanded to the notion of origins and epistemological justification of the space production practices. Henry Lefebvre has, with special rigor, developed a conceptual framework to address the matters of power relations and their accommodation in the ontology of the spatial (Lefebvre, 1991). The application of his conceptual triad, consisting of *representations of space*, *representational spaces* and *spatial practice*, establishes clear position on joint agency of power and knowledge in the processes of space-production. In the 1970s, in the light of fostering of what, not only, Lefebvre addressed as advanced capitalism, his concern was about the rise of *the abstract space* which promotes the *domination*, as opposed to *appropriation* of space.

In this kind of understanding, the representational aspirations of power or – the production of representations of space – are crucial to the outcomes of contestation processes and overall control over the space of the city.

According to Lefebvre, in the present world order the representations of space, produced by power and knowledge, collide, with the representational spaces of the users, which they seldom manage, or even aspire, to reach. Relying on myriad processes of scientific reductionism they asses and then reproduce what was found through available and officially recognized media, only to set the ways for intervention which is to be based upon and which is justified by the articulated representation.

The potency of the symbolic, important since the first spatial practices left marks in the natural space, is decisive in the era of abstract space. In Lefebvre's words: "Space may be marked physically, as with animals' use of smells or human groups' use of visual and

auditory indicators; alternatively it may be marked abstractly, by means of discourse, by means of signs. Space thus acquires symbolic value. Symbols, on this view, always imply an emotional investment, an affective charge (fear, attraction, etc.), which is so to speak deposited at a particular place and thereafter 'represented' for the benefit of everyone else. In point of fact, early agricultural and pastoral societies knew no such split between the practical and the symbolic." (Lefebvre, 1991, p.141)
What easily gains crucial weight, when this argument gets to be positioned in the framework of contemporary planning debates is the *separation*, between the symbolic and the practical through representation, which is found here to occur on many different levels as an inherent process of production of planning narratives.

2.2 Urban competitiveness and entrepreneurial representational logic

The constitution of global network/hierarchy of cities, the skyrocketing rates of foreign direct investment and the mobility of high-qualified workers have been recognized to had given rise to the phenomenon of urban competitiveness – an imperative for urban governments of 'doing what it takes' to position their assets high in this conceptual, but still very real, scale of desirability. (Friedman, 1995; Castells, 1996; Sassen, 2001) In effect, the entrepreneurial character of contemporary urban governance has been recognized as one of its main features (Harvey, 1989), pinpointing thus the ways in which spatial and its qualities become both tools of, and arena for, the processes of promotion and trading. With the decline of nation states' powers and jurisdictions, these play out, increasingly, as primary determinants of urban futures, while forming expressly naturalized context of planning practices. (Carmona et al, 2009).
It has been widely agreed by now that culture and its spatial manifestations play important role in creation of urban brands (Evans, 2001; Kunzmann, 2004; Landry, 2000; Jensen, 2007). The cultural assets employed in the process of branding can be very varied, from architectural cultural heritage artifacts, which imply the aura of authenticity by the virtue of 'proven' authentic history, to flagship cultural architectural projects which imply the constantly living, regenerating cultural activity that suppose to present the city as a vital part of the global world. (Judd & Fainstein, 1999; Miles, 2005; Strom, 2003) All these fragmentized associations tend to be subsumed under a desirable image, the role model of sorts that we intent to capture in the notion of 'authentic global city'.
Importantly, this city-text is understood here as a representation of the existing place, the phenomenology of which implies myriad complexities that are curated through the process of cultural urban branding. (Chaplin and Stara, 2009) Another concept which intends to systematize and which successfully captures the notion of expanding cultural and place-related bases of planning is that of a narrative approach to cultural urban brands, where planning activities are seen as underpinned and, indeed, frequently fully informed by preconceived stories about the place. (Jensen, 2007)

Similarly, the discursive and semiotic processes at play have been considered by scholars who tried to understand their agency and importance in contemporary planning and governance schemes. (Jensen & Richardson, 2003; Harris & Hooper, 2004; Healey, 2004; Duhr, 2007). The wider picture of sea-change from essentialist to relational geography clarifies the simultaneous popularization of strategic spatial planning (Healey, 2004). The essentialist approach, aspiring to order and objectivity, has given way to relational approach which understands the space as "social construct" and in which "'places of the mind' are as significant as physical objects and flows". Taking this into consideration, in her definition of strategic spatial planning Patsy Healey designates it as "self-conscious collective efforts to re-imagine a city, urban region or wider territory". (Healey, 2004, p.46)

As curating, storytelling and re-imagination equally imply valorization, selection and simplification of uttermost complexity of the urban, it seems that only the "optics" of "representational logic of urban intervention" maintain enough analytic credibility when addressing contemporary urban planning and governance. More specifically, the question in focus is the one of the general 'climate' of the entrepreneurial urban governance, the ways in which it influences the formation of planning narratives when they work with signs and metaphors and, in turn, the relation of these narratives to the phenomenology of the place.

2.3 The production of the informal - Social appropriation of space, its 'visibility', its symbolic loads.

The polarization between the formal and informal culture broadly introduces the parallel realities of formal and informal city. While the urban intervention interpellates the user through its formal discourse (Harvey, 1996; Jameson, 1997; Balibrea, 2004), in the realm of the informal the users produce the meaning through the wide variety of their agencies and interactions. Here we consider the manifestations of urban informality in the light of the notion of appropriation, as advanced by Henry Lefebvre.

Amongst those categories defined in Lefebvre's opus, appropriation is one of the few that truly and undeniably "hold the side" of the citizen, standing for the processes that endow the space with symbols implying "time (or times), rhythm (or rhythms)" and spatial practice (Lefebvre, 1991, p.357). It especially strongly relates to his favoring of the use value (as opposed to exchange value) of space. For Lefebvre, understanding appropriation lies at the very core of the new science of space, as he calls on to planners to apply the "imaginary invested in appropriation (of time, of space, of physiological life and desire)". (Lefebvre, Kofman and Lebas, 1996, p.155).

Appropriation thus produces symbolic value, also identified as *difference* – alternative to the imposed homogeneity. It is produced through the use that infests the representations of power by means of its collateral symbolisms. The result of this collision is the 'city in itself' – the place and the phenomenon.

Given the pursue for the 'authenticity', imposed by the entrepreneurial climate in urban governance, planning narratives have recently intended to incorporate some of the semantic 'products' of informal practices – the alternative artistic cultures and the allure of their corresponding spaces are increasingly used as powerful material of branding and promotional activities in cities. The dispersed, unsynchronized semantics of the "bohemian" activities are tracked down, recollected, synchronized and introduced into overarching narrative of "the creative and open place to work, invest, create and live" (Vivant, 2010, p.107)

Not all products of informal practices of appropriation, however, can be seamlessly blended in the preconceived city-word of 'authentic global' role-model. The blurred border-line of informality gains again very determined and strict presence when this kind of semantic recycling cannot be easily (or at all) undertaken. And if they are not suitable to be promoted and integrated into the nexus of strategic planning narrative and entrepreneurial governance narrative, the *differences* are disregarded or stigmatized.

Still the "city in itself" exists outside the narratives as a superior *oeuvre* that supersedes the product and enters into conflicting, unclear and dialectical relationships with its institutional form (Lefebvre, Kofman and Lebas, 1996). The structuring of social and cultural urban geography reveals these conflicting tensions, not only in terms of quality of life, but also in terms of identity construction when the semantic hierarchies between the center and the periphery are recognized in the narratives. The urban centers are source-fields of iconographies and symbolisms of representation, leaving the less significant periphery existing "in itself" but, also, at the safe distance from the curated space of representation (Harvey, 1993).The notion of visibility then gains prominence suggesting the "out of sight, out of mind" principle that permits fine-tuning of the representative "city-in-itself" with the narrative, while the distanced ghettos, informal settlements and other *differences* can be seamlessly overwritten by the dominant representational logic.

In Sarajevo, however, the specific topographic context of the city has permitted for a situation of peculiar semantic ambiguity. While the recent investment has tended to 'materialize' into ever-more spectacular architectural forms indicative of global-city well-being, their backdrop, the 'city in itself', all too clearly demonstrates the *difference* as it elevates it to prominent display surrounding the representative city-center.

3. Sarajevo, its informal realities and its imagined futures

3.1 The hills of Sarajevo – the becoming of the informal city

The social and cultural geography of Sarajevo is, not surprisingly, as complex as the city's turbulent history.

Being founded by the Ottoman Empire in the XV century, as the most western administrative center of the regime, the initial urban structure nestled in the outset of the valley of river Miljacka, taking advantage of the topographic configuration to introduce

the unmistakably oriental urban organization – the market-place in the valley and the residential areas around the hills. In the late XIX c, the city was conquered by Austria-Hungary which continued to fill-in the widening valley towards the west, organizing the Central-European urban structure of blocks in the orthogonal disposition of streets with sustained construction around the hills. In the immediate aftermath of the WWII the newly founded socialist regime revolutionized, yet again, the manner of urban planning and development, relying entirely on the principles of the Athens Charter. Formal and project-based occupation of land continued to be predominantly directed at the flat valley of the river, as the large housing estates and their generous pseudo-parks sprung-up, one by one, to accommodate the ever-intensifying influx of migrants (Figure 1). Coming from the countryside and the smaller cities of the Republic alike, attracted by the possibilities of employment offered by the industrialized capital city, these blue-collar workers were the ones to pioneer the self-initiated construction of single-family homes that were soon stigmatized as illegal settlements. The unfortunate, yet common, socialist approach of putting all stakes of industrialization in the narrow urban areas of the biggest cities and turning blind-eye to the necessity of the regional development, resulted in overcrowding of Sarajevo's housing stock (Bublin, 2006). While around 1910 the city population numbered 21 377, by the 1920s it doubled, only to reach some 70 000 in the early 1940s. With the post-WWII onset of intensive processes of de-agrarization, industrialization and urbanization, the number of inhabitants increased to 213 101 in the early 1960s. The increasing influx of migrants to Sarajevo was unmistakably followed by the growing informal housing that almost exclusively occupied the steep slopes of the surrounding hills – a terrain too complex to be urbanized through the large housing schemes employed by the socialist-modernist planning practices.

The trends of growing informal settlements continued through the 1970s and 1980s, only to escalate after the Serbian aggression and the siege of the city that ended in 1995, when the wave of war-provoked migrations splashed hillsides of the Miljacka valley.

This distribution of the formal city in the valley and informal city on the hills (Figure 2) not only created a clear social and cultural geography in which the line separating the valley from the slope and the flat from the steep turns into borderline between two different worlds, but also collaterally produced a complex and problematically rich urban panorama in which the image of the city, however and wherever contemplated, pays equal tribute to formal and informal through the monumentality of the visible (Figure 3).

3.2 Fostering the formal representation in transition: the plans, the pamphlets, the prescriptions

The second half of the 1990s in Sarajevo has been profoundly marked by the overall shift of epic proportions: from socialism to neoliberal democracy, from Fordist to Post-

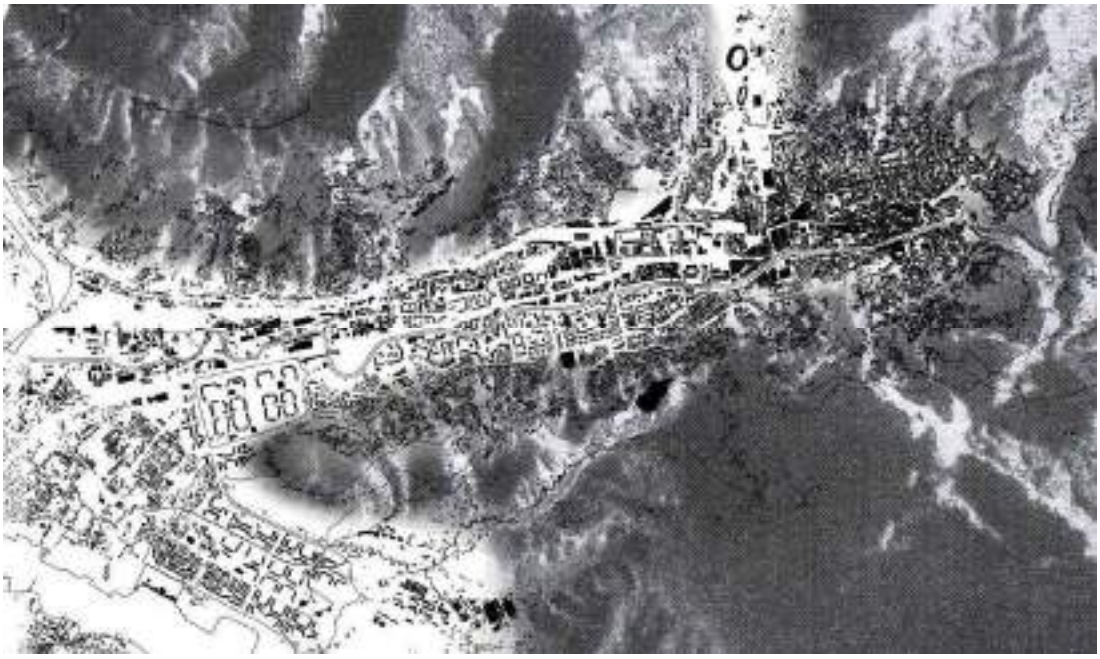

Figure 1. Urban morphology of Sarajevo in its topographical context

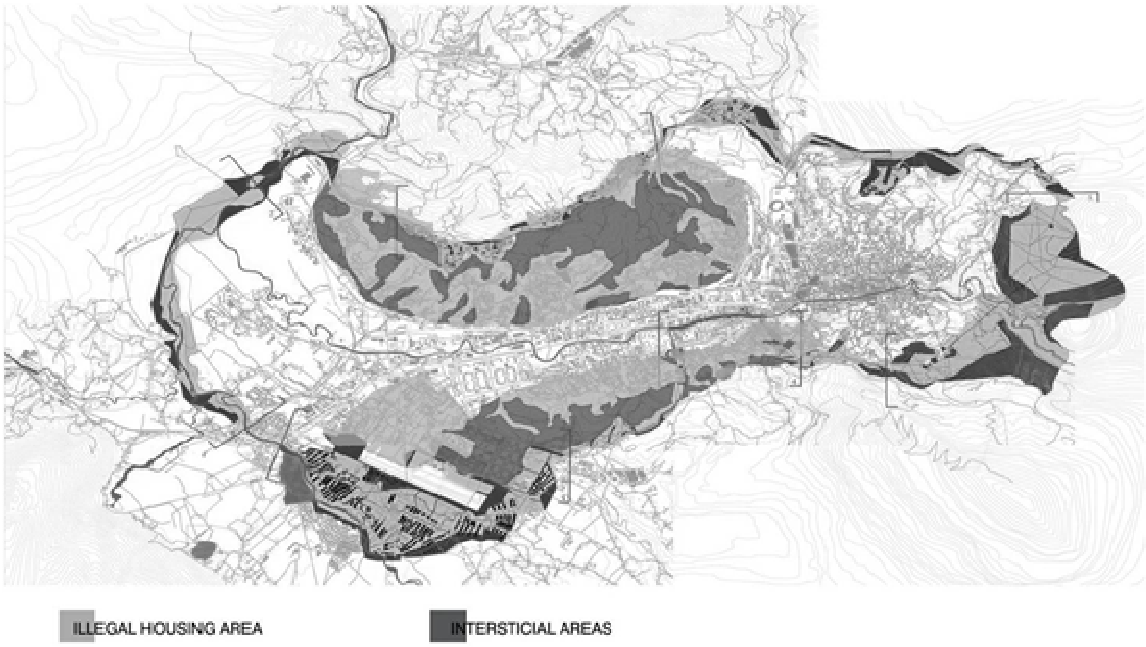

Figure 2. Distribution of informal housing areas on the hills surrounding the city

Fordist economy, from war to peace. All these intertwined processes have been immediately articulated, both popularly and academically, by being subsumed under the concept of transition, the recognition of the overall "abnormality" which asked to be overcome by applying "good practices" of the "normal" world (Stening and Horschelmann, 2008). In the realm of planning and urban governance, this meant, among other things, the introduction of the new logic of representation, the one that would supersede the nation-building identity formation, so typical of the socialist era, and answer to the new situation of the neoliberal global market (Pichler-Milanović, 2005). The recognition of the unfolding urban competition and of the fact that development and investment depended directly and uncompromisingly on the quality and skillfulness of representation, introduced range of innovations into activities of the Development Planning Institute of the Sarajevo Canton (DPISC), the ultimate institutional authority in the realm of spatial and economic planning of the city.

The first post-war spatial plan, issued in 2006, demonstrates these changes in a multiplicity of ways (DPISC, 2006). The document opens up with enumeration of 'general and specific goals' that give it a strategic dimension. Three of these acquire specific prominence for their mobilization and circulation in range of other documents and turn into a motto of sorts that synthetizes the main aspirations of the city (DPISC, 2006, p.4) The first one: "Profiling of the space of Sarajevo Canton as the ambience of lucrative (sustainable and highly profitable) business" is further elaborated to designate science and knowledge-based economy, small and middle-size enterprises, food-production and tourism as the principle economic bases of development. The second one relates to the "ambience of enjoyable living" that sets the goal of providing "humane, healthy and creative living through the elevation of quality and standards". Finally, the third one demands that Sarajevo Canton be profiled as "regional and European metropolis", and thus encompasses the previous two by stating that 'the environment has to be made attractive for the international capital", as well as for the "young professionals", so that it provides for their permanence in the country. The framework narrative that these basic strategic goals constitute echoes, despite its generality, in the subsequent chapters that intent to specify "The Projection of Spatial Development and Spatial Systems". Inside the proposed categories (natural resources and conditions, population and settlements, economy, dwelling and residential development, social infrastructure, agricultural land, etc.) the informality is addressed exclusively as a process and as technical entity – "the informal construction" – a problem that requires rehabilitation and control.

Springing from the bases set by the Spatial plan, this kind of overarching strategic spatial narrative divaricates and reappears in other, more specific documents. Two are addressed here with particular curiosity: The Investment Guide – Sarajevo: a Profitable Business Location (DPISC, 2008a) and Sarajevo – Presentation (DPISC, 2008b). Both are available for download at the official web-site of the DPISC, and both are intended to represent the city, following the basic strands posed by the strategic goals.

The Investment Guide is directed at potential investors with the purpose of providing a range of useful procedural information (founding the company, getting construction permit). More importantly, however, it provides a list of potential investment locations in which undertaking of construction is preferred, as well as the intensive visual support in the form of images and maps that are to represent the city as the "profitable business location". Here the representation is employed in a rather more pragmatic form - the territory of the city is reduced to the range of locations "covered" by the Master plans that selectively reproduce the city of the future (Figure 3) Without an exception, all 17 Master plans are situated in the flat valley, promising further polarization between the normality of the formal and otherness of the informal settlements. This kind of 'selective recognition' is reinforced through the rich photographic documentation that accompanies the entirety of the text and that 'narrates' the 'authentic global city' into being – a task accomplished by means of romantic panoramic views (Figure 4) and snap-shots of recent examples of global architecture (Figure 5), in each one of which the heavily populated hills are somehow eluded.

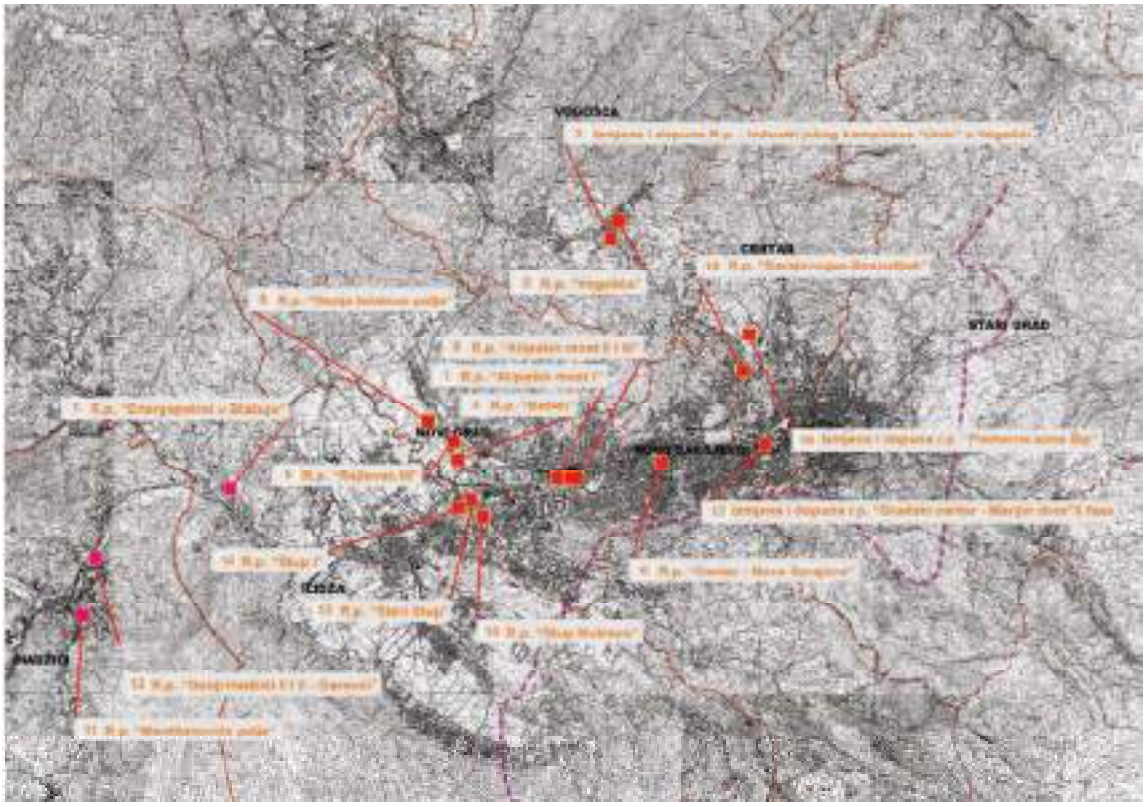

Figure 3. Future is selective: the position of the potential investment locations exclusively situated in the Sarajevo valley

Figure 4. The panorama of Sarajevo on its blurred background – the handy 'fog' disguises the informal world

Figure 5. The recent architectural "prides" of the city photographed from the fortunate vantage point that evades the visibility of informal housing

Figure 6. Sarajevo by night and its hills covered by night-tome fog

Figure 7. The 3D view of the Marijin Dvor new city center and its upcoming architectural wonders

Finally, the Presentation of the Canton Sarajevo entitled "Yesterday Today Tomorrow" complements the palette of representational logic by recreating the city in the light of its formal identity (DPISC, 2008b). Informality has no place in neither one of the temporal categories covered by this colorful document that features architectural monuments, events of culture and natural riches. Again, the graphic illustrations selectively "recreate" the favorable views (Figure 6), employing this time also the 3D visualization (Figure 7) to communicate the imagined futures of the city, and all that without any consideration of the part that dozens of thousands of informal households are to play in its construction.

4. CONCLUSIONS: Overlooking the vividly visible - The syndrome of the phantom city and its discontents

Informality is pervasive but rarely imposing in its visibility. The very real concept of "periphery" implies its safe distance from the affluent, manicured and identity-forming center. This distance and implicitness are not to be underestimated.

The fostered "dual city" of Sao Paolo (Dear and Lucero, 2010), for an example, exists both in its hybrid physicality and in its dual aspiration to the production of identity and culture: the white, global, corporate, establishment culture Vs. non-white, local, ghettoized culture, that occasionally semantically "harasses" the formality of the center by means of graffiti. Except through this kind of very ephemeral overlappings, the fragmented social geography can be appreciated almost exclusively by studying maps and contrasting snapshot separately taken in the mutually isolated dual realities.

It is the visibility of contrasting artifacts, however, that unsettles the spirits of the liberal democratic myths – the phantasmagoric images of the squatter-tower in Caracas have circulated the world, as an ambiguous message craving decipherment and reaction. The 45 stories high unfinished office tower, hosting some 600 families of the urban poor has provoked wildly varying insights – from those which designated it as "breeding ground for radical social change", to those which saw in it "an unintended parody of the society that created the squatters' dire situation to begin with" (Woods, 2011).

Still the intensity of fascination reveals the concealed civilizational impasse, demonstrating how formal representation of appropriation makes all the difference.

So too, in Sarajevo, the semantic stratification of the panorama has posed a challenge for the policy-makers and the planners alike. (Figure 8, Figure 9) And as it occurs with challenges, it also indicated the open-ended way to innovation, a chance which, if handled with greatest of (technical and humanistic) care and audacity, can result in the invention of something new.

The disappointment of the answer so far given to this challenge has not been in its practice of "overwriting", for the realm of representation seems to be the first frontline of any fight for betterment in the world order pervaded with signs, images and narratives.

Figure 8. The semantic layers of the panorama – new development icons in the foreground and the informal settlements on the hills in the background

Figure 9. New development flagship projects contrast with the 'city in itself'

As for the part of it that falls to planning, it has been already well recognized, that "issues of representation are an important part of the persuasive capacity of strategic planning. They have impacts in carrying framing concepts from the arenas of policy articulation to the arenas where decisions are made about specific investments and regulatory norms and permits." (Healey, 2004, p.46)
This investigation is dedicated, thus, to reflection on the paradox of representation in planning practice, when confronted with the issue of informality.
It has been demonstrated, with these ends, how pioneering strategic spatial planning and policy of post-socialist Sarajevo intent to navigate through the representational realm, by constructing narratives and embedding them in documents that truly hold wagers on the future of the city. Furthermore, it has been shown how these narratives, as semantic constructs, collide sharply with the unarticulated semantic loads of the 'city in itself'. The operativity of these narratives proves to be, therefor, both pragmatic and semantic. While they strongly influence the distribution of investment inside the complex social geography of the city, the signifying capacity of urban intervention is seen as productive of identity.
It has been aimed to show, however, that, before the intervention itself has been made effective, the signification and signs enter the planning practice through the narratives of planning. Separation of the practical and the symbolic can thus be found in the metaphoric content of the spatial vocabulary that pervades contemporary planning practice. The aspiration of urban governments to the 'authentic global city' results in mobilization of spatio-cultural concepts that address those features found to be 'in tune' with the elusive qualities of this ultimate role-model. Meanwhile, informality is what prevents the urban landscape to become, as some scholars address it, 'discourse materialized' (Schein, 1997).
However more the construction of narratives related to places proves to make a crucial part in the creative labor of the contemporary planning practice, it is worth remembering one simple and ingenious observation: identity is not nice (Venhuizen, 2010), and it has never been. The formal identities narrated through artifacts of castles and fortresses managed to incorporate and supersede their original stories, sometimes related to the true traumas of war and subordination. Similarly, when facing the phantomlike existentialities of representation-less urban images, it falls to the planners and policymakers to invent new narratives that will have enough potency to forefront our contemporary battles, many of which are fought in the real space of the informal city.

EVALUATING MAJOR TRANSPORTATION INFRASTRUCTURE IMPACTS USING GIS AND MULTICRITERIA DECISION ANALYSIS: THE CASE OF EGNATIA MOTORWAY IN GREECE

Athanasios P. Vavatsikos 1, M. Giannopoulou 2, Y. Roukounis 3

Abstract

Renowned for their ability to deal with spatial problems, commercial GIS software packages can play crucial role in spatial decision making processes, given that they are provided with sophisticated tools that allow both private and public organizations to manage and analyze spatial referenced data. In order to expand GIS abilities to the consideration of decision criteria, OR/MS researchers strongly pronounce in favor of developing synergies between GIS and multicriteria decision making tools. The rationale of this integration is the GIS ability to store and manage and visualize geographically referenced data and the efficiency of Operational Research tools for modeling decision problems. As a result MultiCriteria Spatial Decision Support Systems (MC-SDSS) provide a consistent framework that allows alternatives ranking combining both spatial data and DMs preferences according to a selected decision rule. Regarding to their applicability in situations that involve classification, ,multiattribute decision models are considered as a very attractive procedure in urban and regional planning concerning the appraisal of transportation infrastructure construction.

In the present a spatial multicriteria evaluation of the impacts derived by the realization of Egnatia Motorway is performed. Egnatia Motorway is considered one of the most significant interventions that have taken place in Greece during the early pre-Olympic Games period and up to the year 2007. With a length of 670 km, it crosses 12 prefectures starting from the Igoumenitsa Port, which provides links by boat to Italy, ending to Kipi in Evros (Greek-Turkish borders). It is a dual carriageway with two traffic lanes per direction with an overall construction cost of about 6b€. Aiming to enrich Northern Greece's potential in transport industry and tourism, European Union has heavily invested in its construction.

1. Introduction

Land-use suitability mapping and analysis, that aim to identify appropriate spatial patterns for future land uses according to specific requirements, preferences, or predictors of some activity, have been widely accepted as one of major fields of interest between GIS analysts (Collins et al, 2001). The ability of the contemporary GIS software packages to support geoprocessing tools such as overlay procedures led both scientists and practitioners to refer to them as Spatial Decision Support Systems (SDSS). However, there is growing consensus about the limited role of GIS as SDSS (Pereira & Duckstein, 1993). This criticism is mainly addressed to the lack of adequate techniques that allow DMs preferences contribution to the final result; and to the fact that Boolean overlays identify as solutions only those that simultaneously satisfy all the analysis' criteria (Laaribi et al, 1996; Chakhar & Martel, 2003).

Recent advances in both GIS technology and Multi Criteria Decision Making methods (MCDM) led many authors to recommend integrations between the two research areas. The rationale of this integration is the GIS ability to store and manage geographically referenced data and the efficiency of Operational Research tools for modeling decision problems. As a result, MultiCriteria Spatial Decision Support Systems (MC-SDSS) provide a consistent framework that allows alternatives' ranking combining spatial data and DMs preferences according to a selected decision rule (Anagnostopoulos & Vavatsikos, 2007).

At the same time evolutions in software technology allowed the development of tools in order to support decisions for semi structured problems. Concerning the development of build-in modules in the commercial GIS packages, ESRIs ArcGIS, Microimages Inc. TNT GIS and Clark Labs IDRISI provide tools for suitability index estimation according to a weighted average of the criterion maps. In particular, IDRISI supports estimations based on Ordered Weighted Average decision rule and a calculator-like module for criterion weights estimation of a pairwise comparisons matrix (Eastman, 1993). The last decade efforts focus on the development of more comprehensive solutions in order to meet DMs requirements. These efforts were encouraged by the provided mediums for preparing, compiling and running macros and development platforms, which permit application programs writing using objects and their build-in properties as well as methods in compliance with programming languages such as Visual Basic and C++.

Transport infrastructure is considered as a regional development project. The new European transport policy (EU–European Commission, 2002), has acquired a clear development dimension, and is directly linked to the policies for the social, economic and territorial cohesion of Europe. This is enhanced by evidence from numerous research studies (Vickerman, 1996; Faludi, 2006).European Spatial Development Perspective (ESDP) explicitly refers to the significance and the consequences of the European transport policy for the organization and development of the European area (EU–European Commission, 1999). It is suggested to assess the spatial impacts of European transport infrastructure on the basis of the following criteria: (a) impact on

land use, (b) impact on productive systems of regions, (c) impact on spatial structure, (d) impact on the income and production, (e) impact through regional reinforcement measures, and (f) impact through the spatial differentiation of public intervention.

In Greece, transport infrastructure constitutes a valuable tool in spatial policy. The General Framework of Spatial Planning and Sustainable Development and the Special Spatial Planning Frameworks consider the investments in transport infrastructure as works of regional development (Ministry for the Environment, Planning and Public Works, 2007). The assessment and evaluation of spatial impacts caused by transport infrastructure is a special multidisciplinary task and requires systematic investigation and monitoring, but it has not yet been explored in Greek bibliography.

The Egnatia Motorway (Figure 1) is one of the largest transport projects constructed lately in Europe, and was included in the top priority projects of the Trans European Transport Networks (TENs-T). The motorway, 670km long, crosses Northern Greece horizontally from Igoumenitsa to Kipi on the Greek – Turkish border and is connected via vertical axes northwards to the Pan – European Corridors and via the PATHE (Patra-Athens-Thessaloniki) motorway and the western Ionian axis, to the rest of Greece. It is designed and built as a dual closed carriageway of international standards and comprises numerous long twin bridges, a large number of tunnels, 50 interchanges, 350 underpasses and overpasses, and 720 km of service roads. Moreover, it links all major urban centres, 4 ports and 6 airports (Egnatia Motorway Observatory, 2005).

Figure 1. Egnatia Motorway horizontal axis

At the national level, the Egnatia Motorway represents the backbone of the Northern Greek transport system, making it possible to break the isolation of remote Regions such as Epirus, Western Macedonia and Eastern Macedonia and Thrace. At the European level, it links Greece to Europe and the Middle East, while it operates simultaneously as a point of confluence for the merging transport flow from the Balkans and South-Eastern Europe. It is expected to operate as a zone of cooperation

promoting selected economic activities, transport and energy networks, exchanges of technical knowledge, as well as the effective preservation of the environment and of cultural heritage. It is there that the Pan-European Corridors IV (Berlin-Sofia-Thessaloniki), IX (Helsinki – terminating at Alexandroupoli) and X (Vienna-Belgrade-Thessaloniki) terminate (Spiekermann & Wegener, 2006).

The importance of the project and the investment size necessitate supplementary actions, beyond construction, that would multiply benefits and mitigate the impacts from operation. It is necessary to monitor and assess the impacts of the Egnatia Motorway, not only on transports and the operation of the road network, but also on the economic, social and territorial cohesion, the environment, and the general spatial arrangement of the geographical zone crossed and influenced (Fourkas & Papasiopi, 2006).

In the present paper an integration among GIS functionalities and multi-attribute decision making models such as Analytic Hierarchy Process (AHP) (Saaty, 1977) is proposed in order to estimate the impacts provoked by the construction and operation of Egnatia Motorway in regional level. For that reason the 12 prefectures crossed by the motorway, are evaluated with the use of socioeconomic, environmental and transportation indicators. The proposed framework can be used as a valuable tool that allows public investments' evaluation in regional level, as well as inter-regional inequalities' estimations.

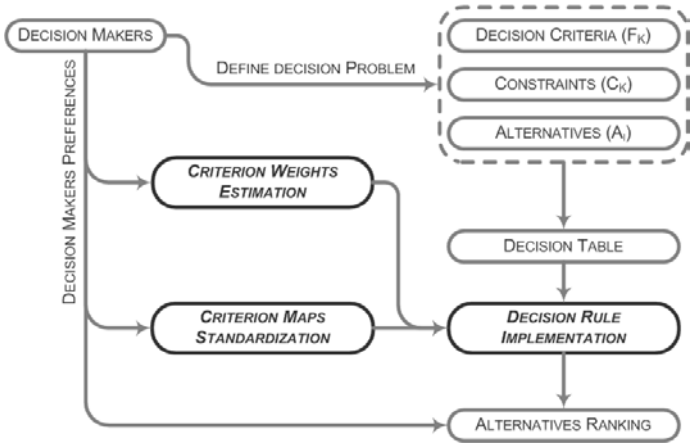

Figure 2, Decision making flowchart

2. Spatial Multicriteria Decision Analysis

Rational decision making is characterized by a coherent sequence of actions that ensures DMs from dubious results in the final outcome. The methodological framework, as it has been stated by H. Simon (1960), can be distinguished in three phases (Figure 2). In the intelligence phase, decision space is well stated by the objectives and sub-objectives identification, and constraints criterion maps determination. In the design phase, feasible alternative scenarios are determined

performing Boolean overlays among the constraints criterion maps. After the analysis decision table formation, criterion maps relative importance is estimated and utilization procedures of the geographical data are performed. Finally, in the choice phase suitability index maps are derived as the synthesis result of the per criterion utilities under a certain decision rule implementation. Moreover, the stability of the final outcome is tested to changes regarding the former steps of the analysis, including either the consideration of new criteria or alternatives to stakeholders' preferences. When conflicts arise a compromise solution for implementation in the study area is identified.

At the most rudimentary level, GIS-based multicriteria decision analysis can be thought of as a procedure for combining geographical data and value judgments (the DMs preferences) to obtain information for decision making (Malczewski, 2006). Spatial multicriteria analysis aims to the ranking and/or the selection among candidate locations through estimations regarding a graded variation of suitability. The nature of the above integration is complementary given that GIS is a powerful tool for managing spatially referenced data, while MCDM methods are efficient tools for modeling spatial problems (Chakhar & Martel, 2003). Furthermore GIS based land use suitability evaluation expands the aspatial nature of traditional MCDM methods given that evaluation criteria vary across space. On the other hand MCDM allows the consideration of decision criteria allowing suitability mapping (Malczewski, 1999). The last is most commonly achieved by scaling attributes data to a common ratio scale and then to combine them by means of weighted average.

2.1 Analytic Hierarchy Process

Developed in the late 70s, AHP is a scaling method for deriving priorities (weights) for a set of activities according to their importance (Saaty, 1977). Since its release, the method has been widely used because it elicits DMs' preferences in a friendly and easily understood manner. As a procedure, AHP belongs to the family of methods that use pairwise comparisons in order to estimate relative preferences among decision analysis parameters in semi-structured decision problems. The method is based on three principles: the decomposition of the decision space to its fundamental elements, the comparative judgments, and the composition or synthesis of priorities.

The first of these principles is accomplished by breaking down the decision problem to its components by developing decision hierarchies. In general, the objectives tree is defined exclusively by the DMs aiming to represent their experience and intuition over the problem. Comparative judgments principle has to do with the development of a solid base for establishing priorities among the decision parameters. Local priorities are obtained by comparing qualitatively each node against each of its peers with respect to its parent node using the nine levels of the fundamental scale of preferences (Saaty, 1995). Technically this is achieved by forming pairwise comparison matrices $A = [a_{ij}]_{n \times n}$, where the ratio a_{ij} assigned by the DMs expresses the dominance relation of the factor in row i when it is compared against the factor in

column j. The measure of the dominance relation is determined by using the strict preference (A_iPA_j) and indifference (A_iIA_j) preference structures (Equations 1,2). Consequently pairwise comparison matrices are positive and reciprocals (Equation 3), and the elements in the diagonal equal to 1 (Equation 4). Local (or relative) priorities or weights are then established as the principal eigenvalue λ_{max} of the pairwise comparison matrix solving the system of Equations 5. When the transitive property holds (Equation 6), the matrix is consistent and λ_{max} equals to n. Since in real-life situations it is quite rare to obtain consistent judgments by the DMs, AHP provides measures of inconsistency as a function of the deviation between λ_{max} and n.

$$A_iPA_j \rightarrow a_{ij} > 1 \quad (1)$$

$$A_iIA_j \rightarrow a_{ij} = 1 \quad (2)$$

$$a_{ij} = 1/a_{ji} \quad (3)$$

$$a_{ii} = 1 \quad (4)$$

$$(A - \lambda_{max} I) \times w = 0 \quad (5)$$

$$a_{ij} = a_{ik} \times a_{kj} \quad (6)$$

2.2 Spatial Analytic Hierarchy Process

The framework for applying AHP in site suitability analysis studies, known as spatial AHP, has been firstly introduced by Banai-Kashani (1989) in the late 80s. According to this approach in a GIS environment, the overall priority Sj of an alternative location j is estimated as the weighted summation of the standardized criterion maps (Equation 7). As a procedure, standardization enables the transformation from the natural and constructed scales of measurement to the DMs' preferential system enabling the addition of commensurate attribute maps ensuring coherent results estimation. Standardization with respect to a specific objective can be performed using both relative and absolute measurements. Technically spatial AHP in GIS environment is implemented as the weighted average of the standardized attributes row data. Summarizing, the method is carried out in the following steps (Voogd, 1983; Malczewski, 1999):

Step 1: Analysis overall goal determination.
Step 2: Constraints implementation and alternatives determination.
Step 3: Define a consistent family of criteria for the alternatives evaluation and their spatial patterns (criterion maps).
Step 4: Standardize attributes row data x_{ij}.
Step 5: Obtain ratio weights w_j for the analysis decision criteria.
Step 6: Calculate the per criterion suitability index S_{ij} by multiplying standardized attributes row data x_{ij}^s with the corresponding criterion weight w_j.

Step 7: Generate suitability index S_i using the sum operator on the S_{ij}.

Step 8: Rank alternatives according to S_i.

$$S_i = \sum_{j=1}^{n} w_j r_{ij} \qquad 7$$

3. Problem formation and Evaluation Criteria

3.1 Egnatia Motorway Observatory Indicators System

Egnatia Odos S.A. (EOSA) established and operates the Observatory of the Egnatia Motorway, which collects, processes, and provides valid and updated data regarding parameters in order to: (a) support the integrated management of the motorway, (b) contribute to the utilization of the project in the cohesion and development of a greater area, and (c) contribute to the harmonized assessment of TENs-T impacts on the cohesion of the European area (Vickerman, R., 2004).

A central element for the operation of the Observatory is the organization of the information system that provides a potential for recording, calculating, and monitoring of 50 various indicators. Raw data originate from official and reviewed sources except raw data for some traffic and environmental indicators originate from measurements undertaken by component EOAE Units. The indicators are compatible and comparable with the indicators used by basic EU programmes (ESPON, 2005; ASSEMBLING, 2005; EEA, 2004). The indicators concern specific properties and are grouped in three categories related to socio-economic and territorial changes, environmental impacts and the transport infrastructure and operation of the road network.

Figure3. Egnatia Motorway and the examined alternatives

Among these indicators, twenty have been chosen for this particular application and have been subjected to the necessary changes and modifications in order to become

suitable for the purposes of the research. The examined influence zone includes the transit route of the axis, which is directly influenced. For its definition, the spatial level which is represented by the Prefectures is considered more useful in operational terms. Therefore, the transit route from the West to the East consists of the following twelve Prefectures, which are part of five Regions: Thesprotia, Ioannina (Region of Epirus), Trikala (Region of Thessaly), Grevena, Kozani, (Region of of Western Macodonia), Imathia, Thessaloniki, Serres (Region of Central Macedonia), Xanthi, Rodopi and Evros (Region of Eastern Macedonia and Thrace). This area covers 32.000 Km^2, representing 49% of the total surface of Regions and 24.5% of the national territory. According to the 2001 Census, the actual population adds up to 2.319.052 inhabitants. The Prefecture of Thessaloniki is the most populated of the Prefectures, since it concentrates 27% of the population.

3.2 Decision Hierarchy Formation

The need for performing MCDA approaches in order to gauge the examined prefectures occurs given that there is no effective solution that dominates all the others in the analysis. Figure 4, shows the rankings of the alternatives to the examined indices. Granted that, it is rather difficult for both practitioners and researchers to handle effectively the amount of information. In order to avoid the above drawback AHP is used in the present paper aiming to establish a composite index of suitability enabling thus sufficient ranking of the alternatives.

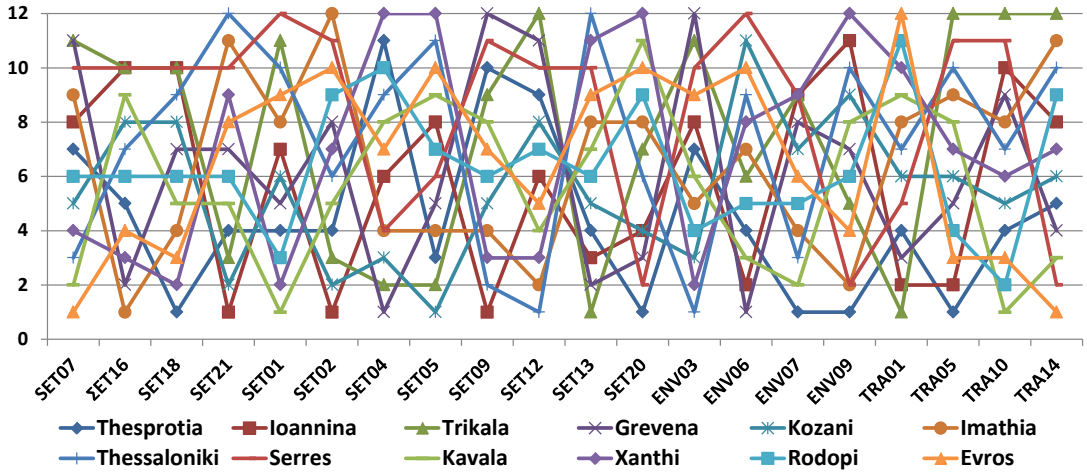

Figure 4. Alternatives profile to the analysis criteria

In order to enable coherent evaluations among the analysis objectives and subobjectives a five level hierarchy is formed (Figure 5). The first level consists of the analysis goal which is the effective ranking of the examined prefectures while in the last level is occupied by the analysis alternatives. The twenty indices that are used for the alternatives evaluation are grouped under socioeconomic, environmental and transportation objectives that should be improved by the Egnatia Motorway

realization. Moreover socioeconomic objective is further subdivided into socioeconomic and planning indicators in order to build clusters that ensure coherent evaluations during the process of deriving relative priorities i.e. the contribution of each objective to the final outcome. Finally the contribution of each alternative to the indices satisfaction is standardized using the maximum score method (Voogd, 1983). The last is a linear utilization approach which allows sufficient transformation from the natural scales of measurement to the DMs' preferential systems and thus the performance of weighted average as decision rule for synthesizing the per criterion impact scores.

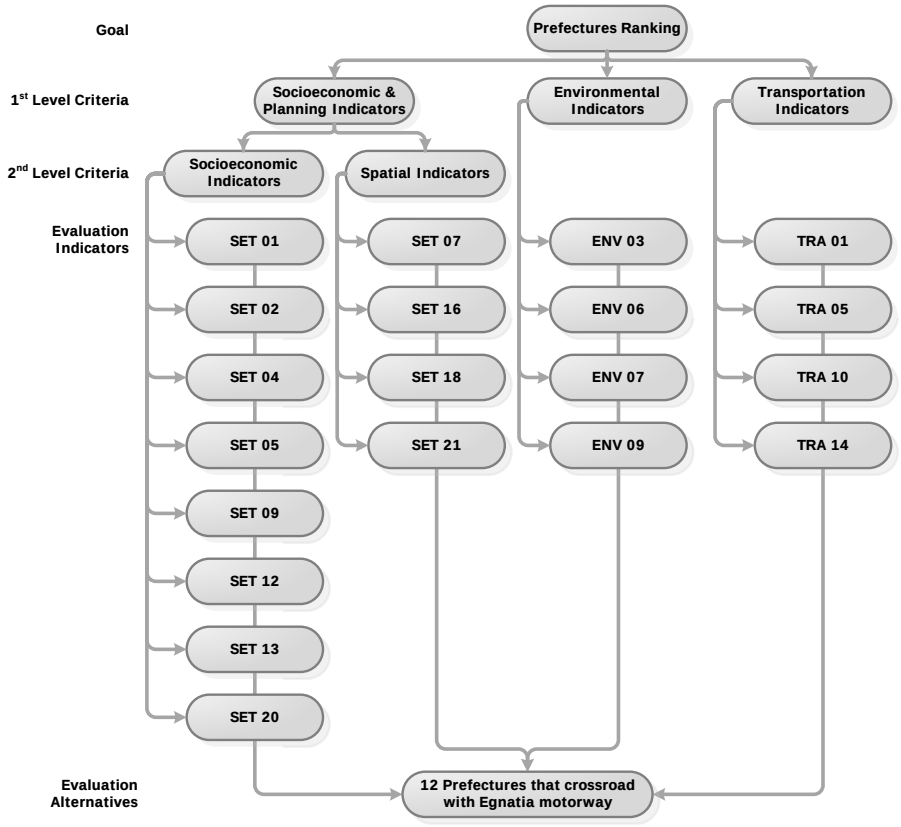

Figure 5. Decision hierarchy

3.3 Socioeconomic Indicators

SET01: It defines the percentage of 2011 population of every prefecture's municipalities which have the main axis of Egnatia Motorway passing within their boundaries comparing to the total population of the prefecture. The indicator's purpose is to assess the population which is potentially benefited directly from the road axis on the level of everyday trips.

SET02: It defines the Annual Average Domestic Product (GDP) 2000-2007 per prefecture. The improvement of transport infrastructure results in an increase of the production factors' mobility and markets' improvement of accessibility.

SET04: It records the average annual rate of change of the declared income per taxpayer 2002 – 2007 in constant prices 2000, per prefecture, as a factor of the area's level of development and prosperity.
SET05: It records the percentage of the unemployed change 2004-2008 per prefecture. The unemployment rate is considered to be one of the main indicators of the development status of a region.
SET09: It determines the population change 2001-2007, per prefecture. The objective of monitoring this indicator is the identification of the macroscopic effects of transport infrastructures improvement on the increase, retaining or decrease of a region's population.
SET12: It determines the change of density population 2001-2011 per Prefecture. Density is a basic indicator of the distribution of population in relation to the motorway's axis.
SET13: It records the Total Gross Value Added (GVA) Annual Rate Shift 2000-2007. The GVA is a basic structural characteristic of a regional economy and it is affected, among others, by the improvement of the movement of goods or the markets' accessibility.
SET20: It refers to the change of total work circle of the Enterprises 2000 – 2005, per prefecture. Entrepreneurship is potentially enhanced by the operation of transport infrastructure, as enterprises improve the accessibility and have an impact on increasing the production factors' mobility and on market integration.

3.4 Spatial Indicators

SET07: It records the distance (km) of the Industrial Areas and certain other productive infrastructure located in each prefecture from the closest intersection of the motorway. The optimum connection of the road network with the productive infrastructure is generally a basic development parameter of the productive activities.
SET16: It defines the percentage of change of urban land use (continuous, linear and un-continuous development) in the areas around the nodes of each prefecture.
SET18: It estimates the average change of land value 1998 – 2007 within the direct influence zone of the axis as well as in selected areas in each prefecture. The purpose of calculating this indicator is to examine the effects of the operation of the road axis on land value.
SET21: It records the change of attraction that takes place among the prefectures' capitals after the improvements in distance brought by the construction of Egnatia Motorway and depends on the exact distance from the road network before and after the operation of the Egnatia Motorway and on 2001 population.

3.5 Environmental Indicators

ENV03: It presents the change of fragmentation of organized settlements before and after the axis' operation per prefecture. The fragmentation of settlements is calculated as follows: [number of settlements] x [average permanent population] / [average area]x(1/100) and has important implications in their urban organization, proper operation as well as safety of their residents.

ENV07: It defines the change (%) of the technical surfaces along the Egnatia Motorway 1998 – 2007 per prefecture in the areas nearby the interchanges. The conversion of rural and natural land into technical surfaces is a cause of biodiversity loss and reduction of natural resources.
ENV08: It indicates the relation between the environmentally sensitive areas and the road network as well as the potential options that they would be affected by human activities.
ENV09: It captures the change in density of the crossings of the national road network with surface waters per prefecture (crossings/km), before and after the operation of the Egnatia Motorway and intents to identify the sensitive spots from the perspective of the potential impacts of the axis on water supply.

3.6 Transportation Indicators

TRA01: It records the change (%) 2000 – 2005 in the average daily distance travelled (in km) per prefecture of the vehicles that travelled between two successive interchanges of the Egnatia Motorway during one year. The traffic volume is the basic indicator for the depiction and examination of the movement on the axis.
TRA05: It estimates the change of the average time distance between the capital cities of each prefecture after the operation of the Egnatia Motorway by road means of transport. The time distance between these cities is a basic indicator for the estimation of the transport cost of persons and goods.
TRA10: It estimates the change of the average time distance between the prefectures' capitals after the operation of the Egnatia Motorway by road transport modes. The time distance between these cities is a key indicator for assessing the accessibility and provides basic information for the calculation of the transport cost of persons and goods.
TRA14: It records the change (%) of the trips 1996 – 2006 before and after the operation of the axis within the boundaries of each prefecture. The impacts of the axis on the trips' characteristics are related to the change in mobility, the trips' extension and the operational linkage of the areas.

Table 1. Analysis Scenarios Criterion Weights

	Crit. 1	**Crit. 1.1**	**Crit. 1.2**	**Crit. 2**	**Crit. 3**
Scenario 1	0,540	0,333	0,667	0,297	0,163
Scenario 2	0,333	0,333	0,667	0,333	0,333
Scenario 3	0,333	0,500	0,500	0,333	0,333
Scenario 4	Each index derives a weight of 1/20=0,05				

4. Results analysis and discussion

In the present four scenarios are examined according to the estimation of the criterion weight. In the first (Scenario 1) the relative importance is estimated through the performance of pairwise comparisons as it is imposed by the AHP. On the other hand the last scenario (Scenario 4) considers the case where all the analysis indices

correspond equally to the analysis. Scenarios 2 and 3 correspond to compromise situations. In particular scenario 2 reflects the situation where the first level criteria are of equal importance while the third scenario the previous assumption to the second level criteria as well. Table 1 summarises the weights for each evaluation scenario.

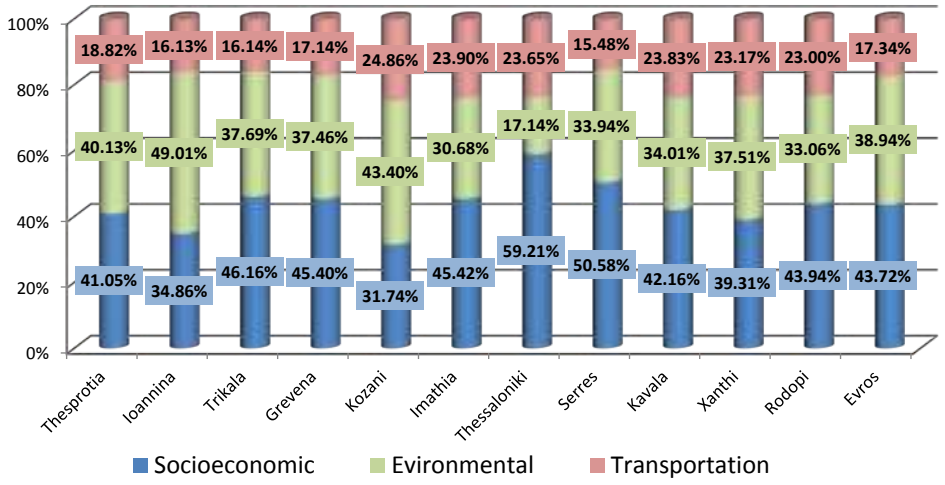

Figure 6. First level criteria impact to the prefectures rankings

With respect to the first Scenario (AHP) it is noted that for the majority of prefectures, the socioeconomic criteria have the highest impact on their final ranking (Figure 6). Exceptions are the prefectures of Ioannina and Kozani the performance of which on the environmental and transportation indicators impacts more on their final ranking. This can be explained by the fact that these prefectures include areas of outstanding natural beauty and moreover, they have significantly improved their transportation infrastructure. It is worth mentioning that the ranking of Thessaloniki Prefecture which includes the metropolitan area and adds up to around one million inhabitants, is mainly shaped by the socioeconomic indicators and secondarily by the transportation ones.

The rankings of the twelve prefectures to the examined scenarios of the analysis are presented in Figures 7. From the spatial distribution (Figure 8) of the suitability index it is obtained that Thesprotia and Kavala prefectures are ranked in the first two places while Trikala and Serres are ranked last to all the analysis scenarios. Thesprotias' ranking can be explained by the fact that emerges as one of the most important entrance gates in Greece given the presence of significant port infrastructure. Respectively, the role of Egnatia Motorway seems to be less beneficiary for Trikala and Serres given that only a limited part, close to their administrative borders, is crossed by the horizontal axis.

With respect to the differences that occur in the alternatives ranking, it is noticeable that Evros which is ranked 10th and 9th to the first two scenarios, is ranked 3rd in

scenario 3. On the contrary Ioannina suffers the most in the third scenario ranked in the 9th place from the 4th that possesses in the first two scenarios. The above can be explained by the good performance that receives Evros prefecture to the environmental and transportation indices that gain high relative importance to the third scenario. Regarding to the other prefectures the changes to the ranking series it is not noticeable. Shortly, Kozani Prefecture remains in the 3rd ranking place while three others (Rodopi, Grevena, Imathia) improve their rankings by one place, while two other are downgraded by two places (Thessaloniki, Xanthi).

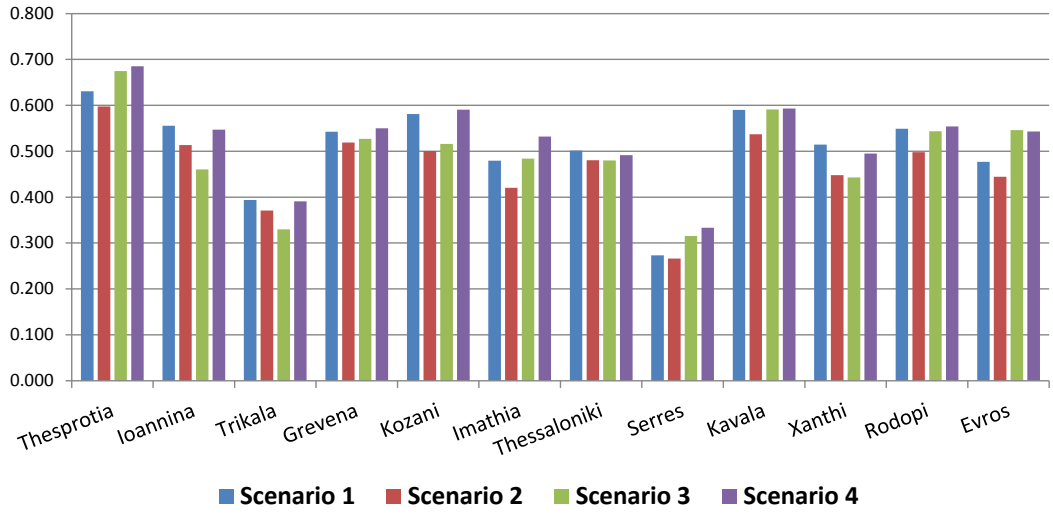

Figure 7. Prefectures rankings to the analysis scenarios

5. Conclusions

The realization of Egnatia Motorway consists one of the most important intervention that have been utilized in northern Greece during that last two decades aiming to enrich connectivity among the capital cities and with the major international transportation axes. Since the establishment of the Observatory services by the Egatia Odos S.A. a variety of socioeconomic, environmental and transportation indices have been developed in order to monitor and assess the spatial impacts of the motorway. In the present twenty of these indices are combined in order to derive a composite index for ranking the prefecture that crossroad with the horizontal axis of the motorway. Technically this is achieved combining GIS technology and Multicriteria Decision Analysis methods. The approach combines GIS abilities for managing and visualizing spatial data while AHP provides a consistent framework for the integration of decision makers' preferences to the planning of future interventions. The above synergy allows practitioners and policy makers to identify and visualize the impacts provoked by the operation of significant public works and in the same time to identify the presence of intraregional inequalities. Thus, the proposed approach can be proved significant in order to support future decision related with the planning of future interventions in the examined area.

The Competition for the Financial Surplus between Municipalities and Multi-municipal Administration in France

An Analytical Framework for Land Policies

Nicolas PERSYN
Ph.D Student, University of Paris-1, Research Team Géographie-Cités

Abstract

This paper considers municipalities and their multi-municipal administration as separate actors involved in the struggle for the financial surplus created by urbanization. It proposes an analytical framework for land policies in the French context.

In France, since the 1980's, municipalities can cooperate in a multi-municipal administration in order to share financial, technical and human resources. Different levels of integration exist, and some jurisdictions, such as land policies, can be shared by both administrations. The issue of the coexistence of these two decision-making scales has been addressed in terms of inefficiency of urban planning procedures : the territorial dynamics occur at a multi-municipal scale while municipalities still retain important decision-making power in this field.

But this coexistence has not been integrated in the analysis of the interactions of local actors around land policies. Traditionally three actors are identified, in the "triangle" of land policies: the public local administration, the land owner and the developer. We argue that in the French local administrative context, this "triangle" can be considered as a square: municipalities and their multi-municipal administration are separate stakeholders. They can have different political aims and different strategies to achieve it.

Needham and Verhage (2003) proposed to analyze these interactions in terms of struggle for the financial surplus. This surplus is defined, for a land development project, as "the difference between the market value of the completed project and the minimum production costs" (Needham and Verhage, 2003). The local administration aims to recover some of it to finance facilities, infrastructures, and social housing. From this point, land policies are seen as means for the local administrations to appropriate a part of the surplus.

In this paper we argue that the struggle for the financial surplus can become an analytical framework to understand the interactions between municipalities and their multi-municipal administration as well as their own strategies. The land policy tools, and the objectives they try to achieve might be contradictory, and by implementing them, municipalities and multi-municipal administration might conflict with each other. This analysis through the financial surplus brings a complex view of the relations between these two stakeholders.

The struggle for surplus analysis is applied to the case of the Pays Voironnais, a multi-municipal administration located 25 kilometres north from Grenoble in the French Alps. The study of the actors' relations is based on interviews. It is completed with an observation of the land policy tools implemented by the municipalities and the multi-municipal administration.

Introduction

Land policies are a major stake for urban development in all developed countries. In France, the question is very important because of the housing crisis, the dynamics of urban sprawl (Couch, Petschel-Held, Leontidou, 2008; Vilmin, 2008; Wiel, 2010) and the difficulties to produce building land (Verhage, 2002; Vanoni, 2007). The French situation is made more complex by the coexistence of two local authorities that may share competences: the municipalities and their multi-municipal administrations. The municipalities can cooperate in a multi-municipal administration in order to share financial, technical and human resources. Different levels of integration exist, and some jurisdictions, such as land policies, can be shared by both administrations.

The issues of this coexistence and the difficulties that it creates for land policies have been addressed in terms of political complexity (Adef, 2006; Adcf, 2011), cultural obstacles (Renard, 2009) or financial and technical limitations (Vilmin, Brumelot, 2011). We argue that those explanations are not sufficient to understand the stakeholders' interactions, especially between two public local authorities. Like Needham and Verhage (2003), we think that the sharing of the financial surplus arising from the development process is the central issue of local land policies. The relations between the stakeholders of land policies, but maybe of urban planning in general, may be analyzed as a competition for this financial surplus. We use here this analytical framework in application to a French example, the *Pays Voironnais*, focusing on the housing production.

The paper is divided in 3 parts: we shall first introduce the French administrative context of planning policies. Then we will show that land policies are a way to shape the distribution pattern of the surplus. Finally we will show that in the *Pays Voironnais* the relations between municipalities and the multi-municipal administration reveal a form of competition for the surplus.

1 - The French local administrative complexity

Traditionally France has been a centralized country. But since the 80's, several competences have been decentralized and transferred to the local authorities: *regions*, *départements* and *communes* (municipalities). Those local authorities are represented by assemblies directly elected by the population. This administrative context is really complex because of the so-called "general competence clause". This clause implies that every local authority has general competence over its territory: they have designated jurisdictions and powers, but they can intervene in any domain if their territorial interest is at stake. This leads to complex situations where two local authorities are involved in the same project, or the same program, but with divergent

interests and strategies. The municipalities are the most important authorities, because of their proximity to the inhabitants and because of their competences. They are the major local authority in the urban planning and housing policy domains, they are also competent in designing the urban transport systems, and they are the main local tax collector.

If that were not enough, a new local authority has been created in the 90's: the *intercommunalité*, which we will call "multi-municipal administration", and which is an association of several municipalities. Those multi-municipal administrations were created in reaction to the tiny size of the French municipalities. France is known for the numbers of municipalities on the metropolitan territory (36000, when the Netherlands have 415 municipalities, Germany 12000 and Italy 8100), and for their small size. The average size of the French municipalities is 14.9 square km and the average population is 1700 inhabitants (42000 in the Netherlands, 7500 in Italy, 6700 in Germany). This historical heritage is a problem in terms of territorial coherence because the decisions of the municipalities, which are the strongest local authorities, concern only a small part of the territory. It is especially problematic in urban situations: all the French urban areas are fragmented in several municipalities. How, in this situation, to build a coherent urban master plan, to design a new transport system, to struggle against urban sprawl?

To address this issue, the legislation has created three kinds of multi-municipal administrations: the *communauté de communes* (less than 50.000 people), the *communauté d'agglomération* (between 50.000 and 500.000 people) and the *communauté urbaine* (more than 500.000 people). But those associations of municipalities are not compulsory, and they are voluntary. This explains that not all the French territory is covered by these administrations (the areas where municipalities do not cooperate in such an administration are mainly rural areas, or are in the capital region). And most of the time, when the municipalities do cooperate, it is not on a territorial or functional basis, but according to political affinities. Therefore the multi-municipal administrations often do not cover the urban areas but are smaller. Another thing that we have to mention about the multi-municipal administrations is that they are not directly elected authorities. Considering that they are voluntary gatherings of municipalities, the legislation decided that the councilors in those administrations will not be elected by all the population living in the multi-municipal territory, but will be chosen among municipal councilors. This may lead to a lack of legitimacy for multi-municipal administrations, especially when they are confronting the municipalities.

The domain of urban planning (planning policies, land policies and development process), has traditionally been the competence of the municipalities. The main document in this domain, the local urban plan (*plan local d'urbanisme*) is elaborated by municipalities. It decides on the future land uses in the municipality and is binding on third parties. The building permit is also a competence of the municipality and has to follow the prescriptions of the local urban plan. The multi-municipal administration intervenes on two levels. First, it elaborates the territorial coherence plan (schéma de coherence territorial) which is a land-use plan on the multi-municipal scale. This plan became very important in the past decade. Even if it

can't impose land uses on the scale of the land plot as the local urban plan can, its prescriptions have to be integrated in the local urban plan. Secondly, during the development process, the multi-municipal administration can intervene. But the municipality also has this possibility. The sharing of the development operations between the two authorities relies on local arrangements: some municipalities decided to transfer to the multi-municipal administrations competences such as "major equipments and infrastructures" or "operations of territorial interest" which allow the multi-municipal administration to intervene in very important operations.

Although the municipality still has the main decisional power, the multi-municipal administration is increasingly seen as a better scale to address the planning issues (housing, equipments, transportation and environment). This explains the success of the territorial coherence plans, and the several incentives to build multi-municipal administrations and/or use such plans. These incentives come from the central government, which tries to identify the good practices among different programs like Scot-Grenelle[1], or reinforce the multi-municipal administration through legislation[2].

But in the field of urban planning, the municipalities are often reluctant to abandon a competence which is seen as essential: for municipal councilors, not having the ability to guide the uses of land and the housing production, and to approve the building permits, renders the municipality almost useless.

2 - Local land policies as the distribution of a financial surplus

In the field of urban planning, in spite of the reluctance of municipalities, the multi-municipal administrations are more and more central. They are often leaders in projects in urban transports, or in the social housing production. But in the field of land policies, the multi-municipal administrations are not yet very involved. The land policy tools such as compulsory purchase, preemption right or the *zone d'aménagement concerté*[3] (ZAC) are in most cases still municipal tools. Several analyses have explained this obstacle. Some authors (Adef, 2006) point out the institutional constraints, while others emphasize the cultural and political aspects (Charmes, 2007). If these analyses are quite convincing, they always look at land policies as if they were like any other kind of public policies, and don't consider land in its specificities.

On the contrary, we think that land policies cannot be analyzed in the same way as other public policies, because land takes a particular role here, with several

[1] « Grenelle » is the name given to large consultation governmental programs in France. In 2008 the Environment's Grenelle took place, which led to two Grenelle Laws, and a series of governmental actions. The *Scot-Grenelle* are territorial development plans identified by the government, which are exemplary of the Grenelle Laws orientations.

[2] A recent law, effective in 2014, modifies the local electoral rules. The multi-municipal councilors will be partly designated by electors and not only by the municipal councilors.

[3] The *zone d'aménagement concerté,* is an operational public proceeding applying to a development zone. It allows the local authority to elaborate a general plan, and to plan the public facilities.

dimensions: economic, juridical, and physic. Dealing with property and land as an economic good and as a juridical object, land policies need to be seen through a particular focus: the production of a financial surplus. Therefore we hypothesize here that **municipalities and multi-municipal administrations are involved in a competition for the financial surplus arising from land development**.

We define this financial surplus as the "difference between the market value of the completed project and the minimum production costs" (Needham, Verhage, 2003). This surplus arises at different moments in the land development process, and has different origins. The figure below shows the different factors responsible for the financial surplus. We can separate "internal" factors, that directly concern the plot, and "external" factors, that take place on other lands. Internal factors occur only at a precise step of the development process. But external factors may occur at any step.

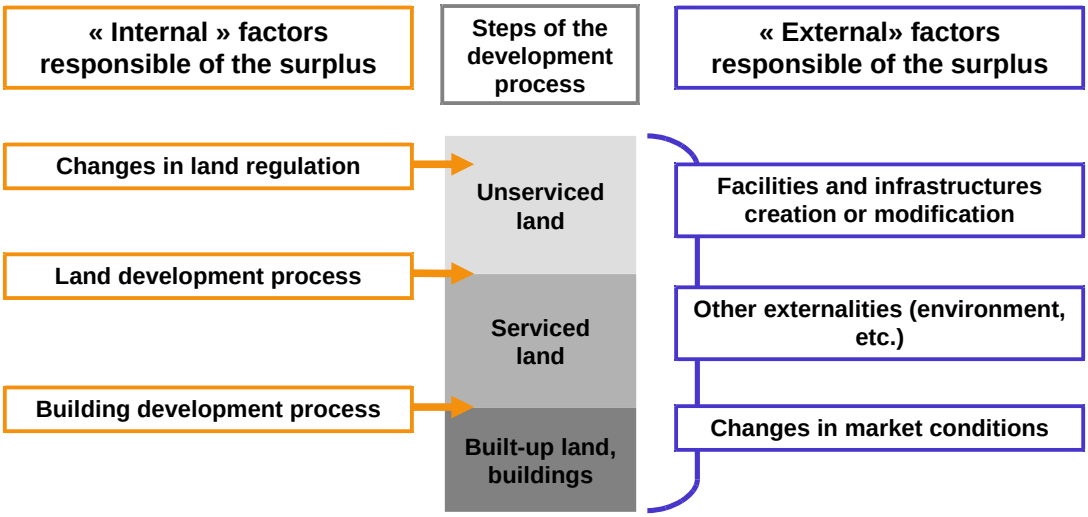

Figure 1 : factors responsible for the financial surplus in land development

The figure does not represent which are the agents at the origin of the surplus. But we can guess that local authorities are central: they decide on the *changes in land regulation* and can intervene in the *development process*, they also *create or modify facilities and infrastructures*, and are often involved in the production of *other externalities*. But if they are influential in the production of the financial surplus, local authorities may also affect the allocation of this surplus. Because the major question about financial surplus is: who gets it at the end? In other words, this may be summarized as: who finances the urbanization process? Does the local authority get a part of the financial surplus to finance equipments, infrastructures and social housing? Or on the contrary is it the original owner who gets the surplus?

This distribution pattern is influenced on two levels: the legislative framework, over which local authorities have no influence; the land policy tools used by local authorities[4]. These tools may be considered as a way to modify the

[4] It is here that the juridical dimension of land takes place.

distribution of the surplus: when a surplus, arising from any kind of factor, goes to the original owner, the local authority can implement a tool that will allow it to get a part or the totality of the surplus. Let's take an example. A municipality decides to build a new train station in a suburb. Automatically the value of the properties around this new station rises (financial surplus), without any internal modification, only because the geographical situation becomes more profitable. If the municipality does nothing more, this surplus will go to the owners when they sell their land. But, if the municipality implements a tool such as a taxation of the properties near the new station, or tries to purchase these properties before the construction of the new station to develop a new neighborhood, it will get a part of the surplus back. But the leeway of the municipality is limited by the legislative framework.

In Europe, the sharing of the financial surplus may be very different from one country to another. In France, the surplus traditionally goes to the original owner, maybe because of the French tradition that implies that the property is something "sacred". The legislative framework limits the possibilities for the local authorities to get a part of the surplus back. But it doesn't forbid it, and municipalities and multi-municipal administrations can use different tools to split the surplus. The attitude of the local authorities can explain the distribution pattern. In the Netherlands, on the contrary, financial surplus is mainly recovered by the municipalities, because they purchase land to develop it themselves. But between France and the Netherlands (which are of course an extreme example), the legislative differences are quite small: the French municipalities have the right to do what the Dutch do. And, regarding some points, they have more powers than the Dutch. The differences in the capacity to recover the surplus are therefore relevant to the local practices.

The question of who gets the financial surplus is more far-reaching than it may seem at first: it is another form of the question *who pays for the urbanization process*? As Needham and Verhage (Needham, Verhage, 1998) indicated it, when the local authority gets a part of the surplus back it is a way to finance the "quality of urbanization": public facilities, infrastructures, but also the servicing of lands. The idea for public authorities is not to act as private companies and gather the surplus to increase their capital. Recovering the surplus has to be seen as a way of financing the public expenditure on the quality of the urban space.

In this situation, we may imagine that there is a competition between the different stakeholders of land development process to catch the surplus. These stakeholders have often been presented as a triangle: the owner / the local authority / the developer. Several research works refer to this triangle to analyze the stakeholders' interactions (Vilmin, 2008). But we think, as we started to mention previously, that the local authority cannot be considered as unique in the French local administrative context. During the analysis, the distinction between municipality and multi-municipal administration is essential to understand what the public strategies are: the municipality doesn't have to interact only with owners and developers, but also with the multi-municipal administration. That is the reason why we propose to analyze not the triangle of land policies, but the square of land policies: the owner / the municipality / the multi-municipal administration / the developer, and especially the relations between the two local authorities.

Figure 2 : Stakeholders in land policies: from the triangle to the square

The purpose of this paper is to present the results of a small research about **the competition for the financial surplus between municipalities and their multi-municipal administrations**. This competition, as we will see, may take several forms: the use of land policy tools; a political struggle in general; a competition for the appropriation of the planning competence.

This investigation took place in the *Pays Voironnais*, a French multi-municipal administration, which is representative of the global relations between municipalities and multi-municipal administrations in France.

3 - Urban planning and land policies in the Pays Voironnais: the sharing of competences between multi-municipal administration and municipalities.

The *Pays Voironnais* is a *communauté d'agglomération* gathering 90.000 people, 34.000 jobs in 34 municipalities. It is situated 25 kilometers north of Grenoble, an important agglomeration of 400.000 people. The proximity and the demographic and economic weight of Grenoble make the *Pays Voironnais* dependent on its large neighbor. This dependence appears in several forms: employment, demographic dynamics and public facilities. The territory of the Pays *Voironnais* is composed of a central city, Voiron, 20.000 people, of a rural space to the north and to the south, of the *Isère* plain, which is more dynamic economically, and which is crossed by important transportation infrastructures (roads, highways and railroads).

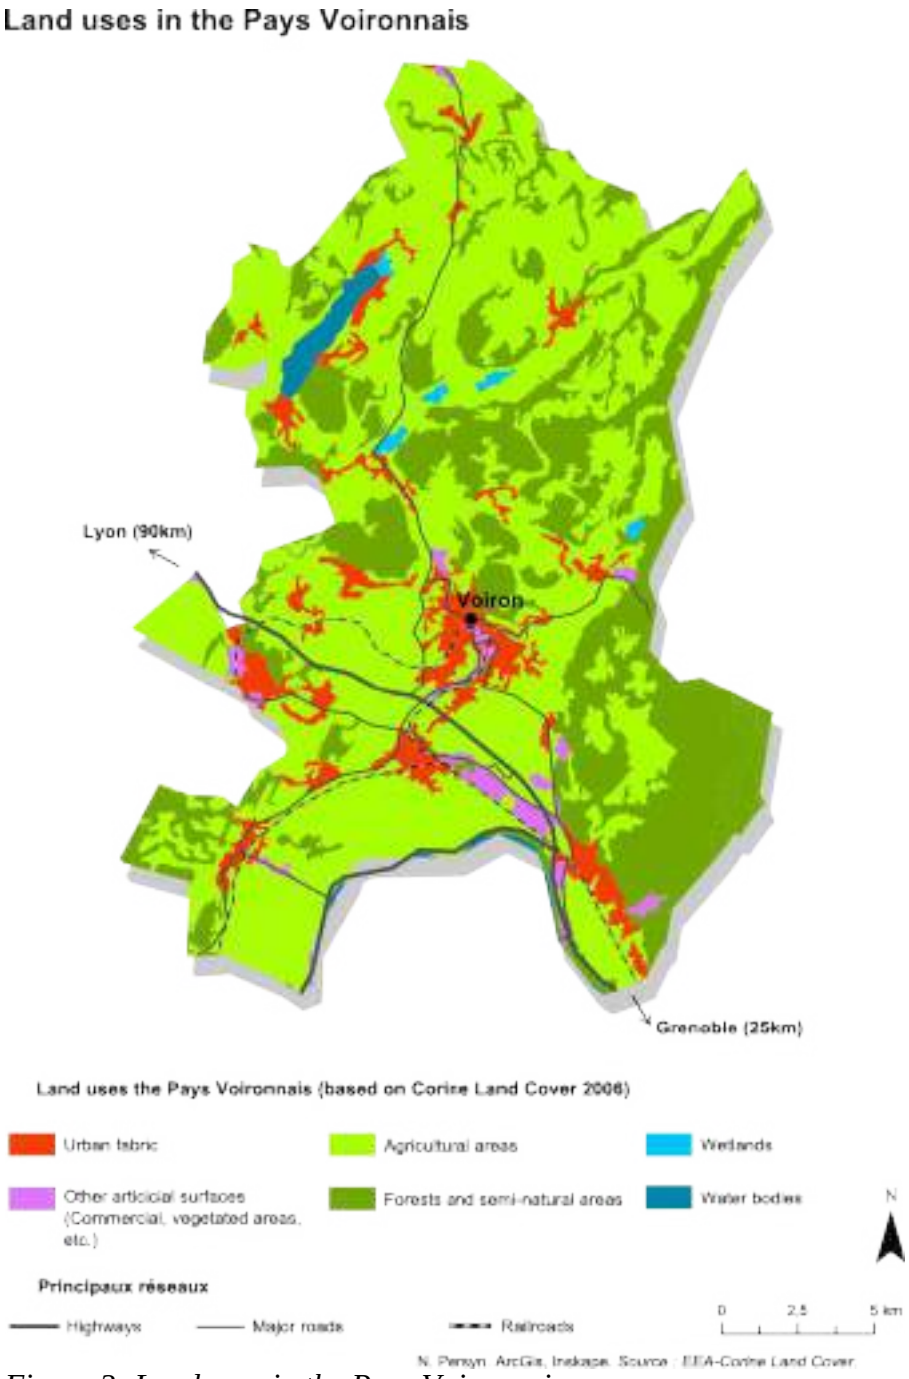

Figure 3: Land uses in the Pays Voironnais

The multi-municipal administration was structured early compared to other multi-municipal administrations in France: while the majority of French multi-municipal administrations were created in the 90's or after 2000, the first administration gathering several municipalities was created in 1974. It was created in reaction to a new town project, led by the state: the municipalities didn't agree with the idea of receiving 200.000 new inhabitants in thirty years. So they set up a multi-municipal administration that gave them more weight in front of the state and the

Grenoble agglomeration. This point is important because it shows that the *Pays Voironnais* was originally devoted to urban planning issues.

The different competences concerning urban planning are shared between the *Pays Voironnais* and the municipalities. The multi-municipal administration has competence over the territorial coherence plan, which allows it to have an great weight in the land use decisions. But the municipalities still elaborate the local urban plan, which is the most precise document for land uses. In terms of political weight, the municipalities have greater control on land use than the multi-municipal administration. The competence concerning social housing has been transferred to the multi-municipal administration. It elaborates the housing local program (*programme local de l'habitat*), that, for 5 to 10 years, states the objectives of the local authority in terms of housing, and that can impose social housing ratios. For social housing, the multi-municipal administration also intervenes financially, granting subsidies to municipalities for projects including social housing. Multi-municipal administration has a competence called "development operations of structural importance". This means that it can intervene, or completely elaborate and lead any project corresponding to this category. But this is only possible if the municipalities agree.

In terms of land policies, the competences are mostly in the hands of the municipalities. The local urban plan is a major instrument, but other kinds of instruments can be used by the municipalities: building permit, preemption and compulsory purchase right, taxations and contribution to the equipment imposed on the developers, etc. The multi-municipal administration doesn't have such competences[5]. But in 2005 it introduced a new land policy program: when the municipalities buy a land or a building in order to develop a project, if this purchase is too expensive for the municipal budget, they can ask the multi-municipal administration to buy it by themselves, and to sell it back to the municipalities after a few years, during which the project will be elaborated. So it is not a direct intervention of the multi-municipal administration in the land policies, but rather a support.

If this sharing of competences doesn't reveal a competition for the financial surplus, it establishes that the municipality is, *de jure*, predominant in urban planning and land policies domains. But does it means that the municipality is more able than the multi-municipal administration to catch the surplus? And how does the multi-municipal administration, which seems to be in a week position, try to catch this surplus? How does the competition for the surplus between the municipalities and their multi-municipal administration occur?

4 - Two forms of competition for the financial surplus

[5] Except for economic development and industrial zones

The competition for financial surplus between municipalities and the multi-municipal administration takes two forms: an indirect – political – competition for the sharing of competences, in other words for the ability to catch the surplus; a direct competition, to catch the surplus, in development operations.

We have seen that the ability to distribute rights in land is central because it impacts both the creation and the distribution of the surplus. Municipalities and the multi-municipal administration both want to hold this competence. It is now the competence of the municipalities, but things are changing. Through the territorial coherence plan, the multi-municipal administration is able to influence the municipal decisions in terms of land uses. But the *Pays Voironnais* wants to go further, and is currently trying to obtain the transfer of the urban planning competence from the municipalities. In this case, the multi-municipal administration will be able to decide by itself on the land uses through a multi-municipal local urban plan. But for the moment municipalities are mostly reluctant. Some municipal councilors think that is would be a good thing: it would ensure a coherence of the land uses decisions. Some others are reluctant but think that this transfer is inevitable. The majority of them think that it is not a good thing because it is the most important competence of the municipalities. Between the municipality and the multi-municipal administration the discussions on this point are numerous and lively.

There is another case in which the multi-municipal administration has taken an important stand: the adhesion to the local land public agency (*etablissement public foncier local*). Such agencies have existed in France since 1991. Their role is to financially and technically assist municipalities when they purchase land. These agencies are independent and are financed thanks to a tax. But they can't act without the approval of the municipalities, and they operate as associations to which the municipalities or multi-municipal administrations adhere. So they don't have a political but only a technical role. As we have seen, until 2011 the *Pays Voironnais* played this role with its land policy program. But in 2001 the Grenoble agglomeration, the neighbor of the *Pays Voironnais* implemented a land public agency. At this date, the *Pays Voironnais* refused to adhere because it wished to remain independent from Grenoble. This situation changed in 2011, after the two agglomerations learned to work together, particularly through the elaboration of the territorial coherence plan. In 2011 the *Pays Voironnais*, and the municipalities, of course, decided to adhere to the land public agency. But the multi-municipal administration imposed a condition that is not present in other cases: when a municipality wants to submit a project of purchase for a plot or a building to the public agency, it has to submit it before to the *Pays Voironnais.* This situation makes the multi-municipal administration central in the land policies: it can check all the municipal purchase projects, and if it does not agree with the idea or the technical modalities of this project, it can decide to not submit it to the public land agency. This means that the municipality will not be able to complete this project (because it needs the financial help of the agency).

Of course even with this competence, the multi-municipal administration cannot get back the surplus arising from the land development. But it is a way to control the transactions of the municipalities.

The competition for the surplus may also be direct. Some urban development or renewal projects are led both by a municipality and the multi-municipal administration. In such situations can we read the relationships between these authorities as a competition for the surplus? Of course, not all the discussions are guided by this stake. But the surplus is often at stake. We will here take two examples, two municipal operations were the multi-municipal administration have been intervening.

The first is an urban renewal operation in Voiron, the central town in the *Pays Voironnais*. The municipality wants to redevelop a brownfield near the train station. Part of the site of 8 ha is occupied by a former plant, and the other part is not built. The objectives are to build houses (with 25% of social housing) and to extend the adjacent hospital. To the north the site is bordered by the railroad. The stake here for the municipality is to finance the public facilities and infrastructures. New roads have to be built, especially one crossing under the railroad. At first, the municipality wanted to charge this expenditure on the developers. But the developers can't both support this expenditure and build social housing (which is sold at a lower price than the market one). The municipality then wanted to reduce the social housing ratio, so that the developers should be able to finance the infrastructures, because of the increase of the exit price of the global project. The multi-municipal administration was opposed to this solution: it is responsible for the social mix in the territory and wants that ratio to be respected. The solution that the municipality found was to present the new road under the railroad as relevant to the interest of all the municipalities of the *Pays Voironnais* and not only to the city of Voiron. Arguing that it will improve traffic conditions in the central town and therefore in the heart of the *Pays Voironnais*, the city of Voiron wants the multi-municipal administration take on the expenditure. The question is not solved yet, but the *Pays Voironnais* seems to be reluctant to pay for works it consider relevant to the municipality.

This is not a real competition to *catch* the surplus. This surplus, arising from the development process, will go to the original owner of the land. But if the municipality doesn't get it back, it doesn't want to finance it through equipments. It can charge the developers without threatening the operation's balance, so it turns to the multi-municipal administration to finance this surplus.

Another example may illustrate this point. As we mentioned it, the *Pays Voiron*nais is in charge of the network development: water supply, sanitation and some roads. Because the local financial resources are rather limited the multi-municipal administration wants to limit their extension. It therefore encourages the municipalities to locate the development project on plots that are already serviced (brownfields) or that are close to the existing networks. This incentive is supported by the existing discourse around sustainable urban development and the compact city: the urban development needs to be situated in the existing city, or at least in immediate proximity. But if this solution allows the multi-municipal administration to reduce expenditures, it is not the cheapest solution for the municipalities. Brownfields are generally more expensive that greenfields. Building on the brownfields complicates the elaboration of the project and makes it more difficult to

find the financial balance, especially when the project includes social housing. There is therefore a tension between the municipalities and the multi-municipal administration to identify the plots that will welcome a housing project. Once again, it is not really the capturing of the surplus that is at stake here, but the possibility for the multi-municipal administration not to finance it. This situation imposes some difficulties to elaborate the project on the municipalities: if they want to make the developer build houses at a reasonable price, they will have to finance the surplus of both the original owner and the developer.

These two examples illustrate a general situation in France: the financial surplus arising from the urban development is very rarely caught by the public authorities. It goes, depending on the step of the development process at which it arises, either to the original owners, or to the developers. Despite the former (Topalov, 1984) and the recent (Lacoste, 2009) reflections about the possibilities to tax, or better, to get the surplus back, the local practices are still favourable to private parties: land owners and private developers. Locally, the authorities do not really try to catch the surplus. We see several reasons for this.

For most of the researchers, the main reason is that the electoral weight of the land owners at a local level is very important, especially in the peri-urban municipalities where the demographic pressure is high. This makes the municipalities and the multi-municipal administration reluctant to change the sharing of the surplus. But this explanation, if it is true, is insufficient. For us, the main reason is that the tools that should be used to influence the sharing of the surplus are either inappropriate or missing. Many land policy tools are extremely difficult to use for local authorities. On the one hand, the procedures to implement such tools are very long and complicated, and a lot of municipalities, but also multi-municipal administrations don't have the human, technical and financial means to overcome these difficulties. It is for example the case of the preemption right or the compulsory purchase procedures. On the other hand, the implementation (but in fact the whole development project) is subject to great uncertainty, because of the multiple legal remedies possible: when a municipality wants to use its preemption right it has to be very careful if it wants to avoid the possible legal remedies from the owner. But the local authorities also point out a lack of tools. Especially, the impossibility for local authorities to force an owner to build, when its land is designated as building land, can lead to reduced land availability, which means competition increase, a rise in prices and in financial surplus. It also means that the owner has great power in front of the local authorities (the owners who want to develop their land at low prices are rare): it is hard for the public bodies to influence the sharing of the surplus.

The fact that they are not able to get the surplus back leads the municipalities and the multi-municipal administration to compete in order not to finance it. They try to impose on the other to finance the surplus of the owner or of the developer. As we have seen, each local authority has its own assets. But the actual context, even if the municipalities still have an important weight, seems to turn in favor of the multi-municipal administrations. The recent law about the local administration, which will apply in 2014, will reinforce the multi-municipal administrations. The central state

incites the multi-municipal administrations to act in the urban planning and land policy domains. And at the local level the practices tend to ascribe a greater role to multi-municipal administrations.

Conclusion

The definition of the distribution of the financial surplus is the central stake of local land policies. The two local authorities that may shape the distribution pattern, i.e. Municipalities and multi-municipal administration, compete with each other. But they rarely compete in order to recover part of the surplus: in France, the legal framework and the local practices generally lead to grant almost all of the surplus to original owners and developers. They still are local variations of the distribution pattern, which are due to the decisions of the municipalities or the multi-municipal administrations, but in general the local authorities don't catch it. There is therefore a competition between the two local authorities about two points: first the power to decide on the distribution pattern; second they compete *not to finance* the surplus.

This competitive situation doesn't seem to ensure the best output for land policies or planning in general. The question of how to finance the urbanization is currently limited by the local practices: that the local authorities, and hence the inhabitants, finance the facilities and infrastructures, while land owners and developers take advantage of these amenities without paying. This makes very complex for local authorities to create social housing or important infrastructures.

Of course, municipalities and multi-municipal administrations are not always at loggerheads, and they are more and more able to build projects together. But the distribution of the surplus may be an important obstacle to these projects. We tried here to provide an analysis framework for these obstacles and for the relations between stakeholders in the land development process.

Self-organized Urban Growth Shaped by Institutional Rules

Empirical Experiences from Beijing

Shuhai Zhang[1], Terry van Dijk[2], Gert de Roo[3]

Abstract

Beijing, as capital city of China is undergoing a striking fast urban growth process. The increasing dynamics and uncertainties along with it already become a key issue as well as a great challenge for contemporary planning debate. Among the various perspectives, there is an emerging body of research trying to address and solve it by touching upon complexity science. This paper aims to contribute to this debate through an empirical study on case of Beijing urban region. As one of the most developed cities in China, Beijing had experienced tremendous urban expansion over the last thirty years. Meanwhile, Beijing land use plan is featured by a strong control system supported by the Chinese unique land ownership system. This plan performed well in functionality such as urban growth management, preservation of farm land and open space. On the other hand, it created illusions that reality could be well controlled and changes could be well created. In reality however, more and more dynamics outside this powerful plan can be found lately. We'll explore these informal urban land use changes in this paper, with evidence coming from Beijing land use data, two land use plans of Beijing, and interviews on urban planners and private developers. We expect this evidence can indicate potential autonomous changes under a self-organized mechanism instead of controlled reality. Moreover, we have disagreement with the complexity based discussion on this point that a self-organized urban region is totally unpredictable. Instead, we take a perspective called institutional constrained self-organization. The influence of institutional settings on self-organization urban progress could also be found in the empirical study. Through all of these, the influences of both self-organization mechanism and institutional settings on urban growth and their relationship during this urban process can be well analyzed. Then the main concern of land use planning, As one type of institutional power, could be reconsidered and clarified: telling what to achieve and what to avoid.

Key words: self-organization, urban growth, institutional settings, Beijing

1. Introduction

The past decades has witnessed an astonishing urban growth process in China, particularly for some very big cities in the eastern part of the country (Wu & Yeh, 2007; Deng et al., 2010). Beijing, as one representative for this situation, is now one of the most dynamic metropolitan area in the whole universe. The dynamics can be observed extensively: the over flourishing of Beijing urban region, increasing employments and investment, better service in education and health care, convenient information network, abundant daily flow of population, goods and information, et al., all of which leads to large amount of urban land consumption. The expansion of urban land, on the one hand can better meet the urgent demand for more residential, commercial and industrial space; on the other however, acts as trigger to stimulate additional regional development. Therefore, the demand and supply of construction land in Beijing urban region are now positively interacted and mutually promoted, well supporting high-speed growth during this period. This situation greatly benefits from demographic bonus due to regional gradient urbanization, meaning immigrants from both rural areas and other cities are coming national wide. From this perspective, we can conclude that the trend of rapid growth with loads of land consumption in Beijing urban region will also not change in the coming years. The increasing and lasting dynamics create a rather complex situation which becomes a great challenge for both planners and policy makers.

In addition, the increasing negative effects coming along with this fast urban land growth has put sustainable development under high risk. Ecologists and environmentalists remind us that negative effects of this fast growth is ignorable, of which two aspects are most alarming First, increasing tension between sharping decrease of farming land and Chinese farming land regulations. For food safety reasons, China has been long emphasizing on a policy of self-sufficiency food crop. According to this policy, every provincial level region (Beijing urban region is also one of provincial level region), no matter how developed it is, has to conserve certain amount of farming land. What's more, this policy is reinforced by a code named arable land balanced system, which means the exact same amount of arable land as growth of urban land should be supplemented during urbanization process. It in general causes decreasing quality of arable land as in these big cities like Beijing as potential arable land resources are rather limited (Tan, et al., 2005). Secondly, environmental implications of fast urban growth are becoming serious including depletion of natural resources and descending level of underground water (Bao and Fang, 2012; Varis and

Vakkilainen, 2001), air pollution (Wang and Xie, 2009; Chan et al., 2005), traffic jams (Zhao, 2010; Kombe, 2005; Gwilliam, 2003), et al.. Both of the above two negative effects of fast urban growth in practice, also attract research attentions, in order to get in-depth knowledge on urban growth process and find a solution to cope with growing demand for urban space.

If we move one step further to pay attention on the context within which Beijing urban growth is happening, more inspirations could be found. This unique system could be summarized as a strong top-down mandates and a homogeneous urban governance structure (Zhang, 2006; Maskin et al., 2000), as well as a unique land property system (Liu et al. 1998; Li et al. 2010), both of which makes research on Beijing urban growth an additional contribution to current theory and therefore a very hot topic (Wei and Zhao, 2009; Cartier, 2001; Alston et al., 1996). In China, there are two categories of land ownership: state ownership for urban land and collective ownership of villagers for rural land. These two types of ownership however, has a subordinate relation instead of being equivalent. This is firstly because the collective ownership of villagers is not a complete ownership in term of that it is strictly forbidden for utilizing, leasing or selling for non-agricultural use. Urban utilization can only be achieved after transfer of land ownership from collective owned to state owned through a process named requisition. For the loss of land ownership, villagers will get one-off compensation in money or in kind, which according to current national and local standard however, is still rather low and unfair (Ding, 2007; Lichtenberg and Ding, 2009). Besides, the chair of village representative committee who made decisions for villagers collectives act as the bottom level in the Chinese top-down government system and their decisions are largely dependent on higher level government. This makes it clear at least for two points. For the first, two types of ownership in China can be summarized as one as far as urban growth is concerned only if we don't consider growth outside legal context. . And the second, urban growth is in firmly controlled by the top-down government system. The linkage between this top-down structure and land use changes is land use planning, by which distribution and regulation of urban land use are realized. Land use plan is embedded in Chinese top-down governance system and featured by a technical rationale. It is regulations on land use usually for 15 to 20 years. It's main task is for spatial distribution of various land use like industries, dwellings, commercials, et al. and quota of various land use for each lower-level urban region, all of which are mainly pre-determined by a strictly technical planning method system. This state-owned land property system, and the technical spatial planning system together gives a unique context for Beijing urban growth, in term that many western countries on the contrary have private land ownership and dominated communicative planning method.

Right out of the above reasons, Urban growth has been a popular topic in several subjects like urban economics, natural geography, public management and so forth. Topics related with Beijing urban growth also covers a wide range including driving forces, growth mechanism, how planning contribute in urban sprawl, et al.. Much have been much discussed in past research, which is full of diversity with respect of both research focus and methodology. Research basing on the regional and urban economics theories are very much focusing modeling with market factors including demography, economy, transportation, rent, and so forth (Ewing, 1997; Brueckner, 2000, 2001; Anderson & Ge, 2004; Deng et al., 2010). Geographers and planners are quite dominant in urban growth research. Research interests encompass urban land changes (Gaubatz, 1999; Tan et al., 2005), spatial pattern and process (Liu et al., 2002; Gu & Shen, 2003; Deng & Huang, 2004), driving force (Cohen, 2004; Wu & Webber, 2004), urban growth prediction (Chen et al., 2002; Liu & He et al., 2011), and environmental and ecological implications (Chan, H et al., 2005; Güneralpa & Setoa, 2008). In particular, an increasing group of scholars, enlightened by complexity theory, start to use cellular automata model and agent based model recently, making good use of computer science, remote sense and GIS (Chen et al., 2002; Liu and Zhou, 2005; He et al., 2006).

In sum, the above research provided abundant material for this paper. To certain extent, however, they are basing on fact, causes and impacts of urban growth, attempting to explore historical-morphological and spatial characteristics and evidence on urban land use changes of Beijing metropolitan area. Cities are somehow taken as machine when making predictions for spatial-temporal regulated planning and policies, which have profound influences on decision makers. On the contrary, they take little or no account of interactions of stakeholders between different spatial levels, how these macro regulated plan and policies are influencing people on micro-level, how they understand, interpret and respond to them, and ultimately how these responses contribute to the "fact" of urban growth. Factors of economy, proximity, topography and so forth are not the whole story. Although this is largely ignored, we happily find a small part of research touched upon this realm. Zhang's (1997) research provides a number of important insights on mechanism of Beijing urban growth by clarifying the informal constructions in Beijing's older inner city neighbourhoods in urban growth process. Moreover, social equity implications are also taken into account as an inspiration to rethink of the regulatory function of city planning and management. These pieces of work are particularly appreciated because it was an very early in-depth argument on relation between marco-level regulation and local responses although it didn't make this crystal clear. Research from another group of scholars who have strong institutional concerns also shed a light on this debate.

Cartier (2001) argued that inconsistencies in China's land use regime lead to 'zone fever,' arable land loss and real estate speculation. China's decentralized fiscal system and the changing structure of local public finance are also regarded as institutional causes in urban growth (Deng, 2003c). Deng and Huang's (2004) work reveals institutional reasons by making two seemingly contradictory phenomena in Beijing's urban development: development zones and semi-urbanized villages, suggesting the role of uneven land reform in leapfrog growth in suburban area as well as inadequate growth in urban surroundings. It'll be interesting to continue this exploration of macro level institutional influence, in addition to connect self-organization on micro level.

This paper, focusing on urban growth process of Beijing urban region by taking an institutional constrained self-organization perspective, aims to explore the existence of self-organized behaviours within this top-down controlled, technical-highlighted governance style. More than that, interactions between these self-organized behaviours and related institutional settings will also be analysed. Both of the above could contribute to current theoretical debate in both urban growth and complexity theories of cities, as an growing part of planning theory research, as well as suggestions for planners and decision makers in practice.

To achieve the above objectives, the paper is structured as the following. Section two will elaborate the methodology and analytical framework of case study. Section three gives three cases to illustrate different types the self-organized mechanism in Beijing urban growth process, basing on an interview result. In the next discussion part, in depth discussion are made to explore the general characteristics of these three cases and reflect questions in Beijing urban growth process. Also, additional mechanism promulgated in case study are put in a broader arena in the light of self-organization theory, in order to orient this research and also to inform further research directions. The conclusion part will give general brief words on how plan can better work with this additional mechanism being taken into considerations: what to achieve and what to avoid.

2. Methodology

2.1 Perspective

According to an interview on related stake holders, we find additional such a type of growth which is neither in line with policy intention, nor in line with the common technical rationale. Instead of being organized, behaviours of stakeholders seem to be rather emergent and self-property based. self-organized.

This phenomenon could also be well linked to an emerging body of research, trying to address growth and planning issues by touching upon complexity science, or to be more specific, self-organization.

Progress in complexity theories shed a light on planning and urban studies, by providing an alternative perspective and theoretical basis to cope with increasing uncertainties in both urban development and decision making process. According to Portugali (2011), self-organization already Implicitly appeared in the cybernetics writings of McCulloch and Pitts, and then explicitly in studies such as Ashby's psychological discussion on the nervous system and Yovits and Cameron's and Forester and Zipf's studies in the domain of system theory. Nevertheless, dominant opinion on the origin of self-organization, particularly original application of self-organization in urban and regional science, will be referred to related theories since 1960s, mainly including Prigogine's(Nicolis and Prigogine 1977; Prigogine 1980; Prigogine & Stengers (1984) dissipative structures and Haken's (1983, 1991, 2000) theory of synergetics. Although rises in physics, mathematics and cybernetics, gradually it became general methodologies beyond the boundaries of its original domains. Haken's theory of synergetic beyond the domain of laser and fluid, Prigogine's dissipative structures beyond physical-chemical systems (Portugali, 1999/2000). Portugali(2000) himself contributed a lot in applying self-organizations concept in cities and planning. Regional science turned to be an suitable filed to apply self-organization. Application of Prigogine's theory of dissipative structures by Allen and Sanglier (Allen 1981; Allen and Sanglier 1981), who reformulated the static central place theory of Christaller and Losch in the dynamic terms of dissipative structures. The old formulations the landscape reflects an equilibrium state which is the optimized sum of the properties of the various economic forces while the new formulations holds the idea that spatial hierarchical order among the central places is obtained, maintained and then transformed by means of an interplay between interaction and fluctuations, and dissipation. Synergetic theory emphasizes on the interrelations, interactions and synergy among the many parts of the system and its overall structure and behaviour. Weidlich(1994) applied Haken's theory of synergetics to population distribution in cities to create theory of synergetic cites.

Portugalli (2011) summarized theory and research which tries to apply complexity theories into cities as complexity theories of cities (CTC). The domain of CTC already includes a rich body of research on fractal cities (Batty and Longley 1994), self-organization and the city (Portugali, 2000), cities and complexity (Batty 2005), cellular automata and agent base urban models (Benenson and Torrens, 2004), self-organized criticality (Bak and Chen, 1991),

etc. Main achievements of CTC research can be briefly summarized into two aspects. First, it reinterpreted on urban and regional issues which were considered as independent of each other earlier, by using complex networks emerging out of local interactions between urban agents that give rise to the global structure of cities (Portugali, 2010). Second, it added new insights to understanding of cities, inspired by basic properties of complex system such as fractals, self-organization criticality, phase transition, et al.

This paper treats cities as systemic wholes, and scientists and planners as some of the many parts, agents and forces that participate in a complex and spontaneous urban game (Allen, 1997; Batty, 2005; Portugali, 2000). More and more scholars now take this alternative perspectives. Cities are the example par excellence complex systems: emergent, far from equilibrium, requiring enormous energies to maintain themselves, displaying patterns of inequality spawned through agglomeration and intense competition for space (Batty, 2008). Self-organization behaviours in this paper are defined as such a type of local behaviours of stakeholders with the following characteristics: i) they are responses to environmental changes (mainly refer to plan or policy regulations); ii) they are usually not in line with expected effect of regulated policy or plan; iii) they are somehow responsible for large-scale urban structure evolution, which is called contribution to urban development from local-scale decision-making process in terms of principles of self-organization (Batty & Xie, 1994).

2.2 Interview

In order to explore self-organized behaviours on micro scale, this paper adopts an semi-structured face to face interview on various stakeholders with regard to urban growth in Beijing. Under current context in China, public sectors are still very powerful stakeholder (Zhang, 2002). Meanwhile, developers are becoming more and more influential(Güneralpa and Setoa, 2008; Zhao, 2009). Planners as the third force, also have their contribution to some extent although their diverse roles could be either on benefit of government, developers or common people. Therefore, interviewees were selected among these three groups, private developers and government officials are particularly emphasized.

In total, 17 interviewees[4] participated, of which eight are private developers, six are government officials and three are planning specialists (See table 1a). Developer interviewees are from eight different companies, which have significant variance in ownership, organization, scale, developing experiences,

[4]1 of them was interviewed by email and phone call due to an sudden schedule change of the interviewee.

relations with Beijing local officials and so forth (See Table 1b). They can well represent an overall situation of various styles of developing agencies in Beijing. Government official interviewees are from key departments related with growth management. Three of them are from land resource bureau and the other three are from planning bureau, agricultural bureau and industrial part respectively. These 17 interviewees are adequate because hardly any new information can be acquired as number of interviewee increases (See Figure 1).

Table 1a. Basic information of interviewees

	Developers	Government officials	Planning specialists
Number of interviewees	8	6	3

Table 1b. Basic information of interviewees

company names	characteristics	Government department	Number of interviewees
Wanke	biggest real estate company in China	land resource bureau	3
Huarun	Top 10	planning bureau	1
Beijing Chengjian	Top 50, Beijing local state owned enterprise	agricultural bureau	1
Zhongliang	One of the best commercial real estate developer, state owned	industrial park	1
Tianhong	state owned	planners	3
Wukuang	state owned		
Jinxiuzhiye	Small private enterprise		
Qiyeshu	Small private enterprise		

Source: Author compiled. Ranking of real estate enterprises refer Chinese association of real estate.

A preliminary list of items was included in the interview, which covers how stakeholders interpret, understand, respond to certain regulation policy; uncertainties during developing(planning implementation) process and innovative solutions to them; interactions with other stakeholders during a specific developing(planning implementation) process, and so forth. Each item was defined in unambiguous terms. Each interviewee was also informed that information he or she gave would be stored and used in a way that made it impossible to disclose its origin. Specific questions were devised for each specific interviewee according to their characteristics, in order to make them feel relaxed and tell their real feelings as much as possible. Similar questions around the same

item will be skillfully asked in order to confirm the given answers. The interviews lasted from one to three hours. Recording machine wasn't used because most interviewees felt being under surveillance and will talk less. Instead, an assistant helps to take notes while the author is talking with each interviewee. A interview report for each interviewee will organized by the author right after each interview, just to keep the information loss as low as possible.

3. Case study: three types of self-organized behaviours

3.1 Case of Dingxiu Community development: contribution from small developers to spatial decentralization of urban area

The past decade was the best times for real estate developers in Beijing in term of spectacular appreciation of house properties. The idea has been repeatedly confirmed by interviewees that over the past years the only secret for making a profit in Beijing real estate market is to buy a piece of land and develop it. The past decade was the worst times for real estate developers in Beijing in term of inconstant regulated policy. The number of potential customers can be reduced to one third in one day because of a new restriction code on real estate market. On February 16th, 2012, Beijing municipal government announced an official document named *restrictive conditions for real estate consumptions*, according to which only two groups people own the rights to buy a house in Beijing urban region. The first group is Beijing local residents with Hukou (household

registration, see Chan & Zhang, 1999) with no more than two house property and the other group is people without Hukou but have been living and working in Beijing more than 5 years with no more than one house property, proved by a 5 years consecutive payment of social security fund. Actually this was not the first time of governmental intervention on real estate market. Similar regulations already appeared early in 2005 and revised, enhanced, adjusted over past years, all of which are aiming to cope with the so called over heated real estate market, trying to stabilize the over fast upward tendency of housing price at least if this trend can't be stopped. However, the real effects of this intervention on one hand, was not that effective as expected and on the other, had more unexpected effects. Dingxiu company's experiences can well illustrate this observation.

Dingxiu company is a small real estate company founded in late 1990s. Although it's clear inferior position when competed with big companies which is both powerful in finance but also in good relation with Beijing municipal government, this company can still acquire steady growth benefit from good market environment. However, this situation have changed since 2005 when intervention from macro level came occasionally. Many defects of this company are magnified under this new context of inconsistent regulation policies such as complicated stock right structure with many small stockholders, weak capacity in financing, lower anti-risk ability, et al.. According to a co-owner of this company, every policy change could possibly push this small company to bankrupt.

In order to cope with this emergency, the company adopted a series of new strategies, which proved to be very effective later. They did a special and deliberate research on the intention and psychology of Beijing municipal government. They found that the local government may also be in a dilemma between housing price control and local economic development. Therefore, from a pragmatic perspective, this regulation will neither be one hundred precents restrictive nor being revocatory soon. So it could be an appropriate strategy to avoid spatial focus of regulation in the central city and look for opportunities in outer space of Beijing urban region. Moreover, they also realized that the close relations between big companies, particular state owned companies and Beijing municipal government, and information, conveniences they got from this relations just took away the slight chance of Dingxiu developing successfully in central city. On the other hand, property of potential consumers has shifted to people who want better housing instead of people for their first house. So preferable product becomes with relatively large space and decent surroundings instead of proximity to business or commercial centres. By taking the above two ideas into consideration, the company made their final response: leave the central city and transfer their developing activities to suburban districts.

In October 2007, after two years preparation with cautious investigation and successful attempts to build cooperative relations with local county government, they got this 310 thousand squares meters piece of land through bidding. This site locates 50 km north from Beijing city centre and 5 km south from Huairou District centre, which in either ways, doesn't follow the proximity rules. Development aiming is relaxing dwellings, totally European style houses coordinated with ecological orientation in land use plan for this region (See Fig. 2). On messo spatial level we can still find many technical functional considerations in selection of this site. In its surroundings, an industrial-research park for Chinese academy of science was already in construction, as well as the new national digital centre of Chinese film and television, together with comprehensive development of Yanxi Lake area all of which provided a promising prospect for real estate development. Nevertheless, this is not the same rationale of Beijing municipality for the real estate regulated policy.

Figure 2. Apperance of Dingxiu residential area

The company confirmed this was a very smart decision by the achievement of more than 20% growth of their company under such a unstable period. However, what they may not know is that many small companies like them which also got survived in the regulated period adopted similar strategies. Moreover, they didn't realize that they have greatly contributed to the diffused and polycentric urban morphology (Zhao, 2009). It's difficult to tell whether the municipal government will like this result or not, nevertheless it is not what is expected effect of intervention on real estate market.

3.2 Case: Maofangchang piece of land: accelerated growth caused by contingent developing decision

In this case the leading role is Huarun, one of the top ten real estate enterprises in China. Unlike small companies like Dingxiu, Huarun is focusing more on strategic development instead of one single profitable opportunity. Therefore, they make plans for developing activities each year, have their spatial priority, keep intensive interaction with government officials and other companies. Normally, decisions for single developing project is made basing on influential factors like profit rate, total investment, risk, relations with local government departments and so forth. However, long term strategy usually has priority when it's not coordinated with the factors mentioned above. An ideal illustration for this argument can be a very influential event in Beijing real estate company: Maofangchang piece of land. An contingent factor becomes dominant in this deal: annual performance of the company in Beijing market.

This case is unique for many reasons: Firstly, Maofangchang plot of land is the largest piece in area since land leasing has been implemented through market approaches. Second, it became prime site in term of the highest dealing price. Seven influential real estate companies in Beijing participated in the auction, one of which has been paying attention to this piece of land for a long time and did quite a lot preparation work in various aspects. Compared with its competitors, this company was willing to accept lower profit in order to win the auction. After 81 rounds bid, however, Huarun company, out of expectations of many involved companies, finally became the buyer of this auction. And dealing price, 2565 million CNY was almost as three times higher floor price of the auction, which also became the new record of single sale. Calculated by the real estate price of its surroundings, there was already hardly no profit could be made out of this piece of land.

Although Huarun refused to admit all stochastic reasons for this seemingly inappropriate decision, asserting that only economic and strategic consideration were taken into account, they didn't deny various sayings from its rivals." they are anxious about annual performance, pressures are coming from headquarters", "they are crazy because they want to avoid being crazier when available developing land in Beijing runs out, which will come very soon". On the other hand, Huarun made an ambitious goal in its strategy for the coming 5 years which seems not to be achieved according to the its performance over the last two years. Therefore, Maofangchang plot of land meant much more than the land itself. So it's not difficult to understand why Huarun would like to win this bid at all cost. It

seemed they took a big risk, but at least they grasped the opportunity to achieve their ambition.

In fact, the difficult situation Huarun faced was not adequate for them to make their final risky decision because this irrational decision could put them into financial trouble. However, it was made anyway, pushed by the urban planning made in 2004 to a large extent. Beijing urban planning basically sketched a regional divergent landscape in land development. According to this plan, the regions Maofangchang plot belongs to is right one the high-tech industry development zone. This fills developers with firm confidence of prospect for regional real estate development. This confidence can be seen according to what a principal of Huarun said:" We believe the promising prospect for this region, we believe government and customers have same beliefs with us. Superiority of this plot of land is comprehensiveness, not only for dwellings, but also for commercial, sports, and financial real estate development. We have the confidence to elevate the value of the whole region through our comprehensive developing activities." A big publicity program was implemented to achieve what he told, including commercials, forum, hype of related regional news, even published a book, all of which is to describe a magnificent future of this region, trying to create an image that this region has great potentiality of real estate appreciation through interactions with potential customers. In addition, only a small precents (less than 20%) of the whole project was developed as first stage, which for Huarun basically achieves two purposes. On one hand, the left part could wait for higher price which is companied with fast urban development process in Beijing. On the other, they not only release to the public an impression but also cause the fact that real estate products in this promising region is in shortage. Through all these interactions, Maofangchang turned to be a big success, companied with the premium of the whole region. The housing price for the first developing area was around 8000 CNY in 2006, and 9000 CNY in 2009. In 2011, this figure turned to be 35,000 CNY.

The demonstration effect of Huarun's case is significant. During last five years, the dealing record of single plot of land in Beijing was broken many times. Before the depression of real estate market in latter half of 2011, people didn't realize how blindness and over-confidence relying on the very high interactive-created expectations. In 2012, many plots of land used to have bidding record, such as Number 14 Baiziwan Road, Number 22 of Tianzhu development zone, were withdrawn due to affordability problems of developers because of more strict credit policy under regulation times. From this case, municipal plan scheme is not only accepted but also utilized by developers as tools to enhance their effort in convincing people with a very high expectation in regional

development, as well as their real estate product. Growth therefore was pulled ahead and speeded up as expectation increased.

3.3 Case: Key town development project: interactions between government departments and its contribution to multi-centred urban growth

This case shows how self-organized behaviour even exists within the top-down government system itself, how policy orientation is continuously adjusted to coordinate with changing realities. In Beijing urban region, there is a four-level urban network in spatial plan: central city, new sub-city, town and new rural community. For the municipal government, there is always a dilemma between efficiency and equity when making development strategies for these four types of urban agglomerations. Therefore for a long time they adopted a easy solution called Administrative Nonfeasance, meaning without putting special intervention for any level. Under such a governance system, as the central city and new sub-city, particularly central city has significant advantages in competing for investment, migrants, technology, et al., it's no doubt development of small town long lagged behind. On the contrary, various government departments of Beijing urban region are also competing for opportunities to extend authority of its own department. As the landscape of authority within central city and new sub-city are very clear and almost steady, mainly charged by land use bureau, housing and urban-rural construction bureau and so forth, there is little chance for any other department to get involved. On the contrary, towns in periphery area become ideal spatial extension for management authority. Beijing agricultural department, making good use of its tradition management authority in rural area, then becomes dominant power in town development. Cooperated with department of Beijing development and reform, a project of 42 key towns development was launched in 2009. This project earns enough attention from the municipal government because it can somehow help decrease the increasing gap between central city and periphery rural areas. Then in order to avoid turning these key towns into residential sleepy parts of Beijing urban region, a very functional development policy came up to instruct these developments: called production first, and then live. With this policy, key towns are encouraged and requested to build their own industry park which can take in adequate employment to turn key towns into urban units with comprehensive functions. Beijing municipal government also carried out a series of additional measures to ensure the achievements of this policy. First, a special financing platform was built for construction of transportation and industry infrastructures. 500 million CNY was financed by municipal government as initial capital; second, most key towns were provided about 100 square kilometres construction land for the construction of industrial

park. Third, several state-owned companies like SANY Group built production centre in town as supportive strategy to help local development.

It's difficult and not the main concern of this paper to evaluate this town policy. However, it's indeed crucial to explore the pros and cons this policy brings in to local development, particularly the unexpected part, all of which are originally resulted from interactions of various municipal government departments. First of all, these supported policy greatly accelerate development of these small towns. And part of them have found their distinguishing characteristics for competition. For example, Caiyu town as famous tourism destination, Xiaotangshan town provides graceful commercial conference places, industrial service base built in Beiqijia town, famous industrial park in Nankou town, et al. Depending on these comparative advantages, the growth speed of these small towns are really beyond expectation. pre-development for cities. E.g. Mapo, Songzhuang, Xihongmen which used to be small town are now part of central city or new cities.

Secondly, development of small towns just explored a bottom-up style of urbanization, significantly absorbed surplus labours in rural area to relieve employment pressure of central cities. Third, the above achievements also contribute to improving villagers' living standard and enhance social equity.

Meanwhile, cons resulted from this town development policy cannot be ignored either. Although there is a financial platform, town development still can't completely solve shortage of investment due to drawbacks of location, infrastructure and other facilities compared with central city. 38 industrial parks were actually set up and most of them were less efficiently operated, homogenization and less sustainability of industries. Besides, due to the specificity of Beijing as the political centre, experimental behaviour not in line with current institutional framework is not welcomed. This also resulted in lower efficiency of these towns when compared with Yangtze river delta area or pearl river delta area.

4. Discussion

Three cases are given to elaborate an additional mechanism in Beijing urban growth process. In the light of self-organization theory, they can be better analysed, compared and understood. If we regard Beijing urban region as an open complex system, the above case then can be seen more in-depth as various emergent local behaviours driven by certain kind environmental changes coming for upper spatial level. Macro institutional rules, local responses, and its

contribution to upper level aggregate pattern, together form a interacted feedback or feed-forward loop (See figure 3).

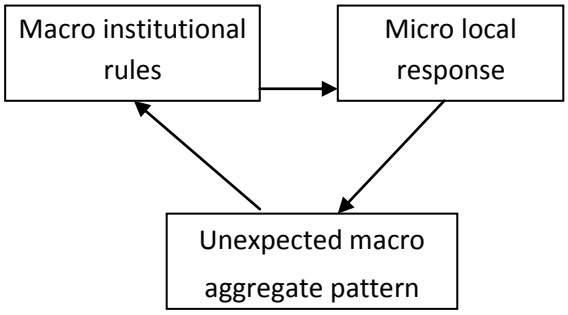

Figure 3. Feedback loops during urban growth process

In all three cases, we see interesting unanticipated aggregate patterns on macro level of urban growth which are actually caused by local interactions and responses between and of various stakeholders. Macro institutional rules or changes of them usually result in certain kind of unexpected local effect. Then local decisions are made as responses, which are rather comprehensive, complicated, even contingent occasionally, however without escaping from the institutional 'rules'. Nevertheless, these seemingly simple rules can still cause various possibilities of complex unexpected aggregate patterns. In all of three cases, elements of self-organized behaviour could be observed.

In Case one, regulation policy on real estate consumption of Beijing municipal government set a simple rule for real estate development and trade: only people with certain qualifications (mentioned in case study) are allowed to buy. This policy is aiming to control the over-speed increasing housing price. However, this policy could result in different unexpected local effects on developers with divergent properties. In our case, this regulation means high risk for developing activities in central city because as a small company, Dingxiu doesn't have either strong financial ability nor a steady relationship with local government, both of which are necessary and crucial conditions to guarantee successful development activities. Therefore, instead of developing with lower price, this small company shift its spatial focus outward to suburban area and put great efforts in product design, in order to attract potential qualified buyers. This process was easily elaborated here but actually cost the company almost 2 years to make the final decision after trying various possibilities like contacting with municipal and local authorities to check the risk of developing in central city, interacted with rivalries, making research on land use plan and people who implemented plan, et al. The decision could be totally different if any main changes during this process happened, which made this very emergent, contingent

and unpredictable. Nevertheless, for this time Dingxiu's moving outward strategy and its many other fellow developers who adopted similar tactics contributed to aggregation of constructions outside central city and act as one important driving mechanism to the fact of a decentralized urban pattern of Beijing urban region (Feng et al., 2009; Cartier, 2011). In the second case, urban planning of Beijing urban region provides public a promising future as well as a divergent growth strategy, following with a snowball effect. They were firstly interpreted by developers as positive signals from Beijing municipal government, which are precious business opportunities. This belief is continuously amplified through peer interactions among developers, real estate customers, and the physical reality of increasing housing price. Higher and higher expectation and confidence about a prosperous real estate market is gradually formed and believed without a shadow of doubt. In practice, this gives rise to irrational investment, particularly when it is combined with individual reasons of real estate company like in Huarun's case the confidence is pushed one step forward due to the pressure of annual performance. The result is, larger scale, faster speed and more in quantity of growth than needed. This could be seen from facts such as the large quantity of real estate stock, the vacancy rate, and land in developer's control without real building, waiting for opportunities of land speculation (Yan and Feng, 2010; Hui and Shen, 2006). Once again, simple rules has dominated the final macro aggregation form through local interactions. In Case three, the institutional rules are not as explicit as the first two. However it's not difficult to find it out when we move our attention to government structure and power relation. As mentioned in the above part, central city development has been long taken charge by several powerful departments, development and reform committee, land use bureau, housing and urban-rural construction bureau and so forth. Other departments like agriculture committee, which according to current administrative structure, are parallel with the above departments, however, with much less management authority. In order to change this unbalanced power landscape, it's necessary to search specific spatial area as base for development. This directly resulted in a series of supportive policy for small town development, particular the industrial parks. The other side of this coin is that the municipal government, as upper level government of these departments, also looks forward a more balanced power landscapes among its sub-sections. Although this feedback forward is rather within horizontal and vertical government departments, but it left physical manifestation in urban growth through pushing forward a multi-centred spatial pattern. Meanwhile, although efficiency of industrial parks in those towns is in general low, facilities and infrastructures built for these industrial parks made those small towns easily merged into the central city as a functional part. It can be regarded as pre-development of central city expansion, accelerating the growth process but also solving part of problems in advance (See Table 2).

Table 2. Mechanism of feedback nodes for each case

Case	Macro institutional rules	unexpected local effect	Local response	Unexpected macro aggregate pattern
Dingxiu	Regulation onreal estate consumption	High risk for developers	Developing moving outside	Decentralization in urban growth
Maofangchang	Master plan on urban growth	High expectation: Over confidence and speculated opportunities	Irrational investment under pressure of annual performance	Faster growth speed
xiaochengzhen	Governance framework and Power balance	Own spatial area for management	Supportive policy for small town development, particular industrial parks.	Multi-centre pattern, pre-development of central city expansion

Here we actually talked two seemingly contradictory elements in urban growth, unpredictable self-organized behaviours and manageable institutional settings. It's necessary to clarify the relation between the two, which can also help us to orient ourselves on a broader arena.

The key to unlock this seemingly contradiction is to pay attention on spatial dimensions. If we conceptualize spatial level into three levels with macro, messo and micro, Beijing urban region as our case belongs to the messo level. Take case 1 as illustrations to explain how behaviours on various level interacts. Beijing implemented a regulation policy on real estate market, as requested by the central government. This can be seen as institutional influence from macro level to messo level. Then this messo level policy subsequently put influences on developers of micro level. Within the framework of policy rules, developers on micro level have to make decisions. It could be made out of expected possible options, also could be created by developers themselves according to their own specific properties or the unique situation they are in. So right on the micro level, it's where the real constrain of institution happens and where the rule shaping self-organization is set. Then thousands of these decisions from individual companies and their interactions contributed to certain kind of physical aggregated pattern in urban growth, which belongs to physical dimension. This is rather result of

self-organization and is too difficult to be predicted. Then there perhaps follows with institutional changes as response to this unexpected physical outcome of the original institutional rules. From this feedback loop we can notice that how wrong or at least inadequate to only pay attention on the relation between physical urban growth and institutional settings on the same spatial level. This is also where the complementary role of the additional self-organized mechanism to current debate on urban growth. Besides the physical and institutional dimension, some scholars also add organizational level in between (Burnes, 2005; Dawson, 1994), which form a matrix together with three spatial levels (See Fig. 4). With this matrix, case study can be oriented and space for research directions are informed as well.

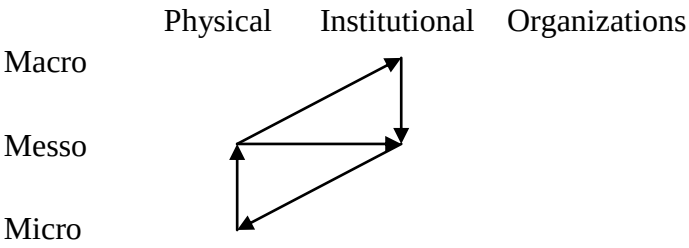

Figure 4. interactions between various spatial scales

5. Conclusion

This paper reported results of three case study, in order to illustrate various types of self-organized behaviour in moment of fast change in Beijing urban region, which is an increasingly important additional mechanism to better understand and cope with this comprehensive and complicated urban growth process. More than that, these self-organized behaviours are not totally unpredictable, but constrained by certain institutional settings and therefore manageable to some extent. The spatial scales matters when physical, organizational and institutional elements interacts among various spatial levels through feedback or feed-forward loops. This complementary mechanism, as we called self-organized urban growth shaped by institutional rules also reminds us to reflect back on current planning: what to achieve and what to avoid.

The pursuit for single causal-relationship in management and planning made decentralized approaches long been ignored or overlooked in China. Inadequate attention on self-organization mechanism leads to various top-down style of regulated policy, trying to create a reality as desired by organizing both changes of reality and behaviours of related stakeholders. This methodology used to be very effective in China during pre-reform times decades ago when economic factors such as labours, finance agencies, fiscal levy, foreign direct investment

were all in strictly control and highly decentralized (Zhang et al. 2012). However, as the Chinese urban system has been turning to become rather dynamic after reform, increasing interactions and networks have been gradually built (Bardhan, 2002). Therefore it's not difficult to understand unexpected results coming out after the regulation policy, which was originally designated to control reality but was inevitably forced to adjust itself to cope with new emergent situations. In order to get out of this trap, the self-organized mechanism in urban growth process should be serious dealt with.

Although the unexpected results of regulated policy could be seen as positive or negative, it's necessary and beneficial for both planners and policy makers to better understand them, in the light of which appropriate urban planning and policy can be improved by enhancing pros and reducing cons, or we can say to be clear of what to achieve and what to avoid.

First of all, the conventional governance idea of single focus in causal relationship, trying to build direct relation between physical growth and institutional settings and trying to use regulation policy to control changes of reality should be adjusted. More attention should be paid on exploring self-organized behaviours on micro level and find out how they were influenced by current planning policy. On the basis of the above, the following can be achieved. Gradually and smartly add incremental intervention on micro behaviour while decremented control on macro level should be reduced meanwhile. Cooperated with this policy orientation, a dynamic in time update system of planning should be built as complementary to current long term land use plan. Last but not least, policy makers and planners should take concerns of interactions between organizational and institutional dimensions, organizational and physical dimensions, and so forth on various spatial levels, Where further research is still needed.

MEGA PROJECTS, HUMAN CAPITAL DEVELOPMENT AND URBAN HOPE: School infrastructure projects in Bogota City during the last 10 years and their Impacts, effects and significance for the urban and social fabric.

cDr.MSc.Arch. Sánchez Guzmán, Santiago[1]

ABSTRACT

The golden Lion award for cities gained by Bogota city during the past 10th Biennale di Venezia 2006 in Italy was a remarkable and worldwide recognition of a planned and well executed urban development vision that through mega projects achieved social processes of inclusion, improvements in life standards for citizens and enhancement of Urban Hope.

Between 1995 and 2007 a visionary development politic carried out by 3 different but consecutive mayors started a trend of physical reconstruction of the city based on megaprojects mostly in three complementary infrastructure branches: Mobility and transportation with the introduction of the BRT system Transmilenio, Education with the construction and renovation of more than 300 school facilities as well as 3 new mega public libraries and Environment due to the investments in new public spaces as parks, bicycle paths, sidewalks, pedestrian bridges and boulevards.

With an investment over 330 Million euro[2] (more than 420 million Dollars, twice the entire cost of the Guggenheim Bilbao) made during the last decade on new school facilities, mostly for children from the poorest sectors of the city, Bogota, the capital of Colombia with nearly 8 million inhabitants, contributed effectively with poverty reduction, social inclusion, urban regeneration and with the improvement of life standards within the city.

According to Becker[3] *"Education, training and health are the most important investments in human capital."*. Thus through the construction of a new network of school infrastructures according to the highest standards and specification in architectonic quality, the mayor office of the city has triggered processes of human capital development as well as urban reactivation, giving to the poorest citizens new perspectives, skills and the hope of a better future.

The following revision of this school megaproject strategy built in Bogota city aim to discuss the impacts and effects of infrastructure interventions in their social and urban fabrics.

1. PRELIMINARY STATEMENTS

"Educate the children and it won't be necessary to punish the men."
(Pythagoras, Quoted by Geary, J. 2007).

Figure 02: Bogota's panoramic view facing north.
Author: Antonio ca2.

The improvement and provision of the School Infrastructure System carried out in Bogota city during the period between 1998 and 2007 is probably the biggest and most important investment made by the city's Mayor Office in the branch of education in it entire history, as well as the first megaproject of this kind built in any Colombian city until these days.

Developed in a relatively short period of time, the Bogota's New School Facilities might be understood as a megaproject made of more than 300 facilities distributed all around the city, which impacts relevance for the citizens in terms of urban and social inclusion, are just comparable with what in 1936 meant for the city the construction of the Campus for the Universidad Nacional de Colombia (Public National University).

The main goal of the megaproject was to actualize and improve the physical state of the existing School facilities of the city due to it old and high deteriorated levels as well as it high seismic vulnerability structures as long as according to a technical previous analysis more than the 60% of the facilities had a high seismic level risk (Rodriguez 2009).

Although the main goal of the project was really specific, the way to achieve it brought several elements into consideration as the role and meaning of the school building in the urban context, or the necessity for a definition of architectonic quality parameters to achieve with the new facilities, rising the complexity and at the same time assuming broad social impacts to achieve with the infrastructure improvement.

Thus having a look at the entire process of the megaproject during those 10 years of work, it is possible to understand 6 different main actions or phases, that might be seen as specific goals and further outcomes:

- To enhance and improve the physical features and spatial quality of the existing school facilities as well to ensure the structural reinforcement from all of them with regard to the highest architectonic standards.

- To increase the capacity of the education system due to the construction of new schools in several sectors of the city without supply of the public service.

- To carried out a Master Plan for Education Facilities that organize allocation and distribution of the public school infrastructures along the city, as well as that determine urban interaction aspects regarding land use, accessibility and environment, promoting equity and social inclusion.

- To create a bridge between the private and the public education sector giving in concession for management and guidance of 23 new public school facilities located in the poorest areas of the city to recognized private groups with previous experience in the education field.

- To clearly define and summarizes spatial and architectonic standards for the new schools and for the updated facilities with regard to the educational models and the kind of academic goals that the Colombia's Education Minister as well as the Bogota's Education Secretary had defined.

- And to actualize a survey of all the Public Schools in the city in order to create an updated and systematized data bank of the real physical state of all facilities as a comparative tool in order to organize, schedule and set up priorities of intervention.

Thus the process of the entire megaproject had been developed bottom-up regarding the previous goals list, starting with the survey of the existing schools in 1998, following with the compilation of architectonic standards in the year 2000 with the publication of the book "Construyendo Pedagogía. Estándares básicos para construcciones escolares, SED" (Rivera et al. 2000), (Building up education. Basic standards for school facilities SED). And mainly building up mostly of the new schools as well as reinforcing structures of the existing facilities between 2004 and 2008 (Benavides 2009).

Different actors have been involved along the process both at the City as well as at the National level, but the main public agency responsible for the management of the project has been the Secretaria de Educación del Distrito Capital SED (The Capital's District Education Secretary), together with the Bogota's Mayor Office. Among other public institutions involved on the project is important to mention the District Planning Department and the Universidad Nacional de Colombia, who through it Planning and Projects Office (Working as a professional consultant office) carried

out the Master Plan as well as the coordination for the Design of the new Schools and the structural reinforcement and renovation of the old facilities.

The successes of such a complex and ambitious megaproject lies in many different variables going from the quality of the professionals involved to the effectiveness of interaction and coordination between public agencies. But is of utmost importance to underlying how at the core of the process, the success in achieving the goals depended on the continuity of a visionary development policy of a more inclusive city, committed with the improvement of life quality levels for it citizens carried out by 3 different Mayors during a period of almost 10 years.

2. DEVELOPMENT VISIONS OF SOCIAL AND URBAN INCLUSION

"Vision without action is a daydream. Action without vision is a nightmare."
(Japanese proverb).

Figure 04: Former Mayors from Bogota between 2005 and 2007. From left to right: Enrique Peñalosa , Antanas Mockus and Luis Eduardo Garzon .

Source: http://www.terra.com.co/noticias/articulo/html/acu24564-preguntele-a-enrique-penalosa-lucho-garzon-y-antanas-mockus.htm

The process of physical reconstruction carried out in Bogotá city between 1998 and 2007 has been studied, discussed and awarded by the media, the academy and planning experts both nationally and internationally during the last years. Mostly focused on the BRT Transmilenio project success, Bogotá has been seen as an example of how effective visionary politicians articulated with serious planning and high quality execution and implementation is a right way to intervene positively the built environment.

Provably the most important recognition in that sense have been the Golden Lion award for Cities that the city obtained in 2006 at the 10th Biennale di Venezia in Italy. "*The Golden Lion Award for cities is awarded to Bogotá, Colombia. This city has in the last decades addressed the problems of social inclusion, education, housing and public space especially through innovations in transport… Bogotá is, in short, a beacon of hope for other cities, whether rich or poor*." (Sennett, R. Khan, A.A. Gormley, A. Hadid, Z. 2006).

Having a close look at the main interventions carried out in Bogotá during this period might be seen that the physical reconstruction strategy was focused on the improvement, reinforcement and consolidation of it urban infrastructure networks.

Thus the reconstruction trend of the city might be understood as the improvement of 3 complementary infrastructure branches and its networks associated on:

- Mobility and transportation with the introduction of the BRT system Transmilenio. Physical improvements of the entire transportation networks used by the system.

- Education with the construction of 61 new schools, the renovation and structural reinforcement of 201 existing facilities and the physical improvement of other 399 existing schools. As well as the construction of 5 new mega public libraries.

- Environment due to the investments in new public spaces as parks, bicycle paths, sidewalks, pedestrian bridges and boulevards, consolidating environmental networks, green corridors and the pedestrian as well as the bicycle paths continuity.

This infrastructural renovation trend of the city motivated by the vision of a more inclusive, accessible and balanced built environment has it roots in a context with tremendous social disparities, dramatic poverty – richness contrasts, unbalanced social infrastructure distribution and a fragmentary urban reality.

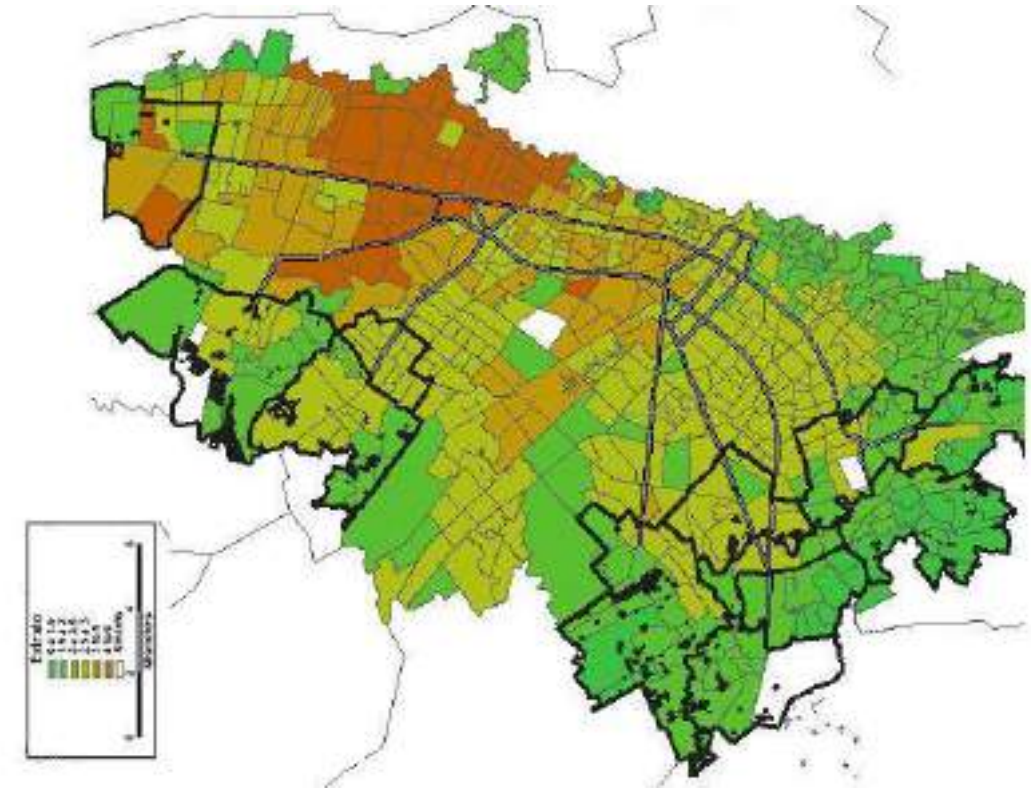

Figure 05: Socio economical distribution in Bogota. In Green tones strata 1 and 2

Source: Steer Daviea Gleave 2000

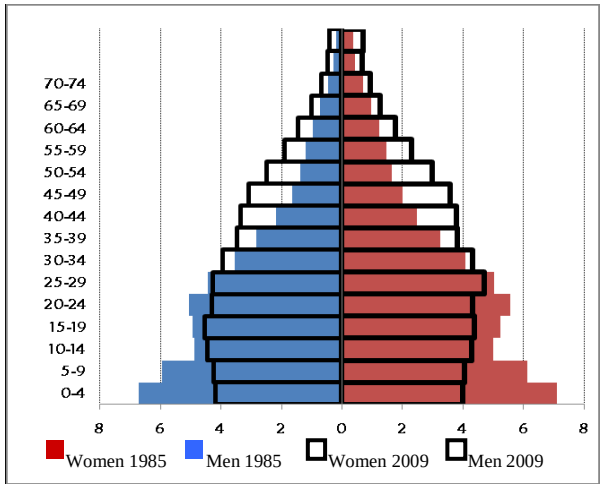
Bogota estimated population was in 1999 about 6'294.000 inhabitants with about the 44% of it population living in poverty and 11.3 in absolute poverty or destitution. For 2003 population living below poverty line was estimated in about 55,3 % (Garzón 2003).

According to Rueda (2003) Bogota was in 1999 about 31000 hectares what means a gross density of 204 inhabitants per hectare and therefore is seen by some city rankings among the largest populated cities of the world as one of the 10th with highest density levels (City mayor statistics 2007). Poverty is spread in the city and there are different figures expressing the real share of urban land use among the different socio economical stratification sectors. According to some of this estimations the strata 0, 1 and 2 (stratification of the population below the poverty line) are concentrating about the 34,6 % of the housing areas of the city while the strata 5 and 6 (Higher income strata) are just the 14%.

Social disparities and contrasts are also visible on the age distribution of the population in the different sectors of the city city, as well as on the household income distribution.

Indicators are strong enough and show some of the social and morphological problematic of the city and lead to understand why at that time was necessary to undertake measures in order to promote physical and social regeneration while reducing poverty and improving living standards and conditions for the citizens.

But this visionary development process seen in Bogota between the period of 1998 and 2007 would not be possible without the right political commitment coming from the heads of the public institutions, which right decisions and effective administration achievements turn into reality ideas and visions of social equity and a more inclusive built environment.



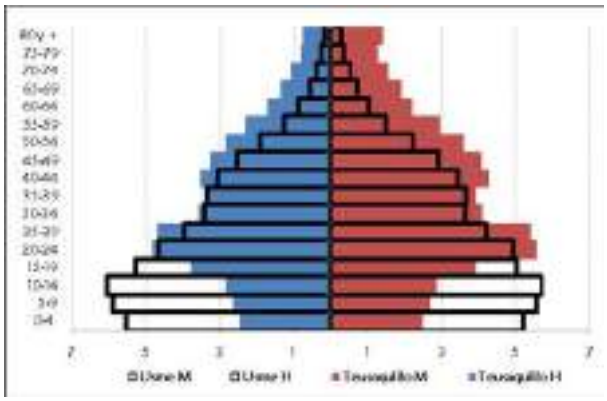


Figure 06: Bogota's population pyramids comparison. Above City's total comparison between 1985 and 2009. Below comparison between the Usme and Teusaquillo sectors in 2005

Source: DANE, Oficina Asesora de planeación. Boletín estadístico sector educativo Bogotá 2009.

2.1 The balance between political continuity and innovation

Perhaps one of the most important key issues that allowed visions turned reality was the continuity of development policies among 3 different Mayors along 4 consecutive administration periods, changing the traditional political behavior of cutting up plans and goals fixed by previous administrations. In that sense the administrative continuity of the 3 mayors started by Antanas Mockus, followed by Enrique Peñalosa and Luis Eduardo Garzon, is a positive example of right balance between the political commitment for policies continuity and the desire for innovation.

The megaproject for new schools facilities is one of the examples of this policies continuity where each Mayor took the achievement of the previous administration and tried to give a step further for the project improvement. Even thought the 3 Mayors were at that time politicians coming from different parties and having different origins they shared the vision and goals and the way the city should go through.

Peñalosa is clear while defining his believes when talking about the visions his administration had: "*What I would propose is that there are at least two kinds of equality that every society should strive to provide for its citizens. First, that all children have access to nurseries, education, food, music, art, and green spaces. This ensures that we all start off on the same footing and are nourishing the same potential. Second, I believe that the first article in every constitution should read "all citizens are equal before the law.*" Peñalosa interviewed by Grunow (2012).

And Mockus as well when talking about the new mega Libraries which Peñalosa started some years before his second administration period: "*One of my dreams is that in a future we will have poets and intellectuals, who saw the light in these Libraries*". Mockus quoted by Caballero, M. C. (2003).

2.2 Education as a priority for development

Never before in the history of the city was development and improvement of the education system for the less income citizens a priority for politicians like in this period. Prove of that are the allocation of the schools mostly carried out in the poorest sectors of the city (strata 1 and 2), the size of the economical investment more than twice the price of museum Guggenheim Bilbao for example[4], the quality of the facilities which projects were designed by some of the best Colombian architects and the administration of the entire network carried out after construction assuring the expenses for it functionality as well as assuring the quality of education itself given to the children.

[4] Investments in education between 2004 and 2008 where about the 31% of the entire budget of the Capital City (SED, Bogota's Mayor office 2004)

Infrastructure Project	Time Period	Units	US Dollar Million.
Transmilenio Phase I *	1999 - 2002	42,4 km	$ 682
New Mega Libraries**	1998 - 2002	3 Facilities	$ 17,4
Public Spaces associated to the libraries		For 1 facility	$ 6
New Schools in Concession ***	1998 - 2003	23 Facilities	$ 57,5 (Est.)
Agreement SED-UN ****	2004 - 2008		$ 421 (Est.)
New Schools		38 Facilities	$ 140
Expansion and Reinforcement of existing schools		201 Facilities	$ 281
Architectonic Improvement of existing schools		399 Facilities	
Total Investment in Educative Related Infrastructure		**About $ 501,9 (Estimate)**	

Table 01: Bogota's Infrastructure investment comparison between Transportation (t\Transmilenio Phase I) and Education related projects during the 10 years period analysis.

With information from: *Angel, S.L. et al. (2011)

** Caballero, M. C. (2003)

***Sarmiento, A. et al. (2005)

****Benavides, S. C. (2009)

Nevertheless the role played by the Education Infrastructures in terms of social inclusion goes beyond their academic main objective as long as the school facility has been understood as an urban node for socialization able to be used for participative activities by the communities. In fact the school is used for scholars as well as for their parents or any other social groups for cultural events, participative talks and sport and leisure activities in some moments. The school facility is used for the Mayor office as well as a place where to meet with the communities, where to get contact with them through special programs like the one to provide food for the poorest citizens for instance.

This influence capacity of the Education infrastructures in the community amplified the role of the education for citizens and goes beyond it own boundaries in giving them the chance to socialize in a dignified built space.

2.3 Public agencies working together

Probably the third key issue that played a relevant role during the entire process was the interaction and support between public agencies in all different aspects present in a megaproject like this.

Cooperation and coordination among agencies was of utmost importance according to Carlos Benavides S, chief director for the Facilities planning and design department of the SED: " *according to the UNESCO and the Latin American and Caribbean countries the different agencies should improve and strengthen the links among them and the national and international organizations as well as with the universities and the professional associations of architects with regard to the improvement of the design, construction and maintenance of Education facilities*" Benavides, S. C. (2009).

Without the active cooperation and coordination between the different public agencies the political development vision from the Mayors could not been possible to see the light as long as some of them are in charge to regulate and approve land use, environmental laws or public services topics that due to the location of the schools mostly in the periphery and in the poorest sectors had a lack of information and technical studies.

3. THE MEGAPROJECT DIMENSIONS AND COMPONENTS

"Para renovar no es necesario contradecir, basta profundizar."
(To renovate it is not necessary to contradict; it suffices to make something more profound)
(Nicolás Gómez Dávila, 1992).
(Translated by Nikos A. Salingaros)

Figure 07: Public School Gerardo Molina. Architect Giancarlo Mazzanti.
Source: http://sancheztaffurarquitecto.wordpress.com/category/arquitectura-colombia/

The megaproject for new school facilities construction had several planning and implementation dimensions which might be understood as a 'step by step' process, where every reached "product" was wisely used as a resource for the development of the next stage.

Therefore is important to underlying the remarkable coordination and guidance effort that the SED perform along the entire process.

The following figure illustrates the different activities and main relevant external "Planning products" (POT and LDT) along the 10 years analysis period, together with every Mayor's period.

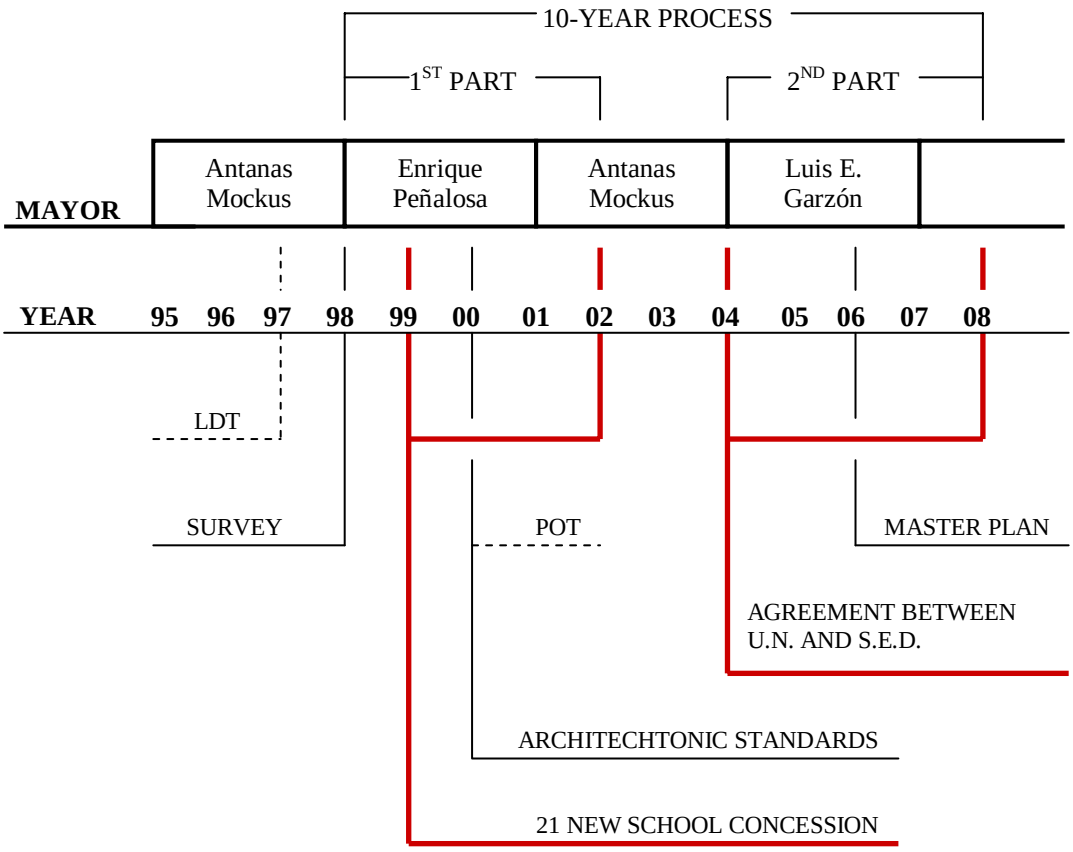

Figure 08: Dimensions of the megaproject 10 years process.
Source: Author.

3.1 The LDT from 1997 and the Bogota's POT

The territorial planning process transformation triggered in Colombia for the law 388 from 1997, better known as the Territorial Development Law (LDT), sought to complement the economic and social planning with the territorial planning dimension, to rationalize physical interventions on the territory itself and to direct it development as well as it sustainability (Fernandez, F. 2007). Probably one of the most important changes introduced with the law for all cities and departments was the obligatory development of a Territorial Plan called POT (Plan de Ordenamiento Territorial) by every Mayor Office and Regional Governor Office, which in the case of Bogota fist version was approved in the year 2000 and had a time frame of 12 years.

The POT territorial strategy is based on three principles; the protection and guardianship of environment and natural resources; the improvement and optimization of infrastructures of mobility, basic services, and social facilities; and the socio economic and spatial integration at different scales. Thus, it identifies three

complementary and interdependent structures to develop its territorial strategy; the main ecological structure composed by environmental and natural elements, rural land, protected areas, and parks; the functional structure composed by general systems of mobility, basic services, public space and social facilities; and the socio-economic structure composed by city centre and centralities networked.

The role the POT played in further urban interventions was crucial as long as it introduces a broad urban and regional perspective of influence and impacts analysis as well as specific goals and guidance's for the articulation between systems or structures and the reinforcement of the urban centralities. In order to achieve all these "allocation and distribution" parameters and requirements the law designates a planning tool called the Master Plan which articulate the macro scale of the POT with the specific scale of the urban project.

3.2 The survey of existing Education Facilities

As a first step for the improvement of existing and the design of new school facilities the SED carried out in the year 1998 a survey and systematized inventory of the Education infrastructures of the cities, with detailed information about quantitative and qualitative physical and environmental features of the buildings, along with an seismic vulnerability evaluation. According to Benavides (2009) the scope of the survey covered almost 667 facilities with an approximated built up area of 1'138.000 Sq m. The evaluation determined that mostly the 63% of facilities had risks under seismic events.

Based on the survey the SED obtained not just a first measurable scope for the physical intervention in existing facilities, but an actualized data bank of the properties in terms of documentation for legalization and regularization of plots with regard to the property law.

3.3 Building up with high architectonic and spatial standards

Parallel developed to the survey of existing infrastructures the SED carried out a research about the desired spatial and architectonic standards to be used in the design of the new schools as well as the parameter to de achieved with the renovation of existing facilities. The project was finally compiled and published in the year 2000, under the name "Construyendo Pedagogía. Estándares básicos para construcciones escolares, SED" (Rivera et al. 2000), (Building up education. Basic standards for school facilities SED).

The book is a useful tool and a fundamental reference for architects and professionals involved in the design of the school facilities, as long as it gives the desired architectonic parameters, dimensions, features and specifications for classrooms, and every interior and exterior spaces to be required. Moreover the book explains and discusses the relationship between education and architecture in order to set up spatial concepts for designers and architects to be achieved within the buildings.

	For New Facilities	For renovation in existing Facilities
Parameter	**Sq m per Student**	
Plot Area / Student	12 Sq m	5 Sq m
Built up Area / Student	6 Sq m	2,7 Sq m
Open Space / Student	9 Sq m	2 Sq m
Amount of Floors	2 Floors	2 Floors
Building Footprint Rate	0,35 Max.	0,35 Max.
Academic Room	**Minimum Rates per Student**	
Kindergarten Classroom	2 Sq m / Student	1,3 Sq m / Student
Medium – High School Classroom	1,8 Sq m / Student	1,2 Sq m / Student
Specialized Classroom	2,2 Sq m / Student	1,5 Sq m / Student
Specialized Workshop room	3,5 Sq m / Student	3 Sq m / Student
Administration and General services	0,45 Sq m / Student	0,26 Sq m / Student
Toilets per Kindergarten children	1 Toilet / 15 Students	1 Toilet / 15 Students
Toilets per Medium – High School children	1 Toilet / 25 Students	1 Toilet / 25 Students

Table 02: Basic School Facilities Standards indexes.

The Document is considered today a reference book about the relationship between architecture and education not only nationally but internationally.

3.4 The school concessions (Chartered Schools)

Between the 1999 and 2002 the SED started the first round of new school construction based on the architectonic standards already delineated.
These first 23 new school facilities build up in the poorest sectors of the city where gave up under concessions contracts for administration and management to recognized private operators with a large experience as the Universidad de Los Andes, The Nueva Granada, the San Carlos and the Nogales School among others.

The model of concession looks for promotes quality in the education for children from the poorest sectors, offering the best Education infrastructure and educators from the highest levels free of charge.

Facilities under the model of concession are administrated for a period of 12 years for operators, which are elected after a public competition regarding their capabilities, experience, educational program and proved quality of past results in the ICFES examination (National recognized final examination for scholars similar to the SAT in the US, or the Maturita in Italy).

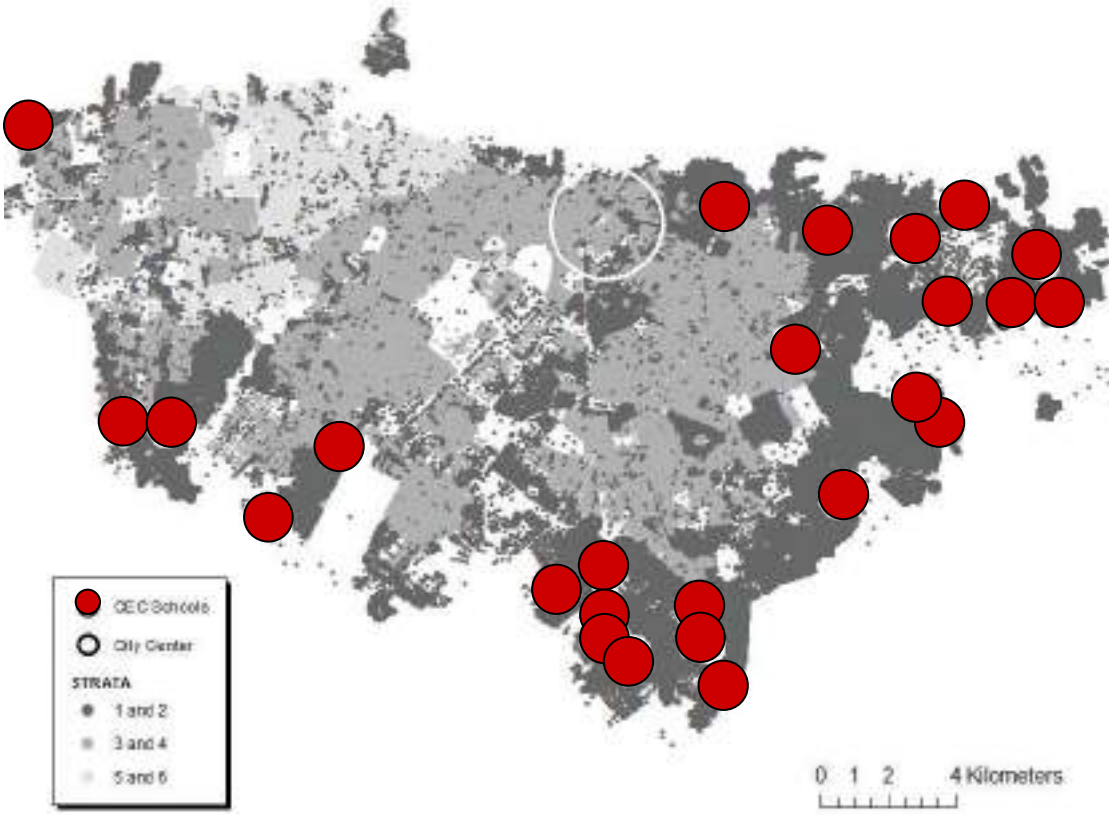

Figure 09: Bogota's schools in concession location with regard to the socio economical distribution.

3.5 The Master Plan PMEE

Probably one of the most important features of the megaproject is the fact that the school facilities are distributed all around the city, mostly in the poorest and less income neighborhoods. This operation of allocation and distribution of the social infrastructures is regularized with Master Plan for School Equipment with regard to the broad parameters established for the planning department of the city in the POT as was already explained.

According to Talavera (2005) "*The Master Plan… has the task to delineate the ordering principles for endowment services, to adopt urban standards and provide indicators to allow future building and implementation planning*."

The Master Plan understood the school facilities as nodes of a network functionally articulated with regard to it spatial characteristics able to be linked by other services, or community uses, aiming to assure a relevant urban and social role to the school building beyond it physical limits. This understanding of the social responsibility that Education Facilities might represent with regard to the specific Bogota's urban

context was of utmost importance for the design and implementation phase of the project as long as determined typological and spatial organizations of the building itself as urban quality standards.

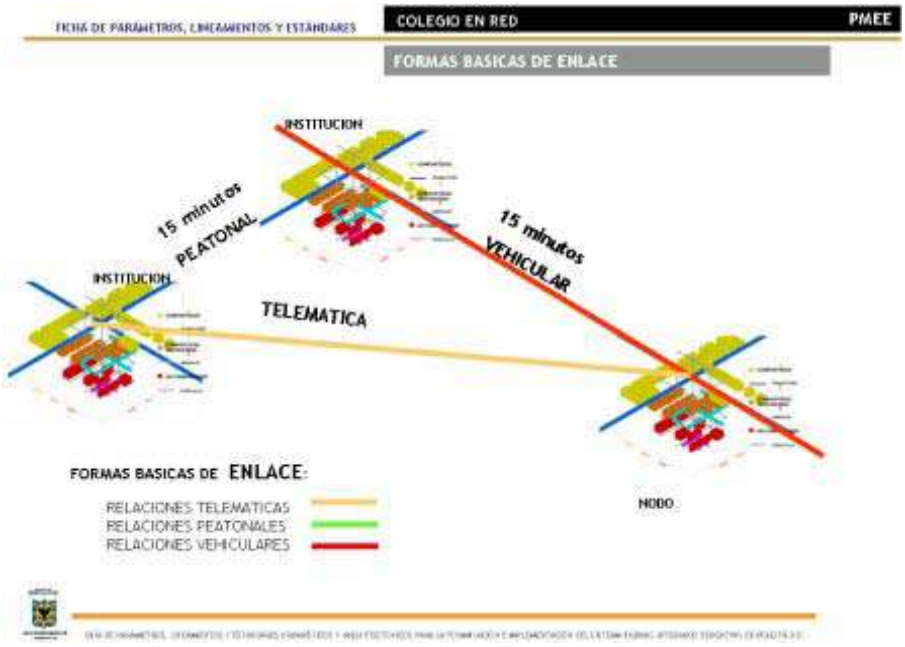

Figure 10: The School facility as urban node working in network and it basic different kind of connections according to the Master Plan for School Equipment.

Source: Decree 449 – 06 PMEE.

http://www.sedbogota.edu.co/archivos/SECTOR_EDUCATIVO/Plan%20Maestro%20de%20Equipamiento/DECRETO_449-06._PMEE._VERSIxN_OFICIAL_REGISTRO_DISTRITAL.pdf

Developed by the Universidad Nacional de Colombia under the direction of architects Henry Talavera and Pedro Juan Jaramillo in a inter-institutional agreement with the SED between 2004 and 2006, the Master Plan is probably one of the most interesting and relevant Infrastructure planning and implementation tools developed in the last years in Bogota due to the aim to promote inclusive spaces for community socialization as well as nodes of urban inclusion and interaction.

3.6 The UN – SED Agreement and the new Facilities

Based on the experience and results obtained from the previous phases of the project the SED started what would be the biggest and ambitious Facility improvement program carried out for any administration in the city before.

The SED organized in two different phases this development endeavor: with the first one they carried out public competitions among the best national architecture offices in order to find out the best proposals for the design and construction of the new Schools.

	No. of Facilities	Students capacity
New Schools	38	111600
Expansion and Reinforcement of existing schools	201	30740
Architectonic Improvement of existing schools	399	
Total	**638 Facilities**	**142340 new places**

Table 03: Goals for the expansion and improvement of the Education Infrastructures in 2004.
Source: Benavides, S. C. (2009)

Thus the SED together with the SCA (Colombian National professional association of architects) elected 5 of the more renowned Colombian architects giving them the chance for the design and construction of 11 new Facilities each one for 1410 students in plots about 7200Sq m and 7 of 940 students in plots of 5200Sq m.

Figure 11: Public School Maria Mercedes Carranza. Architect:Consorcio Arquitectura y Educacion Urbana. Arquitectos Leonardo Alvarez, Sergio Trujillo and Diego Suarez.
Photo: Jorge Gamboa.

The second phase, for existing Facilities improvement, expansion and structural reinforcement, was organized by the SED in a different manner with regard to the big amount of schools and the complexity of the different interventions.

Taking into account the big challenge and in order to guarantee the quality of the facilities as well as to fulfill the chronograms and general expectations of that big

enterprise, the SED subscribed an inter – institutional cooperation agreement with the Universidad Nacional de Colombia in order to get their expertise, guidance and technical support during four years of project development.

Figure 12: Public School Nicolas Buenaventura. Architect: Consorcio Arquitectura y Educacion Urbana. Leonardo Alvarez, Sergio Trujillo and Diego Suarez.
Photo: http://www.bogota.gov.co/portel/libreria/php/x_frame_detalle.php?id=35822 .

The University participation was of utmost importance for the achievement of the goals. It coordinates during 4 years time more than 380 professionals and experts from different fields as architects, engineers, educators, social workers, economists, urban planers, environmental experts, and lawyers among others, focused and working all together.

The different work teams organized by the UN had to react to the big range of different technical problems in existing facilities in order to achieve the high spatial and quality standards defined by the SED, aiming to pull up, renovate and qualify old existing educational infrastructures at the level of performance of new facilities. For that reasons many of the original small interventions had to be reconsidered and had to be reformulate mostly in bigger physical interventions or spatial expansions.

4. FINAL STATEMENTS AND CONCLUSIONS

"Sow seeds for the future harvest"
Old proverb.

Figure 15: Public School Gerardo Molina. Architect Giancarlo Mazzanti.
Source: http://sancheztaffurarquitecto.wordpress.com/category/arquitectura-colombia/

Among the positive impacts reached by the SED and the Bogota's Mayor Office with the planning and implementation of the New school Facilities Megaproject provably those associated to the strengthening of the Social and Urban fabric are of a remarkable importance.

On the one hand the project urban dimension had understood the school facility as the node where to get contact with the community and as a physical link to orientate infrastructure projects associated to the public space and transportation networks in slums and the poorest districts of the city.

And on the other hand less income children had found a dignified place right at their districts where to meet with the community, and where to get the tools and skills to build a perspective for a future.

Besides that it is possible to state that the megaproject promoted the strengthening of the public agencies and institutions involved due to the dimension of the challenge and the responsibilities assumed by them.

Both of these positive impacts, at the community and at the public agencies, reached with the Megaproject had had a remarkable effect on the enhancement of urban hope in citizens as long as agencies had proved commitment and real qualified results and the improvement of the built environment has positively changed.

4.1 Human capital development

It is thought that the investments carried out in education are going to have direct impacts in the human capital of a society as long as through education human resources as knowledge, know how and creativity among others might be spread, understood, discussed and improved.

With the Bogotá's Mayor Office education policy carried out between 1998 and 1997 it is possible to see an effective investment program on human capital development, which future vision aim looks for a more inclusive and equilibrate society and built environment.

4.2 Conclusions

There is no doubt about the usefulness of Megaprojects as a tool to trigger urban and social change regarding it final physical dimensions and it normally Multi and Meta disciplinary processes.

But it positive impacts and influences mostly depend of the accurate statement and understanding of the real problems it is planned to improve as well as on the urban and social visionary foreseen reality is hoped to be built up.

Therefore an evaluation of the possible side effects as well as the non project scenario must be compare with the megaproject scenario in order to determine real positive and negative impacts at the different social and urban scales.

As long as the time frame for evaluation, design and implementation of a Megaproject use to be relatively long different forecast scenarios might be evaluated and compared aiming to determine the right decisions undertaken today.

Megaprojects must not being seen only as a punctual big operation but as a chain link which multidimensional reactions might improve or affect the urban as well as the social fabric.

The spatial distributive strategy implemented with by the SED in Bogota with the planning and construction of the School Facilities between 1998 and 2007 give an example of how a Megaproject might be maximize for the use and improvement of social and urban conditions of the majority of the population.

The visionary development of a more inclusive built environment has found in Bogotá a real built example which allows us to understand a social megaproject as an infrastructure network.

Recovery Plan for Post-Disaster Tourism Destinations Image in Bam after Earthquake

Sahar Nedae Tousi [1], Sina Shahab [2], Amin Masoudi [3]

Abstract

Natural disasters are frequent treats to tourist locations, and have the potential of adversely affecting tourism industry; as one of the world's largest economic sectors. Subsequent to a disastrous event, destinations are faced with not only the daunting tasks of rebuilding infrastructure and communities, but also restoration image of destination; as one of the most significant roles of a travel destination's image is its profound impact on the travel decision-making process. Where communities have considerable economic dependence on tourism related activities, their vulnerability to crisis occurrence is significantly increased, given that they need to maintain a positive image of attractiveness for continued success. Therefore planning can play a central role for economic recovery and changing potential customers' misperception. After studying the importance of tourism industry in the earthquake-prone areas, the present paper aims to define the effects of earthquakes on tourism continuity plan and various ways that they affect the operations and viability of tourism in the Bam city. The study focuses on perception changes and negative impact on the "Image of the Destination" after the 2003 Bam earthquake. It also proposes mechanism to develop tourism marketing strategies tallying with internal and external environment in Bam destination.

Achieving the aim, includes studying the effects of the 2003 Bam earthquake on behavioral intention of visitors to choose Bam destination and economic loss as it's consequence through archival studies by means of published census and statistics. Hence this paper proposes tourism revival marketing strategies by SWOT method. The paper may contribute to the understanding of consumers' affective reactions towards a tourism destination and their influences on future visit intention and by providing a prescriptive list of functions that are dependent to destination or disaster characteristics can serve as a foundation for revival policy making of Bam in post-earthquake recovery.

1. Introduction

Tourism, as one of the world's largest economic generating sectors, can affect regions' competitiveness (Wickramasinghe, 2008). This has made tourism

[1] Shahid Beheshti University, Tehran, Iran - s.n.tousi@gmail.com

[3] Shahid Beheshti University, Tehran, Iran - aminmasoudi@gmail.com

destinations look for the ways to attract more tourists from all around the world. Since potential tourists are exposed to many alternative destinations similar to each other and fiercely competing to get more of the market share, then it is vital for destinations to differentiate themselves from competing ones and to occupy a favorable position in the minds of potential visitors by developing a positive and favorable image (Sahin & Baloglu, 2011). Destination image[4] can be defined as "the perception of a person or a group of people regarding a place (Sahin & Baloglu, 2011)" that can influence tourist satisfaction and their behaviors such as the choice of a destination, the subsequent evaluations, and their future "behavioral intentions[5]" (Chun-yang & Maxwell, 2010). Hence "destination image" is commonly accepted as an important aspect in successful and sustainable tourism development and destination marketing due to its impact on both supply and demand side aspects of marketing. Destination Image can be influenced by several factors including "natural disasters" that may impact on the destination marketability.

According to the World Tourism Organization (WTO, 2003), Natural disaster risk[6] like earthquake is one of the major sources of risk[7] with the potential of affecting tourism destinations (Lehto & et al., 2008). So recreating and managing an attractive image through marketing strategies is an important key to sustainable success for tourism businesses in quake-hit areas. In this regard, the paper aims to:

- Study of the effect of the earthquake on business continuity of tourism sector and define the various ways that it affected the operations and viability of tourism in the quake-hit areas (with emphasis on Bam);
- Propose mechanism to develop tourism marketing strategies and address feasible solutions in order to re-image destination aftermath a sudden calamity considering theoretical concepts and using analytical techniques and hence restore region competitiveness.

As a result, the paper would contribute to understanding of consumers' reactions towards a tourism destination after a natural disaster (with emphasis on earthquake) and their influences on future visit intention and serves as the foundation for policy making for revival of destinations following the earthquake.

2. Theoretical Framework

Disaster refers to "situations where an enterprise (or collection of enterprises in the case of a tourist destination) is confronted with sudden unpredictable a catastrophic change over which it has little control (Lehto & et al., 2008). Disasters that are unavoidable, since they are beyond human control, have been known to transform

[4] image is the sum of beliefs, ideas, and impressions that a person has of a destination (Tasci & Kozak, 2006)

[5] The concept of behavioral intentions can be captured by a tourist's willingness to revisit a tourism destination (Andreassen & Lindestad, 1998).

[6] Natural disaster risk refers to the possibility of being involved in a natural disaster event.

[7] Risk is defined as the uncertainty that consumers face when they cannot foresee the consequences of their purchase decisions.

the reputation, desirability, and marketability of popular tourist destinations (Park & Reisinger, 2010). The occurrence of natural disasters leads to a decrease in tourists' arrivals because of perception change. Therefore, after elimination of the physical hazards associated with natural disasters, the amount of tourists is another significant issue in a tourist destination.

Perception changes can occur after natural disaster occurrences due to their devastating effects because the thought of tourism naturally evokes feelings of enjoyment, pleasure, relaxation, and safety while conversely, disasters arouse distress, fear, anxiety, trauma, and panic in individuals. This can be both serious and long-lasting because of its profound impact on the travel decision-making process (Lehto & et al., 2008). Therefore subsequent to a disaster, destinations are faced with not only the daunting tasks of rebuilding infrastructure, facilities and communities, but also Image[8] Recovery (Travel destination image).

Where communities have considerable economic dependence on tourism related activities, their vulnerability to crisis occurrence is significantly increased and they need to maintain a positive image of attractiveness for continued success. Hence marketing strategies through business continuity plan can play a central role for economic recovery and changing potential customers' misperception.

2.1 Post-Disaster Recovery Plan and Business Continuity Plan Concept

Disaster management for tourism has often focused on the post-disaster recovery phase. The International Strategy for Disaster Reduction (ISDR) defines "Recovery" as the "decisions and actions taken after a disaster with a view to restoring or improving the pre-disaster living conditions of the stricken community, while encouraging and facilitating necessary adjustments to reduce disaster risk". Recovery is therefore about shifting focus from saving lives to restoring livelihoods (UNDP, 2010).

Reconstruction and rehabilitation are considered as main steps of "disaster recovery phase" (Figure 1). These steps are focused on activities that are devoted to restoring the condition to normal. Reconstruction process is associated with the immediate post-disaster activities in order to help affected population for restoring them to normal lifestyle. On the other hand, rehabilitation is the next step after reconstruction and ongoing long-term development. This step not only helps economic revitalization, but also promotes the business continuity (UNDRO, 1992).

[8] Image is an attitudinal construct representing an individual's beliefs, feelings, and general impressions about an object or destination (Lehto, Douglas & Park, 2008).

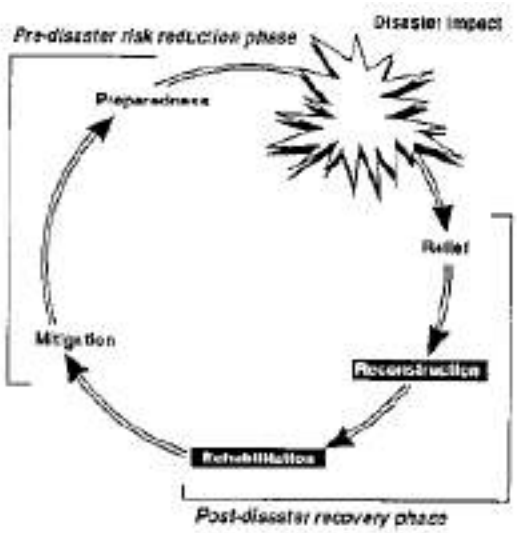

Figure 1. Disaster Management Process (UNDRO, 1992)

Disaster Recovery Plan (DRP) and Business Continuity Plan (BRP) often used interchangeably in various texts. Whereas Recovery Plan is used for retrieval of systems and infrastructure components in a specific time series, Continuity Plan has more expanded scales and scopes, which is associated with determination of components and functions of recovery. Business continuity plan can be considered as an iterative process in order to determine mission of critical business function, policies, processes, plans, procedures which are needed for continuation of activities on unforeseen events (Nickolett, 2001). Instead of the focus on rebuilding of infrastructures or hotels, Business Continuity Plan emphasis on re-launching of different scale of touristic businesses and people who are the target of tourism[9] (NZIER,2011). Proposed activities for the revitalization of long-term business continuity are (Nickolett, 2001):

- Recognize the importance of the tourism market in region and its impact on tourists in order to minimize the effects of reduced demand;
- Determination of the functions of the tourism sector should return to normal;
- Preparing recovery promotional programs;
- The beneficial evaluation of system through: (1) Speed of return to the former condition, (2) Rates of return to former condition, (3) Amount of increased resistance of buildings against next disasters.

[9] Proposed activities for capacity building in communities based on the following steps are (Nickolett,2001):

- Planning (readiness) phase including preventive activities and increase capacity;
- crisis management readiness program including evaluation of effects due to disaster preparedness management and disaster management;
- The step that response during and immediately after the accident including effective contingency plans;
- Long-term disaster recovery step.

The first three steps are outside of the subject of this study and only the final step will be considered.

2.2 Destination Image Concept

It is commonly recognized that destination image[10]-"the sum of beliefs, ideas, and impressions that a person has of a destination (Crompton, 1979; Kotler & et.al., 1993)"- is an important aspect in successful destination marketing; so one important aspect of destination marketing is "destination image management". Several researchers have studied destination image as an independent variable influencing several consumer behavior variables, such as destination choice, decision-making and satisfaction. Due to the importance of destination image in terms of its effects on tourist behavior, researchers have been trying to identify the determinants that define, modify, and strengthen this construct (Tasci & Gartner, 2007) in order to minimize the "gap that may be between "desired brand image[11]" and "perceived one[12]"(Lopes, 2011)" undermining the continuity of the destination business.

Promoting destination image requires knowing about image formation agents or components. Development of the image of a tourist destination is based on the consumer's rationality and emotionality, and as the result of the combination of two main components or dimensions. Beerli and Martin (2004) suggested that "affective" and "cognitive" image together leads to an overall image, resulting either in a positive or a negative image about the destination. Cognitive image is determined by beliefs and knowledge about a place, whereas affective one is all about feelings towards that destination[13]. Overall tourism destination image has an indirect impact on "behavioral intentions". Also destination image literature reveals three sources of image formation factors (Table 1):

A- Supply-side or destination that refers to destination marketers engage in promotional efforts to establish a positive image or to change an existing image.

B- Demand-side or image receivers that is related to their characteristics.

Disaster management literatures show a relation between "perceived influence of natural disasters" and "travel risk[14] acceptance" depending on the type of travel risk and individual tourists' characteristics(such as nationality, gender, Age, marital status, education, employment status, annual income & travel companionship). The rapid increase in natural disasters makes many tourists

[10] According to the World Tourism Organization, the image of an object or situation is defined as (Lopes, 2011) the artificial imitation of the apparent form of an object; Similarity or identity with the form (e.g.: art or design); Individual or collective ideas about the destination.

[11] Desired image is related to how the company wants to be perceived by the target segment (Lopes, 2011).

[12] Perceived image is about how the target segment sees and perceives the brand through a brand image study (Lopes, 2011).

[13] Cognitive evaluation has an indirect influence on the overall image through the affective evaluation. A common agreement among researchers seems to point out that affective evaluation depends on cognitive assessment while the affective responses are formed as a function (Chun-yang & Maxwell, 2010).

[14] Travel risk is defined as the possibility of experiencing a danger while engaging in travel or the consciousness of security and knowledge of the likelihood of damage during travel (Park & Reisinger, 2010).

perceive that travelling around the world is dangerous and risky (Park & Reisinger, 2010). Park and Reisinger (2010) study about "perceived influence of earthquake on travel by demographics" shows that:

- Asian people perceived a greater influence of the earthquake on travel than other nationality group. American and the European travelers feel more comfortable about earthquake.
- Female tourists perceive a greater influence of earthquake than male tourists.
- Low-income tourists are more concerned about travel when the risk of natural disasters is high; probably because they have a relatively lower travel budget and are more concerned about the extra spending and financial losses when involved in a natural disaster accident.
- Tourists with low educational attainment perceive a greater influence of natural risk than high and middle-educated tourists perhaps because they have relatively less social skills and are less confident about their vacation choice. As a whole educated tourists perceive lower risk.
- Family and friend tourists perceptions of natural disasters are stronger than alone people.

C- Independent or autonomous as intermediate factors between demand and supply side that consist of information sources such as news articles, educational materials, movies, etc.

Autonomous agents create general knowledge about a destination, and are out of a destination's immediate control (Tasci & Gartner, 2007). Gartner and Shen (1992) assert that in the case of a disastrous event, distant countries, for which lack of knowledge exists, the autonomous agents, such as news reports, articles, and movies are able to cause a more dramatic change in image due to their high credibility and ability to reach mass crowds than destination-originated information. The intense and sometimes sensational media reporting could play a significant role influencing in consumers' cognition about a destination after natural disasters (Lehto & et al., 2008).

Table 1. Destination Image Formation Factors

image formation factor	**Attribute of image factor**	**location**	**Image formation means**
Supply side	dynamic/ controllable	Destination-oriented	Marketing strategies
Independent	semi-dynamic/ semi-controllable	intermediate	Information sources (educational materials, news, movies, word of mouth, user groups)
Demand side	dynamic/ uncontrollable	Perceiver Characteristics	Socio-demographics, psychologics, tourist's motivations, cultural values, experience and prior visit, attitude, needs

Author's analysis based on (Tasci & Gartner, 2007)

3. Research Methodology

This paper provides a framework for creating business continuity plan. Due to the existing definitions of business continuity plan presented in the previous section, using a strategic approach is the necessary elements to promote the business continuity plan. Strategic planning is possible in each field by answering the following four basic questions (Brewster, MTP, 2005):

- Quiddity of the current situation;
- Quiddity of probable outcome if failure to do corrective action;
- Quiddity of desirable long-term future of the community;
- How to achieve this desirable future and required actions to achieve.

Process of business continuity plan in this research would have the following steps, with focus on the final step of business continuity plan and adoption of strategic planning methodology:

1. The first step: Analyzing the situation and current and future trends (identifying the opportunities, constraints and limitations) by foreseeing, if failure to do corrective action (Nickolett, 2001). Identifying the importance of tourism marketing in the region and the effects of the disaster occurred, can be done using statistical quantitative methods. The output of this step plays a major role in making the plan in next steps.
2. The second step: Drawing out the desirable future through goals setting;
3. The third step: Making improvement strategies and programs for regeneration; at this step, key functions would be identified and risk management prescribed. The output of this step would directly lead to business continuity plan.

There are four types of relationship between development and disaster (Figure 2). Approach of this paper in making strategies is transitioning of phase (--) to phase (-+) to reduce the negative impact of disasters on development - caused by the waste of resources and as a consequence, disruption of economic growth, disruption of programs and destabilization - and to convert it into an opportunity[15] for development.

[15] Disasters could achieve rapid and extensive economic changes by creating economic and political atmosphere which is impossible under normal conditions. Disasters provide opportunities for development through the following items (UNDRO,1992): Creating fundamental changes in environment; Mobilizing national and international resources; Creating new skills and job opportunities; Modernization and development of regional economic basis; Increasing global attention to the area through the media;

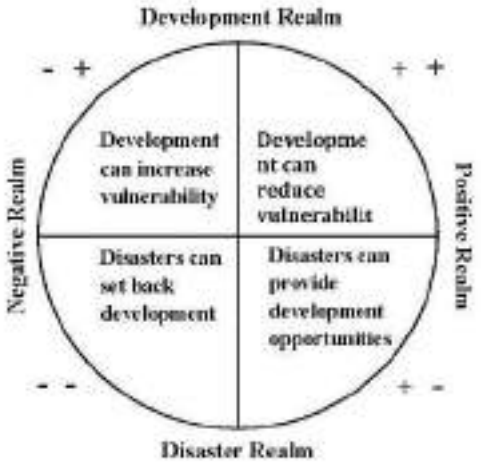

Figure 2: The Types of Relation between Development and Disaster (Stephenson, 1991)

The ultimate success of a strategic business continuity plan is largely dependent on the accuracy of an effective situational assessment (Wickramasinghe, 2008). SWOT technique is one of the best and the simplest in situational assessment. So, Competitive strategies for tourism destinations would be offered by use of strategic assessment matrix according to internal capabilities and insufficiencies and external factors. The proposed model positions the destination's strengths and weaknesses and permits the identification of opportunities to improve Bam destination competitiveness.

The difference between this paper and other researches in this field is in making business continuity strategies, referring to the destination image concept. Accordingly, the situational assessment is done using the SWOT technique, according to the constituent elements of destination image. Demand-related and Intermediate factors will be considered as external factors, outside the system control (opportunities and threats). Also, in the supply-related factors, strengths and weaknesses of the system are considered. In the business continuity plan, strategies are following maximum use of available strengths and opportunities and confronting weaknesses and threats ahead.

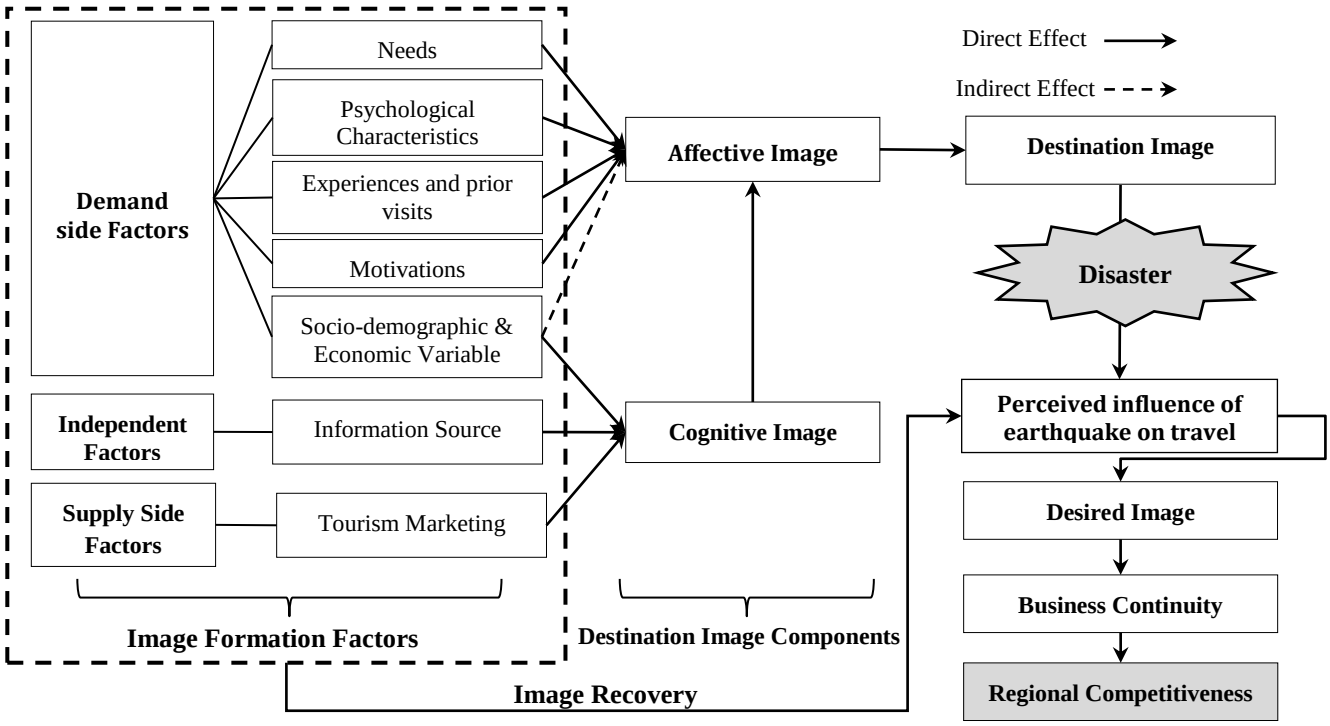

Figure 3. Conceptual Framework of the Study Based on Destination Image Concept

4. Case study

One of the ancient urban centers in Iran is located in Bam City with about two thousand five hundred years old. Due to be at the crossroads of important trade routes including Silk Road and Spice Trade Road and known for the production of silk and cotton garments, this city was of strategic importance. The cultural landscape of Bam and its citadel, which is made entirely of mud bricks, clay, straw and the trunks of palm trees, is a significant symbol of the interaction of man and nature in a desert environment.

Bam tourism industry, a large income generating industry prior the 2003 earthquake, was an important driving force of regional economic development contributes to the employment generation and to the enrichment of many related industries.

After the earthquake, this industry was faced with a severe disorder. 90 percent destruction in the citadel, as a showcase of Iranian architecture, due to the earthquake led to lose its place among the world's tourist attractive poles for several years; Although after the earthquake, citadel and historic perspective of Bam were simultaneously recorded on the UNESCO World Heritage List and the List of World Heritage in Danger, during the twenty-seventh session of the UNESCO World Heritage Committee, and placed in the center of international attention. Bam earthquake, despite all its' damages to the tourism sector, has made the largest international restoration workshop in this ancient city, due to the widespread absorption of foreign experts, including Japanese, German and Italian along with

Iranian experts. Also, this earthquake has raised supports, credits and international attentions for restoration of the citadel.

4.1 Analysing the Impact of Bam Earthquake on Tourism (Situational Analysis) and Outlining the Desire Future

The Bam earthquake was centered approximately 10 km to the southwest of Bam. In terms of human cost, this earthquake ranks as the worst recorded disaster in Iranian history. Damage was concentrated in a relatively small area, of roughly 16km radius, around Bam -a tourist destination on the old Silk Road- famed for its 2,500 year old citadel. The historic city center and fortress ruined. According to field reports, up to 95% of buildings collapsed within the ancient Bam Citadel (Figure 4).

Also, studying the amount of active units by type and location status, based on official statistics published by the Statistical Center of Iran, shows the 88 percent destruction and 11 percent damage to the hotel and restaurant units and also 82 percent destruction and 16 percent damage to business units in Bam after the earthquake in 2003.

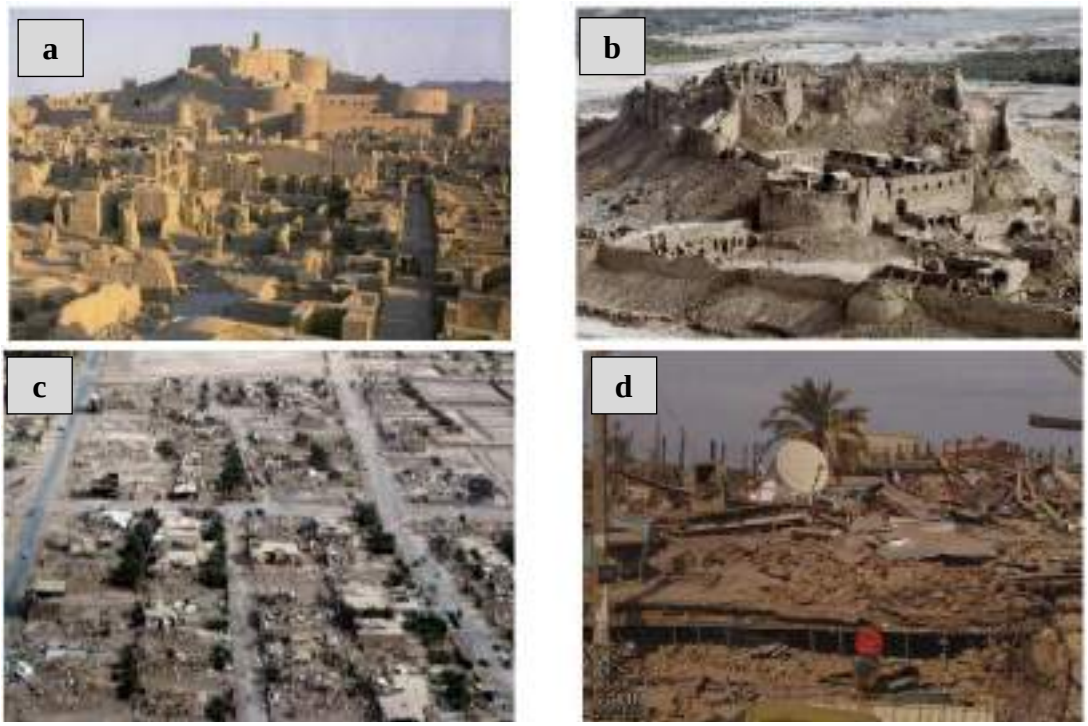

Figure 4. Photo Mosaic of the Citadel of Bam and Surrounding Urban Districts. (a) the Citadel before the earthquake struck; (b) the Citadel after the December 26, 2003 earthquake; (c) residential city blocks razed by the earthquake; (d) mud-brick houses reduced to rubble (Adams and et al. 2004)

It is important to recognize that the impact of such a natural disaster affects not only the immediate communities, livelihood of local people, disruption of natural and built environment which are all important stakeholders at any given destination, but also the minds of the potential travelers. The later will need great attention in the recovery process.

Bam Citadel, one of the greatest monuments of Iran, was almost destroyed by the devastating earthquake on the morning of December 26, 2003. Since this year, in a period of several years, there was no registered visitor, according to official statistics published by the Cultural Heritage, Handicrafts and Tourism Organization of Kerman province.

The 2003 earthquake in Bam caused directly a 100 percent drop in tourist arrivals because of the formation of negative destination image. The ruinous Bam earthquake and the risk of another earthquake have made many tourists perceive that travelling to that region is dangerous and risky. This has caused a sharp decline in region's tourism income and has undermined the continuity of the destination business in future (Figure 5).

So due to the importance of destination image in terms of its effects on Bam tourist behavior and with acceptance of problem solving approach, the main goal of the Bam Business continuity plan is devoted to speed up recovery of the tourism sector by restoring traveler confidence in the region so that visitor flows resume as quickly as possible.

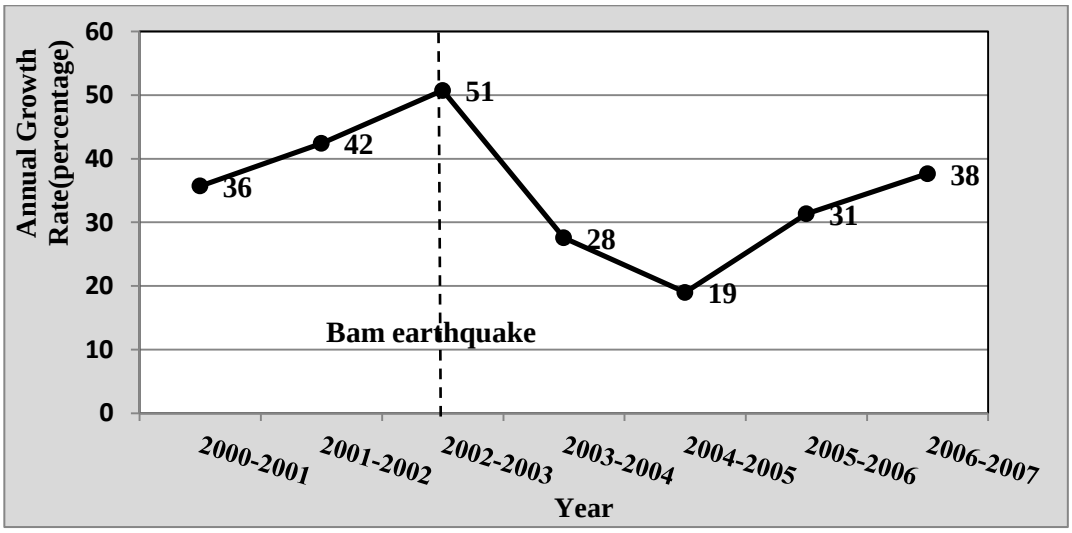

Figure 5. Average Annual Growth Rate of Bam Tourism Sector Income Before and after the 2003 Earthquake due to Authors Analysis Based on Available Official Statistics (Census Data)

4.2 Developing Tourism Revival Strategies

Tourism revival marketing strategies, for establishing a positive desired image or changing the existing image, would be presented in three main parts based on paper's methodology and situational analysis as the result of confronting internal and external factors (Table 2): Destination-oriented or supply-side revival strategies, independent or intermediate revival strategies and perceiver-oriented or demand-side revival strategies;

1- Destination-oriented or supply-side revival strategies

A- Ensuring the sustainability of tourism products in the form of diversification and changing nature of tourism, after the disaster.

Post-earthquake development offers the opportunity to correct the mistakes of the past and make the re-emerging destinations among the best in the world in terms of environmental conservation and community involvement in the planning process. It also offers the chance to rethink and diversify the product offer so that destinations become more competitive in the global marketplace (WTO, 2005).

B- Promoting participatory approaches and decentralized planning and programming for recovery;

As one of UNDP strategies, planning, programming and execution of local level recovery initiatives does not require the complex and time consuming impact and feasibility studies and planning processes of national level long-term reconstruction planning, enabling recovery activities to begin as early as possible after the disaster. Strengthening of community groups to stimulate involvement in planning process also makes them confident.

C- Increasing economic benefits and employment opportunities for the local community and hence sustainable tourism.

Recovery activities should contribute to improving the living conditions of the affected communities and sectors through the revival of production (agriculture, industry), trade and services, and the creation of income-generation/employment opportunities. The goal should go beyond the simple restoration of pre-disaster levels, but aim towards the creation of more sustainable livelihoods for the population. This could be met by improving the living conditions of the affected communities and sectors in Bam through (WTO, 2005):

- employing local staff wherever possible by retraining programs;
- The earthquake disrupted the employment of many of people. Retraining programs are needed to help them find new jobs or to help update their skills while waiting for their former jobs to become available again. Likewise, new employees for the tourism industry need to be trained to replace those who perished and make them more efficient and competitive in order to raise service standards. Building leadership capacity and counseling for those in the tourism sector are also needed (WTO, 2005).

- helping small tourism-related businesses and employees survive the recovery period; Small and medium-sized tourism businesses in the Bam destination, such as restaurants, handicraft producers, have less access to recovery funds than large corporations, so assistance is urgently needed. In addition, many of these enterprises are family-based and may have lost family members in the earthquake. Technical and financial support is needed to help them resume business and increase competitiveness. In this thematic area one policy could be identification and assistance to small enterprises damaged by earthquake through grants and micro-financing.
-

D- Making coordination plan;

Coordination commands would be prepared in this strategy. In reality, multiplicity of actors, national and international, requires improving/maintaining coordination; hence, promoting and initiating recovery activities have to avoid duplications and gaps and to optimize the resources available for sustainable recovery. This could be satisfied through conceiving recovery as an integral part of ongoing developmental process at all levels: national, regional, and local.

E- Making review, refine and maintenance plan in order to update and increase the usefulness of business continuity plan. Since business continuity plan such as cyclical process of strategic planning, requires continues update;

F- Making Risk Management plan;

To make Bam tourism destinations safer and more secure, risk management analysis will be conducted, with special attention to clear communication channels and increase cooperation between the tourism sector and public safety authorities. Training workshops will also be offered in risk and reputation management.

2- Independent or intermediate revival strategies

G- Capacity building to face effectively with negative traveling propaganda for tourism destination and recovering the confidence of the marketplace;

Clear, detailed and abundant information is a key factor to recover the confidence of the marketplace. Effective communications is needed on many different levels: government; business; tour operators; travel agents; the media; and the public. Special attention needs to be paid to travel advisories. The use of special events and development of new products is also needed to help speed the recovery process. In this thematic area policies could be (WTO, 2005):

- Organizing familiarization trips for journalists and tour leaders and
- hosting “hallmark” or “mega” events, involvement with travel writers
- Provide communications expert to help look for and disseminate positive news throughout the recovery period;
- Provide financing to enhance tourism website and email newsletter;

H- Ensuring a stable integrated flow of information to consumers and operators.

Prevention of the malicious rumors spread, that cause harm to destination image, requires sustainable unified information flow for users and beneficiaries and making connection between public and private actors, national and regional organizations and other groups. This could be met tough capacity building in governmental institution for facing effectively with negative advertisements against destination by means of:

- Establishing media center responsible for correct informing;
- Provision of effective contingency plans in order to damages controlling and informing interest groups;

3- Perceiver-oriented or demand-side revival strategies

From a crisis management perspective, a crisis recovery system that is built upon better understanding of consumer psychology in the face of environmental changes can be more effective than one that is built upon suppliers' frame of mind. In this relation Bam demand-side revival strategies are:

İ- Facilitating attraction of tourists all around the world that perceive less risk and are less concerned about travel when the risk of natural disasters:

- Trying to Absorb and motivate American and European visitors that feel more comfortable about earthquake.
- Applying attractive actions for alone and high educated visitors.
- Motivating high income visitors with lower risk perception.

Meeting these strategies require recognition of their interests in defining tourism product; furthermore improving the diversity of tourism infrastructures and the quality of tourism facilities and services that is necessary for these groups of tourists.

J- Changing nature of tourism to meet short term goals and business continuity in the age of reconstruction.

In this relation, disastrous tourism seems effective. Disaster tourism is used to designate tourism to sites of natural disasters (Robbi, 2008). Pottorff and Neal (1994) in their discussion of marketing implications for post-disaster tourism destinations posited that disasters sometimes actually attract visitors that may be curious about the damage left behind. This approach to utilize visitor's mass convergence tendency could be effective to tourists who are driven by novelty, curiosity and competence.

K- Persuading visitors about destination safety and restoring confidence in the minds of potential visitors. Destination marketers should therefore ensure that messages communicated after the disaster is effective at persuading visitors that the destination is safe. Additionally, marketing messages should serve to defray any misinformation prevalent in media which has the potential to significantly affect the rate of economic recovery for the destination (Lehto, Douglas & Park, 2008).

L- Presenting Bam cultural landscape and enhancing the visitor experiences. This could be done through:

- Preparing educational programs;
- Organizing cultural programs such as local festivals and exhibition for both the local domestics and international tourists;
- Developing, publishing and marketing interpretation materials preferably unified in product line and quality with Bam identity (such as souvenir guide book, brochures and information leaflets;
- Improving site presentation and interpretation;

Table 2. The Summary of Bam Situational (SWOT) Analysis after 2003 Earthquake

External factors		
Image factors	**Opportunities**	**Threats**
Supply Side Factors	• Bam registration on the UNESCO World Heritage List and the List of World Heritage in Danger after the earthquake, in 2004, as a factor to absorption of international attention; • Creating opportunities to Modernize and develop of regional economic basis; • Opportunity to correct the mistakes of the past and making fundamental changes; • Having chance to rethink and diversify the product offer so that destination becomes more competitive in the global marketplace; • Drawing the attention of the world to Bam and its cultural landscape as opportunities for economic development of the region; • The inscription of Bam and its cultural landscape on the world heritage list; • Revealing much of the archaeology in the Bam area after the 2003 earthquake; • Attraction and mobilization of international scientific, technical and financial aid and credits for renewal of historic buildings and sustainable development of tourism through UNESCO, Japan and Italy; • Bam Citadel as the largest international workshop for historic restoration experts & scholars and archaeologists from around the world; • Creation of the potential for tourism development with natural crises; • Appearance of the skills and new job opportunities related to reconstruction of the city;	• Destroying about 90 percent of the citadel and Impossibility of visiting from all parts of it; • Increase in population and social instabilities caused by migration of natives and immigration of non-native people to the city; • Reduction in safety and environmental comfort as a factor to outgoing of local capital; • Reduction in regional competitiveness ability; • Formation of negative perceived image in potential travelers regarding safety and security Instability and as a consequence sudden fall in the number of visitors; • Increase in unemployment rate with finalization of post-earthquake reconstruction; • Existence of open work sites where relatively few structures have been completed;
Independent Factors	• Increasing global attention to Bam area through the media;	• Lack of real knowledge between autonomous agents about Bam situation that has caused a more dramatic change in image; • Negative messages communicated after the disaster by high creditable medias have access to mass crowds;
Demand side Factors	• Less influence of the earthquake on American and European visitors' travel intention; • Less influence of earthquake on high-income tourists' intention; • Lower earthquake risk perception in educated tourists; • Lower perceptions of natural disasters in alone people; • Presence of visitors that are curious about the damage left behind the disasters;	• Perception change, especially in low-income visitors, Asian visitors and low-educated tourists; • Presence of further seismic action that contribute to a feeling of insecurity and uncertainty;

Internal factors		
Image factors	**Weaknesses**	**Strengths**
Supply Side Factors	• The possibility of delisting of Bam by UNESCO because of Inability to control the informal settlement; • prolonged reconstruction because of shortage of credit among other national projects; • The 15-year period in the recovery projects due to the sensitivity and complexity of the reconstruction of Bam Citadel; • Disregarding of national institutions to the issue of tourism and crisis; • Lack of the awareness of the rebuilding process and the situation in Bam after the disaster; • Lack of proper policies in order to take necessary scientific and financial assistance of UNESCO for recovery projects; • Under-developed tourism and related facilities appropriate for high income and educated national and international visitors; • Poor preparation for facing another earthquake; • Lack of Active Tourism Controlling Authority; • Inadequate Marketing promotion strategies; • Absence of systematic management of the territory and poor Coordination among local, regional, national and supranational tourism authorities; • Under-developed tourism and related facilities appropriate for high income and educated national and international visitors; • Poor preparation for facing another earthquake; • Lack of Active Tourism Controlling Authority; • Inadequate Marketing promotion strategies; • Absence of systematic management of the territory and poor coordination among local, regional, national and supranational tourism authorities;	• Existence of dependency, economic and cultural sense of belonging and interaction with residents and natives of Bam; • Attractiveness of Bam as an outstanding example of a fortified settlement and citadel in the Central Asian region, based on the use mud layer technique combined with mud bricks; • Touristic attractions of Bam Citadel as promoting economic growth; • High degree of authenticity and integrity in Bam Citadel in spite of the severe damage incurred during the December 2003 earthquake; • Presence of an ensemble of exceptional testimonies to the development of settlements dating back to Neolithic times; • High degree of authenticity and integrity in Bam Citadel in spite of the severe damage incurred during the December 2003 earthquake; • Presence of an ensemble of exceptional testimonies to the development of settlements dating back to Neolithic times;
Independent Factors	• Lack of media coverage and Problem with inquisitive visitors;	-
Demand side Factors	-	-

Authors analysis based on (Iranian Cultural Heritage, Handicraft and Tourism Organization (UNESCO, 2008) and other information sources

5. Conclusion

As shown in this paper, after 2003 earthquake and in the post recovery phase, Bam has been facing not only with daunting task of reconstructing, but with rehabilitation and as one of the most important parts, image restoration. Devastated Bam destination image caused serious problems in tourist viability due to rigorous earthquake influence on behavioral intention of visitors. Bam, as a city with considerable economic dependence on tourism related activities, needs to look seriously for feasible solutions in order to re-imaging destination and hence restoring region competitiveness and its viability; So this paper tried to promote a revival strategies framework for continuing business after earthquake by means of SWOT situational analysis in the form of three image formation factors; since linking the perception changes of the traveler to the destination is important for destinations to effectively manage image formation and change.

As a result, this paper may contribute to the understanding of consumers' affective reactions towards a tourism destination and their influences on future visit intention and by providing a prescriptive list of functions dependent to destination or disaster characteristics can serve as a foundation for revival policy making of Bam in post-earthquake recovery. It also serves as a call for active research into issues relating to the effects of natural disasters on the consumers of the tourism product in the affected areas due to the importance of managing image and image recovery after a crisis situation; Since From a crisis management perspective, a crisis recovery system that is built upon better understanding of consumer psychology in the face of environmental changes can be more effective than one that is built upon suppliers frame of mind. So cognition of differnces between feasible solutions for revival marketing strategies based on tourists with different socio-demographic background is necessary.

Study on Pedestrian's Speed and Density under the Mid-low Density: Comparison of Pedestrian Behavior on the Station Square between Chiba, Japan and Shanghai, China

Shouni Tang[1] , Dongyun Kwak[2] , Toshio Kitahara[3]

Abstract

Context

The correlation between pedestrian's speed and density is a key point in walking space research. In the field of walking space, there are massive investigations about the correlation between speed and density under the high pedestrian density. Under the mid-low density condition, the question about the correlation between pedestrian's speed and density is not a hot topic in previous researches.

In fact, pedestrians are under the mid-low density condition at all time. And the station square is also a place where there are many pedestrians. Additionally, much attention has been attracted to pedestrian-oriented planning and the cultural implications of place-making in urban planning. Therefore it is necessary to discuss the correlation between speed and density under the mid-low density and compare pedestrian behavior on the station square between Japan and China in order to clarify the different characteristics of pedestrian behavior in dissimilar cultural contexts.

Method

We took the north square of JR Nishi-Chiba Station in Chiba, Japan and the fourth square of Dapuqiao Station in Shanghai, China as two examples. These two squares both have steps and flat. We took videos for one hour in spare time and rush time on these two station squares. We then investigated the situation of pedestrian streams in

[1] Ph. D Candidate, Graduate School of Engineering, Chiba University, Chiba, Japan, Email: archpsy@yahoo.co.jp,

[2] Assistant Professor, Graduate School of Engineering, Chiba University, Chiba, Japan, Email: dongyun@tu.chiba-u.ac.jp,

[3] Professor, Graduate School of Engineering, Chiba University, Chiba, Japan, Email: kitahara@faculty.chiba-u.jp,

the spare time and in the rush time. By images of these videos, we drew pedestrians' pathways from parts of the videos. So we could get the information of speed, density and shortcut behavior by these pedestrians' pathways.

Statistics & Analysis

From the statistics of data, we could describe the characteristics of speed and density during different periods on the two squares. After the statistic of speed and density, we calculated separately the correlation between pedestrian's speed and density on the steps and on the flat in the spare time and in the rush time.

Conclusion

After the analysis, the characteristics of pedestrian behavior were as follows:

General characteristics on the two squares: the speed is slow and the density is low in the spare time; the speed is fast and the density is high in the rush time. The speed on the steps is slower than on the flat. Under the mid-low density walking space, the correlation between speed and density is weakly positive correlation. It is different from the correlation under the high density walking space. In other words, a certain degree of density can make pedestrians speed up.

Different characteristics on the two squares: pedestrian's speed on the square of Dapuqiao Station is slower than JR Nishi-Chiba Station. Shortcut behavior on the square of Dapuqiao Station is more obvious than JR Nishi-Chiba Station. These results suggest that pedestrians in some parts of China adopt shortcut rather than fast walking for quickly reaching the destination, but pedestrians in some parts of Japan more adopt fast walking. These results are useful to create walking spaces which will be more suitable and effective for person's behavior in dissimilar cultural contexts.

Keyword

Density, Speed, Pedestrian, Station Square, Shortcut behavior

1.0 Context

The correlation between pedestrian's speed and density is a key point in walking space research.(Fruin, J.J., 1971; Pushkarev, Boris. and Zupan, Jeffrey. M., 1975) In the field of walking space, there are massive investigations about the correlation between speed and density under the high pedestrian density.

For studying the effect of the high density on the pedestrian, some researchers

divide pedestrian's density into 3 sections. In the section B and C: density > 1.1 p/m^2(person/m^2), it is taken as the high density section and pedestrian's walking is not free, the correlation between speed and density is negative.(Minegishi. Yoshikazu, 2008; Nishida Yoshihiro, 1985) But in the section A: 0.0 p/m^2 ~ 1.1 p/m^2, it is taken as the mid-low density section. In the section A, some research refer to the part of 0.5 p/m^2 ~ 1.1 p/m^2 , and the correlation between speed and density is considered negative or not obvious.(Morita Takao, 2004; Hirai Noriyuki, 1993)

Under the mid-low density condition, the question about the correlation between pedestrian's speed and density is not a hot topic in previous researches.

In fact, pedestrians are under the mid-low density condition at all time. And the station square is also a place where there are many pedestrians. Additionally, much attention has been attracted to pedestrian-oriented planning and the cultural implications of place-making in urban planning. Therefore it is necessary to discuss the correlation between speed and density under the mid-low density and compare pedestrian behavior on the station square between Japan and China in order to clarify the different characteristics of pedestrian behavior in dissimilar cultural contexts.

2.0 Purpose

This research will take the part of pedestrian density 0.0 p/m^2~0.35 p/m^2 as a condition object, and discuss the correlation between the pedestrian's speed and density on the flat and on the steps.(Nishida Yoshihiro, 1984)

3.0 Observation

We took the north square of JR Nishi-Chiba Station in Chiba, Japan and the fourth square of Dapuqiao Station in Shanghai, China as two examples. These two squares both have steps and flat. We took videos for one hour in spare time and rush time on these two station squares.

3.1 Observation in Japan

3.1.1 Place

JR Nishi-Chiba station north square is in Chiba, Japan. This square has a pure function of transportation. It makes the motivation of walking simple.This square is divided into two parts: flat and steps.(Figure 1, Figure 2)

Figure 1 JR Nishi-Chiba Station

Figure 2 JR Nishi-Chiba Station North Square

3.1.2 Observation time

2010/07/02 It is under the mid-low density condition.
12:30-13:30 spare time(lunch)
17:30-18:30 rush time(go home)

3.1.3 Tool

25mm wide-angle lens camera and timing device.

Figure 3 Dapuqiao Station

Figure 4 Dapuqiao Station Entrance 4 Square

3.2 Observation in China

3.2.1 Place

Dapuqiao Station Entrance 4 square is in Shanghai, China. It is a part of a circular plaza around the subway station. This square also has flat areas and steps.(Figure 3, Figure 4)

3.2.2 Observation time

2011/04/21 It is under the mid-low density condition.
12:00-13:00 spare time(lunch)
17:00-18:00 rush time(go home)

3.2.3 Tool

25mm wide-angle lens camera and timing device.

4.0 Comparison of pathways

We then investigated the situation of pedestrian streams in the spare time and in the rush time. By images of these videos, we drew pedestrians' pathways from parts of the videos. So we could get the information of speed, density and shortcut behavior by these pedestrians' pathways.

4.1 Pathways of JR Nishi-Chiba station square

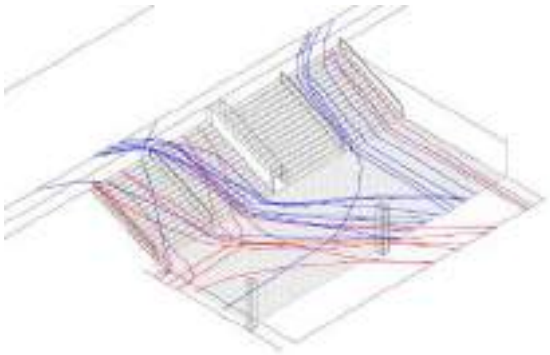

Figure 5 Pedestrians' Pathways on JR Nishi-Chiba Station Square (60s in spare time 12:30-13:30)

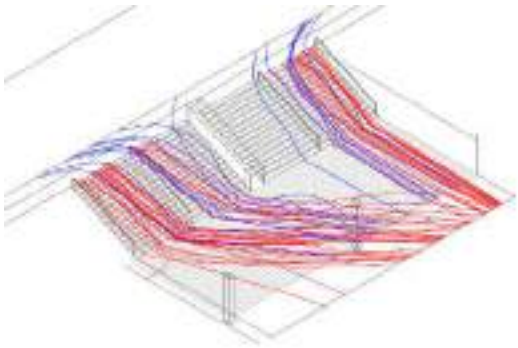

Figure 6 Pedestrians' Pathways on JR Nishi-Chiba Station Square (60s in rush time 17:30-18:30)

We took the videos of JR Nishi-Chiba station square for two periods: 12:30-13:30; 17:30-18:30. Then we chose 5 minutes rush time video from every period. We printed 60 pages of image for every minute video. Through these images, we can draw the pathways. Figure 5 and Figure 6 is pathways for one minute(60s) in spare time and in rush time. In these figures, blue lines are pathways of going up steps; red lines are pathways of going down steps. We find that there are more people going up steps in 12:30-13:30 and more people going down steps in 17:30-18:30.

4.2 Pathways of Dapuqiao Station square

In the same way, we took the videos of Dapuqiao Station square for two periods: 12:00-13:00; 17:00-18:00. Then we chose 5 minutes rush time video from every period and drew the pathways. In order to describe the situation of pedestrians clearly, we showed figures of pathways for 60 seconds. In Figure 7 and Figure 8, red lines

are pathways of going to entrance; blue lines are pathways of going to exit; green lines are pathways of passing. We find that there are more pedestrians to enter the gate in 17:00-18:00.

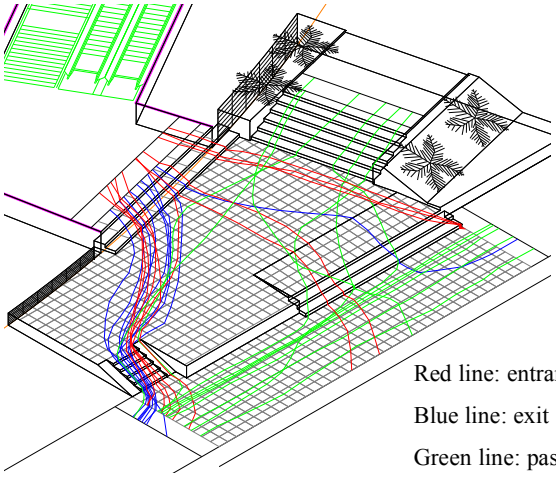

Figure 7 Pedestrians' Pathways on Dapuqiao Station Suare (60s in spare time 12:00-13:00)

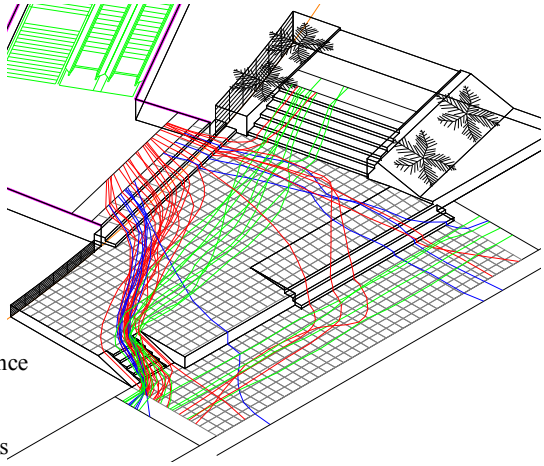

Figure 8 Pedestrians' Pathways on Dapuqiao Station Square (60s in rush time 17:00-18:00)

4.3 Comparison

Pathways on the square of Dapuqiao Station are very concentrated and crowded. Although the square is huge, a large number of pedestrians choose the most narrow steps, because it is the nearest path. These results suggest that shortcut behavior on the square of Dapuqiao Station is more obvious than JR Nishi-Chiba Station.

5.0 Statistics of speed and density

5.1 Data

We got the time for one pedestrian through flat and steps by the video. The number of samples from this 5 minutes is 100 on the flat and 100 on the steps for every period. The speed and density of samples will be counted one by one.

5.2 Definition

Speed is the speed that one person was walking on the step or on the flat at the midpoint of the pathway.

Density is the density that this person was walking at the midpoint of pathway.

5.3 Statistics

From the statistics of data, we could describe the characteristics of speed and density during different periods on the two squares.

5.4 Period comparison

5.4.1 Speed

In this statistics, speed is a key point, because it is an indicator that we can evaluate walking is free or not. The speed of pedestrian is slow at the period of spare time; and it is fast at the period of rush time on these two squares. The effect of time is significant.(Table 1)(Table 2) In the same time, the variation of speed on flat and on steps is uniform.

All in all, under the mid-low density condition, the speed of pedestrian is fast and walking is comfortable, but we can not say that walking is free completely. We must consider other condition.

Table 1 Period Comparison Speed Statistics on JR Nishi-Chiba Station Square(m/s)

Time	Position	N	Mean	Std. Deviation
12:30-13:30	Flat	100	1.4099	0.22514
	Steps	100	0.8159	0.16402
17:30-18:30	Flat	100	1.5737	0.25870
	Steps	100	0.9790	0.24276

Table 2 Period Comparison Speed Statistics on Dapuqiao Station Square(m/s)

Time	Position	N	Mean	Std. Deviation
12:00-13:00	Flat	100	1.3335	0.2299
	Steps	100	0.7199	0.1539
17:00-18:00	Flat	100	1.4880	0.2044
	Steps	100	0.8865	0.2009

As shown in Table 1 and Table 2, pedestrian's speed on the square of Dapuqiao Station is slower than JR Nishi-Chiba Station during these two periods of time .

5.4.2 Density

On JR Nishi-Chiba station square, the density of pedestrian is low in 12:30-13:30,

the mean of density is 0.0888 person/m^2. And it is high in 17:30-18:30, the mean of density is 0.1517 person/m^2.(Table 3) On Dapuqiao Station square, the mean of density is 0.0896 person/m^2 in 12:00-13:00 and 0.1293 person/m^2 in 17:00-18:00.(Table 4) There are middle density condition at times and low density condition at times on these two squares.

Table 3 Period Comparison Density Statistics on JR Nishi-Chiba Station Square(p/m^2)

Time	N	Mean	Std. Deviation
12:30-13:30	200	0.0888	0.0471
17:30-18:30	200	0.1517	0.0566

Table 4 Period Comparison Density Statistics on Dapuqiao Station Square(p/m^2)

Time	N	Mean	Std. Deviation
12:00-13:00	200	0.0896	0.0324
17:00-18:00	200	0.1293	0.0286

5.5 Position comparison

There are two parts on this square: flat and steps. As shown in Table 5 and Table 6, the speed of pedestrian on the flat is fast in 2 periods of time, it is 1.4918 m/s on JR Nishi-Chiba station square and 1.4108 m/s on Dapuqiao Station square. The Speed of pedestrians on the steps is slow in 2 periods of time, it is 0.8974 m/s on JR Nishi-Chiba station square and 0.8032 m/s on Dapuqiao Station square. The variation of pedestrian speed on the flat is larger than on the steps on these two squares.

Table 5 All Periods Speed Statisticson on JR Nishi-Chiba Station Square(m/s)

Position	N	Mean	Std. Deviation
Flat	200	1.4918	0.25546
Steps	200	0.8974	0.22223

Table 6 All Periods Speed Statisticson on Dapuqiao Station Square(m/s)

Position	N	Mean	Std. Deviation
Flat	200	1.4108	0.2304
Steps	200	0.8032	0.1971

5.6 Up & down comparison

Taking the speed of going up steps and going down steps into consideration, we do some statistics as Table 7 and Table 8. The results suggest that speed of going up

steps is slower than going down steps on these two squares.

Table 7 Steps(up & down) Speed Statistics on JR Nishi-Chiba Station Square(m/s)

Steps	N	Mean	Std. Deviation
Up	77	0.8106	0.18761
Down	123	0.9518	0.22558

Table 8 Steps(up & down) Speed Statistics on Dapuqiao Station Square(m/s)

Steps	N	Mean	Std. Deviation
Up	135	0.7735	0.20218
Down	65	0.8649	0.17163

6.0 Analysis

After the statistic of speed and density, we calculated separately the correlation between pedestrian's speed and density on the steps and on the flat in the spare time and in the rush time.

6.1 Flat and Steps speed-density linear fit comparison on JR Nishi-Chiba station square

Figure 9 and Figure 10 are the speed-density scatter diagrams of flat and steps on JR Nishi-Chiba station square. According to scatter of two figures, the scatter distribution of Figure 9 is more uniform than Figure 10. And the characteristic of fit linear of flat is more obvious than fit linear of steps. In other words, the correlation between speed and density on flat is more obvious than on steps.

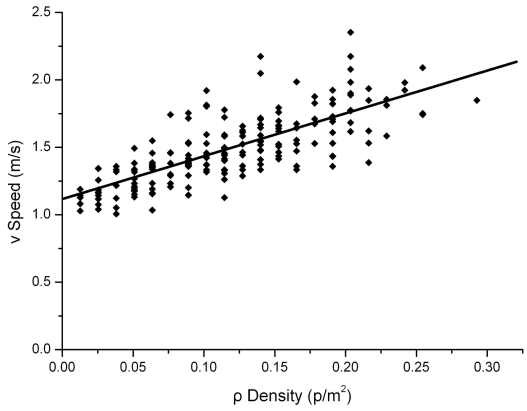

Figure 9 Flat Speed-density Linear Fit (2 periods of time) n=200

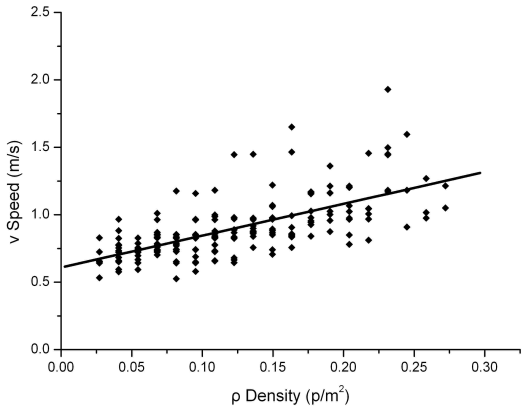

Figure 10 Steps Speed-density Linear Fit (2 periods of time) n=200

On the other hand, The fit linear of flat is steeper than steps, so variation of speed on flat is faster than on steps.(Figure 9, Figure 10)

6.2 Flat and Steps speed-density linear fit comparison on Dapuqiao Station square

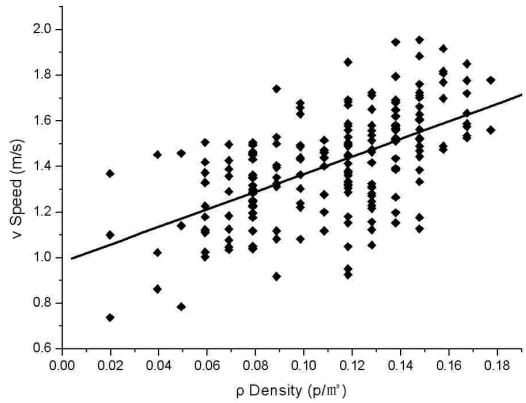

Figure 11 Flat Speed-density Linear Fit (2 periods of time) n=200

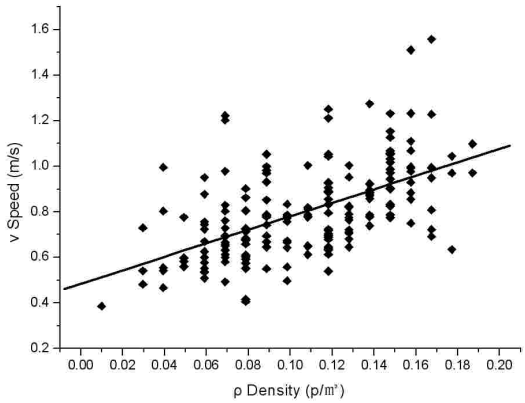

Figure 12 Steps Speed-density Linear Fit (2 periods of time) n=200

Although, the central tendency of the fit linear on Dapuqiao Station square is not stronger than on JR Nishi-Chiba station square, the characteristic of fit linear is obvious. In other words, it is necessary to discuss correlation between speed and density of these two squares. The fit linear of flat is steeper than steps, so variation of speed on flat is faster than on steps.(Figure 11, Figure 12)

6.3 Correlation between speed and density on JR Nishi-Chiba station square

Table 9 shows the correlation between speed and density. On the flat, the correlation is 0.755; on the steps, the correlation is 0.649. Wherever on the flat or on the steps, the correlation is significant at the 0.01 level(2-tailed). It shows that the speed and the density appear weak correlation in relation to the mid-high pedestrian density, but it is positive correlation.(Density is the most important effect on speed under the high density condition, but it is one of effects on speed under the mid-low density.)

The point of positive correlation is very important, because it is different from under the mid-high pedestrian density. Despite that this research have some differences of research condition and method from the previous researches, it is an interesting result nevertheless.(Table 9)

Table 9 Correlation between Speed and Density on JR Nishi-Chiba Station Square

Position	N	Correlation (speed & density)	Sig. (2-tailed)
Flat	200	0.755(**)	0.000
Steps	200	0.649(**)	0.000

** Correlation is significant at the 0.01 level(2-tailed).

6.4 Correlation between speed and density on Dapuqiao Station square

As shown in Table 10, the correlation between speed and density on the flat is 0.581, and the correlation between speed and density on the steps is 0.573 on Dapuqiao Station square.

The correlationn between speed and density on Dapuqiao Station square is weaker than on JR Nishi-Chiba station square. It is the result of pedestrians and environmental(the station square) interaction: Dapuqiao Station square is more complex than JR Nishi-Chiba station square; there are some different characteristics of pedestrians in different areas.

Table 10 Correlation between Speed and Density on Dapuqiao Station Square

Position	N	Correlation (speed & density)	Sig. (2-tailed)
Flat	200	0.581(**)	0.000
Steps	200	0.573(**)	0.000

** Correlation is significant at the 0.01 level(2-tailed).

7.0 Conclusion

After the analysis, the characteristics of pedestrian behavior were as follows:

General characteristics on the two squares: the speed is slow and the density is low in the spare time; the speed is fast and the density is high in the rush time. The speed on the steps is slower than on the flat. Under the mid-low density walking space, the correlation between speed and density is weakly positive correlation. It is different from the correlation under the high density walking space. In other words, a certain degree of density can make pedestrians speed up.

Different characteristics on the two squares: pedestrian's speed on the square of Dapuqiao Station is slower than JR Nishi-Chiba Station. Shortcut behavior on the square of Dapuqiao Station is more obvious than JR Nishi-Chiba Station. These results suggest that pedestrians in some parts of China adopt shortcut rather than fast walking for quickly reaching the destination, however pedestrians in some parts of

Japan more adopt fast walking. These results are useful to create walking spaces which will be more suitable and effective for person's behavior in dissimilar cultural contexts.

CENTRALITY AND METROPOLIZATION: DETERMINING FACTORS AND REPRESENTATION

DAVID COHEN-SCHNEE[1]

INTRODUCTION

Metropolization can be defined as the extension of recruitment areas with intensified commuting. In this context of increased mobility, what does centrality mean?

This article attempts to answer to that question. We shall first examine the classic methods of identifying centrality: by concentration and attraction. We shall then present an original approach developed by French geographers that will enable us to elaborate our own method of identifying centrality. In order to define centrality, all of these methods have recourse to indicators of concentration and attraction. In addition, they consider that centrality can no longer be apprehended at the level of just one commune, and that communes must be grouped together in order to reach a significant level of centrality. We shall explain how these groups can be constituted.

When we have observed the results of this method, we shall conclude by evaluating the possibilities of development for the territory under study: the Gironde. Depending on the type of transport development strategy and the associated urban planning strategy, we shall obtain contrasting results for the territory.

[1] GRETHA UMR CNRS 5113

1. Identifying subcentres

a. Methods based on concentration

Methods based on concentration presuppose that a concentration of enterprises has a significant effect on the urban spatial structure (cf. spatial distribution of population, employment and property rates). They identify centrality in terms of local density peaks. These methods differ in the manner in which they identify these peaks. We can distinguish two types of methods based on concentration. One descriptive statistics as indicators of centrality while the other uses density gradient models.

Among the methods of the first type we retain those developed by McDonald (1987[1]), and Giuliano and Small (1991[2]). There are many differences between these two approaches. The main controversy focuses on the indicator retained. While McDonald uses, among others, the work/population ratio, Giuliano and Small consider total work density to be a better indicator. They argue that the presence of population is not characteristic of centrality. For them, centrality is based on the proximity of enterprises (cf. localised externalities). Whereas McDonald considers that a work/population ratio > 1 expresses the capacity of a space to attract its neighbourhood.

Frédéric Gaschet (2001[3]) opts for this ratio after demonstrating that the work density retained by Giuliano and Small is too sensitive to certain factors:

- disparity linked to how long the different spaces have been urbanised
- heterogeneity of the proportion of non-urbanised space in different zones
- heterogeneity of the spatial breakdown used

[3] Frédéric Gaschet - *La polycentralité urbaine* – Thesis - Université Montesquieu-Bordeaux IV - 21 December 2001

- disparity of ground consumption per product unit, depending on the economic activities in question

The second type of method is developed, by Craig and Ng (2001[1]), McMillen (2003[2]) and McMillen and Smith (2004[3]), among others. These methods specify the function of the density, whether parametric or non-parametric. The interest of these more or less sophisticated methods lies in their capacity to define density peaks in relation to their distance from the centre. There is thus no need to adapt centrality thresholds in function of their distance from the centre, as we find with Giuliano and Small.

b. Methods based on attraction

Jean R. Boudeville (1972[4]) makes a distinction between an urban agglomeration (defined as a homogeneous region), and a region of polar attraction (which is heterogeneous i.e. it links centres with each other by means of flows)

We can distinguish two types of flow:

- material and immaterial flows that feed enterprises
- flows of people in transit, particularly commuters

The first type mobilises a reticular and dispersed space. We are interested in the second type because they mobilise a local and more or less compact space. This space is the subject of our study: local urban structuration through labour and centrality.

[3] Daniel P. McMillen and Stefani C. Smith - *The numbers of subcenters in large urban areas* - Journal of Urban Economics 53 – 2003 - pp. 321-338
[4] Jacques R. Boudeville - *Aménagement du Territoire et Polarisation* - Editions M. TH. GENIN - 1972

The method known as the preferential flow method is a good means of evaluating the attraction of urban spaces. This method enables us to distinguish gravitational attraction (linked solely to the weight of the territory under consideration) from a underlying attraction. Depending on whether this is positive or negative, we speak of "barrier effects" or "preferential effects". Global observation of flows and any reciprocity between them enables us to determine whether certain flows are dominant or not.

c. Berroir and Mathian's approach (2004[1])

Berroir and Mathian's approach has the advantage of combining the two previously mentioned approaches (concentration and attraction). They define five absolute or relative indicators of concentration and attraction. Using these measuring criteria they then proceed in stages:

- identification of node communes
- consolidation of multi-commune poles
- definitive formation of multi-commune poles

Figure 1 : Identification, consolidation and formation of multi-communes poles

[1] S. Berroir, H. Mathian et al, Mobilités et polarisations : vers des métropoles polycentriques – Le cas des métropoles franciliennes et méditerranéenne, for PUCA, January 2004

The great advantage of this method lies in its capacity to model the grouping together of contiguous communes that function together. Based on this method, we can construct a method of identifying centralities in Gironde.

2. Subcentres, commuting and metropolization

a. An approach based on concentration and attraction for the Gironde department: Method

Let: x_i: home-workplace travel inside commune i

y_i: share of commune i employment relative to population

χ a threshold of x

ψ a threshold of y

$$\begin{cases} X_i = 0 \text{ if } x_i < \chi \\ X_i = 0{,}5 \text{ if } x_i > \chi \end{cases}$$

$$\begin{cases} Y_i = 0 \text{ if } y_i < \psi \\ Y_i = 0{,}5 \text{ if } y_i > \psi \end{cases}$$

Then $X_i + Y_i = \{0 ; 0{,}5 ; 1\}$

Aggregation criteria for forming Areas of Multi-commune Cohesion

Communes that reach the stability threshold and the work rate threshold, or communes that achieve only the stability criterion cannot claim to be a part of an area of multi-commune cohesion, their operational modes being largely self-centred.

An aggregation of communes implies that they meet the following conditions:

- a work rate that exceeds the threshold;
- contiguous;
- employment in excess of the thresholds 1500 or 5000 jobs, depending on whether its location is rural or urban, for at least one of the communes applying to form part of an aggregation.

Commune categories

Different types of centrality are thus defined depending on the conditions:

- communes that remain below the thresholds, regardless of the indicators, are classified as towns
- communes whose employment figures exceed the threshold are classified as cities

The distinction between a town and a city thus corresponds to its size, provided it meets no other conditions.

- communes having only the stability rate in excess of the threshold are classified as residential
- if, in addition, the employment figure exceeds the threshold, the commune is classified as an autarchic subcentre

When the majority of jobs provided in the commune are occupied by residents, the autarchic character of the commune is clearly asserted: few employed members of the active population leave the commune to work and, reciprocally, a large share of jobs in the commune are occupied by residents. If, in addition, the quantity of jobs does not exceed the threshold, the residential rather than economic vocation of the commune is clearly asserted. Against this, if the quantity of jobs exceeds the threshold, the term "subcentre" can be applied.

- communes in which only the employment rate exceeds the threshold are classified as centres

When the concentration of work is high, we can speak of a centre, in the sense that this commune acts as a focus for employment. However, because the quantity of jobs is too low, we cannot speak of centrality.

- moreover, if the quantity of jobs exceeds the threshold, the commune is classified as an "extrovert" subcentre.

When it meets both conditions, we can speak of a subcentre: employment is considerable and concentrated. However, jobs are not occupied primarily by residents, many of the active population leave the commune to work and, reciprocally, jobs there are occupied to a considerable extent by an active population from outside the commune: we can thus speak of extroverted commune employment.

- communes with an employment rate and a stable rate in excess of the thresholds are classified as local centralities because the quantity of work available in the commune does not allow it to radiate largely;

- moreover, if the quantity of jobs exceeds the threshold, the commune is classified as a primary centrality: it meets all the conditions.

b. Subcentres and commuting in the Gironde department: Results

The candidate communes for grouping in order to constitute areas of multi-commune cohesion are: Bordeaux, Blanquefort, Mérignac, Le Haillan, Bruges, Cestas and Bouliac; Libourne, Saint Emilion, Pomerol, Vignonet, Saint Pey d'Armens, Saint Hippolyte and Saint Etienne de Lisse; Lesparre and Blaignan; Pauillac and Saint Julien de Beychevelle; Blaye and Cars.

The Areas of Multi-commune Cohesion method enables us to highlight certain striking characteristics. The first obvious feature that comes to the fore when we examine the maps is the almost total disappearance of the residential commune status and autarchic subcentre, with the exception of Soulac sur Mer. The second characteristic is the disappearance of the primary centrality status at the level of the commune. Third, a considerable number of communes have regressed to the rank of town. Fourth, the economic size of communes in terms of the quantity of jobs has increased greatly with the result that many towns have become cities, particularly within the urban unit of Bordeaux where the peripheral communes of the CUB have considerably increased their economic weight. Fifth, although the agglomeration comprising Arcachon, La Teste de Buche and Gujan Mestras concentrates jobs, this employment is insufficient in relation to the local population for it to exceed the centrality thresholds or aspire to AMC status. However, the reciprocal flows between these communes would enable it to meet the conditions for stability. Sixth, the fact that some communes regressed from the rank of primary centrality to lower ranks enables us to formulate the hypothesis that the department space was structured differently between these two dates: a change from local recruitment zones to an inter-connection of departmental sub-spaces.

c. Some urban planning and transport choices for the Gironde department: a prospective approach

The Gironde territory is subject to powerful demographic and land use pressure that completely upsets the major traffic flows and the balance of territories inside the department. Depending on the strategies adopted for transport and urban planning, and the combinations thereof, we shall see that certain choices can render territorial balances more vulnerable. We have chosen to give precedence to the transport strategy over the urban planning strategy.

We start by defining two scenarios for the transport strategy. The TER and Trans' Gironde networks are of limited efficiency: a 45-minute travel radius from centre city Bordeaux using a modal public transport system scarcely exceeds the limits of the agglomeration. If we take into account the time lost in transit changes and waiting, which can be longer at certain times of day, this radius is reduced even further. However, the intercity networks are not the only source of difficulties in PT links between communes in the Gironde department. The public transport network in the agglomeration of Bordeaux has other shortcomings: once we leave the corridors served by the tramway, the possibilities of finding a quick link to a destination in the Bordeaux agglomeration are reduced. In order to develop a network of public transport, the department needs to free itself from these constraints and limits. Hence the need to increase the current PT offer, but also to improve the quality and inter-connectability of the services provided. Two options can be retained:

- a scenario with a hierarchical system of serving priority centres: increasing the speed and efficiency of the network by applying a system of priority status for certain stations and stops, thus enabling the Bordeaux agglomeration to increase its attraction radius. This scenario could be summed up as "Faster/Farther".
- a scenario with a generalised system to serve all stops stations in the urbanised territory: increasing the efficiency of the public transport network

by eliminating or minimising transit changes, augmenting the number of urban stations or stops, extending secondary and tertiary branches of the public transport network in the metropolitan area. This scenario could be summed up as "Territorial accessibility".

These two logics are complementary and non-exclusive: the efficiency of the public transport service depends on a combination of the two scenarios.

Two principles can be applied to organise PT networks regardless of the scenario retained:

- enhanced exchanges between the Bordeaux agglomeration and the rest of the department
- improved meshing of the urban tramway system inside the agglomeration

Appel à projet PUCA "Lieux Flux Réseau dans la ville des services"
Pour un scénario de transports collectifs, quels scénarios de développement urbain?
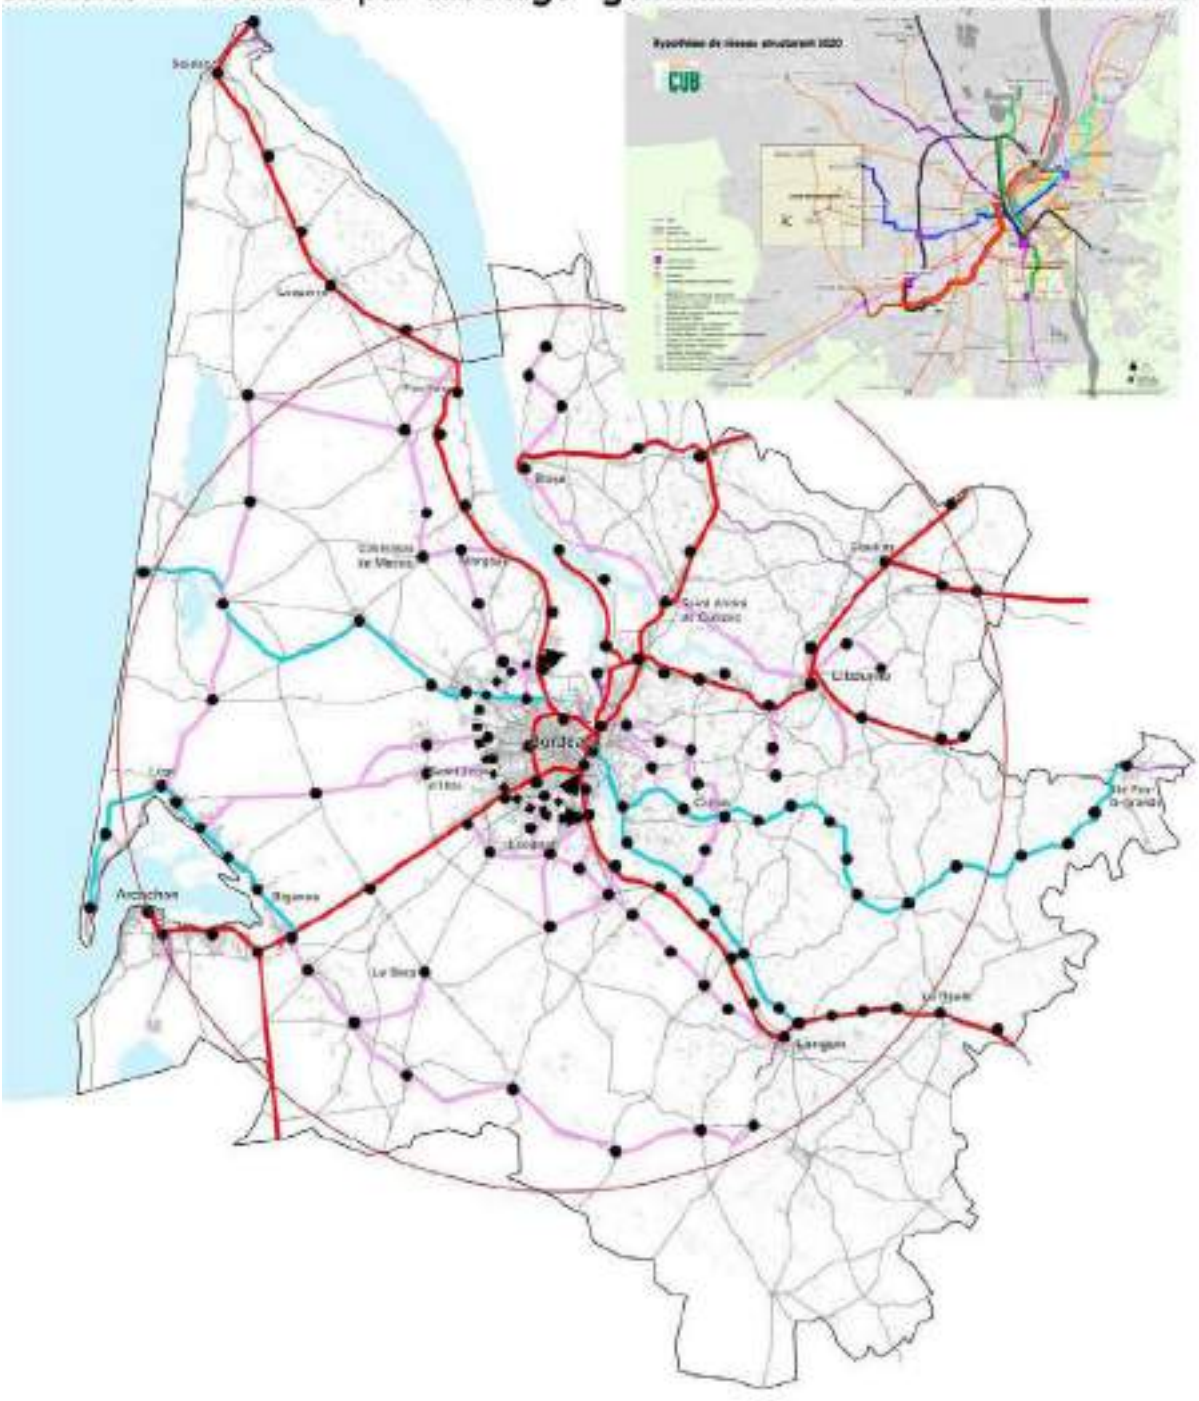
Approche comparée sur les agglomérations de Bordeaux. Coimbra. Karlsruhe.

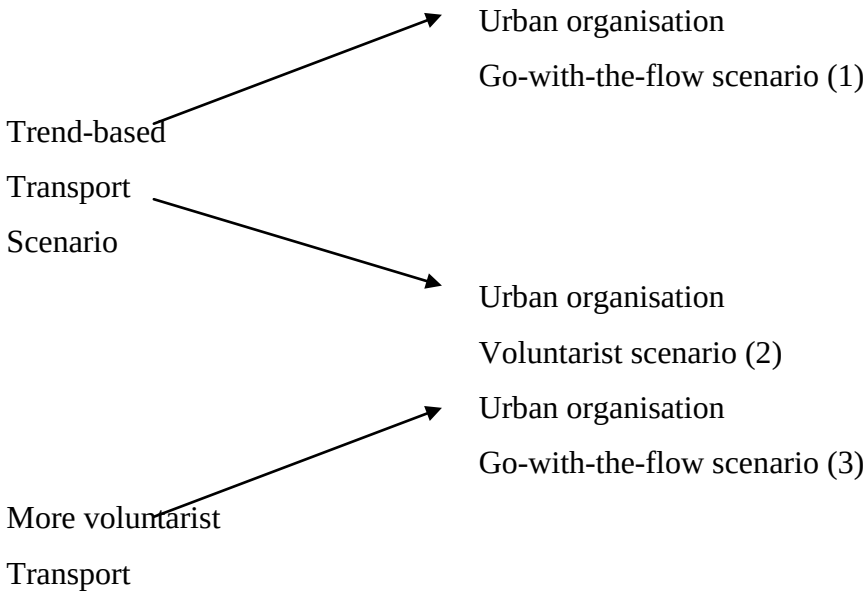
Scénario 2 "Desserte par cabotage" généralisée à l'ensemble du territoire

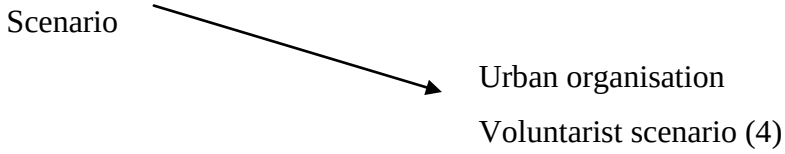


Urban planning choices reflect these transport issues and influence the structuration of the Gironde territory:

- a "go-with-the-flow" scenario: continuing the urbanisation movement without any particular re-evaluation or urban renewal, continuing the current public transport development policy, fragmented political control, lack of cohesive public action, little or no change in the centre-periphery dichotomy
- a voluntarist "Rhineland" scenario: organising the territory into an urban necklace in which public transport (particularly tram-train) acts as a channel for urban development (development supported by public transport policies, public policies for reorientation and urban renewal in and near the leading centralities, train station neighbourhoods, TCSP corridors). This generates secondary urban agglomerations which themselves produce polarities; we can distinguish two approaches, one aiming at residential zones, the other targeting service centres.

The type of territory provides a framework for the elaboration of two possible scenarios for territorial structuration combining transport and urban organisation.





"Go-with-the-flow" urban organisation corresponds to a progressive disconnection between the networks and the underlying urban infrastructures. It is characterised by the absence of an ambitious development policy that prioritizes train station neighbourhoods and the corridors served by the PT. Paradoxically, developing the PT offer would favour the risk of urban sprawl and the occupation-based segmentation of territories by forcing households to reside in increasingly remote zones while continuing to access central activity hubs via effective PT services.

Voluntarist urban organisation (centralities, intermodality, exchange centres) corresponds to the creation of effective urban support systems around the PT networks. The subcentres served by PT being reinforced by urban development and priority densification policies implemented around centralities and train station neighbourhoods, thus rendering polarities relatively independent with regard to the city centre.

We can infer the consequences of urban development choices in function of the retained public transport scenario.

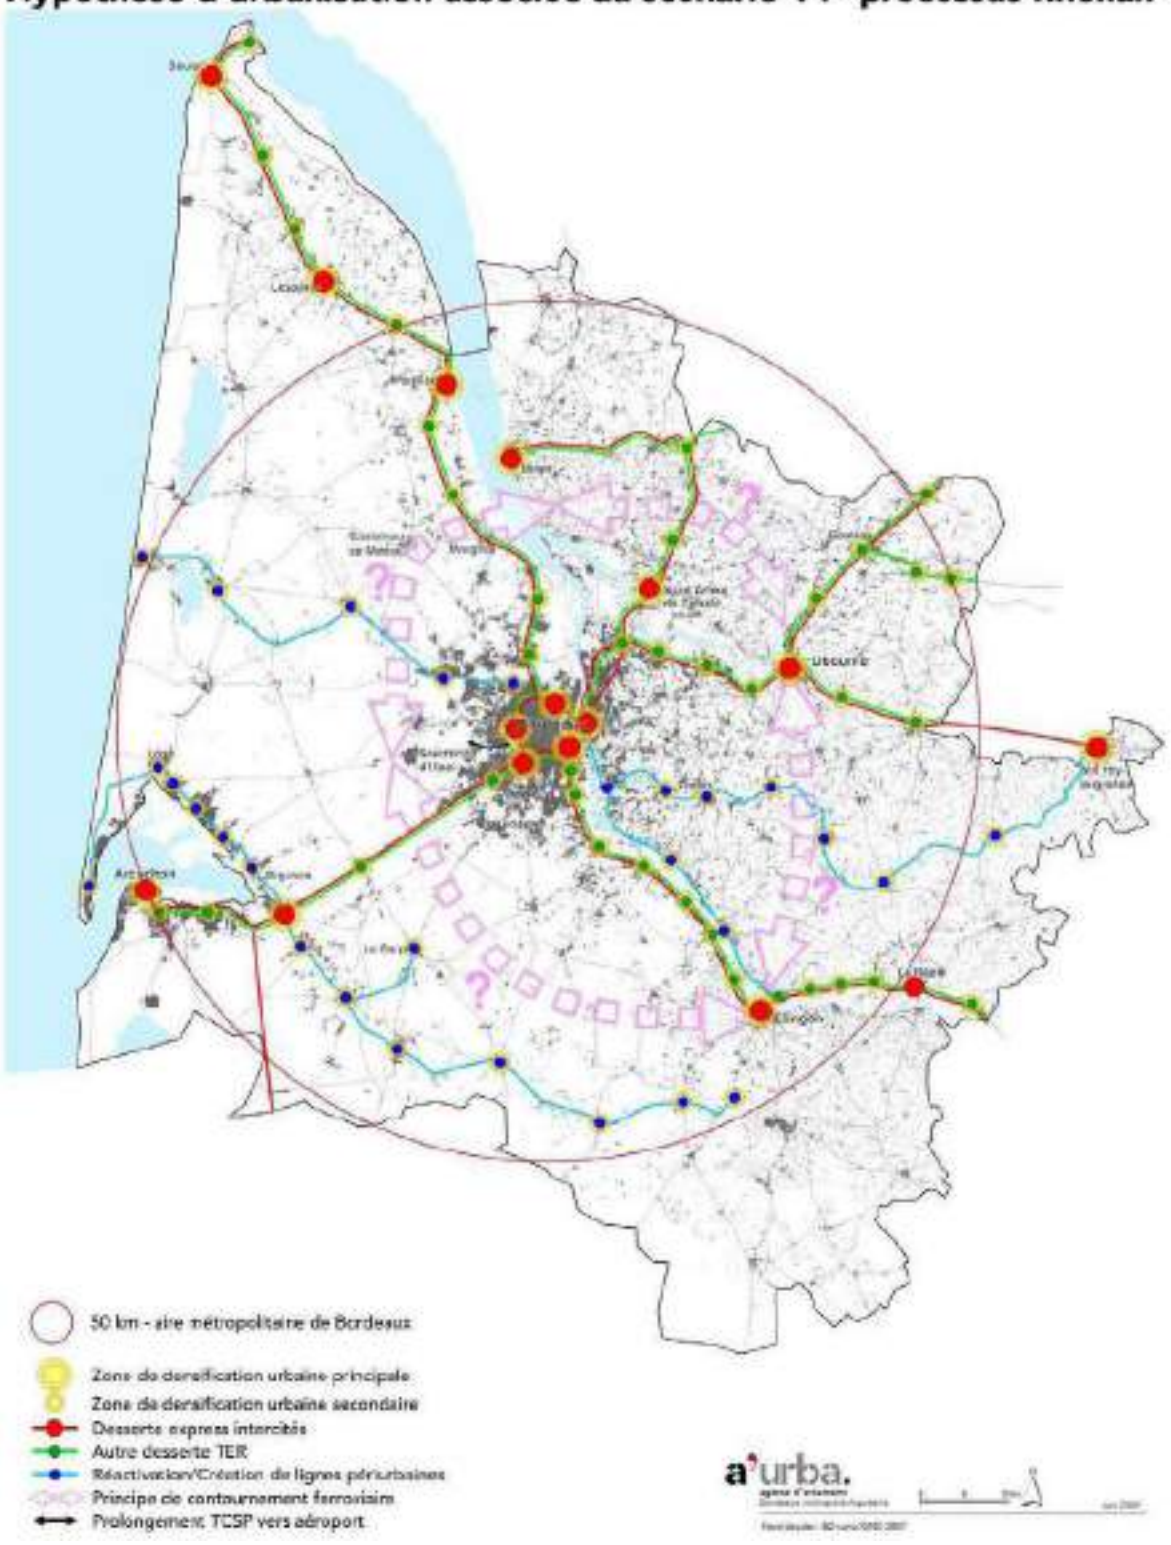
(1) The Rhineland process associated with a hierarchical service

Densification takes place primarily around the polarities constituted by stations served by express inter-city trains. Secondary densification zones are identified around other stations and stops. Outside of these territories, urban expansion is neutralised. This urban policy can be used to curb urban sprawl but also to reinforce the main centralities in the territory. For this development model, the priority centralities would be Soulac, Lesparre, Pauillac, Arcachon, Biganos, La Réole,

Langon, Sainte Foy la Grande, Libourne, Blaye, Saint André de Cubzac and the Bordeaux agglomeration. This model is hierarchical: the Bordeaux agglomeration continues to be the main centrality and the subcentres all converge toward it via a radial public transport network. This model thus asserts a **monocentric** vision of the Bordeaux metropolitan area, dominated both demographically and economically by the agglomeration toward which the mobility system converges.

Appel à projet PUCA "Lieux Flux Réseau dans la ville des services"
Pour un scénario de transports collectifs, quels scénarios de développement urbain?
Approche comparée sur les agglomérations de Bordeaux, Coimbra, Karlsruhe.

Hypothèse d'urbanisation associée au scénario 1 : "processus Rhénan"



(2) Urban dispersion associated with a hierarchical PT service

Densification takes place around the existing urban cores but not primarily around stations or stops in the public transport network. All built-up zones may be terrains for densification, particularly in a close radius around stations and stops served by public transport. The main centralities of the territory (centres, areas and nodes) are no longer the subject of priority densification in the territory: this model is thus a-hierarchical by virtue of the absence of consultation between the urban players. The main result of this model is the dispersion of dwellings around the stations and stops in the public transport network: it is an "**leap-frog**" model.

(3) The Rhineland process associated with a detailed PT service to the territory

Densification takes place primarily around stations or stops in the public transport network. Because the network is close-knit, more stations and stops will be densified. The urban development model nevertheless remains hierarchical. The network converges toward the large agglomerations in the territory (Bordeaux, Arcachon and Libourne) and the subcentres (Gujan Mestras, Sainte Foy la Grande, La Réole, Langon, Coutras, Lesparre, Blaye, Saint André de Cubzac). It would be logical to expect an increase in their power of attraction and their centralising capacity. Even if the Bordeaux agglomeration were to continue to exert a powerful influence, it would be part of a **multi-polar** development model.

(4) Urban dispersion associated with a detailed PT service to the territory

Urban extension develops through densification around stations and stops but also through urban dispersion beyond these. Because the transport network is close-knit

and dense in the region of the three main agglomerations, we can expect conurbations to form and extend around these agglomerations. This development model is characterised by "**urban sprawl**".

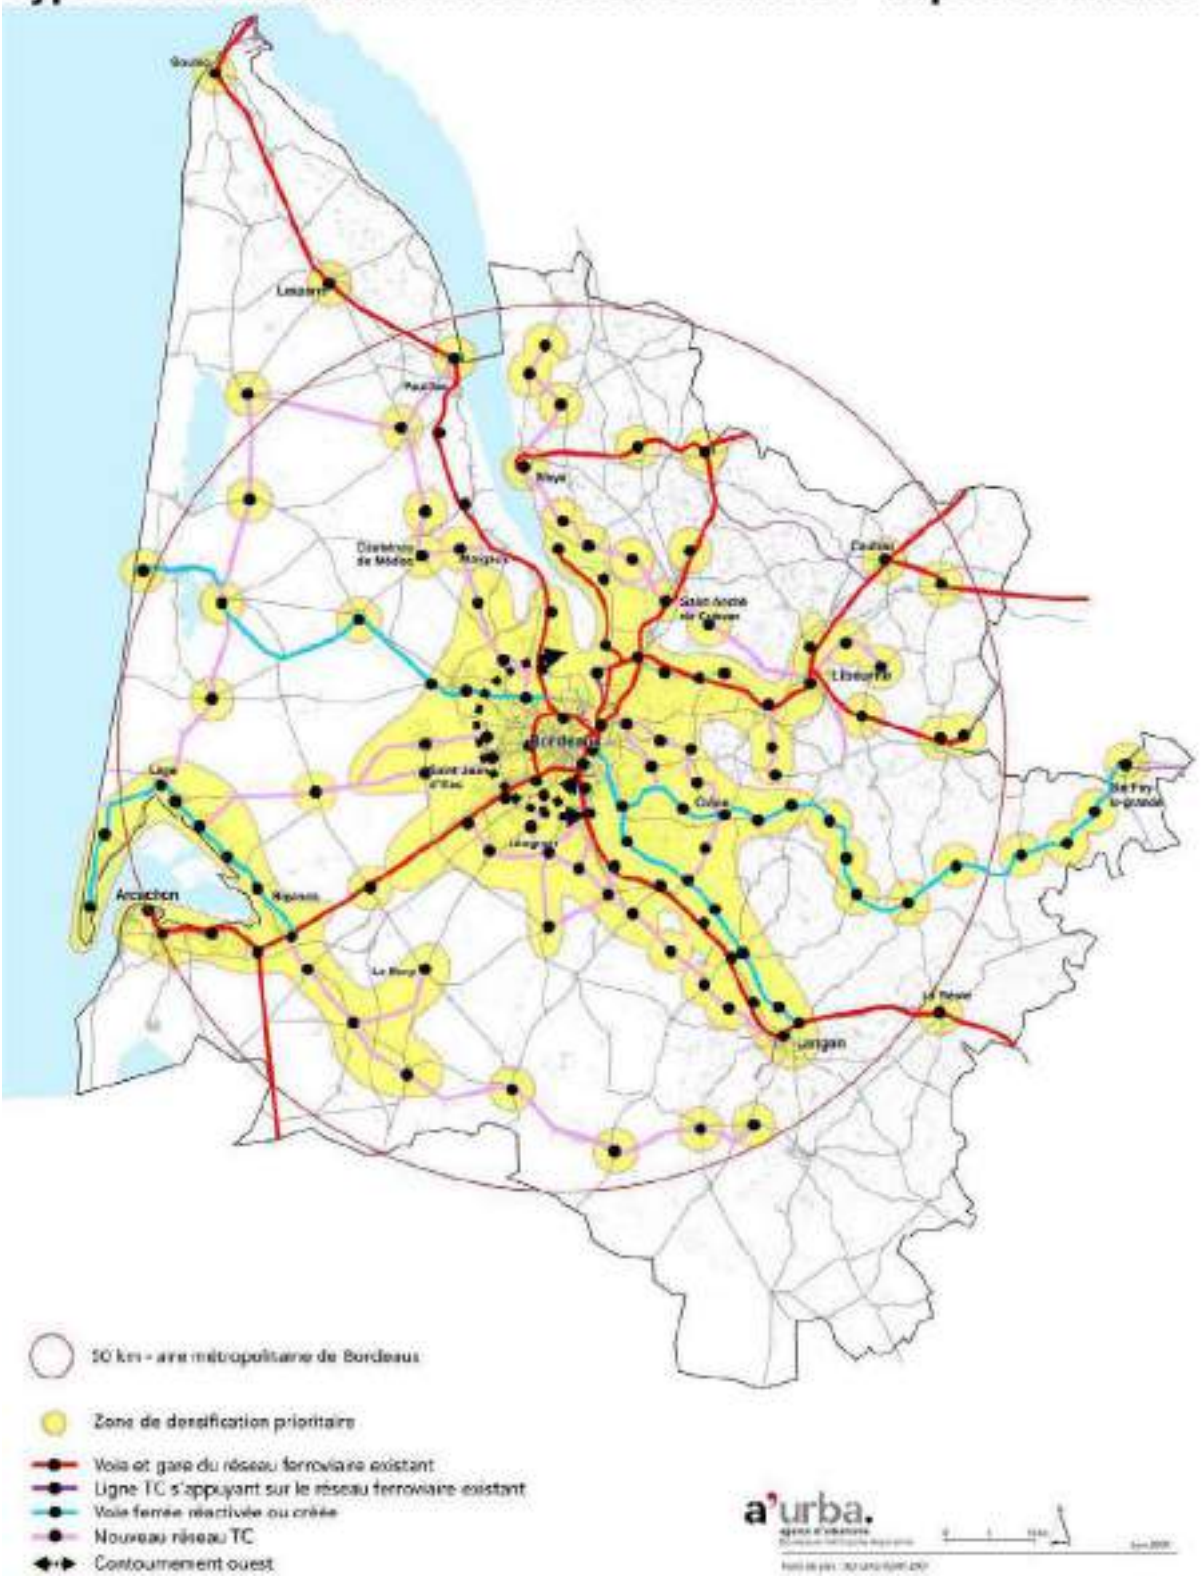
Hypothèse d'urbanisation associée au scénario 2 : "dispersion urbaine"



We would like to explain the densification of urban blots on the prospective maps. This process makes it easier to observe the urban phenomena that characterise the different development models: "monocentric", "leap-frog", "multi-polar" and "urban sprawl" development.

Our study thus enables us to demonstrate that there is no ideal strategy for transport or urban planning. In reality, it all depends on the how they are combined: a transport strategy will be effective for a given urban strategy in relation to previously established development targets, but could be completely ineffective for another urban strategy. We wish to stress yet again that the two transport scenarios described in this study are not opposed to each other but perfectly complementary.

CONCLUSION

We find centrality at agglomeration levels greater than the commune and which concentrate economic activity and employment and attract the main flows of commuters. If centrality is not diluted in the metropolization process, we still find risks linked to the extensive and intensive increase in mobility.

Development choices for transport services and the associated urban planning are thus determining factors for the future development of the Gironde. We can infer two complementary types of policy recommendations from these observations: one for the public transport system, the other for economic development. Local decision-makers are thus faced with two main choices for each policy.

For the transport system:

- to serve the whole urban area population settlements;
- to serve the main subcentres.

The "egalitarian" approach enables workers to settle anywhere in the surrounding countryside whilst having close access to the public transport system, whereas the "hierarchical" approach serves more remote places in less time (thus eliminating geographical and time constraints).

For economic development:

- to concentrate and densify activities in the principal subcentres;
- to enlarge and spread activities all over the urban area.

In other words, if policy-makers prioritize a "concentrated approach", this implies a constraining planning decision. If policy-makers prioritize the "spread approach", this implies that the land-use market will have a strong influence on the location of economic activities

By combining these two choices, four consequences can be inferred:

1. development of urban-sprawl;
2. leap-frog urban development;
3. concentration around the CBD;
4. distribution around the principal subcentres.

COMPACT CITY DEVELOPMENT AND THE CHALLENGE OF ENVIRONMENTAL POLICY INTEGRATION

A multi-level governance perspective

Rien van Stigt[1], Peter Driessen[2], Tejo Spit[3]

Do not cite without prior permission of the author

Abstract

Sustainable urban development entails integration of environmental interests into decision-making at the local level. In order to achieve this, higher tiers of government, may compel municipalities to explicitly consider environmental objectives or even prioritize them by demanding compliance with national standards, thus, at least theoretically, restricting local government's room to manoeuvre in balancing all relevant interests. This paper explores the extent to which national standards narrow the range of local options and what this means for sustainable urban development. Adopting a multi-level governance perspective to three cases of inner-city redevelopment, we find that environmental standards are either not problematically restrictive or, if they are, sectoral policy offers ways to circumvent them. From a sustainability perspective, this may lead to undesirable outcomes. A combination of approaches may solve this predicament.

1. Introduction

Over a period of some twenty-five years now, since the publication of 'Our common future' (WCED, 1987), the concept of sustainable development has attracted the attention of scholars. Researchers, especially in Europe, have amassed a large body of literature on a particular aspect of sustainable development, namely the integration of environmental policy into other policy sectors (Jordan and Lenschow, 2010; Jordan, 2008; Persson, 2004; Nilsson and Persson, 2003). This concept, known as 'environmental policy integration' or EPI, is wholeheartedly accepted at the (supra)national level and there is much political commitment to it, especially in the EU. However, at lower levels of government, its implementation in everyday decision-making still faces many challenges (Jordan and Lenschow, 2010). As 'Our common future' explicitly mentioned cities as the focus points for sustainable development, it is

interesting to look at the implementation of EPI at the municipal level, the outcome of which must be sustainable urban development.

In their study of the urban politics of climate change, Bulkeley and Betsill (2005) drew attention to the fact that local authority's aspirations for sustainable development cannot be understood in isolation. Instead, using a multi-level governance perspective (Hooghe and Marks, 2001), they demonstrated that local sustainability policy can be greatly affected by the circumstance that authority is shared among different, state and non-state, actors and institutions. It appears that this multi-level governance character of EPI can, in part, explain the observed 'implementation gap' (Nilsson et al., 2009). The growing body of literature on EPI, however, rarely offers analyses of policy implementation at the local level (Watson et al., 2008); insofar as it does address the multi-level governance characteristics of EPI, the literature concentrates mainly on the national and supra-national level (Nykvist, 2008; Catenacci and Sgobbi, 2007). There are, however, several recent accounts indicating that the pursuit of sustainability objectives by regional or local authorities can be severely hampered by other governing institutions at different levels of the state (Bulkeley and Betsill, 2005; Alahuhta et al., 2010).

By contrast, it can be argued (e.g. Newig and Fritsch, 2009; Bradshaw, 2003) that higher authorities can best safeguard relatively weak interests, such as the quality of the environment. Indeed, the European Union (EU) and many countries outside Europe have adopted a system of quality standards that regulate environmental aspects such as air and water quality and/or energy performance of buildings. Such regulations, in principle, constrain local authority's room to manoeuvre in making trade-offs between social, economical and ecological interests, which, according to Campbell (1996), comprise the essence of planning for sustainable urban development. In the Netherlands, where there are many land-use claims in urban areas – partly as a consequence of national land-use policy, geared to save green and open space – professionals involved in urban area development have indeed claimed that national environmental standards unnecessarily complicate and restrict local development (OTB, 2011; De Zeeuw et al, 2009).

This paper addresses two questions: How and to what extent is local room to manoeuvre restricted by sectoral regulations from higher tiers of government? And how do these restrictions influence the outcome in terms of sustainable urban development? We tackle these questions by analyzing how environmental interests are balanced with other, social and economic, interests. We do so in particularly complex cases, namely inner-city redevelopment near railways, that we deem characteristic for many highly burdened, high-density developments worldwide.

The rest of this article is structured as follows: First, we present an analytical framework, describing the multi-level governance aspect of EPI in cases of urban redevelopment. Second, we look at the role of EPI in the type of urban redevelopment discussed here. Then, after going briefly into the research method used, we give an

overview of the indicators of EPI that are relevant in this type of case study and of the national and provincial requirements that are set with respect to each of these indicators. Next, we present the three cases and the ways in which the most relevant aspects of sustainability have been weighed in each case. Finally, we discuss the findings in the light of our analytical framework and present our conclusions.

2. Environmental policy integration from a multi-level governance perspective

EPI 'refers to the integration of environmental aspects and policy objectives into sector policies' (Persson, 2004). This entails weighing those consequences as well as measures to prevent or mitigate them against other competing interests. Although many authors (for an overview, see Hamdouch and Depret, 2010) have shown 'win-win' situations to exist, trade-offs between environmental objectives and sectoral goals are inevitable (Jordan, 2008; Lafferty and Hovden, 2003). Adopting a normative perspective, the question has been raised regarding the relative weight of environmental considerations in these trade-offs (Jordan and Lenschow, 2010).

Conceptions of EPI appear to vary from 'weak', where environmental consequences are merely *considered* (Schout and Jordan, 2007), to 'strong', where environmental objectives are given 'principled priority'(Lafferty and Hovden, 2003). Moreover, from an analytical perspective, questions have been addressed as to where EPI occurs and which factors are conducive to EPI or, conversely, hinder efficient integration of environmental objectives into sector policies. With respect to the former, EPI literature distinguishes between horizontal and vertical environmental policy integration (Lafferty and Hovden, 2003). Horizontal EPI pertains to an overarching strategy for EPI by some central governmental authority, whereas vertical EPI concerns integration of environmental objectives throughout a particular ministry's sectoral policy. With respect to the latter type of questions, as to what types of measures and strategies may lead to EPI, Persson (2004) distinguishes normative, organizational and procedural factors. Among the normative factors are political commitment, societal backing and fundamental changes in political paradigms. Organizational factors are those pertaining to the architecture of government and non-government institutions. Procedural factors are tools that enable consideration of environmental consequences in decision-making, such as environmental impact analysis (EIA) and strategic environmental analysis (SEA) (Sheate and Partidario, 2010; Nilsson and Dalkmann, 2009), action plans and consultation procedures. Weber et al. (2010) essentially use the same categories.

Although little research has been done into the actual outcome of EPI in day-to-day decision-making, several authors identify an 'implementation gap' (Nilsson et al., 2009) between political rhetoric at the (supra-)national level and policy outcome 'on the ground'. In Finland for instance, integration of river basin planning and land-use planning was reported at the highest governmental tier, but practical implementation at regional and local levels was deemed to need further development (Alahuhta et al., 2010). In Great Britain, local climate policy was hampered by economic development

policy at the regional level (Bulkeley and Betsill, 2005). Conversely, European and national intentions for greening municipal waste policy were severely hindered by local dynamics of the sector in Great Britain (Watson et al., 2008) and Sweden (Nilsson, 2005). In analyzing EPI it is, therefore, necessary to take into account the mutual influence of distinct levels of government (Bulkeley and Betsill, 2005). A particularly useful framework to do so is the concept of multi-level governance, the 'reallocation of authority upward, downward, and sideways from central states' (Hooghe and Marks, 2003). Hooghe and Marks (2003) distinguish two types of multi-level governance: Type I concerns multiple tiers of government, whereas Type II is about the distribution of authority over different state and non-state actors and institutions. Nykvist (2008) terms this vertical and horizontal integration, respectively. Vertical integration in this sense is, however, not quite the same as the vertical dimension of EPI distinguished by Lafferty and Hovden (2003), which does not explicitly include multiple tiers of governance (Steurer, 2008).

A multi-level governance perspective might help understand how the existence and functioning of multiple tiers of government influences EPI at the local level. Such influence may be more profound when the amount of local autonomy, which varies between dimensions of sustainable development and policy sectors (Bulkeley, 2010), is high to start with.

3. EPI in compact urban development

Traditionally, local autonomy in the field of urban development is high. Local authorities are best placed to weigh local interests (De Roo, 2000) and therefore resolve the conflicts between economy, environment and social justice (Campbell, 1996). Campbell suggests that planning for sustainable cities amounts to negotiating three interconnected conflicts: between equity and economic growth, between environmental protection and economic growth and between equity and environmental protection. Clearly, solving the latter two conflicts can be regarded as EPI. In Campbell's view, it is in negotiating these conflicts that the road toward a sustainable city is thought to emerge. This would amount to a 'weak' mode of EPI, because it implies that environmental interests could 'lose'. Many countries have, however, adopted a far more 'strong' mode of EPI in that they have, at the national or, in Europe, at the supra-national level, put in place a system of environmental quality standards to be observed in urban planning, thus principally prioritizing environmental interests.

Many scholars and practitioners hold the view that the concept of the 'compact city' can contribute to achieving sustainable urban development. The term 'compact' does not merely refer to building in high densities (dwellings or workplaces) but rather encompasses intensive use of urban space characterized by: a mix of functions (living, working, leisure, amenities) in, indeed, high densities; a relatively small grain; and the proximity of nodes of (public) transport (Neuman, 2005). The 'compact city' concept could be helpful in preventing urban sprawl (Breheny and Archer, 1998; Breheny,

1997), as it has been in the United States' growth management (Janssen-Jansen, 2005). Compactness, however, also entails the risk of deteriorating environmental and spatial quality (Janssen-Jansen, 2005) and of exposing large numbers of people to natural and industrial risks. This has become known as the 'compact city dilemma' (De Roo, 2000; 1998; Bartelds and De Roo, 1995). The dilemma could be resolved by either relaxing national standards or by allowing local authorities, under certain conditions, to deviate from those standards (De Roo, 2000; Glasbergen, 2005), so as to negotiate a state of what is perceived locally to be 'sustainable', much as envisaged by Campbell (1996).

How do local authorities solve this type of dilemma? And how much freedom to manoeuvre is left to them by higher tiers of government? To answer these questions, one should investigate how each of the relevant interests plays a role in local decision-making and how national or regional regulations may influence the outcome of balancing these interests.

Assuming that EPI is more problematic in complex situations, we examined three cases of inner-city redevelopment near railways. Many comparable situations exist in the Netherlands and elsewhere, and the complexity is comparable to that of brownfield redevelopment, which is receiving attention worldwide as a contribution to sustainable urban development (Raco and Henderson, 2006). Characteristic properties of these urban sites are the coexistence of sources of noise and risk – due to the transportation of dangerous substances and a history of industrial land-use – to which large numbers of people are being exposed. Often, road traffic is intense, aggravating the environmental problems mentioned and adding a powerful source of air pollution.

4. Method

First, we derived from scientific literature those indicators of sustainable urban development which are relevant to EPI in the cases studied. For each of these indicators, we then identified regulations and requirements, set by European, national and provincial governments. Next, of each case, we analyzed the land-use plan, as we perceive it to be the codification of a decision-making process among stakeholders. In addition, we studied the underlying documents, such as ambition statements and preliminary designs. For each of the indicators identified, we established each municipality's objectives, as well as the consequences for decision-making of the restrictions imposed by higher tiers of government. In each of the three cases, we interviewed stakeholders, who could inform us about the way all interests were weighed: the alderman responsible for the project, the municipality's project leader, the project's environmental advisor and a representative of the developing company. These interviews were semi-structured. First, respondents were asked in what way 'sustainability' was made operational in each particular case. Next, for each operational aspect, those interviewed were asked in which way and to what extent they felt helped or hampered by provincial, national or even European government. The relevant indicators (section 5) were used as a checklist during the interview. All

interviews were electronically recorded, typed up and slightly edited, after which transcripts were sent back to the interviewees for comment. The results were used to elaborate our analysis of the land-use plans and underlying documents. We selected developments in three Dutch cities, namely Tilburg, Woerden and Zutphen. We chose cases that were well-documented, where land-use plans were recently finalized, in medium-sized cities (where integration appears not to be hindered by the sheer complexity of the administration). Furthermore, in order to be comparable with respect to the interests being balanced, developments must be mixed-function, within existing city limits and situated near railways on which both passengers and dangerous substances are transported. The cases are representative of many similar situations in the Netherlands and elsewhere.

5. Indicators of sustainable urban development

What are the indicators of urban sustainability and which of those are indicative of EPI? Several authors have suggested sets of indicators (Shane and Graedel, 2000; Shmelev and Shmeleva, 2009), ranging from air quality, energy consumption and resource use to liveability, health and preservation of cultural heritage. The European Commission's guidelines on integrated environmental management (EC, 2007) list a somewhat similar, although not exhaustive, set, which adds local governance and land-use planning. Finally, many Dutch municipalities use a location's sustainability profile consisting of 24 indicators, including the use of resources; local environmental quality; nuisance from noise and odour; safety and security; quality of amenities; access to public transport; green space; urban and residential quality; social cohesion; work; diversity; and IT infrastructure in the area (Nielsen and Jensen, 2010).

Clearly, not all of these indicators are helpful in studying EPI. Neither are all of them relevant to the type of development studied here. From the suggestions above we selected only those that are related to environmental interests and therefore indicative of EPI. Furthermore, we only included in our analysis those that are directly influenced by the redevelopment itself. We propose the following set of indicators: energy efficiency and clean energy production; building materials and waste; water management; urban transport; quality of air and soil; noise; risk; and green space.

Energy efficiency and clean energy production are obvious indicators mentioned by many scholars studying urban sustainability and are directly affected by urban design. A second obvious set are building materials and waste, also mentioned in all of the literature cited above. In our view, however, these are restricted to the development phase itself – hence the explicit term '*building* materials'. Water management, here, is about water *quantity*: allocation of space for infiltration and storage of rain-water put a direct claim on land-use; the collection of sewage and the quality of surface and ground water are regulated on the scale of the water system as a whole and therefore not of direct concern here. Since our objects of study are in close proximity to railway stations, it would be trivial to assess the dimension 'urban transport' by measuring distance to public transport. Instead, we look at urban design that favours transport by

bike and on foot, discourages local car traffic and stimulates the use of rental cars instead of private car ownership. Indicators for local environmental quality are also mentioned frequently in the literature cited: soil and air pollution, noise and industrial risks. These are deemed relevant because of busy road and rail traffic and former or possibly remaining industrial activities. The amount and quality of green and open space is a further obvious indicator, mentioned by many of the authors mentioned above. Density and the mixing of functions are a characteristic of the objects of study and therefore not discriminating. Biodiversity, which in itself is an important aspect of sustainable development, is deemed irrelevant in the case of inner-city redevelopment projects.

6. Regulations and requirements

For each of the sustainability indicators identified in section 5, we now turn to the restrictions imposed by European, national and regional tiers of government. These are summarized in Table 1.

Energy efficiency and clean energy production
The EU Energy Performance of Buildings Directive (EC, 2010) has been implemented in national legislation for new buildings, setting a minimum requirement for energy performance (EPC), which will be tightened over time (BZK, 2011).

Regarding the use of energy from renewable sources, the EU (2009) merely requires national action plans stimulating renewable energy sources..

Building materials and waste
The European Directive on Waste (EC, 2006a), does not specifically cover building materials. Dutch building regulations demand that emission of greenhouse gasses (during use) and depletion of resources are quantified (BZK, 2011), but no requirements are set.

Water management
At the European level, water management is governed through the Water Framework Directive (EC, 2000). At the national level, implementation resulted in a set of water quality standards and the obligations for municipalities, during the preparation of land-use plans, to identify the effects on water flow and quality and consult the regional Water Board on measures to mitigate these effects.

Urban transport
There are no requirements for urban transport at the European or national level.

Air quality
The EU Directive on ambient air quality and cleaner air for Europe (EC, 2008) has been implemented in national legislation, requiring municipalities to assess a development's contribution to ambient concentrations of certain air pollutants. European standards must be observed, although, temporarily, exceptions have been made possible.

Soil quality

The European Commission has put forward a proposal for a framework Directive (EC, 2006). The Dutch national legal framework consists of the Soil Protection Act and concomitant regulations, including standards for a range of pollutants.

Noise

The European Environmental Noise Directive (EC, 2002) aims at comparable methods for measuring noise in all member states and at informing the population about noise levels in their environment, but does not actually set noise standards. The Dutch Noise Abatement Act, however, does provide such standards, specified for particular types of noise. The legal framework contains a targeted noise level maximum and a range of exceptions, mostly for inner-city locations in the vicinity of railways and highways. Since the law was found to be inflexible in intensively used urban areas, local government was allowed to deviate from national standards, taking the so-called City and Environment approach in which nuisance by noise must be compensated by other qualities of the environment (Weber and Driessen, 2010). As a last resort, constructional measures can be taken to limit exposure to noise inside the buildings; these include the so-called 'deaf façade' – which has no windows or doors which can be opened – and a design situating living rooms and bedrooms on the quiet side of the building.

Risk

There is a strict norm for the probability of death due to a calamity involving use and transport of dangerous substances, which must be complied with in decision-making on urban plans. Moreover, a guidance value for societal risk[4] exists, exceeding which compels local government to account for the risk in relation to the societal benefits of the proposed development and the measures taken to reduce the risk and abate possible effects. In order to put an end to recurring conflicts between safety and urban development, national government has established transportation ceilings for most of the transport routes, including those influencing the developments studied here.

Green space

National spatial policy aims to guarantee a basic level of spatial quality (VROM, 2006), which includes issues covered by legislation on nature and environment. With respect to the amount of green space, a target value for new developments (of 75 m^2 per dwelling) is set.

[4] i.e. the probability that a group of people is killed as a direct consequence of a calamity, as a function of the size of that group.

	Regulations	Tilburg	Woerden	Zutphen
Energy efficiency and clean energy production	National EPC standard for new buildings. Experiments with GSHPs* enabled by CRA*. Provincial subsidy for sustainable energy.	PPP* sets EPC* lower than national requirement. Land-use plan enables GSHPs. PPS initiates local sustainable energy supply..	EPC as nationally required. Land-use plan enables GSHPs.	EPC lower than national requirement through CRA. Land-use plan enables GSHPs. Local sustainable energy supply commissioned.
Building materials and waste	No requirements.	PPP sets high targets for GPR* scores.	No explicit targets. Use of GPR is encouraged. GPR-score is high.	No explicit targets. Developer takes voluntary measures.
Water management	Water quality standards and obligation to consult regional water authorities.	Comply with national requirements.	Comply with national requirements.	Comply with national requirements.
Air quality	Air quality standards and possibility to temporarily circumvent these through national action program	Comply with national requirements Prevention of street canyons Limited increase near sensitive forms of land-use.	Comply with national requirements.	Comply with national requirements.
Soil quality	Soil quality standards. National and provincial subsidies.	Comply with national requirements. Remediation and experiments with GSHPs facilitated through CRA.	Comply with national requirements.	Comply with national requirements.
Noise	Ambient noise level standards and possibility to give exemption. Standards do not apply when certain constructive measures are taken at building level.	Comply with national requirements, including exemption and constructive measures at building level.	Comply with national requirements, including exemption and constructive measures at building level.	Comply with national requirements, including exemption. Support from Ministry in re-establishing industrial noise limits.
Risk	Standard for individual risk. Orientation value for societal risk.	Comply with national requirement for individual risk. Strong lobby for national measures to reduce societal risk, but still above orientation value.	Comply with national requirements. Societal risk accepted in view of national transport ceilings and local measures.	Comply with national requirements. Societal risk accepted in view of national transport ceilings and local measures.
Urban transport	No requirements. Guidelines for stimulating transport by bike and foot	New underpasses. Follow national guidelines. Stimulate rental cars.	Follow national guidelines.	New underpasses. Follow national guidelines.
Green space	Target value for green space.	Green public space. No quantitative targets.	Green public and private space. No quantitative targets.	Green public space. No quantitative targets.

* EPC = energy performance coefficient; CRA = Crisis and Recuperation Act; GPR: see text; GSHPs = ground source heat pumps; PoR = program of requirements; PPP = public-private partnership

7. Case studies

7.1. Tilburg

In Tilburg, with just over 180,000 inhabitants (CBS, 2008), an elongated strip of land along the railway adjacent to the city centre, is now being redeveloped into an area of metropolitan character. Plans feature transformation of the formerly industrial site into a high density mix of functions: offices and apartment buildings, some of them high-rise, as well as higher education, leisure and a conference venue. From the start, ambitions for quality and sustainability have been high. Tilburg municipality acquired the central part of the area at considerable cost and, in a public-private partnership (PPP) with a real estate developer, must now fit several functions into a patch of ground that is highly burdened by the railway.

Accomplishment of Tilburg's high ambitions for sustainable energy, building materials and urban quality, reflected in high targets for sustainability score GPR[5], is left fully to the discretion of the PPP. Other dimensions of sustainability require Tilburg to comply with national standards, as can be seen in Table 1, depicting the municipality's room to manoeuvre. Balancing high densities, which are consistent with metropolitan characteristics and necessary for commercial viability, with acceptable levels of societal risk and railway noise is posing a particular challenge. National transport policy, contributing to sustainable development from its own perspective, aims to intensify rail transport, both of passengers and goods. The expected increase in noise levels would complicate the projection of housing directly along the railway, as would the increase of societal risk caused by rail transport of dangerous substances. Planning for office space directly along the railway could

[5] GPR (gemeentelijke praktijkrichtlijn = municipal practical guideline) is a method for assessing the level of sustainability of buildings.

reduce noise levels in the remaining area and would reduce societal risk, but meets with poor market expectations. The volume of shops, leisure and amenities is simply not sufficient to fill out the portion of land that is most heavily burdened by noise. A key to solving the noise problem would be to create a university campus, which is desirable to both the PPP and the university, but would again influence societal risk. Furthermore, this option depends on the university's selling its current buildings at a reasonable price.

In view of the importance of rail transport of dangerous goods to societal risk, Tilburg and other cities along the railway have organized an intensive lobby for lowering transport intensities; this has resulted in transport ceiling values that national government, the province and the municipalities involved have now agreed upon. After completion of the development, however, societal risk will still exceed the guidance value by a factor of more than five. Tilburg municipality balances this risk by taking extra construction measures and incorporating safety features in the urban design. A considerable part of the dwellings realized are exposed to noise levels above the maximum exemption value and requires constructive measures to ensure adequate levels inside.

Those interviewed indicate that soil remediation is facilitated by allowing an area based approach (instead of a case based one). However, as little as possible soil will be removed that, due to national requirements and at considerable cost, would have to be treated before disposal or re-use. This, of course, restricts building design.

7.2. Woerden

Woerden has a population of about 33,000 (CBS, 2008). Along the railway, a city-owned strip of land was initially intended for building offices, partly to shield the existing residential area from railway noise. However, due to projected congestion on the incoming roads, the plan was abandoned. Instead, starting in 2007, when the market for office space had dwindled, a new land-use plan was made, providing space for compact urban dwellings, mixed with a small proportion of other functions. In its intended form, the plan could comply with national requirements on railway noise only by introducing a large, uninterrupted building block parallel to the railway tracks, entailing, however, an increase in societal risk, albeit below the guidance value.

The city council only recently realized that comparable initiatives had been simultaneously launched along the railway, thus providing too many apartments for the local market. The plan was again halted. A former military complex, across the railway and situated farther away from it, is currently being developed after a European procurement procedure. The original program goals included high ambitions regarding energy performance, GPR-score and noise. However, in the course of detailing and implementation, many goals were dropped, likely due to the unexpectedly high cost of soil remediation, retaining only the low energy performance coefficient. Interviews in this case suggest that the province's requirements for soil remediation are too strict and that more of the original sustainability ambitions could

have been accomplished if a longer period of time would have been allowed to accomplish the intended level of soil quality. The municipality's room to manoeuvre is being perceived as limited, although Table 1 shows that it is comparable to that of Tilburg.

7.3. Zutphen

Zutphen has about 43,000 inhabitants (CBS, 2008) and is situated along the river IJssel. Across the railway, which runs along the historic city centre, a large industrial area was established in the 1930's, originally hosting relatively heavy types of industry. In more recent times, some industrial companies have moved out of the area to make room for amenities such as a cinema, large-scale retail and an indoor children's playground. Part of the area is now newly parcelled out for commerce and industry, whereas the most southern part, 'Noorderhaven', situated between the railway, the remaining industry and the river, is reallocated for residential and mixed use. The plan entails medium-rise offices along the railway (as a shield against railway noise), as well as reduction of industrial noise. Part of an old harbour, now filled, will be restored and two new underpasses will connect the new quarter with the city centre, just across the railway.

Analysis of the land-use plan and underlying impact assessments reveals that only national noise regulations pose serious restrictions. Interviewees termed all other environmental issues 'business as usual'. Noise can, within national regulations, be dealt with in the urban design: closed building blocks and a row of office buildings facing the railway. Industrial noise is being reduced and zoning is re-established so as not to overlap Noorderhaven. Furthermore, road traffic noise will be limited by using silent materials and setting a low speed limit. Interviews revealed that development is being hampered by uncertainty regarding the plans of national authorities on the frequency of future passenger and freight trains. To a much lesser extent, the effect of the national plans on the risk caused by transport of dangerous substances by rail also posed uncertainty.

Zutphen has the ambition for the whole of the area to be CO_2-neutral. For Noorderhaven, specifically, an energy performance amounting to 75% of the value demanded by Dutch building regulations was laid down in the Crisis and Recuperation Act. The municipality has commissioned energy supply of Noorderhaven to a private consortium. The land-use plan provides for the use of GSHP's. National regulations regarding air, water and soil quality do not pose serious restrictions on Zutphen's autonomy to develop Noorderhaven, as is shown in Table 1.

7.4. Overall findings

Contrary to our initial assumption (see section 1 and 2), our findings do not indicate that implementing EPI through national standards is problematically restricting the room for municipalities to manoeuvre in balancing interests, with the exception of the very complex situation in Tilburg. Compliance with most national requirements can be accomplished in a 'business as usual' manner. Regulations on noise and risk do pose

restrictions that can, however, be dealt with in the urban design. This workability is a result of policy change with regard to those aspects of sustainability that the past has shown to be problematic: either national standards have been relaxed or authority has been devolved to municipalities, for discretionary implementation (De Roo, 2000; Miller and De Roo, 2004). For example:

- Prior to 1997, Dutch soil quality standards were aimed at achieving natural background values; since 1997, a certain amount of pollution is accepted, varying with the planned land-use (Boekhold, 2008).

- In 1989, societal risk was defined as a limit value , whereas in the late 1990's the limit was transformed into a guidance value (De Roo, 2004).

- Air quality near roads is no longer assessed at the kerbside, but at a point that is representative for a stretch of space along the road, maximally ten meters from the side of the road. Furthermore, if air quality standards will be exceeded as a result of a development, compensation in other areas or temporary exceptions are allowed.

- Until 2007, exemption values for noise had to be established by the province upon request, whereas a municipality can now itself set the value (Weber et al,.2011).

In both Tilburg and Zutphen, SEA was performed, but did not perceivably lead to weighing environmental interests with social and economic interests in decision-making. Rather, SEA seems to be a summation of sectoral impact studies, the main purpose of which is to ascertain that intentions are indeed feasible. Surprisingly, no use has been made of instruments such as LOGO[6] (Simeonova and Van der Valk, 2010; Simeonova, 2006) and MILO[7] (Runhaar et al., 2009; Weber and Driessen, 2010), that have been developed for supporting integration of environmental policy in the early stages of spatial planning.

Instead, prices of and demand for real estate appear to greatly determine the outcome of negotiations within Campbell's (1996) triangle. If, in the Tilburg case, for instance, it will turn out not be financially feasible for the university to trade its current property for a new campus in the Spoorzone area, either more dwellings will be built which will be exposed to undesirable levels of noise and risk or less real estate will be realized, possibly causing a considerable financial loss. By the same token, in the Woerden case the plan was halted altogether as a result of market expectations in the real estate sector. This dependency on the property market is also reflected in the explicit wish to maintain flexibility in land-use plans, leaving space for the developers to adapt the actual layouts – and thus the number of dwellings – to housing demand.

In all cases, uncertainty about restrictions was deemed more troublesome than the actual restrictions themselves. Rail transport intensities, determined at the national level, have long been uncertain, as well as the outcome of societal risk assessments.

[6] Locale Geiedstypologie en Omgevingskwaliteit = local area typology and environmental quality.

8. Conclusions and discussion

The aim of this paper was to explore how and to what extent a municipality's room to manoeuvre in local decision-making is restricted by sectoral regulations from higher tiers of government and how these restrictions influence the resulting land-use plans in terms of sustainable development. Our analysis suggests that requirements imposed by higher tiers of government do indeed ensure that environmental aspects are given 'principled priority' (Lafferty and Hovden, 2003), thereby narrowing the range of options in local decision making. The extent to which this restriction of local discretion is problematic, however, was found to depend upon the dimension of sustainability considered. For some types of environmental impact, standards are established that must be strictly observed and that, in practice, can be fully complied with. For other types, regulations are – or have been made – less strict or can be circumvented. These impacts, clearly, are being *considered*, but do not essentially alter the plans. As a consequence of merely marginal consideration of the standards, potentially unhealthy and dangerous situations are being accepted; this was found previously in the case of noise (Weber and Driessen, 2010) and that of risk (Ale, 2005).

Thus, looking at the normative meaning of EPI, a Type I multi-level governance perspective reveals that a national environmental quality standard, which can be regarded as a 'strong' normative interpretation of EPI, at the local level is principally treated as a boundary condition. If requirements are relaxed, allowing local government more freedom, the resulting room for manoeuvre appears to be used to support other than environmental interests. Such a normatively 'weak' interpretation of EPI, resulting from the perception that a 'strong' reading would be too restrictive, is not helpful in promoting sustainable urban development.

A further conclusion is that the concept of multi-level governance allows us to mark distinct differences between tiers of government in the normative, organizational and procedural factors distinguished by Persson (2004). In addition to differences in objectives between tiers of government (Bulkeley and Betsill, 2005; Nilsson et al., 2009; Watson et al., 2008), differences appear to exist in conceptions of norms and procedures. We found political and administrative support for national noise regulations, for instance, to be quite low at the local level. This is not to say that noise is not considered. Rather, it is considered to contribute to a rather vague conception of 'quality' of the living environment. Thus, instead of making an explicit trade-off between noise levels and other interests, balancing interests is done implicitly. This reveals another difference, namely that, at the local level, tools and procedures, specifically intended to facilitate explicit trade-offs (such as the City and Environment approach mentioned in section 6) or to formulate ambitions for environmental quality in the early stages of planning (such as LOGO/MILO, see section 7.4), in practice do not live up to the expectations with which they were conceived at the national level (see also Runhaar et al., 2009). The merely marginal way in which SEA is found to be used here – and elsewhere (Bina, 2008)– also indicates that, between distinct levels of

government, substantial differences exist in appreciation of impact analysis as a support for decision making. One could argue that this lack of integration is precisely the *effect* of the existence of national standards, as they are being perceived to be boundary conditions. In that case, however, it is hard to understand why, in the cases examined, no use has been made of tools that specifically create room for manoeuvre in situations where standards cannot be met. These observations confirm earlier findings that procedural measures are not very successful in bringing about EPI (Nilsson et al., 2009).

Lastly, we conclude that consultation with higher tiers of government, as on societal risk in the Tilburg case, is a key for municipalities to be able to treat environmental issues as an interest, rather than a boundary condition. In a comparable setting in Sweden, however (Polk, 2011), it was found that a network of civil servants, linking across governance levels, increased institutional problem-solving capacity in sustainable urban planning, but that radical solutions, including absolute standards, were not put into practice in the actual planning context.

What does all of this mean for achieving EPI? It could be argued (PBL, 2011) that non-negotiable, centrally established, norms should be abandoned in favour of an integral balancing of the quality of the living environment at the local level, while maintaining or even improving environmental quality. The evidence presented here suggests that this is unlikely. A combination of 1) centrally established norms, safeguarding a minimal environmental quality and 2) procedures to assess what level of quality above this bare minimum can be achieved and at what cost could overcome the pitfalls of relying solely on either approach.

Housing Policy and social change in communist-run municipalities in the suburbs of Paris

Lina Raad
UMR Géographie-Cités, University of Paris 7 – Diderot
e-mail: lina.raad@gmail.com

Introduction

The inner-ring first suburbs of Paris have changed dramatically in recent times. This area developed in late nineteenth and early twentieth centuries, as a result of rapid and massive industrialization (Rhein, 2005). The fast growing industry led to the settling of blue-collar workers and during the 1920s and 1930s many communist municipalities were elected in this area. The Communist-run municipalities of the so-called "red belt" built numerous social-housing units and developed public facilities for blue-collar workers. Since the 1960s the "red belt" has been deeply affected by deindustrialization and experienced economic and demographic decline. Despite a decrease of Communist vote, several communist-run municipalities retain the majority. Since the late 1980s, certain towns began to implement a new urban and housing policy, in an attempt to fight against pauperization and deterioration.

Saint-Denis, located north of central Paris is an archetype of the red belt. The town hosted the main industrial area in Europe in the late nineteenth. At the beginning of the twentieth century, a socialist mayor was elected. Then the municipality rejoined the Communist Party after the split between socialists and communists in 1920. From the late 1960s Saint-Denis has been experiencing deep restructuring and redevelopment. From the late 1980s, the communist "reformists" have been changing their municipal policies to attract private developers and middle-class newcomers. Nevertheless they are trying to maintain their low-income population at the same time, in an attempt to reach a type of "controlled gentrification". How are these ambivalent strategies implemented? More generally, what degree of control do local governments have on social change? Many studies emphasize the determining role played by local government in social change and gentrification (Lees, 2003; Smith, 1996), but very few focus on the restraints opposed to gentrification. We try to provide an overall view of local policies' influence on social change process, analyzing supports to the settling of middle-class residents as well as policy implemented to guarantee housing for low-income residents.

I. Social change and urban policy in Saint-Denis

1.1. Local policies' influence on social change processes

In French literature, the role of local policies in social change processes has been one of the major issues at stake in urban research during the 1960s and 1970s. At that time, several studies denounced "renovation-deportation" plans in old centers (Coing, 1966). On the

contrary, Anglo-Saxon research about gentrification has neglected local policies' influence for a long time (Lees, 2003). It finally became a research issue in gentrification debates during the 1990s. Many studies deal with local governments' supports and incentives to gentrification. Within the framework of neo-liberal policies criticism, several authors emphasize the alliance between local governments and private investors to evict working-class categories from inner cities and attract middle-class categories (Levine 1987; Smith 1996). Usually, academics tend to focus on one single aspect of public policies' role in gentrification: for example on official discourses on gentrification (Colomb 2006; Rose 2006), on particular urban plans within a neighbourhood, or on condominium developments (Davidson & Lees 2005). Nevertheless there is a lack of research addressing intricacy and diversity of political actions interfering in social change. There is a need for complete and precise analyses of public policies at the scale of local governments, taking into account the whole municipality's neighbourhoods and not only those experiencing gentrification. Moreover it is necessary to consider a detailed analysis of local policies, including housing policy as well as urban planning policy and land policy. Finally, although limits to gentrification are a recurrent issue (Ley & Dobson 2008), there are very few studies about restraints opposed to gentrification by local governments. Communist-run municipalities are particularly relevant to tackle such an issue because of their ambivalent political strategy.

1.2. Saint-Denis

Saint-Denis was founded at Gallo-Roman time and grew consistently in late nineteenth, as a result of rapid and massive industrialization. Saint-Denis' industrialization essentially took place in *Plaine Saint-Denis*, a 780 hectare plain because it offered huge land opportunities close to railroad tracks and Paris canal. From the late 1960s deindustrialization hit the town, leading to a loss of 25.000 industrial jobs between 1965 and 1985. At the beginning, the local officials tried to preserve industrial activity and working-class population: they prevented service-sector development and private-housing construction by means of zoning regulations (Albecker & Fol, 2010). Such a policy strategy was applied in the same way in other Communist-run towns (Collet, 2010). In the 1980s the local debate in Saint-Denis was focused on industrial wasteland's future, opposing a conservative view and a development-oriented one. Due to the increasing of communist "reformists"[1] within Saint-Denis municipality in the late 1980s, local policies radically changed, aimed at attracting service-sector businesses in the town. The *Stade de France*[2] building enabled the local officials to carry out their development plan for *Plaine Saint-Denis*. From the bargaining with the State for the *Stade de France* location, they obtained the funding for the highway's roofing, the building of two train stations, the extension of the subway line and for public spaces. These facilities made the town attractive to property developers, all the more so land values and property prices were very low. *Plaine Saint-Denis* is now the third center of service-sector businesses in Paris metropolitan region. But despite economic development, unemployment and pauperization continued to occur in Saint-Denis, due to the gap between the skill level required for the new jobs and that of the resident population (INSEE 2010). Furthermore, a boom of housing construction took place in *Plaine Saint-Denis* fostered by the local decision to promote owner-occupation, in contrast with a traditional preference for

[1] This Communist line emerged in the late 1980s and supported economic development around service-sector businesses. For example, Saint-Denis mayor between 1991 and 2004 (Patrick Braouezec) was a communist reformist, as Saint-Denis current mayor (Didier Paillard).

[2] The Stade de France is the national stadium built in *Plaine Saint-Denis* from 1995 to 1997 for the 1998 Football World cup.

social housing. Private housing's development is at the heart of Saint-Denis new housing policy promoting social diversity to fight impoverishment and housing deterioration. The goal of such a strategy is as a matter of course to attract middle-class newcomers but also to enable residents in upward mobility to home-buy. Nevertheless the local councilors try to avoid as much as possible the displacement of low-income residents, faithful to their traditional support to working-class and disadvantaged population.

The paper is based on a survey led in three Communist-run municipalities in the first suburbs of Paris: Saint-Denis and Bagnolet, located north of central Paris; Vitry-sur-Seine, located south of central Paris. The fieldwork combines interviews of local officials with study of urban planning tools. Purposely, the survey has not been restricted to housing policy, but also takes into consideration urban planning policy and land strategies. More precisely the research looks into means of social change control. In this paper, I will develop Saint-Denis' case.

II. Attracting middle-class newcomers while maintaining low-income population: a controlled gentrification?

In this section, I will expose the tension between both sides of Saint-Denis' housing strategy, combining promotion of owner-occupation to attract middle-class residents and supports to working-class housing.

2.1. Promotion of owner-occupation

Since the Communists gain the majority in Saint-Denis municipality they built numerous social housing units, essentially between 1949 and 1974. As a result Saint-Denis counts around 50% of social housing. During the 1980s a renewal plan took place in a part of the old center: insalubrious housing was cleared out and essentially replaced by new public housing (80% of new units). At that time the local councilors were still hostile to private housing developments. Their main goal was to provide quality public housing in a central location with many facilities, for working-class and secondarily for middle-class residents[3]. Such an ambitious plan was meant to attract some middle-class residents but after twenty years, many middle-class residents have left the neighbourhood (Raad, 2008).

In the 1990s Saint-Denis' Communist "reformists" decided to develop private housing construction, which represents a radical change in local housing policy. *Plaine Saint-Denis* was already attractive to property developers in service-sector businesses, so that housing construction increased very rapidly. The boom of housing construction was all the more striking that no housing was constructed in *Plaine Saint-Denis* during 1928 and 1990. Moreover it happened after a demographic decline unstopped since the 1960s. During the 2000s Saint-Denis was one of the most dynamic town in housing construction in Paris metropolitan region: 3.935 housing units were built between 2000 and 2007 in Saint-Denis. The majority is located in *la Plaine* neighbourhood (2.454 for the same period, representing 60% of Dionysian production). This housing production led to a dramatic population increase: between 1999 and 2008, Saint-Denis population increased from 85.994 to 103.742 inhabitants. In majority, the new housing units are designed for owner-occupation or private

[3] In France, social housing was at the beginning developed to house working-class people as well as middle-class. But from the 1970s, middle-class residents began to leave to buy their homes. As a result, public housing population got poorer.

renting. Local urban planning documents[4] set the proportion of each type of housing among new construction: in Saint-Denis the local councilors decided to build 32% of social housing, 5% of social home-buying and 63% of private housing. In a town with more than 50% of social housing, this shows a real change in housing policy. The urban planning councilor doesn't hide the desire to attract middle-class residents as its words show: "*When you decide to make 60% of home-buying housing, it means very clearly that we want to settle and attract what is called middle-class.*" (Interview with Stéphane Peu, 2009). Nevertheless, the support to private housing construction and owner-occupation goes together with social housing promotion: Saint-Denis produced a significant number of social housing units during the 2000s in opposition to the majority of Paris metropolitan region municipalities. Moreover, local councilors developed some tools to fight against developers' speculation in order to control the increase of property prices. These tools are to be seen in an emerging land strategy designed to maintain low-income population.

2.2. Emerging land strategy to control land prices

From the start Plaine Commune (the multi-municipal administration) introduced the *Building's Quality Agreement* that is a bargaining tool between property developers and local government. This document includes several instructions about housing's quality and recommendations particularly about land prices. Instructions about housing's quality aim to prevent new housing units from deterioration. For example it is forbidden to build condominium developments with more than 50 property lots. As for recommendations, the *Building's Quality Agreement* sets a maximum land price[5]. By such a control on land prices, the local councilors try to limit property prices. Indeed they presuppose that a low land price is going to be reflected in property prices and limit their increase. Saint-Ouen, an adjacent Communist-run town, has a different strategy: they preferred to control directly property prices. Their *Property Developers Agreement* sets a maximum property price and the municipality uses pre-emption to limit the increase in property prices. Saint-Denis opposes its anti-speculative strategy to Saint-Ouen's one, arguing it is better to control land prices than property prices. According to Saint-Denis administration, if the capital gain is not for the property developers when they offer for sale the housing units, the first buyer is going to win the capital gain when he resells its home. But Saint-Denis strategy doesn't completely guarantee that low land prices will be reflected in property prices. Nevertheless, Saint-Denis strategy is not only focused on property prices, insofar as the majority of its residents cannot buy a home at market prices[6].

The multi-municipal administration and the main social landlord in the area – *Plaine Commune Habitat* – developed in 2005 a cooperative society to promote social home buying. The housing units are first designed to *Plaine Commune Habitat* tenants and secondarily to other social landlords' tenants. Therefore the aim is to enable social housing tenants to buy a home at low prices. In France social home buying is not significant; many societies assert they develop social home buying but in realty, they only use tax advantages and zero interest loans[7]. *Plaine Commune Cooperative for Social Home-Buying* offers homes at a lower price and security for buyers. The multi-municipal administration sells land plots at low prices to the Cooperative in order to reduce home prices. Once again, what enable to produce cheap

[4] We mean Territorial Coherence Plan and Local Housing Plan that are multi-municipal urban planning tools.
[5] Land prices cannot exceed 450 euros/m2 of net floor area.
[6] Property prices for new housing goes from 4.000 to 5.000 Euros in Saint-Denis, compared to an average of 8.400 euros/m2 in central Paris.
[7] Zero interest loans are granted to households home-buying for the first time. The amount depends from the home's location and the households' resources; it can reach up to 38% of the total amount of the property price.

housing is low land prices. This is part of a more general land strategy aimed at controlling land prices.

According to Saint-Denis local councilors, low land prices are the solution to build cheap housing designed for owner-occupants as well as social housing tenants. Thus they chose to control land prices rather than property prices. Here we have to precise that after a stage of massive construction of social housing after World War II, the social housing construction has been very limited after 1977 particularly because of a reform of the housing's funding system. In such a context, the ability to produce social housing is particularly important in towns like Saint-Denis with a huge demand for social housing. As the territory became attractive to property developers, the local councilors particularly worry about limiting land prices. Moreover they are trying to anticipate *Grand Paris Plan* that is a huge transportation plan for Paris metropolitan region. In Saint-Denis two new subway stations will be opened: one resulting from the extension of line 12 in *Plaine Saint-Denis* and one forming a part of *Grand Paris Express* new line in the southwest of Saint-Denis (Pleyel). That is why the local councilors are thinking about introducing a *Strategic Land Plan*. First it has to locate strategic spots in the multi-municipal territory, that is to say places that are likely to develop in the future particularly because of transportation plans. The multi-municipal administration aims at buying land in those strategic spots, in order to limit land and property prices' increase and prevent working-class displacement. Besides land's ownership enables them to get the surplus back coming from transportation plans. For now Plaine Commune has an agreement with Paris metropolis Land Public Corporation, which allows it to carry land plots for seven years. But the *Strategic Land Plan* implies to create a new organization that enables land carrying for more time, from 15 to 20 years. Eventually Plaine Commune land strategy is essentially serving housing policy. According to local councilors, land prices' control is crucial to (1) enable sufficient social housing construction in the future, (2) build social home buying and (3) offer cheap private housing for owner-occupants.

Conclusion

Research about local policies' influence on social change processes tends to focus on supports to the settling of middle-class residents but rarely looks into restraints opposed to gentrification. We argue it is necessary to lead a detailed analysis of local policies in various fields at the scale of local governments to give an overall view of local policies' influence on social change. Even though theoretical debates about gentrification are focusing on land values and rent gap, it is surprising that gentrification fieldwork doesn't deal with land policies given the consequences for housing policy.

Saint-Denis local policy is ambivalent since it aims at attracting middle-class residents while guaranteeing housing for low-income residents. Saint-Denis housing policy rests upon land prices' control to enable construction of social housing and cheap private housing. Nevertheless the majority of Dionysian residents cannot buy a home at market prices. Even social home buying isn't affordable to many of them and only represents a small proportion of housing units. For the most part, low-income Dionysian residents cannot afford living elsewhere than in social housing or in private renting. According to local councilors, land prices' control enables social housing construction but given the huge demand in this sector, housing policy at a local scale may not be sufficient.

Children's mobility patterns in the Urban Environment Case Study - Lisbon

Sílvia Shrubsall [1], Frederico Henriques [1], Ana Cardoso de Oliveira [2], Isabel Natário[3]

Abstract

Physical characteristics of Portuguese (mostly littoral) built up areas, as a result of its recent rapid urban expansion and population growth often away from adequate public transportation solutions led to a considerable change in mobility choices. As a rapidly motorising society, Portugal adapted its urban environment as well as traffic and pedestrian circulation conditions to benefit private vehicles and their higher speeds. Economic growth favoured the number of kilometres driven which, despite recent improvements, increased road accidents to unacceptable numbers. Responsibility for urban safe mobility is split amongst different institutions often not yet well coordinated. Road users, who have been adopted busier routines, still show poor awareness towards safer and sustainable road attitudes.

If adolescents' car-oriented lifestyle is to be reversed by making it more active and autonomous whilst still increasing real and perceived road safety and promoting the benefits of sustainable transport modes, a clear understanding of current mobility patterns and their relationship with the built environment and modern existence needs to be carried out. The objectives of the Portuguese research project "Children Pedestrian License" are to diagnose young road users' mobility patterns and to promote responsible, active and safe mobility for this generation. The applicability of some of the methodology developed for this project was examined in a practical way through a case study in Lisbon.

This study involved a comprehensive examination of current commuting patterns in the private school *Colégio Moderno*. This paper explains what data has been collected and describes an in-depth investigation of around 350 set of surveys applied to 3rd through 8th grade children and their respective parents. The analysis offers first insights into the identification of these urban adolescents´ mobility patterns and an understanding of the specificities of inner-city private school students. They tend to have longer commuting distances, regular access to several vehicles per household and stating preferences by bicycle rides which rarely fulfilled. This paper presents and discusses the results for children´s journey home from school and describes how they will be used to contribute to enhance urban mobility choices in Portugal. Lessons from this piloting work have already being used in a

thorough implementation of the Children Pedestrian License to 120 students in a public funded school (*Escola EB1 n.º 2 da Parede*) in Greater Lisbon.

1. Introduction

Various factors have led to restrictions of movement of vulnerable road users, including perceived or real road safety and security risks, considerably easier access to private vehicles and physical or psychological barriers created by the built up environment (Wittink, 2001). In developed countries, children have been particularly affected by this phenomenon associated to: (1) shrinking number of children per family, (2) parents (particularly mothers) busier life style and (3) rising lack of informal social control.

Urban planning options (McDonald, 2005) – including primacy for networks dedicated to motorised vehicles, urban dispersion (Carvalho & Gomes, 2009) and increased daily commuting distances - associated to widespread access to home technological entertainments, people are been driving away from the public urban space as a place for (more or less) spontaneous social interaction. The environmental, economic, social, gender and age as well as physical and psychological health relationship with children car-oriented daily life, have been analysed through different studies across various disciplines (Hillmand, et al., 1990; Valentine, 1997; McKendrick, 2000; National Research Council, 2005; Pooley, et al., 2005; Johanson, 2006; Brown, et al., 2008; Fyhri, et al., 2011).

The reduced young road users´ exposure to road risk as pedestrians and cyclists has led to fewer child road fatalities in developed societies, like Portugal (ETSC, 2010; ANSR, 2012). However, in Portugal, the number of child road fatalities is still greater than the EU average (Figure 1).

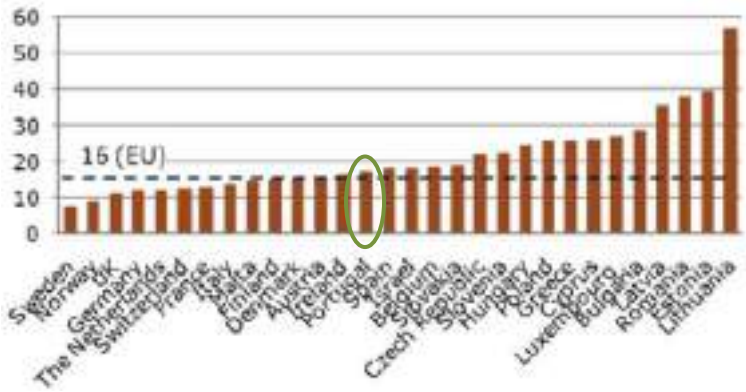

Figure 1. Child Road Mortality. Average values for years 2005, 2006 and 2007 (ETSC, 2009).

On the other hand, research carried out elsewhere shows that there is an association between the decrease in children´s pedestrian mobility and the deterioration of physical and psychological health as well as their social skills and autonomy (Cooper, et al., 2005; Mackett, et al., 2005; Viegas, 2010). An international report on children obesity shows that Portuguese children are amongst the weightiest in the world (Rito, 2009).

The authors are not aware of systematic studies on current mobility patterns of the Portuguese population. An accurate diagnose of the real situation including children´s and their care-takers´ preferences and motivations is required to set attainable mobility programmes and identify adequate measures to influence their mobility choices and complement a rare recent report (Cordovil, et al., 2011).

This paper reports on the preparation and establishment of the first pilot-study within the Children Pedestrian License project (Section 2), which is being undertaken at CESUR, *Instituto Superior Técnico* and *Associação Lavoisier*, benefiting from partial funding by *Fundação para a Ciência e Tecnologia*. The main output from this research project is expected to be a tool which, whilst increasing children and adults awareness towards the importance of walking safely and hence contributing to change their habits, systematically identifies children mobility patterns and supports the identification of appropriate engineering, planning and educational measures. The pilot study (Section 3), based at *Colégio Moderno* in Lisbon, was used: (a) to test, in practice, for the receptiveness of key parts of the developed "Children Pedestrian Licence" methodology, (b) to gain depth of understanding of some of its steps, and (c) to modify the initially proposed method where necessary. Data for the exercise was collected in-situ by means of a survey and an in-depth mobility investigation was carried out to assess the scale and nature of everyday travel and associated influencing variables (Section 4). Conclusions and identification of subsequent work are described in Section 5.

2. Children Pedestrian Licence Project

The main purpose of the Children Pedestrian License project is to promote responsible, active and safe mobility for young road users which in turn requires regular identification of their mobility choices in different urban structures. In order to achieve this, an initial methodology was developed against the vague background of a German programme with the same name.

The proposed framework incorporates mobility choices, perception of road safety and security, plus physical activity levels. The methodology is divided into four main phases:

1. *Project Statement*. Key outcomes from this initial stage are a formal agreement for the project implementation between various local organisations and the identification of required resources;
2. *Training Strategy*. Includes a course provided by the local police to roughly half of the children participating in the project. This training includes theory

and also a practical part in the vicinity of the school, with indication of the safest routes to school;

3. *Diagnosis of Mobility Patterns*. Data is collected by carrying out surveys to children and their parents on their perceived risks and mobility choices. Before and after the training by the police (Phase 2), surveys are applied to trainees and their parents as well as to a control group. Data collected is analysed for initial and changes in motivations and real choices, through descriptive and statistical analyses; and
4. Investigation of Relevant Measures. Relevant complementary remedial measures will be identified by multidisciplinary teams with a context sensitive approach.

Each project phase has been broken-down into steps. The subsequent activities to the four stages listed above are the choice of suitable measures and their implementation and monitoring. Each application of the project culminates (although does not finishes) with a public ceremony where trained children are granted a "Pedestrian License" (Figure 2).

Figure 2. Picture of the Children Pedestrian License (in Portuguese).

As part of the piloting application in *Colégio Moderno*, the study here reported was restricted to the Diagnosis of Mobility Patterns (Phase 3) which will be detailed in the subsequent sections of this paper.

3. Methodology

The process for developing the pilot study in *Colégio Moderno*, which focused on the Diagnosis of Mobility Patterns (Phase 3 - Section 2), consisted of three steps: (1) Assembling Data and (2) Data Analysis presented in this Section; as well as (3) the Identification of Mobility Patterns described in Section 4. The project statement, the training phases and the identification of relevant measures are not discussed in this paper as they were beyond the scope of this pilot study. As such, a control group was here unjustified.

3.1 *Colégio Moderno*: general description of its context

The mobility patterns of *Colégio Moderno* students are related to:

- social-economic context of its students;
- its geographic location; and
- urban characteristics of its surroundings.

Colégio Moderno, is located in the inner city of Lisbon, which is the capital of Portugal. The capital´s population is just over half a million with an average family size of 2.24 and an area of around 84 km^2. The Lisbon Metropolitan Area, has around three million inhabitants representing approximately 27% of the Portuguese population (INE, 2012)

The area surrounding *Colégio Moderno* is considered a typical (probably slightly bigger) inner-city affluent area of Portuguese urban areas. Indeed, *Colégio Moderno* is located in *Campo Grande* Parish, one of the 53 parishes of the capital. *Campo Grande* is a typical consolidated inner urban area with a mixed of residential, services (such as shops, companies and public institutions) and cultural areas (including the Lisbon University, museums and art galleries). Buildings are generally between four and seven floors high with streets catering for access traffic as well as long distance through traffic. The school neighbourhood has sidewalks with high degree of street connectivity. There are pedestrian crossing facilities, though markings are not always well maintained. In the public space, features for people with reduced mobility are irregular.

This area, which is generally flat, is well served with public transports including the underground, buses and commuting trains. Recent bicycle lanes, with little to none commuting use, have been introduced in the main roads of *Campo Grande*. Car parking is charged under a pay and display scheme.

Colégio Moderno is a private renowned school which, therefore, attracts students from a wider area than *Campo Grande*. Indeed, unlike state owned school, private schools area of influence is not regulated and the distance travelled by children as well as the means chosen to do so are potentially different. This school provides paid school bus service to students who request it. Lately a number of private organisations, such as the Automotive Club, have set up regular bus services which are also used by school children, including *Colégio Moderno*.

3.2 Assembling Data

Although an initial scheme for collecting and processing data had been designed within the Children Pedestrian License project, an opportunity arose to merge efforts with the international research project "*Independent mobility as a critical aspect of children development and quality of life- a longitudinal comparison over four decades in England, a cultural comparison over two decades with Germany, and an*

international extension to other countries" (Policy Studies Group, 2012) coordinated by the Policy Studies Institute at Westminster University, London. This project was being implemented in Portugal by *Faculdade de Motricidade Humana* (FMH). The authors considered that collecting the same variables (partly covering both projects at that stage) would facilitate national and international comparisons and the transferability of knowledge and experiences. They supported FMH in the general set up activities at national level, including survey translation, authorization request from the education ministry and initial survey application, as well being responsible for all the activities related to contacts, data collection and analyses at *Colégio Moderno*, which represents the inner-city study in Portugal.

The process for data collection at *Colégio Moderno* began with contacts establishment followed by delivery of survey forms to school psychologists. Children took home a brief explanation of the study together with the request to participate in it as well as the adults´ survey form. Children, who were allowed to participate in the study, filled in their forms at school and brought back from home their parents filled in forms, which were then collected from school.

Colégio Moderno insisted in collecting data with little support from the project team as a way of decreasing school academic activities disruption. Although their openness and willingness to collaborate is greatly appreciated, it led to one flaw which limited the analyses procedures. The code that should have been inserted in the surveys to allow matching children to their respective parents, failed to be filled in the forms. Information was collected for children and adults, but establishment of their relationship is impossible. Data for children and adults was managed and analysed separately. Although the loss is measureable, some important analysis and subsequent conclusions are still possible.

IST team coded and verified the collected data for *Colégio Moderno*. Data was collected for 327 children, aged 8 to 14, between 3rd and 8th school grades. Children surveys´ had 15 questions grouped into six major categories: journey to and from school; context sensitive walking permission; bicycle and public transportation riding permission and skills; household neighbourhood characterisation and; child´s age and sex. Response rates (94%) for adults' surveys were high; adding up to 306 forms with 17 questions each.

This paper focuses on the analysis of *Colégio Moderno* students' replies.

3.3 Data Analysis

Within the context of the collaboration with PSI/FMH, following initial descriptive analysis at IST, *Colégio Moderno* database was merged with the national database and joined analyses were carried out mainly by FMH with IST support and included in the European report (Cordovil, et al., 2011) (see Assembling Data). For the piloting study within the framework of the Children Pedestrian Licence project,

further analyses were carried out to the 327 questionnaires (4 excluded for missing data) applied to *Colégio Moderno* students, here described.

Most parents (83%) claimed that their choice of *Colégio Moderno* was related to the perceived better teaching quality from a high profile private school. Only 9% of the parents referred that it was the nearest school to their home which, most likely, impacts children journeys to and from school.

Descriptive analyses (Section 4) interpreted in the light of previous studies, as well as the school context, have led to the identification of a set of variables to include in two binary regression models considered focusing on their relationship with the students walking home from school.

One of the questions of the questionnaire was whether the child was going to return home from school walking all or most of the way (or was going to return home by any other mode on the day she/he answered the questionnaire). This resulted in a binary variable, Y, which was taken as a very close proxy for children that usually walk home from school. It was, therefore, chosen as the response (dependent) variable in the first binary regression model developed to identify which factors $\mathrm{x} = (\mathrm{x}_1, \ldots, \mathrm{x}_\mathrm{p})$ seem to be important in its explanation:

$$Y_i \sim Bin(1, \pi_i), \qquad \mu_i = E[Y_i|\boldsymbol{x}_i] = \pi_i,$$

$$logit(\pi_i) = log\left(\frac{\pi_i}{1-\pi_i}\right) = \beta_0 + \beta_1 x_{1i} + \cdots + \beta_p x_{pi}, \;\; i = 1, \ldots, 323$$

From within the list of available variables and their respective descriptive analysis, the first set of candidate covariates was constituted by those that were more prone to influence the usual student´s mode of transportation from school. The variables considered are presented in Table 1.

Table 1. Initial variables considered in the regression models.

Variable	Children´s characterisation
x_1	age
x_2	sex
x_3	allowed to cross alone a busy street
x_4	travelled on her/his own to school on that day
x_5	allowed to use public transportation by him/herself
x_6	travelled to school with her parents on that day
x_7	travelled to school with another adult on that day
x_8	travelled to school with older child(ren)/teenager(s) on that day
x_9	travelled to school with other same age or younger child(ren) on that day

Results from fitting this first model (Section 4) justified the development of a second regression model. This model adopted as a binary dependent variable, Y, whether the child "was going to return home from school walking (all or most of the way) or by public transportation" or else "was going to return home by any other mode". It was assumed that public transportation users are at a certain point of their journey also a pedestrian which is the base for merging both classes of road users.

Models were first estimated numerically by maximum likelihood, using the statistical software R-project. Afterwards an automatic variable selection procedure based on the relative goodness of fit measure Akaike information criterion, AIC, was implemented in order to choose the most relevant covariates (Akaike, 1974). AIC compares the goodness of fit of different models where each covariate is successively included and deleted.

These analyses contributed to the identification of key aspects of students' mobility patterns in their trip home from *Colégio Moderno*.

4. Results and their discussion

Roughly half (161) of the 323 surveyed children were girls. Two classrooms per grade participated in the study. As the students each grade are homogenous in terms of age, the distribution per age of the surveyed children is very regular between the usual 8 years-old third graders and 13 years-old typically in the eighth grade. For some analyses, three age-group classes have been considered: 8-9 years old (primary school), 10-11 years old (middle school) and 12-13 years old (high school). The sample has one child in the 3rd grade who were 7 years old and was merged with 8-9 years old group for analysis purposes, and twelve 14 years old and one 15 years old children whom for some reason have not progressed into subsequent grades and have been merged with 12-13 years old group for analysis purposes. The number of children per age group is as shown in Table 2.

Table 2. Number of children surveyed per age group.

Years-old	Number of children
8-9	92
10-11	110
12-13	123

Analysis on mobility choices by children's gender has led that to no statistical significant differences in any of the age groups.

The survey considered various options for children to travel to and from school: on foot, by bicycle, school bus, public transportation (including local bus, train and underground), car, as well as other ("other" responses were identified as taxi and motorcycle). Answers on children´s modes used to go to school and from school are presented in Figure 3. Most children travel to and from school by car, 83.2% and

60.3%, respectively. Public transport is the second most used mode (7.6% and 19.4% on the journey to and from school, respectively) followed by the school bus which has a share of 4.3% and 12.3% to school and from school, respectively. Non-motorized modes (on foot and by bicycle) have lower modal share, 2.4% and 5.8% on the journey to and from school on foot, respectively, and 1.5% and 1.5% on the journey to and from school by bicycle, respectively. The differences in the transportation modes to and from school are statistically significant ($\chi^2(5) = 45.95$, $p<.05$).

	To school	From school
on foot	8	19
by bicycle	5	5
school bus	14	40
public transportation	25	63
car	272	196
other	3	2

Figure 3. Travel modes, to and from school.

When asked how they would prefer commuting to school, about half (151 out of 320) of the children indubitably believe that bicycle would be their first choice. Car and public transportation (22% and 19%, respectively) were indicated as a second preference. Only 23 children would prefer walking. The difference in choice between the two more active travel modes (7% and 47% for walking and cycling, respectively) might indicate an accurate child awareness towards journey length. Indeed, according to parents´ surveys, 53% of the children travel longer or much longer to school than they did when they were their children´s age.

Interestingly, as children grow older they gradually and slightly lose interest by bicycles (58, 53 and 41 children for 7-9, 10-11 and 12-15 years old, respectively) and show increasing preference for traveling by public transportation (8, 19 and 35 for each age group, respectively) and private vehicle (11, 24 and 34 for each age group) instead.

Figure 4 shows that children´s age does impact their actual transportation mode to and from school. Comparing (A) the modes which allow autonomous mobility (on foot, by bicycle and by public transport) with (B) the modes linked to adult

supervision (car and school bus) there is a modal transference from A to B as the children grow older. For example, the car share in the journey from school of younger children (8 and 9 years old) is 64.8% and the public transportation share is 5.5% whilst for older children (between 12 and 15 years old) is 50.8% and 37.7%, respectively. The differences in the transportation modes to school according to age groups are statistically significant ($\chi^2(10) = 29.01$, $p < .05$), as well as the differences in the transportation modes from school according to age groups are statistically significant ($\chi^2(10) = 56.49$, $p < .05$).

	To school			From school		
	8; 9	10; 11	12; 13	8; 9	10; 11	12; 13
on foot	2	4	2	4	8	7
by bicycle	3	0	2	3	0	2
school bus	4	7	2	19	15	5
public transportation	1	5	18	5	11	46
car	82	91	99	60	74	62
other	0	3	0	1	1	0

Figure 4. Modes to and from school by age groups.

The differences per age in mode of transportation used to commute is associated with children´s gradual increased authorization for being more autonomous road users in terms of crossing streets, using public transportation and travelling by themselves.

Figure 5 shows clear differences in children's license to cross alone by age groups, what they perceived to be, busy roads. Only 15.2% of the younger children are allowed to cross main roads whilst in the older age group this value raises to 84.6% (5.6 times more). The differences in license to cross main roads by age groups are statistically significant ($\chi^2(2) = 102.21$, $p < .05$).

Permission to travel alone on public transportation by age shows a similar pattern, increasing from 4.3% to 60.2% of children allowed from the younger age group to the older age group, respectively (see Figure 5). The differences in permission to travel on public transport by age groups are statistically significant ($\chi^2(2) = 94.52$, $p < .05$).

Although permission to cross main roads and use public transportation without adult supervision rises with age, the proportion of children who actually walk does not increase accordingly. On the other hand, there is a disproportionate increase of public transportation riding. Indeed, about 2/3 of children who are allowed, do use public transportation on their way home either with or without adult supervision (Figure 5)

	8; 9	10; 11	12; 13	8; 9	10; 11	12; 13
not allowed	78	49	19	88	93	49
allowed	14	60	104	4	17	74
to school on foot	2,2%	3,6%	1,6%			
from school on foot	4,3%	7,3%	5,7%			
to school by public transportation				1,1%	4,5%	14,6%
from school by public transportation				5,4%	10,1%	37,7%

Figure 5. License to cross main roads and to travel on public transportation alone by age groups (bars and Y-axe on the left) and modal share actually chosen (line and Y-axe on the right).

Figure 6 shows children travel autonomy from adult supervision on their journey to and from school for which differences were found between the two different journeys ($\chi^2(4) = 70.06$, $p < .05$). This was a multiple choice question. On the journey to school most children travelled with adult supervision (parents or other adult, 74.2%) whereas only 3.7% travelled on their own. However, on the journey back home there is an increase in the proportion of children who travelled on their own to 10.0%, as well as decrease in the children travelling with adult supervision to 69.8%.

	To school	From school
Child of same age or younger	48	45
Older child/teenager	47	34
Another adult	42	110
Parent	277	163
Travelled on my own	16	39

Figure 6. Travel autonomy to and from school.

An increase on the number of children who travelled on their own can be observed, on both journeys to and from school, as the children grow older (Figure 7). There are statistically significant differences both on their way to ($\chi^2(8) = 24.75$, $p<.05$) and from school ($\chi^2(8) = 49.43$, $p<.05$).

	To school			From school		
	8; 9	10; 11	12; 13	8; 9	10; 11	12; 13
Child of same age or younger	19	14	12	15	12	26
Older child/teenager	18	18	11	15	12	22
Another adult	13	13	18	35	51	35
Parent	80	93	62	55	53	48
Travelled on my own	1	2	12	1	5	32

Figure 7. Travel autonomy to and from school by age groups.

To enhance understanding on the role of the various factors in children´s mobility patterns suggested by the analyses just described, two binary models have been further developed (Section 4).

The first model focus on the relationship between "walking from school" / "not walking from school" and the described independent variables identified as the only relevant ones (see Methodology):
(1) the child is allowed to cross alone a busy street (x_3),
(2) the child did travel on her own to school on the questionnaire day (x_4), and
(3) the child is allowed to use public transportation on his/her own (x_5).

$$\widehat{logit}(\pi_i) = -1.37 + 1.38x_{3i} - 1.36x_{4i} - 1.44x_{5i}$$

Model 1 - "walked from school" / "not walked from school".

This final model was found to be a good fit through a Pearson qui-square test (p-value= 0.6644). It was further checked for anomalous high residuals or influential points and none were spotted.

Assuming, then, this model as adequate for the data under analysis, odds ratios were estimated for each variable and are presented in Table 3, together with corresponding credible intervals (CI).

Table 3. Estimated odd ratios for Model 1 and corresponding confidence intervals.

	Variable	Odd Ratio	Confidence Interval
x_3	allowed to cross alone a busy street	0.26	95%, CI: 0.06;1.33
x_4	travelled on her/his own to school on that day	3.97	95% CI: 1.12;16.17
x_5	allowed to use public transportation by her/himself	0.24	95% CI: 0.06;0.88

This translates in that, holding x_{3i} and x_{5i} fixed, the odds of a child returns home walking is 3.97 times larger if he/she had travelled by on his/her own to school and, holding x_{3i} and x_{4i} fixed, the odds of a child returns home walking is 0.24 times smaller if he/she is allowed to use public transportation. The odds relating to being allowed to cross alone busy streets are not significant as the correspondent CI includes the odds ratio value of 1.

As the number of children walking back from school all or most of the way (19) was small, a second model was considered for explaining the binary variable indicating whether children have walked or used public transportation in their way home (82 in total).

For this second model the variables that showed to be relevant are:
(1) age (x_1).
(2) the child is allowed to cross alone a busy street (x_3),
(3) the child did travel on her/his own to school on the questionnaire day (x_4), and
(4) the child is allowed to use public transportation on his/her own (x_5).
(5) the child travelled with parent to school on the questionnaire day (x_6).
(6) the child travelled with other adult to school on the questionnaire day (x_7).

$$\widehat{logit(\pi_i)} = -3.68 + 0.24x_{1i} + 0.67x_{3i} - 1.10x_{4i} - 2.40x_{5i} + 2.16x_{6i} + 1.96x_{7i}$$

Model 2 - "Walked or used public transportation from school" / "Not walked nor used public transportation from school".

This final model was found to be a good fit through a Pearson qui-square test (p-value= 0.431). It was also checked for anomalous high residuals or influential points and they were inexistent. So, considering once again this model as adequate for the data under analysis, odds ratios for each variable were estimated (Table 4).

Table 4. Estimated odd ratios for Model 2 and corresponding confidence intervals.

	Variable	Odd Ratio	Confidence Interval
x_1	age	1.28	95%, CI: 1.00;1.63
x_3	allowed to cross alone a busy street	1.95	95%, CI: 0.83;4.82
x_4	travelled on her/his own to school on that day	0.33	95% CI: 0.08;1.20
x_5	allowed to use public transportation by her/himself	0.09	95% CI: 0.04;0.20
x_6	travelled to school with her parents on that day	8.67	95% CI: 2.34;39.48
x_7	travelled to school with another adult on that day	7.09	95% CI: 1.62;39.17

This translates in that, holding x_{3i}, x_{4i}, x_{5i}, x_{6i} and x_{7i} fixed, an increase of 1 year in the child age results in an increase of the odds of a child returns home walking or public transportation of about 28%; holding x_{1i}, x_{3i}, x_{4i}, x_{6i} and x_{7i} fixed, the odds of a child returns home walking or by public transportation is 0.09 times smaller if he/she is allowed to go on local buses; holding x_{1i}, x_{3i}, x_{4i}, x_{5i} and x_{7i} fixed, the odds of a child returns home walking or by public transportation is 8.67 times larger if he/she child did travel to school with his/her parents; holding x_{1i}, x_{3i}, x_{4i}, x_{5i} and x_{6i} fixed, the odds of a child returns home walking or by public transportation is 7.09 times larger if he/she child did travel to school with other adult. The odds relating to being allowed to cross alone main streets as well as sex are not significant as the correspondent CI clearly includes the odds ratio value of 1.

Results here presented have confirmed expectations - which were both common sense and supported by knowledge developed in the literature (Section 1) - towards children's current dominant use (71.8%) of cars for commuting. The fact that 177 out of 305 of the surveyed households have regular access to two or more vehicles (while only 26 claim no systematic access to car) might have exacerbated this difference in relation to non-private schools. The same socio-economical basis might

have impacted other results (in relation to gender, available adult supervision and average travel distance) and will need to be compared with other national contexts. The willingness to participate in the project and the receptiveness to potential changes to mobility choices are further key aspects for which longitudinal cross-national studies are required.

5. Conclusions

Whilst private cars can have a positive role to play in children´s lives - facilitating safer and more comfortable access to many learning and leisure destinations, the problems generated by children car-dependency for daily commuting are leading to an increase of physical, psychological and social problems and a decrease in the quality of the urban environment.

This paper reports a stage in the development of a methodology aiming at contributing to children's safe autonomous mobility by both developing children´s skills and adults´ perceptions and willingness to accept children´s autonomy. The work summarises the framework´s most relevant characteristics and describes their partial use in a pilot study, in a private school, in Lisbon. The early results show a real prospect of achieving a methodology that will be adequate to current Portuguese context and transferable to other countries. However, at the present national economic circumstances, it is difficult to assess the extent of readiness to implement the complementary required planning, transportation and educational measures to attained noticeable changes.

The study provides a description of dominant variables influencing the choice of walking, both in isolation or combined with public transportation, of students at *Colégio Moderno*. Although 207 (67.9%) parents claimed to have walked or used public transportation to school when they were children, from analysis of children´s replies to the survey, it emerged that, in their way home from school, most are driven and only (5.8%) walk all or part of their way. Results show that age is the single most contributing factor of the variance in adult free supervision mobility. Results seem to point to commuting distances as a likely reason for students not to walk to school. Gender does not emerge as playing a role on mobility choices. Although there are significant differences between modes used by children to go and return from school (possibly associated to other family members schedules), the chances of walking home is higher if the child also walked in the morning.

It was acknowledge that the methodology is being applied from the scratch and that problems which could emerge from this pilot application would be used in the revaluation of the initial proposal. Based on in *Colégio Moderno* pilot study in 2010/11, the surveys were refined to include for example the distance household-school and more socio-economic variables. Data collection is being repeated in *Colégio Moderno* which will also going to allow matching children replies to those of their parents. An on-line version of the questionnaire, which has been recently implemented, is being tested.

The refined methodology, in its more complete version, is being replicated in a public funded primary school in *Parede* (Greater Lisbon) with the support of *Cascais* Local Authority. Data for the training and the control group are being collected and will be analysed. One important aspect of this project is to raise visibility of the travel behaviour of children and the roles of their parents in a country where that has not yet been a priority.

The Children Pedestrian Licence project and associated methodology has the potential to become a valuable tool for improving attitudes regarding road safety by providing children with skills for safe autonomous mobility for at least three reasons:

1) Firstly, human error is the biggest contributing factor to road accidents. It is, therefore, important to train children from an early age on the importance for adopting a safe responsible behaviour as pedestrians increasing later the probability of embracing a similar attitude as drivers.
2) Children are also a good vehicle to influence adults' behaviour and perceptions. Based on anecdotal evidence in other areas which required relatively quick change of adults´ habits (such as recycling and smoking), it is expected that this project will bring positive impacts not only on children but also on the school community, parents, teachers and citizens in general.
3) Thirdly, as it has a comprehensive set of questionnaires, it will be a good sourced for systematic monitorisation of travel patterns of children and their families. Comprehensive analysis of available data make deepen the understanding of physical environmental, social and individual contributor factors to parents´ choice for their child mobility which in turn generates better opportunities adjusting policies to prevailing circumstances.

The changing scope of regional planning: From spatial to 'growth-oriented' planning in Denmark

DANIEL GALLAND
Department of Development and Planning, Aalborg University, Fibigerstræde 11, DK-9220 Aalborg, Denmark (e-mail: dgalland@plan.aau.dk)

Paper to be presented at the Association of European Schools of Planning (AESOP) 26th Annual Congress in Ankara, Turkey, July 11-15, 2012

Abstract

Regional planning in Denmark originally emerged as a spatial framework to address socio-economic disparities and to provide physical arrangements in light of an equal development paradigm. As such, its socio-spatial foundations created a comprehensive structure for spatial development reflected in the advancement of several generations of legally binding regional plans. However, influenced by the outcome of a recent structural reform and due to a thorough amendment of the Danish Planning Act, the domain has been subjected to radical changes in the past years. Crucial amongst them is the fact that the spatial logic adhered to regional planning has been replaced by a space-less rationale geared mainly towards facilitating economic growth. Based on an in-depth analysis concerned with the history and evolution of Danish regional planning, this article qualifies a number of factors embedded in the transformation of the domain. The article concludes that several theoretical and practical implications emerge from the changed conception and institutional capacities associated with regional planning.

Key words: regional planning; spatial planning; spatial development; planning conception; planning logic; planning policy; Denmark.

Introduction

The planning domain in several European countries has been traditionally associated with the guidance of spatial development through the use of policy instruments embedded in hierarchical top-down structures (see European Communities, 1997). Planning at the national level in these contexts originally became key in allocating investments and social welfare resources throughout national territories. Within such regulatory and managerial framework, regional planning was primarily introduced as a coordinative tool and a cross-sectoral policy field and practice, which distinguished itself from other forms of planning due to its spatial nature and distributional character. In contributing to attain equal development, regional planning thereby fulfilled a series of functions aimed at the regulation of land uses, the balance of economic growth, the planning of infrastructure and the spatial coordination of many different sectoral policies.

However, spatial planning systems and policies have been subjected to radical changes during the past couple of decades (see Healey et al., 1997; Hajer and Zonneveld, 2000; Salet and Faludi, 2000). Amongst others, the structural shifts associated with this domain mainly concern its modified policy contents, its changing conceptual logics and its evolving institutional arrangements. Throughout Europe, it has been shown that these aspects of spatial planning tend to evolve in function of political and economic driving forces (e.g. Healey et al., 1999; Albrechts et al., 2003). In terms of Danish national planning policy, for instance, evidence shows that the traditional steering role of spatial planning that was originally established in pursuit of equal development has been supplemented or even substituted by balancing or strategic roles that rather align with environmental and globalisation agendas (Galland, 2011). At the regional level, the Danish statutory spatial plans formerly implemented via hierarchical mechanisms have been replaced by new development planning and growth-oriented policies generated by unprecedented institutional arrangements (see section 4 below).

In line with the above, Danish regional planning as a whole has been evidently subjected to profound changes particularly during the past decade. While its original scope intrinsically emphasised the management and control of spatial development based on an equal development orientation, recent shifts have caused the domain to align with growth agendas in pursuit of more 'appropriate development' in accordance to the Danish Planning Act. These shifts have generated important implications not only in regards to the contents and logic of regional planning but also in connection with its policies, institutional arrangements and roles. Based on this general context, the aim of this paper is to explore what actual shifts constitute the transformed conception of regional planning, how they take place and what potential implications emerge from them.

The paper is structured as follows. The first section theoretically describes the scope and functions that have historically characterised the field of regional planning. This is followed by an illustrative synthesis of recent shifts associated with the domain. The second section explores the underpinnings of regional planning in Denmark from a historical perspective. It describes initial attempts to carry out regional planning followed by an analysis of a highly influential structural reform, which ended up shaping the Danish planning system and thereby the institutionalisation of regional planning back in the 1970s. The third section delves into the evolution of Danish regional planning and discusses the contents and features pursued by the several generations of regional plans put forward since the 1980s until 2005. The fourth sec-

tion analyses the contents of a new structural reform and the implications that it brought along to the planning domain, including the creation of new policy mechanisms and institutional arrangements at the regional level. Finally, the last section assesses the different shifts comprising the transformation of Danish regional planning and the implications and challenges that emerge from these shifts.

This article builds on document analyses and retrospective interviews that have been conducted from 2008 until 2011. The description and analysis of the case draw from policy documents and reviews concerned with Danish spatial planning, regional plans, regional development plans and business development strategies. The analysis is further based on structured and semi-structured interviews conducted with national and regional planners involved in plan and strategy-making processes. In addition, interviews have been conducted with Regional Growth Fora board members representing regional councils, municipal councils, educational and knowledge institutions as well as local businesses.

1. The changing conception of regional planning

The genesis of regional planning as a field attracting policy interest can be traced back to the 1960s. Regional planning in countries such as Denmark, the United Kingdom or the Netherlands generally emerged in response to two major problems, namely the socio-economic disparities between regions and the spatial and environmental issues provoked by particular growing urban areas. In tackling the former, regional planning surfaced as a 'spatial framework for unequal development' with the aim to lessen major income inequalities among regions (Friedmann and Weaver, 1979). In confronting the latter, it arose to provide new functional arrangements to specific urban regions facing rapid population growth and increasing urban sprawl product of rising standards of living and personal mobility (Glasson, 1974, page 10).

The underpinnings of regional planning at the time were clearly embraced in the following definition by Friedmann (1963):

> *'Regional planning is the process of formulating and clarifying social objectives in the ordering of supra-urban space. The basic question, therefore, is: How are activities to be distributed in space so as to meet social objectives? Alternatively, what are the proper social objectives in accordance with which activities are to be allocated in space?' (Friedmann, 1963, page 171)*

In recognising the relationship between social welfare purposes and spatial arrangements, this definition evidently holds functional significance as to what regards the need to attain the spatial ordering and distribution of human activities. In a Scandinavian context and in Denmark in particular, this awareness was guided by the principle of 'equal development', which legally constituted the underlying orientation of regional planning. In connection with Friedmann's definition but also widening its scope, the Danish Town Planning Laboratory defined regional planning as follows:

> *'The purpose of regional planning is to provide a plan for the use of the land and the natural resources of the region on the basis of a general social view in which regard is being paid to the protection of the environment and the interplay with economic planning' (Danish Town Planning Laboratory, 1974, page 31).*

The inherent socio-spatial logic of regional planning embedded in the above definitions implied the coordination of multiple and long-standing sectoral policies and objectives to achieve a more even distribution of economic development between regions. As an overarching policy field, regional planning thus attempted to coordinate aspects of land-use allocation and their geographical distribution together with population balance. Spatial planning policies that demanded regional coordination evidently varied from country to country, but generally included housing and employment policies, transport infrastructure projects, urban and regional economic development measures, agriculture, the siting of waste facilities and the management of environmental resources, amongst others (Vigar et al, 2000; Tewdwr-Jones, 2001; Hajer and Zonneveld, 2000).

In Denmark, this coordination challenge was geographically implemented through the design of a hierarchical spatial arrangement of urban centres based on service provision and how such centres positioned themselves in relation to one another within their own regions. The spatial logic and cross-sectoral emphases associated with this rational form of planning aligned with the 'equal development' orientation of the domain and thereby also with the achievement of public interest objectives. Concerning its mode of implementation, regional planning was commonly exercised through regulatory mechanisms consisting of hierarchical institutional arrangements and provisions that lower levels were legally bound to comply with (see European Communities, 1997; Enemark, 1999). Indeed, the practice of regional planning was embedded in a system designed *ad hoc* to control and steer growth and development at different territorial scales.

However, planning systems and policies have been subjected to radical shifts during the past two decades (e.g. Healey et al, 1997; Albrechts et al, 2003), which have caused the spatial planning domain to adopt different roles (Galland 2011). In this sense, the overall conception of regional planning has also changed not only in terms of its logic but also in relation to its contents. For instance, the inclusion of more sectoral policies and (sustainable development) objectives (Haughton and Counsell, 2004) during the early 1990s certainly challenged the field to embrace and adopt new coordinative measures. By the late 1990s, the adoption of specific European directives made the field even more complex. At the same time, the continued move towards innovation and competitiveness in Europe caused the objectives of regional planning to skew more towards the pursuit of economic growth agendas (e.g. Amin and Thrift, 1994; Newman and Thornley 1996; Scott, 2000) in the 2000s. More recently in specific geographical contexts, several if not most planning responsibilities formerly adhered to regional level for the guidance of spatial development have been re-scaled (e.g. Gualini, 2006). In Denmark and Norway, for instance, planning system shifts derived from local and regional structural reforms implied the re-scaling of provisions, tasks and responsibilities once in charge of regional planning (see Østergård, 2005; Bukve et al, 2008).

The mode of implementation and the institutional landscape of planning have also been exposed to important adjustments (e.g. Albrechts et al, 2001). In Denmark as elsewhere in Europe, the traditional hierarchical structures and regulatory mechanisms of planning have been considerably replaced by new arenas shaped by a range of actors (e.g. Healey 2007; Nischwitz, 2007). Contemporary planning systems thereby tend to place the regional level in a position where authorities no longer seem to regulate or control lower levels through regional spatial plans but rather collaborate with other actors in establishing new initiatives for the management of regions (e.g. Hajer and Wagenaar, 2003; Healey, 2006). This whole situation concerned with shifts

in logic, contents and institutional arrangements inevitably raises a need to question the extent to which the tasks and achievements once delivered by regional planning still occur in practice. In what follows, the paper delves into the genesis and evolution of regional planning in Denmark to create an understanding of the domain based on its logic, contents, functions and roles.

2. Initial attempts towards regional planning and the genesis of the Danish planning system

2.1. The planning efforts of the post-war era

The underpinnings that support the Danish planning system lie on the awareness of creating functional cities through a comprehensive and enforced administration of land uses. These physical planning premises have traditionally entailed the enactment of town planning regulations and the zoning of urban districts since the first half of the twentieth century. For instance, the Planning Act of 1938, a planning by-law imposed on municipalities containing urban areas, provided the basis to regulate how towns ought to develop. The Act introduced the procedures for providing disposition plans (municipal plans) and town plans (by-law local plans) with binding effect for landowners (Gaardmand, 1993). These two types of plans were provided by the municipalities and adopted by a special department under the Ministry of Interior.

However, disposition plans were only provided for the major cities and the Act did not stipulate a legal basis to safeguard a clear demarcation between urban and rural areas or for controlling urban growth. The resulting urban sprawl of the following years eventually led to the enactment of a Town and Countryside Zoning Act in 1949 (Enemark, 1999, page 18). Aiming to preserve the open countryside, the Act introduced zoning as a tool to prevent further speculation in rural lands. Inter-municipal urban development committees were appointed with the aim to provide urban development plans, which were based on land use regulatory principles (zoning provisions) that deliberately projected specific areas for urban expansion in connection with the implementation of infrastructure development. Plans thereby identified three development zones, namely inner, medium, and outer zones (Gaardmand, 1993, page 40). Whereas inner zones referred to areas where development was allowed in adjacency to built areas, medium zones were considered as potential areas for expansion and outer zones banned development. At first, these plans were elaborated for the four largest cities (Copenhagen, Aarhus, Odense and Aalborg) but several other smaller urban areas followed suit throughout the 1950s and 1960s (Michelsen et al, 2005, page 8).

As it occurred in most of Western Europe, growth thinking based on industrial development significantly influenced the Danish cities of the post-war years. In Denmark, however, this paradigm was not unique. The realisation of the welfare state was being pursued in a parallel fashion, which sought for equal development in connection to delivering social goods (housing, education, careers, employment) for the whole population. But through disposition plans and urban development plans, however, these objectives only seemed sensible and appropriate for larger urban areas. Such plans could therefore be perceived as a rational attempt to create progressive and expanding cities based on the coordination of new developments with employment sites and service provision. While Denmark's largest cities were expected to benefit from

these considerations, it was only Copenhagen that seemingly accomplished these objectives notwithstanding the generation of a number of negative side effects.

Furthermore, while the planning regulations of first couple of post-war decades did not stipulate any considerations above the urban level, economic growth began to concentrate predominantly in Greater Copenhagen. In line with substantial industrial development and job creation, this urban area experienced significant net positive migration from 1950 to 1970 whereas most other regions in the country continued to lag behind (Studsholt and Hvidtfeldt, 1990). This situation led to a major political debate concerned with unequal development, which came to be known as 'the unbalanced Denmark' (Christoffersen and Topsøe-Jensen, 1979). Consequently, the need for more comprehensive planning in light of the accomplishment of welfare objectives was rendered essential. In what follows, some of the first attempts to carry out regional planning in Denmark are described as well as the contents of a highly influential structural reform of local government, which after its implementation during the 1970s ended up shaping the scope and functions of the first generation of regional plans.

2.2. The first planning exercises above the urban level

The renowned 1947 Finger Plan for Copenhagen was the first planning initiative above the urban level in Denmark. It came to represent the first comprehensive planning attempt to coherently address matters such as mass transport, industry development, housing and nature preservation in a supra-urban scale. Since the industrialisation of Denmark in the late nineteenth century, Copenhagen had begun to suffer from urban sprawl in several directions well beyond its urban core. Hence, the Finger Plan projected an ordered expansion of Copenhagen outwardly along five corridors (the fingers) into rural areas towards the west and north of the inner city and in direction of nearby towns. Each corridor allowed for urban development based on moderate population increases and housing stock positioned in function of suburban railway lines. The space between the corridors was preserved for agricultural and recreational purposes. Although the plan was not politically adopted, it was highly valued in the guidance of local development in the decades following its publication (Jensen, 1992).

(Insert Figures 1a & 1b about here)

Aarhus, Denmark's second largest city, was inspired by the Finger Plan to develop its own 'Regional Plan for Greater Aarhus' in 1954, which consisted on an expansion along two urban corridors in northwest and southwest directions from the urban core (Michelsen et al, 2005, page 10). Updates of both regional plans for Greater Copenhagen and Greater Aarhus were voluntarily prepared by these cities in cooperation with their neighbouring municipalities in the early 1960s. While these plans can be essentially considered as preliminary attempts to implement coherent planning at a supra-urban scale, a more formal basis for systematic and coherent regional planning was still needed in addressing the socio-economic and spatial issues stemming from the 'unbalanced Denmark' debate.

In addition to these plans, a first Regional Development Act was passed in 1958. The Act authorised the Ministry of Trade to provide financial aid to site industrial firms in regions undergoing severe economic problems and where employment op-

portunities were much needed. Most of the Jutland peninsula was targeted as an area for regional development, particularly North Jutland, where direct grants to assist capital investments were made possible (Danish Town Planning Laboratory, 1974). In 1966, a comprehensive regional analysis carried out for this region generated a physical plan specifying a regional centre, growth areas and developing cities as well as principles for the development of traffic infrastructure (Bredsorff et al, 1966). The plan projected the development of the whole region towards the year 2000 and it became distinctive from the former city-region planning exercises in that it was the first real attempt to generate a sound regional plan comprising urban, rural, coastal and potential growth areas in connection with infrastructure development and environmental preservation. Other Danish regions such as Funen and South Denmark followed suit some years after.

(Insert Figure 2 about here)

Also in 1966, the national Land Planning Secretariat published an influential report entitled 'Regional Planning and Regional Divisions'. This report designated cities and towns as national, regional, municipal and local centres, respectively, in accordance to the type of service functions that they were to deliver (Landsplanudvalget Sekretariat, 1966). Such urban pattern rationale (known in Danish as *bymønster*) followed a hierarchical spatial arrangement of urban centres based on service provision and how they positioned themselves in relation to one another over the territory.[1] Without attaining legal status in the immediate years following its publication, the logic of spatial intervention was rendered reliable preparatory evidence for the implementation of the 1970 reform of local government structure as well as the preparation of regional plans a decade afterwards (see next subsection). As a whole, this hierarchy of service centres aimed at providing a sensible solution towards achieving a more even spatial distribution of socio-economic growth throughout Denmark.

(Insert Figure 3 about here – Hierarchical pattern 1966 and 1981)

2.3. The 1970 structural reform and the consolidation of the Danish planning system

Denmark underwent a radical local government reform in 1970 that played a significant role in ultimately defining the scope and functions of regional planning in the future. The implementation of this reform was materialised through decentralising public sector tasks while reconfiguring the administrative division of counties and municipalities. Altogether, the transformation to the post-war welfare society in Denmark required a coordinated effort whereby municipal and regional planning would turn out to be fundamental. Local authorities took the initiative to materialise the structural reform where popularly elected members dominated a Local Government Commission founded in 1959. During the eleven years it took for the reform to concretise, the Commission's work focused on addressing inequality aspects stemming from rapidly growing towns such as the demographic unbalances and economic

[1] For example, to be a regional centre, a city should have comprised services and functions such as colleges, hospitals, retail areas, libraries, technical schools, and so forth. In addition to these functions, a national centre should also have a university, larger retail centres, hospitals with at least 12 specialties, and several other requirements.

side effects that jeopardised the future of rural communities at the time (Jørgensen and Vagnby, 2005).

The context for the execution of this structural reform was based on the recognition of planning as a societal need. The key structural expectations and challenges, amongst others, were constituted by the significant general population increase, a reduction of rural population due to mechanisation of the agricultural sector, the need for land due to rapid urban development (housing, transport, industry, service), a fall in average household size (from more than 3,5 to less than 2), a general increase in real incomes leading to a raise in consumption patterns, a significant rise in car ownership, and a significant growth in education, research and development activities (Vagnby, 2005).

Before 1970, Denmark was divided into 86 municipalities and 1366 rural districts contained within 25 county council districts. This demarcation showed a sharp distinction between the urban and the rural. Indeed, rural districts were too small (in terms of territory, civil servants and population) to handle local tasks effectively while the urban extension of many of the former municipalities had already spread outside their formerly defined boundaries. As a result, the 1970 reform amalgamated rural districts into 277 municipalities and reduced the number of counties to 14.

(Insert Figure 4 about here)

A continuous transfer of tasks from national to regional and local levels with regards to planning, social services, health care and education followed in the years after. The counties were strengthened financially and were made responsible for regional planning as well as health care amongst other tasks and responsibilities. In addition, a restructuring of the financial system took place where reimbursement schemes were replaced by block grants and financial equalisation schemes between the more and the less developed municipalities (Elbo, 1981). The structural reform also enabled the possibility of economies of scale and further savings. Once the reform was implemented, counties and municipalities were deemed sizeable enough to ensure that welfare provision was effectively dealt with. Moreover, counties and municipalities were also authorised to collect their own taxes (Jørgensen, 2004).

The reform was followed by the legal consolidation of the Danish planning system, whereby planning law reforms were implemented from 1970 until 1977. These reforms included the Urban and Rural Zones Act in 1970, the National and Regional Planning Act in 1973 and the Municipal Planning Act in 1977 (Enemark, 1999). The 1973 National and Regional Planning Act became the first statutory policy at the national scale, which made it compulsory for counties to submit regional plans to national authorities. On these premises, the principle of equal development was legally adopted and the Danish planning system was rooted on the basis of the principle of framework control, by which plans at lower levels must not contradict planning decisions made at higher levels (ibid., page 17).

(Insert Figure 5 about here)

The 1970 structural reform together with the creation of the Danish planning system significantly contributed to promote not only an overall decentralisation of industrial development but also of administrative infrastructure to safeguard a more equal socio-economic development across the country. Such decentralisation contributed to meet the developmental needs of more peripheral regions while enabling a better access to

public and private services that would have otherwise remained in larger urban centres. All in all, the rise and consolidation of the planning domain at the time can be portrayed as 'the spatial expression of the welfare state' (Jensen and Jørgensen, 2000).

3. The evolution of regional planning in Denmark (1980 – 2005)

The institutionalisation of regional planning in Denmark was the result of an attempt to implement coherent planning for areas above the urban level, whose first signs had already been witnessed in the cases of North Jutland and the city-region plans for Copenhagen and Aarhus that were delivered during the first two post-war decades. The passing of the National and Regional Planning Act in 1973 marked the initiation of regional planning in Denmark, which adopted a more tangible form after provisions for the establishment of regional plans were put forward in 1977.

The first generation of Danish regional plans was advanced in 1980. Since then, the domain adopted a cross-sectoral focus in attempting to coordinate the multiple objectives of spatial planning in coherence with welfare values and in pursuit of equal development. This was materialised through a physical-functional orientation embedded in the distribution of socioeconomic development objectives and the management of environmental assets. The spatial reasoning behind regional planning thereby sought to provide a coherent framework for municipal planning based on legally binding land-use provisions. As such, these provisions required the counties to advance regional plans that included the designation of zones for urban development, recreational purposes, nature protection, environmental resource management, infrastructure development and the siting of regional facilities (such as waste or energy facilities), amongst other relevant themes.

As a whole, the practice of regional planning in light of the above rationale was comprised by 7 generations of plans prepared by each of the 14 Danish counties from 1980 to 2005. Regional plans were advanced based on a time frame of 12 years, and were revised and updated at least every 4 years (typically after the election of county councils). The first generation of regional plans published in 1980 was followed by updated versions delivered in 1985, 1989, 1993, 1997, 2001 and 2005, respectively. The process for preparing the plans typically included two periods for public debate. The first hearing comprised a call for ideas and solutions open for civil society organisations, while the second concentrated on the draft plan to be discussed by county and municipal actors. The elaboration of the first generation of regional plans was rather lengthy and included several revisions before final drafts were adopted. For instance, the county of North Jutland put forward yearly detailed proposals since 1977 until the first regional plan was finally adopted.

There were three generations of regional plans advanced during the 1980s, which defined the hierarchical pattern of urban centres for each individual county.[2] The key

[2] Based on the 1966 report 'Regional Planning and Regional Divisions' described in the previous section, the Ministry of Environment published an updated version entitled 'Report of the Future Urban Pattern' in 1979. This report hierarchically defined the urban pattern of every Danish urban centre based on service provision. It then became legally adopted in the 1981 National Planning Report wherein national, regional and local area centres were defined. For a detailed overview regarding the evolution of Danish national planning policy, see D. Galland, 'Understanding the Reorientations and Roles of Spatial Planning: The Case of National Planning Policy in Denmark', *European Planning Studies* (Forthcoming October 2011).

roles of towns and cities with respect to service provision and infrastructure development were thus defined for every single county. Through the urban pattern logic, plans sought to ensure equal development by strengthening weak areas partly at the expense of stronger ones. Moreover, this set of plans put forward guidelines concerned with natural resources management while also highlighted aspects that addressed the open country and the designation of special natural and agricultural areas. Guidelines related to energy facility siting (i.e. windmills) were also supplemented in the latest generation of plans in that decade (1989).

Two more generations of regional plans were advanced in the 1990s, which were considerably influenced by shifts in national planning. A new Planning Act, which entered into force in 1992, integrated and simplified planning and zoning provisions that were previously addressed by the several planning acts originally advanced in the 1970s. This shift allowed for national, regional, municipal and local planning as well as zoning and the administration of rural areas to be merged into a single law. Beyond these functional adjustments, a highly remarkable shift was the Act's opening chapter stating that the purpose of planning was to aim towards 'appropriate development in the whole country and in the individual counties and municipalities…' (Ministry of Environment, 1992). This orientation shift came in direct contradiction with the 'equal development' paradigm that characterised Danish planning ever since it was conceived.

Regional planning provisions during the 1990s were made more complex due to the implementation of two legally binding national planning directives that were included as amendments to the Planning Act in 1994 and 1997, respectively. The first directive addressed the safeguarding of coastal zones, which made regional plans responsible of ensuring their protection. The second directive dealt with retail trade regulations, whereby regional plans were meant to pose restrictions regarding the location of these facilities, amongst other constraints. In addition, groundwater quality considerations were also given special emphasis, particularly in the generation of regional plans of 1997. Beyond these inclusions, the two generations of plans advanced in the 1990s continued to designate aspects related with the urban pattern, infrastructure development and the use of rural areas based upon socioeconomic considerations (i.e. demographic and labour market trends).

The final two generations of plans were published in 2001 and 2005. These plans differed from the former given the inclusion of environmental themes following the enactment of European Union directives. Environmental impact assessment became an additional responsibility of regional planning after the passing of a EU directive that had entered into force in 1999. Regional plans thereby acquired the duty of specifying guidelines on the location and design of projects that were likely to have significant effects on the environment. Moreover, special responsibilities concerned with water resources protection and water quality were similarly assumed by regional planning in response to another EU directive adopted in 2000. For instance, groundwater protection became a stronger consideration with the designation of nitrate-vulnerable areas while the protection of cultural history in the landscape was also embraced through the identification of valuable cultural environments in regional plans. The last generation of regional plans of 2005 was the last of its kind, which maintained legal status through a national planning directive that entered into force in 2007 (Østergård, 2005). The directive stated that the 2005 regional plans should be integrated into the municipal plans generated by the new municipalities.

Altogether, the regional planning domain became increasingly more comprehensive in the course of every decade. From three general themes (urban and infrastruc-

ture development, recreation areas and natural resources management) covered throughout the first three generations of plans during the 1980s, regional planning continued to add and orchestrate several other themes related to different sectors during the 1990s and early 2000s. However, the shift in the thematic character of regional plans also implied that the domain gradually placed more emphasis on environmental considerations rather than societal ones. This turned out to be particularly evident after the Environmental Law reform of 1991, the shift from equal to appropriate development stated in 1992, and the enactment of EU directives in 1999 and 2000. Whereas the first three generations of regional plans constituted a base for socio-spatial development, the latest generations showed that the spatial logic embedded in the hierarchical urban pattern of regional plans decreased in importance.

Regional plans became imperative not only as a binding instrument for municipal plans with sectoral interests and objectives, but also as a conciliatory tool to balance sectoral considerations. For instance, regional planning became useful in ensuring that a particular sectoral decision was not undertaken at the expense of another (e.g. a transport decision impacting heavily on environmental assets). Another capacity provided by regional plans was the coordination of municipalities in joint matters transcending their own boundaries. In this respect, the regional planning process proved beneficial in balancing conflicting interests and in coordinating objectives related with traffic services (such as harbours, railways and roads) as well as the siting of 'undesirable' facilities (e.g. solid-waste treatment plants, sewage disposal sites, petrochemical plants and even windmill parks) (Studsholt and Hvidtfeldt 1990). Furthermore, the process also enabled the possibility of stakeholder participation including negotiations between municipalities and counties as well as two periods of public debate regarding aspects of draft plans (Studsholt, 2000)

4. The new Danish planning system and the rise of 'growth planning' at the regional level

In 2007, the implementation of a new reform redesigned functional and territorial structures of local and regional governments based on the creation of larger municipalities and regions with different decentralised tasks and responsibilities. This section addresses the implications that this reform generated on the planning domain in general, and on regional planning in particular. The character and background of the reform are firstly examined followed by a discussion concerned with new policies, strategies and institutional arrangements that have emerged at the regional level since then. The main argument put forward is that the spatial character of regional planning has been replaced by a new space-less rationale largely dominated by economic growth objectives.

4.1. The 2007 structural reform[3]

A new structural reform of local and regional government created in 2002, enacted in 2005 and put into effect in 2007 resulted in the restructuring of the political and ad-

[3] This section partly draws from two reports published by the Ministry of Interior and Health in Denmark (2004 and 2006), respectively. The reports are entitled 'Agreement on a Structural Reform' and 'The Local Government Reform – In Brief'.

ministrative map of Denmark. The reform consisted of an updated territorial demarcation of municipalities and regions. While the former 275 municipalities were merged into 98 new ones, the 14 former counties were abolished and replaced by 5 new regions. Overall, the reform entailed a major redistribution of tasks as well as the creation of a new financing and equalisation system.

In determining the need for a new reform, a Commission of Administrative Structure was appointed by late 2002. With the support of ministries as well as regional and municipal entities, the Commission described alternative models for public sector organisation and concluded, by early 2004, that a whole reform in terms of territorial boundaries and transfer of tasks was needed. The Commission's final assessment deemed the reform necessary by evidencing several weaknesses associated with the former local government structure. More specifically, the Commission highlighted the inappropriateness of the territorial size of administrative units for task performance under the premise that overlapping responsibilities and functions between them created vast inefficiencies. In addition, the Commission was demanded to address matters concerned with economic sustainability, citizen participation, quality in service delivery and possible choices between service providers as well as coherence between technical competence and economic responsibilities (Ministry of Interior and Health, 2004, 2006).

An 'Agreement on a Structural Reform' was then made later that year between the government (The Liberal Party and the Conservative Party) and the Danish People's Party, which rendered the preparation of 50 bills on the division and distribution of tasks by level of government and sector. All bills were adopted by mid-2005, covering municipal, regional and state responsibilities in the fields of employment, business development, transportation and roads, culture, nature, environment and planning, taxes, social services, health care and education.

In accordance with the Agreement, the aim of this new reform was to '…maintain and develop a democratically governed public sector with a sound basis for continued development of the Danish welfare state' (Ministry of the Interior and Health, 2004). From an economic standpoint, benefits from synergy effects were to be obtained through merging local and regional administrative units via wage administration, customer service or the possibility of economies of scale, amongst other savings. Consequently, the new municipalities after the reform turned out to be significantly larger both in terms of squared kilometres and population, i.e. the merging of municipalities caused a raise in average population from 20,000 to 55,000 inhabitants.

In light of the above, the 2007 structural reform signified the outcome of a process mostly geared towards efficiency considerations and managerial effectiveness. While its mandate called for an assessment of several geographical criteria that could form basis for future decisions, no key recommendations concerned with spatial structure were delivered as such. In this sense, territorial considerations pointing towards classical peripheral problems of some counties, the functional relationships (e.g. mobility and commuting patterns) between them or the appraisal of other geographical criteria were entirely disregarded in the decision-making process (Jørgensen, 2004, page 11).

(Insert Figure 6 about here)

4.2. Shifts in the Planning Act, the emergence of regional development planning and the birth of Regional Growth Fora

Beyond the reorganisation of the political and administrative map of Denmark, the 2007 structural reform also resulted in a crucial amendment of the Planning Act. This modification brought along important shifts to the Danish planning system and its configuration, which prompted the making of new planning policy at different levels. An important outcome was the strengthening of national and municipal levels of planning at the expense of the regional level. In this sense, while the purpose of the Planning Act and its aims nonetheless remained unaltered, spatial planning tasks and responsibilities formerly adhered to regional planning were transferred to the municipal level. Some of these aspects included the designation of urban zones, the location of transport facilities, the administration of agricultural interests, the preservation of cultural and historical heritage, the use of water resources, and several other environmental management tasks. In obtaining the right for land-use planning in both urban areas and the countryside, the Act provided municipalities the necessary autonomy to generate proposals and make decisions.

Furthermore, national planning was similarly 'strengthened', mainly in relation to its capacities and institutional arrangements to overview municipal planning and local land-use planning. The Ministry of Environment adopted a monitoring role that allowed national authorities to intervene in municipal planning in connection to themes and projects of international, national or regional relevance. In doing so, the Ministry established a number of environmental centres across the country to secure the implementation of national policy objectives concerned with nature protection, water resources management, national infrastructure projects, coastal zone management, retail trade and environmental impact assessment (Østergård, 2005).

The Act's former chapters specifying regional planning provisions were thus repealed and replaced instead by regional development plans (RDPs).[4] These plans are aimed at describing the 'desired spatial development' of each region, which includes several themes formerly undertaken by regional plans, i.e. the development of cities and towns, rural districts and small-town peripheral regions, nature and the environment, business, tourism, employment, education and culture (Ministry of the Environment, 2007). The intent of the RDPs is meant to utterly break away from the legally binding mandate, aim and scope of the former regional plans. In principle, the RDP can thus be conceived as a 'soft' policy instrument for the new regions whose aim is provide an 'umbrella' for development initiatives to inspire and partially support the making of municipal plans. In this sense, the RDPs reject the idea that regional planning is still expected to manage spatial planning at the municipal level. This statement is illustrated by the following quote:

> *'The regional development plan will not be able to manage in detail and will not have the role of deciding where various functions will be located. If regional councils, the councillors and employees do not abandon the old way of thinking, the regional development plans will fail and remain sparse documents' (Nielsen, 2005)*

As strategic tools, the RDPs are the outcome of bottom-up, process-oriented, multi-stakeholder settings undertaken by regional authorities in close collaboration with municipalities, interest organisations, educational institutions and other actors in each

[4] Prior to the implementation of the reform and to determining the existence of regional development, the Danish Government had already appointed a Regional Planning Committee (*Regionplanudvalg*) in 2002 with the task to give recommendations to upgrade and simplify regional planning in Denmark. In doing so, the Ministry of Environment commissioned different international organisations to carry out studies of regional planning systems in other Nordic countries as well as in England and Germany.

region. So far, the only generation of RDPs was advanced in 2007, a time where municipalities were deeply struggling with implementing the structural reform and preparing a new generation of comprehensive municipal plans. This situation essentially limited the inclusiveness and ownership of several bottom-up processes and in many cases caused the municipalities to adopt an indifferent attitude when it came to implementing the RDPs.

In spite of these initial challenges and limitations, the rationale behind advancing RDPs portrays the regions as members of a partnership strategy aimed at supporting the central government's focus on strengthening Denmark's role in the global economy. The 2006 national planning report clearly positioned itself in accordance with globalisation by stressing the need to renew spatial planning as a prerequisite to pursue the growth and competitiveness demands. Based on this premise, the RDPs could be regarded as an attempt of the central government to improve Denmark's position in the global competition. In this sense, both regional and municipal levels are increasingly expected to become strategically co-responsible for a broader economic development, adjustment and adaptation (Ministry of the Environment, 2006).

In line with such positioning on economic growth and competitiveness and along with the creation of RDPs, the 2005 Business Development Act handed the new regions statutory responsibility to set up partnership-like entities known as Regional Growth Fora (RGF). Comprised by representatives from regional and municipal councils, local businesses, trade unions and knowledge and educational institutions, RGF have been in charge of fostering and advancing initiatives to improve local conditions for economic growth. In doing so, these agencies hold the task of preparing business development strategies based on the strengths of businesses in the regions, which focus on the government's four drivers of economic growth (adopted through the EU from the OECD): human resources, entrepreneurship, accumulation and sharing of knowledge, and access to new technology. The main role of RGF is to ultimately make recommendations to regional councils and the state as to what regards funding for specific regional development projects and the allocation of EU Structural Funds, respectively.

There is a high degree of interaction and co-dependence between the RDPs and the RGFs' business development strategies given the fact that both need to ensure full cohesion with one another. In accordance to the 2005 Business Development Act, business development strategies should constitute part of the foundation of the RDPs themselves. In view of the RGF's legal positioning and their inherently strong decision-making nature coupled with the seemingly fragile clout so far embedded in RDPs, the implementation of the latter is most likely to be conditioned by their strict alignment with the interests pursued by the former. This scenario has somehow struck the first generation of RDPs advanced in 2007, which in subsequent years saw a rather limited implementation of its proposed strategies. However, a new generation of RDPs is expected for 2012, which is likely to undergo quite a different process and thereby render distinctive outcomes. This is mainly due to the shifting preconditions to embark upon more inclusive bottom-up processes based on already existing municipal plans (2009) and business development strategies (2010). RDP processes are also likely to undertake an alternative cause given the fact that municipalities have already overcome the turmoil of implementing the structural reform and have thereby been presented a new opportunity to prioritise the making of RDPs.

(Insert Figure 7 about here)

5. Discussion and concluding remarks

The evolution of regional planning in Denmark leads to the general discussion that the overall conception of the domain has been significantly mobilised, which has thereby entailed a profound transformation of the domain particularly during the past five years. In this sense, the preceding analysis leads to three main conclusions. The first conclusion is that the contents and logics of regional planning have importantly shifted as a result of specific development orientations as well as other political driving forces. Regional planning was originally regarded as a societal necessity (to address uneven development) and as an orchestrated effort to alleviate the pressing urban and rural development issues of the post-war decades. This became evident in the advancement of (supra-urban) planning exercises seeking for the ordered expansion of city regions with respect to sectoral matters (i.e. mass transport, industrial development, housing and nature preservation). Moreover, in pursuit of providing a comprehensive framework for developing a whole region, the regional plan of North Jutland advanced in 1966 covered urban, rural and coastal development matters in correlation with infrastructure development and environmental preservation. These examples could be regarded as the first genuine attempts in pursuit of regional planning based on equal development and spatial coherence.

The cross-sectoral quality of these initial plans persisted throughout the consolidation of the domain in the 1970s and later with the advancement of regional plans. Of utmost relevance was the establishment of an urban pattern logic, which yielded hierarchical spatial arrangements within individual counties. This enabled a more even spatial distribution of demography, labour market and economic growth, which together with the 1970 structural reform contributed to secure a more equal socio-economic development across the country. In safeguarding the achievements made after the consolidation of regional planning, the same socio-spatial approach was pursued by the three generations of regional plans put forward in the 1980s. However, due to supra national and national interventions as well as the Planning Act's shift from equal to appropriate development, the contents of regional plans gradually placed more emphasis on environmental themes during the 1990s and early 2000s. Along with these thematic shifts, the spatial logic embedded in regional plans steadily decreased in importance.

The most radical shift, however, stemmed from the 2007 structural reform that abolished the counties and thereby most provisions associated with regional planning. This situation prompted the birth of five new regions with the task to pursue regional development planning instead. While contents wise the new regional development plans inherited most thematic aspects from the former regional plans, the spatial logic formerly embedded in the latter was replaced by a spaceless rationale geared towards the promotion of growth. This has entailed that the cross-sectoral nature of the plans be now exclusively regarded in light of drivers of economic growth while the balance of conflicting sectoral objectives appears to be largely overlooked. In other words, the conception of regional space once based on the equilibrium of socioeconomic aspects, environmental quality, land use and infrastructure development from inter-regional and intra-regional scopes has turned out to be fully dissolved. The absence of spatial thinking has thereby created an important policy gap, which could be likely to generate sectoral issues especially in connection with aspects transcending municipal boundaries (see third conclusion below).

The second conclusion can be explained through the outcomes of more recent shifts related with the policy mechanisms and institutional arrangements associated with regional planning. After its genesis and first decades of practice, regional planning in Denmark became consistently shaped by policy mechanisms designed *ad hoc* to yield legally binding physical land use plans. As of 2007, the statutory character of such mechanisms shifted into a new strategic scheme aimed at generating regional development plans. In contrast to the former, these new plans could be regarded as soft policy instruments geared towards generating visions for desired regional development. There is thus a general shift from coercion to guidance, implying that the allocative function once delivered by regional planning has ceased to exist.

In terms of institutional arrangements, the hierarchical structures previously in charge of plan making and implementation have also been considerably altered. The new Danish planning system currently relies on a much flexible version of the principle of framework control, implying that the regional level no longer directly imposes its provisions on municipalities. Although in principle the regional development plan does still hold a steering role over municipal plans (i.e. according to the latest version of the Planning Act the latter cannot contradict the former), it is precisely municipal actors who have significant influence in the process of defining the contents of regional development plans themselves. Besides, such plans are similarly meant to ensure cohesion with the growth fora's business development strategies, wherein municipal councils and private sector actors hold substantial decision-making powers. Therefore, the implementation potential of regional development plans mainly depends on the ownership that regional councils in liaison with municipalities and other groups of actors develop in supporting a common vision for the development of their regions. As only one generation of plans has so far been advanced, the extent to which these strategies are able to succeed remains to be seen.

The third conclusion concerns the shifting role of regional planning from being a 'Panopticon' to a facilitator of growth. The traditional structure of the Danish planning system based on the principle of framework control enabled the regional planning domain to ensure spatial coherence through the coordination of municipal and other sectoral plans. Through this mechanism, regional planning thereby originally adopted a 'Panopticon' role that directly intervened and safeguarded inter-municipal coordination in spatial development matters. Given the fact that the legally binding nature of regional plans has now been replaced by economic growth-oriented policies that neither oversee regional space nor hold a factual enforcing character, it can be concluded that the 'Panopticon' role of regional is no longer being assumed whatsoever.

The absence of the 'Panopticon' role may imply that municipalities face serious challenges due to their potential lack of collective expertise. This may actually hold true in cases where municipalities embark upon projects transcending their own boundaries or wherein an array of sectoral issues requires coordination for the sake of balancing regional space. An example is the implementation and maintenance of EU-sponsored development projects formerly endorsed and upheld through regional planning intervention. Another clear example where municipalities might encounter challenges concerns the management of environmental issues such as groundwater and surface water quality affected by the leaching of old industrial areas. Yet another case is that regarding the grants of special agriculture permits based on the compliance of *ad hoc* regulations, whose assessment is dependent on particular know-how and capacities that individual municipalities have not probably yet assumed. A further im-

plication is that regional population balance or labour market considerations are no longer overseen in unison with other sectoral plans.

The above implications suggest that the harmony provided by regional plans in bringing together different sectoral policies is currently at stake. Yet, the absence of this 'Panopticon' role could also entail a range of new opportunities for municipalities to generate innovative arrangements aimed at the implementation of inter-municipal networks. Through inclusiveness and ownership, for instance, municipalities still hold the possibility to advance a common framework of goals and strategies in relation with regional development plans and their implementation. In this sense, the extent to which regional development plans succeed to perform as real partnership strategies will potentially determine whether the domain recoups its former coordinative capabilities. But to do so, regional development planning as such will have to overcome the challenges of strengthening bottom-up processes while also being capable of generating a strong ownership amongst actors.

In sum, the whole conception of regional planning has experienced a substantial transformation in recent years. This concluding section has emphasised that such conversion is comprised by significant shifts concerned with: (i) the contents and logics of regional planning; (ii) the policy mechanisms and institutional arrangements associated with regional planning; and (iii) the role of regional planning in contributing to cater for development in the country. Several potential challenges and implications derived from each of these shifts have also been put forward. It is also concluded that the capacities and outcomes of regional planning as formerly conceived have ceased to exist. In this sense, regional planning as a comprehensive mechanism to deal with uneven spatial development has been transformed into a domain that mainly aligns with growth agendas. In addition, regional planning as a tool to ensure the ordered expansion of urban areas has been suppressed.

The endurance of regional planning values in the new regional development planning domain is likely to depend on the regions' ability to facilitate a sound symbiosis between the former values of regional planning and the growth values of business development strategies. This will therefore be contingent upon the regions' capacity to incorporate them in the on-going bottom-up development processes for the 2012 generation of plans. However, a successful symbiosis could be hampered by an increasing agenda on governmental austerity, which is currently causing that Danish municipalities centre even more on economic growth objectives to fill in budget potholes. In addition, with the strengthening of national and municipal planning and the significant clout that business development strategies possess at the regional level, the future of whatever is left of regional planning seems highly dependant on decisions that will be made beyond regional councils themselves.

THE TRANSFORMATIONS IN LAWS BETWEEN 2002-2012 AND THE 'LEGAL' FUTURE OF TURKISH CITIES

Ceren Gamze Yaşar [1]

Abstract

Keywords: legislation, urbanization, urban planning, Turkish Cities

The laws that draw the frame of the urbanization and urban planning in Turkey has undergone a dramatic change in recent years. With housing and construction sector gaining ground in Turkish economy, the pressure over the legislation concerning urbanization and urban planning has been increased. The market demands more, so do the government. Within this context the legislation of urban planning and urbanization in general became more capital oriented and more centralized in political and administrative terms. Eventhough there is a tendency of decentralization originating from European Union Harmonization Process, decentralization remains superficial and most of the steps have been taken back with the recent changes in laws regarding planning authorities in central government and local governments.

These changes in laws will have varying impacts on cities and countryside, but the impact on the place and moment where those two, the city and the countryside, are juxtaposed, the impact is highly predictable: urban sprawl as a form of urban growth disorder (Yaşar, 2010). Within the framework of this paper, the legal background of contemporary urbanization in Turkey will be in focus. The laws and amendments to the laws made after 2002 up to now will be evaluated with reference to their observed and possible results in urban space, in Turkish cities.

The structure of the paper will be based on the laws; we will start with the study of the transformation taking place in the legal system after the elections held in 2002. Then, we will continue with observing the spatial results, the solidification of this legal framework. Last but not the least; by synthesizing all these analyses, we will discuss the issue in the theoretical level. In other words, we will start from the case, then attempt to build a stairway to the theory if possible.

1. Introduction

"Answered prayers cause more tears than those that remain unanswered"[2]

From "with the aim of housing production in accordance with development plans" to "with the aim of housing production"[3]

We are in the course of wide and radical changes in legal framework. Every field is under a restructuration process; from health, education, public services in general to working conditions and rights, administration and distribution of authorities, and production of space. The elections done in 3rd of November in 2002 will probably be considered as a milestone in this process in near future when the results of those changes in society and in space are comprehensively grasped. Between 1991-1999 and up to 2002, Turkey was governed by eight different coalition governments or minority governments. This situation reduced the pace of possible changes and shifts, and decreased the decisiveness and power of the government in the restructuration process of legal framework. Especially after the coup d'état in 1980, the neo-liberalization process in Turkey is accelerated, but the legal changes to meet the needs of the neo-liberalization process has caught the needed pace with the single party government. In 2002, the leading party, Justice and Development Party (JDP) has been elected to take the control of the government, and majority of the Turkish Grand National Assembly has become members of JDP. In following elections the situation has not changed; A single-party government with a majority of chairs in the Assembly: strong and decisive. With this, the neo-liberalization process has been accelerated. As a matter of fact, amendments to the laws, as a way of changing how state and society behaves, has become the main agenda of assembly and government.

In recent years, urbanization and urban development have entered a new phase. Housing is highly commodified like it was never before; construction sector has become a core sector in urban economies. As a result, cities are widely suffering from the problem of urban growth disorder[4] showing symptoms of urban sprawl: excess production of developed urban land, dispersed peripheral settlements, fragmented cities, illegible macroform, consumed rural areas and housing problem. (Yaşar, 2010). To put bluntly, as we name it, urban growth disorder is one of the main problems that contemporary cities are suffering from. This disorder has some specific spatial features dominating the newly produced urban space. Nowadays the production of urban space is so mass in scale that this spatial feature dominates cities in general as well. One of the mainstream transformation taking place in the legal framework that is mentioned above is the restructuration of urbanization and urban

3 "In Law No. 4706; e) The phrase in the article 7/B "with the aim of housing production in accordance with development plans" is replaced with "with the aim of housing production". Law No.5228 Bazı Kanunlarda ve 178 Sayıl Kanun Hükmünde Kararnamede Değişiklik Yapılması Hakkında Kanun (2004/07)

4 The concept, "urban growth disorder" is proposed by the author. (Yaşar, 2010).

development. The market pressure and government's perspective over urbanization is translated into the official language of government.

Within the framework of this paper, the legal background of contemporary urbanization in Turkey will be in focus. The laws and amendments to the laws made after 2002 up to now will be evaluated with reference to their observed and possible results in urban space, in Turkish cities. Ankara with her housing sector and periphery will be the reference of the observed results. The results are easily observable especially in the periphery of Ankara, where mass scale high-rise housing projects are taking place, high development rights are given (whether it be realized or not), and in where mass scale urban transformation projects are conducted (whether it be in the periphery or in the core) Streetless, centerless and endless, copy-paste housing areas in the middle of fields and in the middle of the city.

The legal framework of urbanization and planning is not a well-structured, legible one; with the transformation process mentioned above, it is becoming more and more chaotic. The transformation takes place in a fragmented way, bit by bit; therefore it is hard to decipher the direction that urbanization and planning heading to, and it is hard to understand situation comprehensively. In order to overcome this problem and make it more understandable, the laws and amendments to the laws, related with urban sprawl and housing will be classified with their emphases, and/or results. First of all, urbanization and urban development related laws are selected[5] and with a pre-reading the pattern of changes are noted. With reference to this pattern, a classification is produced. The laws can be distributed into three main classes which are: 1. restructuring the power and the authority; 2. restructuring the land market and land uses; and 3. restructuring the housing sector. These three, together provides the basis for urban development and urbanization. Some of the laws can be classified under more than one class due to their contents, yet most of them fall under one of these classes. A total of 17 laws, 2 draft laws[6] and 2 decree laws are selected and their related parts are classified and analyzed. Selections and classifications are made with reference to problem of urban sprawl and housing sector.[7]

5 It is crucial to note that the selection of laws and decree laws is made with reference to the relevance to production of urban space and the power relations in producing urban space. As a highly relevant and special case; the laws related to regulating housing sector are also included.

6 One of the draft laws is accepted in 16th of May, while this article was on the eve of completion; so, the number of laws under inspection becomes 18 and draft laws are decreased to one.

7 For a more deep and general analysis on the legal background of urbanization in the case of Turkey, the work of Balaban (2008), which includes the legal background of urbanization with all its aspects classified and the transformation took place between 2002-2007, can be seen.

2. Laws and Production of Urban Space: The Change in the Legal Background of Urbanization and Housing Leading to Urban Growth Disorder between 2002 and 2012

In this part, the way that the urban space is produced will be traced back in the transformation of the laws after 2002. Neo-liberalization is an ongoing process dating back to 1970s, and in this continuum, the years 1980 (coup D'état) 2002 (JDP - single party government) are significant points, that deserve to be considered as a breakpoint. After the elections held in 2002, National Assembly, with a strong and synchronized voice, fastened the process of law making, and a significant amount of them are on the production of urban space. It is also important to note that 2001 was the year when a deep economic crisis took place in Turkey.[8] It is easy to read the impact of capitalist demands from the government, from the laws. However, this is not a one-sided and one-way process; in the case of Turkey, the impacts of state interventions are highly effective over the production of space in the capitalist form of cities (Balaban, 2008). In other words, laws, as the official and operative language of state, are also effective over the way of the production of urban space.

Before proceeding to the evaluation of selected laws, it is crucial to keep in mind that not the whole of laws but selected relevant parts will be highlighted and for the sake of being perceptible, simplification and summation will be used. It is the pattern that should be deciphered, as a matter of fact; we will highlight the relevant parts. This paper should not be seen as a structured picture of planning system and urbanization today but instead considered as a picture of the pattern of change in the legal framework of urbanization in the case of Turkey. In order to take this picture in high resolution, a significant sum of laws are analyzed, the number of laws can be increased via expanding the frame, but for operational purposes we will focus on the ones related with urbanization and housing production. The classification of related laws by years can be found below table.

Table 1. Selected and Classified Laws by Years[9]

year		2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	Draft

8 According to Boratav (May 2010) in recent years, three similar crises are faced in Turkey in relation with global situation of economy and crises. These are 1994, 2001 and 2008-2009 crises. Moreover, the results of the global financial crisis of the year 2011, is not yet evaluated for the case of Turkey.

9 The laws will be explained in the following parts.

A special note on the table 1 and general frame of the work is the acceptance of the Law on The Transformation of Areas under the Risk of Disaster. With this law, the production of urban space in existing urban areas and in urban periphery/rural areas surrounding cities has been restructured radically.

2.1 Restructuring the Power and the Authority: Distribution of authorities between central and local governments and participation of public

The laws falling under this heading are analyzed in two dimensions implying two different sides of the tension. One is centralization-localization debate and the other one is enabling-disabling the participation. The balance between the local and the central bodies in production of urban space is not a clear and direct one. In other words with the changes in laws the authority is both centralized and localized at the same time. The second tension, the participation issue is clearer; most of the laws do not even mention it. With the law on the Transformation of Areas under the Risk of Disaster, the authority of central government has become indisputable and unquestionable. If a building is marked as under risk, demolition and transformation will take place within a short period of time without question and dispute. The participation to the decision making process is not in the agenda of the government and local governments previously, and the only way is to sue the decisions, plans etc. With the law it is now impossible to sue the decisions of demolition and transformation; in article 6, clause 9, it is clearly stated that *"Lawsuits and legal proceedings concerning the disputes related to the transfer transactions and the expropriation performed according to this article shall be executed and concluded only according to the value, and those related to the identification and the demolition works and processes shall be executed and concluded only according to the building and wreckage value."* With this law, the production of urban space has totally lost its democratic state that never has been acquired actually, and become an act of a powerful central government with an indisputable authority.

In the year 2004, a significant amount of laws are accepted. With 5216 - The Metropolitan Municipality Law (July 2004), the rural areas surrounding the metropolitan cities has come under the rule of the metropolitan municipality. A circle is drawn, taking governor's office as the center with a changing radius based on the population of the metropolitan city.[10] To put bluntly, the rural areas under control of government's provincial organization; governorship, has become areas controlled by metropolitan municipalities. This can be seen as a step to localization yet participation of people (residents of urban and rural areas) is still lacking. Also Localization only takes place in metropolitan scale, not in lower scales.

Another significant law is 5162, the one On Changing The Mass Housing Law (May 2004) is the first step of the inevitable rise of Housing Development Administration

10 Temporary Article No.2

(TOKİ). With Article No.4 TOKİ is authorized with making and approval of the development plans in every scale, in urban transformation zones and in areas defined as mass housing development areas or areas owned by TOKİ. In addition to this, TOKİ is equipped with extended expropriation authorities. This law is on the centralization side, also participation is not even mentioned. The control of TOKİ over the production of housing and urban space converges to absolute, and this creates a tension between the authorities of metropolitan municipalities and TOKİ.

The last related law of 2004 is 5104 North Ankara Urban Transformation Law, a law specifically made for Ankara. With this law, the authority of metropolitan municipality of Ankara over the urban transformation project conducted in the north entrance of Ankara without any proposed mechanisms of participation of residents. The approving authority of the development plans produced is the Ministry of Public Works and Settlement[11]. In the year 2006 with the Law 5481, Metropolitan Municipality has become the approving authority.[12]

In 2007, with 5609 The Law on Making Amendments to The *Gecekondu* Law (March 2007), TOKİ is equipped with wide authorities once in the possession of Ministry of Public Works and Settlement.[13] The transformation of *gecekondu* areas has become an issue of TOKİ with this law and the clearance and replacement of *gecekondu* areas with mass housing projects is fastened with this law. The empowerment of TOKİ continued with the Law 5793 (July 2008). The authority of TOKİ is increased in *gecekondu* areas[14], the areas under risk of disasters[15] and the public land subject to privatization[16].

In 2010 the authorities of municipalities over the production of space is increased with the law 5998 The Law on Making Amendments to The Municipality Law (widely known as Article No.73). The key point of the law is the urban transformation issue. Municipalities (and metropolitan municipalities where existent) has become the main actor in the projects transforming *gecekondu* areas, the old city parts, areas that are under disaster risk, the improved lands or unimproved lands; for the purpose of housing production.[17] However, it will be superficial to consider these changes as a sign of localization. It is true that municipalities and metropolitan municipalities are authorized over the production of urban space, with a nearly absolute control; bodies of central government are authorized as well.

With the last chain, the decree laws number 644 and 648, the distribution of authority has become more stratified. In the year 2011, after the national elections, the ministries in the cabinet have been restructured. The Ministry of Public Works and

15 Article No.10
16 Article No.15
17 Article No.1

Settlement has become The Ministry of Environment and Urbanization and the authorities of the ministry, some of which were once passed to TOKİ, have given back to the ministry[18]. Moreover, the ministry is authorized with the control, acceptance and making of environmental plans and master plans (in accordance with environmental plans). The general decisions over the growth of the cities, over the housing sector, over the production of urban space in general, are now under the rule of the Ministry of Environment and Urbanization.[19] While this paper is in progress, the first draft law, Law on the Transformation of Areas under the Risk of Disaster, has passed[20]. With this law, urbanization, urban development and transformation will enter into a new stage. In 20 years 14 million flat will be evaluated, and if necessary demolished and rebuilt.[21] There is no control mechanism over the decision making process, not in national scale and not in local scale. The decisive authority is the cabinet and the decisions made are unquestionable.

Centralization of the authority of the production of space is the main result of the changes summarized above. However, significant sum of so called localization of authorities also has taken place, within this time period. It is a twin process, heading for both sides, however centralization dominates. But this does not imply that the localization and centralization processes are in conflict with each other. The metropolitan municipality, municipalities (where metropolitan municipalities are not existent), Housing and Development Administration and last but not the least The Ministry of Environment and Urbanization, these three bodies have powerful authorities over the production of urban space. The planning authorities given to metropolitan municipalities cannot be solely regarded as a step to localization and decentralization of power. This authority points out the direction of more urban development. Between central and local, there is a hidden and underlying consensus over the approach to the production of urban space in its widest sense. In addition to that, when the authorities of the local and central governments cross in production of urban space, or housing in specific; there is a consensus for more. In other words, there is no control over proposing more land development rights, housing areas or urban development in general. If the housing project proposed by TOKİ is conflicting with the master plan of the city, prepared by the municipality; this does not prevent TOKİ to produce housing in that specific area. Same goes for the Ministry of Environment and Urbanization, the transformation of existing urban areas and rural areas on the every part of the city will be considered on their own, isolated from the overall needs of the city. We are in the beginning of this new, highly powerful and widespread transformation era, and we cannot measure the impacts yet, but with the hint given by the changes of the legal framework after 2002

and the urban space produced with reference to it, we can assume that this period will be more central, and more powerful enabling fast operations.

2.2 Restructuring the Land Market and Land Uses: Commodification and recommodification of space

The mechanisms controlling the outer limits of production of housing, developing lands and urbanization are under transformation as well; especially laws related with conservation are under reconstruction. In the year 2004, a significant amount of related laws are accepted. 5216 The Metropolitan Municipality Law (July 2004) is the most significant one. Within the circle defined in the previous part, metropolitan municipalities are authorized to produce plans of scale 1/25000 and 1/5000 in accordance with the Environmental Plan[22] (Ministry of Environment and Urbanization is authorized). Disaster issue is also mentioned in the law and metropolitan municipality is authorized to evacuate and demolish buildings under risk. Furthermore, with villages becoming neighborhoods, they have become possible further growth areas, as a part of urban areas. Even though those villages are not urbanized in its social, spatial and economic sense; they have become urbanized in administrative terms. They have become a significant part of urban land market and commodified in terms of urban land. Whether it be already developed or to be developed, these lands, that are on the outskirts of cities, are subject to land speculation. Agricultural production, in most cases is not enough to prevent land speculation and urban development. One of the most significant observance of the results of this law is the case of Ankara. In the year 2007, the Master Plan of Ankara has been accepted within the boundaries defined by the circle drawn by 5216 with reference to population. With the plan, the development plans proposed by district municipalities has become invalid, but in most of the part the previously given development rights are preserved. The population provisioned for the metropolitan area for the year 2023 is 7.5 million where the population for the year 2009 is 4 million. A population of 3.5 million has been turned into development rights on the rural periphery of the city.

Two other laws; 5226 The Law on the Amendment to the Cultural and Natural Heritage Protection Law and 5178 The Law on the Amendment to the Pasture Law are highly legible examples of the shift in the perspective in laws; “conservation” becomes “conservation while using, with the principle of sustainability”[23]. With 5226, conservation has become secondary to the “sustainable usage” of related areas while with 5178 pasture fields are opened to development. In both cases development and commodification of new lands become a part of the conservation laws. In other words, the antagonistic nature of conservation laws, antagonistic with reference to urban development, becomes synergist with development.

---

22 Article No.7 clauses a and b.

23 A detailed work on the changes of the usage of the words can be found in Duyguluer, F. 2010, KBAM Conference Presentation, İmar Hukuku’nun Muğlak Kavramları.

With the law 5104, specifically designed for Ankara, focusing on the transformation of the northern entrance of the city, a massive amount of urban land, and *gecekondus* on it, has gone under transformation. In other words, previously urbanized land is recommodified and has become subject to transformation. In the year 2005, another significant law was passed, 5403, Law on Soil Conservation and Land Use. The aim of the law is described as "conserving and 'developing' land, with sustainable development principles which are undefined and obscure. Another significant part of the law is the definition of non-agricultural lands. These lands are defined as [24] areas planned as housing areas and for other uses. In other words, if an area is planned to be urban, than it becomes non-agricultural land. In addition to that, even the absolute agricultural lands and irrigated farming areas can be subject to housing development, if ministries considered development as public interest and produce projects accordingly.[25] With an amendment to this law made in 2007, Law No.5578 a temporary article authorizing the development over already developed agricultural land, granting pardon for development in exchange with a defined sum of money.[26] A similar law is passed in 2008, which now includes the pasture areas as well.[27]

In 2006, with Law No.5491, The Law on Environment has been changed, and the popular concepts, sustainable development and conservation-usage balance have taken their place in the law, and the authority on preparing environmental plan has been given to the Ministry of Environment[28]. In 2010, with the Law No. 5998, The Municipality Law has been changed. Widely known as Amendment of Article No.73 the commodification of surrounding rural areas has been fastened. Metropolitan municipality is authorized to produce plans of "Urban or rural, developed or non-developed land" and again the control mechanism over the 'overproduction of urban space is not in the agenda.

Decree laws 644 and 648 increased the authority given to Ministry of Environment and Urbanization, while bringing together the two different ministries theoretically working antagonistically to each other. As a matter of fact, conserving the environment is now in the hands of the urban development apparatus of state, which consequently fastens the process of urban development and which clears the way. This year, last month, to be specific, Law No. 6292, widely known as 2B Law, is passed. The forest areas that have lost their forest features, or so they say, are, from now on considered as possible urban development areas. It is crucial to remind that most of our cities, especially major ones are surrounded with 2B forest areas, which likely to be subject to urban development, most probably without a controlling master plan, or without considering the need. Supply is freed from need, and in some cases even demand. Another significance of this law is that, it enables the rent gathered from the sales of the 2B land be used in the massive transformation attack,

24 Article No.3 Clause i.
25 Article No.13
26 Article No.6
27 Article No.2
28 Which later merged with Ministry of Public Works and Settlement and has become Ministry of Environment and Urbanization (2011)

as well as being the reserve land stock. The acceptance of the transformation law (Law on the Transformation of Areas under the Risk of Disaster) has brought the issue on a far different level. A draft law are of significance here; The Draft Law on The Conservation of Nature and Biodiversity which perfectly shows the change in the conservation perspective. The antagonist position of conservation laws has been lost. Production of urban space prevails.

As we summarized above, the planning system in Turkey is not a well defined and comprehensive system with clear boundaries and authorities, and it has a tendency to increasing entropy. If we add the changing perspectives on conservation to this, the picture will get clearer. The changes made in laws are bit by bit and not so well designed or well written, yet they are ideologically consistent. More urban development, more housing, more rent is the core of the changes. The boundaries of development, the limits are abolished, once and for all. Endless cities are inevitable.

1.3 Restructuring the Housing Sector: Highly commodified housing and state as an entrepreneur in the sector

Ownership of housing and more development rights are what most of the society is 'praying' for; and answered prayers will cause more tear than that remained unanswered; tear for the future of the cities. 4966 is the number of law that can be considered as the first major step that has changed the housing sector dramatically. With this law, the law 2985, Mass Housing Law, has been modified, and the rise of the TOKİ has begun. Land office has been left under control of TOKİ, and TOKİ has been authorized to produce housing with wide authorities and housing projects for profit. Another significant authority given to TOKİ is the authority to give credit in demand for housing. The unstoppable rise of TOKİ has begun with this step. Following this, in the year 2007, a law on housing finance, law no 5582 has passed. With this, state now pursues not only the supply side but also the demand side, to assure the consumption of produced housing. Mortgage system is not as developed as the ones in western countries but the long term credits are gaining ground in housing market. The middle class, the real target of mortgage system is indebted for long term.

In recent years, the role of housing sector has been increased in economy. The sell and build structure in the market made it less risky to produce housing for the provider and the market is stirred with the help of changes in laws, and with acts and encouragements of government. While European countries one by one fall by crisis, this is the reason that Turkish economy has somehow survived: the late massive urbanization. As the mayor of Istanbul, Kadir Topbaş has said It is the achievements in the construction sector that enables us to say that we did not face the crisis that is

taking place in global scale[29]. But the future is not as bright as Topbaş and in general members of JDP are declaring.

The three axes of change in general lead to an increase in demolish and build urbanization. Existing parts of the cities are under transformation in mass scale and the surroundings of cities, the rural areas on the periphery are as well. This creates a specific form of development, which is repeating itself everywhere. In the following years the housing typology and urban space produced in this era will be named specifically and criticized most probably. Planning, as we barely know it, will come to an end, if the draft law on Transformation of Areas under Disaster Risk is passed.[30] As an underdeveloped country, with a state that does not have enough capital accumulation under its control; a strong and powerful planning process, and planned urban development is not what we have experienced. Moreover, it seems like we are not going to experience it in near future as well. Unplanned nature of Turkish cities, solidified in the case of Ankara, is brought into a new era with the mass housing movement and the housing sector following mass housing approach of TOKİ, in spatial terms. This time, the problem is not only basically the unauthorized housing, but also and mainly housing produced in planned areas. (Yaşar, 2010)

JDP has discovered the power of housing in discourse; in reproducing political power. State as a strong actor in housing sector, without a concern of solving the housing problem of society including poor, and with a market and profit oriented approach strengthens the power of government as we observe up to now. Later or sooner, with this pace of production, the housing sector will enter into a crisis, with an excess of supply, and with over-urbanization of land.

2.4 Laws and Context

Table 2. Classification of The Laws Analyzed, National-Local Elections, Crises and Housing Construction Permissions[31]

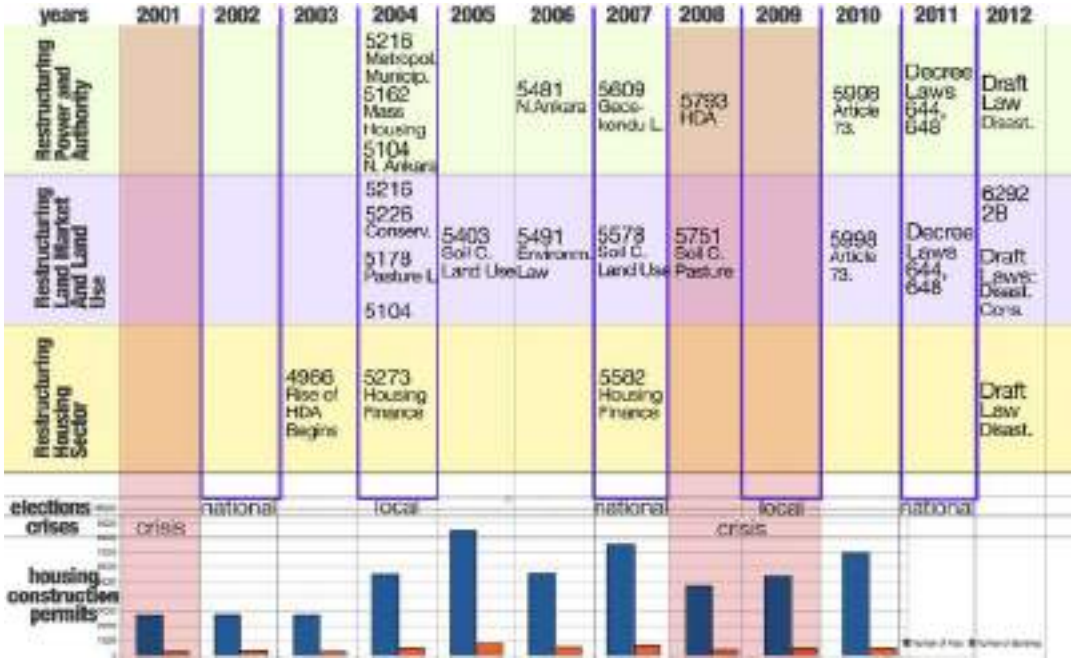
30 After we have written this paragraph, it is passed.

31 TUİK, 2001-2010 Housing Construction Permission Statistics, www.tuik.gov.tr, Accessed in May 8th, 2012.



The main breakpoint in the laws has take place in 2004, and right after that, the construction permissions have increased. In general, in years the permits are increasing in number, and with the acceptance of the law on the transformation of the areas under the risk of disaster, this will likely to boom. The crisis took place in 2011 all over the Europe, which is continuing, is not included in the table due to its lesser impacts on Turkey. Thanks to construction sector and the boom in the housing market, the arrival of the crisis has been delayed.

3. Space Produced In The Case Of Ankara: TOKİfication and Apartmenazed Cities

One most important result of these changes in the legal framework is the mass housing movement, taking place in national scale, transforming the housing sector widely and deeply. Not only TOKİ became the main actor in housing sector, but also the scale of the housing projects has been changed. Especially the mass housing provision for middle class has been accelerated, and a single form of stereotype housing dominates the market; that is: point block, generally high-rise, banal apartment blocks in the middle of car parks, without street and centers.

The legal framework of production of urban space and housing is as complicated as summarized above. However this complexity, in a sense, is not observed in the produced urban space. Same old story goes everywhere. Repetitive spaces without identities are the widespread result of demolish-build urbanization. Whether it be on the periphery, or core of the city; this fact does not change. In this part, the contemporary urbanization of Turkish cities, framed by the laws summarized above will be summarized in visual terms. The reasons and results of this form of urban

development, which is purposefully left outside of this paper, have to be debated as well. Within the framework of this study, we will focus on illustrating the urban space produced, with the legal framework drawn after 2002.

4. As a Conclusion: Bringing the Debate up to Theoretical Level

One of the most prominent writers in the field of urban geography, David Harvey, constructs a theory (on the Marxist ground) for understanding the urbanization under the capitalist mode of production. The flow of capital into the urban environment can be explained by the over accumulation in the primary circuit of the capital and the

flow of capital from the primary to the secondary circuit. (Harvey, D, 1985; pp.3-7) Production of urban space takes place in the secondary circuit of capital. In advanced capitalist countries, this theory can be applied for explaining suburbanization and urban sprawl. In the periphery countries, countries that are underdeveloped, it cannot provide a suitable explanation at first sight. As Balaban states (2008), it is rather through the interventions of state that capital flows to the secondary circuit of capital. In other words, it's not the over accumulation problem in the primary circuit but the state policies that has given rise to the production of urban space. With the laws explained and summarized above, this pattern becomes clearer. The question of the reason why state has chosen to encourage urban development is of importance here. State is not a self generated entity isolated from the capitalist society. State has impact on society and the reproduction of capitalism, yet it is also under control of it.

Several critiques are made on the theory of Harvey considering urban development as a secondary circuit of capital, where in the primary circuit of capital; excess surplus is acquired. Harvey was criticized by being too economic deterministic; ignoring the role of actors.(Balaban, 2008) Especially in the case of under developed, periphery countries such as Turkey, the process differs as we mentioned above. If the ideological apparatus of state, laws are considered as well, the reading will be more complicated. Is this the only way that capitalism realizes itself in the field of urbanization, urban development and housing in the form of laws and legal framework; or is this one of the selected possibilities? What is the impact of the changes on the future of our cities? Or on rural areas; the 'insignificant' rest? *"A general condition"* says Harvey (1985, p.7) *"for the flow of capital into the secondary circuit is therefore, the existence of a functioning capital market and, perhaps, a state willing to finance and guarantee long-term, large-scale projects with respect to the creation of the built environment."* Furthermore, a credit system, creating "fictitious capital" is also needed. In the case of Turkey, we have both, but some unique elements have to be mentioned. First of all, State (TOKİ) is the most important and one of the most powerful actors in the housing market. After the acceptance of the transformation law[32], Ministry of Environment and Urbanization and TOKİ have become much more powerful over the housing market. In other words, state rules the market, with a power converging to absolute; which is an altered form of capitalism, not liberal but capitalist. The second issue is, in the case of Turkey, the process in the provision of housing is reversed. It is not build and sell, rather its sell and build. To put bluntly, whether it be a housing area produced by public sector or private sector, the builders first sell the rights of housing and with the money they get, they build. This characteristic of housing production makes it less risky and more guarantied for the builder; and makes it more investment-like for the buyer. You pay for a house which does not exists yet, so you pay less, and in the following years, when it has been built and surroundings are urbanized, the price will increase dramatically. Commodification of housing as an investment good, together with state policies and sell and build production of housing, has made "the built environment for consumption" (Harvey, 1985) highly profitable that it has become

32 The Law on the Transformation of Areas under the Risk Of Disaster.

one of the core elements f the economy in Turkey. Harvey says, “the main thrust of the modern commitment to planning (whether at the state or corporate level) rests on the idea that certain forms of investment in the secondary and tertiary circuits are potentially productive”, in our case we are sure of this potential due to the state policies and the sell and build system, at least for now. The question, “where the capital embedded into urban land does come from?” is a vital one. Turkey is a country with high levels of foreign debts, and the debts are continuing to accrue. We can assume that, a significant part of the housing finance comes from external resources, which are the developed countries. If this is the case, Harvey's theory is applicable in global scale, from advanced to underdeveloped countries.[33] We can think in global scale and explain the flow of capital from the primary circuit to the secondary circuit with over accumulation, but accepting it and ending the debate here will be cutting corners.

In the case of Turkey, housing has become so central that construction sector is named as the locomotive sector. The built environment for consumption has become one of the most important commodities produced. It has nearly replaced the production taking place in the primary circuit of capital. But it is a very unique commodity; it consumes land. Land is becoming scarcer in time. Housing is not disposable and the numbers of flats are rising in time. Moreover, it’s a commodity that the potential buyers are strictly defined and grouped; not anyone can buy any house. It is a primal need as we all know, but this commodification has divorced the demand from the need. With this sort of unproductive production; a secondary circuit dominancy over the primary circuit, crisis is inevitable and close.

JAPANESE COOPERATION FOR URBAN PLANNING IN THE OLD CAPITAL OF DAMASCUS

A CASE STUDY OF "RESTORATION-TYPE" FAÇADE IMPROVEMENT

Matsubara Kosuke[1],

Abstract

Historic cities are cultural achievements that are gradually created by inhabitants over the centuries. In developed countries, the conservation of historic cities seems to be generally acknowledged as a method of community development that does not depend on huge exploitation. On the other hand, no sufficient countermeasures have been taken in developing countries because most native stakeholders are still interested in development. Here we could focus on so-called "International Cooperation", but urban conservation for historic cities where inhabitants actually live is still a minor consideration except for some government-based conservation projects for monuments and isolated examples of cultural heritage.

In this paper, I take the example of a conservation project which has been carried out by JICA (Japanese International Cooperation Agency) in Damascus, the old capital of Syria. The target area for the project is "*Qanawat* South". Although the origin of "*Qanawat* South" dates back to the Roman age, efforts for urban conservation have not been well organized, partly because the area is located outside of the so-called old city registered as a World Heritage Site. For example, the master plan of 1968 indicated the redistribution of the traditional quarters, while some conservation laws have been restricting the regeneration of the area. Moreover, there is not yet any consensus among the stakeholders concerning the historical value of the quarter; they are still questioning why the area should be conserved rather than being freely sold or developed and what and how they should contribute to conservation.

Based on analysis of the actual situation of *Qasr al-Hajjaj* Street, this paper examines a method called "restoration-type" façade improvement adopted by JICA, for which the final goal is not only to maintain the appearance of the street but also to activate the life of the habitants of the street.

[1] University of Tsukuba, Tsukuba, Japan - matsub@sk.tsukuba.ac.jp

1. Introduction

Since the Japanese planner Gyoji Banshoya (1930-1998) elaborated in cooperation with Michel Ecochard the master plan of Damascus in 1968 (still active today), Japanese/international cooperation in Damascus has been ongoing as one of the rare cases in which Japanese architects and planners are working in the Middle East. The example reported here is the latest technical project named “Damascus Metropolitan Area Urban Planning and Development Project” which started in September 2009 and will be completed in August 2012. One of the principal objects of the project is to suggest conservation ideas for the local heritage area, "*Qanawat* South" (surface: 0.28 km², population: 8,870), and, in particular, those involved are suggesting a façade improvement project for a historic street called *Qasr al-Hajjaj*.

The problems with the degradation of the living environment along the *Qasr al-Hajjaj* Street are partly caused by the decrepitude of traditional houses made of woods and bricks. Although previous surveys did not aim for structural reparation, it is certainly recognized that one of the reasons for the degradation of the living environment is the fact that habitants easily abandon their houses and demand rapid re-development regardless of historical value. This is a vicious cycle that has continued for some decades but specialists participating in international cooperation projects cannot always interfere with this since the project terms are limited. What such specialists can do is give habitants an occasion or the awareness to be motivated to resolve the problems by themselves. Façade improvement is not a complete resolution of the problems but can be a first occasion to get habitants participating in the efforts. Specifically, it is expected that habitants start taking pride in their town and participate in the management of the living environment taking advantage of the apparent façade improvement. Here, specialists make proposals and contribute to this process within a limited term.

The object of this survey is to examine “restoration-type” façade improvement based on the analysis of the actual situation of *Qasr al-Hajjaj* Street. Some similar projects have been previously carried out in Syrian cities where many historic landscapes such as old city *souk* and historical road outside of city walls still exist. The difference between these previous projects and JICA projects is that they adopted drastic improvement methods such as the uniform replacement of zinc shutters and the standardization of the height of buildings, while JICA tries to re-discover and maintain the original state of the façade as far as possible, defining façade improvement as “restoration-type” façade improvement.

The methods taken in this survey are as follows: 1. Chronological survey of the reasons why restoration-type façade improvement is necessary (Chapter 2), 2. Elaboration and analysis of an integrated façade plan (Fig. 5 and 6) based on field surveys of façades in relation to spatial composition in plans and the extraction of the elements composing the façade (Chapter 3), 3. Clarification of obstructive elements in the original historic façade and analysis of their background and actual situation (Chapter 4) and 4. Suggestions to restore original façades based on the findings of this survey (Chapter 5).

2. Spatial Characteristics of the Street and the Necessity of Façade Improvement

2.1 History of the Urban Formation and Spatial Composition of the Street

The target area of "*Qanawat South*" is located in the south west of the old walled city of Damascus called "Old Damas". The fact that it is located outside the old city means that the area is not within the scope of the World Heritage Site which was registered in 1979. However, the area is still an important historic area which dates back to the Roman age and which was developed in the 16th century when the Ottoman Empire started to rule Syria.

There are two historical roads from the *Bab Srij* Gate which is the south west gate of the old city. *Bab Srij* Street was developed as a *souk* (traditional shopping street) connecting Damascus with the ports of the East Mediterranean, while *Qasr al-Hajjaj* Street, which was a transport road connecting to southern villages or even a pilgrimage to Mecca, was developed as a housing area for new residents such as Turkish bureaucrats. Nowadays the street is still a densely populated area with traditional houses with courtyards.

Although the street seems simply to be a crowded area, there is a kind of spatial order. *Qasr al-Hajjaj* Street is a north-south axis which is almost a straight line from the *Bab Srij* Gate to the south border of the area. On the other hand, there are small alleys that cross the north-south axis from east to west - 18 alleys in total, 7 of which are on the east side of the axis and 11 on the west. There are 2 blind alleys in the east (28.6% of all east alleys) and 8 in the west (72.7% of all west alleys), showing the difference between east and west. In the south of the area where modern apartments are rarely built, traditional spatial composition of housing as a "private space"

accessed with blind alleys can still be found.

2.2 Urban District Planning System and Changes in Street Landscape

Changes in streets caused by modernization include the re-construction of traditional two storey or three storey houses into modern apartments (4 floors maximum) implemented by the district plan. The actual district plan was elaborated by the Damascus governorate from the 1970s onwards based on the principles of the master plan of 1968. In the master plan, Ecochard and Banshoya predicted the decrepitude of traditional houses made of dry brick and suggested the renewal of some historic housing areas including the target area.

The district plan shows a clear road line to be respected for the new construction, followed by a strict rule of a 2m set-back from the original lot line. As a result, the street is now regarded as an “existing-misfit”(anomaly). In fact, this district plan is a system to allow the construction of modern apartments, which is more rational from the viewpoint of land use and adjusting the road line. With this system, the streets are widened and a modern block is created, almost automatically creating a modern built-up area. It is clear that the district system is based on modernist policies originating from CIAM.

2.3 Actual Living Environment and the Necessity of Façade Improvement

There are no ideas for conservation in the district plan adopted by the Damascus Governorate but the Department of Antiquities of the Ministry of Culture (MOC) has introduced some systems for historic conservation: 11 “historic monuments” were designated in 1964 and a historic protection area was designated for most of the buildings along the street. These conservation systems are quite strict and are given precedent over the district plan. As a result, re-construction in the protected area has become almost impossible even though the houses are severely damaged and should be renewed at least from the viewpoint of the master plan. In addition, achieving the mutual agreement of the habitants is difficult in general so the implementation of the district plan is now coming to a halt. In such a situation, the decrepitude of traditional houses has become more and more serious and various problems such as room deformity, wall and roof collapse and the unsanitary state of the dried brick walls have occurred. On the whole, habitants cannot re-construct houses in the protected area but some modern apartments with incoherent set-backs can be found outside of the protected area.

Basic actual land use is for housing but some houses have small shops on the first floor (Fig. 1). The street, which is 514m in length and between 4 and 6 meters in width, is a one-way street but traffic is heavy and it is not safe for pedestrians.

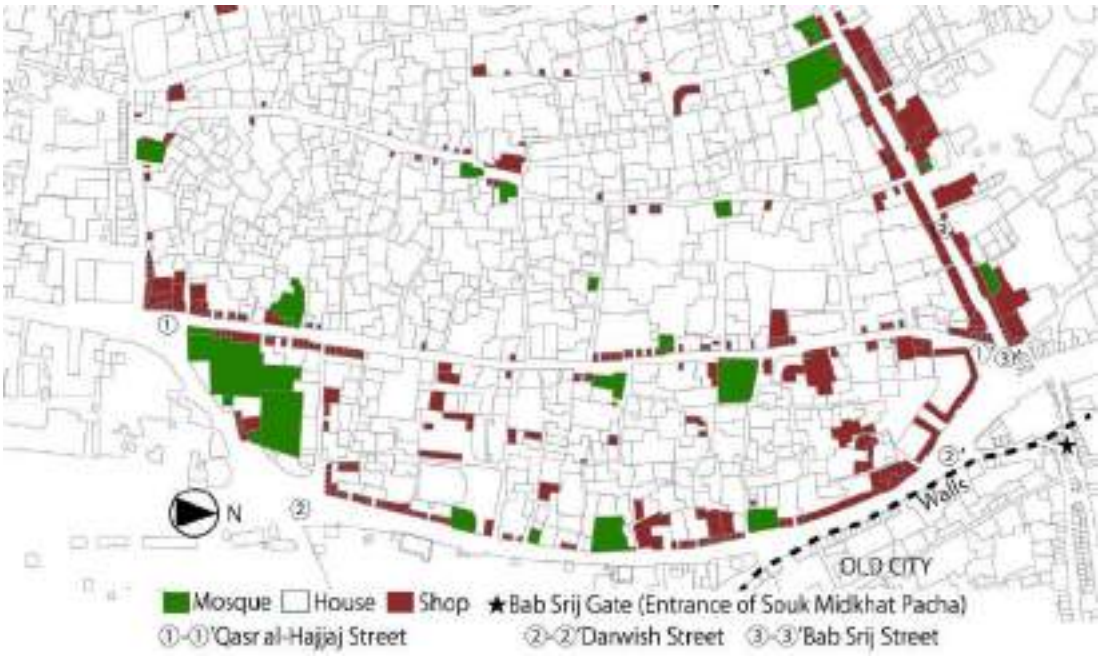

Figure 1: Actual Land Use along the Street

In fact, the situation on *Qasr al-Hajjaj* Street is quite different from that of *Souk Midkhat Pacha* which was the object of a façade improvement project in the past (Photo 1). Past projects included some radical methods such as replacing shutters with neo-traditional wooden doors or apparent unification of building heights and wall finish. However, these radical methods are still debatable since one of reasons that the old city is attractive stems from its spatial variety.

Photo 1. Case of *Souk Midkhat Pacha* (Left: Before Improvement, Right: After Improvement)

Even it is though connected with *Souk Midkhat Pacha*, *Qasr al-Hajjaj* Street is a modest curve and basically a housing area. It is not possible to neglect the small differences in houses and shops, the differences in building materials and the differences in height because these small differences are the characteristics of each building. The unification method is not appropriate for *Qasr al-Hajjaj*. It is necessary to search for a new method of authentic restoration of the original historic façades based on minor repairs conducted in the traditional manner but that also helps the habitants to improve their living environments.

3. The Façade of *Qasr al-Hajjaj* Street

3.1 Overview of the Façade

In the project, we made various plans and maps of *Qasr al-Hajjaj* Street. Here, I have unified a floor plan and a façade plan for research purposes (Figure 5 and Figure 6). The façade plan, created from the façade photos, describes all the elements of the façade.

Before I examine these elements, let's look at an overview of the street. Existing houses of 2 or 3 floors are sharing walls and are joined with each other. The borders of these houses are plastered with *Krusa* (الكلسة) in the traditional way it is not possible to distinguish between them on the façade plan. However, there are blocks separated by alleys: 8 blocks on the east side and 12 blocks on the west side of the street. Façade analysis will be conducted for each block as a separate unit for examination.

Modern apartments, which are the highest buildings except for the *minarets* of mosques, number 2 on the east side and 3 on the west. For example, apartment A is set back from the street and moreover its ground floor houses shops with a pillared corridor whose design originally dates back to the French mandate period. From the viewpoint of conservation, it can be said that this modern apartment building detracts from the traditional façade. Because of the existence of these modern apartments, traditional-type façade improvement is not possible.

3.2 Basic Elements of the Façade

Four categories of essential elements to be analyzed have been pinpointed on the

façade plan as follows (Fig. 2): 1. doors, 2. windows, 3. Shop shutters and 4. decoration (including traditional balconies called *Shurfa* (شرفة) , revealed beams etc.). Small and optional elements such as individual tiles, materials for finishing walls that are not part of the structure, modern equipment such as electric cables or exterior parts of air conditioners and greenery are excluded from the analysis. The elements of the 4 categories are subdivided into wood/iron and 1st/2nd/3rd floor, etc. in order to understand the number, surface and percentage of the elements as essential information for façade evaluation (Table 1).

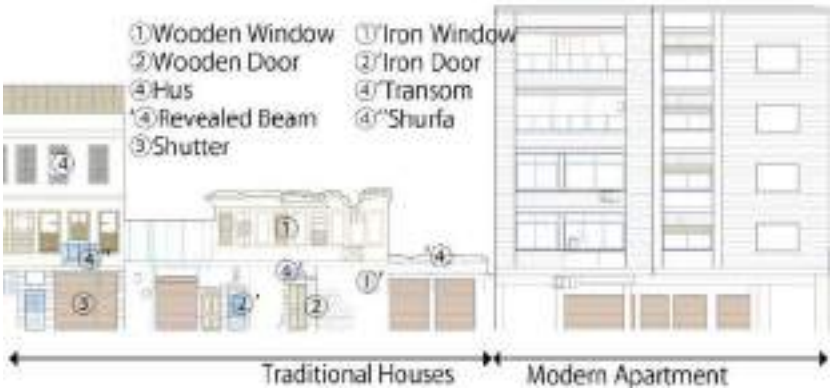

Figure 2: Examples of Façade Elements

3.3 Analysis of the Elements

Based on the essential information organized in Table 1 and Table 2, I examine the elements whether they are original or traditional elements of the façade or not. The viewpoints I take into account are the original state of the façade as an ideal goal of façade improvement and the traditional spatial composition of commercial and housing areas in relation to the floor plan. Illustrating some examples of elements in Figure 3 and Figure 4, and the overview of the façade plan in Figure.5 and Figure 6, the elements are analyzed as follows:

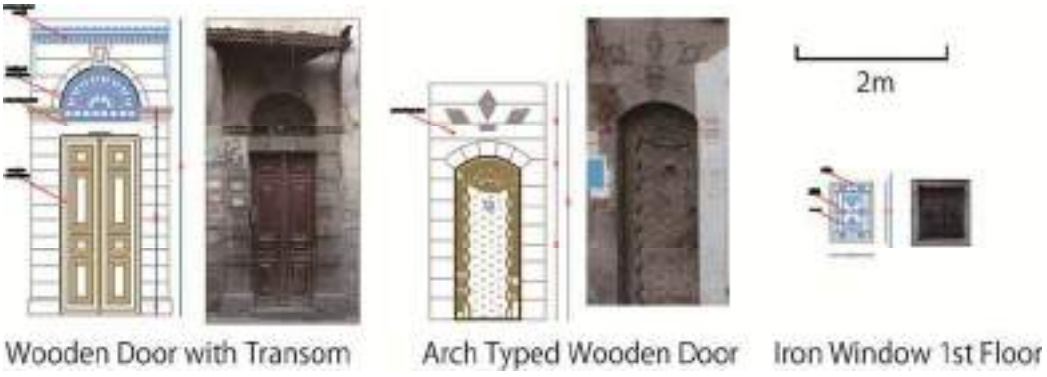

Figure 3: Examples of Elements (Doors and Windows on the 1st Floor)

3.3.1 DOORS :

The doors are openings on the first floor. There are 40 on the east side and 49 on the west side of the street. The average span of these doors is 10 - 13 meters but spans are not the same and are related to the composition of houses that have courtyards. In general, because of Islamic customs respecting privacy, the doors of a house located at the intersection of a street and a small alley tend to face on to the small alley as a private space and are not to be opened onto the street which is more a public space. Examining all the doors of the houses located at intersections today, most doors face on to the street regardless of Islamic custom, but a tendency to face doors on to alleys was observed in some cases in the south part of the street where traditional spatial composition still remains. Doors were originally made of wood but they are being replaced with new materials such as iron and over half of doors today are made from iron. Almost all doors are arched and 16.5% have arched transoms. Although there are only a few compared to the case of the old city, the arch is rarely a traditional element. On the whole, doors, which are positioned corresponding to the spatial composition of the street and traditionally decorated, are considered as an important original element to be restored.

Figure 4: Examples of Elements (Windows on the 2nd Floor and Decoration)

3.3.2 WINDOWS:

Windows are located on each floor but appearance between the 1st floor and other floors is different. Windows on the 1st floor (66 on the east side and 91 on the west) are relatively small and not unified in specific form. On the other hand, average height from the ground to the bottom of the window frame is about 200 cm which is quite high. This is due not only to the common custom in Damascus of raising the floor to avoid the cold, but also to the Islamic custom of privacy so that passersby cannot look in through the window.

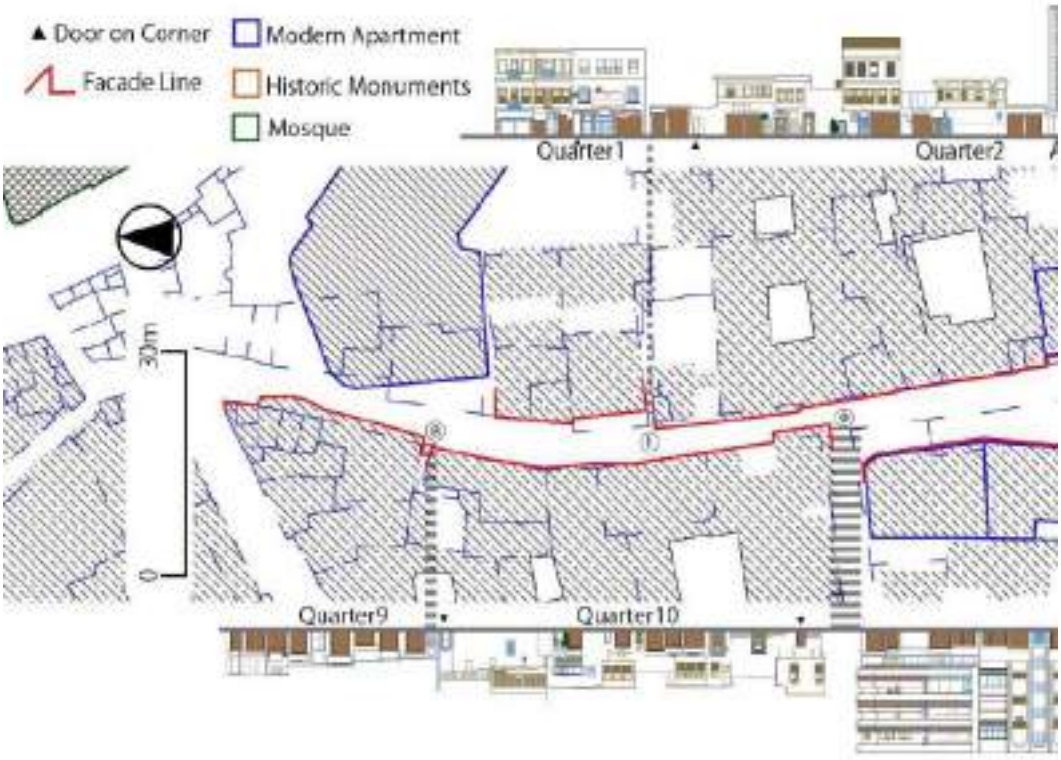

Figure 5: Integrated Façade Plan (Northern Part)

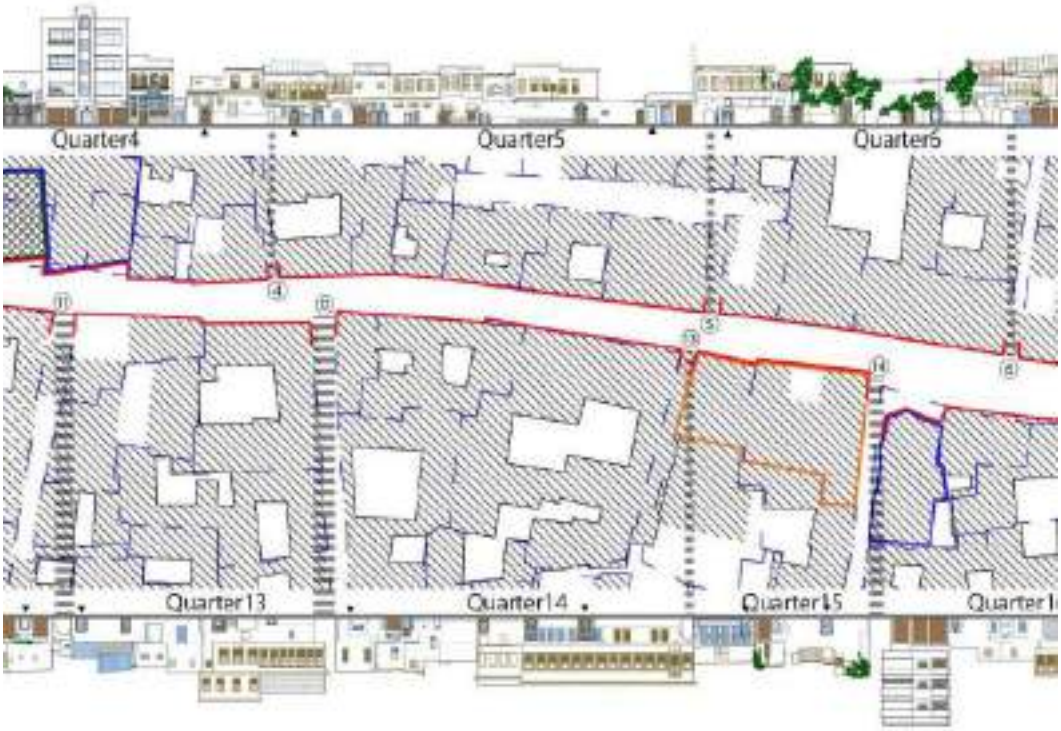

Figure 6: Integrated Façade Plan (Southern Part)

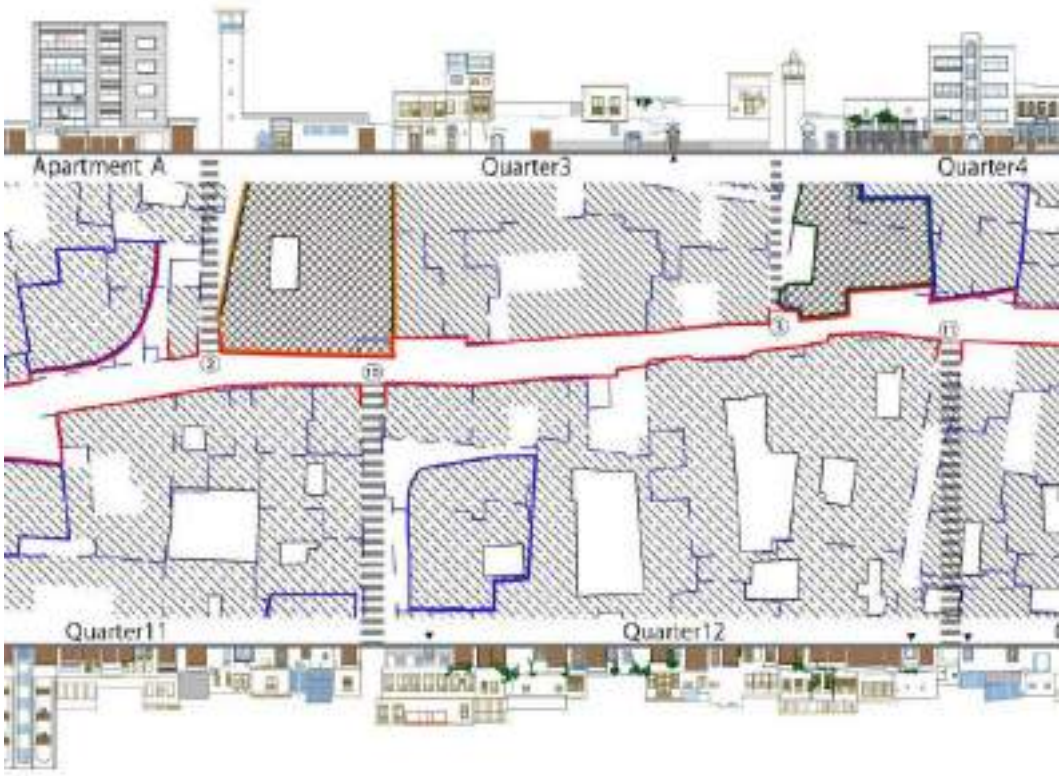

Figure 5': Integrated Façade Plan (Northern Part)

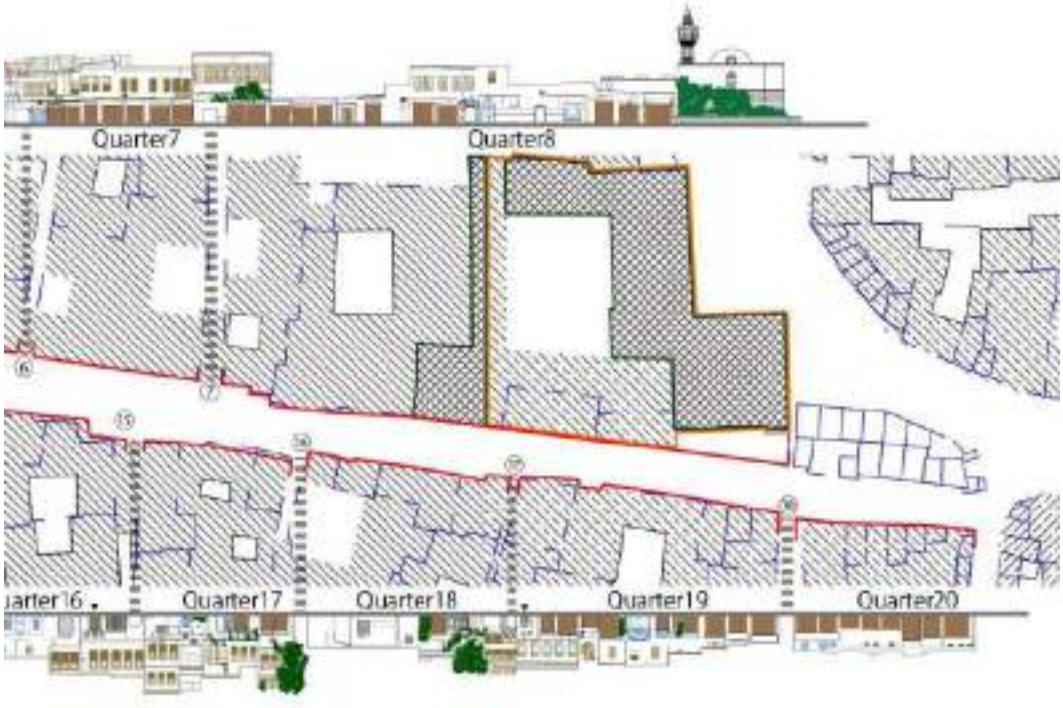

Figure 6': Integrated Façade Plan (Southern Part)

The windows on the second floor are many and huge; their total surface is the second largest element of the whole façade. There is unity of size and form and window frames are traditionally decorated. Movable wooden window covers called *Hus* (حص), which means "wooden sculpture", covers the windows. There are also bay windows which give the impression of three-dimensionality to the street landscape. Not so much difference is found between the windows of the 2nd floors and those of the 3rd floors. From the viewpoint of window frame materials, the number of wooden and iron windows are almost equal on the 1st floors, while there are many more wooden windows than iron windows on the 2nd floors. For this reason, it is assumed that people don't hesitate to replace wooden frames with iron frames for windows on the 1st floors (these being small and not unified) while they tend to conserve traditional style and materials on the 2nd floors. On the whole, windows, especially those on 2nd floor and above, are regarded as important original elements to be restored.

3.3.3 SHOP SHUTTERS:

Almost all the shops have shutters on their frontage and their total surface are is the largest in the whole façade. Although the number of shutters is lower than that of *Bab Srij* Street, the ratio of shutters on façades on *Qasr al-Hajjaj* Street is 6.9% on the east side and 9.9% on the west side. Shutters are found frequently in the south part of the street. All modern apartments have shutters on their frontage on the 1st floor. The shutters are made of zinc and their form is not traditional. Although the function of the shutters today cannot be ignored, it is difficult to evaluate them as an original element.

3.3.4 DECORATION:

Traditional decoration includes *Shurfa*, which are wooden window covers, *Hus* which are bay windows that allow people to see the street while being hidden themselves and *Hujur* (الحجر), which are traditional stone tiles that decorate the rims of doors. Some of these decorations have been replaced by iron materials. The bay windows of the 2nd floors and above give an impression of three-dimensionality to the landscape. The existence of revealed beams supporting bay windows and of wooden eaves also modulates the landscape. These elements are the result of extensions by the habitants and are a typical traditional townscape. Due to their delicateness and the vagueness of boundaries, it is difficult to grasp the exact number of these decorations. However, traditional decoration is certainly considered as an original element to be restored.

4. Obstructive Elements in the Original Construction

Shutters were not included in the original construction. Shutters were already regarded as obstacles in previous projects and they were uniformly replaced with wooden doors. However, this is not applicable to *Qasr al-Hajjaj* Street because of differences in the situation. In addition, there are some other obstructive elements such as those that were originally made from wooden materials but that were replaced by iron. It is necessary to take measurements for each obstructive element based on detailed examination.

4.1 Shutter Obstruction

Historically speaking, the frontage of shops was equipped with folding wooden doors. Although it is unknown when the wooden doors started to be replaced by shutters, there is photographic evidence from around 1860 showing shutters in *Souk al-Taweel* which are assumed to be the first shutters used in the old city (Photo 2). The use of shutters, which are superior to traditional wooden doors in terms of safety and ease of maintenance, rapidly spread throughout Damascus. It was accelerated by the introduction of modern apartments.

Shutters are hand-operated and rolled into boxes at the top of the frontage when the shops open. The boxes double as signs for the shops (Photo 3). The boxes are made of iron and there is no unity of form, color or size. However, they have the capacity to store a rolled shutter and this makes them protrude around 1m into the street. These boxes hide the arches or arch-type transoms recognized as original factors and as a result, the percentage of transoms is only 4.1 % of the number of all the shop frontages in the street. Moreover, the row of boxes, which are gaudy and not unified, also hide the revealed beams and eaves and spoil the three-dimensionality of the street landscape. These are the most serious obstructive elements in the original façades (Photo 4).

Photo 2: *Souk Al-Taweel* in 1860

Photo 3: Boxes as Signs

Photo 4: Boxes hiding Arches

Photo 5: Iron Door (right)

4.2 Obstruction from Iron Materials and Other Devices

Decrepitude causes materials to change. Doors and window frames that were originally made of wood tend to be replaced by iron (Photo 5). Makeshift repairs of collapsed walls using zinc or haphazard brick-laying is also regarded as an obstruction to the original façade. Even some traditional elements such as *Shurfa* and *Hus* have been replaced with iron or concrete materials. This change of materials must be based on demands for strength because these decorations have an aspect of practical use. However, these synthetic materials are an obstruction that do not match the wooden elements.

There are other obstructions excluded from the analysis in Chapter 3: the jumble of electricity cables on the walls of houses (Photo 6) and electricity boxes and exterior parts of air conditioners. Thick ducts on the walls of bakeries also obstruct the original façades (Photo 7).

Photo 6: Electricity Cables on *Hus*

Photo 7: Duct on Bay Window

In general, it has been necessary to take measures against the strong sunshine in Damascus. Today, people use zinc or even vinyl without hesitation as a material for eaves or arcade roofs. Sometimes advertisements are painted directly on to the walls.

5. Conclusion

The restoration of the original façade of *Qasr al-Hajjaj* Street is composed of the following elements: doors positioned in relation to spatial composition in the floor plan, decorated windows corresponding to the raised floor and reflecting Islamic customs, bay windows as a result of extensions by habitants giving an impression of three-dimensionality to the landscape of the street, and some small decorative and structural elements such as revealed beams or eaves, *Shurfa* and *Hus*. On the other hand, there are some obstructive elements such as shop shutters, iron materials and devices related to equipment used in the shops/houses.

The issue is that these obstructive elements (shutters/iron materials) are so important from the viewpoint of daily use that they cannot be easily removed. Restoring the original façade should be limited to the restoration of appearance in order to balance with the functions that are necessary today. The façade of modern apartments can also be improved using traditional style. What it is important to realize is that the principle is to provide wooden elements which have the same strength and ease of maintenance as iron elements and to prepare individual materials to suit the situation of the façade without just relying on uniform standards. We will need to resolve the issues surrounding budgets and staff. Fusion of traditional craftsmanship and new techniques and materials is also important. These efforts will contribute to habitants improving their living environments by themselves.

A View From The Ground

Implications for the literature on the 'models of the development process' based on a model of praxis and an associated mapping study.

Jonathan Drane*

Keywords: Property development process, property developer, property development models

---

Abstract.

This article identifies limitations in ontology and epistemology in the literature related to 'models of the development process', through a mapping exercise, which places existing views gained through visors of economy, political economy, institutional and social theory in perspective with a relative view of praxis.

Proponents of this field of study who have reviewed it over the twenty years since its contemporary categorical analysis (Healey 1991, 1992), (Gore & Nicholson 1991) suggest, in many cases, that they could gain collectively from an increased view of praxis in the property development mechanism, and associated empirical engagement with property developer actors.

A model of praxis in the commercial 'property development mechanism', is introduced which is founded on a taxonomy of 'lots and land parcels', 'value tension', 'arbitrage transaction', 'title distribution' and a 'plurality of developer types' who 'transition the parcel' within a series of alignments, both constrained and empowered by prior 'collective manifestations' by 'creating parties'.

The bookends of the literature used in this paper, are set at 1991 and 2012 over two decades, starting with Patsy Healey's articles on the development process (Healey 1991, 1992) and ending with David Adam's very recent article on 'notional property developers' (Adams 2012). The literature is first mapped, dissected and surveyed for limitations due to existing theoretical frames. The central tenets of the author's model are then used as a lens for clarifying inadequacies based on praxis.

The study discovers attraction to the topic by the most erudite of scholars, with often brilliant and revealing high level accounts, which are through sometimes conflicting visors. Amongst this chorus however, the voices are still trying to come to terms with what is really happening on the ground. The article provides increased definition of the property development process from a view of praxis, and an associated way forward for filling gaps in the knowledge base on this important topic.

1.Introduction

Property development transforms the face of our cities, and is responsible for many of the physical shells that form our skylines and their sometimes grandiose building forms. The property developer is a significant transactional actor in this phenomenon, the often un-popular gatekeeper who commands the mechanism, and a member of our society who primarily holds a key to a growing channel through which much of our cities must pass, to change and grow. As such, despite it being the realm of what is seen often as remote, romantic and even dangerous 'archetypal' characters, this mechanism enjoys a powerful and unique position in our urban creation and associated societal processes.

The literature on the *'models of the development process*' [1] which describes the overall world and modalities of the property developer, whilst it once invested considerable effort into research into this enigmatic realm, in the past twenty years is lacking somewhat in collective terms with this same endeavor. Local authorities and their urban planners however, still continue to rely substantially on private commercial developers to provide new supply in housing and other building markets.

This paper both clarifies this, and uses a literature mapping study and a comparative model of praxis, as a means of quantifying other specific gaps and recommendations for moving forward with any future research.

The often recognized themes relating to inadequacy in the literature, include a lack of direct knowledge of commercial property development and paucity of engagement with developer actors as a source of empirical data. Of controversial deliberation also, is the incidence of conflicting theoretical perspectives, which have shown fashions and signs of bias to prior regimes and academic disciplines. This study will add to this chorus at conceptual level; the prevalence of amorphous descriptions of processes that are not grounded in any particular site, snapshot views where a time lapse approach is required, and a lack of mechanistic emphasis in favour of structural, institutional and sequential descriptors.

At the heart of the gap also, is a central theme related to the lack of detailed treatment of the dynamics of land parcels and title pattern transitions, which goes to the heart of the developer dynamic and mechanism, together with a disconnect with the literature in the area of commercial valuation theory and legal property rights, (generalist textbook accounts aside) which could help bridge this gap, and serve as a guide to further research in this area. These themes will be explained in some detail through the introduction of a model of praxis proposed by the writer.

For those unfamiliar with the term 'models of the development process', they chart or describe 'the realm of property developers' and its related actors, events, structures, roles, rules and relationships through either words or graphical means. It

[1] Terms noted in italics are defined in a glossary at the end of the article.

should be noted that the subject has courted continuous conflict and controversy in the field, due to the obvious disparity between visions (of city planners) and implementation (by developers).

Those from the planning and urban theory arena who have been credited with a central definition of this topic are Patsy Healey with her 'Institutional Model' (Healey 1992) and Michael Ball (Urban Development Theorist) with his 'Structures of Provision' (Ball 1998, 2002). These and others' works in the field will unfold through this article, as well as the limitations of the current models and their relevance to contemporary practice and industry structures, which have grown since the early 1990's.

For clarity also, the author's general area of study is 'the influence of the property development mechanism on the growth of cities'. A brief outline of the author's work is provided at the rear of this article in the appendix.

1.1 Some Definitional Matters

This paper explains the nature and extent of the disconnect in the literature, with essential aspects of the property development process, as well as other limitations due to historical and sometimes fashionable theoretical perspectives. The study involves a survey of the literature on the '*models of the development process*', with a graphical mapping output which brings this and other *ontological* and *epistemological* inadequacies to life. The writer guides this exercise also, through a proposed model of *praxis* that is founded on a *taxonomy* based on the nature of title, entitlement and the dynamics of land parcels and their distribution and transition, through what is termed *fallow*, (or obsolete/dilapidated) to a fully developed state.

The need to rely on terms such as ontology, epistemology and praxis arose from the increased awareness by the author of the range and difference in theoretical perspectives, the level of engagement with property developer actors, and the associated data collection methods, all of which are subsets or forms of either ontology and epistemology. A glossary (see appendix) was an inevitable result of this, and terms requiring definition are shown in *italics* in the text for the assistance of the reader.

For ease the term *epistemology* is used here in the context of 'how we source knowledge' and relates predominantly to data collection methods. *Ontology* is used in the context of 'theoretical perspective' or 'how we see the world'. *Taxonomy* is used in the natural sciences as a means of classification of organisms, and here is used in a phenomenological perspective, to classify different traits of what is termed the development mechanism and its central elements and forces. *Praxis* is defined as 'practical philosophy', or a concept or theory of actual practice (and is not framed in the Marxist context).

1.2 Basis of the Proposed Model of Praxis: Case Studies Townsville

The model of praxis introduced here is based on two case studies: The Palmer St Precinct and The Railway Precinct in a regional city- Townsville in Far North Queensland, Australia, where two separate *fallow* (or obsolete/dilapidated) precincts became the subject of intense commercial 'mixed re-development' stimulation, over a period of 5 years in 2003 to 2008. The study is part of a PHD dissertation by the author, who is a professional commercial builder, and a prior practising property developer.

Figure 1- Map of Australia & Townsville. (Google Maps)

Townsville is seen by Queenslanders as 'the capital of the north' and enjoys a mult-sector economy which includes, government, defense, tertiary education, resources and tourism, together with one of the major ports in Australia (Figure 1).

Figure 2- Aerial view of the Palmer St Precinct in Townsville. (Previously the old harbour area). (Google Maps).

The cases include interviews with developers and related actors, and reviews the transformation of the former historical harbour area in Townsville, into a mixed use precinct (Figure 2). One site within the Palmer St case study is used to bring the model to life called the Gateway Project, see Figure 2 above and photograph (Figure 3) below. The case studies are still in progress at time of publication.

Figure 3: Gateway Tower Project: 112 Apartments.

From its harbour origins the site was used first as a meat works then languished at its lowest point of dilapidation, where it became a temporary surface car park site. Between 2003 and 2008 it went through a series of transitions including a rezoning (related to the precinct), a title consolidation, a development approval and a series of market and financial pre-commitments, to become a 112 apartment mixed use tower as shown above.

The model is also grounded on the observation of several other commercial mixed use sites of this nature found in the two case studies, as they moved historically through phases from dilapidated to developed, the transitions of which are marked and measured by both value improvements and parallel 'title pattern transitions'. This observation of transitions by these two 'markers' in a 'time lapse' sense is seen as the central platform of the praxis model, around which all other activities, forces and plays revolve in cycles as depicted in Figure 4. The model is explained in more detail below.

1.3 Comparing The Praxis Model to the Literature

The proposed model is used with its themes and categories, as a lens to distil the state of the literature, and the areas that need to be addressed when moving forward. The limitations of a singular account of praxis, and the basis of two case studies is recognized, but strengthened by discourse based on the author's direct commercial building experience over the decades from 1976 to 2012, which parallels a large part of the study period of the literature (1954- 2012). The author was also directly involved in the Gateway Project as initiating developer.

2. A Model of Praxis: The Development Mechanism

The proposed model takes a different view of the development process, by depicting it more as a mechanism and phenomenon, driven by various actors in spasmodic intermittent interactions, which occur under certain circumstantial alignments and collective manifestations . Since land is the key resource to a property developer, the model focuses on land as the central platform for all the various plays and circumstances that occur. These principles are shown in figure 4 below, which centres on the land parcel, and the essential elements and dynamics that constitutes its transition from one titled state to the next.

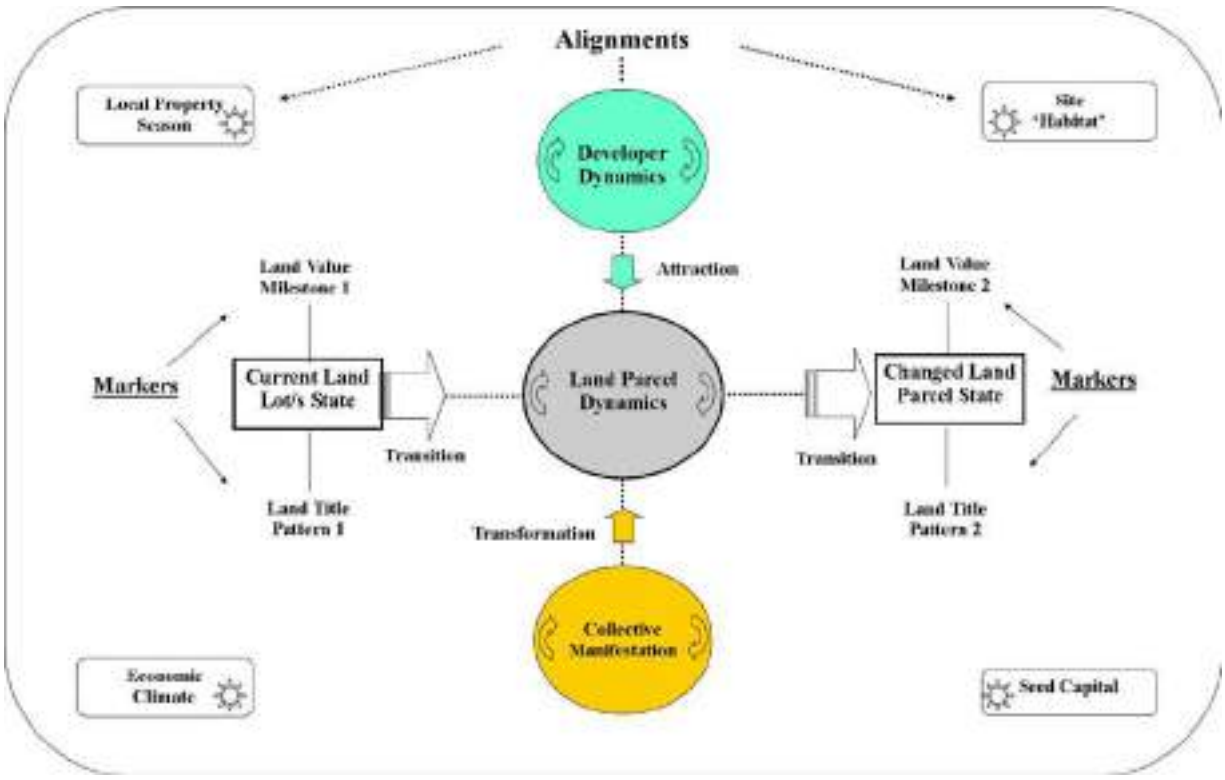

Figure 4 - A 'Three Elements' Model of Land Transition Leading to Construction & Titled Property.

Three essential elements rotate independently in their own spheres, and combine in an alignment of elements and other conditions, to create a transition in the land parcel, which together with other ongoing transitions, lead over historical time to a constructed building and titled property. These elements are 'Land Parcel Dynamics', 'Developer Dynamics', and 'Collective Manifestations'. These and their associated traits are expanded below and in a taxonomy later in the article.

The elements are depicted in terms of underlying forces behind the transition of land: attraction- the land parcel dynamics 'attract' developer types; transformation- creating parties manifest a vision for the land parcel and its surrounds; and circumstance- a series of alignments occur under certain political and economic circumstances which are identified by environmental factors including economic climate, local property season, developer 'site habitat' and seed capital. Developer habitat includes pre-conditions conducive to development including prior zoning, acquisition capacity and parcel potential. The three forces combine with the elements to transition the parcel to its next state. Taking these elements and forces in turn:

Land Parcel Dynamics: The model focuses fundamentally on the 'land lots' that constitute a potential land parcel which has commercial possibility and then viability, for the construction of a building which then becomes a titled property. For clarity, a land lot of itself may attract no commercial development interest, but its relationship and collection with other adjacent land lots forms what is termed here a land parcel. Like an animation of a stick figure which moves with the flick of pages in a note book , the model centers its view on the lots in the land parcel, and how they change title patterns and transition toward a construction state, based on the alignments noted in the model. Since the transitions rely on circumstance, they may take months, years (or even decade/s) to occur, and this concept is at the key of understanding the time lapse nature of the model of development (and as a mechanism and not just a process).

Developer Dynamics: The many transitions are effected by different 'developer types' who are suited (and attracted) to the stage of transition that the land parcel is undergoing. A developer might be suited to just purchasing, rezoning or 'optioning' a land parcel and consolidating title before holding it or selling it to another developer type or party. Similarly another developer might be suited to taking the consolidated site and obtaining a scheme approval with a local authority, before selling the site to another developer or party.

A central ingredient to all the transitions is the notion of *third party title distribution*, where existing title patterns are changed to achieve a greater yield of titles that are tradeable (without title, there is no tradability). A farm may be consolidated then subdivided into hundreds of sub-lots or titles, or a former city car park site may be schemed to achieve a multiple apartment block with numerous titles.

Alignments: The trigger for these separate actions is related to the notion of 'attraction' to the land parcel by the developer parties, 'arbitrage' and 'value tension' which relates to the differential potential value of the land parcel related to surrounding or 'influencing' parcels and 'amenity'. These factors will, together with conducive economic 'climate' and local 'seasonal' business factors, determine viability and eventual transition, but only at specific alignments.

Collective Manifestations: For the total historical length of the land parcel transitions, 'creating parties' such as city planners, public lobby groups and elected officials manifest the desired outcome for the land parcel, within the realms of city plans and visions, while developers adapt or reject the visions to their own ends! This 'troubled tango' appears to attract a great deal of the attention in the related literature on development and city planning.

The collective action of all the creating and developing parties acts as a 'collective manifestation' process which spans the historical period of the transition of the land lots.

Figure 5 below illustrates this mechanism in action for the Gateway Tower site. The figure charts the two key markers; land value change and title pattern change that occurred on the site over historical time from its 'fallow state' as a surface car park to its 're-titled property' state as a new apartment tower over a five year period.

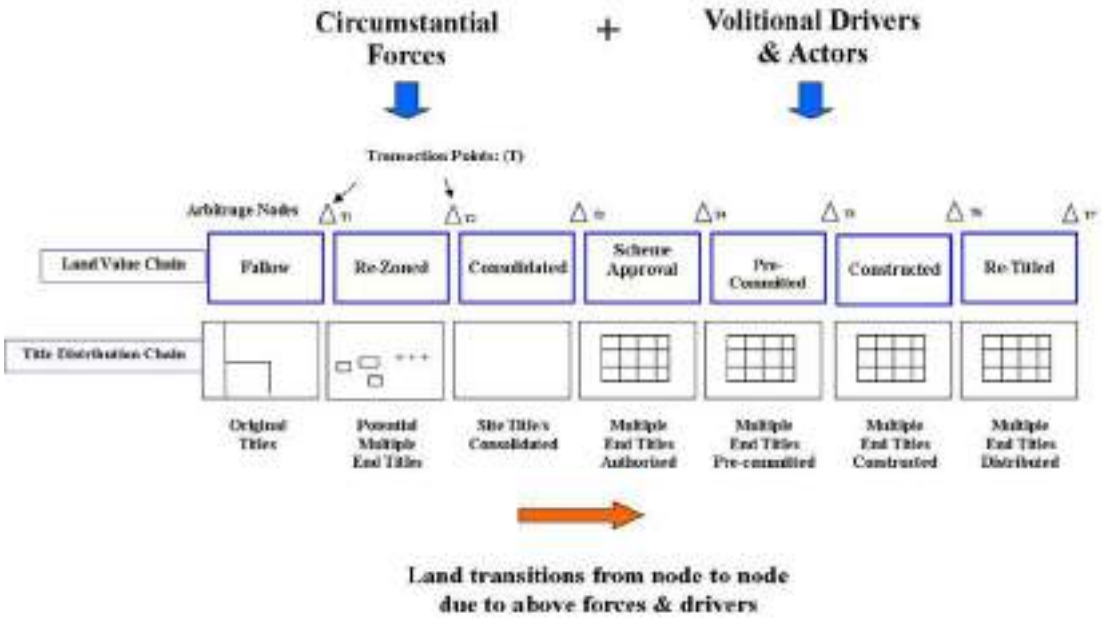

Figure 5 - Example of land transitions & value changes based on the Gateway Tower site, Townsville Australia (from the author's dissertation, in progress).

2.1 Central Themes of The Model of Praxis

The themes narrated to this point in this article and graphically depicted by figure 4, (above) are summarised in the following thematic statement, and used in the study as a basis for the model of praxis, and its comparison to the current models and theories.

Thematic Statement: *The model is founded on a taxonomy of 'lots and land parcels', 'value tension', 'arbitrage transaction', 'title distribution' and a 'plurality of developer types' who 'transition the parcel' within a series of alignments, both constrained and empowered by prior 'collective manifestations' by 'creating parties'.*

3. The Literature on 'Models of the Development Process'

Bounded by the term 'models of the development process', the survey of the literature was guided by three categorical articles on the subject (Healey 1991, 1992), (Gore & Nicholson 1991) which uncovered 26 relevant models to that date going back to 1954, (Form 1954) and ended with a very recent article by David Adams (Adams 2012). The period from 1991 to 2012 was surveyed based on key scholarly papers on the topic related specifically to models, including David Adams, Alan Hooper, Simon Guy, John Henneberry, Michael Ball and Eddie Coiacetto.

The survey was conducted (where possible) in date order of the articles/books, to obtain a sense of history and context, as well as the sequential development of models, through cross fertilization of ideas. Several texts of an historical nature were included in the survey, and provided the author with industry context and theoretical trends of the day. The more detailed findings and graphs are covered in the next sections, whilst this section is more descriptive of the nature of the models and their limitations.

Of interest is the fact that the 'trail nearly runs dry' in 1992, with the work of Patsy Healey and her, *"institutional model"*, (Healy 1992) which provided an intricate, potential commercial and social template for the development of a grounded model, based on both empirical and theoretical layers, guided by a 'Giddensian' lens, (Giddens 1984). Gore and Nicholson's advocacy for Ball's "*Structures of Provision*" model (Ball 1986) also has significant merit, providing a flexible modeling method based on changing process and contingent circumstance, the absence of which marks much of the literature. Although Michael Ball has held both a candle, (Ball 1998) and then a torch (Ball 2002), for his 'Structures of Provision', this also has not been the subject of further development except in its use by David Adams in his review of 'speed of supply of house building' (Adams 2009). From these 'beginnings', little eventuated except for ongoing erudite commentary and analysis of the state of the understanding of the development process, and the lack of empirical engagement (Adams 2012). Adams is even bold enough to say this year:

"The substantive academic account of what typifies the property developer has still to be written", (Adams 2012).

3.1 The Limitations of Theory

How is one to view a phenomenon, which for the majority of its existence remains either invisible, or observable to only a few actors, and then through the alignment of mere circumstance, and the power and action of 'creating and developing parties' manifests a structure (in this case a building then a titled property)?

It is often thought, and a key limitation of most of the models surveyed, that the 'development process' precedes the immediate construction of the building and ends with its completion. This misconception is perhaps understandable as the most visible and tangible stage of the process attracts the most attention, and so there is an impression across most of the models that the development process is represented as a finite set of processes which are captured in a snapshot when a time lapse view is more relevant.

There are those who would argue that those preceding processes are the subject of planning and city strategy, however going back in time on a building development that has just been placed on a 'land parcel', the common thread into deep history of this event is the actual series of original lots that eventually, by some folly, luck or design combined, or were combined and melded into the 'parcel' that became able to be commercialized, and which led to the subject building. It will be shown that this history constitutes in effect a collection of sub-projects and time-lapse transitions in the land parcel which in total, form the 'development mechanism' and result in the building's creation. The dynamics of interaction of each of these sub-projects has its own individual complexion and participants, some of whom may have no continuity and no link to actor parties in later or prior 'sub-projects'.

Another theme that predominates the literature is the notion of amorphous process descriptors, which occur without reference to a site or the history of these sub-projects, that occurred well prior to the final construction project, and on the very same site.

For now, the key explanation lies in the nature of available theoretical perspectives that prevailed in the period studied. Emerging from the 1950's where the key relevant academic disciplines were Economics, Geography, Architecture and Town Planning, and the primary theoretical stances were Urban Ecology, Marxism, and Classical Economics, the models were both enabled and constrained by these points of view.

Sociologist William Form (Form 1954) interestingly, broke ranks with the urban ecologists and advocates of classical economy, by establishing a sociological emphasis, developing a model which mixed four 'conjeries' (developer, industry, home owners and Government authorities) with six themes related to their political and organizational characteristics, yet his work remained substantially un-followed.

Instead the neo-classical schools predominated in parallel with the neo-Marxist views that emerged, the latter of which formed a ground wave it would seem in both the works of sociologist Anthony Giddens, (Giddens 1984) which influenced then geographer David Harvey (Harvey 1985). His three circuits of capital based on a Marxist and economic philosophy extended Marx's non spatial emphasis to an 'historical geography'. In viewing this model however it seems to 'hover' well above the cityscape at a theoretical level. Harvey's three circuits, although reaching into the realms of housing fabric and production/consumption landscapes, also provides an interesting precursor to a deeper understanding of what would become known as 'corporate real estate'. The 'circuits of capital' are seen here however to be more a macro, industrial, urban fabric creation model, than a direct model of the property development process itself (as outlined here).

The 'circuit broke' it would appear in the late 1980's, with the publishing of Susan Barrett and Patsy Healey's work on structure and agency (Healey 1990) which, together with McNamara (Healey et al. 1988) who critiqued the prevailing theoretical traditions (Neo-Classical and neo-Marxist), took the Giddensian notion of structuration, (Giddens 1984) and applied its central concepts to a model of development. Here it would seem the models were left in an unfinished state and woven into the ongoing works of Healey and others.

Theoretical assumptions	Economic processes	Event-sequence	Agency
Neo-classical	Fraser Harvey, J.	Munton and Goodchild	Kaiser and Weiss Drewett Barrett *et al.* 1978
Marxist	Harvey, D.	Boddy	Ambrose Ball

Fig. 11. Models of the development process[2]

Table 1- Patsy Healey's summary of theoretical assumptions and model categories (Healey 1991, p 236).

Healey captures the state of theoretical stances that underlie the models to that date in table 1, showing and further describing the limitation created by a lack of empirical engagement, as well as the constraint of theoretical visors used to chart the phenomenon.

Exceptions to the lack of grounding of the models in the concept of title and land parcels are prominently; Doreen Massey and Alejandrina Catalano's (Massey & Catalano 1978) work on exposing the rise and prevalence of 'landed capital', and the change in the nature of ownership of land from the earlier era of 'landed gentry'.

Her use of a Marxist visor clarifies the era of landed gentry, whilst oversimplifying the era of 'landed capital' but delves helpfully into the then, historical nature of ownership, and assists as an historical foundation of any ongoing development of a model in this area.

'Land use transition' itself is covered to a certain extent in the literature through Drewett's 'transition layers model', showing changes in state from rural to urban (Drewett 1969), (Hall et al. 1973). Kaiser and Weiss also illustrate land transitions from 'urban interest' to 'active development', and then 'residence', (Kaiser & Weiss 1970) although this does not concentrate on the complexity of title transition and associated interactions in the process. Other notables on land transition include Bryant, (Bryant 1982) who draws on Drewett's transition table, but informs on the nature of 'latent landscape', which alludes to the uncertainty of and potential for change in land parcels based on their existing condition, whilst Goodchild and Munton extend the understanding of the complexity of parcel transition, and the varying and contingent nature of different role plays and interactions (Goodchild & Munton 1985).

Property rights and the relationship to the development process are covered to some extent by Julie Grove-Hills (Grove-Hills et al. 1990) in the rural context, and suggest a useful research strategy which has seen no apparent ongoing development.

Refreshingly David Adams describes the principles of land title and entitlement in some detail through the 'Doctrine of Tenures and Estates', (Adams 1994) which forms an essential understanding of the foundations of the development process, missing in other accounts of development models.

Due to the number of models (26) and the body of articles and books that are related to the study, (103) the categorization and description of the difference and limitations of the models is best summarized in the following section, where the literature is mapped based on historical, geographical and theoretical perspectives, and data collection methods. It is also reviewed in light of the proposed model of praxis which is described in the next section.

4. Analysis

Literature mapping is a recognized method of analysis, involving the graphical depiction of themes and categories within literature sources through a mapping process. The process helps clarify and classify literature and establish commonalities, constraints and gaps (Hart 2005).

The analysis was based on the review of the literature of the 'models of the development process', and sought to discover the inadequacies due to both ontological (theoretical perspectives) and epistemological (sources of knowledge) factors through the following:

1. A Mapping Study: The dissemination of models and study types based on a categorical analysis, and associated graphical depiction through a series of literature maps.
2. A Proposed Model of Praxis which is compared to current models: The placement of existing models and studies gained through visors of economy, political economy, institutional and social theory, in perspective with a relative view of praxis (the proposed model noted herein) on a literature map.

4.1 Dissemination/Categorisation of Articles

The literature under survey involved 103 articles/books, and within these 14 'graphical models' and 12 textual models guided by Healey and Gore and Nicholson, as well as other key theorists works.. The articles chosen for study were based on the term 'models of the development process' and relevant cited references. These articles/books were classified into five types: graphical model, textual model, study, history and general (the latter including theoretical analysis/summary/text books) in table 2. These categories were used and identified by use of their own graphic marker across all outputs of the survey, including charts and maps (figure 6).

Table 2 below shows the 103 articles broken down into the various article types and figure 6 the graphical markers used to identify the various article types:

	Graphical Models	Models	Studies	History	General	Total
No	14	12	33	7	37	103
%	14%	12%	32%	7%	36%	100%

Table 2- Breakdown of literature by type of article.

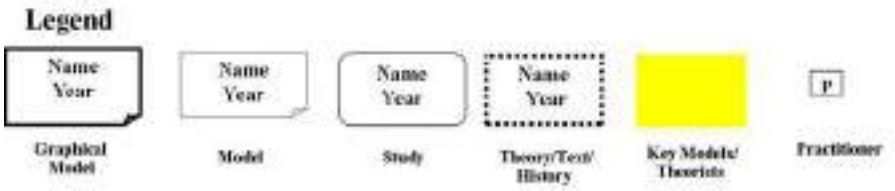

Figure 6: Legend for graphical mapping showing study and model types

The articles are drawn from academic literature, including books and journals that are recognized and referred to by the various key authors. Table 3 shows only six practitioners were noted within the author ranks. (See note 1 in appendix for list of practitioners).

	No	%
Academic	98	94%
Practitioner	6	6%
	104	100%

Table 3- *Breakdown of literature by academic versus practitioner.*

The topic of 'models of the development process' has been studied by five main disciplines as noted in table 4 below. Town and urban planning predominates at 38%, whilst economists (23%) and sociologists (10%) are also well represented. Of interest is the lower percentage of business and finance based articles (7%) although it is suggested that theory building of the nature found in the studied disciplines differs from the more financial and econometric nature (Harris & Cundell 1995) of the business literature, although Robert Beauregard breaks ranks with his rich depiction of the texture of property markets (Beauregard 2005).

A recent commercial article on the development process (Costello & Preller 2010) shows low intersection with articles studied here. This is however a subject for further study outside the bounds of this article.

	No	%
Economics	40	23%
Geography	13	7%
Town Planning	66	38%
Sociology	18	10%
Finance/Business	13	7%
General Text/History	26	15%
Totals	176	100%

Table 4- Breakdown of literature by disciplines applied to the articles.
(Please note the total exceeds the number of authors, because the above represents the number of times a specific discipline was used in articles).

The categorization of articles was based on identification of the traits shown in table 5 (below).

Categories										
Type	Theory/ Praxis	Position	Data Collection	Discipline	Theoretical Stance/ (Bias)	Sector	Participants	Town/City	Country	Geo Position
Sub-categories										
History	Theory	Academic	Theoretical Analysis	Economics	Classical	Residential	Polies	Place	Canada	CBD/Urban
Theory		Practitioner	Statistical Analysis	Geography	Marxist	Commercial	Planners		USA	Fringe
Model			Case Study	Architecture	Pol Economy	Industrial	Agents		UK	Regional
Summary (Text)			Survey/ Questionnare	Town Planning	Institutional	Mixed	Builders		Other	Rural
Study			Interview	Sociology	Morphology		Developers			
Mixed	Praxis		Focus Group	Finance			Mixed			

Table 5- Categories and sub-categories used in the mapping study.

The literature was read based on the above filters and (for economy) based on a 'search hierarchy' of abstract-section/chapter-relevant text, i.e. where abstracts did not provide the necessary information, chapters or sections then text relevant to the categories were read and filtered for relevant information. Key models were however all reviewed in detail.

A spreadsheet was used to record relevant chapters, text, quotes and charts. The information was distilled into the relevant charts in this article. Content analysis was therefore not based on purely technical computer searches of key words.

4.2 Mapping Typology

The mapping study was founded on the proposition that there were limitations in the literature due to existing theoretical perspectives and data collection methods. The research design included the potential revelation and quantification of these limits.

The following literature maps were devised as part of this design:

1. Theory-Praxis/Data Collection type.
2. History/Theoretical Perspective.
3. Geography/Sector/Country type.

(Please note that the maps have been designed to fit into the A4 portrait format of this article, however larger size versions are shown in the appendix in landscape format for the assistance of readers).

Theory-Praxis/Data Collection Map

The theory-praxis map (see figure 7 over page) distilled 'theory versus praxis' against a comparison of data collection methods, which ranged from purely literary/theoretical accounts, to secondary data collection, then actual engagement with actors through case studies, questionnaires, surveys and interviews. For clarity y-axis grading of 'theory' was defined by a more *objectivist* stance whilst praxis a more *constructionist* approach (Bryman 2008). See glossary.

History/Theoretical Perspective Map

The history-theoretical perspective map (see figure 8 over page) placed authors in a timeline across six decades from the 1950's to the current decade, (2010's) and within their theoretical category of Neo-classic, neo-Marxist, political economy, institutional, praxis and sociology. The grading of these categories from top to the bottom of the chart reflected an increased depiction of actors, and their associated drivers and relationships.

Geography/Sector/Country Map

The geographic/sector/country map (see figure 9 over page) identified actual field studies undertaken within the articles and plotted them by Country, City/Town and Sector (residential, commercial etc). It also created a concentric mapping pattern, emanating from the center of the map, which represented city studies, to outer circles which included fringe, regional and rural studies. This was designed to reveal concentration on particular sectors and geographical predilections.

Model of Praxis Versus Current Theory

The proposed praxis model was distilled from figure 4 and its key thematic statement noted earlier, which covered the essential components and themes of the model and its drivers and mechanisms. The taxonomy was divided into three 'phenomenal' elements: 'Land Parcel Dynamics', 'Developer Dynamics', 'Manifestations' as well as alignments as shown. Each of the underlined themes were split into traits which were placed on a matrix on the y-axis, and against a historical timeline on the x-axis.

Existing theories were then plotted onto the matrix based on author name and year, to show graphically the incidence of 'coverage' of a particular theme (of the proposed model) within the current theory, and within an historical period. Coverage could mean specific or general mention of such themes in the article or book. It should be noted that the review of all articles and books was based on distilling key aspects of the sources, to allow this process to be done effectively and economically, within the bounds of this article.

5. Results

The literature maps showed the changes, evolution, predilection and cross fertilisation of theoretical stances across seven decades, as well as data collection tendencies. Statistical table 6 draws from the Theory-Praxis map (figure 7) and shows the predominance of more constructivist theoretical stances (72%) to objectivist, (28%) however a high incidence of the use of secondary data and literature, (60%) compared to direct engagement (40%).

Data Collection Method	Objectivist	Constructionist	Totals	%
Secondary Data				
Literature only	6	11	17	
Statistical Data	11	8	19	
subtotal	17	19	36	60%
Direct Engagement				
Case Study	0	10	10	
Questionnare	0	5	5	
Interviews	0	9	9	
Subtotal	0	24	24	40%
Totals	***17***	***43***	***60***	***100%***
%	28%	72%		

Table 6: Statistical representation of theory types and data collection methods.

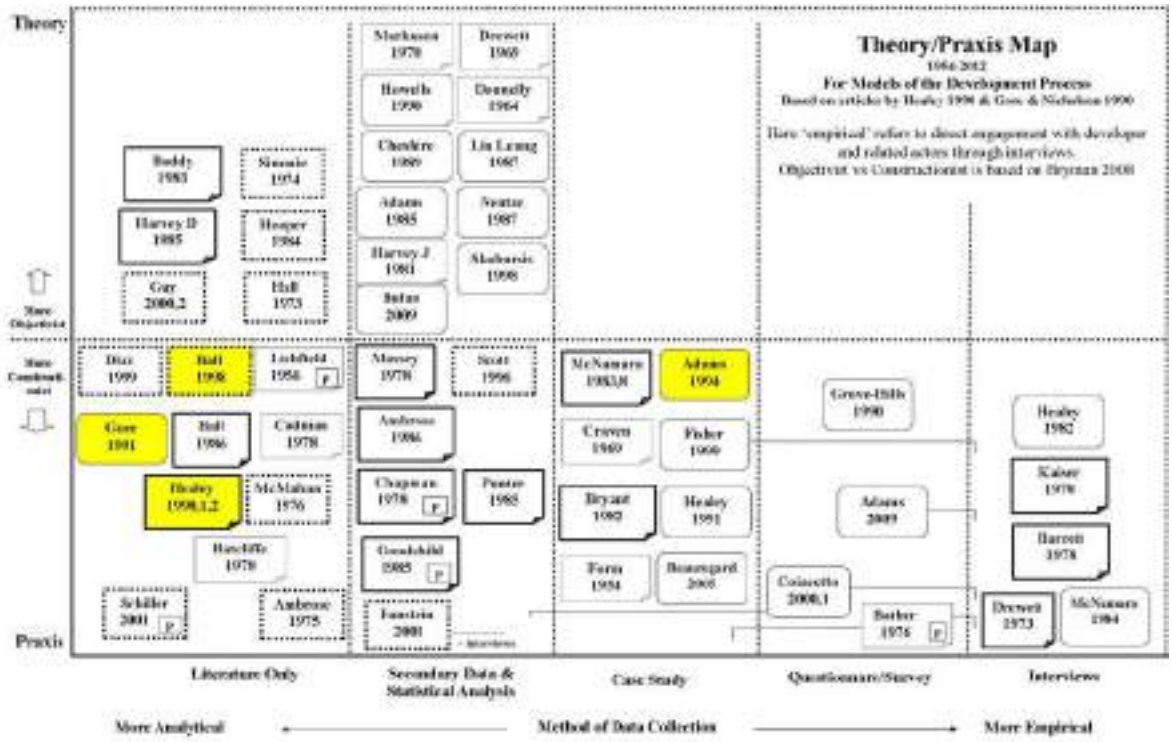

Figure 7-Theory/Praxis Map for Models of the Development Process 1954-2012.

Figure 7 illustrates 60 key author's out of the total of 103 articles, (based on their standing and relevance to the models studied) in the theory-praxis/data collection grid. Only 5 articles involved questionnaires and 9 articles the use of interview of developer related actors. Amongst the three forms of 'direct engagement', case studies were the highest form of interaction with 10 recorded. This however seems a low incidence over all.

Only three articles could be classified as a description of praxis (Bather 1976), (Drewett 1973 and (McNamara 1984) grounded by direct interaction with developers and related actors. Whilst Goodchild and Munton (1985) provided the closest model to a view of praxis (perhaps due to Goodchild's professional status as a chartered surveyor), it was not accompanied by direct engagement (except for Goodchild's obvious experience). Similarly Coiacetto's study (2000) revealed a more contemporaneous view of developer behavior, grounded by secondary data collection and interviews.

The vertical grading (theory/praxis) also served to filter out positivist approaches which relied on the statistical analysis of secondary data, which 'floated' to the top and middle of the chart. Collectively however, this and the other articles did not make for a substantial current depiction of either developer behavior, nor a development model.

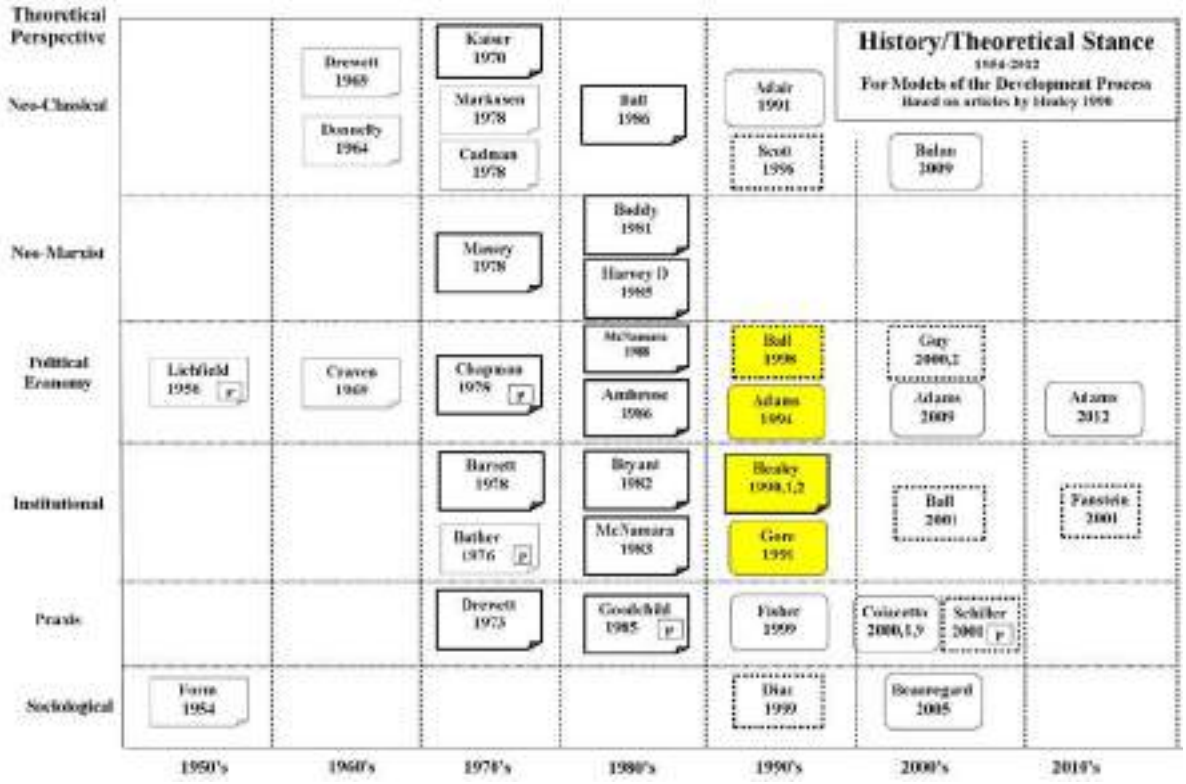

Figure 8- History/Theoretical Stance Map for Models of the Development Process 1954-2012.

The history/theoretical stance map, (figure 8) showed the limitations brought to the development of theory by a predilection toward theoretical visors with camps forming across neo-Marxist, Neo-classical and then institutional frames.

The map is useful in showing the fading of neo-classical and neo-Marxist emphasis over the decades, as the apparent ground wave of institutional and social frames invaded the theoretical landscape. All graphical or other models run dry however in the early 1990's. The remaining decades were spent in debates by the leading theorists as shown.

The geography/sector/country map, (figure 9) reveals an emphasis on regional and fringe studies, a paucity of both commercial and central business district studies, and the fragmentation of international research coordination. Residential studies dominate the literature and in fringe/regional settings. The UK leads in this research by study number, and there remains an apparent divide in theoretical perspective with USA's roots in a more neo-classical and statistical modeling tradition.

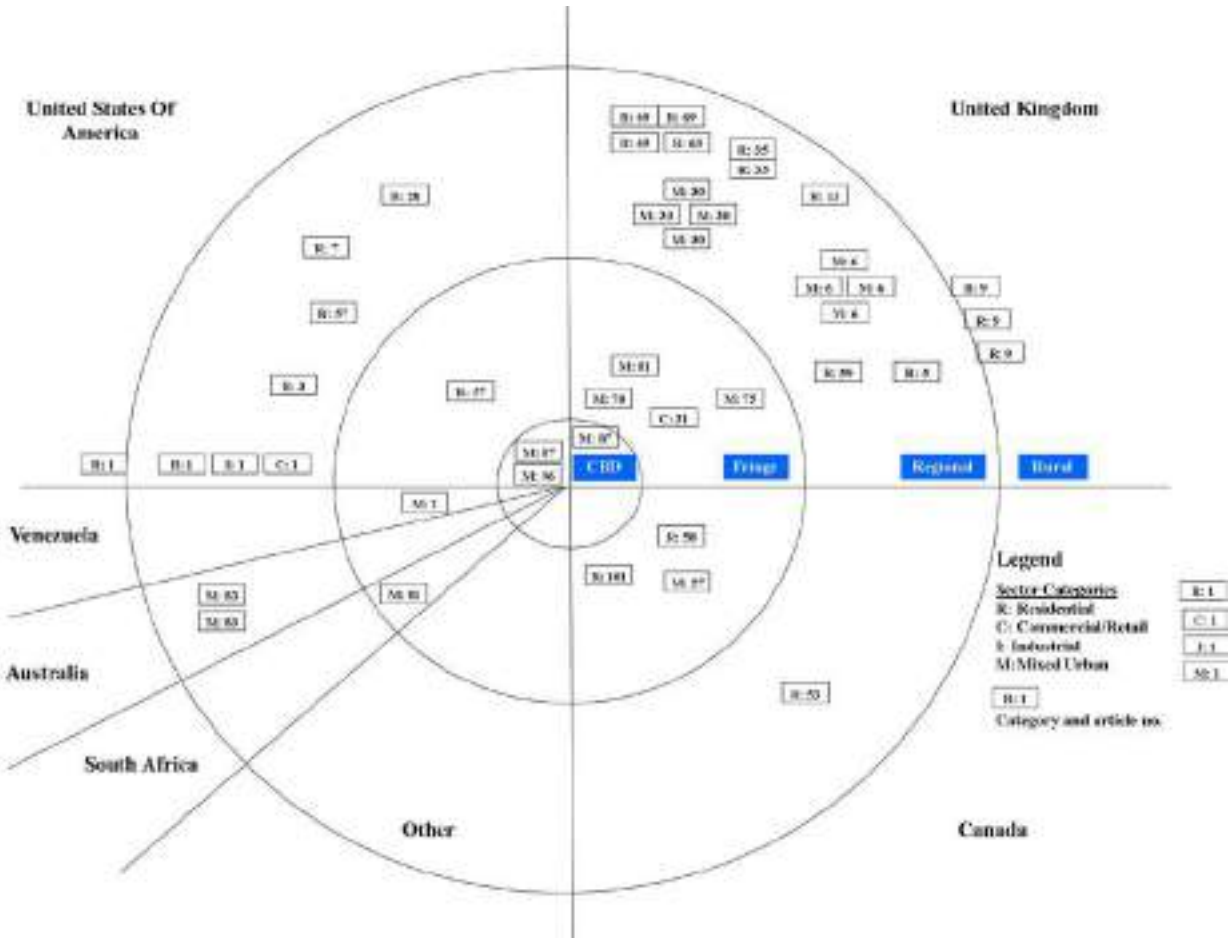

Figure 9- Geography/Sector/Country Map
for Models of the Development Process 1954-2012 (a register of articles on the map is shown in the appendix)

5.1 Praxis Matrix versus Current Theory- Taxonomy Tables

The taxonomy tables for the model of praxis showed how the existing literature 'covered' the various components and themes in the taxonomy. The areas shaded in grey highlight 'coverage'. The gaps are circled. It should be noted that the taxonomy diverges from typical 'process depictions' by establishing a foundation of dynamics and traits that underlie a mechanism. Another distinction which drives the descriptors in the taxonomy is the occurrence of 'conditions and factors precedent' to transition occurring, in favor of a sequential list of events. This introduces a mechanistic theoretical lens which is contingent and flexible.

Table 7 - Land Parcel Dynamics: Showing Gaps in the Literature (Circled).

Taxonomy (Elements-Themes-Traits)	Existing Theories						
1. Land Parcel Dynamics	1950's	1960's	1970's	1980's	1990's	2000's	2010's
Lots and Land Parcels							
Individual adjacent lots					Adams 1994		
Adjacent lot relationships- physical & commercial			Bather 1976		Adams 1994	Schiller 2001 Beauregard 2005	
Adjacent cityscape amenity relationships			Bather 1976	Bryant 1982	Adams 1994	Schiller 2001 Beauregard 2005	
Potential change in lot patterns- distribution or consolidation					Grove-Hills 1989		
Potential change in lot title and entitlements-change in use					Grove-Hills 1990		
Land parcel potential - initial and potential title patterns							
Land parcel potential transition							
Land parcel genesis							
Title Distribution							
Tradeable title patterns					Healey 1991 Adams 1994 Grove-Hills 1990		
Lot/title pattern change-distribution or consolidation							
Change in lot /title and entitlements-change in use					Grove-Hills 1990		
Parties to distribution- Ownership change			Massey 1978	Hooper 1984 5	Adams 1994	Schiller 2002	
Potential titled property/product						Schiller 2003	
Value Tension							
Differential adjacent lot/parcel values	Lichfield 1956	Drewett 1969		Adams 1985	Adams 1994	Schiller 2001	
Differential adjacent amenity values				Bryant 1982	Adams 1994	Schiller 2001 Beauregard 2005	
Commercial potential and viability- residual value			Barrett 1978	Hooper 1985	Adams 1994	Schiller 2001 Beauregard 2005 Adams 2009 Bullen 2009	
Attraction to transition status			Bather 1976			Schiller 2001 Beauregard 2005	
Arbitrage Nodes							
Arbitrage node based on differential value tension						Nauta 1987	
Transaction potential for transition		Drewett 1969		Bryant 1982			
Developer attraction					Adams 1994	Schiller 2002	
Third party attraction to transaction (e.g. purchaser/investors)					Adams 1994	Schiller 2002	
Volitional transaction potential							

Table 7 illustrates clearly gaps in the essential description of the dynamics of the distinction between lots and land parcels, parcel genesis and associated title transitions/patterns. The existing theory in effect is by this ruler, in its early stage of development in these areas.

Table 8- Developer Dynamics: Showing Gaps in the Literature (Circled).

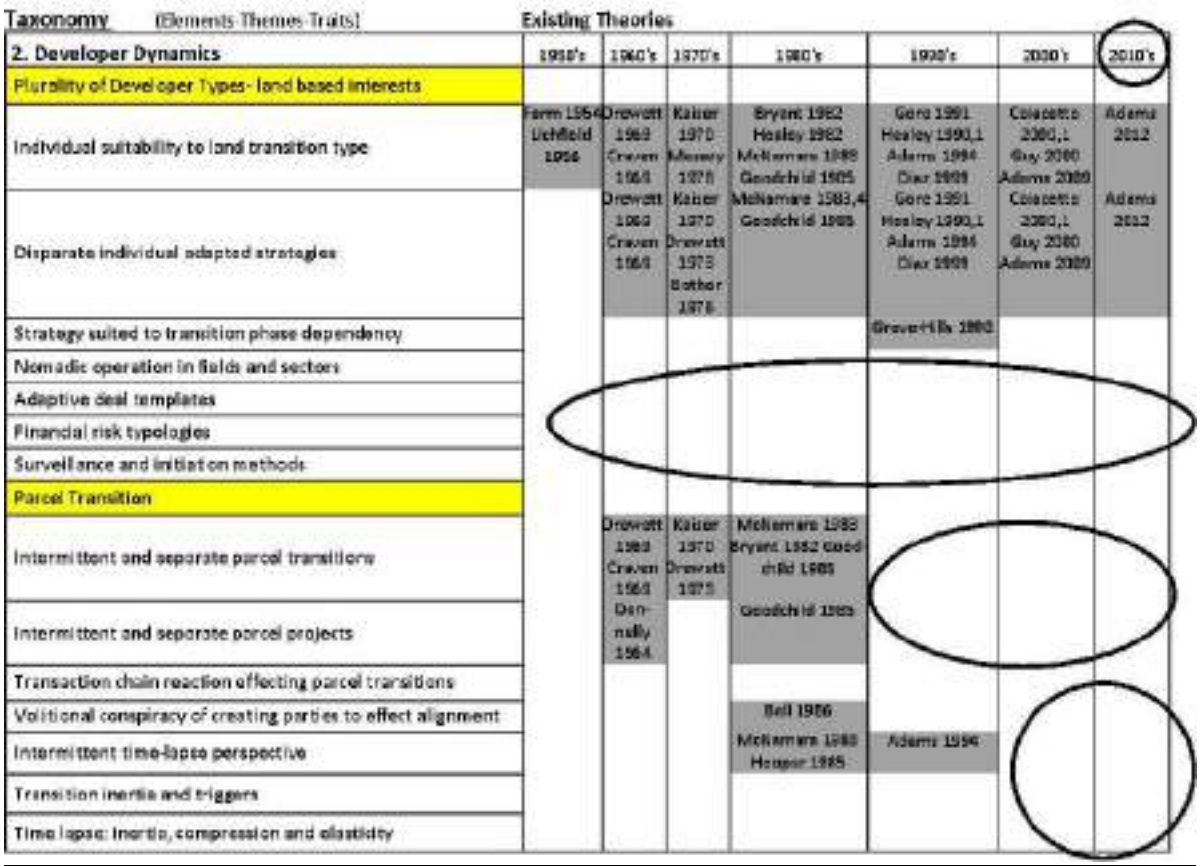

Table 8 illustrates that 'Developer Dynamics' are well covered in the understanding of the plurality of developer types and adaptation to different land uses and phases. However their essential nomadic behaviors and associated adaptive strategies types including nomadic site selection, adaptive deal templates, financial risk typologies and surveillance methods are not covered and particularly in the current context. Parcel transition and its both visible and invisible natures are not well identified.

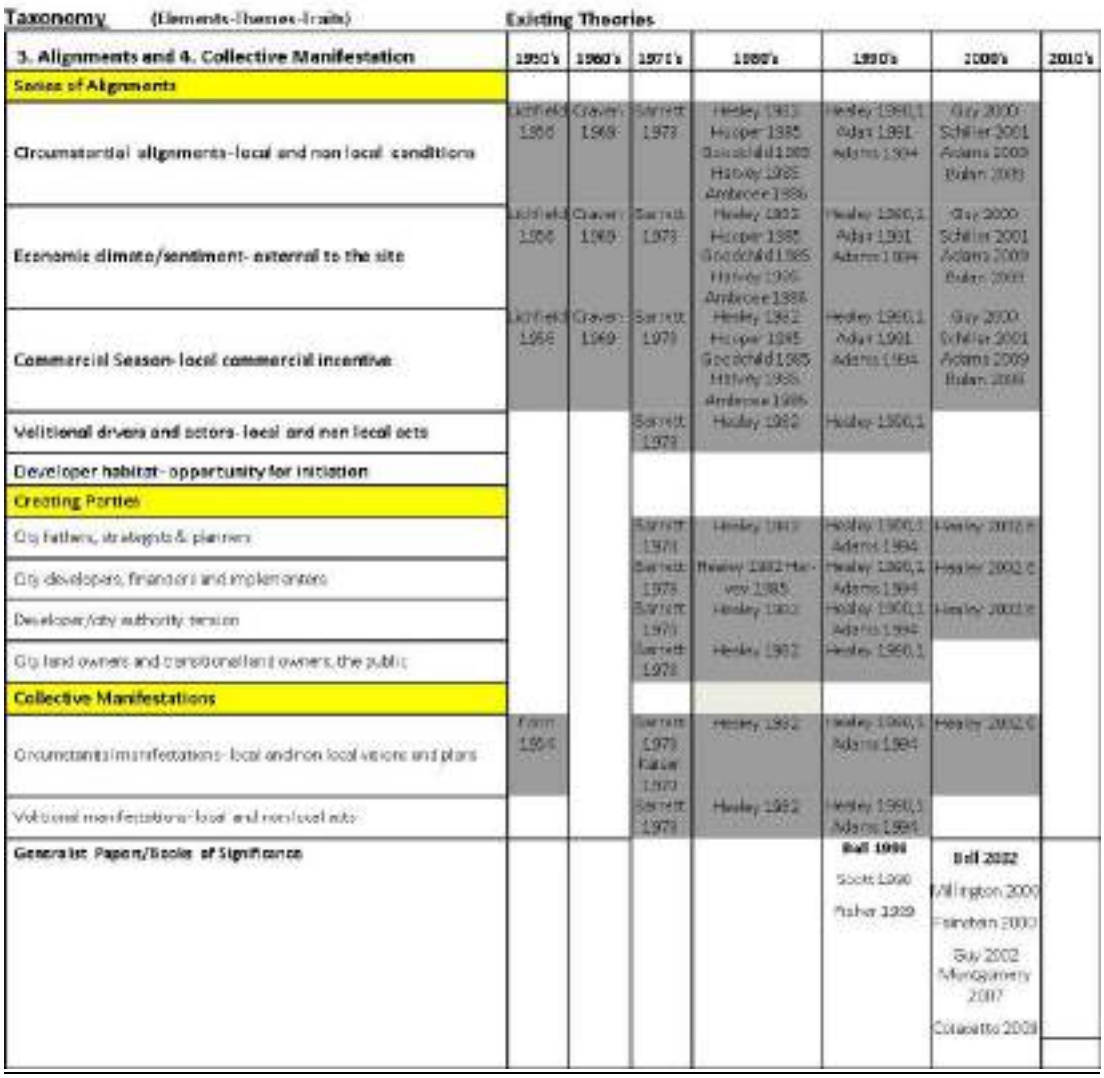
Manifestations & Alignments

Table 9 shows an extensive coverage of the area of collective manifestation which is related to the collective visions of creating parties, as this is a central tenet of the architectural and urban theory areas. The notion of circumstantial and volitional alignment is also well covered although in a classical economic and econometric manner (collectively).

Table 9- Manifestations and Alignments: Showing Gaps in the Literature (Circled).



Taxonomy (Elements-Themes-Traits)	Existing Theories						
3. Alignments and 4. Collective Manifestation	1950's	1960's	1971's	1980's	1990's	2000's	2010's
Series of Alignments							
Circumstantial alignments-local and non local conditions	Lichfield 1956	Craven 1969	Barrett 1973	Healey 1982 Hooper 1985 Goodchild 1985 Healey 1986 Ambrose 1986	Healey 1990,1 Adair 1991 Adams 1994	Guy 2000 Schiller 2001 Adams 2009 Balen 2009

Generalist Papers/Books of Significance					Ball 1998 Scott 1998 Fisher 1999	Ball 2002 Willington 2000 Fainstein 2001 Guy 2002 Montgomery 2007 Cowlitto 2008	

6. Conclusion

Using literature mapping techniques, the study clarified limitations in the literature on the 'models of the development process', based on the nature and conflict of various theoretical perspectives, lack of empirical engagement with developers and related actors, the need for greater understanding of developer practice and a substantial lack of emphasis on commercial and city centre studies. Most importantly, in the last two decades there has been virtually no growth in research in this area, especially like earlier eras, which paralleled the booms of the 1970's and 1980's and their aftermath.

The model of praxis introduced a mechanistic view based on three key elements: 'Land Parcel Dynamics', 'Developer Dynamics', 'Manifestations' which rotated in their own spheres but aligned under certain conditions, to trigger transitions in land

parcels. This 'reactive' model is based on a more phenomenological and ethnographic representation and understanding of the contingent and mechanistic nature of property development. This was compared with relevant theories in the literature, and the area of land parcel dynamics and land title transitions is not covered in detail at site level, nor the nomadic adaptive tendencies of the developer.

Development theory is outdated and in need of placement in the context of the contemporary (current) property development industry. Since the time of creating such models (1991) for example property trusts, both un-listed and listed have been created as a receptacle for the distribution principles noted in the proposed model. Equity and debt funding has taken other dimensions with the invasion of the equity layer with 'mezzanine finance', clouding the notion of ownership of individual project investments, and luring unsuspecting members of the public into often dodgy 'second mortgage' funding schemes.

Parallel with any further concerted studies and theoretical representations on the development mechanism, a current depiction of industry structure (Coiacetto 2009) as well a current history of the industry is essential, since Scott's excellent history went only until 1996 (Scott 1996) and that was in Great Britain.

Patsy Healey's institutional model remains, even after two decades, an extensive important timeless framework for theoretical and empirical analysis, but sits in a state of suspended animation. Michael Ball's model on 'structures of provision' also provides another key contingent perspective that has not been adopted substantially. Both are compatible with the proposed model of praxis, and it is suggested that this paper perhaps form a catalyst and framework for further investigation into this important area.

Amongst all the articles and books however, one passage rings in the author's ears, and was said apparently only in passing by Alan Hooper to Patsy Healey (Healey 1991, p. 232);

"Hooper (personal communication) has described such models as a 'machine waiting for a power source'."

The proposed model of praxis is a first step in revealing and understanding the nature of this, as well as a focus on theoretical perspectives that recognize that although the overall property development mechanism holds within it structures, actors, institutions and associated behaviors, as well as the essence of economies and political economies, the overall phenomenon ultimately has at its central platform the time lapsed, spasmodic transition of titled land to titled property.

Any study and associated theory of this vast and complex topic therefore, should perhaps be founded in this perspective, in effect– a view from the ground.
