= 0.0022kg (kg-NOx/km) × 22.4 (hr)/ 60 × 33.5 km/hr ×116,271 (People) ---(6)

=0.0022 kg × 0.373 (hr) × 33.5 ×116,271

= 3196.30 (kg- NOx /year)
= 3.20 (t- NOx /year)

3.2.3 Summary

Total emissions reduction by the policies is 346.67t-CO2/year in GHG and 6.97 t-NOx/year in NOx. The reduction undoubtedly benefits the global environmental challenges. In addition, considering the people who decide to choose to live in CBD instead of suburbs, GHG emissions reductions will be additional. The policies of Toyama certainly contribute to mitigate GHG and local air pollution.

4. Other Policies

Previous section has shown the core policies of the city, light rail and compact city, and Toyama also came up with supporting policies for variation in modal choices and CBD's attractions. Toyama's Cyclocity is a service by which one can rent a bicycle in the inner-city area and return it at any of the 15 stations scattered around the CBD. This service first became available in March 2010, and over the subsequent five months, the service was used around 24,000 times and registered 850 people as members (as of October 2010).

Cyclocity uses the same system as the Paris Velib system, in which those intending to rent a bike first register online and then use an IC card or enter a registration number at their desired station. Registered users pay 700 yen a month as a membership fee and rental is free for the first 30 minutes, 200 yen for the following 30 minutes, then 500 yen per 30 minutes thereafter. The pricing reflects that the organiser of the system expects people to use bikes for short rides over short periods of time.

The system is useful for supporting the compact city idea as it supplements the public transit system and gives the residents more choices for modes of transportation. City officials have commented that this system was being widely used in less than a year from its introduction, which is a very short period of time. The reasons why introduction of Cyclocity was a strong political will by the City Mayor Mori, 100 % covered initial cost subsidy by MOEJ, the relatively wide roads in the inner city area of Toyama, and the mutual understanding of the city's compact city initiative within city hall departments, such as the police department, which is in charge of roads' usage and safety.

Figure 2. The Cyclocity System in the Centre of Toyama
Note: Left - A Cyclocity station in front of Toyama castle. Middle - Users pass their registration card over the IC reactive port next to a bicycle when renting. This is exactly same system as Velib in Paris. Bicycles are also imported from France. Right - One of Cyclocity's stations at night; all stations operate 24 hours.

5. Challenges

There are three major challenges that the City of Toyama faced: the financial burden, the coordination between the prefectural and national government, and the cooperation between local businesses and citizens.

LRT (Light Rail Transit) system is the city's biggest investment. Generally, in Japan, except for the biggest cities like Tokyo, Osaka, and their adjacent cities, it is difficult to make a profit with fixed-rail systems. Governments mostly invest in construction and maintenance of fixed rail networks. The profitability of the lines in mid-sized or smaller cities depends heavily on the reduction of operation costs. For the case of Toyama, the initial cost of its light rail transit system was subsidised considerably, as was its maintenance. In terms of actual operations, it is realising a profit and the positive externalities to urban planning and mobility benefits for citizens are significant. Therefore in Toyama as well, the total cost and benefit is not profitable. However, considering the negative externalities of using single occupant vehicles causing to both local and global environment, the investment in this LRT is commendable.

Coordination between the prefectural and national government, the prefectural government and the city government is actively facilitated partly because these entities are situated next to each other in front of Toyama Castle. This geographic proximity that has led to the strong partnership in creating Toyama's compact city. Initial investment for the Toyamako line from the prefectural government amounted to 16% and that from the city government was 33%. The national government also subsidised the line significantly as it is considered a project of MLIT. The Ministry has had a policy of subsidising the introduction of LRT systems since early 2000s. The partnerships here and the resultant outcomes of their combined efforts demonstrate that it is essential to be on good terms with other governmental bodies in making drastic changes in urban planning.

With regards to cooperation between local businesses and citizens, the city has realised successful partnerships between the private sector and its citizens. Because all Toyama's private transport businesses operate under one big company, Toyama Regional Railway, which is in charge of both fixed rail and buses (except for those belonging to JR), obtaining a consensus for use of public transit system was easier than in other cities. Furthermore, many local business owners wanted to invest in public-private joint venture companies in the operation of the LRT. In addition, nearly 80% of citizens stated that they are highly satisfied

with the new LRT lines . Thus the compact city initiatives and LRT development have been favourably welcomed by both local businesses and citizens alike.

6. Conclusions

The city of Toyama provides a good example to fast growing cities in the Asia-Pacific region as the city is promoting multi-core development, which is a useful concept for cities undergoing rapid growth. As it could reduce both GHG and NOx, it is a good policy measure for co-benefit of GHG mitigation in urban areas. The overall messages for mid-sized cities are the following: 1) Importance of multi-stakeholder initiatives, 2) Importance of a top down political will, and 3) Leapfrog in the development of a multi-core compact city;

First, the importance of multi-stakeholder initiatives reinforces the importance of building partnerships among the different levels of government, private sector, and citizens in urban planning policies. Aomori compact city was a stereotypical representation of Japanese government-led regional development projects prominent in the past: excessive investment in building and infrastructure and little interest in conceptual framework and management to run the new investment (Kono 2011). Toyama has created an original plan by creating many partnerships among stakeholders, such as railway companies, small business owners, and through a constant dialogue with the citizens.

Second, a top-down political will is important to pursue the big projects like Toyama. Toyama has been headed by Mayor Masashi Mori since 2002, who has a strong aim to make the city attractive and sustainable. His sense of crisis was blossomed as changing the city into Transit Oriented Development and the city official and citizens well cooperated to his idea. In a way, he is like a former Curitiba mayor, Jaime Lerner or Bogota mayor Enrique Peñalosa, who were succeeded to make both cities transit oriented development in a short period.

Lastly, considering leapfrogging to a multi-core compact city, it is important to plan ahead to determine smaller city boundaries. City officials say that even cities that are currently experiencing rapid urban expansion like China, it is important to work on the compact city idea. After all, it is very hard to compress a city once it has broadened. Especially in this age of scarce energy sources and global warming, cities should not just expand—they should leapfrog toward a multi-core compact, transit-oriented style city depicted by Toyama.

An Evaluation of Planning and Organization Process of Sporting Event: The Case of Formula 1 in Istanbul

Prof.Dr. Ferhan Gezici Korten, gezicif@itu.edu.tr
Istanbul Technical University
Serra Er

1. Introduction

From rational planning to collaborative planning, it has been well known that planning involves complexity through the negotiatons among different actors. Harvey (1989) has defined the occurring paradigm shift in urban policies as the "transformation from managerialism to entrepreneurialism"; using the term "governance" instead of "government", emphasizing that the authority to organize space is in the hands of a fragmental power involving many actors.

On the other hand, cities have been changing with the winds of globalization, transforming economic structure from production to more consumption based economy. This economic structure which the private sector has raised inside, the open market dynamics and re-distribution mechanisms have been modified only for certain classes, has become more dominant. Therefore, real estate, construction sector, cultural industries and organizing events have become rising sectors within the cities.

Especially in the 1990s, international events have increasingly become a new tool for attracting visitors, bringing revenue for the cities and enhancing their competitiveness, while Amin (2007) and Urry (2002) called this process as "selling places for pleasure". There are variety of reasons why cities may wish to host these

events, the most compelling being the promise of a vast economic windfall forecast by economical impact studies (Burns and Mules, 1986; Hiller, 1998). Given these forecasts, an increasing number of developing economies have joined the bidding frenzy, insisting on their right to receive a share of the monetary spoils and hopefully kick-start their development. Discussions generally focus on three main points: the organization and financing, the effects, particularly the economic effects and the legacy and sustainability of the events. Not only the direct economic impacts through the visitors spendings, but the secondary economic impacts have also be the research interests (Gratton et.al, 2001; Roche, 2000). Generally the events have been used as urban regeneration tools, while the changing land use pattern and increasing land values have become a significant agenda for the urban studies.

Nowadays, many of the entrepreneurial cities desire to implement the urban development policy by establishing public-private partnerships and these partnerships have been seen as products of the new economic and political understanding (Evans, 2005; Smith, 2007). Mega events are always encouraged by the business elite or implemented by carefully mobilizing their support. Political actors have been a part of this elite coalition because public funds and subsidies of governments are inevitably needed for the implementation of mega events. In fact, the decision to host a mega event is the consensus of the bureaucratic elite, who have been chosen officially, and the government. This decision has become a part of the grassroots democratic decision-making process. The organizers, developers and sponsors assume that the events are absolutely successful; either there are none or very few, negligible negative effects (Hiller, 1998; Bodwin et.al.2002). The lack of transparency in the process continues to be dominant in the implementing organizations (Horne and Manzenreiter, 2006).

Mega events require the mobilization of public resources, which is a reflection of political decisions but not a public consensus, due to the large financial burden that they have caused. Generally, public spendings on these events have been legalized, emphasizing the long-term gains; urban infrastructure and renewal projects, the

increase of international recognition and tourist visits (Hall, 1992; Andranovich et al., 2001) (Figure 1). There is a high cost for maintenance and the truth is that it is now very difficult for a sports facility to be financially viable without some degree of public subsidy (Aman et.al, 2009; Horne and Manzenreiter, 2006).

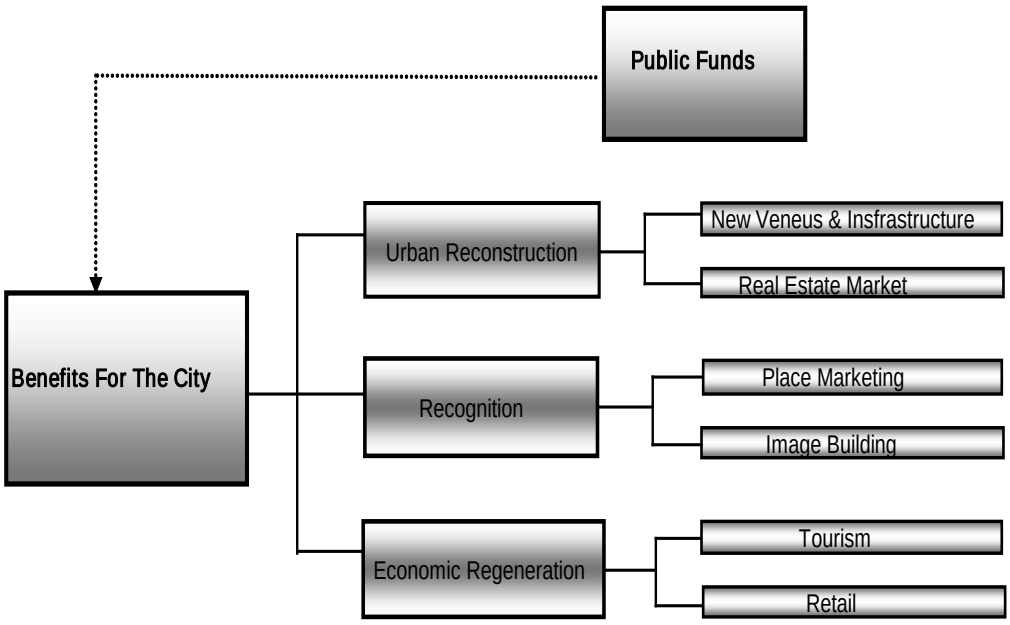

Figure 1: Public Funding and Expected Benefits of Mega Events

The aim of this paper is to examine the hosting process of Formula 1 as a sporting event in Istanbul. However, after the year 2011 Formula 1 events will no longer take place in Istanbul due to the lack of audience and very high costs, and it contains important lessons for Istanbul. Therefore, the paper tries to put forward the issues of Formula 1 event in Istanbul, considering the planning and organization process, rather than expected economic impacts. Planning process would include the selection of "Tuzla Akfırat region" as the location of the event and functional changes, while the organization process includes the actors that involved in the formation process of Istanbul Park, along with the funding structure.

2. Location Decision and Planning Process of Formula 1 Istanbul Park

Location choice for an international event within the city would be considered with the requirements of event and the priorities of the city itself. Furthermore, the location decision of the event mostly defines the benefits of the event. While the venue and public infrastructure should be constructed in a location within the city to provide maximum benefits for urban redevelopment, the location decision would guarantee that there would not be a problem neither at the neighborhood of the event, nor the other parts of the city. If the location of event would require transportation infrastructure such as a new airport, highway or subway, not only it creates high public spendings, but the land use pattern and the land values are influenced by the events as well (Darcy, 2006).

Before evaluating the location decision and planning process of Formula 1 Istanbul Park, we summarize the story of interest for Formula 1 in Turkey. The live broadcasts of the races on Cine-5 in 1995 and subsequently on NTV in the 2000s with the enterprise of some individuals have raised an interest for F1 in Turkey (Okumuş, 2008). At this point, sympathy of the society for the "red colored car", even if not for F1, played an important role (Özener, 2009).

Turkey's Formula 1 adventure started not with the rising expectation from society, but with the enterprise of some business elites in the 2000s. With the support of the government, the municipality and the professional organizations like the Istanbul Chamber of Commerce, the snowflake turned into an avalanche (snowball effect) and the residents of Istanbul suddenly found the race in their homes (Okumuş, 2008).

Matters escalated after Bernie Ecclestone, president and legal owner of the Formula One Administration (FOA) procured a boat in Tuzla, Istanbul met with the president of the Turkish Automobile Federation (TOSFED), a member of the World Motorsports Council. The beginning of the 2000 was the time when Ecclestone

started meeting with potential entrepreneurs from all over the world, making comments about organizing GPs in countries other than in Europe and the Far East. In the 2000, as Formula 1 prepared for new racetracks, Turkey, Beirut, Russia, Saudi Arabia, China and Dubai were mentioned in the GP options that the FOA had approved.

On Champions' Night, organized by the Turkish Automobile Federation and Motorsports Federation (TOMSFED) in January 2002, it was announced by the president that they had received a letter of approval from the F1 boss. This occasion pulled the trigger, now it was time to choose the city and with the support of the central administration, officially start the F1 adventure of Turkey.

It was announced to the public by the Formula Association members that a Formula 1 event is a prestigious tourism opportunity that should not be missed. Three big cities (Istanbul, Antalya and Izmir), that were willing to get a share from this promising pie of economical income and the tourism potential, were put into a nine month long race. The chosen city was Istanbul, as the site selection for the Formula 1 races in Istanbul took much less time - in one month compared to the city selection. The chair of National Olimpic Comittee suggested that the land surronding Olimpic Stadium within the European side of Istanbul would be the most suitable location since it would decrease the infrastructure cost with its existing one. However, it was reported that the location decision was made by Bernie Ecclestone and preparations started for the construction of the race track in Akfırat, Tepeören at the Asian ring of Istanbul. Therefore, the location of event is expected to stimulate new development within the periphery of metropolitan area by asking high cost infrastructure.

The Istanbul Chamber of Commerce (ITO) was the candidate to realize the Formula 1 project, the chosen land was the one that the ITO rented from the Prime Ministry Directorate General of Foundations in order to construct a university. This location was contradictory to the master plan of the city; it was also a foundation forest that was within the limit of a long-distance conservation area for water reservouir basin (Figure 2).

With the Formula 1 race track selected at the Akfırat, Tepeören locality, rumors of foul play took place in the media. Some said "*the good luck bird landed on the region*" (URL-1), some said "*The champion of the Formula 1 has already been decided*" (Saymaz, 2003). The landowners, the sizes and quantity of these lands belonging to certain capital groups were announced in the media (Mercan and Gün, 2006). However, the decision of Istanbul Park is not the only stimulating effect for the region. While Akfırat was one of the neighborhood of Kartal municipality in 1978, it became an independent "belde" municipality. Although one of the neighboring municipalities (Kurtköy) has faced with the new housing development projects in 1985, Akfırat was a small and quite village in the perihery of Istanbul until 1998. Sabiha Gökçen Airport awaked the real estate investors in 2001. Later, Formula 1 as a flagship project has attracted the investment to Akfırat since 2003 (Figure 3). Formula highways combine airport and city center to Akfırat. Professionals agree that construction of highways is the main impetus for the transformation of Akfırat and increasing land values.

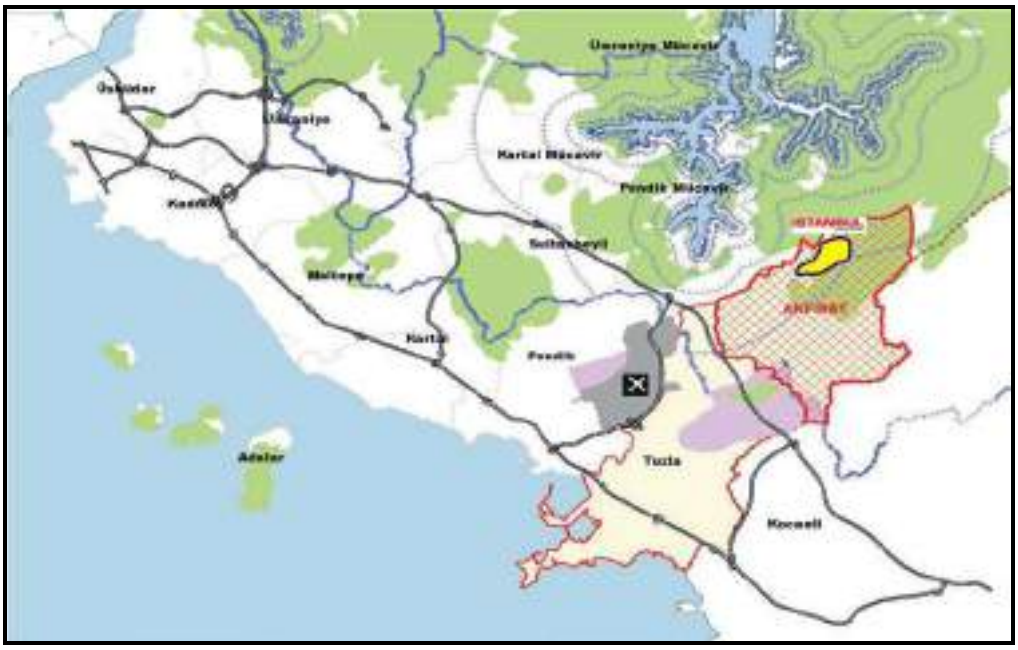

Figure 2: The location of Akfirat and Formula 1 Istanbul Park

During the location decision process, the toughest opposition was not the concern about the economical impact of the activity, but about the mistake made in location decision and the environmental risks it would bring. Eleven organizations such as the Chamber of City Planners objected to the land chosen for the construction of the race track. The president of ITO, however, considered this objection as a mass opposition and saw the Environmental Impact Assesment report as the largest obstacle to the Project.

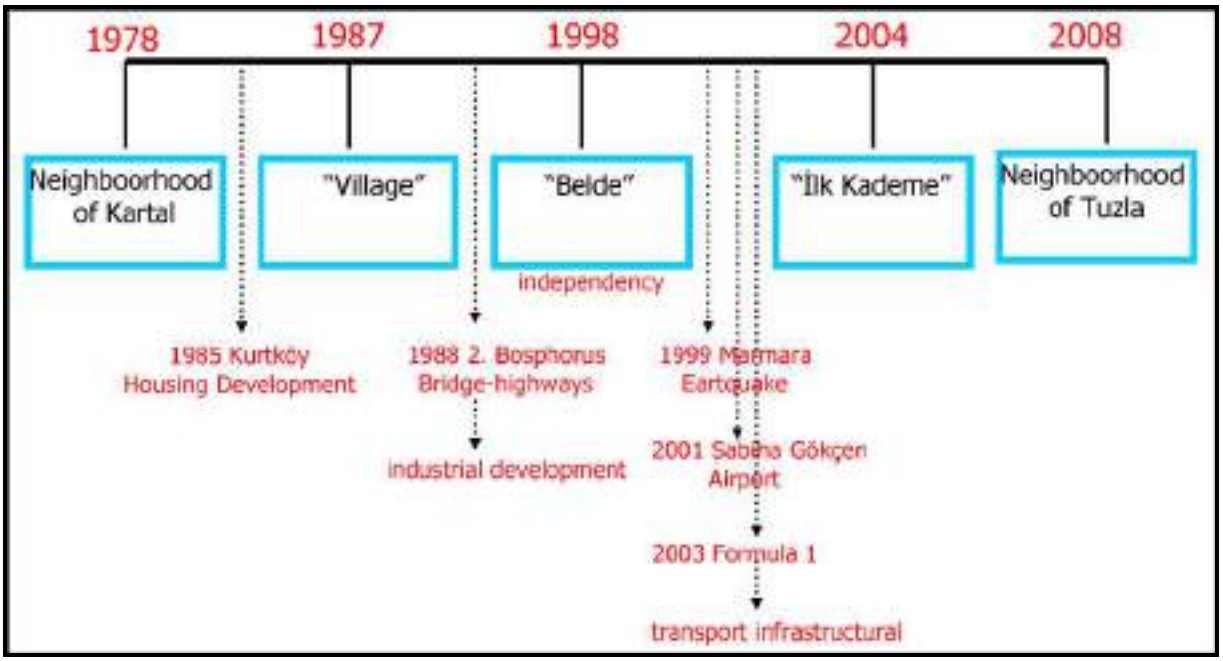

Figure 3: The stimulating factors for Akfırat during the 30 years (1978-2008)

Regardless of the objections to the site selection and the decisions of the upper scale plan, in the 09.09.2003 approval dated and 1/50,000 scaled plan change and with the 1/5000 and 1/1000 scaled master and development plans prepared according to this plan, Tuzla district, Akfırat area, the parcels considered for Formula 1 were removed from "Forest Area and Area for Forestation" legend and added to "Formula 1 Istanbul Automobile and Other Motor Vehicles Sport and Competition Area" (Figure 4).

Soon after, the construction of the Formula 1 race track commenced on September 10, 2003. According to the 2004/7214 ordinance, which was approved on April 28, 2004 by the Council of Ministers, "Formula 1 Istanbul Automobile and Other Motor Vehicles Sport and Competition Area" was announced as the "Tuzla Akfırat Tepeören Tourism Center". Thus, Istanbul Park was relieved from the on-going discussions about the site selection and the planning process, however the local and central government are both from the same political party. Therefore, the story of

Formula 1 indicates that it has been a top-down decision by ignoring the public interest.

3. The Organization and Financial Structure

FIYAŞ (Formula Istanbul Investment Inc.) was established in February 2003 to construct facilities, manage and organize sporting activities by the ITO (Istanbul Chamber of Commerce) and ITO Educational and Social Services Foundation with a capital of 10 trillion TL. Even though FIYAŞ had a wide mission regarding the sporting activities, the main purpose of its foundation was to become the investor of the Formula 1 race track of Turkey. The company guaranteed to pay 2, 000 dollars monthly for the first years for the 2250 acres of area that they had rented from the T.R. Prime Ministry Directorate General of Foundations. Starting from 2005, when

the first races were held, it would rise 2% per annum, 30, 000 dollars of monthly rent (Mercan, 2003).

According to the agreement, FIYAŞ could not undertake the management of the racetrack, therefore Motor Sports and Organizations (MSO) was established and took charge of the management. The company would make the promotion of Formula 1 and manage the income. (Url -2; Url - 3). On July 24, 2002, the government decided to pay 13.5 million dollars racing charge to the organization in order to support and undertook the guarantorship duty of the Formula 1 races and in August of 2003, a 7-year contract was signed with FOA.

As the cost of the Formula 1 circuit, Istanbul Park, rose drastically from 25 million dollars to 130 million dollars and there was a risk of completing the construction on time, with the intervention of the central administration, the Turkish Union of Chambers and Stock Market (TOBB), the Istanbul Metropolitan Municipality (IBB) and the Istanbul Provincial Administration were involved as partners to the Istanbul Chamber of Commerce (ITO), who started to undertake all of the costs. By 2009, 40.65% of the shares belonged to FIYAŞ, 39.92% to ITO, 0.73% to ITO Foundation, 3.66% to ISTON A.Ş. (IBB), 3.66% to ISFALT A.Ş. (IBB), 3.66% to KIPTAS (IBB), 7.69% to Istanbul Provincial Administration (İ.İ.Ö.İ)[1] (Figure 5).

Although staging different activities other than Formula 1, it did not create any profit from management in the first two years. Therefore, it was thought that Istanbul Park would be better managed by the private sector. The bidding for the management of Istanbul Park was held in June 2006. The only offer was made by the Turkish Travel Agencies Association (TÜRSAB). However, an agreement regarding the terms of management could not be reached with TÜRSAB. Soon after a proposal was made to Bernie Ecclestone, the president of Formula One Management (FOM) and the race track was rented in 2007. Istanbul Park Organization Inc. was established for the

[1] Interview with F. Gündoğan,14.07.2009.

management of Istanbul Park, with 100% participation of FOM. According to the agreement, Istanbul Park Organization Inc. would manage the Formula 1 circuit, Istanbul Park for fifteen years with an annual rent of 3 million dollars.

In January 2009, something unexpected happened; Bernie Ecclestone announced to the media that he wanted to resign from the management of the Istanbul Formula 1 race track. As a matter of fact, FOM president had never managed a race track before; his first management experience was Istanbul Park. After this statement, the ideas and concerns about the projects for rescuing Istanbul Park were begun to be intensely discussed in the media (Tek, 2009).

Since the Istanbul Park Race Track, was rented from TR Prime Ministry Directorate General of Foundations with a build-operate-transfer model for a period of 20 years; FIYAŞ has been paying 30,000 dollars as rent since 2005, on the other hand, receives 3 million dollars from Istanbul Park Organization Inc. as annual rent for management. FIYAŞ also receives 45,000 dollars annual rent from the GSM transmitters on the racetrack. With all of this rent income, it seems impossible for the Istanbul Park investment to interest FIYAŞ. When we asked about the expectations from the investment, FIYAŞ executive's response indicates how far the interest of the investment is: "*The return is impossible. We have made some calculations, indicated some foresights, but not much comes out of these. Considering that we have spent 200 million TL for the race track, it sums up to a 10% interest per year, we spend that money as rent. It means that we have to make 20 million TL annually in order to get an interest in 200 years*"[2].

Looking at the financial situation in context of the Istanbul Park Organization Inc., the chart does not seem promising. The only income that the Istanbul Park Organization Inc. gets from Formula 1 racing is provided through the revenue earned through ticket sales. All of the revenues from sponsorship and broadcasting rights are transferred to FOM. It seems impossible to level the income – expense ratio for the

[2] Interview with F. Gündoğan,14.07.2009.

events other than Formula 1 without the backing up of a strong sponsor to cover the expenses of the events[3].

The executive of the Formula 1 circuit, Istanbul Park indicates that the maintenance costs are also very high due to the size of the race track. It is also clear that there is no financial interest on the annual cost of the 13.5 million dollars that the Republic of Turkey Prime Ministry Promotion Fund pays to FOM. It was thought that the interest of this expense would be covered by the value-added tax expenditure of the 50,000 tourists who would come to Turkey for Formula 1. This calculation method is problematic considering the 2009 Istanbul Park Grand Prix tickets sold to the tourists were no more than 10.000. After all these, there has been an uncertainty about the future of the Formula 1 Grand Prix in Istanbul. After the year 2011, Formula 1 events will no longer take place in Istanbul due to the lack of audience and very high costs, while it contains important lessons for Istanbul.

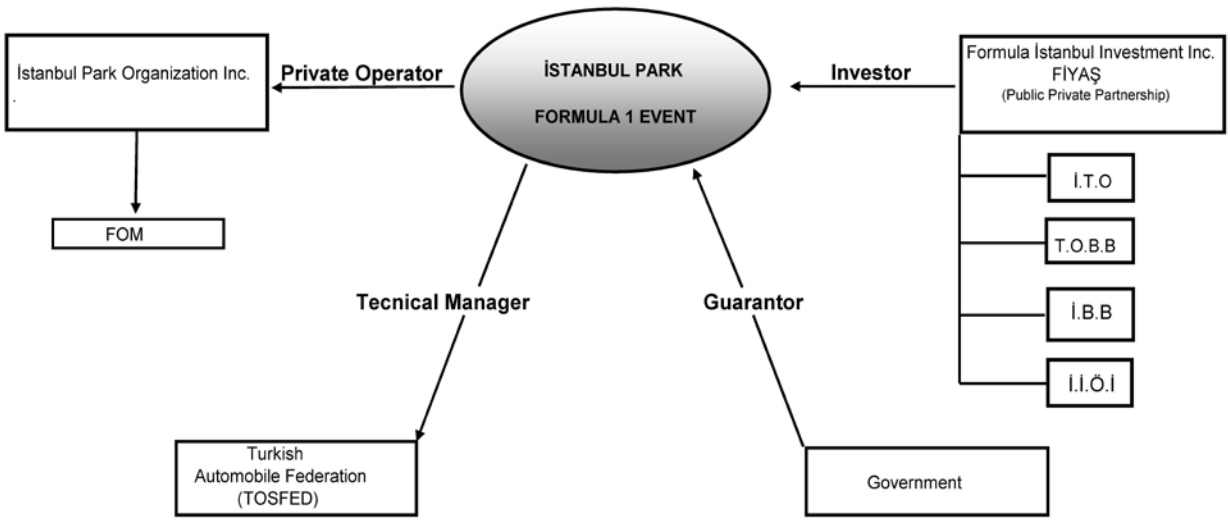

Figure 5: The organization scheme of Istanbul Park Formula 1 Event

[3] The interview with C. Güçlü, 13.07.2009.

The Bahrain Grand Prix is set to return to the Formula One calendar 2012, with the Turkish GP to be dropped. Simone Perillo, general secretary of the Formula One Teams Association, tells The Associated Press that Turkey did not make the cut while Bahrain will be held in November 2012.

4. Conclusion

Evaluating the main issues regarding the site selection and organization process of the event in Istanbul constitutes the aim of this paper. Istanbul Park Grand Prix was organized not by the public will, but a group of business elites who wanted to bring the Formula 1 event to Turkey, convincing the public will to be the stakeholder of the event.

A group of business elites' stimulating global scaled sports events, persuading central and local government to be the stakeholders, is a phenomenon seen not only in Turkey, it is a common feature of almost all global scaled events. The role of public in this case of Istanbul Park Grand Prix, could not go further than solving the problems that had been raised by the discourse of urgency; the plan had to be done urgently; the license had to be taken urgently; the facilities and infrastructures had to be constructed urgently. In fact, an adequate social consultation did not take place in all these discourses of urgency, the social opposition, which is related with the site selection of the event rather than event itself, has not been taken into consideration, besides, the opinion of "social opposition had been against development" was attempted to be imposed to public. Public opinion had not been informed that hosting such a high cost event actually carries "great risk". Public sector has failed to perform its most important role; proving the legitimacy of the event, defining and controlling the accountability tools, while it took the risk as well.

Furthermore, Istanbul Park as the stage of the event, was constructed in a "Forest Area" and a "Water Basin", without any environmental concern. It was built

physically larger than needed and this has caused the maintenance costs to skyrocket. Financially, the cost of Istanbul Park is huge, however the participation levels have not been achieved, turning out to be a lot lower than the capacity.

Contrary to widespread world examples, the Akfırat Region is not a rundown zone nor a region that had lost its reputation or needed the urgent development of infrastructural development. In the case of the Istanbul Park Grand Prix, the event and the infrastructure investments for the event have raised the pressure upon the region. Therefore, Formula 1 is one of the main stimulating factors of development within Akfırat by making the region "accessible", "well-known" and so-called "prestigious", while there is not any sustainability of the event anymore considering the high expectations.

The Preliminary Study on the Design of Rural Public Space in Rapid Urbanization Sichuan, China: a Case in Zhaoyan Village

Abstract

Under the rapid urbanization process, the fluidity between urban and rural has increased; the traditional inward-looking lifestyle in rural China has collapsed gradually as well. Meanwhile, space structure has transformed dramatically, traditional public space has declined, and however, the modern public space hasn't turned up. Because of the misunderstanding of difference between urban and rural lifestyles, many rural planning copy the way that constructing urban public space, as a result, the space cannot coordinate with the need of rural daily life. How to create a public space that peasants really need is quite an important problem. In the rural planning project of Zhaoyan village, Dazhou, Sichuan Province, the design was focused on the two central public spaces at the second half of 2009. An overall investigation was done before and after the reform construction. In this paper, a design strategy of public space which is able to adapt the reality of contemporary rural China through the work that summarize and analyze the whole project data, combined with several related theories, such as sociology, architecture and urban planning. Exploring the strategy of rural public space design and suggest a further guidance related to the design practice: conclude the lifestyle of peasants; respect the exiting functional public space.

Keywords: Urbanization, rural lifestyle, public space, Zhaoyan village, design strategy

Under the arrangement of the tutor, the author was lucky enough to come into contact with the reconstruction project in Zhao Yan village in Da County, Si Chuan province in August, 2010. This extremely characteristic transformation project had been launched by the local government in Da County, whose purpose was to respond to the government's job evaluation on "the new rural construction" project through reconstructing key villages within the scope of the county. As the key demonstration village in Da County, Zhao Yan village situated on each sides of the Ting Fu road, which is the main path to Zhen Fushan, an important 4 A level scenic spot in the county. For various considerations, it has become the key area of this activity.

Zhao Yan village has formed a certain scale early in the Qing dynasty. It was

reported that a person in this village whose family name was Zhan had successfully made himself an assistant minister in the imperial court. Except him, there were many other prestigious families in this village as well. Even up to today, lots of old houses and tombstones in the Qing dynasty that are incompletely preserved can still be found. Nowadays, Zhao Yan village comes under the jurisdiction of the pavilion village and has been divided into nine communities. According to the official statistics, there is a total population of 1526 and there are 413 households in this village. This reconstruction project focuses on the fifth and the sixth community with 91 households and a total population of 406. Ranging to 7 meters and being built in 1997, Ting Fu road has been the main road in this village, which was first built to connect the pavilion town and Fu Shan village with its southern end pointing to the 4 A level scenic spot--- Zhen Fushun. The whole village covers 2340 mu of cultivated land, which is divided by residents in this village and situation differs in different communities: the first community (a mu of three points/per person), the second community (a mu of two points/per person), the third community (eight points/per person), the fourth community (a mu of four points/per person), the fifth community (seven points five/per person), the sixth community (seven points four /per person), the seventh community (six points five /per person), the eighth community (nine points /per person), the ninth community (nine points/per person). The industry structure of this village is based on agriculture and its main project is aquaculture and lotus planting, along with a small amount of single season rice and corns etc. In the time of midsummer, those large lotus ponds present the beautiful and breath-taking scenery, just like the famous Chinese poem goes “The green lotus leaves stretch to the sky”, which does leave a deep impression on the author. In addition, in the beginning of the design, the village has already had a sound infrastructure as well as a perfect system of water, electricity and gas, other facilities like public toilets and stores have existed in there, too. However, the village still lack of necessary garbage collection points and proper management to the street lights that have been damaged; meanwhile, villagers have no essential education and sports facilities as well as a public space for necessary gathering and festival celebrations. As to farming cartilages, most of the existing farming cartilages within the scope of the design were built along the street after 1997, among which, only 14 of them were built in the period between 1950 (land reform movement) and 1997, 11 of them were built before the land reform movement and 2 of them had a hundred year’s history. The architectural style of these cartilages is what is popular in the village now, that is, brick buildings covered with ceramic tiles outside, the only reason for that is because there is a modification in 2004 that houses with traditional structure are to be separated from others by the painting in the gables of the farming houses. Generally speaking, the living standard of the villagers in Zhao Yan village has been fully guaranteed, but the further social public life as well as the spiritual life are still deficient and need to be improved immediately.

This project only focuses on the major areas of the village due to the urgency of the design task. With the responsible attitude for government and humanistic care, the design team decides to choose the public space as the core of this design by taking the content of this project and problems caused by the phenomenon of rural hollowing into consideration. But here comes the problem: as a rural project, what kind of public space is more fit in with the requirements of the villagers? Should it be a square or a more casual public space? If it is a square, then is there any similarity between the design of the rural square and that of the cities'. At the same time, what should they do to reflect the rural characteristics? With all the concerns mentioned above, the design team puts their own understanding of the rural areas into the design of this project.

The idea of the design comes from two aspects: on the governmental level, in order to achieve the goal of the evaluation, the plan will focus on the design of several public spaces, hoping that they can form a visiting line along with other scenic spots so that the main achievement of the new rural construction project will be highlighted. While on the villagers' level, designers hope to explore the public spaces that belong to the rural areas as much as possible and to present the rural characteristics. From this perspective, in the overall planning, designers have selected two key sections: the square with the village committee sitting on it and the southern area of the village with the most intensive farming housing distribution. The reasons for site selection can be listed as follows: first, they all located on the side of the pavilion highway, on one hand, it is good for the construction and presentation of the landscape and caters to the demands of the superiors' visit and inspection; on the other hand, considering the factors of accessibility, sites that are convenient for villagers to come and go will be conductive to the use of the space and improve the significance of the space on the villagers. Besides, two pieces of main design area all own relatively open land, which can be transformed into appropriate public space and ensure that the idea of the designer, Party A's requirement and local people's needs will be satisfied at the same time. While in the design of these two pieces of land, the design team thinks that it would be better to treat the village square as the democratic rally square without huge modification for it has already existed in there, so only the walls around the square and its internal facilities will be transformed and more energy is going to be put on the other side of the village square. The selected land of the village square situated in the settlements on the roadside, which is about 45 meters wide, 65 meters deep and covers an area of 3000 square meters, shaping like the bow of a ship. This place used to be a farmland possessed by a farmer living nearby and it is chosen as the best place to put the square for its good location, its comprehensive landscape display as well as its accessibility and availability for public activities.

As to the specific design of the square, several questions must be taken into account: What will happen if squares, a public goods, appear in the villa where the

environment is quite different from that in the cities? What measures shall designers take to minimize the disadvantages brought about by this difference? What kind of squares are villagers' public squares? What shall be contained in these squares? How can designers make villagers feel a sense of belonging? These questions lead to the concept and the starting point of the design of the squares. In the designing process, designers take into account the particularity of the rural environment while purposefully lower the openness and liquidity of the public space. Meanwhile, they decrease the area of afforestation, the sole function of which is to add beauty to the squares. In choosing materials, simplicity and convenience are given top priority for the sake of construction difficulties and follow-up management. In designing their looks, traditional and modern elements are combined to satisfy the taste of rural residents.

Though rural areas experienced the impact of the globalization as well as the city, most of rural areas are still kept in a rather closed circumstance. The villagers under such a circumstance could hardly accept too much openness and mobility, so the designers design walls to separate the space. At the same time, the admiring attitude towards the city makes the villagers' judgment on city lingers on its features. In constructing the spatial distribution and shape, the designers adopt the modern construction technique to allocate the space. In the northeast of the square, there are footsteps leading to the farming houses. The architects design the opening shape into a visual focus of the background environment. Therefore, there appears landscape axis in the north of the square. At the end of the axis, there is a two story pavilion. In the northern part, the open land can be used for the main active region. In order to enlarge the active space, the virescence was designed behind the wall, in this way, it can beautify the environment and won't take too much space. A couple of chairs were paced at the edge of the active region for the villagers to relax. Deciduous trees whose color changes according to different seasons are planted for the villagers to escape heat in summer. To the designer himself, the understanding of rural areas comes from his childhood and elder generation's influence. The designer try to put this traditional and nature sense into his plan. The designer use the local material to design the modern building and retained the modern and traditional flavor of the building. In terms of the wall, the designer use the traditional garden method to simplify the structure, and the local way to modify the pictures on lattice windows. The peasant painting and publicity columns show the simple and unadorned features of the village. Finally, the villagers use the big stone water vat to separate the space and prevent the motor vehicles from going through, which also reveals the plain nature of the village.

However, there are several incidents happened during the implementation process of this plan. The farmer who lived directly opposite the square thought the wall of the square affects his house's geomantic omen, so he opposed the construction in front of his house. So the architect had to slightly modify the original

design. The walls designed to be the centre of the landscape were replaced by the heads of door and some tablets, in this way, the farmer's problem was solved and the local color of the building was retained. However when it comes to the pavilion, since the location of the pavilion was the farmer's pigpen, the pulling down of the pigpen would cause damage to the farmer's profit. Further more, how can a two story pavilion fit for a pigpen? Due to all kinds of reasons, the compensation for the farmer had not been made, so the farmer was against the plan. Moreover, another farmer's house has a long history, so the designer decided not to reconstruct it, which irritated the owner. She thought that the planners jut put on act, and didn't take the residents' need into consideration. Though the designer and the workers explained several times, she insisted on her own idea and result in the failure of the project.

These incidents made the team realize that the design of the rural public space is not easy. The popular city system may not fit well for the rural circumstance, due to the great discrepancy between the city and the rural area. However, numbers of city modal are being copied blindly, and it gradually becomes such a trend that the majority would follow.

The upsurge of new rural construction has begun since the Central Government put forward the slogan in 2005. It has been carried out for 6 to 7 years up to now. However there are few qualified projects we can see today. Here are several reasons for the phenomenon. From the perspective of local government, although the new rural construction was proposed by Central Government, it was the local government who carried it out. The investment of the projects in new rural construction does a less important promoting role in the development of local economy. So, local governments have not much interests in this kind of low return rate investment. In addition, local governments had some financial problems because of the tax system reform practiced in 1994. The implement of new rural construction made the problem worse. As a result, most of the local governments have no interest in it. While, since the Central Government had put forward it and determined to improve people's livelihood and the rural living standard. Therefore, the local governments can not ignore it. In order to make sure that the new rural construction runs well, the upper level governments have to take the job as one of the contents in the assessment of basic-level government work. Meanwhile, they sent government officers to check the projects in rural area untimely so that the policy can be made into practice. Spontaneously, many projects of new rural construction are finished in a short period just for the check from upper officers. So, it is unnecessary and impossible that designers play important roles during the whole process. Designers are just the instruments of governments to finish the projects. Inevitably, these kinds of projects are vulgar and bum.

From the side of designers, there are two kinds of attitudes, admixture and misunderstanding which led to the problems of new rural construction. Among the two attitudes, the former has a great majority people; fewer people make unfavorable

influence on new rural construction because of their misunderstanding. For the former attitude, as we have mentioned before, this kid of rural projects can not get the strong support from local government. So, a lot of problems happened in the process of design and construct. For instance, overload in blindfold, lack of money, and relaxed control in projects. The design companies that are well-organized and well-capitalized have no interest in the rural projects. On the one hand, it is hard for them to get a good economic and social reward from the rural projects. These large design companies have established their good fame and stable development model. They emphasize the output value and brand. Hence, the rural projects become their last choice. Even though sometimes they are forced to accept this kind of projects, they would not spend much energy in it. In older to survive, those new and small design companies accept the high risk and low reward rural projects without reluctance. They ignored the quality, brand, and tasty for collecting more money in the competitive market. Their main purpose is enlarging their company. Actually, the “fast food” model projects contribute a lot to the success of some of the new design companies. But these companies loose interest in rural projects as soon as they become strong. Not all the companies do as what I said, but the phenomenon has a great bat influence on new rural construction. After all, it is the rural villages that loose most in the end. For those companies that misunderstand the rural projects, it should be pointed out that it differs from the admixture in a great extent. We can see the differences from the real finished projects. Designers are not familiar with the rural situation and the distinction between cities and rural area. But they hurried to sole and improve the rural problems with their limited knowledge at the same time. As a result, the urbanized program produced in rural construction when the doctrinarism thought is taken into practice. This kind of situation always happened in the small design companies that are established not long and too weak to accept other lager projects. But different from those small design companies mentioned above, they are ambitious about architecture and society. They are also taking their credit and brand as important factors. Consequently, they are willing to spend more time in some small rural projects. However, they failed to finish their ideal designs because they are lack of knowledge and experience that can help them make a correct judgment about the rural situation. But, it is undeniable that their attitudes should be affirmed. Besides, these design companies mentioned above, some entities and individuals have participated in new rural construction. Because people who from cities have different interpretations and ideas on rural civilization and life. Many unsuitable designs appeared in rural program. These designs have no promoting effect on new rural construction. What’s worse sometimes, rural inside contradictions are intensified by the unsuitable designs.

Viewing the situation of current domestic new rural construction, most of the new rural construction can be classified into the category of being made crudely. Those that are outstanding and classical cases often trend to come from the

researchers who have a profound understanding and experience of social activities, from the relevant researchers in universities and some major research centers engaged in the study of all kinds of splendid architectures and city formulation. These researchers and institutions have good familiarity with rural areas, which can obtain sufficient funds through various channels and can be able to gain adequate time. Under the help of many comprehensive conditions, they have completed the project in their hands as expectedly. In addition, in this special area such as Wen chuan, thanks to the great attention central government paid, the excellent designs can achieve enough social returns, so all kinds of design companies just rushed to bid, and then they thought carefully, no wonder the excellent works were designed.

However, when we review the situation that the China's rural construction is facing, how can we expect to find out some carefully designed and suitable local public space? Let alone the protection and succession of rural culture. However these stereotyped and copied plans also can arise questions: why the urban formulation cannot be learned by rural areas.

The Chinese traditional society is a continental culture society featured as isolation. Rich resources, the vast plowland and the risk of invasion from abroad make Chinese traditional society form a economic model that is self-sufficient and inner self-recycled. In such a circulation system, on the one hand, the role of the countryside is a producer, which means that farmers meet the demands of farm produce and handicraft articles from the city through continuously hard-working yields; in return they obtain money and other high-class handicrafts that are necessary to daily life. On the other hand, the city mainly plays the role of consumers who accept the grain and handicrafts from rural areas, while consuming the citizens process these raw materials for a second time so as to make them become the high-class handicrafts and then put them into market for consuming. However, when the 19th century British people forced China to be open by the opium war since then the situation has changed, when the solitary self-circulated economy system was gradually broke down, industrialized business rapidly occupied the market in cities, the countryside started to be broke away from economic system.

Since then, the opposite relationship between China's cities and rural areas began to be formed gradually, also the economic gap between cities and rural areas began widening，rural areas were gradually being marginalized in economy and society, so it formed sharp contrast to the top developed cities under the influence of globalization. In such a background, more and younger rural labor forces left their home for a way into the city to change their conditions of life. Therewith rural hollow problem appears. At the same time, because the whole China's social was shocked fiercely by western culture, and excessive radical influence after the political movement of liberation, the traditional Chinese public society based on blood tie began to collapse, which was substituted by social relations based on the geopolitical relationship. Following is the constantly changes of ways of living and

producing and the disappearance of traditional Chinese rural culture. Many rural "family tree" disappear, the sharply reduce of the worship activities and neglect of traditional festival, all of these changes are the proof of this phenomenon.

The rural spatial settlement model began to change when the social changes are reflected on the space aspect. Traditional Chinese rural settlement model is organized on the basis of blood tie. The rural areas were distributed by surrounding the ancestral house beginning with the earliest settlers. In the process of construction, Fengshui would be taken into consideration and then formulate a certain space form (it is believed that Fengshui affects the family's destiny, fortune, prospect etc.), and at the same time, each family will have its own ancestral hall (ancestral hall may be located in ancestral house in a small family, in a big family the ancestral hall will be built separately), which is equivalent to a church and a court in the western town. And the public space in village is also distributed by setting the ancestral house or ancestral hall as center, which reflects the Chinese value and worship on family and blood relations. In some rich or large-scaled village, the public space was surrounded by independent drama stage, the performance would be showed on which when festivals, weddings and ancestor worship, which was considered as one of the events for family reunion. The events not only enrich the spiritual life of the residents but promote the relations among the families.

The changed rural settlement, its settlement organization form has drifted into geopolitical relations from blood relationship. Furthermore, rural economic stantard is quite low under the comparison between urban and rural, so the farm houses in village often gathered near the main traffic network, buildings always stand toward roads, which get rid of the traditional concept of fengshui (there are superstitions and dregs in the traditional concept of fengshui, but which makes great contribution as for the natural combination between the buildings and the environment), instead putting economy as the primary factor to consider. The village was no longer divided by the past family name, but was divided by the upper governmental administrative standard. At the same time, because of the weakening of blood relations, the originally existing ancestral temples that gradually disappeared turned to be the modern administrative office buildings and village committees. The current existing public space in villagers either regards village committees as center organization or can't provide the room for need of festival and villagers' daily life, under the conditions of which there is no point mentioning the cultural activities in rural areas.

Based on what we have discussed above, we can see the current situation of China's rural areas. Under the economic globalization, China's rural areas have been marginalized. And shocked by the western modern culture, these areas have lost their traditions, while the modern lifestyle has not been formed. What's more, villagers' spiritual life is humdrum., and their income is very low. With the above analysis, China's rural areas are always in a relatively closed circumstance and have not surpassed reginal limits markedly. Therefore, when designing public spaces in rural

areas, designers should take the following aspects into account.

1. The design should encourage and highlight the regionality and uniqueness of rural areas.

Designers should be encouraged to set stages, ancestral halls and other cultural or belief buildings so as to promote and regain villagers' cultural identity gradually. Meanwhile, designers should encourage villagers to construct public buildings in a traditional way. On the one hand, traditional crafts could be retained: on the other hand, we can save costs. In this process, architects and planners can participate in the design and promotion as technological guidance. Moreover, spatial patterns and building styles can make use of local features and some traditional elements, such as, dry pepper strings, corn strings, haystacks to add local colors and enhance villagers' identity to the traditional culture. At last, designers should excavate historical sites and make them become a visualized manifestation of rural characteristics.

2. The design should take rural economic and technological conditions into consideration.

In light of the disparity of the capital and constructive level between rural areas and cities, architects should suit measures to local conditions and use local materials as much as possible when they design and construct buildings. They should avoid using expensive materials and those that require much to constructive technology. Otherwise, the project will exceed the budget or some difficulties in construction will come out. Even if the project went well, economic burdens of rural areas would be increased and some big difficulties would happen in their later maintenance.

3. The current situation of rural areas, villagers' ideas and interests should be considered well in the design.

In the Chinese traditional society, land resources belonged to the private property. Because of the interpersonal relationship based on blood tie, however, as the old saying goes, "One should always keep all benefits for one's own people", villagers were willing to sacrifice some of their lands to construct public buildings in the past. But with the rapid development of the society, although public ownership of lands exists in rural areas, lands have been farmed out to villagers respectively. For the traditional interpersonal relationship has disappeared, villagers care more about their own interests. So, it will be difficult to build public spaces in rural areas. Though the government has planned compensation policies, villagers' lost lands and newly-built public spaces are practical problems designers need to solve. For this reason, designers should pay more attention to how to make rational use of land resources and meet villagers' needs.In addition, designers should not do any change to existing facilities in a village, unless they could be adjusted or reconstructed reasonably. When designing facilities in public spaces, designers also should try not to disturb villagers for fear of unnecessary contradiction.

As for the industry, the current "new rural construction" is overcorrect. No matter what a village is, big or small, near or far, poor or rich, it seems that a good

industrial planning is to hail the slogan of tourism. And those designs of public spaces carried out are always full of commercial and urbanized atmosphere. In fact, it is quite common for people in the city to see such designs, which can not show local features of rural areas at all. Furthermore, villagers' cultural identity and sense of belonging can not be satisfied through these designs. And building public spaces will consume lots of resources. So, these designs can not get villagers' approval. As a result, designers should focus on the relation between industries and spaces, and suit measures to local conditions, so that they can promote the rural culture and economy at the same time.

The current situation of China's rural areas is the result of China's national conditions. In general, rural circumstances are always in a relatively closed and static state. In light of the globalization, no fundamental changes would happen in China's rural areas as for its current state. Therefore, the design of public space in a village should focus on its status in the whole China or in the whole world. Besides, designers should analyze the space needed in the process of the construction rather than copy the design of the cities' or impose some notions for cities on rural areas. Only in this way can the designs of public spaces in China's rural areas reach a higher level and can we solve rural problems faster and better.

Perspectives in Governance and Global South Urban Crises: The Case of Nairobi

Joseph Kedogo Masilwa, Johannes Hamhaber[1]

Abstract

Drastic changes in global urbanisation trends, coupled with political and socio-economic insufficiencies, have resulted in severe societal problems that necessitate new and innovative discourses, policies and practices, in spatial development and planning. Recent and past global, political-economic crises have significantly influenced Global North's spatial policies and practices, which in turn have also profoundly impacted the planning and policy agenda in the Global South. Using the case of Nairobi, Kenya as an example, this paper looks at the linkages between global crises, European policies and their impact on the Global South's urban policies and practices. Nairobi exemplifies many Global Southern cities that are currently experiencing rapid urbanisation coupled with increasing socio-spatial inequalities, urbanisation of poverty, environmental degradation and proliferation of slums. Attempts to deal with these urbanisation challenges has led to several policy and action initiatives, which however have failed to adequately deal with the challenges and in fact some of those initiatives have contributed significantly in worsening the situation.

Subsequently, since the 1950s, each decade has seen a paradigm shift in initiatives and approaches towards these urbanisation challenges. Currently there is the shift from government to governance which is taking root in urban planning institutions and practices. Indeed 'good urban governance' is increasingly being seen as a prerequisite for dealing with these complex urban challenges in the Global South. However, the urban arena in the Global South has become very complex and fragmented, involving heterogeneous actors at various scales, all with disparities in their powers, roles, interests and perspectives. Furthermore, these actors possibly have different paradigmatic positions which stand in the way of attaining common ground and effective cooperation. As a result, tackling these perpetual urban challenges of the Global South necessitates an appreciation of the actors' relations that could lead to an appropriate multi-level urban governance system, geared towards sustainable and inclusive urbanisation.

Consequently, this paper examines Nairobi's urban arena, focusing on the roles and perspectives of 'low income housing' actors, both formal and informal. Employing a multi-level-actor analysis and following an analytical framework from Giddens' structuration theory, its concepts of structure, modality, and interaction are explored.

It examines the actors' different paradigmatic positions and interests that hinder attaining of mutual understanding and effective cooperation which is necessary for 'good urban governance'. Finally, with the aim of proposing alternatives for improvement, it points towards the search for appropriate innovative discourses, policies and practices; and effective ways of involving all the relevant stakeholders and actors, both weak and strong, towards dealing with the Global South's urban challenges.

Key Words: Urban housing crises, governance, actors, policies and practices

The need for new discourses and practices - the global urban arena

Globally, ongoing socio-economic, political and environmental changes are resulting in severe societal crises. These changes in addition to questioning existing models and discourses also raise new questions necessitating a better appreciation of contexts and development of appropriate discourses in spatial development and planning. Future and current urban planning must be more cognisant of past, present and future challenges such as globalization, climate change and environmental degradation, rapid urbanisation, immigration, global economic and financial crises, increasing poverty, marginalisation, and slum proliferation. Furthermore, there is need for planning to interact appropriately with challenges and opportunities afforded by increased awareness and the demand for democratized decision-making processes and socio-economic rights by ordinary people. Accordingly, with the ongoing shift from government to governance discourses, the urban planning arena is awash with many new planning approaches such as collaborative planning, strategic spatial planning, participatory urban appraisal and community action planning.

However, a closer look at the global urban arena reveals great disparities between theory and practice, normative and positive, as well as the desired and reality in terms of inclusiveness, effectiveness and responsiveness to societal needs. Besides, current policy and academic discourse continue to view Global South's urbanisation through a prism of "abnormality" or "exceptionalism", terming it "pathological" or "dysfunctional" due to rapid substantial structural population growth without commensurate poverty reduction which greatly contrasts the Global North's urbanisation experience (UN-Habitat, 2010). Moreover, economic growth in the Global South is not reducing informal settlements neither is it improving the lives of the majority of its residents; depicting a fundamental lack of political will to deal with the urban problems in a systematic way, which is compounded by failure in policies and initiatives. These policies and initiatives, usually driven by powerful interest groups, have often times failed to benefit the urban poor partly due to political structures that preserve the undesirable status quo. Additionally, rapid urbanisation has also been fuelled by non-traditional reasons for example populations escaping hunger and conflict. This could be due to failing agriculture due to not only natural environmental causes, but also due to global political-economic reasons. In addition, persistent regional and internal conflicts continue to generate refugees and internally displaced people. Thus spatially, despite many informal and formal links and networks, many urban areas in the Global South may be misconstrued as uncoordinated patchworks of informal settlements and gated communities, industrial zones and luxurious resorts, refugee camps and golf courses and many other fragments (Coy, 2006). In sum, all these complexities mentioned above, raise questions and demand answers that transcend conventional discourses, policies and practices. They point towards the need for deeper self-reflection and appreciation of the situation, in both global and local contexts.

This paper therefore attempts to discuss those complexities facing Global South's urban areas, which became more apparent since 1950s. Since that time, the world has

continued to experience very rapid urban growth, such that majority of the global population is now urban. What is more is that UN-Habitat (2010) projects that by 2050 over 70 percent of the global population will be urban, terming them *Homo sapiens urbanus.* However, this recent rapid growth is concentrated in the Global South, and is in fact happening through the growth of informal settlements, in that; many urban areas are growing at the same rate as informal settlements. For instance, in 2005, informal settlements in Sub-Saharan Africa were growing at 4.53 per cent compared to urban growth rate of 4.58 per cent per year. Moreover, in some countries such as Sudan, Central African Republic and Chad, the informal settlements accommodated around 90% of their urban population, and in total, one billion people, representing a third of the global urban population, currently reside in informal settlements (UN-Habitat, 2005 2010). Proliferation and persistence of informal settlements have been seen to represent societal failure or unwillingness to deal with problems besetting the poor members of society. Depending on the prism through which the problem is viewed, at different times in history and according to different actors, it has been described as a different form failure including: economic, policy, planning and market failure; failure to provide; failure to modernise; failure to benefit from or tame globalisation; and currently it is being viewed as failure in governance (Tosa, 2009; UN-Habitat, 2003, 2009b).

Indeed, since 1950s, each decade in the Global South has seen a different conception or a dominant paradigm on how to deal with informal settlements. It started with modernisation, progressing to the current governance paradigm with 'good urban governance' being seen as a panacea for dealing with these complex multifaceted Global South urban challenges. What is more, is the Global South informal settlements arena has experienced a proliferation of actors and stakeholders both international and local, formal and informal , state and non-state, all with different interests, resources, powers, perspectives and approaches. However, this scenario generates a number of questions for instance: why the various approaches have failed, why the paradigms shifted, who defines the dominant paradigm and whose paradigm it is. In briefly trying to look at these questions, this paper, also examines the possibility of different actors following different paradigms while at the same time purporting to be pursuing the current paradigm espoused by the prevailing powerful actor's interest at the particular time. This is explored Giddens' *Structuration Theory* following its concepts of structure, modality, and interaction; which demonstrate a "duality of structure" i.e. continual interaction and mutual constitution of 'structure and agency'. In this theory, modalities i.e. frames of reference, allocative and authoritative resources, and norms; provide linkages through which structures are generated and maintained in the flow of practices or interaction (Giddens, 1971, 1976, 1979, 1984). Therefore, could this be evident in the informal settlements' arena that is comprised of many actors with different frames of reference resulting in a multiplicity of social worlds, 'rationalities' and practices co-existing in the arena with complex power relations? Consequently, in an attempt to explore the above, the following section of this paper briefly presents the Global South's informal settlements' challenge against the backdrop of the situations in the Global North. This is followed by a glimpse into the policy, politics, polity and

governance context of Nairobi Kenya. Subsequently, the actors' paradigmatic positions and frames of reference are briefly reviewed, and finally the conclusions discussing the role of competing paradigms in Global South's informal settlements arena are presented.

Global South's Urban Crisis in a Global Context

Soon after the Second World War, the Global North's economy quickly recovered and grew well past pre-war levels, experiencing an economic boom with rising incomes and general improvement in social well-being that lasted till the 1970s. Fordism as a "regime of accumulation" was characterised by mass production and mass consumption in protected domestic markets with Keynesian economic policies as the prevailing mode of regulation (Aglietta, 1979). However, for most Global South countries which were still under colonial rule, the post War period saw the struggle for independence, which was often very bitter and violent, but also brutally suppressed. Growth of informal settlements was checked by laws that prohibited the natives' entry into urban areas, and also through brutal evictions and demolitions of native settlements in and around the urban areas. Informal settlements were seen as generators of disease, crime and political dissent (Myers, 2003).

In the 1960s, many African countries became independent and removal of restrictive laws led to massive rural-urban migration that overwhelmed the urban areas, leading to rapid growth of informal settlements. To deal with the many problems besetting these new emerging countries, 'modernisation' became the global development paradigm aiming to transform these countries from 'traditional' into 'modern' societies. Informal settlements were seen as a problem of 'backwardness' that would be solved by modernising. Therefore, informal settlements were demolished, and were to be replaced by 'modern public housing'. As public housing proved to be inadequate, a *laissez-faire* approach towards informal settlements ensued, as the urban crisis was seen as a temporary situation that would disappear with economic growth and modernisation (Obudho and Aduwo, 1989; Weru and Bodewes, 2001) Failure of modernisation practices brought the dependency discourse to prominence in the 1970s. In response, International Labour Organization and the World Bank advocated a basic needs development strategy, in which housing needs were addressed through site and services schemes as aided self-help. The 1960s and 1970s approaches were based on Keynesian principles, with the state playing a dominant role, in a top down manner. However, the public housing produced was highly inadequate and unaffordable to the urban poor and as a result, informal settlements grew exponentially.

The breakdown of Fordism and Keynesianism, and the coming into power of conservatives such as Margaret Thatcher and Ronald Reagan lead to Post Fordism; and Neoliberalism became the dominant paradigm in the 1980s (Harvey, 2005). Towards the end of the 1970s, as the Fordist model was breaking down, the Global North experienced stagflation and an economic crisis exacerbated by the 1970s oil shocks. The oil crises also generated enormous profits for petrochemical corporations

that recklessly lent them through commercial banks to Global South countries. These countries were mostly run by corrupt leaders who diverted the money from development to overseas accounts or purchased weapons to repress their subjects. However, declining commodity prices due to stagflation in the Global North, and the increase of interest rates, produced a possibility of Global South's debt-defaulting, triggering a debt crisis and possible collapse of banks (Hart, 2001). To prevent this from happening, the lending countries directed the IMF and World Bank to bail out those Global South countries. The bailout was given on condition of implementing Structural Adjustment Programs (SAPs). Thus neoliberal policies also referred to as the Washington Consensus, spread to the Global South, with devastating effects to the local economies as well as social wellbeing of these countries (Hart, 2001; Broad, 2004). Furthermore, to cut costs, Global North manufacturing shifted to the Global South, where to compete for foreign investment, bargaining processes between Global South governments and multinationals led to low wages, deplorable working conditions and extreme levels of labour and environmental exploitation. Thus Taylorism was introduced into Global South contexts which had very lenient regulations producing 'bloody Taylorism' (Lipietz, 1982; 2008). Moreover, neoliberal policies required the withdrawal of the state from service provision and a shift towards reliance on the private sector and civil society, henceforth, in dealing with informal settlements the government was required to be an *enabler*, to create an *enabling* environment for the private sector and other non-state actors, to deal with housing problems. As a result, many Global Southern states abdicated the role of housing provision, but the private sector and the market, despite many incentives did not take the role. With increasing poverty, inequalities and marginalisation, proliferation of informal settlements continued in the 1980s (UN-Habitat, 2006).

The realisation that unregulated market and globalisation forces, were causing serious social and natural environmental degradation globally, even threatening the very existence of the human race, led to Brundtland Report and the Rio Earth Summit; thus Sustainability and Sustainable development became the dominant paradigm in the 1990s (Fergus and Rowney, 2005). The government's role became that of regulating the market forces. To deal with Global South's urban problems, Sustainable urban development was prescribed, to produce liveable and inclusive cities with social harmony, economic and environmental sustainability. Participation of the target groups and bottom up practices were emphasized. Therefore participatory slum upgrading projects led by the civil society were proposed which aimed at improving the environment of informal settlements and regulation of security of tenure (Sietchiping, 2008). Deepening globalisation, and increasing role of non-state actors towards the end of the 1990s among other forces brought to prominence the 'good governance' paradigm in the 2000s that called for partnership between the governments, private sector, civil society and supra national entities among others. Furthermore, at the end of the Cold War, Global Northern countries, which had previously turned a blind eye to corruption, repression and violation of basic rights and civil liberties in the Global South, through multilateral and bilateral organisations, demanded institutional reform to create 'good governance'. Additionally, the Millennium Development Goals (MDGs), aimed at addressing

Global South's problems, specifically mentioned good governance and reducing slums as its targets. However, for different actors involved, good governance has different definitions, approaches and understandings, thus it motivates different practices among them (Kirby, 1997). In dealing with informal settlements the government's envisioned role was that of a partner-to partner with other stakeholders in the form of public-private partnerships and creation of city-wide and nation-wide city strategies and alliances such as espoused by the 'Cities Without Slums' initiatives. All in all, these initiatives have produced very little impact on the Global South's urban challenges and the problem of informal settlements persists, calling for more appropriate attention and actions.

Table 1: Paradigm shifts in prescribed responses to Global South's urban crises

Paradigm	Containment	Modernisation	Basic needs	Neoliberalism	Sustainability	Good Governance
Decade it was dominant	1950s	1960s	1970s	1980s	1990s	2000s
Geo-political and economic context	Post war era Late colonial	Independence Keynesianism	Oil shocks Stagflation Debt crisis Fordism crisis	Thatcher-Regan Post Fordism & bloody Taylorism	End of Cold war Globalisation deepens	New Millennium
Development orthodoxy	Containment (by law & force)	Modernisation (accelerated growth & trickle down)	Basic needs (dependency theory-redistribution)	Economic-liberalism Enabling approaches , state roll back	Sustainable development	Good governance and MDGs
Urban and housing strategies	Restriction repressions eviction and demolitions Maintain purity of the city	Slum demolitions replaced with modern public housing	sites-and-services, aided self-help	housing without houses, create an enabling environment	Slum upgrading urban management tenure regularisation	Public-private partnership, Cities alliances
Role of the state	Architect for idealist cities	Planner for development	Provider of basic needs	Enabler of the private sector	Regulator of market forces	Partner with stakeholders
Mode of governance	Authoritarian & Clientelist	representative democratic	Managerialist	Corporatist	Pluralist	Inclusive democratic

Based on these criteria, the study identifies five dominant paradigms that dominated the Global South's urban housing arena in various decades. They are; containment, modernisation, basic needs & redistribution, neo-liberalism, sustainable development, and finally good governance. Seemingly, periods in history and other geo-political and economic forces at one time or another, have favoured a particular paradigm over others, making them dominate discourse and policy. Nonetheless, these paradigms are ideal types, and do not exist in pure forms or revolutionarily replacing each other, but the new paradigms have evolved from the previous ones and in fact as shall be discussed later, they all continue to co-exist and are actually competing in the Global South's urban arena.

Additionally, several ideal types of modes have been identified, i.e. the informal arrangements that define the governing relationships among actors in the urban arena. They include, authoritarian, clientelist, representative democratic,

managerialist, corporatist, populist, pluralist democratic, inclusive democratic, oligarchical, criteria driven, entrepreneurial consensus, inclusionary argumentation, pro-growth, and welfare (Rakodi, 2003; DiGaetano and Strom, 2003; Healey, 2003; Healey, 1997; Pierre, 1999); with each paradigm having a peculiar preferred mode. However, whilst in theory each paradigm prescribed a different mode, in practice, any given time there prevailed hybrid forms such as authoritative/clientelist. In sum, the paradigm shifts presented, reflect dominant discourses and policies that dominated the Global South's informal settlements and urban housing arenas. Indeed, policy and programme documents reflect closely those paradigm shifts. However, there was and still is great variance between what was desired or intended as compared to what was actually practiced. Different actors or stakeholders have acted following different paradigms; depending on several issues including their vested interests, motives, and sources of funding and knowledge. Additionally, the socio-economic and political contexts in with the initiatives are conducted also play a significant role.

Structuration perspective in Global South's urban governance arena

The different perspectives in the Global South's urban crises, governance and paradigms shifts in the informal settlements, housing policy and practice arena, could be viewed through Structuration Theory. According to Structuration Theory (Giddens 1984), there is a 'duality of structures'; in that social structures make social action possible and at the same time social action creates those very structures, presenting a continual interaction between, and mutual constitution of, 'structure and agency'. By defining *structuration* as being "the structuring of social relations across time and space, in virtue of the duality of structure" (Giddens, 1984 pp. 376); and *structures* as being 'recursively organized rules and resources' that both constrain and facilitate or enable social actions, and structures existing as 'memory traces' (Giddens, 1984 pp. 377); This theory could provide a way of situating the actions and interactions of actors involved in housing, policy or governance within structuration processes.

Pursuant to Structuration Theory, three modalities i.e. interpretative schemes, facilities and norms, mediate the linkage between social structure and human interaction. Firstly, interpretative schemes are shared stocks of knowledge which actors draw upon to interpret actions and achieve communications while interacting, and thereby producing, reproducing or reinforcing structures of signification or meaning. Interpretative schemes include semantic codes and discursive practices and are "the core of mutual knowledge whereby an accountable universe is sustained" (Giddens, 1979 pp. 83). Secondly, Facilities are allocative and authoritative resources through which actors exercise power and realise their inattentions, thus creating structures of domination. Facilities are thus, "reproduced relations of autonomy and dependence in social interaction" (Giddens, 1979 pp. 93). In urban governance therefore, the existing or prescribed authoritative and allocative systems not only depend on different actors' vested interests, but also on routine social relations, practices and institutional designs all structured by deeper values and

conceptions such as paradigmatic positions (Healey, 1997). And finally, norms are rules that actors use to sanction behaviour and produce legitimacy i.e. the structures of legitimation, hence norms are "the actualization of rights and enactment of obligations" (Giddens, 1976 pp. 86), norms are standards and laws that define how actors should act within a particular context.

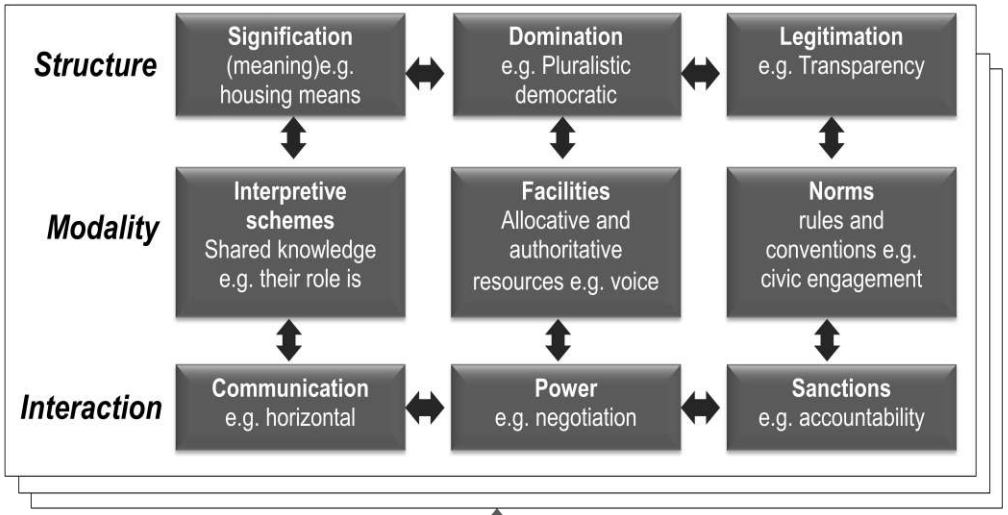
Hence, while interpretative schemes reveal what terms like urban problems, informal settlements, housing policy or good governance mean for a certain actor; facilities depict what resources are used or should be used (normatively) to meet the stated common objective. It is by means of facility that it is determined who is or should be included or excluded in governance process, in addition to determining who has or should have a controlling stake or voice in a governance setup. In this way, with more facility determine whose paradigm becomes dominant. Conversely, norms show the justification or reason for pursuing certain normative actions or taking a certain housing policy or good governance stance, by stating what and why it should be done because of what. In sum, these structuration concepts could aid in the appreciation of the complex and multifarious milieu that encompass the Global South's urban governance and housing issues, and as such, the Nairobi's informal housing and policy arena.

As discussed in the previous sections, attempts to deal with the Global South's urban problems including informal settlements have been inadequate; and each decade since the 1950s has seen a different dominant development orthodoxy and preferred approach towards these urban problems. This is shown mainly in paradigm shifts in discourse and policy and programme documents and the actions of powerful interest groups whose voice dominated the scene in each decade, beginning with restriction and modernisation, and the latest paradigm being 'good governance' as shown in Table 1. There are many and varied definitions of governance and its normative form good governance, however, a common denominator among them is that they concern certain actors making binding decisions that will enable or constrain their own, or others actions and interactions. Governance includes the regulation, co-ordination and interaction systems amongst these diverse actors, with varied interests and positions. However, governance means different things to different actors, leading to different actions and expectations and creating multiple structurations. Moreover, the situation is complicated further by differences in meaning of the normative 'good governance'. Consequently, through Structuration Theory, the various actors in Global South's urban governance arena, acting, interacting or preferring different paradigms can be seen as having different frames of reference and therefore different structuration, thus acting in a certain way and producing certain structures that define, shape and direct actions and interactions in the arena, for themselves and other actors.

Table 2: Structuration in Global South's housing and urban governance arena

Governance

Systems of regulation and co-ordination governing interactions, interconnections and relations amongst a plurality of actors at various spatial scales. A socio-economic and political steering logic with multi-centred and multi-level systems. However, the term (good) governance elicits different meanings to different actors leading to different expectations and actions.



Urban and Housing discourses

Housing means more than a roof over one's head, but what does it mean to different actors? For instance housing as: shelter, product, noun, verb, service, assistance , or human right. The Global South's urban housing arena has seen several paradigm shifts in dominant discourse, policies and programmes. Global paradigm shifts translate into both global and local actions, policies and programmes, such as 'self help, 'housing by the people' and 'housing without houses'. The process by which different actors take different paradigmatic stands could be inferred as structuration.

Paradigmatic positions in Nairobi's informal settlements arena

In theory all the actors and stakeholders involved in the informal urban housing arena in Nairobi, have closely followed the paradigm shifts and changes in policy and approaches as shown in table 1 (GoK, 2005; UN-Habitat, 2003; Huchzermeyer and Karam, 2006). All the policy and programme documents have at least in part referred to the dominant orthodoxy, for instance in the 1990s almost all programs and initiatives mentioned 'sustainability' or 'sustainable urban development' while currently they mention 'governance', or 'good governance'. However, in practice, there is great variance between the desired changes or action compared to the actual changes or actions that were taken (Pugh, 2001; UN-Habitat, 2009a), and in fact, the actors have often acted or interacted according to different paradigms, with different frames of reference. Indeed, this was observed in the ongoing field-study in Nairobi's arena, firstly, based on what the actors said about themselves, and their policy and programme documents, their modus operandi, why and how they acted and interacted with other actors; secondly, analysing what other actors said or thought about the particular actor under consideration, what the actor did or should have done; thirdly based on scholarly evidence, studies and discourses about the said actors; and finally all this was explored through a 'structuration, housing and governance' framework presented in table 2. A summary of the findings presented below show the co-existence of multiple paradigmatic stands and frames of references by different actors, all involved in the same policies and programmes, and in the same locations; all which could contribute to a fundamental lack of mutual understanding and could also prevent the attainment of common ground, necessary for 'good urban governance' or effective initiatives, policy, projects and programs.

From the international level, multilateral organisations are the major players in Nairobi's informal settlements arena, and indeed, over the different decades, they have introduced, influenced or decided most of the time what the dominant paradigm should be. These include the United Nations Human Settlements Programme (UN-Habitat), World Bank and International Monetary Fund (IMF), Cities Alliance, and United Nations Development Programme (UNDP) among others. While all these actors currently promoted good governance, there was divergence in their approaches; for instance the World Bank, providing financial and technical assistance, and in terms of governance highlighting public-private sector management and the rule of law, was seen to have a more neo-liberal stand, focusing on enabling the market and private sector to work towards solving housing and urban problems (Pugh, 2001; Omenya and Huchzermeyer, 2006; World Bank, 2008; Kedogo *et al.*, 2010). Then United Nations organisations such as the UNDP and UN-Habitat emphasised human development aspects such as horizontal coordination, collaborative action, and human rights. Currently, UN-Habitat aims at socially and environmentally sustainable urban areas and adequate shelter for all emphasising community participation themes, all this in line with the sustainability paradigm (UN-Habitat, 2010). The Nairobi informal settlements arena also has several bilateral agencies and development assistance programmes from various countries, either acting directly or supporting the government and the civil societies. These include

German Agency for International Cooperation (GIZ), Swedish International Development Cooperation Agency (SIDA), the United States Agency for International Development (USAID), and Italian Development Cooperation (IDC), just to mention a few. These bilateral agencies mainly reflected values and priorities of their mother countries, but mostly followed a basic needs paradigmatic approach. Moreover, beyond their divergent approaches, these alliances, multilateral and bilateral agencies have complex internal governance arrangements resulting in heterogonous paradigmatic views, even within those institutions.

Currently, at the national and local government level, all ministries, parastatals, and all state agencies have governance and good governance in their policies, mandates, service chatters, programmes, and short term and long term plans and visions. However in dealing with the informal settlements their approaches varied depending on the party affiliations, visions, vested interests, and motives - both positive and negative. For instance, on the one hand, some departments persisting in evictions and demolitions were seen leaning toward the restriction paradigm with authoritative governance approaches and seemingly apathetic to the plight of slum dwellers, but more interested urban renewal and beautification to attract tourism and international business and. On the other hand, other departments favour a more welfare, provision of subsidised public housing akin to the modernisation paradigm (GoK 2011). While some politicians were engaged in more clientistic modes of governance with patron client relations with residents, slumlords, private militias and local mafias; other politicians' engagement with informal settlement was more populist, setting out initiatives that seemed to address the needs of the majority, but in fact were only symbolic and without any resource allocation to match them, the only aim being to gain political power. All this is further complicated by varying personal and political interests of the ever changing key personalities in those institutions, rendering the position of those institutions even more inconsistent (Huchzermeyer and Karam, 2006; Mitullah, 2008).

The private sector, with varied actors ranging from giant multinational corporations to small informal enterprises, appears seemingly to have benefited immensely from the persistence of informal settlements, which enable payment of low wages and maintain a pool of casual labours, thereby sustaining 'bloody Taylorism' which in turn propagates more informal settlements in a vicious cycle. Private sector involvement in improving the situation in Nairobi's informal settlements has been minimal. The public-private sector initiatives espoused in Good urban governance paradigm have in practice merely been tokenism; the private sector involvement has been limited to a few corporate social responsibility projects and funding of some civil society activity. Thus private sector actors, seen to be gaining from the status quo have preferred a *laissez-faire* approach in a neo-liberal paradigmatic manner that maintains the current status quo, with its many layers that sustain the exploitation of the urban poor.

The informal settlements arena in Nairobi is teeming with Civil Society Organisations (CSOs) varying in scale from international to grassroots level, all with

diverse interests and approaches. They include Non-Governmental Organisations (NGOs), Community Based Organisations (CBOs), Religious or Faith Based Organizations (FBOs), and many other formal and informal community self-help groups and Non-State Actors (NSAs). The 1980s saw the proliferation of CSOs when multilateral and bilateral organisations began channelling development assistance directly to NGOs, following a Structural Adjustment Programmes (SAPs), a neo-liberal approach, also due to an aid ban to the Government towing to Kenya Governments reluctance to reform, reduce corruption and embrace the SAPs (Syagga *et al.*, 2001; Kedogo *et al.*, 2010; GoK 2005). Currently, there are some human rights oriented CSOs following a sustainable and rights based paradigmatic theme, but also many pragmatic project based CSOs, following a basic needs approach. While many CSOs purport to represent the views of the informal settlements dwellers, it has been observed and argued that many CSOs, being dependent on donor funding, aligned their agendas with that of donors' primary interests and paradigmatic approaches. Moreover, some CSOs have been seen to be gaining from the current situation and have apparently opposed several interventions in the informal settlements, preferring a *laissez-faire* in a neo-liberal paradigmatic way. All these have resulted in myriads of conflicting approaches, duplication of efforts, wasteful competition and sometimes outright violence experienced in many slum upgrading initiatives (Mittulah 2008)

One of the main goals of the good governance paradigm is to ensure the views and voices of the most weak and vulnerable in society are taken into account and heard in decision-making, which would result in more responsive actions towards the needs of the urban poor. However, the voice of the majority of the urban poor in Nairobi's informal settlements is rarely heard. Several Civil Society Organisations (CSOs) have set out to represent the voice of the urban poor, but only ended up representing the views of their funding organisations. Moreover, an attempt at increasing participation in government led projects has often been hijacked by powerful interest groups or other gate keepers. In Nairobi, the informal settlements residents also displayed a variety of preferred approaches, influenced by their relative income, and more so based with their contact with NGOs or government led initiatives. Some residents also expressed fear for any slum-upgrading activity as from their past experiences, slum-upgrading only lead to further displacement and worsening of their welfare (Syagga *et al.*, 2001; Huchzermeyer and Karam, 2006). However, many preferred public housing that would be leased to them at subsidised rates, with a more supportive government that protected and listened to them; an approach that seems contrary to the prevailing dominant paradigms. The poor, who with time have increasingly become more vocal and active in demanding for democracy, basic rights and justice, have often blamed the government for neglecting them, and failing to protect them from the vagaries of society. Moreover, many residents have become more and more suspicious of upgrading initiatives, both by state and non-state actors, as they saw these initiatives and their outcomes would not be in their best interests. Accordingly, all these findings point to the need to review the current approaches leading to the development of more effective and responsive approaches and strategies suited to the needs, locations, policy and political milieu and all the surrounding complex issues. As shown in Nairobi's informal settlements' policy and

practice arena, there is simultaneous co-existence and co-presence of sometimes competing paradigms ranging from containment to good governance, not only among different actors, but also within the different departments of given institutional actors, and even between individuals acting in them. There a strong indication that these competing paradigmatic stands could also be contributing to lack of political will, poor implementation of policies and programme initiatives, inappropriate policies and initiatives and many other such factors which prevent effective solutions to the urban problems but in fact perpetuate the deplorable living conditions for many residents in Nairobi.

Conclusions

This paper, while focusing on Nairobi, has discussed the Global South's urban arena in the context of prevailing urban crises, global geo-political and economic forces, and complex policy and political contexts, which is complicated further by presence of a myriad of actors with differing interests, resources and approaches. While there was convergence in theory, there was wide divergence in practice. Whereas, currently most of the actors said and wrote according to the prevailing good governance paradigm, the term produced different meanings for different actors. This could be explained by the fact that different actors could be having different paradigmatic references i.e. the ideological postulates, implicit theoretical foundations and representations of the world that frame their definitions, actions and interactions. Moreover, changes in dominant paradigms in the larger arena seem to have resulted only in changing of names and labels of initiatives, while the underlying paradigmatic approaches of many actors prevailed. For example when the term 'austerity' becomes politically incorrect, it is replaced with 'efficiency' without any policy change. This is also exemplified by the fact that to some actors in the Global South's arena the term good governance is just as other aid conditionality, and is therefore viewed the same way Structural Adjustment Programs were viewed (Doornbos, 2001; Mkandawire, 2007). In sum, could all these explain why many actions aimed at or purporting to improve the lives of the urban poor in fact end up worsening the situation further, deepening further the layers of exploitation of the poor? Therefore, with these actors possibly have different paradigmatic positions standing in the way of attaining common ground and effective cooperation, tackling these perpetual urban challenges in the Global South necessitates an appreciation of the actors' relations, actions and interactions, taking into account their different frames of reference and stands, as this could lead to an appropriate multi-level urban governance system, geared towards sustainable and inclusive urbanisation.

Light Rails to Sustainable Mobility?

Mette Nielsen[1]

Abstract

Taking its point of departure in the mobilities paradigm, this paper applies a theoretical framework of narratives and storytelling to analyse and describe the rationales behind implementation of light rail in the case of Bergen light rail in Norway. Through the analysis it is demonstrated that there is not one overall rationale for implementing light rail, many arguments are evident in various contexts. Furthermore, findings in this paper show that planners, policy makers and other stakeholders shape stories for or against the implementation of light rail through the use of narratives that are linked to global discourses of light rail. By looking into the narratives and stories around light rail, generated in the policy and planning phase, the process of creating visionary concepts for light rails can be unfolded. The central claim of this paper is, that the formation of a clear concept for a light rail project is crucial when forming the basis for the decisions for the political process and the decisions made later in the implementation and operation stages of the light rail project. Furthermore, a clear concept is necessary to identify the criteria for a successful system and evaluate the outcome and more importantly to institutionalise this concept among all actors involved in the process to ensure that there is agreement around the concept. Through findings from the Bergen Light rail case, the concepts and arguments for implementing light rail in this local setting will be presented to exemplify how concepts for the light rail can be shaped in the policy and planning phase and show how the lack of a clear concept can extend and complicate decision making processes. The paper moreover provides a more general perspective on the effectiveness of creating clear concepts in order to steer new infrastructure projects and urban interventions through the political process and secure the outcome of these projects are recognisable in proportion to the visionary concept.

1. Introduction

1.1 Reintroducing the Tram

After Second World War old tram systems were abandoned in many European cities. After decades where the tram, in many cities, was the preferred mean of urban transportation and had structured urban development, the introduction of the car caused a radical innovation in the transportation sector and made other modes of travel inflexible and fragmented compared to the seamlessness that the car could offer. (Urry, 2007, pp. 119). The attributes of the car made it impossible for the tram system to compete as the preferred mode of transportation for the everyday journeys. As the system of auto mobility became well established it overtook the role as the central mode for urban transportation. (Beckmann, 2000). In 1932 General Motors bought up the US tramways in order to close them down (Urry, 2007) and in Bergen, Norway the last tram was dumped in the fjord in 1965 (Vollset, 2007) both symbolic acts to cement the beginning of a new area of auto mobility. In the recent years there has been a change in discourse around urban mobility. Coming from decades with

[1] Aalborg University, Denmark, metten@plan.aau.dk.

policies that supported automobile oriented cities, many policymakers today seems to recognise that this propensity needs to change in order to deal with increasing travel demands, struggle for space and liveability in the cities and the growing CO_2 emissions from the transport sector while at the same time enhancing mobility (European Commission, 2007). One solution, caused by this new direction, is a reintroduction of the tram which has had a technological upgrade and a new name - light rail. In many European cities there has been increased political interest in the possibility to implement light rail. Europe is the densest light rail continent with 170 systems in operation and nearly 100 more in construction or planning (UITP, n.d.). Furthermore, light rail in many cities, has proven to be a successful tool to change the urban mobility system away from the car-oriented approach, which in many cities have resulted in modal shifts, passenger increase and decrease in car-use in the cities (The National Audit Office, 2004; Bottoms, 2003).

This new mode of urban transportation has some features that, in a technical sense, make it different from both metros and busses; lower construction cost than metro, in many cases the system runs in prioritised lanes, it is integrated in street level and intervenes with the urban environment. It has a higher comfort level and regularity than traditional bus systems. (Hanssen et al, 2005). There are several technical documents and evaluations of light rail as a technology, however there is need for a more holistic understanding for the genesis of light rail system; why are light rail suddenly relevant, and what has caused this change and which rationales are behind the decisions to implement such systems? The goal with this approach is to understand how light rail projects are framed in the policy and planning process in different local contexts and which influence this framing has for the political and public process that the project passes afterwards and for the later stages of the project. A narrative and spatial understanding (Jensen, 2007) of light rail will be provided through this paper to show how arguments for and against light rail are shaped and fitted to the local urban context with a reference to other local spatial dimensions (other urban development projects or historical attributes or symbols of the city), hereby creating a local 'concept' behind the implementation of light rail.

1.2 General discourses, Global and Local Concepts

As experience, culture and growth gain importance, cities worldwide are engaged in constructing images and representations according to these trends (Jensen, 2007). According to this trend it is evident that many European cities have a wish to integrate light rail as a part of their urban branding and urban development strategy, and as a tool to improve the city´s positions in the global competition for growth and liveability. A literature review of research around light rail supplemented with a review of relevant material for newly implemented light rail lines, shows that one strong discourse for implementing light rail is the wish to create an identity for the city - creating an image of a modern and visionary place that should facilitate future growth. (Hanssen, et al. 2005; Hedström, 2004). An indication that show that the rationale for implementing light rail is beyond the purpose of getting people from A to B, hence facilitating discussions involving more that transportation purposes. Likewise, at the international scene, the discussion around implementation of light rail proves to be based in a variety of discourses that both supports and opposes the need of implementing light rail. These discourses can be characterised as general that might be applicable in many local contexts, and hereby they are not connected to any particular local agenda or spatial referent. Tait and Jensen (2007) describes that global ideas, models and concepts for urban development (e.g. waterfront developments or business Improvement districts) are shaped by professions such as planning, urban design or urban management, and these global

ideas, models or concepts travel to around the globe and is translated into local contexts. In this transformation process the model or the 'concept', as I will term it in this paper, are given local meanings and are often attached to spatial localities. However, if the translation process is not linked to one overall discourse and hereby framing a local 'concept' that makes the project relevant in the local setting, then the light rail project could face difficulties in communicating the various actors in the process. Furthermore the project could face difficulties in addressing opposing views because of the lack of a clear vision and hereby clear concept. The Bergen case presented in this paper will exemplify this.

Light rail is obtaining an important role in the normative discussions around the future urban mobility system globally, and especially in many middle-sized European cities. A literature review of official European and international documents around light rail made it evident that there exist some general discourses around light rail on the global level. Furthermore the literature review identifies the discussion around light rail to be derived from the general discourse of the liveable city - with an emphasis on the historic dimension in the story of the liveable city; how do we move on from the past? What is the wish for the future? Some discourses are continuously repeated in the official reports and forms general discourses for and against light rail. Proponents and opponents derive narratives from these discourses in the local translation process of creating stories for and against the implementation of a light rail project and hereby shaping a local 'concept' for the project. The key challenge is to link the general discourse with a local challenge or situation at hand.

The general discourses are summarized in table 1.

Discourse	Narratives
The liveable city	- modernity - quality of life - identity and image - attraction - the creative class - health - Culture and experience (new culture for urban mobility) - the creative class (Florida) - behavioural change - regeneration of urban areas - urban transformation - city competition
Struggle for space in the cities	- Public transport can structure future urban development and reduce the need for mobilised individual transport in the cities. - restricting car-use in the cities
Backbone of the public transport network	- efficient transport system - multimodality - quality in public transport - attractiveness - show investment in public transport
Rail factor	- citizens preferences for rail born transport - the indirect effects of rail (economic development in corridor, symbolic value) - More than a transport system (consumption of transport forging personal identity)
Economical feasibility	- Cheaper than metro. - Attractive public transport for smaller cities - cities as engines for economic development
Growth	- Urban development potential - Economic vitality - settlement

-Culture

Discourse	Narratives
Economical feasibility	- not cost effective -Time consumption as the economical measure
Accessibility	- restricting car use, causing congestion - not solving congestion
Capacity	- Capacity problems should be the argument for upgrading the public transport network

Table 1. General discourses around light rail (based on literature review and case studies).

Table 1 outlines the dominant general discourses for and against light rail which has been identified through the literature review. Figure 1 is an illustration of how these general discourse forms global concepts and models that are translated by planners, politicians and other stakeholders from the global to the local level and framed to the local context, where the arguments/discourses passes a filter before the official concept for the project is established.

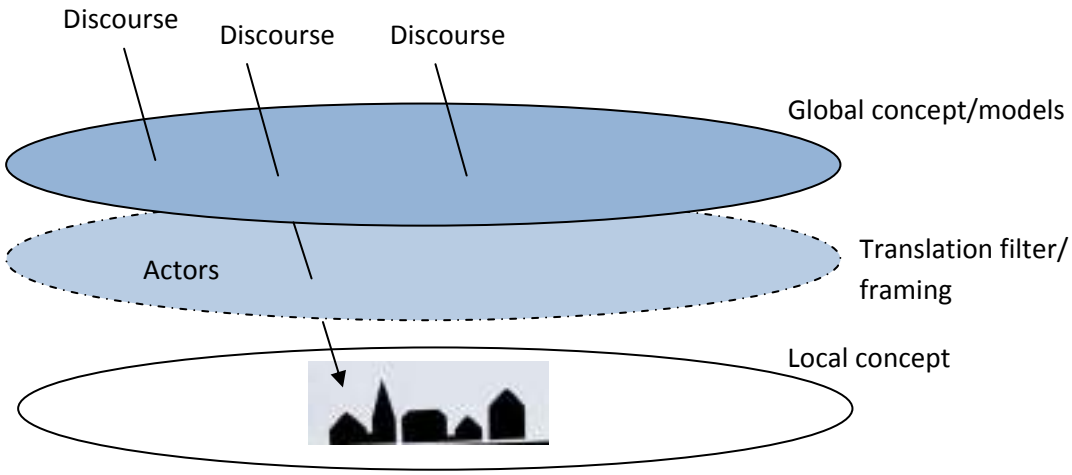

Figure 1 Translation from general discourse on global concept level to local concept with spatial reference (own figure inspired by work of (Tait & Jensen, 2007))

The means by which ideas, concepts and models travel requires an understanding of the context in which they are produced and in which they travel and are adopted. (Tait & Jensen, 2007, pp. 109). The translation process activates numerous actors that serve an important role in framing the local concept through their actions and their use of narratives to support this framing. The aim with this paper is thus to identify the importance of framing the local 'concept' for light rail projects, and to provide a case example of how this framing has happened. The framing will be unfolded through the use of a narrative - spatial framework (Jensen, 2007).

1.3 Stories and narratives of Light Rail

Understanding the role that stories and narratives play in planning has a great importance when unfolding the arguments shaped in the policy and planning phase for light rail systems (and the genesis that comes before this phase) (Flyvbjerg, 1991). The stories told can be deconstructed and provide a critical view of the normative arguments in use in the stories. There is a presence of plot and character in stories that is valuable to understand the stories being told in policy and planning - what is the story about, and what is the plot about and which chain of events structures the plot? Stories can also function as a catalyst for change and hereby shape new imaginations of alternatives (Sandercock, 2003). Often stories serves as inspiration when they are re-told, and good storytelling involves persuasive powers that can mobilise emotions and cause change, which is also called 'narrative rationality' (Throgmorton, 1996, pp. 48).

Using a theoretical framework of narratives to unfold the rationality behind light rail systems is valuable because the stories told in the different light rail cities seems to vary, and there are indications of differing rationality behind the decision to implement light rail systems in the different contexts. It is important to understand this difference in rationality because light rails, as a new urban mobility mode, has to find its place physically socially, economically and discursively within a landscape in which there are already physical structures, social practices and economic entities that overcome distance and structure mobility in sedimented or locked in forms. (Urry, 2007, pp. 52). There is a relation between the story and place in all light rail cities, and therefore emphasis in the analysis in this paper should be on understanding these place-based narratives to unfold the local concepts (Jensen, 2007). Any planning story has a spatial referent which is also the case for light rail systems. Hence the central claim of this paper is, that the rationality behind light rail and how the concept of this urban intervention is framed can be understood better when analysed through a spatially sensitive framework. Jensen (2007) provides an analytical frame to understand the representational logic of urban interventions. He argues that in order to understand the representational logics both a narrative dimension and a space dimension needs to be applied. The analytical frame is illustrated in table 1.

Narrative dimension	*Information* *Temporal order/structure* *Causality* *Plot* *Discourse institutionalization*
Sense of place dimension	*Relations to other places* *References to physical attributes*

Table 1. Analytical framework for the representational logic of urban interventions (Jensen, 2007).

The analytical frame is a checklist that is taken into account in the analysis.

2. Analysis

2.1 Case-study Methodology

A case-study methodology was applied to explore the use of narratives and story-telling to frame the local concept of the light rail project in Bergen, Norway. This qualitative approach provides a valuable basis for understanding and explaining light rail as a phenomenon and the rationalities behind implementation of light rail. Explorative interviews with key stakeholders from the policy and planning phase were conducted. Furthermore, document studies supplemented the unfolding of the use of narratives in the policy and planning phase. The case and stakeholder interviews are presented in table 2.

Case	Case study timing	Case Characteristics	Stakeholder interviews
Bergen, Norway (250.000 inhabitants)	May, 2011	- First light rail line finished in 2010 - strong political focus - public debates	Municipal planner Politician - left wing Public transport authority Local Researcher Technical engineer Head of the Local Business life

Table 2 Case description

The case presented in this article was selected to show a critical case (Flyvbjerg, 1991) where the actors in policy and planning process has struggled to form a clear concept for the light rail project, hence causing the process of Bergen light rail to be the heavily discussed subject in Bergen for 15 years and also delaying the decisions significantly. By applying the analytical frame I will now look into the narratives in use in the cases of Bergen light rail and identify the local concepts for this project and the narratives in use to frame this concept.

2.2 'The Silent Monster' - A case of political struggle for Bergen light rail

In June 2010 the Queen of Norway opened the first light rail line in Bergen. It was a symbolic day since opponents of the light rail had worked long and hard to reach to this point and the policy and planning process of Bybanen was the most heavily discussed case in the media for a period of fifteen years (Vollset, 2007). Since the last tram was abolished and dumped in the fjord in Bergen in 1965, the establishment of new urban rail born transportation has been discussed politically and publicly, and many different technical solutions have been presented (Nielsen, 2011). The pictures illustrated in figure 2 captures some of the stories that have been told about Bybanen in Bergen in this heavily discussed project.

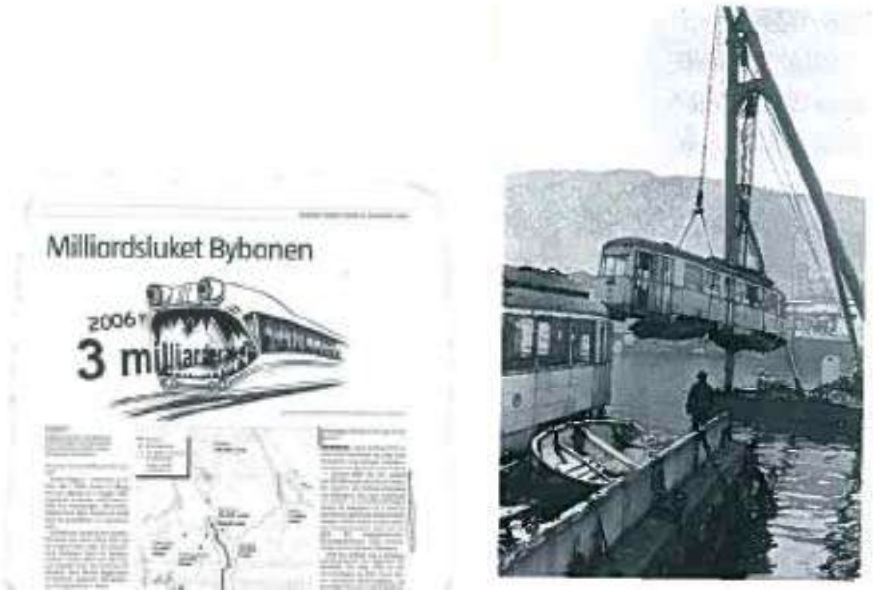

Figure 2: Left: Article presented in the local newspaper Bergens Tidende by opponents, the headline was that the light rail would literally swallow milliards of Norwegian kroner (Hartmann, et al., 2006). Right: picture from year 1965 when the last tram was symbolically dumped in Bergen Fjord to symbolise the beginning of a new era. (Rasmussen, 2011).

Like many other cities Bergen closed the tramlines in the 1960ies due to the introduction of the automobile. In 1946 each Norwegian on average travelled 4 kilometres pr. day. In 1960 this had increased to 18 km pr. day. Concurrent to this development the tram and the local rails were abolished. Furthermore, investments in road infrastructure made the car even more indispensable. The car changed its status of 'welfare-good' to a 'necessity' as Bergen city sprawled. Though, increasing auto mobility started to cause problems in the city; congested roads lack of accessibility and time delays (Vollset, 2007). The struggle for space in Bergen raised the discussion of 'the liveable city': how should the city develop in the future? (Potter, 2011; Eide, 2011). The normative discussions around this question drew clear front lines for stakeholders for or against a new agenda for urban development to start a value based discussion where all arguments were valuable if it supported the future development the different stakeholders supported. Therefore a reference to the political context is important when evaluating how the local concept for Bergen light rail was framed, or more correctly to say; the many ways in which the concept was framed by different actors through the policy and planning process, and the genesis of this.

2.2.1. Actors

The narratives used in the process around Bybanen in Bergen can roughly be divided into proponents and opponent of the light rail. However, the picture is not as clear as such. Three main categories could be identified consisting of narratives derived from the rationality of different professions/groupings; engineers, architects and environmentalists which illustrated how different professions are framing the project in various ways. The rationality of these different professions proved to be very different. The 'groupings' of professions are not divided by clear boarders; it is more right to say that the narratives in use in the process generally originate from different rationalities within these professions, and the span of actors using these specific narratives seem to

be more varying (Vollset, 2007; Rasmussen, 2011; Potter, 2011; Eide, 2011). The many varieties of arguments in use reflect a diffuse process where the 'translation' of the global model of light rails was not initiated by one global discourse of light rail. Almost all global discourses (table 1) were activated in the argumentation and this caused confusion around the concept for the local project. It was not one story being told but many opposing stories. In this process the 'narrative rationality' and the ability to mobilise emotions was essential (Sandercock, 2003; Throgmorton, 1996).

The dominant discourse among the stakeholders that held the engineering rationality was the economic discourse; creating a debate of how to value transportation, getting 'the most transportation for the available money', specially the road directorate, which is a national organisation, shared this belief and hence became a dominant actor that managed to mobilise public and political support for against the light rail project. The main reason for their opposition was that a stated proposal for financing of the light rail was made by the proponents of the light rail which involved financial means collected through road toll would be transferred to a public transport project (Eide, 2011; Potter, 2011). Based on traffic model calculations the road directorate argued that the light rail project couldn't cope with the increasing congestion; new roads had to be build to meet the future demands and likewise socioeconomic calculations showed that the light rail project was far to expensive. More busses could be inducted when new roads were build, this would by all means be the most cost effective solution based on their rationality (Vollset, 2007).

It is obvious that the road directorate had a very central role in the debate around Bergen Light rail. Their rationality was rooted in the understanding of traffic as cost benefit calculation based on traffic modelling with time savings as the important factor to evaluate on socioeconomic benefit of the infrastructure project; and in this perspective the light rail project didn't make much sense.

Another group of stakeholders can be framed as the environmentalists, and in the Bergen case the environmental arguments proved to be important. The awareness of the environment started growing in Bergen in the eighties 'Gatebruksplanen' from 1989 was the fist realisation of that planning for cars had happened at the expense of pedestrians, cyclists and public transport users (Eide, 2011; Vollset, 2007). The environmental movement in Bergen 'Naturvernforbundets' initiated the fist hearing of a plan to construct a light rail called 'Bybanehøringen' from 1989. However, the increasing environmental problems also became much more visible for the people living in Bergen in the beginning of the 2000s. Due to the location of Bergen between seven fells and close to the seaside, the smog from the increasing car traffic in some years lied as duvet and created a visible picture of the downside of the growing individual car traffic (Figure 3) (Rasmussen, 2011). This picture became an important argument for the need to shift planning towards more sustainable modes, including the possibility to construct a light rail.

Figure 3: Bergen city covered in smog from the traffic in the first years of 2000 (Rasmussen, 2011).

The main arguments in use within this environmentalist grouping in favour of the light rail project, was that the light rail should be provide an efficient public transport network that could serve as an attractive alternative to the car, hence indicating that this was solely a matter of getting people from A to B as fast as possible. Therefore it was important that the alignment of the tracks was made in direct lines to ensure a high speed for commuters of the line. This argumentation didn't fit with the rationality shared by many planners that the light rail should be an urban project. In their story the most important goal of the light rail was to ensure that the system was integrated in the urban environment and enabled frequent stops at the relevant urban destination. However, if the light rail was to have many stops along the route this would reduce the speed and the environmentalists saw this as a big disadvantage if the light rail should be a realistic alternative to the car (Vollset, 2007).

Various 'experts' was brought in from other countries to tell about the successful outcomes that the light rail had facilitated in these countries, and hereby provided spatial referents. Hereby the global discourses around light rail had an important role in the local arena in Bergen and initiated the translation of these to the local context (Vollset, 2007; Potter, 2011). The argument of perceiving the project as more than a transport project became an important argument in the process, especially since this argument was a valuable counter reasoning towards the road directorate which used the traffic models, and the engineering determinism that follows with using these models, to evaluate on the direct economic benefits of the project and hence overlooking the indirect benefits that the light rail project could have in order of structuring urban development and increasing market prices in the corridor (Rasmussen, 2011). It therefore became a principal question of how infrastructure benefits and disadvantage could be valued.

2.2.2 The Mothers of Bergen Light rail - and the making of Bergen Light Rail as a Urban Project.

The important actors who made the choices that finally resulted in the decision to build Bergen light rail were women, and in the stories told about Bergen light rail in the media these woman are called

'The mothers of Bergen light rail' (Hustvedt, 2010). Gunn-Vivian Eide (from the green left wing party SV) was the first politician to suggest that the financing for the light rail project, which had been subject for great discussions, could come from the toll-money in Bergen, where car-drivers paid tolls to finance new infrastructure projects, by this Gunn-Vivian seriously challenges the vision for the mobility future in Bergen since the toll money was originally indented for road infrastructure. This was not considered an unpopular move amongst the road directorate since their rationality around traffic planning and prioritisations was somewhat different (Eide, 2011). In 1996 the politician Elisabeth Tryti followed up on this initiative by preparing for a transport financing agreement called 'Bergensprogrammet' where the toll revenue, amongst other priorities, should finance the light rail project in Bergen. But because of strong political opposition towards the use of toll money paid by car-driver to finance public transport project, a compromise was made the 'Bergensprogrammet' should be a package that both covered money for public transport, cyclists and new road infrastructure. The party SV, which was considered proponents of the light rail and initiated the idea with toll money to finance the project, didn't support the transport program since they thought that they would the compromise the original intent with implementing of light rail; to reduce car traffic. Therefore they didn't vote for the proposal which indicated that they could no longer support the local concept of the light rail if it ended up being a compromise that didn't change the traffic prioritisations and mobility hierarchy towards greener modes. The Bergensprogram was implemented without the support of the SV party (Vollset, 2007).

The final concept for the light rail in Bergen was framed when responsibilities for public transport in Bergen city was handed over from 'Fylket' (the regional authorities) to the municipality in Bergen in year 2001 where the first light rail office was establish as a section under the Planning Department (Potter, 2011). The shift was caused by a political awareness amongst the municipal politicians that the public transport system in Bergen Centrum had been neglected for ages on behalf of providing a network in the less populated area that serviced every nook in the region due to the regional politicians focus on nursing for the districts where they were elected (Eide, 2011). This shift finally manifested the light rail project in Bergen as an 'urban project' where the final concept create the possibility for an urban lifestyle where you didn't have to own a car or at least could prevent the purchase of the second car in the household (Potter, 2011). However, by looking into the official planning documents this concept doesn't come across as very clear. However the project originally wasn't rooted in this department and the financing of the project ended up being a compromise between two visionary concepts; 'the efficient road scenario' and the 'life in the collective city' (Potter, 2011). When you visit Bergen today you will see this compromise; many places you see densification in the light rail corridor and construction of new quarters along some stops, but you will also experience a city where the car still has a high prioritisation. Table 3 summarizes the discursive and spatial aspects of the Bergen case.

Table 3. The case of Bergen Norway

		Proponents	**Opponents**
Narrative dimension	*Information*	Factual but not well structured argumentation. Proponent's views don't from a clear concept.	Clear and consistent argumentation based in the economic and capacity discourse - choose the most cost-effective solution.
	Temporal order/structure	Before the city was a congested and polluted place, with Bybanen it will be a liveable place.	Congestion can be solved with road infrastructure; busses can handle the need for capacity in the public transport sector.
	Causality	Urban competitiveness is dependent on a new urban transport system that will restructure the city	Facilitating traffic is a requisite for growth, we cannot reduce the flow of traffic - time losses are expensive for the society.
	Plot	Strong plot: the struggle between the car and the public transport - what do we want for the future. The result is the compromise made in 'Bergensprogrammet' half/half soulution.	Money earned from the motorists shouldn't pay for public transport. Value for money is to facilitate the flow and ensure capacity.
	Discourse institutionalization	Heavily embedded in many of the general discourses around light rail: 'liveable cities discourse', 'struggle for space in the cities'.	Heavily institutionalised discourse. The road directorate evaluates due to a model based method where timesaving's and accessibility is the important factor.
Sense of place dimension	*Relations to other places*	Strong relation to 'best practice example in other light rail cities' - the city competition of creating the liveable city. The most important argument	Not articulated - focus on the local challenges and how to solve these.
	References to physical attributes	Not many references to local physical attributes - the light rail project is not specifically linked to this more to sprawl and congestion issues in general.	No link to physical attributes.
The final concept	*Main argument*	Creating the collective city - with the choice to live in proximity to public transport (deselecting purchasing car no. two)	
	Discourse	*Weak institutionalization of concept (not all are clear on arguments):* 'Backbone of the public transport network' - trying to change the modal split by introducing an alternative lifestyle choice 'the collective city'	

3. Conclusions

The Bergen case exemplifies the importance of forming a clear local concept for any project that requires significant interventions in the urban and cultural landscape. The formation of a clear concept for a light rail project is crucial for the project to pass smoothly through the political process and even more importantly, to ensure that the aims and goals with the project are clear for all stakeholders from the beginning of the project. In Bergen the concept for the light rail ended up as a compromise that neither fully supported the proponents or opponents for the light rail project, and thus it can be difficult to identify the original intend and purpose with the light rail project as it is formulated today, not herby saying that the project haven't been successful in many aspects, especially in changing cultural perception public transport after the system has now been running for more than a year.

The lack of a clear concept and purpose for the project can furthermore have some implications for the later stages of the project. Choosing the final alignment of the system can be very different depending on the purpose of the system; was the intend to transport people as fast as possible from A to B, or was the light rail a tool to structure future urban development, or was it a part of an urban branding strategy? With the absence of a clear concept that defines the aim with the project it is challenging to define success criteria for the system and guide the project through the implementation and operation process. It is therefore argued that focus for future light rail project and other urban intervention projects should be placed on creating a clear stories and concepts for such a project, hereby making it relevant in a local context. This could be by applying the project to an overall strategy for the future urban development which politically gives the project an important role to play in future development strategies. This will ensure that the concept is institutionalised and passes the political process with fewer obstacles.

Moreover, the Bergen case exemplifies a trend of city competition and creating the story of 'the liveable city' which is evident in many middle sized European cities. In this intense city competition within a globalised world, global concepts such as light rail or harbour front developments is constantly 'travelling' and entering new geographical arenas where local actors tries to grasp and narrate these ideas and use them in a local context to keep the cites 'fit' for competition in order to facilitate economic growth. But in this strong competition of implementing new global ideas many cities often end op looking the same, especially those cities that have not managed to integrate the global concept in the local context and activate the potentials that such concepts might have. Light rail projects are translated very differently across European cities; In France light rail projects are often perceived as urban projects where a significant part of the budget for such systems are covering urban regeneration processes and urban design features along the route (Johansson, 2011).This generates new mobile spaces in the city and in many cases causes a reordering of the mobility hierarchy in the French cities because implementation of light rail is often followed by restrictions for car-traffic. In some German cities e.g. Freiburg the light rail system plays an important role in facilitating an efficient urban mobility system that is integrated in the urban environment and linked to the regional and national networks (Schade, 2011).

In this paper I have shown how the stories told light rail systems are considerably different in various national context etc. due to the differences in how the global concepts has been activated in a local context and how these new concepts find their place physically, discursively and culturally. Furthermore there is a very clear connection between the concept and the effects of the systems. The technology light rail doesn't cause change in itself, it is the framing of the concept in the local context that defines the role the system should play in the existing *mobility system* (Urry, 2007) and the potential effects that the system could cause. Discussions around public transport is a highly valued based discussion, even though many technical arguments are often activated, therefore planning professionals have to acknowledge the importance of the translation process from global to local concept in order to make the project relevant in a new context.

SOUNDING BRIGHTON: DEVELOPING AN APPLIED SOUNDSCAPE STRATEGY

Lisa Lavia [1], Östen Axelsson [2], Max Dixon [3]

Abstract

In order to help develop an applied soundscape strategy for the City of Brighton & Hove, in the United Kingdom, we conducted a social survey, as part of a project called Sounding Brighton, via a questionnaire study. The survey, in which members of the public were invited to participate anonymously, was supported by the EU COST Action TD0804 "Soundscapes of European Cities and Landscapes", in cooperation with Brighton & Hove City Council and Local Action Teams. In total, 354 individuals, 15 years or older, completed the questionnaire. It consisted of four parts: (1) noise annoyance, (2) favourite outdoor location in Brighton & Hove and the social and recreational activities it entails, (3) what sounds are appropriate to the favourite location, and (4) demographic data. Using hierarchical cluster analysis, 5 categories of favourite locations, as well as 5 categories of recreational soundscapes, were found. The categories of favourite locations in Brighton & Hove were named: 'Beach & Seaside', 'City Park', 'Peri-Urban Recreation Area', 'My Space', and 'Downtown City'. The recreational soundscapes were named: 'Urban Nature', 'Distant Nature', 'Urban', 'Seaside', and 'Urban Beach'. A Chi Square analysis showed that there is a statistically significant and meaningful relationship between the social and recreational activities that people find suitable in their favourite outdoor location and the degree to which they find that specific sound sources are appropriate there. The next step in the development of an applied soundscape strategy is to identify and map all areas of Brighton & Hove that fall under the five categories of favourite locations, and to decide on their acoustic objectives in line with the five categories of recreational soundscapes.

1. Introduction

As the European Noise Directive illustrates, management of the acoustic environment is currently predominantly focused on sound levels and noise mitigation (EC, 2002). Consequently, the single objective is to reduce sound levels below an acceptable guideline value (cf. WHO, 2000).

Noise researchers have started to realize that the current approach to the acoustic environment needs to be complemented with an approach that acknowledges the positive aspects of the acoustic environment (e.g., Brown & Muhar, 2004). A strict

[1] Noise Abatement Society, Brighton, United Kingdom – lisa.lavia@noise-abatement.org
[2] Stockholm University, Stockholm, Sweden – oan@psychology.su.se
[3] Independent consultant, London, United Kingdom – maxdixon1@hotmail.co.uk

focus on acceptable guideline values may be counter-productive, because once they are reached there are no incentives for further improvements. As a result of these insights, some noise researchers adopted the concept of 'soundscape' in the late 1990s (Schulte-Fortkamp & Dubois, 2006). This marked a paradigm shift in the way noise researchers studied the acoustic environment.

The term 'soundscape' refers to the acoustic environment of a place, like a residential area or a city park, as perceived, experienced or understood by people, in context (cf. Axelsson, 2011a; ISO, 2012). It is the acoustic equivalent to 'landscape' (cf. Council of Europe, 2000), and includes all sound sources, wanted as well as unwanted. Managing the sounds of places can, therefore, be referred to as 'soundscape planning' (e.g., Axelsson, 2011b).

Unlike the current approach to managing the acoustic environment, soundscape planning is not primarily about reducing sound levels. Soundscape planning is not even necessarily a question of how loud sounds are, rather, what sounds are appropriate to, or belong to a place. There is no one ideal soundscape; and what is deemed an appropriate soundscape can change over time to reflect the evolving needs and/or uses of an area. To decide which soundscapes are good (i.e. appropriate), it is necessary to consider which activities the soundscape may enable at a place (Brown & Muhar, 2004).

The present paper reports the results from a pilot study conducted in the City of Brighton & Hove, in the United Kingdom, exploring the possibility of integrating a *soundscape* approach with a recent method for spatial planning and land use management called *sociotope* mapping. Sociotope mapping was developed in Stockholm, Sweden, to help avoid conflicts between residents and the city administration when increasing the density of the city space (Ståhle, 2002, 2003, 2006). A sociotope map is developed through user surveys, where urban planners are informed about how residents use and value urban open spaces from a social point of view. Together with expert assessments, this results in a GIS (Geographic Information System) map with areas marked in different colours representing their user values (e.g. enjoying the street life; nature appreciation; playing with one's children; or having a picnic). The sociotope maps then help the city planners to take the user values into consideration in the planning process. In Brighton & Hove this model is being adapted to encompass *soundscape*, by incorporating the sounds people find appropriate to the sociotope into the maps.

2. Method

2.1 Questionnaire

To explore the relationship between soundscapes and sociotopes, we conducted a social survey, using an electronic questionnaire that consisted of four sections. (1) To allow respondents the opportunity to register complaints about noise, as a service to the community (see Section 2.2, paragraph 2, below) the first section concerned

noise annoyance. It was based on the ISO/TS 15666 question with verbal rating scale (ISO, 2003), with the amendment that the response category 'Not at all' was divided into the two response categories 'Not at all (don't hear it)' and 'Not at all (hear it but not bothered by it)'. Sections (2) – (4) then concentrated on local soundscape quality as follows: (2) In the second section the respondents were asked to name their favourite outdoor location in Brighton or Hove, and to indicate to what degree a list of 27 social and recreational activities would be suitable in this location (6-point category scale: 'Don't know/not applicable', 'Not at all', 'Slightly', 'Moderately', 'Very', 'Perfectly'). (3) In the third section the respondents were asked to indicate to what degree a list of 29 sound sources would be appropriate in the favourite location (5-point category scale: 'Not audible', 'Slightly audible', 'Moderately audible', 'Clearly audible', 'Completely dominant'). (4) The fourth, and last, section concerned demographic data, such as in what area of Brighton or Hove the respondents live, gender, age, as well as occupation.

2.2 Participants

The participants were residents in Brighton or Hove, 15 years of age and older. They were recruited via advertisements in local newspapers, via Local Action Teams (residents groups organised by the City Council; http://www.safeinthecity.info/), and via the Noise Abatement Society's local network of contacts.

The recruitment materials invited residents of the city to 'have their say' about 'how they experienced local sound quality'. This wording was particularly important in order to differentiate the activity from traditional approaches to surveying for noise annoyance. In other words, the project was specifically designed to gather data about local soundscape quality as its primary purpose.

Nearly 700 persons visited the electronic questionnaire. Out of all visitors, 537 completed the first section on annoyance, 395 completed also the second section on favourite location, 382 completed the third section on appropriate sounds, and 354 completed the entire questionnaire, including the fourth section on demographics data.

Out of the 354 respondents who completed the entire questionnaire, 182 were females and 172 were males. A majority lived in the most highly noise exposed central parts of Brighton & Hove, and were 35–69 years old. With regards to occupation, 70 % were employed, 17 % retired, and 8 % self-employed. The remaining 5 % were unemployed or students.

3. Results

The present report concentrates on the relationship between sociotopes and soundscapes, and presents the results for the second and third sections of the questionnaire.

3.1 Sociotopes

To identify the number of different kinds of sociotopes among the named favourite locations in Brighton & Hove, the 395 complete responses to the 27 variables of the second section of the questionnaire were analysed. First, the verbal data was transformed to a numerical 6-point scale (0–5). Secondly, the 395 × 27 matrix was subjected to a hierarchical cluster analysis, and the 395 rows in the matrix were clustered (SPSS 19 for Windows; Squared Euclidean Distances; Furthest Neighbour/Complete Linkage). Inspection of the agglomeration schedule, as well as a range of potential solutions, revealed that 5 main categories of sociotopes could be identified in the data.

Separately, for each of the 5 categories, median values were calculated for each of the 27 variables. Then, for every category, the variables with the highest median values were used to interpret and name the 5 sociotopes. In addition, the names of the favourite locations that the respondents provided were used to guide the interpretation.

The first sociotope was most highly associated with the variables ‘Appreciating the sea’, ‘Appreciating landscape/scenery’, ‘Walking, jogging’, ‘Wind/wave/kite surfing’, and ‘Swimming/bathing’. The median values for these variables were all above 4.0, indicating that these social and recreational activities were found very suitable for the first sociotope. This sociotope was named ‘Beach & Seaside’ (N = 149).

The second sociotope was most highly associated with the variables ‘Appreciating landscape/scenery’, ‘Walking, jogging’, ‘Appreciating parks and gardens’, ‘Individual outdoor exercise’, and ‘Picnic/barbecue’. The median values of these variables were all above 3.0, indicating that these social and recreational activities were found moderately suitable for the second sociotope. This sociotope was named ‘City Park’ (N = 117).

The third sociotope was most highly associated with the variables ‘Appreciating landscape/scenery’, ‘Walking the dog’, ‘Walking, jogging’, ‘Appreciating wildlife’, and ‘Experiencing peace and quiet’. The median values of these variables were all above 4.0, indicating that these social and recreational activities were found very suitable for the third sociotope. This sociotope was named ‘Peri-Urban Recreation Area’ (N = 56).

The fourth sociotope was most highly associated with the variables ‘Appreciating landscape/scenery’, ‘Appreciating wildlife’, ‘Experiencing peace and quiet’, ‘Appreciating parks and gardens’, and ‘Watching people go by’. The median values of these variables were just above 2.0, indicating that the social and recreational activities were not strongly associated with the fourth sociotope. That this sociotope often was associated with “My own garden” indicates that this is a place where the

individuals could relax and ‘be themselves’. This sociotope was named ‘My Space’ (N = 44).

The fifth sociotope was most highly associated with the variables ‘Watching people go by’, ‘Experiencing active street life’, ‘Eating (Café, Cafeteria)’, ‘Outdoor events’, and ‘Walking, jogging’. The median values of these variables were all above 3.0, indicating that these social and recreational activities were found moderately suitable for the fifth sociotope. This sociotope was named ‘Downtown City’ (N = 28).

3.2 Soundscapes

To identify the number of different kinds of soundscapes among the named favourite locations in Brighton & Hove, the 382 complete responses to the 29 variables of the third section of the questionnaire were analysed, using the same method as for sociotopes above. Among the 382 cases, 5 main categories of soundscapes could be identified.

The first soundscape was most highly associated with the variables ‘Birdsong’, ‘Wind in trees, etc.’, ‘Other wildlife’, ‘People walking’, and ‘Seagulls’. The median values of these variables were all above 2.0, indicating that these sound sources were found appropriate when moderately audible in the favourite location. The first soundscape was named ‘Urban Nature’ (N = 132).

The second soundscape was most highly associated with the variables ‘Birdsong’, ‘Wind in trees, etc.’, ‘Seagulls’, ‘Children playing’, and ‘People talking’. The median values of these variables were just above 1.0, indicating that these sound sources were found appropriate when slightly audible in the favourite location. This means that sounds should only be heard in the background, and not be present in the foreground. The second soundscape was named ‘Distant Nature’ (N = 88).

The third soundscape was most highly associated with the variables ‘Seagulls’, ‘People shouting’, ‘Road traffic’, ‘People talking’, and ‘Amplified music’. The median values of these variables were close to 2.0, indicating that these sound sources were found appropriate when moderately audible in the favourite location. The third soundscape was named ‘Urban’ (N = 85).

The fourth soundscape was most highly associated with the variables ‘Flowing water’, ‘Seagulls’, ‘Children playing’, ‘People walking’, and ‘People talking’. The median values of these variables were near or above 2.0, indicating that these sound sources were found appropriate when moderately to clearly audible in the favourite location. The third soundscape was named ‘Seaside’ (N = 55).

The fifth soundscape was most highly associated with the variables ‘Seagulls’, ‘People walking’, ‘Children playing’, ‘People talking’, and ‘People shouting’. The median values of these variables were all above 2.0, indicating that these sound

sources were found appropriate when moderately to clearly audible in the favourite location. The third soundscape was named ‘Urban Beach’ (N = 22).

3.3 Sociotope-Soundscape concordance

To investigate the concordance between the 5 sociotopes and the 5 soundscapes, a 5×5 contingency table was created based on the 381 respondents who had completed both the second and the third sections of the questionnaire (Table 1). A Chi Square analysis shows that the distribution of the data in Table 1 is statistically significantly different from that expected by chance (see numbers in brackets) (χ^2 = 126.0, DF = 16, $p < 0.001$). This shows that there is a relationship between the social and recreational activities that people find suitable in their favourite outdoor location and the degree to which they find that specific sound sources are appropriate there.

Table 1 shows that ‘Beach & Seaside’ sociotope was strongly associated with ‘Seaside’ and ‘Urban Beach’ soundscapes, and weakly associated with ‘Distant Nature’ soundscape. ‘City Park’ sociotope was associated with ‘Urban Nature’ and ‘Distant Nature’ soundscapes, but very weakly with ‘Seaside’ soundscape. ‘Peri-Urban Recreation Area’ sociotope was strongly associated with ‘Urban Nature’ and ‘Distant Nature’ soundscapes. ‘My Space’ sociotope was most strongly associated with ‘Distant Nature’ soundscape. Finally, ‘Downtown City’ sociotope was strongly associated with ‘Urban’ and ‘Urban Beach’ soundscapes, but weakly with ‘Urban Nature’ and ‘Distant Nature’ soundscapes.

Table 1. Contingency table for 5 sociotopes and 5 soundscapes

	Soundscape					
Sociotope	Urban Nature	Distant Nature	Urban	Seaside	Urban Beach	Totals
Beach & Seaside	41 (49.5)	15 (32.7)	31 (31.9)	44 (20.6)	12 (8.3)	143
City Park	46 (40.2)	34 (26.5)	27 (25.9)	4 (16.7)	5 (6.7)	116
Peri-Urban Recreation Area	34 (19.1)	20 (12.6)	1 (12.3)	0 (7.9)	0 (3.2)	55
My Space	7 (13.5)	17 (8.9)	12 (8.7)	2 (5.6)	1 (2.3)	39
Downtown City	4 (9.7)	1 (6.4)	14 (6.2)	5 (4)	4 (1.6)	28
Totals	132	87	85	55	22	381

Note: Numbers in brackets are the values expected by chance.

4. Discussion

The current approach to the acoustic environment – based on sound levels and noise mitigation – needs to be complemented with an approach that acknowledges the positive aspects of the acoustic environment. To this end, the present paper explores

the possibility to integrate a soundscape approach with sociotope mapping. With this pilot study we have established that the present method is useful for identifying distinct sociotopes and soundscapes; and have shown that there is a meaningful and statistically significant relationship between them.

The relationship we have found between sociotopes and soundscapes means that people agree to a large extent on the degree to which a specified set of sound sources is appropriate in a place that is suitable for a specified set of social and recreational activities. This clear and meaningful relationship was not necessarily expected. Rather, people could be in disagreement in this respect, which would mean that sociotopes and soundscapes would be uncorrelated. The latter would have meant that all 5 soundscapes would have been appropriate in all 5 sociotopes, and there would have been $5 \times 5 = 25$ soundscape/sociotope categories. We have found that people typically expect an urban park to have a park soundscape, a beach a beach soundscape, and a city centre a city soundscape; although, of course, there is still room for significant variation and appreciation of local distinctiveness within these general soundscape categories.

Whereas it could be stated that current noise policy, for assessment, measurement and enforcement purposes, presupposes that acoustic environments are more or less uniform and should not exceed a specified guideline value with regards to sound levels (e.g. 55 dBA; EC, 2002; WHO, 2000), the Sounding Brighton survey results show that soundscape may – and probably should – vary, depending on what social and recreational activities are deemed suitable for a space by the users of the place. For example, in some places, such as the city centre during the daytime, moderately loud sounds may be acceptable, including road traffic and people noise. In other places, like the city's parks, many people would like to be able to relax at most times of the day; indicating that such a place should be dominated by the sounds of nature but that the sounds of other people may be acceptable when slightly audible. These results indicate that current government and local government policy related to the acoustic environment must be further developed and better adapted to suit human needs.

With regards to urban planning, the method used in the present paper could be used to identify and decide acoustic objectives for an area depending on what social and recreational activities it is intended for. A next step could be to develop soundscape mapping to complement sociotope maps.

With regards to the City of Brighton & Hove, the next steps in the development of an applied soundscape strategy would be to identify and map all areas of the city that fall under the five categories of favourite locations, and to decide on their acoustic objectives in line with the five categories of recreational soundscapes. It would then be important to further evidence the research by conducting in situ questionnaire studies with visitors to these areas to further evaluate how the soundscapes of these areas are perceived in reality.

5. Concluding remarks

We found a statistically significant and meaningful relationship between sociotopes and soundscapes. In essence, an urban park should have a park soundscape, a beach a beach soundscape, and a city centre a city soundscape. Where soundscape is not taken into account residents may experience loss of health and wellbeing as well as annoyance, particularly in places which would otherwise normally be restorative.

Our results show that it is possible to integrate soundscape with urban planning and design. Sociotope mapping may be expanded to incorporate soundscape, as a tool for soundscape planning. Such a tool would help urban planners to take soundscape into account at an early stage of the planning process. Surely, this would contribute to sustainable urban development, in promotion of health, well-being and quality of life of urban residents.

ECOLOGICAL PLANNING AND STRATEGY ANALYSIS FOR THE AREA IN ARID DESERT

GU Xuanyuan

PhD student, Tongji University

Email:guxuanyuan@vip.sina.com

Abstract

Climate change has become the focus of the world. Today the ecological environmental protection and energy saving technologies are maturing. Planning and Construction need to fundamentally change the traditional concept and methods, and use advanced technology to achieve harmony between man and nature. Arid desert region, as the planet's most fragile ecological area, where people developed through building activities to improve the living environment and alleviate further deterioration, is the typical region with great research value.

In this paper, through the analysis of this kind of regional climatic conditions, three special characters were underlined to be aimed at urban planning. The most important element is water supply, which safeguard all the biology. Then is energy saving, because the main method to keep a comfortable temperature in the high-heat area is to supply large energy, and normally solar energy is affluent in arid desert. In addition, we also need to resist wind and fix sand to protect the living environment.

The traditional building wisdom, as the reference of modern planning for the area in arid desert, is worth of learning. For example, shadow space was used to promote the convection between the hot and cold in small scale to get breeze in micro-environment. And building material with heat insulation like soil and thick brick was used widely to refuse the heat wave outside. In addition, Karez is one of the most outstanding achievements in desert people have done, which even affecting on people’s drinking supply today.

According to the analysis on regional climate character and traditional building wisdom above, some strategies in urban planning were proposed. The first was

compact layout, including the function layout of land use, building layout of space combination and residential unit layout with special community mode. The second was to build an efficient transport system and road network to advance the comfortable degree and decrease the consumption of nonrenewable energy. The third was to use local plants to establish green system with different levels and irrigation technology. The fourth was to suggest characteristic image and guideline on buildings, which could cope with high-heat and dry environment at the beginning and through historical accumulation gradually becoming a regional artistic and cultural value.

Finally, by using the low carbon planning concept and appropriate environmental protection and energy saving technologies effectively, the living environment in arid desert would be improved. As one of the new domain people try to explore to apply to climate change, the area in arid desert is expected to become the new home of the human.

Keywords: Climate change; Urban planning; Arid desert

Introduction

Land desertification is a global environmental issue. Since the existence of historical records, in China, there are 12 million hectares of the land have been turned into deserts, while at present, the desertification area has accounted for over 18% of the national land area[1]. To trace the reasons, most (accounting for 95%) of the land desertification was caused by human factors[2]. Therefore, doing a good job of protecting the land, developing and utilizing the land in a scientific way and conducting ecological comprehensive development rectification in planning and human constructions shall play an important role of relieving the desertification problem and improving the human habitats.

This Paper is based on the research of ecological planning strategies of extreme dry desert areas, and it is aimed at improving human life and working conditions through the ecological development construction activities of independent areas under typical climate conditions and intervening the desertification process through ecological measures.

1 Energy conservation and emission reduction have become the hot topics of the research of current planning and construction

Since the 2009 Copenhagen Climate Conference, the issue of climate warming has caused the broad concerns of the whole world; although the parties of the Conference failed to reach a consensus at the end, they have put the slogan of “Saving our mutual earth” into their schedule.

Meanwhile, the research of worldwide environmental protection and energy conservation has been booming. For example, a Masdar City has been planned for construction in the deserts areas of United Arab Emirates, and it shall be constructed into the world’s first “environmental protection city” that is totally dependent on solar energy to realize self-sufficiency and self-containment, and the zero emissions of waste water and auto emission and CO_2. Its goals of zero emission, zero waste and sustainable environmental protection have provided important experiences for the planning and construction of deserts area.

Starting from the Eleventh Five-year Plan, the environmental protection concept of energy conservation and emission reduction in China has been transformed from the original research and appeals into practical numeral planned targets, and the performance assessments have been conducted on the local governments and mayors. Not only has the nation promulgated a series of laws and regulations, enhanced the relevant policy system of energy conservation emission reductions, but also invested in ten major energy conservation projects, totaling more than 500 energy conservation projects[3]. On such a basis, the practice research of ecological planning and construction has entered the substantial stage.

Dry desert areas belong to the extremely feeble areas of the ecological system, and the effective utilization of energy and resources shall play an outstanding role in the aspects of energy conservation and emission reduction, and the ecological transformation on human habitat is not only an active intervention of the adverse environmental condition, but it is also an important research practice for the present planning practice of our nation’s low-carbon cities. Hence, an in-depth transformation on the production mode, life style and the basic planning concepts has been formed.

2 The Climate Characteristics of Extreme Droughts and Key Planning Points

The dry desert areas are widely distributed worldwide, and in our nation they are mainly distributed in the northwestern areas, which feature dry climate and scarce rain, sparse vegetation, and relatively such fewer humanity scenes as the population and cities, and are the areas that manifested the feeblest ecological system[4]. In the localities, it is extremely tough to conduct general outdoor activities, and with regard to such aspects as the air’s temperature, humidity, wind speed and heat radiation,

they most manifest the environmental characteristics of discomfort, thus affecting the working efficiency and human health. However, the areas' annual sunshine hours are all over 3000 hours, and are featuring the excellent conditions of utilizing the solar energy. Therefore, regarding the climate characteristics of these kinds of areas, their planning and constructions are mainly manifested in the following aspects：

a) Water cycling and intensive utilization

b) Sufficient utilization of solar energy

c) Windbreak and sand fixation through planting measures

d) Construction of comfortable human habitat

3 Drawing Experience from the Traditional Architecture Wisdom

Although these areas feature adverse conditions of natural environment, they have inspired the boundless wisdom of human being, especially regarding the constructions of the traditional architecture, which reflect the great achievements made by the locals in their fights with the nature. Through such special construction modes, they have been fighting against the threatening climate condition, which worth to be learned in modern planning and construction. For example：

3.1Sufficient utilization of shadow and gray space to form local temperature difference counter-flows

In the architecture and planning of these areas, the retaining walls on the roofs, narrow lanes and deep window holes are utilized to form the shadow and gray space; due to the dry climate, there is a big difference between the temperature in the shade and in the sunlight, therefore local air counter-flows can be easily formed, thus increasing the degree of comfort in local areas. Therefore, in the planning, the complex space construction is usually adopted in the courtyard so as to provide the shadow space in different times and different locations (Halike, 2005) , and meanwhile, through the shadow and gray space to organize the public open space, to form the main outdoor activity sites of the residents.

3.2Thick walls are laid with local insulation materials to fight against the high temperature

Local clay or bricks are mostly adopted for the traditional architecture, which feature excellent thermal properties, are heat-insulated and sound-insulated, without

chemical reactions, and the material units are small and they have stronger plasticity and elasticity, and even in modern time, they can be used in combination with stone, wood and steel materials, and they also cost lower.

3.3Kariz water gathering system

Kariz is an artificial facility used for the farmland irrigation and residents drinking by intercepting the underground water in areas with specific landform conditions, and it is the life line for the local agricultural production and residents' livelihood. Through an underground water collection, an enclosed channel that is shaded and protected from the wind is formed, thus greatly reducing the water vaporization, so it is a typical example of scientific use of water through human constructions. (DENG, 2010)

4 Planning Counter-measures

4.1 Compact Layout and Concentrated Functions

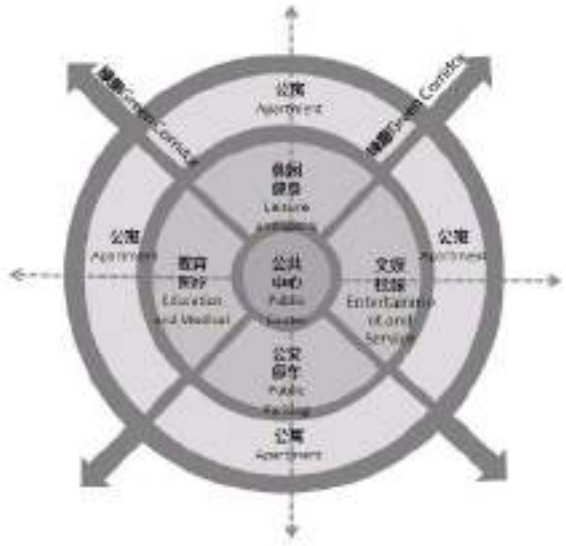

Figure 1. Diagram of functional configurations

In dry desert areas, due to the vast land and sparse population, the construction conditions are hard; generally it is necessary to have compact layout so as to reduce the invasion of the wind and sands. As for the public service facilities that are constructed in one period, it would be favorable to have concentrated layouts, have compound functions and comfortable environments so as to form intensive public cores and reduce energy dissipation and waste. Meanwhile, the service scope of the public service centers shall be moderately expanded, so as to reduce the construction volume.

The residential neighborhood shall be laid in a compact way so that, on one hand,

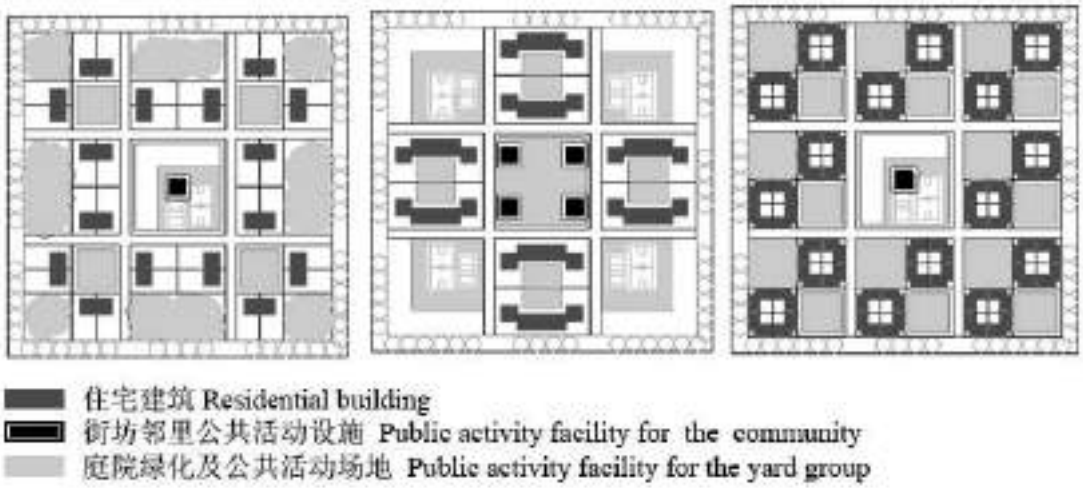

Figure 2. Diagram of functional layouts

shadings can be provided between the adjacent buildings, and, one the other hand, the visual concerns between the neighbors can play a soothing effect on the environmental psychology of the residents in the desert areas. It is possible to learn from the enclosure mode of residential layout, so that the shade space can become the activity centers of the neighborhood with mutual supervision and mutual cares.

4.2 Separate Setups of the Road System

The urban roads, due to the differences in the supporting transportation tools, shall be somewhat separated. As for the traffic of motor vehicles, according to the principle of convenient and flexible, the roadway should be settled down to every garage, but meanwhile, the driving time of the vehicles should be limited and public transportation should be encouraged by making endeavors to create more comfortable and efficient running conditions. As for the traffic of non-motorized vehicles and pedestrian traffic, efforts shall be made to provide special routes that are relatively shaded and moistened so as to reduce the discomfort of slow moving traffic. Therefore, roads for motorized vehicles and non-motorized vehicles or walking traffic shall be set up separately, and the road environment shall also be designed separately; while reducing the construction costs, these measures can create comfortable environments of walking traffic and biking traffic. It is also necessary to make efforts to adopt the design without the pedestrian lanes for the designs of the road cross sections and set them up with shadows.

Figure 3. Diagram of motorized lane and non-motorized lanes

Parking lots or garages shall be deployed with shading facilities so as to reduce the energy consumptions of the vehicles' pre-cooling. The outdoor concentrated parking lots can be provided with integral sunshade panels and meanwhile they can be combined with the solar energy heat-collecting panels so as to supplement the municipal power supply, or provide the charging services for the electric automobiles. What is worth mentioning is that since the technologies of electric automobiles have become increasingly mature, in the future urban planning, the deployments of charging stations shall also be taken into considerations.

4.3 Humanistic Outdoor Spaces for Public Communications

Regarding the outdoor spaces for public communications, in order to strengthen the comfortable feeling of the environment, sunshade system shall be provided, which can be divided into three levels：

a) Pedestrian lanes: By utilizing arbor for shading, meanwhile, combining with the shades of the bushes on sides of the pedestrian lanes, the counter-flows of cool air can be enhanced and the temperature can be reduced with the water scenes in local areas.

b) Shaded activity sites: Through constructing the solar gathering and adumbral system in the sites of public activities and combining with the water scenes, a small climate environment can be created. The special light and shadow effects, while enhancing the shaded areas, can also manifest landscape characters.

c) Shaded gray spaces: Shaded corridors should be provided to form a transition between the indoor space and outdoor space.

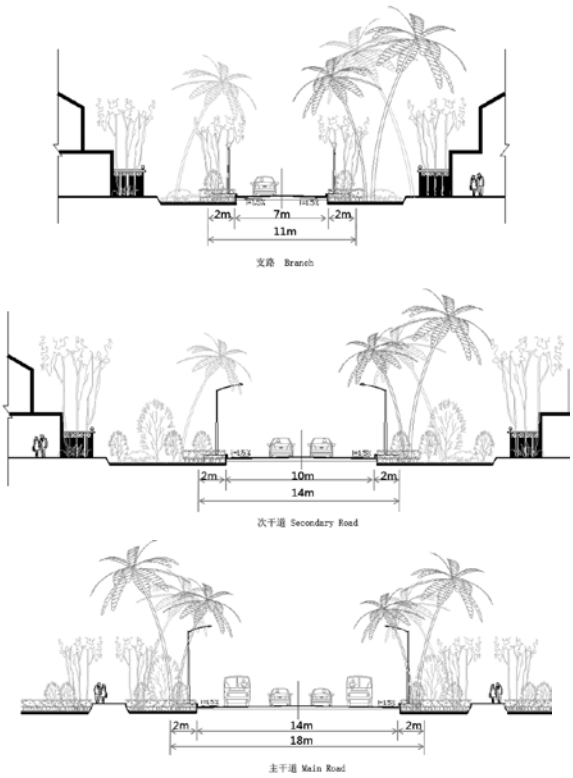

Figure 4. Road cross-section diagram with motorized lane and non-motorized lanes separated

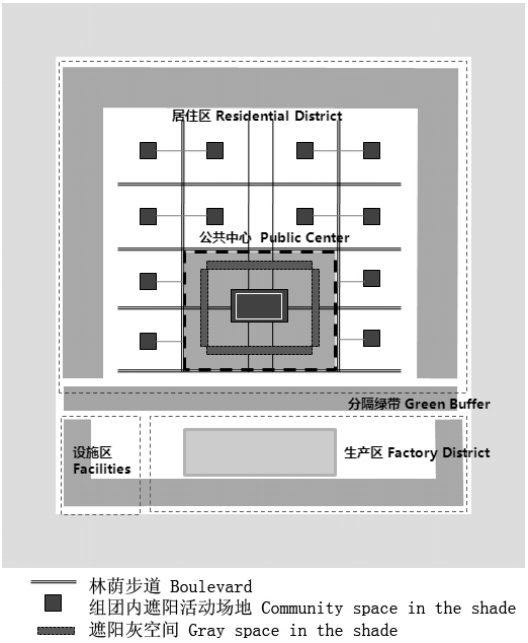

Figure 5. Diagram of outdoor spaces with public communications

4.4 Set up Green System in Different Layers

The planting costs in the dry desert areas are extremely high, and the planting effects of most local plants

that adapt to the local climate are not strong. Therefore, the landscape function of planting should be somewhat weakened, and the functions of windbreak and sand fixation and ecological nourishing should be elevated accordingly. Regarding different land sections and different planting needs, emphasis should be given to a green system with different position, different investments and diversified plant arrangements.

a) Outer sand protection green belt: In the vicinity of the planned areas and the directions from which the sandstorms are coming, the green belt for windbreak and sand fixation should be planted. The importance of providing such greening belts is similar to that of the setup of the flood wall and they shall be arranged and their seeds shall be selected in a scientific way, basically giving less consideration to the landscape effects. Meanwhile, nursery gardens shall be set up in their surrounding areas for cultivation and planting observations, which form a mutual enhancements and supplementations with the green lands of windbreak and sand fixation. By this way, the green belt can be maintained through timely supplementary planting. The planting vegetation in such green belts need to have concentrated irrigations with drip irrigation technology through the municipal water pipelines.

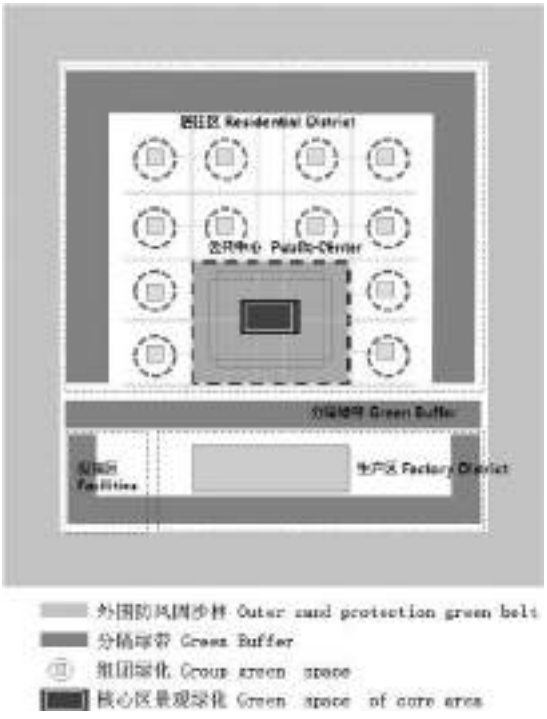

Figure 6. Diagram of outdoor green system layouts

b) Inner sand protection green belt: Green belts with certain heights shall be set up in the surroundings of the areas where there are intensive resident activities, which shall feature both the function of windbreak and sand fixation, and the function of landscape and shadowing. As a result, while the residents can be protected from the harms by sandstorms, they can also acquire a psychological cooling sensation through visual effects and elevate the degree of comfort. Such kinds of green belt have concentrated irrigations with drip irrigation technology through the municipal water pipelines also.

c) Group green space: Courtyard green space shall be set up in the residential building groups which are combined with the resident activities, which mainly feature the landscape and shadowing functions, and somewhere the arbors planted with flowers for appreciation. They shall be irrigated with reused water after anaerobic effluent treatment from living waste water.

d) Green space in core area: Intensive and high efficiency green space shall be provided in the public core areas, which mainly feature the landscape and shadowing functions; Meanwhile, the hardened ground surface and arbor planting shall be combined with each other ,and sometime the lawn patches and flowering plants for appreciation are also needed. They shall be irrigated in a concentrated way through the municipal water pipelines.

4.5 Elastic Reservations and Rapid Construction

Since during the initial construction phase of the dry desert areas, it mainly features the intensive construction, with the smooth operation of the energy and ecological system as the main goal; when the development of an area is relatively stabilized, it will, just like most of the cities and towns, attract more people to settle down here and practice their occupations, which expand the city functions. Therefore, in the planning, it is necessary to provide the possibility of future expansion so as to avoid the damages to the newly formed green belts and the ecological system caused by the expansions of the growth borders of cities.

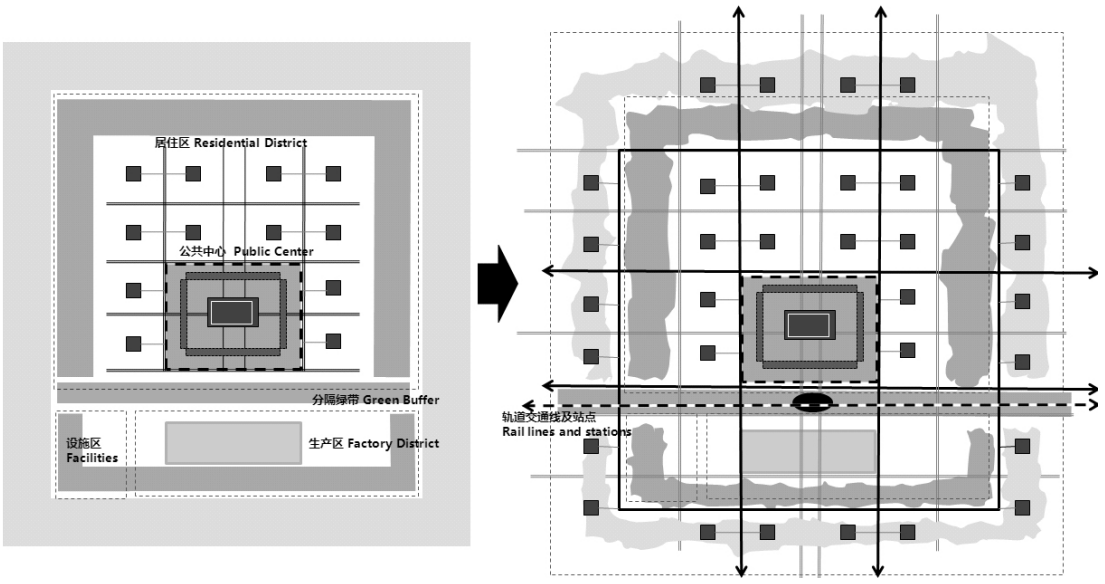

Figure 7．Diagram of cluster expansion and transformation

a) The planning of road networks shall mainly be based on square grids, with

reserved possibilities of outward expansions.

b) Protect most of the living vegetations, which is potential to be transformed into urban green belts with different functions in the process of urban expansion.

c) New area shall be developed with the form of blocks so as to avoid removing and reconstruction.

d) Since the civil engineering activities are mostly conducted outdoors, it is necessary to elevate the construction speed and efficiency and shorten construction periods. For the engineering facilities which need constant maintenance and some functional blocks with shorter utilization periods, they would be preferable to adopt the modular components, which feature elasticity of transformations, or the modes of out-site production and on-site installations can be adopted so as to elevate construction efficiency.

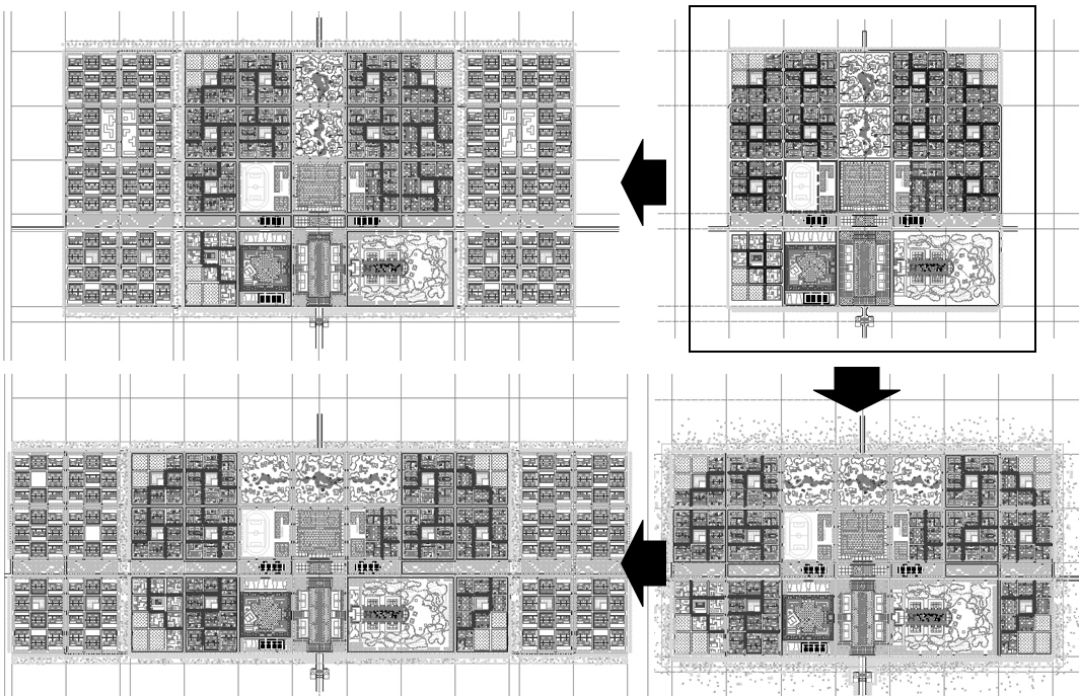

Figure 8. Diagram of urban growth

5 Relevant Ecological Technical Assurances

During the process of realizing the above planning measures, the applications of energy conservation and environmental protection techniques are indispensable, especially regarding such aspects as the reclaimed water utilization, electric generation with solar energy and windbreak and sand fixation. At present there have

been rapid progress in domestic and foreign energy conservation and environmental protection techniques; however, although some techniques are advanced, they do not feature the conditions for wide applications, either because the technical process is too complicated or the costs are high, or they are too particular about some preconditions. Nevertheless, dry desert areas are bound to be the important areas for human beings to fight against the nature through science and technology, and the steps of their research and exploration shall never cease.

In the following, some of the relatively mature ecological technologies that are suitable for uses in the dry desert area are selected so as to ensure the realization of the measures.

a) Greening plantations and plant irrigation techniques: Generally there are three kinds of irrigation techniques as border irrigation, furrow irrigation and drip irrigation, among which the drip irrigation technique features the most advantages. Based on a simple principle, the drip irrigation technique drip the water onto the precise locations of the plants. Compared with the open type irrigation which has 40% water used efficiently, the efficiency in the use of water with the drip irrigation technique can reach as high as 70～80%, so the limited amount of water can get maximum benefit. It not only can effectively save resources, control evaporation, but can also reduce the plants needs on fertilizers, prevent the soil's salinization and prevent weed growth.

b) Techniques of windbreak and sand fixation: There are generally such three categories as biological sand fixation, engineering sand fixation and chemical sand fixation.(LIU, *et al*, 2002)

Biological sand fixation technique: establish artificial vegetations or protect and restore natural vegetation, and generally it is necessary to provide mechanical or chemical sand fixation techniques as supplements. Local plant species shall be selected first for the biological sand fixation.

Engineering sand fixation——sand barriers which blockade the movements of sands through engineering measures, are divided into the two forms of flat layout and vertical layout.[5]

Chemical sand fixation——fix the flowing sands by utilizing the sand-fixing agents. Sand fixing agents can be directly sprayed on the ground or mixed with sand soil, and it can form a protective membrane with the sand soil, thus effective fix the sand and prevent the movements of the sand soil; meanwhile, absorb and reserve the rain water so as to ensure the vegetation viability and speed up the growth; for example,

the uses of water retention agents, ABT, and PG reagent.

c) The technique of geo-thermal heat pumps: Retrieve the heat from the shallow soil or underground water or release heat to them, and, through the geo-thermal heat pumps units distributed in the various rooms, directly change it into the heat wind or cold wind, or provide heating or chilling for the rooms.

d) The technique of reclaimed water recycling: Currently the membrane separation technique is adopted commonly but features high costs. The reclaimed water technique in combination with biological technique has gained certain market shares. And the technique utilizing the nuclear technique will be used to greatly reduce the costs, but which have not been widely promoted.

e) Solar power technology: Concentrated solar energy power station features low costs and high efficiency. The concentrated deployments of patches of solar energy heat collection devices can make the utilization of solar energy sufficient. In addition, the application of solar photovoltaic walls panels as hanging components on the building facades is also an effective means of reducing the energy consumption of single units.

Results

By using the low carbon planning concept and appropriate environmental protection and energy saving technologies effectively, the living environment in arid desert would be improved, especially from water supply, energy saving and wind resist and sand fixation. We can see from the historical immigration and the wisdom of people how to govern the diverse lands that even the environment is threatening but people will never give up to conquest new lands for living. As one of the new domain people try to explore to apply to climate change, the area in arid desert is expected to become the new home of the human.

Conclusions

The ecological planning and construction of dry desert areas manifest the human beings' splendid vision of improving the living environment through science and technology, mitigating climate change and creating a harmony relationship with nature. Amid the current era when the techniques of environmental protection and energy saving have been constantly maturing, the planning and constructions in many areas are still following the behindhand strategies and approaches, while such concepts of low-carbon, energy saving and environmental protection are still a mere formality. Therefore, how to concretely fuse the low-carbon concept in planning and

practically utilize appropriate techniques of environmental protection and energy saving is an important step that all the practitioners of planning shall be striving for.

Notes

1. Based on the statistics revealed by State Forestry Administration P.R. China, in 2011, the sandification land in China had reached 1731100km^2, accounting for over 18% of the national land area, affecting 30 national first class administrative regions (provinces, autonomous regions and municipalities). The desertification land in China had reached 2623700 km^2, accounting for over 27.33% of the national land area.

2. Excessive deforestation accounted for 32.4%, overgrazing 29.4%, overuse 23.3%, inappropriate utilization of water resource 6%, sand dune movements 5.5%, urban and factory and mine constructions 0.8%.

3. It is specified by the revised "Law of energy conservation", which was executed on April 1st, 2008 that the resource reservation is one basic national policy of our country.

4. This kind of areas usually features big temperature difference, enormous sand, and the soil layers have coarse quality and lack organic substances and are strongly salinized. The annual rainfall is less than 250mm, with some areas even having less than 20mm, while the annual evaporation capacity reaches 2400mm～3000mm. There is strong northwest wind, and there is a tremendous amount of sand blown by wind. The average temperature in summer is above 30 ℃, with the highest summer temperature

5. The flat-laid sand-buffer is made of such materials as the firewood, stalk, clay, tree branches, laths and pebbles, which can reduce the wind's speed and fix the sand surface. The vertical sand-buffer involves the setups of lines of blockages on the passing routes of the sand blown by wind so as to reduce the wind speed and deposit part of the sand, thus playing the functions of windbreak and sand fixation.

COMPETING REGIONAL DEVELOPMENT DISCOURSES: CONCEPTUAL FOUNDATIONS, AND THE RECENT EVIDENCE

Hüseyin Çiçek[1], Ayda Eraydin[2]

Abstract

Over the last few decades, the regional development discourses and theories have changed substantially, parallel to changes in the economic regimes in world. The shift from the traditional regional development theories, which focused on industrialisation efforts via large-scale enterprises and transfer of central government funds to disadvantaged regions, to regional development based upon endogenous capabilities and potential of innovation and knowledge creation.

This paper provides an overview of the theoretical literature on regional economic growth and examines its conceptual foundations, major competing paradigms, and aims to discuss and evaluate the explanatory power of different theoretical frameworks to explain the growth of regions in Turkey in the recent period. In order to achieve this aim, after deciphering and concretising various classical and contemporary regional economic and territorial models, the paper introduces the studies on the evaluation of three main types of approaches to regional development namely external state support, development based upon local dynamics and knowledge based economy in the Turkish regional/provincial context.

Using the panel data on 81 provinces and annual figures from 2005 to 2008, the research evaluates the regional models with more explanatory power compared to the others. The findings are important to discuss effect of the contemporary theories that emphasize the endogenous factors.

1. Introduction

The regional development discourses and theories have changed substantially, parallel to changes in the economic regimes in world. The shift is mainly from the traditional regional development theories to regional development based upon endogenous capabilities and potential of innovation necessitating knowledge creation.

This paper aims to discuss and evaluate the explanatory power of different theoretical frameworks to explain the growth of regions in Turkey. In this context, paper firstly provides an overview of the theoretical literature on regional economic growth and examines major competing paradigms. Later, regional development policies of Turkey are encapsulated. After giving hypothesis of the paper in the fourth section, in the fifth section empirical model design is explicated. Main characteristics of variables used in the econometric analysis are

[1] Dolsar Engineering, Ankara, Turkey - hcicek@dolsar.com.tr
[2] Middle East Technical University, Ankara, Turkey - ayda@metu.edu.tr

briefly explained in the next section. Model results are explained in the seventh section. Finally main findings of the paper are summarized in the conclusion section.

2. Development Theories

Regional development theories were built up by perception and representation of current socio-economic environment; assumptions on society, individual and market; objectives and policy tools. Regional development paradigms have evolved parallel to the changes in these concepts. Three paradigms define the regional development history spanning from post-war years towards the contemporary world (Eraydın, 2004; Tekeli and Pınarcıoğlu, 2004).

The first paradigm that had been the basis of the theories and policies in regional development up to the 1970s crisis was parallel to national economic development discourses dominated by planned development idea in the Keynesian welfare state period. The 1970 crisis became the turn of the policies that emphasised market dynamics and competitiveness as the source of growth. In this era, local production dynamics and to achieve competitive advantages by the use of local capabilities were underlined. The increasing forces of globalization in 1990s caused to birth of the third paradigm, which has been developed around knowledge economy concept.

The context of regional development approaches that is also defined by mode of regulation, regime of accumulation and mode of production in three periods are summarized in Figure 1.

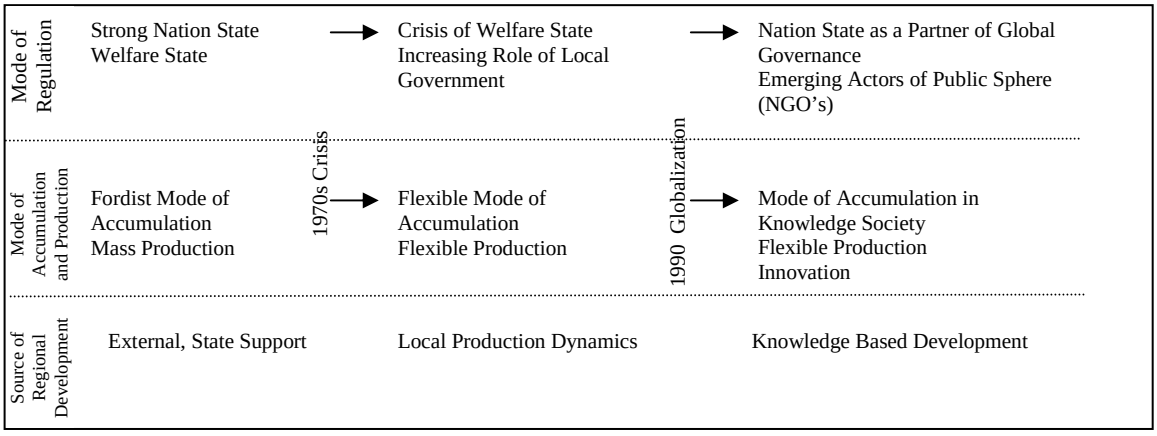

Figure 1 General Characteristics of Three Regional Development Periods

2.1 External State Support

The 1930 crisis and Second World War led to Keynesian welfare state policies, which aimed to bring regulations to the existing capitalist systems, especially the ones related to the redistribution of resources. It offered a planned developmentalist perspective and defined state as the main actor of development. In this period, it was believed that regional

development can be initiated by external support mechanisms, which facilitate the development process by creating infrastructure and leading productive units rather than regional internal dynamics. Therefore, it was argued that local resources can be activated and supported by transfer of resources by the state. Strong nation state and measures for public resource transfers for development were the main characteristics of the first period.

The regional development theories of this period have a high level of abstraction (Eraydin, 2002). They reflect the economic principles and aimed to define basic factors of development, such as external economies and multiplier effects. Regional growth, in this period, was defined as externally driven (external demand, redistributive decision of the state, external decisions of transnational companies). Factors of regional development were outlined as large scale investments, economies of scale, agglomeration economics, externalities and capital accumulation-investment dynamics, vertically integrated economy, and traded interdependencies (Eraydın, 2004).

The dynamics of regional economy were theorized in growth pole theory and economic base theory. Besides, some theoretical efforts were focused on defining regularities of spatial organization and emphasising locational choice problem of production units as well as service enterprises. Economic base theory defines basic sector as the source of development of regional economies that induce multiplier effect on the other sectors and the total economy. According to this theory, selling locally produced goods and services to consumers outside of the region create economic development (Stough and Maggio, 1994). Therefore, it accepts regional growth as a function of increase in export demand. Likewise, growth pole theory argues that economic development strategy should focus investment on a specific sector—that is the growth pole, or sectors, to initiate propulsive development (Stimson, et. al., 2006). In Perroux's (1950) original formulation, a growth pole is referred to as a core that is able to facilitate linkages between firms and industries. In essence, growth in this model is dependent on three sets of processes: large firms, knowledge creation and transfer, and new technology (Plummer and Taylor, 2001). Perroux (1950) also viewed management -by government, large enterprises, or entrepreneurs- as the main driver of regional growth. The growth pole concept has been intensively revised, extended and complemented with other modern economic geographical concepts. The literature was consequently enriched by concepts as industrial complexes, formations, industrial districts and clusters (Harrison, 1992).

2.2 Local Production Dynamics

1970 crisis which caused to eventful changes in economic regimes in the world brought new regional development approach based on local production dynamics. The economic crisis was considered as the end of Fordism and the emergence of the new form of industrial production organization. There have been several attempts to theorize the dynamics of territorial development. As some SMEs and SME clusters were less affected in the crisis, were able to recover in a very short period and began to grow, these efforts were focused on post rationalization of successful SME concentrated areas. Therefore, the theoretical attempts of this period focused on the endogenous nature of growth which became the new nodes of growth in the period of new production organisation system. Flexible production system was

the response to the problems of Fordist type of production and industrial districts and clusters were identified as the means of achieving and maintaining local economic success. Several theoretical debates are introduced that discussed the spatialisation of flexible production.

Flexible-production theory blends elements of regulation theory, institutionalist economics, evolutionary economics, and transaction costs according to Plummer and Taylor (2001). As a model of local economic development, flexibility model is technologically driven and hinges on the local integration of firms through the exchange of goods and information. This integration enables to achieve local external economies of scale and scope and minimizing transaction costs. Flexible production theory also emphasizes trust and reciprocity, the role of small and medium-sized firms on innovation, role of R&D for developing differentiated and localized products.

Industrial district and cluster theories, on the other hand, were formulated around geographical proximity, external economies, agglomeration economies and interaction concepts. Industrial district theory and cluster theory foreground collective pool of knowledge, local skilled labor potential, information exchange facilitated by various forms of social capital, especially the cultural norms of trust, local cooperation and reciprocity, production for the same end market, regional production organizations and locally embedded relations (Eraydin, 2004). Informal links through cooperative and competitive relationships, broad product range and high specialization, low transaction cost, creativity and social and economic reform, creative environments also defined as the assets of industrial districts (Belussi, 1999). Therefore, historical and socio-economic factors become so important to understand new industrial districts (Mouleart and Sekia, 2003).

In these theories regional development was perceived as dependent on internal potentials. Local potential was the core of the regional development literature in the 1970s and 1980s. Elements of development were defined as human capital, local integration of firms, exchange of knowledge and experiences, social capital, trust and reciprocity, geographical proximity, external economies, agglomeration.

2.3 Knowledge Based Economy

While in a highly competitive, borderless environment knowledge economy become more noticeable due to increasing globalisation and production, regional development is redefined in this context. Achieving the capabilities of knowledge based development became the core of theories of regional growth, while the importance of local production dynamics lost their dominance. Knowledge, learning and innovation raised its significance in this period and growth dynamics of regional economy were theorized in innovative milieu, learning regions and regional innovation systems.

Innovative milieu theory offers the space as source of innovation and development. The innovative milieu theory is based on relation between actors and their environment; it interprets spatial characteristics to development as the source of innovative processes and synergies. In innovative milieu theory, innovations and innovative actions are the result of a collective, dynamic process of numerous players in a milieu. The theory also defines the

importance of other factors such as, innovation oriented infrastructure, social homogeneity, governance, identity, network synergy, promoted linkages, knowledge transformation and learning. Therefore, innovative milieu theory underline directly the innovative capacity of the different members of the milieu, which depends on the capacity of learning and thus cultural factors, including social capital, trust and cooperative organization.

Similarly, learning regions are considered as an important debate on regional development in which the main actors (politicians, policy-makers, chambers of commerce, trade unions, higher education institutes, public research establishments and companies) are strongly, but flexibly connected to each other and are open both to intraregional and interregional learning processes. Learning regions build their advantage through creation, dissemination, use and improvement of knowledge which requires knowledge creation institutions and infrastructure (physical, communication and production), intraregional and interregional networks and social capital. They also necessitate skilled human capital to use knowledge, continuous education and training for achieving a high level of skilled human capital.

Moreover, elements of innovative milieu, learning regions and system of innovation were formulated in such a way to define a regional innovation system. Regional innovation system paradigm argues that collective learning and cooperative actions are important to enable regional development. Main factors highlighted by the regional innovation system are innovation and innovation policy; knowledge, learning and training system; interaction between actors (firms, R&D institutions, universities, etc.); employment; labor division; soft infrastructure; universities; small and large firms, entrepreneurs; trust and regional budget.

2.4 Determinants of Growth Defined by Different Regional Development Models

As the brief summary of the theoretical debates on regional development, the determinants of growth/development differentiate substantially in different development discourses. In the first period, regional development was accepted to stem out of external dynamics rather than internal dynamics of the region. External interventions can activate internal potentials and led to development. In this period, investments and incentives of state, large scale infrastructure and manufacturing projects sectoral agglomerations were defined as the major means of development.

Regions with local production dynamics have gained importance in the second period when redistributive role of state decreased due to crisis of the state and deregulatory measures adopted. Local skilled labor, entrepreneurship, local cooperation, R&D, small and medium sized firms, knowledge transformation through interaction of businesses, political decision-makers, institutions and the workforce were underlined in the theories of endogenous growth.

Knowledge economy is much more emphasized in the recent decade Different than the theories centered on intangible factors parallel to growing emphasis on endogenous potentials, contemporary theories see dissemination of knowledge, learning, innovation and innovative environment as the sources of regional development. Table 1 summarizes the components of development defined by the different regional development paradigms.

Table 1 Development Factors by Regional Development Paradigms

Explanatory factors	External State Support	Local Production Dynamics	Knowledge based development
Export	*		
Basic sector	*		
Agglomeration in a specific sector	*		
Linkages between firms and industries	*		
Large firms	*		
State support	*

3. Regional Development Policies of Turkey

Turkey has prepared plans to stimulate social, economic and cultural development since the beginning of 1960s. National development plans of Turkey gave a special importance to regional inequalities and developed regional development policies compatible with concurrent regional development paradigms. The period between 1960 and 1980 was state-led policies period for regional policy. State was the main actor and policy tools were developed in this context.

The 1960s designated a new Constitution and “the planned period”. In fact, it was an attempt to rationalise the growth process and put it into discipline in order to avoid the ups and downs in the economy as it was experienced in the earlier period. The same idea was applied to regional questions. In order to improve the capacities of different regions, which is believed to contribute to the economic development, different regional plans were prepared beginning

from 1958. In the First Five Year Development Plan document "Regional planning" has been described as *"the plan that defines the natural resources and their efficient use, which helps the proper use of land and determines and schedules the public activities that are needed"*. The regional development Projects are prepared for East Marmara, Antalya, Çukurova, Zonguldak and Keban regions during the 1960s. As the distribution of regional development projects showed, most of the planned regions were either relatively prosperous ones or the regions with certain potential for development.

In this period new planning system and institutionalisation of national development planning endorsed several studies on regional differences and the settlement hierarchy. Moreover, as a reaction to the strong emphasis on economic development, the debates on the National Physical Planning attracted very wide attention. The discussions on the National Physical Plans indicated the need to blend national economic objectives with the ones related to the spatial organisation of productive activities and the urban settlement system (Tekeli, 1971; Erder, 1969). Although the discussions related to "spatialization of development plans" took place in the official documents, there happened little efforts to institutionalise this aspect of planning. Instead, a group of experts in the State Planning Organisation were assigned to evaluate the regional issues in planning. The context of the regional policies and regional plans prepared in that period were consistent with the import substitution policy that became the basis of industrialisation in the 1960s. The plans mainly tried to define the industries that can have comparative advantage in the domestic economy and put limited emphasis on export promotion.

Although there was no change in the economic policy, 1970s denoted important changes in regional policies. Firstly, the emphasis on public sector investments was faded in favour of private entrepreneurship. The regional development is seen as "*a cooperative effort of defining natural resources of regions and supporting the most advantageous fields of activity in these areas*". This new perspective and the lack of administrative capacity and institutionalisation to implement regional plans meant the end of regional planning. Instead, incentive schemes were defined as the major tool for reaching the regional objective of convergence. Even in the plan documents prepared by State Planning Organisation, it was refrained to use the word *"region"*, whereas several studies conducted in order to determine areas eligible for assistance. The huge rate of inflation, lack of foreign reserves and increasing unemployment during the 1977-80 periods enforced a radical change in the economic and industrialisation model. Import substitution model, which dominated the economic policies for more than twenty years, has been abandoned in favour of export oriented growth. In fact, 1980s became the turning point of economic policies in Turkey, from protectionist attitudes dominated Turkish economic policy prior to this period (Kazgan, 1985, Boratav, 1988) to increasing reliance on market forces.

Under the new economic relations, although encouragement incentives still accepted the main tool of regional policy, Southeast Anatolia Development Plan became the core of attention. In this period, it is also possible to observe increasing attention on "local", which reflected itself on local administrative system, municipalities and local conditions. Reforms, in the form of delegation of power the local bodies stayed unsatisfactory and limited change in the centralised character of the state was succeeded. While the newly emerging conditions created the new models of regional and local institutionalisation and decision systems in

many countries, these issues stayed untouched in Turkey. The state defined several fiscal rearrangements as parts of export oriented development program. During 1990-93 period new regulations related to floating exchange rate and mobility of capital were brought, which aimed to integrate Turkey to the global economy. However, as seen in many places in the world, this integration deteriorated the capacity of the earlier mechanisms and necessitated new fiscal management policies, which was not taken into account by the governments at that period. As a result, the distortion in the balance of public finance and the wrong policies to deal with increasing interest rates caused the crisis of 1994.

1994 financial crisis had important consequences beyond the economy. It caused the decline in income per capita and led to important degradation in less developed regions, especially in Black Sea Coast and Eastern Anatolia. As expected, the period after 1994 financial crisis has been again devoted stabilisation policies and reforms for recovery. The aim was to change the high rate of inflation conditions and to increase private sector investments especially in productive sectors. The change in the strategy adopted by business enterprises was vital, since during the1990s instead of investment private enterprise directed most of their savings to treasury bonds, which increased the domestic debt burden of the state. That is why the new economic policies have been mainly directed to create a new economic environment via controlling both the interest rates and the rate of inflation. This situation caused the dominance of short-term needs in the economic policies. Economic problems and decline in income per capita, however, brought the regional discrepancies back into the agenda. Beginning from 1998 the regional plans have been prepared for Eastern Black Sea and Eastern Anatolia Regions. These regions, which fell behind in the development process, have relatively few resources. That is why although there was strong concern to use local potential for development, still the plans followed the traditional approach and gave a strong emphasis on public investment programs. However, there has been increasing awareness that public resources were limited and all infrastructure and productive activities cannot be realised by the public sector. These contradictions stimulated the discussions on “how to define the regional policies to promote growth in regions with limited capacities in the contemporary economic system, where state has limited financial resources and has limited capacity to manoeuvre the global forces”.

The liberalisation of the economy and the deregulation of the financial markets during the 1980s increased the importance of external factors and brought volatility to the economy. Fewer restrictions on the flow of goods provided for a rise in exports, but also increased the amount of imports, which brought negative impacts on the balance of payments. During the 1990s the economy faced several financial crises, which had a negative effect on the financial and production sectors. Different to the earlier economic crises, the crises of 1999 and 2001 meant job losses in specific activities that employed highly skilled personnel, such as banking, as well as financial problems in some production sectors.

In this period it became clear that the pragmatic solutions introduced in the 1980s were not enough to meet the increasing needs of deregulation in the global market. The liberalisation of the economy and integration to the global markets necessitated new administrative reforms, which were mainly imposed by the International Monetary Fund (IMF) and the European Union. In fact, the rules imposed by the EU during the membership negotiations

were mostly related to social and political issues, including governance. During the 1990s, besides important changes in the economic system and deregulation related to trade and finance systems in the previous decade, several important changes were introduced in Turkey in order to comply with the rules of EU and other international institutions, which affected also the existing structure of urban governance (Altaban and Duyguluer, 2004).

In 1999, Turkey has gained candidate status for the European Union in the Helsinki Summit and internal political developments have led to step up efforts for integration with the European Union (Filiztekin, 2008). Besides, 2001 crisis that Turkey experienced pointed out the need of significant policy change. Therefore after 2001 significant changes occurred in regional policy which is developed in cohesion with EU regional policies. In the Eighth Development Plan (2001-2005) and Ninth Development Plan (2007–2013), substantial changes occurred in the regional policies. In the plans, the global economy is taken as a new social reality which involves both opportunities and threats for national development.

Moreover, the agenda imposed by the international institutions enforced the decentralisation of public administration, which has become a key government priority in Turkey since the early 2000s. New laws were adopted to create new mechanisms to transfer major spending powers to Special Provincial Administrations, Metropolitan Municipalities and other Municipalities. Secondly, the new regulations redefined the new roles for metropolitan governments in the provision of services. The new roles assigned to local governments covered education, health and protection of cultural and natural resources, which meant an increased role for the metropolitan municipalities against central government institutions. Third, the new legislation that was adopted in 2005 increased the resources of local governments. Lastly, the Regional Development Agencies are defined as a part of decentralisation of administrative mechanism, although still the dominance of central government is important in decision mechanisms of the agencies established at NUTS II level.

The Turkish experience is important, since it shows the difficulties in formulating regional policies not only in the past but also in the contemporary period, which is increasingly defined by global pressures. It indicates that it was quite hard to follow the consistent regional policies during the development based on import substitution type of industrialisation due to the fluctuations of the economy, although the state has felt an obligation to give assistance to relatively less developed regions. However, the shift from state led development to neo-liberal economic policies at the national level caused a change in classical regional policies to export promotion assistance to regions. The new policy helped the regions with certain capacities and competence and motivated them to use all their accumulated competence in order to gain competitive advantage in international markets, but did not contribute the ones with limited capacities. The policies in the recent decade, although aware of the new conditions defined by the knowledge economy, it is difficult to say that the efforts to develop the innovative basis of the regions are substantial. Most of the regions do not have the capacity to be integrated to the knowledge economy.

In sum, special importance was given to regional development and the elimination of interregional development disparities in national plans. In order to ensure regional development and eliminating interregional disparities, instruments such as regional

development plans investment incentives and Priority Regions for Development policies, organized industrial zone and small industrial estate and rural development projects have been used in Turkey.

4. Hypothesis of the Study

Recent theories highlight technology and innovation, knowledge and learning, cooperation and competition, network and linkages, cultures and trust, social capital and governance. On the other hand, state support which are recognized as tool of early period, are still employed to reduce regional inequalities.

Although substantial amount of development factors have been proposed by theories and models, neither success of theories nor success of these factors is comprehensively discussed yet.

Therefore, hypothesis of this study is defined as state support has still significant contribution to regional development.

5. Empirical Model Design

Various theoretical framework and empirical analyses have emerged in growth arena as discussed. Substantial amount of factors have been proposed by theories and models. Recent theories highlight technology and innovation, knowledge and learning, cooperation and competition, network and linkages, cultures and trust, social capital and governance. It seems recently that there is consensus on factors of regional development, neither success of theories nor success of these factors is not comprehensively discussed yet.

Therefore, an empirical study was designed to test regional development paradigms/ theories. This test also enables us to identify and explain the relationship between factors and development.

After defining factors for each theory, factors eliminated and factors make sense and specific to the theory are kept. Sets of measurable variables and proxies are developed for each model to try to encapsulate the processes they recognize as driving growth.

Defining and choosing proxies that (best) express intangible factors and limits of available or attainable data are two main constraint of the study. Within this condition, proxies are developed to measure the variables drawn from the review of theories. 18 proxies are developed in preliminary analysis of three regional growth paradigms.

In order to select proxies that reflects factor ideally, factors and indicators identified in empirical studies defined and annual data availability for relevant NUTS 3 regions and for the period of 1980-2010 was checked. Practical limitations on consistent data availability are the main decisive in selection of factors. As there is no time series data for selected factors, study is done for 2005-2008 period.

In order to control unobserved heterogeneity, data for proxies are collected to get panel data rather than cross-sectional data. The period of coverage is from 2005-2008. Collected data is standardized by using variables (i.e. population, employment and area) depending on the nature of proxy.

Figure 2 NUTS 3 Regions of Turkey

It was aimed to use general-to-specific modelling strategy to evaluate the models of local economic growth, but overlapping period of available data is very limited to form a general (over parameterized model). Therefore general-to-specific modelling method is not used. For each theory, static model is established for panel data and tested. Empirical model design and analysis has been conducted using Oxmetrix 6.01. The factors and proxies are listed in Table 2.

Table 2 Highlighted Factors by Theories and Proxies Used

Factors	Proxies
Growth	GDP per capita growth
Export	Export per capita
Basic sector	Share of employment in agriculture, industry and service sectors*
Agglomeration in a specific sector	Share of sectors in GDP*
Large firms	Share of firms in top 100 highest tax to population
Public investment	Public investments per capita
State support	Existence of regional development plan
State support	Development priority provinces
Incentives	Per capita incentives to private sector investments
Local skilled labor	Share of vocational graduate*
Entrepreneurs	Number of established trade companies per 10 000 persons
Local cooperation	Number of established companies and cooperatives per 10 000 persons
R&D	Academicians per person
Small and medium sized firms	Number of SMEs receiving investment and operation credits
Innovation	Number of registered patent
Knowledge transformation and learning	Number of thesis per person
Capacity of learning	Student teacher ratio
Innovative environment	Number of technology development zone
Social capital	Number of established foundations per person
Continuous education	
External economies arise from existence of shared infrastructure, services, information	Number of OIZ Plot

* Interpolated using available data.

GDP per capita growth is used as dependent variable. As GDP data at NUTS 3 level is available until 2001, for 2005-2008 the data is only available for NUTS 2 level GDP values are distributed to NUTS 3 level using electricity consumptions.

6. Main Characteristics of Variables Used in the Econometric Analysis

GDP and GDP per capita values are the basic indicators reflecting the economic development. Although GDP per capita at Turkey performed significant growth, GDP per

capita is very low comparing with EU and OECD countries. GDP per capita in purchasing power standards of Turkey is about 48 % of EU-27 (EU, 2011). Similarly GDP per capita in purchasing power parity of Turkey is approximately 41 % of OECD countries (OECD, 2011).

Analysing GDP per capita at NUTS 3 level for the period of 2005-2008 shows that, increase in GDP and so GDP per capita at Turkey scale is also valid at NUTS 3 scale. Geographical representation of GDP per capita pattern at NUTS 3 regions shows gradually decreasing pattern from west to east in Turkey. Figure 3 shows 2008 GDP per capita by NUTS 3 regions.

Figure 3 GDP Per Capita by NUTS 3 Regions, 2008

Average annual GDP per capita growth rate (2005-2008) by NUTS 3 regions is illustrated in Figure 4.

Figure 4 GDP per capita Growth by NUTS 3 Regions, 2005-2008

In Turkey, public investment, particularly public infrastructure and social investment, is recognized as the most important determinant of capital accumulation, therefore development.

A historical exploration in Turkey public investment, one of the turning points is observed in the early 1980s. During this period, with the start of the transition from inward-looking import substitution to export-oriented and outward-looking structure, structure of public investment policies and priority sectors in public investments have begun to change. In general, the rule is left to national or global private equity actors. Private sector aiming financial profitability directed to investments brings high levels of return. Public sector aimed social profitability and began to intensify areas that are seen unprofitable by private sector, particularly infrastructure investment.

Figure 5 Total Public Investment per Capita by NUTS 3 Regions, 2005-2008

Figure 5 illustrate total public investment per capita by NUTS 3 regions. Ongoing or completed large cost public projects are very important in the distribution of investment to NUTS 3 regions.

Patents, as indicators of innovation plays significant role in economic performance and thus development. Patents per person significantly have increased in 2005-2008 period. This development pattern can be explained by implementation of patent laws, policies and incentives aiming to encourage technological developments increase in the number of universities and share of university graduates.

Even though the increase in registered patent increased in the recent decade, Turkey's registered patent is still very low compared to EU and OECD averages. This situation can be explained by low innovation performance, low investment on science and technology and modest R&D expenditures.

Historical development pattern of patent numbers at national level is also valid at NUTS 3 level but still there are NUTS 3 regions which have no registered patent yet. Geographical

distribution (Figure 6) shows that patents are concentrated on industrialized areas, lowest patent per capita ratio belongs to East and South East Anatolian NUTS 3 regions.

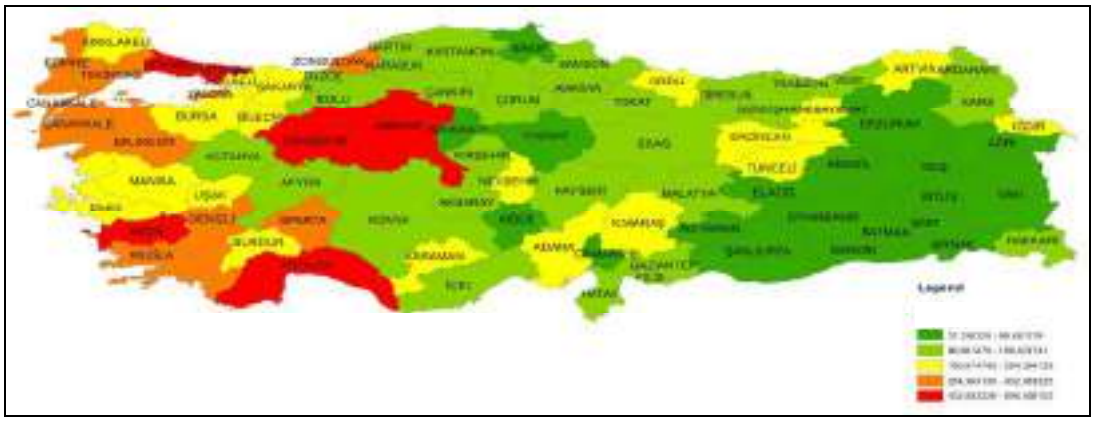

Figure 6 Total Registered Patent per Million Inhabitants by NUTS 3 Regions, 2005-2008

Number of established trade companies and cooperatives is the reflection of entrepreneurship capacity. Number of established trade companies at national scale is increased in the analyzed period, but after 2006, growth ratio started to decrease sharply.

Number of established trade companies per inhabitant shows more homogenous distribution on geography but south east Anatolia regions owns lowest values (Figure 7).

Figure 7 Established Trade Companies per 10 000 Inhabitant by NUTS 3 Regions, 2010

7. Model Results

From the GDP growth relativities for 2005-2008, the general model specification is as shown in Table 3. In the general model specification, the set of explanatory variables accounts for 32,6 % of the variability in GDP growth relativities between regions the period of analysis.

Table 3 General Model Specifications

	Coefficient	Std.Error	t-value	t-prob
Export	-2.99966e-005	0,0009	-0,0325	0,9740
Share of employment in agriculture sector	13,1705	5,7810	2,2800	0,0240
Share of employment in industry sector	12,8216	5,7670	2,2200	0,0270
Share of employment in service sector	13,2870	5,8330	2,2800	0,0240
Share of services in GDP	0,6556	0,1274	5,1400	0,0000
Share of industry in GDP	0,5488	0,0925	5,9300	0,0000
Share of agriculture in GDP	0,4098	0,1080	3,8000	0,0000
Number of large firms	0,1784	1,4900	0,1200	0,9050
Total public expenditure	-0,0004	0,0023	-0,1740	0,8620
Regional plan	-1,4062	2,3880	-0,5890	0,5560
Priority regions in development	-2,1452	2,3780	-0,9020	0,3680
Total incentives investment	0,0010	0,0012	0,9040	0,3670
Share of vocational school graduate	1,4597	1,1970	1,2200	0,2240
Number of established trade companies	0,0454	0,0271	1,6800	0,0950
Number of established companies and cooperatives	-0,1229	0,0677	-1,8200	0,0700
Academicians per person	-0,0251	0,0483	-0,5200	0,6030
Number of SMEs receiving investment and operation credits	0,7082	0,0936	7,5700	0,0000
Number of registered patent	0,1374	0,3037	0,4520	0,6510
Number of thesis	0,0105	0,0062	1,6800	0,0940
Total student teacher ratio	1,4045	0,3417	4,1100	0,0000
Number of technology development zones	-2,9678	2,2610	-1,3100	0,1900
Number of established foundation	0,0147	0,0621	0,2360	0,8140
Plot of OIZ	0,0003	0,0004	0,6000	0,5490
Constant	-1358,3200	580,2000	-2,3400	0,0200

R^2 0.3264279

no. of observations 292, no. of parameters 24

From the set of regionally specific structural variables eleven of them are statistically significant. Share of employment in three main sectors, share of three main sectors in GDP and number of trade companies, number of companies and cooperatives, number of SMEs, number of thesis and student teacher ratio are significant to explain GDP growth rates.

Those regions with higher capacity of learning as measured by student teacher ratio have higher estimated GDP growth relativities. Similarly, those regions with a better, knowledge transformation and learning as measured by number of thesis are predicted to have higher GDP growth rates. Besides, those regions with a better entrepreneurship tradition, as measured by number of established trade companies are predicted to have higher GDP growth rates. More controversially, those regions with higher local cooperation, as measured by the established companies and cooperatives, are predicted to have lower GDP growth rates.

Thus, while capacity of learning, knowledge transformation and learning, small and medium sized firms and entrepreneurship generate GDP growth in the Turkey context, levels of local cooperation is counterproductive.

The remaining variables are not individually significant. It is surprising that the variable intended to capture external state support; public expenditures and incentives to private sector investments and other regional development policy tools –priority regions in development, regional plan are not statistically significant and do not explain GDP growth in the general model. This is not consistent with our theoretical expectations. Similarly, number of large firms and export do not explain GDP growth in the general model.

Besides, local skilled labor as measured by share of vocational graduate, R&D as measured by number of academicians, innovation as measured by number of registered patent, innovative environment (as measured by number of technology development zone, social capital as measured by number of established foundations and external economies arise from existence of shared infrastructure, services, information measured by number of organized industrial zone plot are statistically significant.

Similar to the general model, in the external state support model only share of three main sectors in GDP which are representing agglomeration seems to be significant in terms of explaining the GDP growth. Other factors highlighted by the early paradigm and theories are not statistically significant (Table 4).

Although state support was emphasized in the first paradigm, state support and incentives have been seen as significant policy tool in many countries since first paradigm. European Union and Turkey employ this tool. State support represented by total public expenditure, regional plan, priority regions in development and total incentives investment have no effect on GDP growth according to model results, which is quite interesting.

From the set of variables representing local production dynamics only two of them are statistically significant. Number of SMEs as measured by number of SMEs receiving investment and operation credits and knowledge transformation and learning as measured by number of thesis explain GDP growth rates.

Table 4 External State Support Model Specifications

	Coefficient	Std.Error	t-value	t-prob
Export	0,0003	0,0008	0,3580	0,7200
Share of employment in agriculture sector	2,7918	5,7500	0,4860	0,6280
Share of employment in industry sector	2,5681	5,7630	0,4460	0,6560
Share of employment in service sector	2,8526	5,7850	0,4930	0,6220
Share of services in GDP	0,6288	0,1350	4,6600	0,0000
Share of industry in GDP	0,5582	0,1071	5,2100	0,0000
Share of agriculture in GDP	0,4897	0,1189	4,1200	0,0000
Number of large firms	-0,5014	1,1220	-0,4470	0,6550
Total public expenditure	-0,0017	0,0026	-0,6570	0,5120
Regional plan	1,0588	2,5700	0,4120	0,6810
Priority regions in development	-1,7909	2,6650	-0,6720	0,5020
Total incentives investment	0,0018	0,0015	1,1400	0,2550
Constant	-290,3100	577,0000	-0,5030	0,6150

R^2 0.08726124
no. of observations 292 no. of parameters 13

Those regions with higher number of SMEs have higher estimated GDP growth relativities. Similarly, those regions with a better knowledge transformation and learning are predicted to have higher GDP growth rates.

Table 5 Local Production Dynamics Model Specifications

	Coefficient	Std.Error	t-value	t-prob
Share of vocational school graduate	0,1447	0,9959	0,1450	0,8850
Number of established trade companies	-0,0108	0,0325	-0,3330	0,7400
Number of established companies and cooperatives	-0,0550	0,0504	-1,0900	0,2760
Academicians per person	-0,0827	0,0516	-1,6000	0,1100
Number of SMEs receiving investment and operation credits	0,7164	0,1005	7,1300	0,0000
Number of thesis	0,0143	0,0062	2,2900	0,0230
Number of established foundation	-0,0357	0,0462	-0,7740	0,4400
Constant	30,8007	4,6870	6,5700	0,0000

R^2 0.1666479
no. of observations 292 no. of parameters 8

It is quite interesting that local skilled labor, entrepreneurship, local cooperation and R&D that are highly stressed by second paradigm are statistically insignificant according to the model result.

Three of knowledge based development variables are statistically significant. Knowledge transformation and learning as measured by number of thesis, capacity of learning as measured by student teacher ratio and innovative environment measure by number of technology development zone explain GDP growth rates.

Those regions with higher capacity of knowledge transformation and learning, and innovative environment have higher GDP growth.

On the other hand social capital measured by number of established foundations per person and innovation measured by number of registered patent which are core of last regional development paradigm are not statistically significant.

Table 6 Knowledge Based Development Model Specifications

	Coefficient	Std.Error	t-value	t-prob

R^2 0.06756094
no. of observations 324 no. of parameters 6

8. Conclusion

We have attempted in this paper to test empirically different theoretical frameworks of regional growth for explanatory power of regional growth in Turkey. The transformation in the regional development paradigm can be observed in Turkey's regional development policies and practices. Therefore, it was intended to test for 1980-2010 period, but available data limited the study for the period 2005-2008.

Like many countries, available data to be used as proxies for the factors is insufficient in Turkey. Therefore much of the proxies are general. On the other hand, available time period of collected data is another barrier for such study. For example GDP data at NUTS 3 level is available until 2001. GDP data at NUTS 3 level is calculated by using GDP data at NUTS 2 level by using electricity consumptions. Although this issue is the weakness of the study, the

result of the study seems to be significant to discuss explanatory power of theoretical frameworks of regional growth.

Eighteen broad dimensions representing the hypothesized drivers of regional growth have been derived from the paradigms and theoretical models. A general model was developed within which the dimensions derived for the competing theoretical paradigms/ models were nested. The results of the empirical modeling process are conspicuous. While there are significant contributions of factors of local production dynamics and knowledge based economy in the general model, contributions of elements highlighted by state supported development is much more limited.

Agglomeration in a specific sector, number of small and medium sized firms, knowledge transformation and learning and capacity of learning are the factors that are statistically significant at least two models.

Table 7 Significant Variables by Models

Explanatory factors	**General Model**	**External State Support**	**Local Production Dynamics**	**Knowledge based development**
Export				
Basic sector				
Agglomeration in a specific sector	*	*		
Linkages between firms and industries				
Large firms				
State support				
Local skilled labor				
Entrepreneurship	*			
Local cooperation	*			
R&D				
Small and medium sized firms	*		*	
Knowledge transformation and learning	*		*	*
Interaction of businesses, political decision-makers, institutions and the workforce				
Social capital				
Capacity of learning	*			*
Innovation				
Innovative environment				*
Continuous education				

* Denotes that the variable is statistically significant in a given model

The study shows that while public expenditures and incentives to private sectors that are central to state supported development surprisingly do not have impact on regional growth in Turkey, local production dynamics and knowledge based economy models offer partial explanations of regional growth. Hence, there is no paradigm fully explaining regional growth.

NEW INSIGHTS INTO OFFICE LOCATION AND RENTS

Emília Malcata Rebelo[1]

Abstract

This communication presents a research on the reasons that shape offices locations and respective rent levels, within the scope of increasing globalization. It tests the hypothesis that the factors that shape the spatial structures and rents of the office markets are much strongly determined by urban planning and municipal investments than by variables more market-related, recognized in vast literature (Glascock et al., 1990; Bellini, 2000; Archer and Smith, 2003; Rabianski and Gibler, 2007; Ozuz, 2009). Thus an innovative methodology and model are proposed aimed at supporting the definition of urban strategies and policies concerning offices´ location and relocation, and corresponding influence on rent levels. They resort to a set of planning tools able to express the local characteristics of office markets. They are applied, as a case study, to the Porto's office market (Portugal). Implications for urban policies are inferred from this analysis. Some courses of planning intervention are further proposed that may consist, namely, in the regulation of property markets, in the indirect control on rent levels, and in a more local-based assessment of those markets.

This research is relevant for planning and public policies because it stresses the importance of urban planning interventions in office markets; it develops a urban management upgradeable information system; it overcomes some restrictions of previous location models; it settles a hedonic integrated and interactive non-deterministic model that fits the values that variables underlying rents may assume any time; it develops cartographic display and simulation functionalities (resorting to the use of geographic information systems); and it finally includes agents´ behaviours in the hedonic model of offices´ rents.

The assessment of the proposed model complements and enriches the operational application of hedonic models previously proposed in literature, and includes flexibility devices to support urban planning decisions on office markets. Besides, the results of this methodology and model will probably engender a reassessment and discussion on the role of public intervention versus market factors on urban office rents´ levels and trends.

[1] Universidade do Porto, Faculdade de Engenharia, Porto, emalcata@fe.up.pt

1. Introduction

Globalization processes, the structural organization of firms, information technologies and accessibility networks; the increasing importance of local markets and agents; the variables currently underlying location/relocation decisions and offices´ rents, and the concerns with the social function of land stress the importance of urban planning and municipal investments in the settlement of strategies and policies aimed at office markets.

But what is the relevance of planning options for the spatial structures and for the distribution of rents/m^2 in office markets? And what is the relative importance of public interventions when compared with the free initiative of promoters, builders and sellers? A better indirect control exerted by municipal authorities could launch the performance and characteristics of these markets! In order to respond to these queries, this research proposes an innovative methodology that renders operational the relation between planning and market variables, and offices´ rents/m^2, computing respective influences. It is articulated upstream with an urban management information system with upgrading ongoing functionalities, and downstream with a simulation and display interface (developed in geographic information systems). This operational assessment complements the application of hedonic models previously proposed in literature. The obtained results question the role of public intervention versus market performance on office rents**.**

2. Theoretical framework

2.1. Planning interventions in office markets

Should planning intervene on office markets? Within a global increasingly competitive scope, decisions on offices location/relocation depend more and more on macro-economic variables and, consequently, on public planning policies. And the future of cities, by its turn, depends on their ability to master strategic services, and to attract new office developments (Ihlanfeldt and Raper, 1990).

Municipal planning holds a series of social functions, namely to promote the public interest, to remove negative externalities, and to support the collection of decision data (Klosterman, 1996; Tang et al., 2000). In order to reach these goals, planning shall assure the availability of property for the different kinds of functional uses at acceptable prices, prevent excessive profits upstream and downstream the trade of development land, and guarantee the free the initiative of developers, builders and sellers (Rebelo, 2011), resorting to parameter setting, control over development licences, and distribution of surplus-values.

The municipality being the exclusive holder of development rights is out of question because of the risk that it involves for public finances (Rebelo, 2009). What are, then, the available ways for public intervention in office markets? It can control the development of specific uses and locations, even if it doesn't own property, or

through a temporary property ownership or even participation in public-private partnerships (Correia, 1993; Rebelo, 2009). It may also control specific general or particular developments resorting to planning or fiscal tools. Finally, it can shape property markets through the dissemination of data and guidelines on public participation. Planning intervenes in property markets through plans, regulations, administrative procedures or fiscal devices (Dunse and Jones, 2002). These interventions – through the regulation on development processes - shape the physical form of the built environment, and the territorial distribution of economic activities and values and is performed through (Ihlanfeldt and Raper, 1990; Rebelo, 2009; Rebelo 2011): straight provision of development land; zoning ordinances; legal incentives or restrictions; taxes on property; control of changes in land use or intensity of use; development costs; and investment decisions.

Municipal authorities can control rent levels through direct intervention in the competitive property market (Rebelo, 2011), providing their own alternative land parcels whenever private plots reach disproportionate prices (Tang et al., 2000; Rebelo, 2009).

Legal incentives and restrictions - namely fiscal incentives, zoning ordinances, building regulations, or subsidies -, control over changes in land use or intensity of use, development costs, or decisions on investments are able to shape the profitability of certain areas through their mediation role between the economic cycles, guiding private investments towards certain locations and neighbourhoods (Hanink and Cromley, 1998). Zoning policies also shape offices´ supply and demand (Ihlanfeldt and Raper, 1990), namely through the promotion of office clusters, or through upward pressures on development costs. Different taxation forms are applied on surplus-values in the United States of America, Canada and many Latino-American countries (Rebelo, 2009), that range from the traditional taxes to development rates, and include different kinds of urban regulations. Even the types of development licences – that span from rigid to flexible ones - issued by planning authorities shape the characteristics of the markets, investments, and so the urban built environment (Tang et al., 2000).

These different policies and planning procedures often involve inelasticies in certain locations that result, namely, from bounds to land uses or respective intensities, designation of protection areas, identification of patrimonial buildings (Dunse and Jones, 2002), or delays to respond to demand queries. These inelasticities inevitably reflect on offices rents.

2.2 Variables underlying offices location

The main reasons that traditionally explain offices´ locations and, consequently, respective rents are: centrality/proximity to the CBD (Archer and Smith , 2003; Nitsch, 2006; Greenhalgh, 2008; Jennen and Brounen, 2009; Ozus, 2009); nearness to other businesses, especially insurance companies and financial institutions (Kutay, 1986; Shilton and Webb, 1995; Jennen and Brounen, 2009); amenities, and local

services (Bollinger et al., 1998); accessibility and proximity to transports´ infrastructures and services (Nitsch, 2006; Nappi-Choulet et al., 2007); status, prestige and symbolic meaning of certain areas (Archer et. al., 1990; Krätke, 1992); positive externalities, such as agglomeration economies (Mun and Hutchinson, 1995; Jennen and Brounen, 2009); added value that accrues from the use of productive factors (Fogarty and Garofalo, 1988; Ihlanfeldt and Raper, 1990); nearness to workmanship, providers and consumers of services (Ihlanfeldt and Raper, 1990); and planning and fiscal tools, and public investments (Wasylenko, 1980; Long, 1984; Ihlanfeldt and Raper, 1990; Tang et al, 2000). However, globalization, the structural organization of firms; the progress of informatics and telecommunications technologies, the free circulation of people, and the increasing investments in communications and transports shape new patterns of land use by tertiary activities. Thus the relative importance of these variables on offices, and their impact on respective rents should be reassessed.

Currently, European cities exhibit polycentric layouts in the location of services (Archer and Smith, 2003; Greenhalgh, 2008; Jennen and Brounen, 2009; Ozus, 2009). These result from the internationalization of businesses, the development of information and communication technologies, and the increasing investments in transports and telecommunications, the characteristics of firms, suburbanization of services, and a polycentric distribution of employment poles (Ihlanfeldt and Raper, 1990; Rabianski and Gibler, 2007; Ozus, 2009). These reasons have surmounted the traditional offices´ requirement for centrality that has lost importance on behalf of a greater flexibility in the location/relocation of services. As a result, rent gradients have slowed down, so rents still keep high values throughout a larger territorial cover (Sivitanidou, 1995). Consequently many firms have total or partially moved to metropolitan suburban municipalities, where they benefit from additional spaces with qualified environments at affordable prices/rents (Suda, 1997; Nitsch, 2006). This implies changes in property uses and values (Ozus, 2009). Despite accessibility still keeps a central role, it ceased to mean an easy physical access to certain specific locations, infrastructures and transport services (Nitsch, 2006; Ozus, 2009). It has currently a wider meaning, as it covers a broader territorial extent. So the traditionally centre-targeted activities disseminate more and more, among different alternative poles of offices. But the location and relocation choices of services depend on variables that shape profits, expressed both through spatial (Ihlanfeldt and Raper, 1990) and temporal changes (Rebelo, 2009; Rebelo and Pinho, 2011). So offices that remain in the same location, and during longer terms, undergo physical, functional, and economic devaluation. Offices tend to remain in the same location till they perceive that the differential advantages between and a new potential location and the previous one are big enough to offset the relocation costs (Ihlanfeldt and Raper, 1990). The effects of zoning restrictions on supply and demand are doubtful (Ihlanfeldt and Raper, 1990), despite they have been tackled in several studies (Wasylenko, 1980; Long, 1984; Bourassa et al., 1999; Nitcsh, 2006). When tertiary activities benefit from external or agglomeration economies, they can easily access workmanship and services they can't provide internally (Jennen and Brounen, 2009). Wage levels are also determining in offices´ demand, and can be approached by

variables that measure the distance to employees´ homes (Erickson and Wasylenko, 1980; Wasylenko, 1980), or by the number of workers in the upper tertiary sector (Mills, 1995; Shilton and Webb, 1995; Wheaton et al., 1997; Bollinger et al., 1998; Jun, 1999).

In a nutshell, the variables that best explain office's locations and rents concern their absolute and relative location, their accessibility to the main centres and sub centres, their location inertia, municipal planning and public investments, the dimension of the upper tertiary sector and their average surface according to the provided kinds of services.

Despite its widespread application in the analysis of housing, hedonic models are less often applied to office markets (Dunse and Jones, 2002; Nitsch, 2006; Nappi-Choulet et al., 2007; Ozus, 2009). These models relate a certain variable (price or rent) to a set of underlying attributes, so they clear up rent values (as they identify and compute the effects exerted by explanatory variables), are flexible, and characterize different real estate goods through a limited number of attributes (Knight et al., 1995). If the relation between rents and their underlying explanatory variables is linear, then the regression coefficients of each attribute explain its implicit rent, as valued by the market (even if it is merged with a set of attributes traded together with in a single unit) (Rosen, 1974; Bourassa et al., 1999; Nappi-Choulet et al., 2007). But if the logarithm of the rent is a linear function of the different characteristics, then respective coefficients point out correspondent elasticities (Bourassa et al., 1999; Dunse and Jones, 2002; Nitsch, 2006; Nappi-Choulet et al., 2007; Jennen and Brounen, 2009). Additionally, as the hedonic analysis is framed by microeconomics, it especially suits offices targeted to use (Maleyre, 1995; Rebelo, 2003).

3 Case study

3.1 The Porto office market: evolution

Porto is the second biggest Portuguese city, where the headquarters of the Portuguese Northern firms, as well as most metropolitan services[2] locate. The municipal strategy that prevailed during the nineties stressed that planning should foster the sector of services. So urban planning and public investments during the last decades strongly shaped the patterns of land use by services, and therefore the performance and

[2] Porto metropolitan area is made of nine municipalities (Espinho, Gondomar, Maia, Matosinhos, Porto, Póvoa de Varzim, Valongo, Vila do Conde and Vila Nova de Gaia). 49.1% of the services of the metropolitan area locate in Porto city (23.7% of Portuguese services activities locate in the northern region and 60.1% of the latter locate in the Porto metropolitan area) (INE, 2001). However, the metropolitan services have developed more swiftly in surrounding municipalities than in the proper Porto municipality. The expansion of overall metropolitan accessibilities during the last years, together with Porto's relative reduced surface and geographical bounds has contributed to Porto's loss of leading role. Despite the number of employees in the services sector in Vila Nova de Gaia municipality has surpassed its homologous value in Porto municipality during the nineties (85 496 versus 63 210 employees, respectively), Porto municipality is responsible for the employment of most workers of services per km^2 in the metropolitan area, still keeping a central symbolic meaning.

evolution of the office market. Despite the already consolidated city downtown centre (territorially enclaved), the 1993rd Porto Master Plan - through a comprehensive zoning ordinance - assigned the location of services - both for public administration and for private firms – to the *directional centre*, strategically located in the central area (in Boavista district).

But municipal planning strategies were further supported by other reasons. In the early nineties the Boavista district had many vacant or provisionally-used land plots. Many public infrastructures, equipments and public spaces - namely a set of roads aimed at reinforcing the accessibility networks to central Porto - were also under construction. These public investments have completely changed the urban morphologies, building typologies, and accessibilities to the Boavista district, Porto's intra-accessibilities, and the inter-accessibilities between it and the surrounding municipalities.

Decisions of private agents were shaped by these planning incentives and public works. Thus many office buildings were built, together with the development of high-quality undertakings including housing and trade facilities. The adhesion to the European Union in the mid-eighties attracted the headquarters of many firms to these privileged office buildings, where they could further benefit from agglomeration and internal economies. By the late nineties about 1070 offices (36% of total offices) were already located in this district. As many of these represented regional/local branches of multinational companies – able to afford rents higher than local-based firms - they commanded premium rent-levels, what subsequently involved economic-territorial filtering processes. Within the scope of a strong competition where the available land was progressively shrinking, the demand was willing to pay high levels of rents, and the outstanding planning guidelines and public works increased the value of land, promoters, builders and sellers felt forced to lock up great amounts of capital and to provide better and better quality levels. Afterwards supply overtook demand, but promoters still kept high levels of construction, because they wondered if the economic cycle will invert soon, and they further needed to render profitable their investments.

But during the same decade, offices located in the Porto downtown were still devaluating because this area was tight, population and buildings were dense, buildings were decaying, and a set of planning guidelines and legal restrictions were enforced that hindered the initiatives of real estate promoters – that included a great division of land, and the application of the rent law that kept tenants in strategic locations. As a result land reached top prices, and the development of real estate for rental purposes was out of question because land plot gathering, joining and acquisition was expensive, costly and time-consuming. So offices supply in downtown summed up to second-hand refurbished detached spaces within a narrow territorial scope that involved accessibility and parking shortcomings, despite traditional trade and services mostly remained there. The city council, by its turn, sponsored public-private partnerships in order to implement rehabilitation policies, thus counterbalancing these trends. However, specific regulations towards the

protection of heritage buildings´ have worsened their rehabilitation costs, thus shaping respective characteristics and rent levels. So only the firms with a solid financial foundation – mainly financial institutions and insurance companies – could keep in these prestigious symbolic heritage buildings.

The Porto office market has lost its importance during the last two decades in favour of Lisbon and some Spanish cities, due to the development of accessibilities and telecommunications. Beyond Porto's geographic and legal bounds, suburbanization processes lead to the emergence of a polycentric pattern of offices location in the metropolitan area that mainly results from higher profit expectations in Porto's outskirts due to larger available land plots.

The current Porto's Municipal Master Plan, strategically relieves control on land uses, and is less focused on the upper tertiary sector. Offices are mainly demanded by technology, press and telecommunication firms, public services, financial services, and public administration. To keep abreast of tertiary suburbanization processes and growing competition from other metropolitan poles of offices, Porto office districts consolidated, and their rental levels stabilized.

3.2 The Porto office market: characterization

Porto's office market is structured into three main territorial areas: the downtown/traditional area (that conveys a sense of prestige); the recently developed planned CBD (at the Boavista disctrict); and the transition between both areas (at the Constituição/Marquês district) (Figure 1).

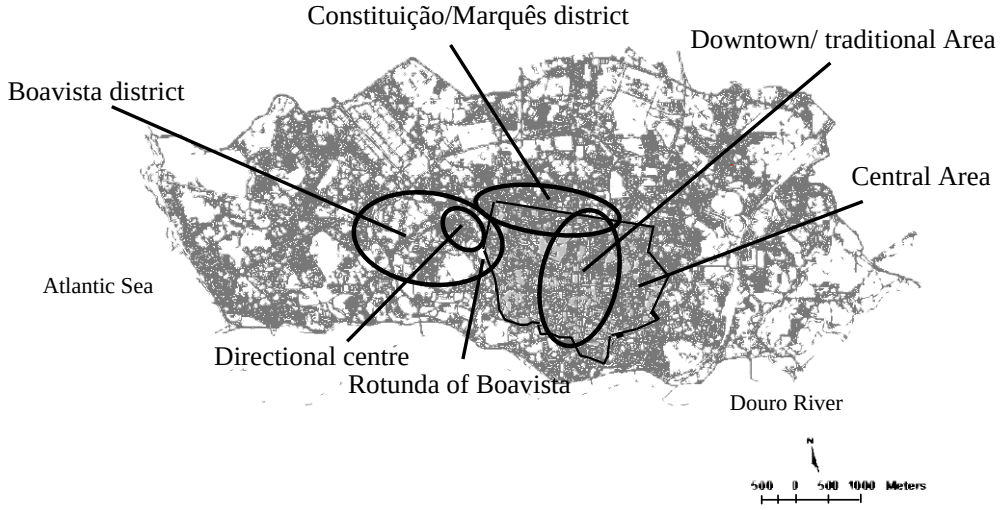

Figure 1. Main office areas in Porto city

The downtown and part of Constituição/Marquês district are mainly characterised by disconnected offices, most of them aimed at liberal professional people. In the former offices mainly belong to old heritage buildings, located in narrow low-lighted streets, almost without public spaces around. In the latter, however, offices mainly locate in middle-sized, middle-aged multifunctional buildings, likewise located along many important streets that provide trade and services. As far as Boavista district is concerned, it holds the most important office buildings of the city (most of them built during the late eighties and the nineties), located in premium bright spaces within high-quality spacious environments[3].

The percent increase of the most representative services in Porto during the nineties was the following[4]: law (17.1%), economics (52.5%), engineering and architecture (16.6%), banks and insurance firms (84.3%), real estate activities (121.6%), informatics (209.6%), and other services to firms (15.8%). So informatics, real estate activities, and banks and insurance firms underwent a swift expansion, whereas law, engineering and architecture and other services to firms registered much lower growth rates. It is also noticeable that the offices most closed to the Boavista district or to downtown most probably remained in the same locations for over longer periods than those settled in older buildings and in less central locations (Rebelo, 2003).

3.3. Methodology

The methodology reported in this article aims at explaining office rents/m^2 [5]. The rental market was chosen because it represented almost 60.4% of total offices in Porto (during the studied period). Besides, the rental regime is more flexible as it fits short-term location goals. Indeed the rental values tend to approach offices´ real worth because offices respond to use goals rather than to investment goals. The microeconomic models to study consumers´ behaviours (including hedonic models) further fit the features of Porto's office market.

First, data was collected and treated. An urban management information system was then settled, which fed an interactive integrated hedonic model. Display and simulation functionalities of this model were further developed. The attained outcomes were subsequently discussed. Finally, conclusions, recommendations, and policy implications for municipal planning on office markets are presented (Figure 2):

[3] In the Boavista district firms can take advantage either from external and agglomeration economies (due to office buildings´ clustering) or from internal economies (due to the set of services available within each proper building).

[4] These variations were computed through comparison between the number of autonomous registered activities existent in Porto in 1999 and the ones existing in 1990, within each kind of activity.

[5] In this research was used the software SPSS 14 for analysis in principal factors and hedonic modelling.

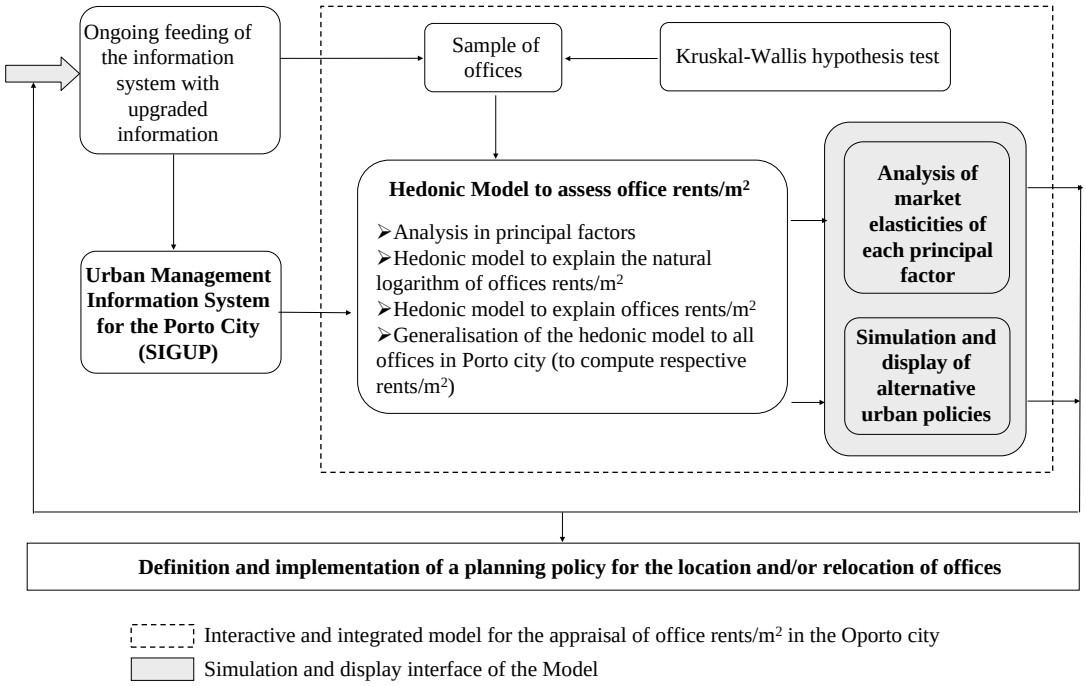

Figure 2**.** Methodological outline of the research pursued

3.4 Urban management information system

The dependent variable (offices rents/m^2) was chosen as a standardised measure of rents that can be easily generalised and compared (namely with other office rental markets studied in literature). The explanatory variables are the ones that are commonly assumed to exert significant influence on offices location and rents (Rebelo, 2009): absolute and relative location of offices; simple distance to the modern planned CBD (in Boavista district); accessibility; temporal inertia of office activities; municipal planning and public investments; dimension of the upper tertiary sector; and average office floor surface, according to the kind of services.

Thus, an urban management information system was specifically designed and implemented in the Porto office market (SIGUP). As data concerning this office market during the nineties is sparse (due to its small dimension and recent development), different diversified data sources were used, such as the Portuguese Statistics Institute (census data: INE, 2001), advertisements in journals, real estate magazines, and interviews with people working in this field. This information system is innovative because each variable are assigned a design and spatial meaning (Bourassa et al., 1999). Data refers to the location and some characteristics of all offices existent in the Porto city in 1990 and 1999 that belong to the most representative activities of the upper tertiary sector (law, economic activities, engineering and architecture, banks and insurance firms, real estate activities, informatics activities, and other services lent to firms).

But considering that many variables in the management information system are strongly correlated, an analysis in principal factors was then pursued in order to identify the orthogonal dimensions that best explain data variance (Bourassa et al., 1999, Dunse and Jones, 2002; Jennen and Brounen, 2009). So the analysis in principal components, and the equamax method with Kaiser normalization of factor rotation were successively applied. The obtained outcome shows that seven principal factors explain 83.6% of the variance (Table 1).

Table 1. Identification, characterization, designation and interpretation of the principal factors

Principal Factors	Most positively correlated variables	Most negatively correlated variables	Explained variance	Designation	Interpretation
Factor 1	Public investments in urban qualification, communications and transports, housing and education	Y coordinate Percentage of offices that changed location between 1990 and 1999	26.7%	Urban planning and municipal investments	This factor assembles the variables that planning controls directly
Factor 2	Weighted distance to Rotunda of Boavista Straight distance to Rotunda of Boavista	Location index of informatics activities Zoning ordinances	16.3%	Metropolitan accessibility	This factor expresses the general metropolitan accessibility (assessed in spatial/temporal terms). It is mostly due the network of streets and transport means that connect the main services poles in the whole metropolitan area (centrered in Rotunda of Boavista)
Factor 3	Location index of law activities	Y-coordinate	10.8%	Distance to Porto's downtown/traditional centre	Law activities (older steady ones) mainly concentrate around the municipal court of justice, deep inside the historical centre. So this factor represents the distance to Porto's downtown historic/traditional centre
Factor 4	Percentage of offices that remained in the same location between 1990 e 1999	Percentage of offices that left the market between 1990 and 1999	10%	Temporal inertia of offices	This factor expresses the tendency of offices to remain in the same location
Factor 5	Location index of real estate activities Public investments in the environment	Percentage of offices that changed location between 1990 and 1999	7.5%	Quality of the natural and built environment	This factor translates the environmental quality (green/public spaces), nearness to equipments, and characteristics of urban typologies and building morphologies
Factor 6	Land Use coefficients Zoning ordinances	Public investments in economic development and tourism	6.9%	Agglomeration and internal economies	This factor positions the location of services in relation to the territorial distribution and economic characteristics of other services, and to the internal characteristics of the proper offices and respective buildings
Factor 7	Total number of activities that belong to the upper tertiary economic sector	Zoning ordinances	5.4%	Dimension of the upper tertiary sector	This factor translates the availability and proximity to specialized workmanship for activities of services

3.5 Hedonic model of office rents/m^2 in the Porto city

A model was then settled, according to a succession of steps, in order to explain offices rents/m^2 in Porto city. Data on the variables of the urban management information system was available (or could be easily computed) for all offices in the

Porto city. However, in order to assess the values of rents/m^2, it was necessary to resort to a sample and – according to the application of the proposed model - generalize the results for the whole office market. All the offices that belonged to this sample were characterized in terms of respective location, characteristics, surfaces, and asked rents/m^2 (Rebelo, 2003; Jennen and Brounen, 2009; Ozus, 2009)[6]. A Kruskal-Wallis statistical test (McMillen, 1995) was used in order to test the significance of this sample (that confirmed it belonged to the whole offices population[7]).

Next, a hedonic regression model was adjusted in order to explain offices rental prices/m^2 in Porto city. Different functional alternative models were adjusted and graphically displayed using the principal factors as explanatory variables. The model that best fitted data is the one that expresses the natural logarithm of rents/m^2 as a linear function of the principal factors (Rebelo, 2011):

$$LN(Rent/m^2) = 0.557 + 0.226F1 - 0.064F2 + 0.021F3 - 0.319F4 + 0.177F5 - 0.294F6 - 0.021F7$$

In this model the principal factor i is represented by Fi, coefficients F4 and F6 and the constant term present a significance level of 5%, the remainder coefficients a significance level of 10%; and $r^2 = 0.904$.

As this is a logarithmic model, the coefficients of the factors represent respective elasticities, as well as their correlations with the dependent variable. Thus this model stresses the importance of each factor in the dynamic explanation of changes in rents/m^2. Office rents/m^2 are, consequently, explained by the derived model:

$$Rent/m^2 = \exp^{(0.557+0.226F1-0.064F2+0.021F3-0.319F4+0.177F5-0.294F6-0.021F7)}$$

As this sample is population-representative, this model can be generalised to all offices located in the Porto city, in order to appraise their implicit rents/m^2 [8] (Figure 3):

[6] This sample represented about 3.6% of the total offices in Porto, and reproduced quite well the percent distribution of offices among parishes.
[7] With a 5% significance level.
[8] Be they available or not in the rental market, in this latter situation the model points out potential rents/m^2.

Figure 3. Office rents/m^2 in Porto city anticipated by the hedonic model

The simulation and display interface further developed supports the definition of strategies and the implementation of measures by municipal authorities in order to guide the location or relocation of services, and the indirect control over their rental levels[9], taking alternative scenarios into consideration (that result from induced changes in the values of some variables). These values are included into the analysis in principal factors and, afterwards, into the hedonic redefined logarithmic model and into the correspondent model of rents/m^2 – in order to test their influence on offices´ territorial location and rents/m^2.

3.6 Discussion of results

The knowledge of the relevant factors in location or relocation decisions is crucial to define and implement planning policies and measures in office markets. Supply and demand inelasticities bind the quantity, location and characteristics of offices and office buildings. But as demand is shaped by the available concrete office stock, and firms seek short-term responses, planning can tackle uncertainty through a better approach to real market conditions prevailing at any moment.

The compared analysis between the characteristics and evolution of office markets among different researched European and American cities clearly show that the

[9] This model may as well be useful to real estate agents, architects and private planners, firms, and all the other remaining parts involved in office markets.

importance of the variables traditionally used in offices´ location or relocation decisions has been changing over time. These changes result from globalization processes and the proper organization of firms that highlights the need for integrated public policies. So a reassessment of the effect exerted by these variables on offices rents/m^2 is, thus, required.

This research points out that variables related to municipal planning and public investments are quite relevant in the explanation of the variance of urban data in Porto's office market (26.7%). Other factors indirectly modelled by planning decisions also contribute to the explanation of variance. These include agglomeration or external economies[10] (6.9%), and the quality of the natural and built environment[11] (7.5%). The increased metropolitan accessibility also expresses a strong intervention of the Porto municipality either through zoning ordinances or through the proper investment in accessibilities (16.3%).

The comparison of the current research with other studies pursued in many office markets show that the role of planning can be exerted under different ways, resorting to different planning tools, with varying intensities. In what concerns zoning ordinances, they don't exert a significant effect on offices development patterns in the Atlanta metropolitan area (Ihlanfeldt and Raper, 1990), but the same doesn't hold true in other metropolitan areas and in different periods. For instance in Hong Kong, despite planning authorities are not intended to intervene in the office market, they end up by shaping its performance, as they tend to deny development licenses in locations where the density of offices is already high. Urban planning - zoning ordinances - and municipal investments – especially in accessibility and urban qualification - (factor 1) are the variables that best explain the increases in rents/m^2 in the Porto office market. Indeed these variables strengthen the attractiveness of some urban areas, so they exert upward pressures on rents/m^2.

Globalization processes – including recent developments in telecommunications technologies (Heikkila et al., 1989; Ozus, 2009) – weaken the importance of the proximity to reference places. But this variable keeps particularly important in some office markets, as is the case of Istambul (Ozus, 2009) where the most recent office sub-centres locate along the main communication streets. This also holds true in Porto where, as expected, metropolitan accessibility (factor 2) decreases rents/m^2 when the distance to Rotunda of Boavista - deeply connected to other metropolitan trade and services poles – increases (Nitsch, 2006).

The distance to the Porto downtown (factor 3) stresses the relevance still kept by the traditional centre on offices location and rents/m^2 that mainly results from its prestige, status, and magnificent patrimonial buildings.

[10] Through promotion of a privileged area for offices location, Porto municipality indirectly induced agglomeration effects over offices prone to locate there.

[11] Despite the majority of the variance explained by this factor accrues from the activities of promoters and builders, the applicable plans, municipal licensing decisions, and public investments are important inputs that underlie this factor.

Porto's offices inertia, reflected on their tendency to remain in the same location (factor 4) – strengthened by the longstanding rental agreements in the historic/traditional centre - exerts a downward pressure on their rents/m^2, as a result of building's age, filtering processes in offices´ uses, and subsequent property devaluation. This comes in line with what happens in other European office markets, such as Amsterdam (Jennen and Brounen, 2009) and Glasgow (Dunse and Jones, 2002). This effect is less noticeable in Paris due to the recovery and re-qualification of office buildings (Nappi-Choulet et al., 2007). However, this variable is not quite relevant in the Istambul office market (Ozus, 2009), especially because of the recent development of simultaneous office sub-centres.

The characteristics of office buildings in the Boavista district – with a good finish, equipments, infrastructures, conveniences and common internal services (factor 5) - tend to push rents/m^2 up. The same effect has been exerted by the positive externalities and amenities attached to the high quality of the urban environment, opposite to what happened, for instance, in Istambul, where the sights over the sea don't add any value to office rents.

Agglomeration economies (factor 6) don't exert such a strong impact as suggested in literature in the Porto office market. Indeed they push rents/m^2 downwards due to tertiarization processes, competition among different office location poles, and also due to the excess supply in high-dense office areas (in order to secure the occupation of offices promoters rent for lower values/m^2 than they are willing to). On the office market of Amsterdam, on the contrary, rents are pushed upwards by location externalities, even if a direct relation between office clusters and urban concentration isn't clear (Jennen and Brounen, 2009). In the Istambul office market external and internal economies, as well as accessibilities, are not so determining as other variables (Ozus, 2009) (namely the number of building's floors, vacancy rates in the neighbourhoods, social equipments, building's aesthetics, and floor surface for rental purposes).

Despite in the office markets of Amsterdam and Istambul the number of offices is strongly correlated to the employment in finance, insurance and real estate activities (Jennen and Brounen, 2009; Ozus, 2009), in the Porto office market this kind of employees tend to decrease mainly due to the strengthening of the information-intensive component of work (what generally improves working conditions in tertiary spaces). Additionally, services employees tend to settle in suburban areas, so they have stabilised or even decrease in the proper Porto city. That's why the dimension of the upper tertiary economic sector (factor 7) exerts a slightly negative effect on office rents/m^2.

4. Conclusions and implications for urban planning

Within the scope of globalization and overall urban competition, municipal planning should stimulate private initiatives aimed at tertiary sector developments, on the one

hand, and regulate and control office rent levels, on the other, keeping them close to local economic conditions, and attractive for both supply and demand.

This article proposes an integrated, interactive and flexible set of tools that - together with different planning and fiscal policies - should support the implementation of municipal strategies and interventions in office markets. It is more flexible than other models referred to in literature, because it fits the conditions prevailing in each moment, and adapts to different urban settings, as it grounds on a strong management information system that can be regularly feed with new and upgraded information on office variables and respective rents. Through the proposed approach, the behaviours of the agents, and the performance of the market can, thus, be monitored. Indeed, the coefficients of the relevant factors underlying rents/m^2 in the model represent respective elasticities. Consequently, any intervention of municipal authorities on the explanatory factors shall strengthen their control over rents/m^2, thus promoting the accomplishment of planning's social function. The mathematical and computational simulation and display device further supports the analysis of alternative decision scenarios for urban intervention (considering that the variables that underlie rents/m^2 may assume different values). This methodology can, thus, be applied to feasible alternatives set up by municipal authorities, in order to select the policies that best fit planning and management-settled goals. It can additionally be replicated in the same city, at different moments, and in different office markets, provided that proper management information systems are implemented and upgraded. This methodology can further support the harmonization of planning policies on offices among different cities and countries, what is becoming increasingly important within the scope of global environments.

APPLICATION OF THE INNOVATIVE INCA ROAD MAP INSTRUMENT TO INTEGRATE FOREST FIRE RISK MITIGATION, CIVIL PROTECTION AND SPATIAL PLANNING - EASTERN ATTICA REGION, GREECE

Kalliopi Sapountzaki[1]

Abstract

Separation and isolation of Spatial Planning from other co-responsible policies for risk mitigation, i.e. civil protection and sectoral risk prevention, leads to unwelcome results: Reservation of a minor role or no role of Spatial Planning for Risk Mitigation; breaks in the Response-Preparedness-Prevention-Remediation chain; duplicated or diverging measures and funding; minimal attention to Prevention and emphasis on Emergency Management; inefficient resource consumption for Risk Mitigation.

All above failures are evident in the Greek Forest Fire Risk Management system which is weak in terms of prevention and ineffective in crisis management being expensive at the same time. These failures are more evident in the forest-fire prone regions of Greece, as is the Region of Attica wherein Athens is located. Despite stringency of the Greek Forest Law its implementation is a big problem because its rationale is totally incompatible with the Housing, Development and Spatial Planning reality and policies. Therefore, the co-responsible agencies for forest fire risk mitigation in Eastern Attica blame one another for the failure of the system instead of attempting mutual understanding and coordination.

The administration of the Attica Region however, had the opportunity to become a partner of the INCA (EU funded) project and apply the respectively introduced concept of “Agreement on Objectives” and the adjoining Road Map instrument in the mixed forest-residential area under the competence of the Directorate of Forests of Eastern Attica”. The present work attempts to present this application and results; also to recommend this approach as a model of Risk Governance even for centralized administrative systems as is currently the Greek one.

The specific application of the Road Map model in the area of East Attica evolved through a series of procedural steps, starting from a partnership establishment and agreement on objectives and goals, accommodating continuous feedback and leading to the implementation of a package of consensual multi- and inter-sectoral measures.

[1] Harokopio University, Athens, Greece – sapountzaki@hua.gr

The application of the model in the test area of Eastern Attica proved to be successful despite pre-existing administrative and cultural adversities. The major decisive factor has been the involvement of Local Authorities in the partnership (or Working Group). The test application indicated that a knowledge intensive institution and constant facilitation of feedback are preconditions of success. It is hoped that the successful experiment of application of the novel Risk Governance process in East Attica will be followed by imitators.

1. INTRODUCTION: The typical shortcomings of natural risk management and the promising INCA road map instrument

It has been acknowledged by scholars and practitioners as well that risk management failures are, more often than not due to the difficulties encountered in coordination / cooperation among the co-competent agencies and between them and the civil society. Some of the reasons / conditions underlying these difficulties have been identified as follows:

- Risk assessment and management has been entrusted to a wide variety of institutions which differ in scale / level of jurisdiction and sectoral responsibility. Taking as an example the case of forest fire risk we can address as co-responsible institutions those of Civil Protection, Forest Policy, Fire Service, Regional and Urban Spatial Planning and Housing Development.
- The policies exerted by above distinct and separate institutions are usually fragmented, introvert, self-complacent and sometimes authoritarian.
- These policies are decided and implemented without the consent, even knowledge, of citizens who may resort to their own plans undermining those of the formal institutions.

Above adverse conditions implying lack of coordination and non-harmonized risk management policies are accountable for:

- Breaks in the Remediation-Prevention-Preparedness-Response (RPPR) chain which however has to be a continuous and cohesive process;
- Marginalization of the role of Spatial Planning in Risk Management despite its outstanding significance;
- Lack of synergies among risk targeting policies;
- Duplicated funding or mutual subversion of risk management measures;
- Inefficient and ineffective resource consumption in the field of risk management policies;
- Irresponsibility of citizens (who usually blame the authorities in case of risk conditions and disaster occurence) and sometimes excessive tolerance of spatial law breaches / illegality on the part of formal spatial planning institutions;
- Risk intensification instead of risk mitigation.

The INCA rmodel of risk management –after the EU INCA project ("Linking Civil Protection and Planning by Agreement on Objectives") that was launched in 2009- was built with the aim to bridge spatial, functional and operational gaps and divergence in approach, competence and perspective between Civil Protection, Spatial Planning and other administrations in charge of prevention (see INCA booklet 2011). For this purpose the INCA pattern of policy-making was formulated as a collaborative process with concrete results to make measures and actions of risk prevention and mitigation efficient, effective, strategically aligned and sustainable (INCA booklet 2011).

The INCA model is founded on two fundamental elements: (a) A consensus building procedure attempting convergence on risk mitigation objectives by all co-responsible authorities and agencies and (b) a "Road Map" instrument. The first is the so-called "Agreement on objectives" (of risk mitigation and management) among all accountable authorities as well as stakeholders, which / who are involved in or affected by the risk and the risk mitigation process. All these actors formulate the Working Group (WG) which agrees on common objectives and the optimum blend of measures in order to reduce or mitigate a given risk.

The "Road Map" instrument (see Diagram 1) is a plan of successive operational steps to lead not only to a memorandum of commonly agreed objectives and measures by the WG but also to their actual implementation, monitoring and control of the respective results, feedback and review of the process.

Among others the INCA model has been applied in the case study area of East Attica region facing forest fires. East Attica region occupies the eastern part of the Region of Attica where the agglomeration of Athens is located.

2. Current deficiencies of Forest Fire Risk management in the Greece

Forest Fire Risk management in Greece is realized in a social and institutional context that is featured by the typical adverse conditions presented in the introductory chapter: (a) a crowd of institutions involved in forest fire risk management which vary in terms of spatial scale and sectoral competence; (b) risk management and other involved policies which are fragmented, introvert and often mutually conflicting; (c) public risk mitigation policies which are counteracted by the private plans of individuals, firms and households.

At first, indeed a wide variety of public institutions and policies are involved directly or indirectly in the causes and the short-, medium- and long-term impacts of forest fires, hence in forest fire risk generation and management. Among these policies, predominant are spatial planning and housing development policies. This is true because:

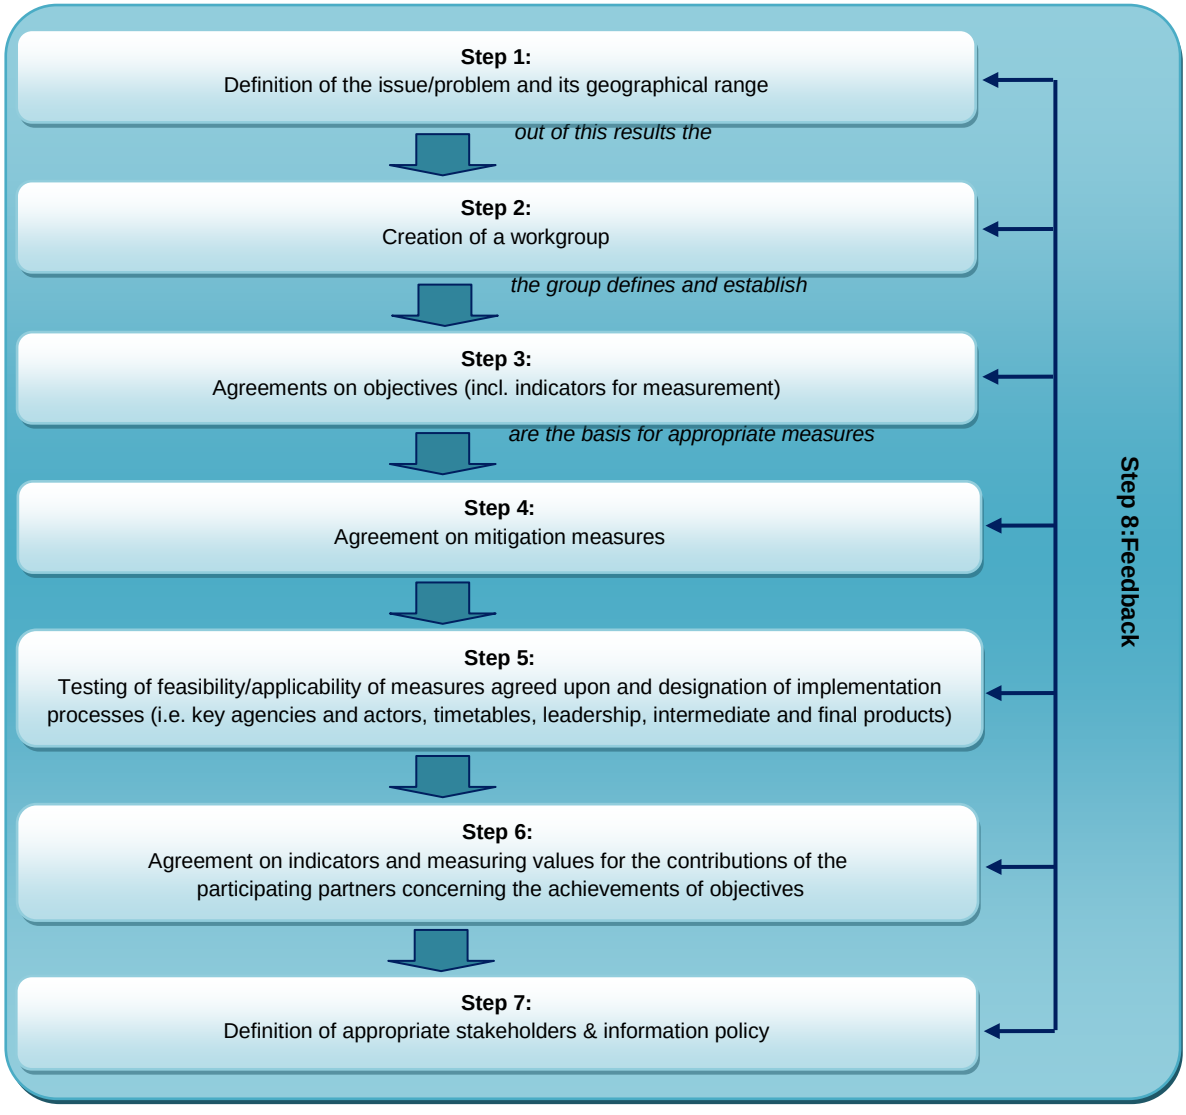
- All causal factors of forest fires (both intentional and those out of carelessness) are related to land use and land cover conflicts and

incompatibilities (mostly between forest land cover and various socio-economic land uses such as housing, tourism, recreation, grazing, agriculture, hunting etc).

- A large part of forest fires are related to the interests of the construction and real estate sectors (e.g. building development corporations); these can be controlled and regulated principally by appropriate spatial planning policies.
- The usual long-term and most catastrophic impacts after forest fires are city plan extensions and expansion of building development rights over burnt (and prior forest) land and in general moving on of mixed land use patterns where built land is entangled in wildland areas. These unwelcomed changes cannot be halted but only via appropriate spatial planning policies.

Despite the land use / cover dynamics generated by spatial, housing, tourism and other policies with land impact (or their absence), these are not taken into account by the policies for forest land protection. In Greece, forest policy is planned and implemented by the Forest Service and its regional extensions exclusively. In particular, the Forest Service exerts forest policy with administrative introversion meaning without coordination with the other policies bearing a land impact. This is the case, in spite of the fact that these other policies are accountable for incidents of forest land elimination (e.g. through arson).

Diagram 1: The Road Map instrument of the INCA Project (INCA project, Del E, 2011)



The variety of formal and informal institutions involved in forest fire risk generation and management refers not only to the sectoral but to the scalar dimension also. Responsible institutions can be found at all administrative levels, the central / national, the regional and the local level. The administrations directly involved in the matter of forest fire risk management are: the central Ministry of Rural Development enjoying competence on forest law and policy formulation at the national level; the Regional Directorates of Forests realizing the national level policy directions in the wildland areas of their jurisdiction; the Forest Service Offices (FSOs) and the Municipalities accountable for forest fuel clearance and other preventive and preparedness measures at the local level.

Secondly, the policies affecting one or the other way forest fire risk in Greece and the respective management actions are truly fragmented, uncoordinated, top-down and introvert. Decision-making in the field of forest policy is strictly hierarchical. Higher levels make decisions and the lower ones follow instructions and implement the generalized forest law and policy. As a consequence a uniform forest law and policy is implemented all over the country regardless of the diversity of factors and land use dynamics exerting pressure upon forest land, in coastal and inland regions, in mountainous and lowland regions, in peri-urban and rural regions and so on.

Lack of coordination is most evident between Spatial Planning and Forest Policy. For Spatial Planning forests and wildland areas are a “black hole” because these areas fall exclusively under the Forest Service responsibility. Under these circumstances, forests are not seen as an environmental amenity (a common good) but are elevated instead to a forbidden fruit, i.e. a factor obstructing realization of private visions and individual rights such as improvement of life quality by means of habitation of the countryside. This is because Forest Policy and the Forest Service have a biased and over-protective attitude toward forests. They view the forest ecosystem as independent from the social one and stand against whatever spatial development demand. Forest institutions protect forest as an absolute value regardless of the needs of the society.

Thirdly, the condition of absolute protection of forest land as dictated by the Forest Service comes in full contrast with the visions / interests of numerous social groups, private agencies and individuals. Examples are the urban citizens who have become alienated to the degraded urban environment of major cities and desire a second home in the forest, building development corporations with interrelated interests, building contractors, real estate agents, tourism entrepreneurs etc. In several cases

these groups realize their plans counter to the policy dictate of forest institutions and often after the tacit tolerance of spatial planning institutions. Indeed, as income levels continued to rise (up to 2009) more and more residents of Athens managed to obtain a legal, illegal or semi-illegal vacation home close to or within the peri-urban or coastal forests of East Attica. Speculators and building contractors turned the demand to profit and offered building plots and expensive villas (legal or illegal) at high profit. Consequently, a constantly changing and risky, mixed mosaic –with forest vegetation and buildings in close proximity- has been gradually created. This means that a common environmental good (the forest) and the associated public interest clashed with the perceived rights of individuals to improve their quality of life by inhabiting the wildland areas.

3. East Attica facing Forest Fire Risk: The INCA Road Map as a convincing response to Forest Fire Risk Management failures

3.1 Why East Attica?

The area of East Attica has been selected as an ideal case for the application of the INCA pioneer model because it represents an instructive example of mismanagement of forest fire risk in Greece (Kaoukis 2009; Sapountzaki et al. 2011):

- Out of the currently thirteen administrative regions of the country, the wider Attica Region is the most fire-prone on the basis of the indicator *percentage of burnt forest area to the total forest land of the Region in the period 1991-2004* (more than 26%);
- In the above period most of the fire events of the Region of Attica occurred in East Attica.
- In the same period most of the fire events in the Region of Attica have been registered as events of unknown causes (66,8% -see figures 1 and 2). Official ignorance of the actual root causes of the catastrophic phenomenon is a precursor of an ineffective risk management system.

The selected sub-region is an area of 193,000 ha which in 2001 amounted to 403,918 inhabitants (National Census of 2001). According to Sapountzaki et al. (2011, p. 1451):

> *"East Attica receives the urban sprawl of the Athens' agglomeration and is dotted with satellite settlements (especially along the eastern coastline) which are continuously growing. They are dominated by second homes or semi-permanent residential developments. Also, East Attica hosts the new international airport "Eleftherios Venizelos" which attracts speculative land uses and entrepreneurial activities yielding high land revenues and raising the land values in the vicinity."*(See map 1).

3.2 Applying the Steps of the INCA Road Map model in East Attica Region toward the objective of Forest Fire Risk Mitigation

Selection of Eastern Attica region and its fire risk problem as the area and issue of concern and application constitutes the 1st Step of the INCA Road Map process (see diagram 1). In the next paragraphs the reader can follow the application of the subsequent Steps (2nd to 8th) and their results.

2nd Step: Creation and establishment of the Working Group (WG) for forest fire risk mitigation in Eastern Attica region.

After the initiative of academic and research institutions, namely the HUA and NAGREF teams-partners of the INCA European project a WG was established to deal with the overall objective of forest fire risk mitigation in Eastern Attica region. This consisted of:

- Representatives of the three involved Directorates of the Regional administration of Attica (Civil Protection, Spatial Planning and that of Forests of East Attica)
- Members of the research teams of HUA and NAGREF (INCA project partners)
- Representatives of the Municipalities of East Attica (local level)
- The heads of the four Forest Service Offices of East Attica (local level).

The WG was envisaged and planned to be as inclusive as possible in terms of the co-competent policy sectors and spatial scales / levels of administration.

3rd Step: Agreement on sub-objectives

During the four meetings of the WG and after intense discussion and some frictions between its members the latter arrived at an agreement on four sub-objectives (goals) to be consistently pursued by every member of the WG. These are:

- *Goal A*: Reduction of the number of forest fire events owing to negligence & ignorance causes.
- *Goal B*: Early detection of fire ignition points.
- *Goal C*: Intense search of the causal factors of the recorded as events of unknown origin.
- *Goal D*: Enhancement of prevention, preparedness and recovery by means of active participation of the Civil Society.

Agreement of the WG upon the above goals means commitment of each one of the partners to work for their accomplishment. It is worth noting that above goals are not independent from but interrelated with each other. Also worth-mentioning is the fact that the range of the greed goals extends over the whole RPPR chain (or risk management cycle) to ensure consistency and continuity among its successive phases.

4th Step: Agreement on mitigation measures

Out of the five measures that gained consensus among the participants of the WG three were actually implemented:

Measure I: Training of the school population (12-14 years old) on forest fire causal factors (including those related to human and physical geography) and self-protection and management issues. This was intended to serve simultaneously goals A and D.

Measure II: Assessing vulnerability and enhancing self-defense of residences versus fires (those in mixed forest residential areas) and creating a relevant geo-data basis. The measure was intended and planned to serve all four goals agreed upon in Step 3.

Measure III: Correction of contradictions, overlaps and/or ambiguities regarding competences of Spatial Planning, Civil Protection and Forest Service authorities as regards their impact on Forest Fire Risk. This measure has been envisaged so as to facilitate goals A, C and D.

Commitment of all participants to contribute to implementation of co-decided Measures is tightly connected to the multidisciplinary dimension of these Measures necessitating input from several fields and the respective WG members. An indicative example is the case of the measure of "Training seminars addressed to pupils". These seminars were implemented in two sessions where the first covered the spatial planning dimension of the catastrophic phenomenon[2] while the second focused on the foresters' and forest fire managers' point of view.

[2] Spatial planning dimension is relevant to the manmade causes owing to economic interests and human activity pressures on forest land, preventive measures related to the control of building development within and around forest land etc.

On the other hand “the spatial data basis for a mixed forest-residential territory” that was indeed realized in a hilly area within the jurisdiction of the Municipality of Kalyvia in Eastern Attica region is also a composite multi-dimensional Measure. The information that was collected includes data that are usable for both spatial planning preventive interventions (e.g. delineation of high risk and vulnerability zones where to impose building construction constraints and locate critical protective infrastructure) and pre-suppression and preparedness planning versus forest fires (e.g. localization of the weak points of the emergency road network etc). These of course are effective ways for rehabilitating synergies and cooperation between Civil Protection, Spatial Planning and Forest Policy to the end of Fire Risk Mitigation.

5th Step: Testing implementation processes and assessing final products
The Measure of the Training Seminars (I) and that of the Geo Data Basis referring to the vulnerability to fires of the building stock in the mixed forest-residential areas (Measure II) have been implemented at the local level (Municipality of Kalyvia in Eastern Attica region) while Mesure III focusing on the correction / demarcation of competences has been implemented at both regional and local levels.

The results after implementation of Measure I have been evaluated by means of questionnaires addressed to the pupils twice (an original version was submitted to the pupils before the Seminars and a copy of it after the Seminars) to allow evaluation of comprehension and assimilation by the pupils of the teaching material and respective messages. The statistical picture of the answers given to specific queries (of the questionnaire) before and after the Seminar on “Self-protection and Forest Fire Management” is offered in the following figures 3, 4, 5.

Map 2 below is indicative of the results after implementation of Measure II. It indicates the overall risk of destruction of houses possibly attributable to construction materials, location of the building, the slope, density and quality of vegetation that surrounds it, also the road leading to it.

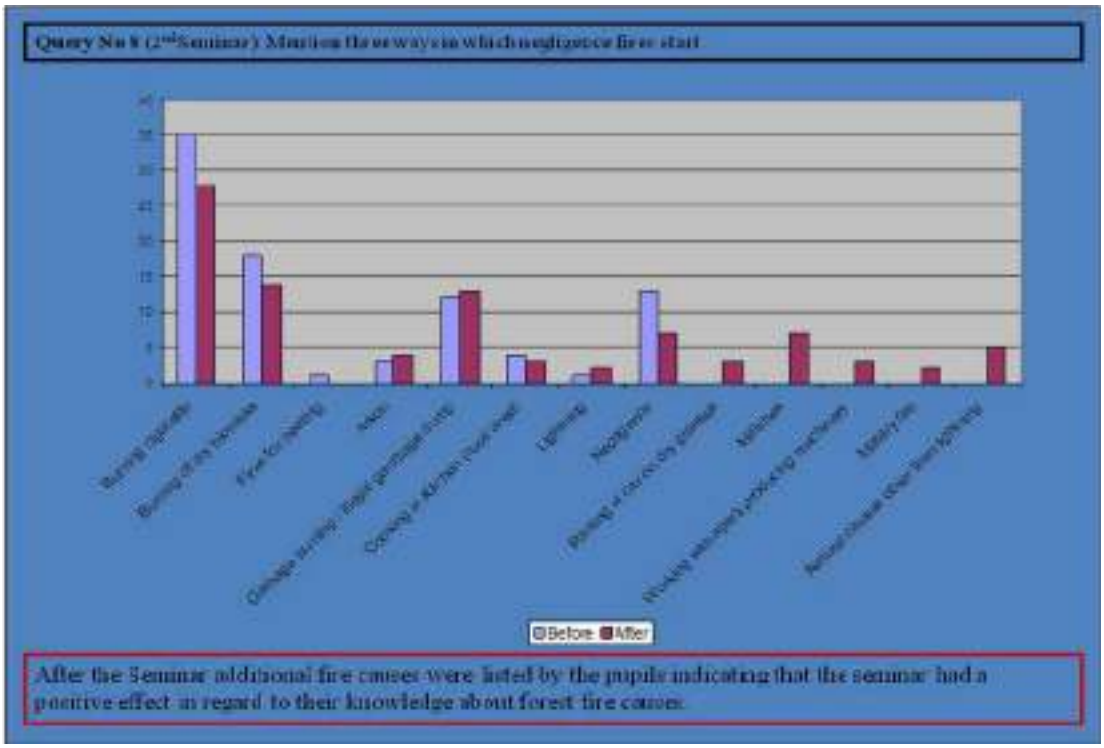

Figure 3. Comparison of pupils' answers to the query "Mention three ways in which negligence fires start" before and after the respective Seminar of the INCA project. *Source: INCA project 2011, Del. D2, Roussos A. and Xanthopoulos G.*

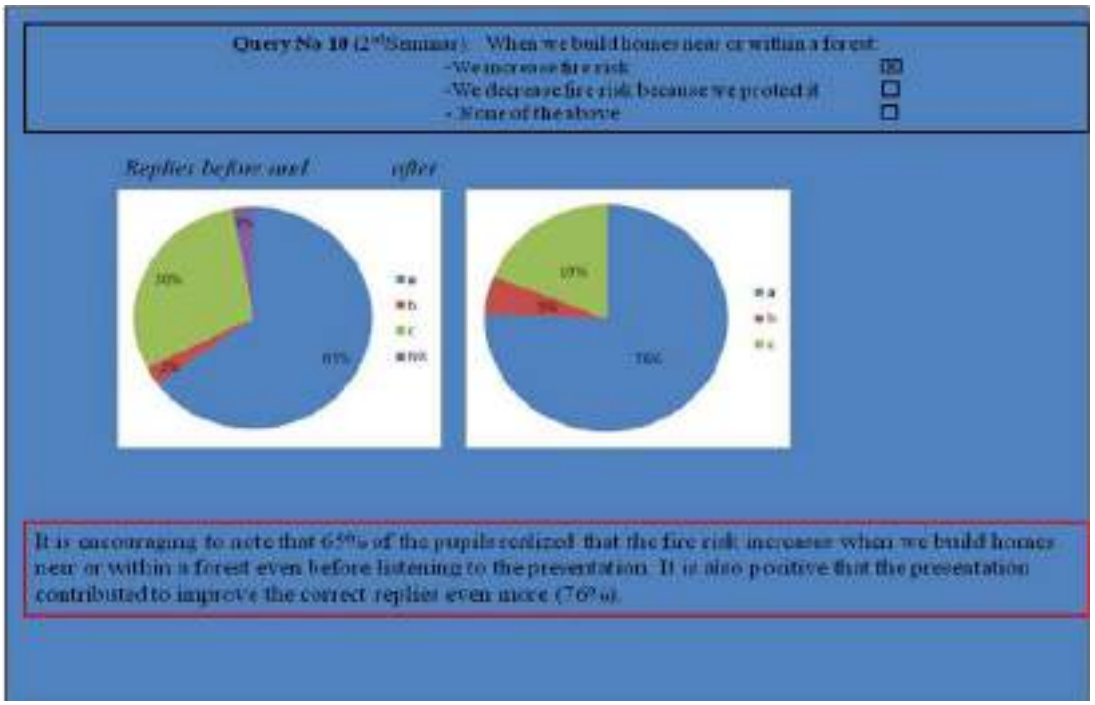

Figure 4. Comparison of pupils' answers to the query "What is the impact of buildings close to or within a forest?" before and after the respective Seminar. *Source: INCA project 2011, Del. D2, Roussos A. and Xanthopoulos G.*

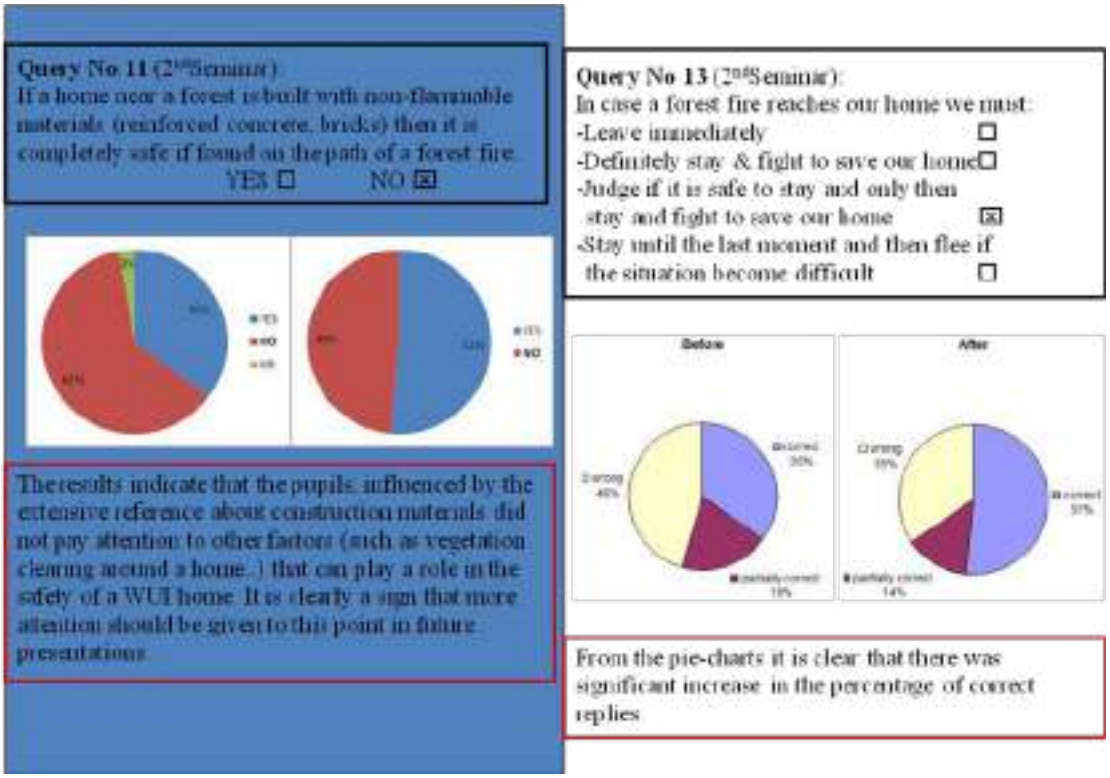

Figure 5. Comparing pupils' answers to queries regarding proper residence-defense and self-protection attitudes (before and after the respective Seminar). *Source: INCA project 2011, Del. D2, Roussos A. and Xanthopoulos G.*

Map 2. Houses and roads are coloured according to the total index (K) of risk of destruction of the building. *Source: INCA project 2011, Del. D2, Kalogirou S. Roussos A. and Xanthopoulos G.*

The statistical picture of the answers to the questionnaire submitted for completion to public officials (at the regional and municipal levels) asking them to address the effect of their own competences on forest fire risk (Measure III) is given in figures 6 and 7. The respondents have been selected to represent all primarily relevant policy fields: Spatial Planning, Civil Protection and Forest Policy. The aim of the questionnaire has been to increase consciousness of public officials regarding their possibility to influence forest fire risk (either in a positive or negative way) as well as clear delineation of competences and investigation of the prospects of cooperation. The questionnaire comprised a number of closed and open questions and the statistical sample amounted to 29 filled in questionnaires that were analyzed then by using methods of descriptive statistics and correlations.

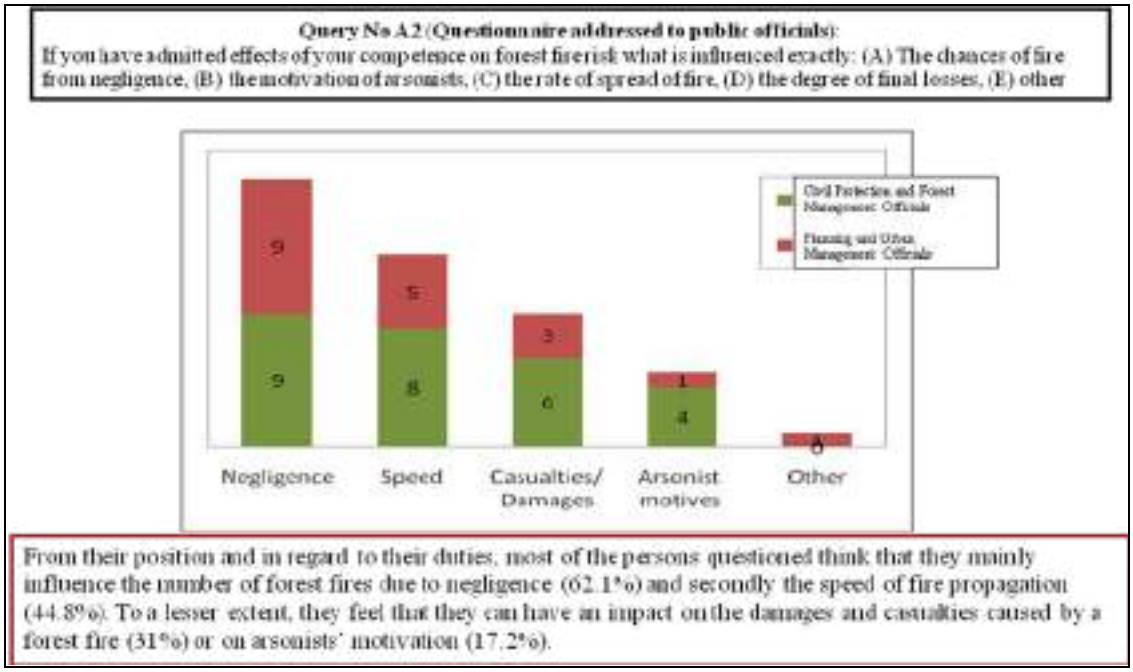

Figure 6. The public officials' answers to the query referring to the effects of their competence on forest fire risk. *Source: INCA project 2011, Del. D2, Sapountzaki K., Tragaki A. and Papachatzi A.*

6th and 7th Step: Indicators and measuring values reflecting the contributions of each partner and monitoring / controlling the achievements with respect to the envisaged goals.

The implemented measures serve the goals/sub- objectives that have been agreed upon by the WG as follows:

- Measure I (Training Seminars on Forest Fires directed to the school population of the Municipality of Kalyvia) contributes to the achievement of Goal A i.e. 'Reduction/Elimination of the number of fire events owing to negligence and ignorance causes' as well as Goal D (i.e. 'Enhancing participation of the Civil Society in forest fire prevention, preparedness and reforestation/rehabilitation processes')
- Measure II (Evaluation and Mapping of fire risk and vulnerability levels of buildings in the Out of Plan forest-residential areas of the Municipality of Kalyvia) establishes the prerequisite information basis for the successful pursuit of all four established Goals.
- Measure III (Submission of a questionnaire to public officials to address ignorance, uncertainties, contradictions and overlaps of public policy competences affecting forest fire risk) serves equally the Goals A, C and D (see 3rd Step).

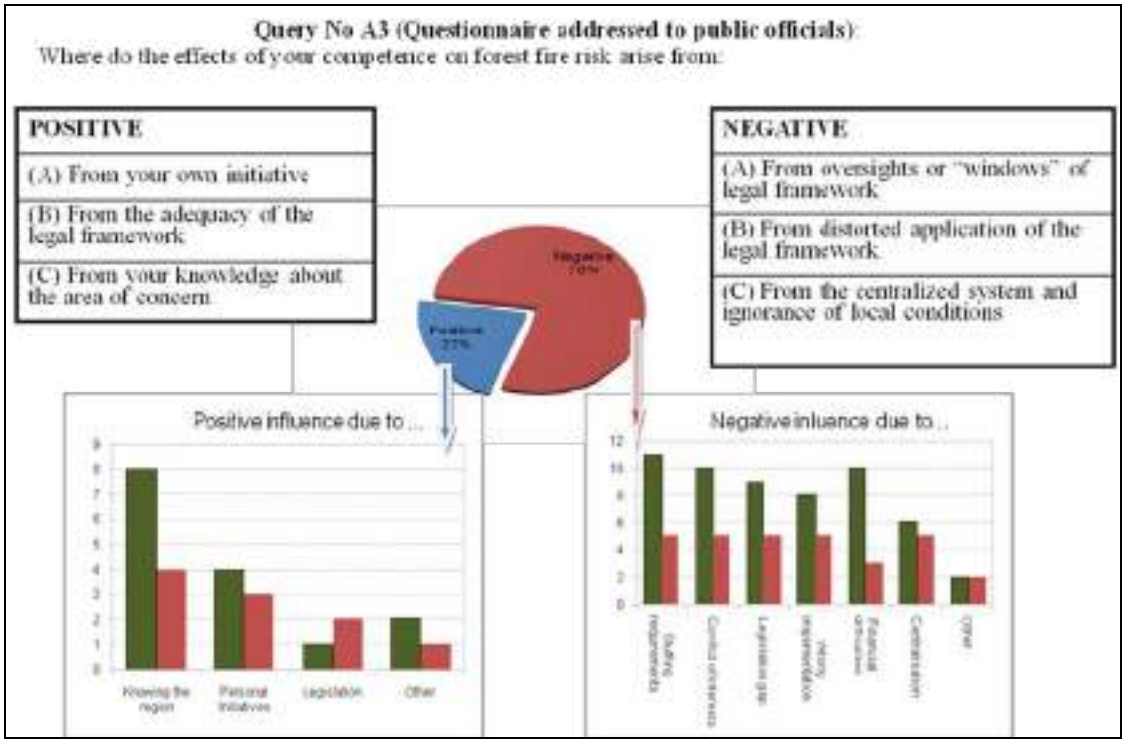

Figure 7. The public officials' answers to the query referring to the reasons behind the effects of their competence on forest fire risk. *Source: INCA project 2011, Del. D2, Sapountzaki K., Tragaki A. and Papachatzi A.*

Current steps of the road map process are preoccupied also with the degree to which the implemented measures fulfill the goals and whether all participants have contributed equally and cooperated with each other effectively. Appropriately planned and selected indicators and measuring values are the response to this challenge. More specifically the indicators that were constructed address:

- the contribution of each involved partner (input, i.e. own resources committed to the implementation of a measure)
- the effectiveness and efficiency of the implementation process with regard to the expected output and/or degree of achievement of the established goal/sub- objective
- the final outcome, i.e. the impact of the applied measure on the overall general objective of reduction of the forest fire risk in the area of concern.

Table 1 presents as an instructive example the monitoring indicators for Measure I (Training seminars on forest fire risk to be offered to school population). Figure 8 shows the estimation of measuring values and classification process for one specific indicator: "Sensitivity of pupils regarding forest fires and respective citizen responsibilities" both before and after the Seminars.

Table 1. Monitoring Indicators for Measure I (Training Seminars for School Population). *Source: INCA project 2011, Del. D2, Sapountzaki K.*

Steps / agents to be controlled	The element to be monitored	Monitoring Indicators
The Input of the involved partners (the Region of Attica, the respective Municipalities, the Research Institution)	Public Schools	Proportion of the Public Schools of the Region/Municipality joining the process of the training seminars (on annual basis)
	Public School- Teachers	Proportion of the school teachers (specialized in environmental education) adopting the measure on annual basis
	School Population	Proportion of the total school population of the Region/ Municipality attending the seminars on a yearly basis
	Academic- research manpower specialized in forest fire issues	Man- hours (on a yearly basis) of researchers (specialized in forest fires) devoted to the preparation of training material and analysis of questionnaires to address lessons learnt by the pupils
The effectiveness and efficiency of the training seminars (output)	Knowledge/ awareness of pupils and their families regarding forest fires	Mean knowledge/awareness indicators derived from answers to an appropriate group of queries (addressed to pupils by means of anonymous questionnaire)
	Sensitivity of pupils (and their families) regarding forest fires and citizen responsibilities	Mean **sensitivity indicators** derived from the answers of pupils to appropriate group of queries
The impact of training seminars on forest fire risk in the Region of Attica	Pupils' residences regarding exposure to forest fires as well as territorial exposure to forest fires of the wider area of East Attica	Proportion of pupils of which their families performed actions mitigating residential exposure
		Risk perception indicators of the pupils that attended the seminars
		Exposure levels of the Out- of-Plan mixed forest- residential areas of east Attica (on the basis of long- term horizons)

Sensitivity Scores are estimated by combining scores attributed to the answers of the following queries of the 1st Questionnaire:

5. What feelings are created to you by forest fires?
19. Do you prefer your residence to be located (A) inside the forest, (B) inside a city or settlement?
20. Would you change your answer above if you were sure that a building in the forest increases the danger of forest fire or of your house to be burnt?

	Before the Seminar	After the Seminar
-5 to 0	4 (10%)	5 (12%)
0 to 5	17 (41%)	12 (29%)
5 to 10	18 (44%)	22 (54%)
10 to 15	1 (2%)	2 (4%)
15 -20	1 (2%)	0 (0%)

Sensitivity scores:
Frequencies and relative frequencies

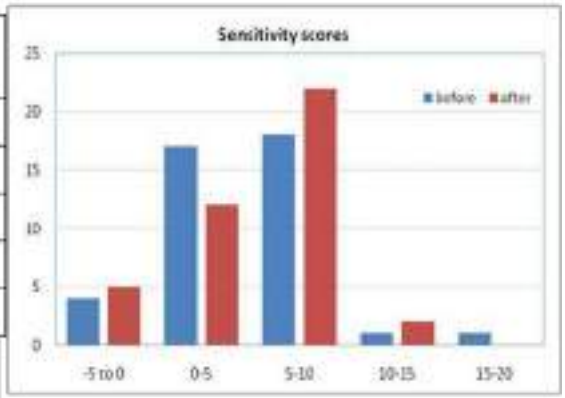

Figure 8. Estimation and classification of measuring values of the indicator "Sensitivity of Pupils versus forest fires" before and after attending an informative Seminar. *Source: INCA project 2011, Del. D2, Sapountzaki K., Tragaki A. and Papachatzi A.*

8th Step: Feedback

The feedback possibility has been employed several times during the INCA Road Map process. First, for the enlargement of the initially established WG (after the 3rd Step) so as to include additionally involved stakeholders (i.e. competent Municipalities, the heads of the Forest Service Offices –FSOs- in the Eastern Attica area etc).

Feedback has also been performed at the 6th Step when it was decided that implementation of measures should start as a pilot case at the local (Municipality) level and not the regional level; also that it should be undertaken firstly by an active Local Authority Organization (the Kalyvia Municipality) and should be performed as a trial case of limited scope (the seminars were conducted for a sample of the school population of Kalyvia and the Geo-data basis was created for only a small hilly forest-residential area falling in the jurisdiction of the Municipality of Kalyvia.

Feedback has been used in several other circumstances and should continue to be employed in the future if the refinement and standardization of the Road Map process is pursued.

4. Conclusions

The results of the pilot application of the INCA Road Map model in the Eastern Attica region and more specifically in the area of the Municipality of Kalyvia proved to be impressive. Without spending even one euro the Municipality by following the process managed to: (a) obtain a valuable Geo-data information basis on the variations of risk of destruction and building vulnerability in a section of its forest-residential areas and (b) organize Seminars for pupils and disseminate useful information to the wider Kalyvia community on forest fire prevention, protection and management.

The INCA Road Map model for risk mitigation represents a radical change and innovation in relation to the rigid political / administrative systems and a significant deviation from the established norms of administrative processes. This is true for even centralized, like the Greek, systems of policy-making.

The INCA Road Map model promotes actually risk management processes that are adjusted to the risk generating conditions; on the contrary conventional management solutions are reflections of administrations' structures, constraints and possibilities. Hence, viability of the model is at the hands of regional and local administrations which have to follow visions and be committed to the matter of risk abatement, environmental protection and public safety rather than retain their introversion and insularism.

The success of application of the model in the case of Eastern Attica region facing the standing and increasing risk of forest fires in its mixed forest-residential areas was due to the following appropriately reflexive and feedback decisions/ actions:

- Enlargement of the initially formulated WG so as to embrace crucial but non-formal actors and agents (members of NGOs, public officials carrying simultaneously the status of a researcher, representatives of voluntary citizen groups, officials with prior experience in organizing drills and in training volunteers, persons at key-posts which INCA members kept personal friendship contacts with etc.)
- Involvement in the working group of a Local Authority to undertake the mission of measures' implementation. The LA level is indeed the most flexible level of administration, the closer to the Civil Society and the easiest in adopting and assimilating novel, innovative processes which are usually ejected by the state's bureaucracy.
- The measures have been opted so that their application would not necessitate extra financial resources. This was possible due to the employment of voluntary citizen groups and utilization of a University's and Research Institution's infrastructure (software and hardware). Should implementation necessitate extra funding it would not ever be realized.

The process of application revealed that a knowledge intensive institution is a necessity and a precondition for success. Such an institution is out of the internal conflicts of the administration pyramid, it enjoys (to a certain degree) credibility and trust, it is acceptable as negotiator and it is the only agent that can refute the consolidated, backward and rigid mentalities strung along with bureaucracies.
In any case the successful application of the measures is only provisional and temporary. No question, the measures have not been embedded in the routine process of the Regional or Local Authorities. Indeed, there is a long distance to cover before achieving such an end but the pilot case application has opened the way.

SPATIAL STRATEGIES FOR IMPROVING CONVIVIALITY IN PUBLIC PLACES: THE CASE OF THE HISTORICAL GOLDSMITH AND TEXTILE ARTISANAL MARKET AREA OF CITTÀ BASSA IN NAPLES

Claudia Trillo[1], Gabriella Esposito De Vita[2],
Carmelina Bevilacqua[3], Gaetano Mollura[4]

Abstract

The effects of the privatization of public and quasi-public places in affluent and well-connected areas of the city and the correspondent decay and abandonment of public places in deprived areas need to be discussed. Under the umbrella concept of conviviality in public spaces, a research project on the rehabilitation of urban areas for commercial and retail uses – as engine of a complex process of production of places of social and cultural mixité – has been defined. In this context, a reflection on the role played by the rehabilitation of traditional and natural market areas inside city centres will be developed in order to favour liveability of public places.
The increasing in the expulsion of commercial activities from the city centre and the proliferation of gated suburban commercial areas have deprived wide areas, creating ruptures in the continuity of the urban grid. According to Gehl (2001), these ruptures are causes and effects of decay and abandonment of public areas. The research main hypothesis is that traditional retailers should be considered an essential element to ensure effective public use of urban public spaces. Thus, conservation and preservation strategies should take them in account as a priority matter, in order to guarantee a high level of conviviality in the urban centres.
The research methodology is based on a qualitative approach. Focussing on the process of impoverishment within local commercial districts – due to functional, logistic and market-oriented policies – the research aims at defining a holistic methodology for interpreting, designing, managing and assessing the refurbishment and redevelopment of those specific areas. In details, in order to apply a case study approach (Yin, 1994), the research group started working with local stakeholders in order to identify the most significant case study to be carried out in Naples, thus selecting the historical market place of Piazza Mercato and its neighbourhood in the Città Bassa of Naples (Italy) that are object of the Local action Plan implemented in the framework of the CTUR and HerO Projects of the URBACT II Programme. Naples presents interesting aspects of public spaces dedicated to identitarian artisanal

and commercial activities inside a dense historical centre – one of the bigger UNESCO sites in the world. After the selection of the case study has been made, a possible strategy for addressing the revitalisation of the area was built and tested, by delivering a set of semi-structured interviews with key stakeholders and focus groups.
The aim of this research has been to produce useful tools for coping with the abandonment of public spaces in former commercial urban areas, and to avoid the risk of generating anonymous and globalized commercial districts. It aims at involving local stakeholders in pilot action plans, to demonstrate the possible effectiveness of the proposed approach. In so doing, it offers useful tools applicable in urban policies, particularly in European cities, characterised by the presence of significant historical centres challenged by both isolation and gentrification processes.

1. Introduction

The contemporary city is affected by a profound crisis due to the loss of cultural identities, of traditional social networks, and of welcoming urban spaces for improving interactions between diverse components of society. (Madanipour, 2010) Places of public life are the expression of this scenario: the agora is changing forms, functions, and symbols, following new trends superimposed by globalization phenomena. The impact on the transformation of public places due to recent dynamics, is revealed by the tendency to produce market-led transformations of public places in affluent areas and the abandonment and decay of the peripheral public realm. (Carmona et al., 2003)
In the following pages a research project will be presented which is aimed at identifying the main components of a process of rehabilitation of urban areas for commercial and retail uses in order to favour social and cultural *mixité* and economic regeneration. The project deals with the increasing globalization process, and consequently with the expulsion of traditional and identitarian commercial activities from the city centre, creating ruptures in the continuity of the urban grid in terms of creation of market-led and anonymous commercial areas on the one hand, and in terms of abandonment and decay of less affluent areas with a strong local cultural character on the other. (Augé, 1992)
The research starting point is the role played by traditional retailers and artisans as an essential element to preserve local cultural character, ensuring effective public use and liveability of urban public spaces. This qualitative approach aims at defining a holistic methodology for interpreting, designing, managing and assessing the refurbishment and redevelopment of those specific areas. This topic will be addressed by developing an urban design tool based on an effective participatory process in the rehabilitation and redevelopment of public places in abandoned commercial areas (Healey, 1997). This tool could be applied within community planning consolidated methods (Arnstein, 1969), in order to best address the physical and spatial component of the mapping and visioning process. Consolidated procedures for collecting and sharing the demand expressed by local communities in

terms of services delivery and public places organization have been developed in different fields of knowledge. Nevertheless, there is a lack of procedures for addressing demand for spatial transformations in order to favour the preservation and development of traditional and identitarian artisanal and retail areas as a driver for a wide urban regeneration process. This topic is included in the research programme of the EU-funded research Commercial Local Urban District Programme (CLUDs) "aimed at emphasizing the strategic role of small retailers – handcraft and typical food – in reinforcing the sense of community, reducing transportation costs and contributing to the creation of an attractive urban environment, thus producing an increase in private investment". (CLUDs Commercial Local Urban Districts, 2011)
In order to identify the way physical and functional transformations of commercial areas in city cores can favour results in terms of social cohesion, economic development, cultural preservation and local liveability, the study started by working with a case study approach (Yin, 1994).
The research focusses on the specific experience of Naples in Southern Italy, which offers a wide range of interesting fields of reflection on the research topics. The group of scholars and local technicians involved in the fieldwork started doing active observations of the Neapolitan urban area in order to identify possible significant case studies to be carried out. The conceptual map of significant areas was discussed with local stakeholders resulting in the selection of the historical market place of Piazza Mercato and its neighbourhood in the Città Bassa district as a case to be analysed. This area has been the core of the Local Action Plan implemented within the framework of the CTUR and HerO Projects of the URBACT II Programme and is now the object of a new project funded by the EU.
Through the experience gained during the execution of the Local Action Plan for this historical area in Southern Italy, this paper aims at introducing and discussing a work in process oriented to coping with the tendency to abandon wide core areas of the city centre by supporting virtuous processes of urban regeneration, and intervening through a participatory process in the rehabilitation of traditional and natural market areas.
This paper is divided into four sections. Having introduced the research in this section, the following sections will:

- Set the context to identify the theoretical and methodological context of urban design, community planning and economic procedures to be applied together to commercial urban districts regeneration;
- Define the framework for the empirical analysis and discuss the pilot area findings; and
- Draw general conclusions, defining the role of local commercial areas as divers of urban regeneration.

2. Setting the theoretical and methodological context

The research project here presented is based on two different kinds of EU-funded research. The first one – the 7FP Marie Curie IRSES project Commercial Local Urban District Programme (CLUDs) – set the theoretical perspective and the

methodological approach. The second one – the development of the case study approach – has been conducted under the umbrella of the Local Action Plan implemented within the framework of the CTUR and HerO projects of the URBACT II Programme.

The conceptual framework of the CLUDs project (CLUDs Commercial Local Urban Districts, 2011) consists of the possibility of merging urban design, community planning and economic procedures in order to build a new tool for renovating degraded public spaces and improving the attractiveness and accessibility of deprived urban areas by focussing on the high potential of local commercial activities. The research can assist policy-makers in coping with the needs of urban regeneration by setting up an analytical process to understand how a public-private partnership oriented to sustain local retail can be both market-led and social-led. These aims can be reached by highlighting integrated approaches related to credit access, local resources promotion, job creation, typical retail protection and community engagement – in order to understand how the territorial milieu can contribute to create the necessary critical mass for improving local urban regeneration initiatives. (Ball, 2003)

The history and culture of European cities reveal the importance of public spaces such as streets and squares, which are deeply influenced by the commercial functions they host. Over the centuries, local retailing models, often integrated with the production of typical services, handcraft traditions and locally produced food, have frequently conditioned forms and organization of the European city. More generally, a higher level of manufacturing, commercial and residential integration is still related to vibrant urban environments, which are rich in urban life and social relations. (Brinkerhoff et al., 2011)

From the social point of view, it is widely recognized that integrated urban environments often contribute to a higher level of safety because of the social control exercised on the public spaces due to their continuous use; for the same reason, they are less likely to became blighted areas, thanks to the involvement of local communities in preserving their values. From the environmental point of view, the residential and commercial balance in each area is a fundamental tool in securing a less car-oriented living model, as small retailers allow residents to meet their everyday needs by walking; thus, it represents a real and proper pillar in ensuring a sustainable urban lifestyle. Furthermore, the link between small retailers and niche local production helps to ensure a more consistent and efficient supply chain, avoiding useless freight transportation costs, as well as reinforcing the relationship between the urban and rural environments.

Although these are remarkable and valuable features in the traditional European urban model, nowadays the changes in the international retail organization system are deeply impacting on the commercial functions of some urban areas. In particular, shopping malls and other large shopping centres present potential forces for dramatically reshaping the urban and suburban landscapes.

The CLUDs rationale is oriented to provide critical mass to weak urban areas through the connection with a broader network of local producers, thus fostering the

concentration of services (urban competitiveness) by connecting them to the production of goods in a wider territorial milieu (urban-rural balance).
The described Joint Exchange Programme CLUDs, reflecting the rationale of Economic Opportunity Zones, focusses on local small retail associations concerned with typical local production and their capacity of bringing together public initiatives, private investments and community demands.
This research project as been developed along diverse routes for empirical applications. In particular, two projects guided by local administrations and oriented to make possible a wide public-private partnership have been chosen to cross the CLUDs theoretical premises with a case study approach. The projects "Cruise activity and the recovery of urban and harbour building heritage: Strong elements of the common interest of sea towns to develop and strengthen the urban tourism sector" (CTUR) and "Heritage as Opportunity" (HerO) of the URBACT II Programme (www.urbact.eu, 2011) have been both developed (2008-2011) by a network of European cities. The core idea of the first one has been to improve competitiveness and liveability of port cities through the waterfront revitalisation (including derelict industrial areas) in an overall approach of the port city development, creating a mix between maritime and urban activities within the framework of an integrated approach of sustainable development. The second project – dealing with the challenging management of historic towns in Europe – focuses on heritage cities throughout Europe, in order to enhance balance between the safeguarding of heritage and the development of the city, taking heritage as an economic driver. These projects are both completed and are now in the process of being implemented in the local policies and are the base of the new projects promoted by the Neapolitan City Council in order to deepening the concept of land consumption in the historic centre.

3. Case study analysis: the Local Action Plan of Naples Città Bassa

Briefly, Naples can be considered one of the prominent ancient settlements in Europe and part of the Mediterranean basin. Its historic centre is a unique example of architectural stratification through the centuries and is still a vibrant catalyst of mixed activities without any museumification phenomena. Along with these positive aspects there are many problems, such as: the high population density; the low education indexes; the severe status of the labour market linked to the lack of private activities and job creation initiatives; the presence of criminal organizations; and the strong rehabilitation needs of the built environment, including the cultural heritage.

Table 1. Naples at a glance

Location	Capital of the Region of Campania - Southern Italy
First settlement	VI century B.C. as a Greek settlement
Population	1,004,500 inhabitants (City Council of Naples, census 2001)
Pop. density	8,556 inh/sq km (City Council of Naples, census 2001)
Unemployment rate	31.39% (City Council of Naples, census 2001)
Income per capita	€ 25,565.81 (Finance Ministry, 2009)

Historic centre	UNESCO recognizes the Outstanding Universal Value (OUV) of the historic centre of Naples (1995).

The complexity of this local scenario of resources and challenges is the humus for nourishing the local initiatives we are going to describe. (Gaber et al., 2007)
The first step has been the definition of the case study domain in terms of location, size, functional organization and general characteristics. Through the dialogue with the Urban Planning Department of the City of Naples, the active observations in different daytimes, weekdays and seasons as well as the discussion with local stakeholders and scholars in charge, a specific area involved in these comprehensive projects has been chosen in order to address the topics of the research.

Table 2. Plans and Programmes which coexist in the study area

Plans and Programmes connected to the ERDF 2007 – 2013	DOS (Strategic Guidance Document); Integrated Urban Plan EUROPE for the historic centre of Naples (PIU EUROPA); Grande Programma UNESCO (UNESCO Great Programme); Strategic Plan of Naples; HerO "Naples Historic Centre World Heritage Site Management Plan (WHSMP)" "Project of renewal of Borgo Orefici" under 2000-2006 ERDF Funds

The coexistence in the same area of various urban planning and management tools, of several UE-funded initiatives as well as of grassroots movements and of traditional local economic activities can be considered the ideal scenario for developing a complex participatory process of urban regeneration to be tested and generalized. The research in progress here introduced has been developing in parallel and − on some topics − in cooperation with the planners in charge for the cited URBACT projects conducted by the City of Naples.
The area of Città Bassa, despite having previously had a strong commercial character, suffers since the end of the Second World War relative neglect and gradual decay. In this context some relevant key issues can be pointed out with regards to: the physical aspects such as location, accessibility, built environment conditions; cultural issues such as historical heritage, monuments, arts and crafts traditions; and social scenario in terms of social deprivation indices.
The work is premised on enhancing local revitalization and regeneration processes by focussing on the potential of an integrated approach to commercial activities, among the key issues related to the urban revitalization of the historical urbanscape. This is to be addressed in Naples by meeting the needs of different stakeholders – the linkage with the cited URBACT projects is "to secure traditional shops and retail trade structures as these ones are struggling to survive and to set up new governance structures for a better coordination of the revitalization activities" (HerO, 2011).

Table 3. Città Bassa: some relevant aspects

Location	Enclave between the port area and the historic centre UNESCO WHS
Accessibility	• 15 km from Capodichino International Airport; • near the Central Railway Station; • served by four metro stations (2 of those need to be completed); • near the local and regional maritime transportation nodes of Beverello Quay and Porta di Massa Quay.
Historical heritage	• Porta Nolana gate of the ancient city walls; • the renaissance church of SS. Cosma e Damiano; • the ruins of Castel del Carmine; • the baroque church of Santa Maria del Carmine; • Sant'Eligio Maggiore Church of the Angevin period dated 1270.
Art and crafts tradition	• Borgo degli Orefici (goldsmith quarter) since the fourteenth century; • Piazza Mercato Old Marketplace; • Antiche Botteghe tessili (textile market); • Typical handmade street food.
Social deprivation	• Unemployment rate (Mercato district 38.01%, Pendino district 40.37%); • Illegal immigration; • Hidden and informal economic activities.
Built environment	• Low level of housing maintenance and technological retrofitting; • Abandoned and decayed public places; • Lack of spaces for pedestrian uses due to cul-de-sacs, squares transformed in parking areas, inefficient street lighting, abandoned ground floors (38% unused sqm – source Si.Re.Na Company); • Buildings which provide physical and visual barriers between the area and the waterfront.

The focus area for HerO projects is Piazza Mercato, which is connected to an overall URBACT LAP named "Città Bassa" (www.urbact.eu/hero) included in a comprehensive intervention called "The waterfront of the historic centre and port area from piazza Municipio to piazza Mercato: a sustainable development through the

improvement of the cruise tourism impact", which also concerns the LAP of the URBACT Thematic Network CTUR (Cruise Traffic and Urban Regeneration) lead by the City of Naples.

Example of a structure of a Local Action Plan. In this sense the LSG can be a good source to identify the key actions as well as to fill out the LAP table.

Figure 1. Example of Local Action Plan organization. Source: HerO Final Results: The Road to Success - Integrated Management of Historic Towns Guidebook; p. 47

The area of Città Bassa of Naples reflects all the issues, criticisms and potentiality related to the integration of typical handicrafts, dense residential uses, traditional commercial activities and the historical character of public places. This wide and articulated area lies between the port and the historical centre which has been listed as a World Heritage Site by UNESCO since 1995.
The study area is included in the range of influence of the Local Action Plan built by the City with the help of its Local Support Group (LSG), within the framework of the URBACT projects. The LSG as defined by HerO is to support the development and implementation of the Integrated Cultural Heritage Management Plan, which is "oriented towards the needs of the historic urban area and its users, offers the unique opportunity to bring the different stakeholders together". (HerO, 2011) The Neapolitan LSG has been formed as the first step of the URBACT projects and has become the main interlocutor of the different kinds of local initiatives such as research fieldworks, entrepreneurships, training and programmes for the control against informal and hidden economy.

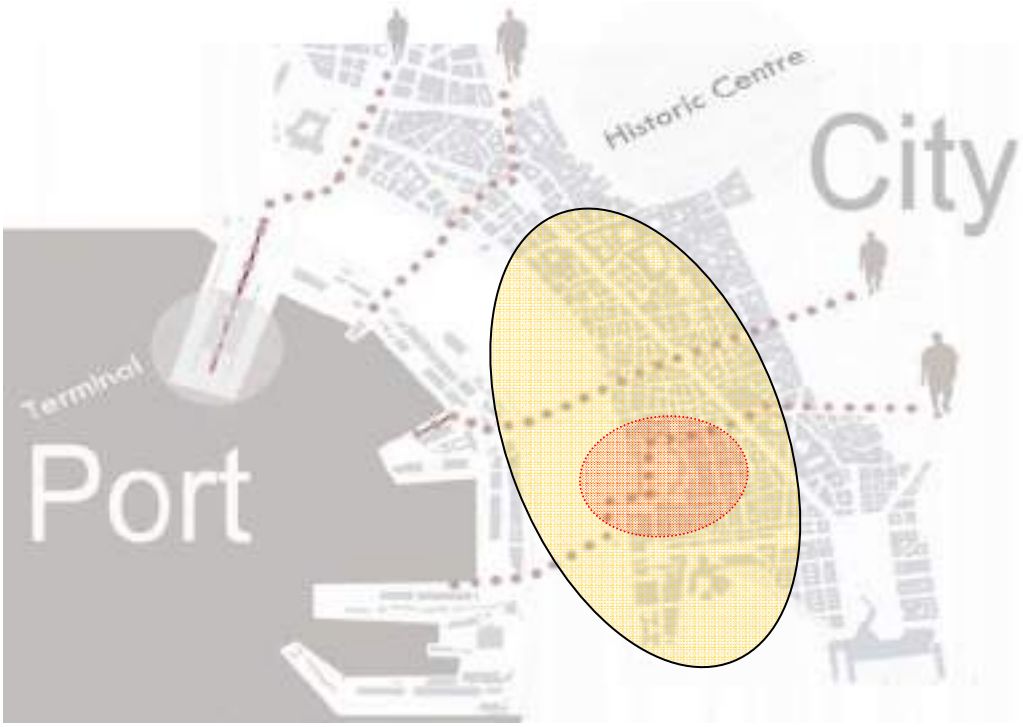

Figure 2. The study area of Città Bassa of Naples and Piazza Mercato. Source: Elaboration by the CTUR Final Report

The Local Action Plan (LAP) of Naples Città Bassa could become an experience of paramount importance – to be analysed, assessed and enhanced due to its mixed and complex character. Focussing not only on social indices and economic issues, the LAP is oriented to integrate both the approaches: built environment and historic heritage rehabilitation on the one hand and economic strategies on the other.
The Città bassa LAP includes the districts of Borgo Orefici/Waterfront (which form part of CTUR) and piazza Mercato (part of HerO) – all closely related to the port and the eastern part of the city – and is aimed specifically at reconnecting the ancient town centre and the harbour as well as regenerating the historic neighbourhoods.
The main topics are development of sustainable tourism, creation of business incubators, increasing commercial attractiveness, and job creation in specialized fields. One of the results obtained by the LAP has been to create an impact at the local level by transferring the knowledge acquired in the URBACT process to local policies, programmes and actors. This has been accomplished by scaling-up some of the action plans at the policy level and integrating them into mainstream services, as well as by securing funding through the Operational Programmes of the European Regional Development Fund (ERDF) for their implementation. In addition, the process has also contributed to creating new partnerships between different levels of government and the involvement and participation of private stakeholders in the development of the project. The LAP has been developed through the active participation of different categories of local stakeholders. (Sanoff, 2000)

Table 4. Città Bassa LAP: main aims and objectives

1	Requalification of the waterfront monumental area and nearby historic urban area;
2	Refunctionalization of the city and the port heritage;
3	Maximize the economic and social impacts of the projects;
4	support the social and economic development of the "Città Bassa" quarter based on historical activities.

4. Conclusions: local commercial areas as drivers of urban regeneration

Starting from the virtuous process launched within the framework of the URBACT LAP here analysed and applying the methodological premises of the CLUDs project, an adaptive model of urban regeneration based on commercial activities is currently being defined - in cooperation with the local stakeholders involved in the transformations of the study area.

Applying the CLUDS methodology, the research aims at building a dynamic architecture of public private partnership PPP in order to enhance the regeneration process during this crisis period. The LAP has been an important instrument for encouraging dialogue between the stronger stakeholders of the LAP area, such as the Port Authority, arts and crafts private consortia and the City Council. By setting up the local support group, the URBACTS projects acting in the area have created a positive process: first, the initiatives developed by public bodies started the auditioning process and the collection of resources; subsequently, private bodies and civil society have become part of the process.

Referring to the logic of Business Improvement Districts (BIDs) – models dating back to the 1970s in the USA, are private institutions aimed at providing supplemental services in underserved urban areas – the wider experience resulting from the implementation of PPPs in North America will be combined with recent experiences developed in Europe that have involved actors from the broader territorial context in order to reach a necessary critical mass for urban regeneration.

The complex and articulated scenario of PPP tools offers the possibility of identify a possible dynamic system of relationships between subjects, actions, resources, roles and evaluation of the results. In particular, the case study approach is needed to design a sort of fuzzy-architecture of the partnership models aimed at facilitating local private and public initiatives within the framework of the common interest of

generating social and economic enhancement. A bottom up approach, oriented not only to collect demands and needs from the territory but also to encourage private initiatives, start-ups, non-profit organizations, and other forms of investments, will be elaborated and discussed with local stakeholders.
As we can see, in the LAP experiences analysed the initiative starts with the involvement of public bodies whose activites are primarily oriented to identify priority for public investments and to engage other public and private stakeholders. This process has been developed by the City of Naples and the LSG using a wide participatory process involving different categories of city-users, producing a huge data and information collection from the territory, providing a big effort in terms of sourcing and integration of financial resources and involving different categories of city-users.
The feedback needed – by applying the tools elaborated within the framework of the WP1 of the CLUDs research – is a model of governance that could enhance the non-profit private initiatives of urban regeneration driven by the development and rehabilitation of commercial areas in a wide profitable and marketable way.

5. Acknowledgements

This presentation draws from the cooperation between the research program CLUDs funded within the framework of the EU IRSES Marie Curie 7FP, the National Research Council of Italy (CNR-IRAT) and the City of Naples (URBACT unit).

Title: The Dilemma of Programming and Mobilising in the Urban Cultural Landscape of the New Dutch Waterline

Keywords: Governance, Institutions, New Dutch Waterline, Cultural Heritage, Landscape

Governance has become a key concept in planning. In this paper we focus on a specific dilemma associated with the emergence of governance as a means of solving collective action problems in the area of planning: the tension between mobilizing and programming. Using the work of Scharpf (1997) and Ostrom (2003) we analyse the problems actors face in dealing with this dilemma. The multi-actor context of many planning problems requires on the one hand the interactive (re)construction of the problems and solutions available and on the other hand the establishment of concrete results. This interactive (re)construction is a communicative process in which actors are mobilised around a certain definition of a collective action problem (Fischer and Forester 1993, Healey 2007). Visionary documents aimed at reframing the problem at hand are typically mobilising. However, to reach implementation, actors must agree on clear norms for programming. Reaching agreement about concrete decisions puts actors on the alert and makes them risk averse, while mobilising requires an open risk taking attitude among actors.

This paper asks how actors in practice deal with the dilemma described above. The paper takes the National Project the New Dutch Waterline as a case study. In this project more than 30 actors cooperate to revitalize a 85 km long former military defence structure in order to preserve defence works that are considered cultural heritage and to preserve and develop the quality of the landscape. The project is situated in an area described as an in between city, or Zwischenstadt (Sieverts, 2003), in which the difference between city and countryside has blurred. The involvement of a multitude of actors and the need to develop new problem definitions that suit a previously unknown challenge, in theory provides the ideal typical context for governance (Albrechts 2004).

The tension between mobilising and programming was dealt with by separating the two activities among two different groups of actors and by dealing with them sequentially. As a result mobilising and programming became disconnected.

New Problems in zones in between cities

The once clear distinction between cities and rural areas is becoming increasingly blurred since changing spatial, economic and cultural dynamics have led to new polymorphic urban landscapes and new perceptions of cities and their periphery (Salet 2009, Ascher 1995, Sieverts 2003). Cities and the countryside are increasingly interconnected resulting in highly diffuse urban forms (Salet & Dembski 2011). This new configuration has been conceptualised as Rurban spaces (Gallent et al 2006), Landscape Urbansim (Waldheim 2006), the Zwischenstadt (Sieverts 2003) or the Città Diffusa (Secchi 1997). In the areas in between cities spatial patterns are still changing, leading to new, unpredictable problems. These problems are difficult to deal with because planning authorities deal with various spatial claims in an uncoordinated and insufficient way. This has two consequences: a loss of spatial

[1] Koen Raats, AISSR University of Amsterdam, Nieuwe Prinsengracht 130, 1018 VZ Amsterdam, The Netherlands. (k.a.raats@uva.nl)

quality can be experienced and the identity of rural landscapes is changing. Especially in the Netherlands the concept of '*verrommeling'*, or 'scenic deterioration' is being used in the public debate expressing the loss of spatial quality in rural landscapes. The concept has a strong negative connotation regarding the unwanted, ugly, disjointed and incoherent spatial development in rural landscapes (Gies et al 2005). Another effect is the loss of identity in rural areas: "Traditional landscapes with their ecological and cultural values become highly fragmented and gradually lose their identity" (Antrop 2004). This is problematic because urban dwellers visit the countryside in their search for recreation, authenticity and identity (Albers & Boyer 1997, Mommaas et al 2000). The spatial transition is caused by the shift of urban functions to the rural periphery.

Economic, cultural and agricultural interests clash in the zones in between cities leading to a chaotic patchwork of different urban and rural functions (Van der Valk et al 2007). Policy makers and planners have difficulty to guide the various spatial claims in these areas with respect to three institutional factors. First, the new evolving configuration at the fringes of cities crosses territorial institutional boundaries (Horlings 2010: 9). The transitions in the zones in between cities exceed the traditional separation of rural and urban municipalities. Second, planning doctrines and the organisation of planning authorities are grounded on the establishment of the traditional urban-rural formation (Van den Brink et al. 2006). The sectoral organization within public bodies regularly divides urban and rural policies, leading to separate and poorly linked policy plans for the zones in between cities. Third, within a diffuse field of power relations, it is not always clear who is responsible for the problems (Kreukels 2004) and which actor has to initiate and coordinate planning processes and eventually. This leads to a lack of *capacity to act* (Horlings 2000: 17). These three institutional factors make the organisation of planning in these areas problematic. Eventually, due to unclear rules and norms, spatial intervention takes place next or across traditional planning orders. This gap can be defined as an *institutional void* (Hajer 2003); a state of a policy sector where clear rules, norms, routines or institutionalized practices are absent.

Besides organisational difficulties, actors are confronted with a dynamic spatial configuration that is still evolving which leads to new problems. Planning authorities are still using 'old' frames when they try to tackle these new problems (Van Ostaaijen et al. 2000: 157). The old frames are based on the traditional urban-rural divide, while in the meantime socio-spatial reality shows that the boundaries between rurality and urbanity are fading. Moreover, the reciprocal relationship between public and private actors requires storylines and a communicative practice to reach a shared perception of the problem situation (Van der Stoep & Aarts 2000: 154). The aim of this communicative activity is to *mobilise* actors to change their attitudes towards the other actors (De Vries 2008), and let them reframe their perceptions about the current spatial transition and the associated problems (Healey 1993, Rein & Schön 1996).

The process of activating actors and the development of broadly supported collective frames are considered as *mobilisation*. When mobilisation of actors is pursued, a spatial plan is used as a tool to involve actors in the planning process. Typically, these processes conclude with the determination of a visionary plan. These plans 'create an image of a dynamic future and give meaning to isolated issues, measures and projects' (Van den Broeck 2004: 181). The

DO NOT COPY

process towards the visionary document is most valuable because it reframes and aligns the perceptions of the actors (De Vries 2008). To prevent that actors drop out in the process because their interests are put under pressure, visionary documents are abstract, lack clear interventions and decisions about the distribution of resources. However, to execute spatial intervention, *programming* is required: this includes an agreement amongst actors about the final physical result and the contribution and distribution of resources and responsibilities. In programming processes, negotiations about goals, resources, responsibilities, and implementation take place, which means that the plan is not a tool as in mobilising processes, but the result of a negotiation process (Faludi & Alexander 1988: 132). Although there is a sharp contrast between the characteristics of mobilising and programming processes, both are needed to reach collective action (Van den Broeck 2004, Albrechts 2005).

Especially in the areas in between cities the contradiction between mobilising and programming is prevalent. Mobilisation is difficult because public and private actors are not aware of the dynamics and scale of the new evolving *Zwischenstadt* and its corresponding problems, which actors persistently try solve with traditional frames, strongly based on the separation of 'rurality' and 'urbanity' (Mommaas & Janssen 2008). In addition, innovative ideas in these regions 'come up against a glass ceiling of regulations and procedures, which makes it difficult to set new agendas for the region' (Horlings 2012: 17). Previous research in areas in between cities showed that mobilisation in these areas lead often to '…container plans [with] compromises in which too many things are interwoven,… integration become a goal in itself, obscuring the focus on resolving actual problems' (Mommaas & Janssen 2008: 27). The abstract characteristic of these mobilising plans makes the gap between mobilisation and programming problematic. Additionally, when actors have to negotiate about the final result and its program, they are aware of the risks of using their individual resources to solve a unclearly formulated collective problem. Above all, reaching collective action is difficult because both mobilisation and programming is required but has opposing characteristics. This leads to the following research question: how do actors deal with the dilemma of mobilising and programming in areas in between cities?

To answer this question, first theory about the dilemma will be reviewed, leading to the formulation of the hypothesis. The roots of the dilemma of mobilising and programming will be examined with the comparison of different planning methodologies with contrasting views regarding the function of a spatial plan in decision-making processes. Second, the research design and methodology will be explained. Third, the case of the New Dutch Waterline will be explicated as an example of a landscape in between cities where actors have to deal with the dilemma. Fourth, the research findings will be confronted with the existing theory in the discussion and conclusion.

Theory: The Dilemma between Mobilising and Programming

The question whether a spatial plan should be considered as an agreement about the final result and its implementation or as a tool to reframe and reshape a problem definition is based on presumptions about the function of a spatial plan in plan making processes. The core of this difference is found in the way planning methodologies consider the relationship between planner, spatial plan and the involved actors differently. To reach collective action, actors should on the one hand reframe and align their perceptions of the problem, and on the

DO NOT COPY

other hand reach an agreement about concrete measures (Van de Broeck 2004, Friend 2000). Mobilising and programming activities lead to different type of spatial plans with distinctive characteristics. In this paper the four main differences between mobilising and programming planning activities are elaborated: goal setting, type of agreement, production of options and the mode of interaction between the actors.

The main goal of mobilising planning activities is twofold. On the one hand the actors are reframe their perceptions about the problems at hand and on the other hand they change their opinions towards the other actors (De Vries 2008). When many actors have diverging interests, a shared definition of the problem and a broadly supported direction for solutions increases the capacity to act (Healey et al 2003). This '…sense of direction reflects the tension and interdependence between different values and interests' …which enables new combinations of different objectives (Giezen et al. 2012: 43). Within the communicative practice in planning, mobilising activities can be considered as 'making sense' of the situation together using diverse types of knowledge for joining and defining problems (Forester 1993, Healey 1993). While mobilising activities generate mostly invisible products (Friend & Hickling 1997), the result of programming processes is a clear agreement about a specific solution and the implementation of the project. Agreement about the final result is also important for legitimacy of planning activities and engaging in contracts with construction companies (Rein 1969).

Mobilising and programming activities lead to distinctive types of agreements.

Reframing the perceptions of actors during mobilising activities often results in plan which can be characterised as a 'grey compromise between various interests' (Van den Broeck 2004: 174). Also, Mommaas & Janssen (2008) criticise these plans because even in the case of consensus. These plans do not stimulate institutional innovation that is required to tackle the rather new problems in areas in between cities sufficiently. However, Giezen et al. (2012) state that ambiguity could be strategic, leading to more flexibility to cope with uncertainty. Programming plans consist agreements about the contribution and distribution of resources. Moreover, the links between goals, resources the results and the sharing of costs and benefits are more clearly determined in programming plans. For reaching implementation, the gap between strategic ambiguity and operationalisation should somehow be bridged.

When plans are used for mobilising purposes, divergence of options is desirable. There are three reasons why variety of alternatives is important. First, the redundancy and variety of options makes project more resilient towards unanticipated changes (Giezen et al 2012: 40). Second, the alternative that is eventually chosen is perceived stronger when it is challenged with other alternatives (De Bruijn & Ten Heuvelhof, 2004). Third, a majority of the actors supports the plan making process and feel committed when multiple options remain on the table. The process of producing the alternatives is important because it uncovers the preferences, values, opportunities and interests of the actors. This is important for exploring win-win situations and framing the project in such a way that the plan is broadly supported. Ideally, every actor can propose alternatives, which contribute to the cooperatively defined problem definition. Van den Broeck (2004) states that it is of great importance to connect abstract ideas and concepts to local problems because it strengthens trusts and local support when then plan needs to be implemented. However, in practice it turns out to be difficult to create sufficient space in the process for retention of alternatives (Swyngedouw et al. 2002).

DO NOT COPY

At a certain moment in time, a selection of alternatives has to be made, but what are relevant criteria and when should an alternative be retained?

According to De Bruijn & Ten Heuvelhof (2004), the production of alternatives should be stopped when learning processes come to a standstill. On the one hand, learning processes can come to a standstill cognitively, actors are unable to address new problem definitions, articulate new alternatives and change their patterns of thinking. On the other hand learning processes could end socially, when actors do not engage new relationships or attempt to understand the viewpoints of others anymore. When both learning processes have stopped, convergence of alternatives is of importance to get a step closer to implementation. However, divergence and convergence of alternatives is mainly executed in a messy process switching from the one to the other (De Bruijn & Ten Heuvelhof 2004). In programming plans, convergence of alternatives is important to determine a plan that can be and implemented. Now, the alternatives are compared by the actors, who possibly all have different preferences. Often, actors use different criteria ranging from political, practical to financial norms but have to agree about one specific option. The result is a negotiation where alternatives drop out and finally one 'best' alternative remains (De Bruijn & Ten Heuvelhof 2004). The divergence and convergence within programming and mobilising activities are conducted in arenas where specific *modes of interaction* determine the plan making processes.

Table 1.1: Characteristics of Mobilising and Programming use of Spatial Plans

	Mobilising	*Programming*
Interaction of actors	Discussion	Negotiation
Input and options	Diverging	Converging
Agreement	Direction	Distribution resources and responsibilities / contracts
Goal	Reframe perceptions	Clear agreement for implementation

The above distinction between mobilising and programming plans is strongly connected with the modes of interaction in plan making process. Although the structure wherein mobilising and programming activities are practiced is diverse, the main difference can be found in the interaction between the actors. A profound analysis of the interaction between the actors is important because, although mobilising and programming practises have opposing characteristics, actors have to reach consensus about the execution of both practices to eventually accomplish collective action. From a rational actor point of view, a crucial condition for interaction, collaboration or partnership is that the outcome of the process should lead to potential welfare gains which can be shared amongst the involved actors (Scharpf 1997, Pressman & Wildavsky 1974). The surplus created by the collaboration and the benefits that the individual actor eventually receives, should be larger in comparison with separate and singular behaviour of actors. It is a challenge to find ways to define problems and connect them with solutions which create additional value and can be divided equitably. According to Scharpf (1997), two activities can help in optimising the additional value and reaching agreement about the implementation: joint production and distribution. This

DO NOT COPY

distinction is also known as the process of 'creation and sharing of value' (Lax & Sebernius 1986). Both activities can be linked to mobilisation and programming activities.

Joint production is the activity where actors are jointly interested in pushing the welfare frontier to its limit to pursue a solution that lead to maximisation of the total value (Scharpf 1997). In this process, actors try to find ways to combine their interests in order to establish a plan that create extra value that could be shared amongst the involved actors. Therefore, actors have to discover the interests, preferences, opportunities and threats of others and should be transparent about their own. This process is very explorative because actors have to localise the zones of 'mutual attractions' and the 'zones of conflict' (Scharpf 1997). Innovative processes that reframe the problem situations and create synergetic combinations of resources, can lead to additional value which cannot be reached by the actors on their own. One specific mode of interaction is connected to the process of joint production: problem solving. The central purpose of these activities is the creation of better projects, because the power of problem solving is joint action (Scharpf 1997: 130). Discussions amongst actors are focused on the possible solutions and the best way of achieving it (Elster 1986, Majone 1989). Joint production requires a, communicative practice, where actors are transparent about their goals and interests, and discuss what they like and dislike. The main goal is the harmonisation of the perceptions that contribute to a consensus (De Vries 2008: 857). Therefore, activities of joint production are expected in mobilising plan making processes.

Distribution requires a different mode of interaction because the basic question here is how the created or existing value should be distributed. The distribution question leads to different behaviour of the involved actors. Cooperation to maximise win-win situations is achieved through negotiations about the distribution of costs and benefits. Actors are not focused on the soft side of planning where definition and reframing play, but try to reach hard agreements about the final situation and application of legal and financial instruments (De Vries 2008: 857). In order to reach an agreement, actors can decide that compensation measures are equitable or multiple decisions can be brought together in package deals to level of advantaged to disadvantaged actors. Scharpf (1997) defines distributive bargaining as the mode of interaction where negotiation about the distribution of costs and benefits can lead to an agreement. This leads to behaviour that can be described as strategic, where actors keeping the cards close to the chest, and mark their positions. This distributive behaviour of actors is typical for programming activities in plan making processes.

The activities of production and negotiation are strongly interconnected but the opposing characteristics make it difficult to combine both activities. In academia, there are different views how to treat the dilemma of mobilising and programming. Scharpf (1997) states that "procedural separation of both types of interaction seems to be useful on theoretical grounds" (Scharpf 1997: 135), but notes that this is hard to reach given the interconnectedness and tension between both activities. It is difficult for actors to see both activities separately, because it… 'may facilitate the coexistence of 'arguing' and 'bargaining', which are … incompatible modes of communication and interaction' (Scharpf 1997: 135). The creation of value and the search for win-win situations is only interesting for actors when satisfactory distribution is in some way guaranteed.

DO NOT COPY

Although Scharpf (1997) advocates the separation of mobilising and programming activities, Van den Broeck (2004) and Albrechts (2004) plead for simultaneously executing multiple tracks where the formulation of a long term vision, the arrangement of long and short term actions, and the mobilisation of different actors are at the same time performed. To bridge the gap between long-term visions and implementation, it is suggested that short-term actions are carried out in order to create trust by solving problems on a very short term (Albrechts 2004: 752). In contrast to Scharpf (1997). Albrechts (2004: 753) points out that during the process of developing a long term vision, "credible commitments to action engagement (commitment package) are needed where [different actors]… enter moral, administrative, and financial agreements to realize these actions."

The dilemma between mobilising and programming activities leads to three hypothesis. First, it is expected that mobilisation and programming activities lead to very distinctive types of plans with opposing characteristics. Second, distinctive modes of interaction characterise mobilisation and programming activities, regarding the theoretical differences between the creation and sharing of value. Third, although mobilising and programming activities are either simultaneously or sequentially carried out, the incompatibleness of the modes of interaction will presumably lead to conflicts between the actors.

Research Design, Case Selection and Methodology

A case study is good way to investigate how actors deal with the dilemma of mobilising and programming in an area in between cities. Regarding to Yin (2003: 13) a case study is a proper way to investigate a phenomenon when the boundaries between the phenomenon and the context are not clear-cut. In this paper, the phenomenon is the dilemma between mobilising and programming and in order to investigate this relationship between this dilemma and its context, an in depth case study is appropriate. To examine the dilemma, the case of the New Dutch Waterline is selected because it is a typical example of a project in the highly dynamic zone in between cities. The revitalisation of the cultural heritage in this project, can contribute to the recuperation and maintenance of the identity and quality in the zones in between cities. It is expected that actors will have difficulty to reach collective action because many actors with different backgrounds are involved and the project comprises various sectors within public bodies.

The New Dutch Waterline is a former military defence line located at the eastern fringe of the Dutch Randstad, containing a combination of different interconnected fortresses, bunkers, flooding fields, dams and dikes[2]. The line was built approximately between 1815 and 1963. The defense line was an ingenious concept; the main idea was to defend the rich urban area on the western side of the dike by flooding fields on the eastern side. When there was the threat of attack, military forces were entrenched in their fortresses and bunkers, positioned on strategic places in the flooded landscape in order to defend Holland.

Today, the New Dutch Waterline has lost the military function it once had. In 1995 the landscape was added to the potential shortlist of heritage for the Unesco list of cultural world heritage. In 2002, the management office New Dutch Waterline was founded with as main target the revitalisation of the landscapes and the hidden military structures. The main idea

[2] Map is located at final page of this paper.

DO NOT COPY

was to make the cultural and historical value more visible and exploitable for the public with one coherent plan. Above all, this project should be a collaboration of different sectors within the public sector. The main challenge was to bridge the political complex situation: more than 35 public bodies were involved starting from five ministries, five provinces, more than 25 municipalities and different semi-public agencies.

To investigate this case in depth, three research methods are used. First, archive study is carried out for the period 1985-2011 at the archives of the national project office of the New Dutch Waterline. Especially reports concerning crucial decisions are investigated. Second, 25 in-depth interviews with involved actors are executed. And third, for the period of one year, one researcher was present as an observer at the national project office of the New Dutch Waterline and observed the practices of the employees from an appropriate distance.

The chronicles of the New Dutch Waterline Project

At the beginning of the nineties many study groups were founded within national public bodies. The goal of these study groups was to attune the plans of different policy sectors and to establish coherent and well consistent policy plans. The national project New Dutch Waterline (NDW) starts when three of these study groups' conjunct in 1992-1993. At the national spatial planning agency, the *Rijk Planologische Dienst* (RPD), the interdisciplinary study group *ArMoLA* was founded in order to bridge the policy gap between architecture, landscape and monuments. Employees from the RPD and three ministries (the ministry of housing, spatial planning and the environment, the ministry of culture, education and science and the ministry of landscape, agriculture and fisheries) were attached to this study group and searched for projects that combined architecture, landscape and monuments: they found the NDW. The second study group was "*Project 33*", initiated by the ministry of landscape, agriculture and fisheries. This was an interdisciplinary study group with civil servants of the ministry, scholars and members of interests groups who had the task to find landscapes of great international importance that ought to be protected from "spatial disturbance". Again: this study group found the NDW. The third study group which looked at this project was the study group *Waterline.* This study was appointed by the RPD and did an explorative analysis of potential new functions in the area, carried out by the Research Institute for Forest and Nature and the University of Wageningen,

Eventually, the study of *Waterline* appears to have ended up in the archives. However, the project was brought back to life again when the new national policy plan for cultural heritage was shaped. The new *Belvedere* policy was a breakthrough for cultural heritage because the existing sectoral and conservative policy was grounded on the principles of conservation and was replaced by a new perspective that was based on the famous statement of 'conservation through development'. The main idea was to make the cultural heritage more accessible and pay for the maintenance of the heritage through spatial development and exploitation (Bloemers 2010, Schoorl 2005). This new policy opened doors for the NDW project: it was introduced by ex-members of the study groups and rather rapidly, the project became an example project in the *Belvedere* heritage policy and rapidly a separate (interdisciplinary) team was founded to set up an organisation and to elaborate plans.

The management office of the NDW was founded in 1999. In the beginning, the management office was part of the broader *Belvedere*-program. At the start of the project, the

DO NOT COPY

goal of the project was not clear, neither was there a definition of the exact problem, and neither a strategy existed that should lead to success. Nevertheless, some 'soft' directions were given by the Belvedere program, which was coordinated by the ministry of culture, education and science. The three main important directions were (1) the project should highlight the unity of the defence line, which included that the current developments in the area must be aligned with one coherent plan and (2) inter-sectoral plans (spatial planning, cultural heritage, housing development, infrastructure, water management and nature) should lead to well-attuned plans of high "spatial quality" and (3) the recognisability and acquaintance of the NDW should be stimulated because the military structure was hidden in the Dutch landscape and was rather unknown to the public.

The start of the project could be characterised as chaotic because many activities were carried out without a supportive and clear strategy. This changed after two years when organisation structure was installed with a political advisory board (Steering Committee) and at the operational level a civil project group (Project Group). The Steering Group, composing representatives of the ministries, the provinces, the municipalities and the water management boards, gave the management office the assignment to develop one coherent visionary document for the NDW. The management office followed two tracks to develop this visionary document: two tours through the area were conducted and a competition was organised between landscape architects.

Eventually two tours through the area of the NDW were organised to discuss the project with local politicians, farmers, cultural heritage organizations and citizens. The first tour comprised an open discussion about the *Belvedere* credo "conservation through development" in the NDW area. The main goal of this campaign was to introduce people to the NDW project and create political and local support for the project. The presentations given revived the historical value and contained a storyline which was grounded on historical images, tales about the rich history and discussions about the opportunities of the cultural heritage. For many people, it was the first time that they heard of the NDW and some experienced this as an exciting collective 'exploratory expedition'. Making people aware of the project using a coherent storyline which was based on the rich historical value can clearly be seen as a mobilizing activity because the involved actors cooperatively frame and reframe the direction of the project. However, people reacted differently; although they broadly recognized the rich history and great opportunities of the project, there was scepticism about the development and exploitability of the NDW. Some local and regional politicians said that the project was unrealistic because there was a lack of financial and political guarantees for implementation.

During the first tour through the area, the management office initiated multiple design sessions to create visionary plans for the NDW which were based on four different themes. Four landscape architects translated the themes in four –diverging- visionary proposals. Finally, the Steering Committee choose for the concept of '*Line in the Landscape'*, however, this decision was never discussed with local politicians, citizens or other actors at the local level. However, three feedback moments were important for elaboration of the plan and shaping and reshaping the vision. The first feedback was provided by the directors in the Steering Group, the second feedback was delivered by local residents and politicians in the second tour which was organized by the management office. And finally at the third moment

DO NOT COPY

of feedback, the landscape architects showed how they applied the collected feedback in the final plan. Finally, the concept of *Line in the Landscape'* turned into the visionary document of *Panorama Krayenhoff* which was eventually determined by the Council of Ministers in 2003. This rather open process where many actors had the opportunity to deliver input for the of the visionary document could be seen as characteristic for mobilization processes.

The visionary plan of *'Panorama Krayenhoff'* was based on a four basic design principles. First, the defence line should become the central marker in the plan: the landscape at the eastern side of the line should be kept free from development, regarding the historical open firing and inundation zone. At the western side of the defence line there was opportunity for development in order to generate financial resources to maintain the fortresses and landscapes. Second, the bunkers and fortresses would be recuperated with the financial support of public resources, and the long term maintenance of the building would be paid by the function(s) in or around the buildings. Third, the plans should lead to a recognizable and coherent ensemble, with a proper distribution of recreational, ecological, residential and water management activities. Fourth, concrete programming should be articulated at the regional level and must be compatible with the overarching visionary document.

Obviously, the visionary document lacked clear measures but did set a direction for development. The visionary, abstract characteristic of the plan was a mindful decision of the Steering Committee. The following anecdote emphasizes this: the author of *Panorama Krayenhoff* made some concrete examples of implications but was obliged to keep them out of the final version because it could lead to resistance by local and regional actors. Strikingly the planners were conscious about the mobilising effects of the process and wanted to capture this with the determination of the visionary document. However, although joint problem finding is a characteristic of mobilising plan processes, in the case of the NWD, an exact definition of the problem was never clearly expressed by the initiators. Nevertheless, many actors acknowledged the importance of the project because the project management was convincingly bringing inspiring opportunities to the table. Furthermore, the level of abstraction made it possible for local, regional and national politicians to attach their problems to the project. Nevertheless, collectively defining and redefining the problem of the project is an important characteristic of mobilisation, it was never an issue in the case of the NDW. The starting point of the project management was convincing people of the importance of the project and give people the opportunity to use their imagination add ideas for the existing path that was already chosen. Striking in this process is the central position of the management office, which organized support for the determined direction without discussing the crucial necessity of the project or linking the project to concrete problems of actors at the local level.

When the *Panorama Krayenhoff* was determined in 2003, actors were sceptical about the implementation of the plan because there were no financial or political assurances given by the involved actors. Therefore, the project management decided to tackle this problem with two measures. First, they made a *Bestuursovereenkomst* in 2005, a formal declaration about the management made by the directors of the provinces and ministries. In this declaration actors agreed on the organisation, the distribution of responsibilities, and they articulated the intention to reserve funds for implementation of the project. Although actors determined officially their commitment in this document, there was yet no long term program been

DO NOT COPY

formulated. And second, to deal with the scepticism about the implementation of the plan, "*Quick Wins*" were executed: small projects which were carried out quickly to show the politicians that the process would not persist in phases of bureaucratic consideration. The *Quick Wins* showed the politicians that the project was effective which indirectly contributed the support for the *Bestuursovereenkomst*.

Because the process of mobilisation was finished with the determination of Panorama Krayenhoff it was decided to change de organisation of the project. The NDW was split up in five different "envelopes" and regional civil servants became responsible for the management. With this measure, the regional level obtained a steering position. It was their task to activate the municipalities and develop projects for the NDW in the envelopes. A crucial qualification was that the projects should square with the overarching visionary document. The establishment of the envelopes was a technique of the project management to bridge the gap between the abstract level of the visionary document and the problems at the local level. Eventually, the plans delivered by the municipalities were brought together in one document: the *Uitvoeringsprogramma,* the implementation plan in 2007. The total costs of the project were estimated at 550 million euros.

Hence, the process of programming conducted at the level of the envelopes, where one crucial question dominated the debate between the actors: which actors would pay for the projects and how are the costs and benefits distributed. Essential that the ministries or provinces did not initiate a new financial program for the NDW project, and that funding for the project was generated form already existing programs. In the financial agreement in 2008, provinces and ministries agreed to dispose both 69 million euros which they reserved from already existing spatial, recreational, cultural and infrastructural programs. This meant that for every local project, municipalities and provinces had to apply for steams of money which were controlled by the provinces and ministries.

The phase of programming led interestingly in some envelopes to conflicts between the regional and local level. Some municipalities did not concede the relevance of the NDW project and disliked the guidelines and regulations executed by the national and regional actors. A number of municipalities had opposing preferences and priorities, for instance, one municipality had elaborated plans for a transport district in areas considered open space regarding the visionary document. Or, in the eyes of the Steering Committee, another municipality disrupted the historical value of the NDW with plans for a new residential area. Eventually, implementation of the plan was in some municipalities difficult, because some civil servants operating at the regional level had difficulty activating municipalities and designing plans that met the requirements of the management office and the visionary document.

Discussion

In the case of the NDW mobilising and programming activities are separated and sequentially executed. The management office recognized the importance of aligning the perceptions of actors and started with mobilising activities, creating an overarching visionary plan which was supported by the public and national, regional, and local authorities. A convincing story based on the historical legacy of the project combined with inspiring opportunities was used to mobilise the public. Eventually this process led to the determination

DO NOT COPY

of a visionary plan that could be characterised as abstract, indefinite, and most importantly, lacked an agreement about the distribution of resources. The mobilising effect of this process was of great importance because national and provincial politicians could link the vision directly to their political agendas. Finally this resulted in an agreement amongst the national and provincial politicians to promise a financial effort. Although mobilisation appeared to be successfully carried out because the goal (reframing perceptions) was accomplished, the process of mobilisation was not sufficiently conducted regarding two shortcomings.

First, mobilisation was only partly been realized. The starting point of the mobilisation process was activation of actors and exchanging perceptions about the project and the opportunities. Nevertheless, an important step was neglected; the project started with an already clear track for solutions while the necessity of the project was never questioned. Moreover, the attendants of the discussions did not had the ability to challenge the direction of the project or to connect local problems to the already determined direction.

Second, mobilising activities were strongly attached to the determination of the visionary document resulting in a temporal mobilisation of local and regional actors. The interests and preferences of local actors were absorbed in this visionary document but were of significantly less important for the planners in the subsequent process. Although the visionary plan *Panorama Krayenhoff* was a product of mobilising process, the implementation of the plan was eventually hindered by local resistance. After determination of *Panorama,* the main question was how much the project would cost and how the cost would be distributed (programming). Therefore, the project management was strongly focussed on reaching an agreement amongst politicians which controlled the resources. This led to significant less attention for local actors in the period 2003-2008. The local actors were only mobilised one single time, during the design of *Panorama,* but when after all implementation of the plan was at stake, new local actors and politicians were in charge which were not mobilised at all.

Thus, the local actors were only mobilised one single time instead of constantly. The created support was translated in *Panorama Krayenhoff,* which turned into a static document, a fossil that slowly lost its support. During the programming activities, local actors experienced *Panorama Krayenhoff* as top-down planning tool, forced by actors of the provincial and national level. *Panorama* was based on the political agendas of 2003-2004, but because the visionary document was determined and was never discussed again, subsequent local politicians were not able to modify the visionary plan according to current political agendas. Although the planners thought that mobilising activities were successfully finished with the determination of *Panorama Krayenhoff,* they created their own resistance by isolating the local partners for a reasonable period of time and closing the discussion for the principles which were captured in the visionary document.

Although *Panorama Krayenhoff* mobilised many actor, the step towards programming remained large. With sequential addressing mobilisation and programming for this long term project, both activities became disconnected leading to resistance concerning the implementation of the project. As a result of mobilising activities, difficult decisions regarding financial and political commitment were moved forward leading to scepticism about the implementation and feasibility of the project. To bridge the gap between mobilising and programming activities, the actors conducted two measures. First, short term projects or *Quick Wins* were implemented, to convince the politicians that the project was effective.

DO NOT COPY

Second, at the regional level *envelopes* were installed, which formed the nexus between the abstract national level and the concrete local reality.

Conclusion

In the NDW project a range of different actors were able to reach collective action in the dynamic area in between cities. The long term project started in 1999 and in 20011, 22 % of the programmed projects were implemented and 32 % was under construction. At the beginning of the twenties, the NDW project matched perfectly in the agenda of politicians to improve the quality and identity of space. However, for reaching collective action two important activities had to be applied: mobilisation and programming. Mobilisation was important for activating the many actors involved in this project and aligning their perspectives. Remarkable was that during the mobilisation in 2000-2003, the discussion was never focused on the direction or necessity of the project. The planners did not open the discussion and take a vulnerable position to reflect on the necessity of the project, or organized the debate concerning the direction of the path that was already chosen. In this perspective, "Joint Production" as Scharpf (1997) defines it, was never accomplished. In the NDW case, programming was of main importance to reach an agreement concerning the final implementation and the distribution of costs and benefits. The examination of the NDW case answers three theoretically grounded hypotheses.

First, theoretical background suggests that mobilising and programming activities leads to distinctive types of plans. The empirical study confirms this assumption: *Panorama Krayenhoff* was the result of a mobilising process and can, in line with the theory, be characterized as abstract, visionary, and lacks clear measures and implications (Albrechts 2004, Van den Broeck 2004). The *Uitvoeringsprogramma*, or implementation plan was the result of a programming activity and is way more clear about the final result and includes agreements about the distribution of resources and responsibilities (De Vries 2008). In practice it remains difficult to connect both plans in a proper way and when programming is conducted; the abstract norms in visionary documents can be interpreted differently, which leads to conflicts between actors forming a serious threat for implementation.

Second, mobilising and programming activities are separated and sequentially addressed in the plan making process. This practice is underpinned by Scharpf (1997) who advocates a procedural separation of both types on theoretical grounds (Scharpf 1997: 135). The *Quick Wins*, projects which were implemented quickly in the process to show the effectiveness of the program, would be supported by the theory of Albrechts (2004), who supports a constant leapfrog between mobilising and programming activities. However, although mobilising and programming was quite resolutely separated, the *Quick Wins* turned out to be not sufficient for bridging the gap: eventually the separation caused resistance of local actors. There was significantly less attention for local actors during the period 2003-2007, when there was a gap between mobilising and programming activities. In this way, some local partners saw the NDW as a top down forced project which eventually resulted in resistance and conflicts.

Third, programming and mobilising activities were carried out in a different institutional setting which exposed different modes of interaction amongst the actors. Scharpf (1997) distinguishes the process of 'arguing' and 'bargaining', which can be linked to both

DO NOT COPY

mobilising and programming activities. To mobilise actors, the planners used a strong story, based on the rich history of the project and powerful imaginations of opportunities. Eventually this led to commitment of regional and national politicians who promised financial support. The most conflicts in the NDW case occurred when actors had to talk about the distribution of costs and benefits. Here, as in line with the theory, the actors acted strategically, marked their positions and kept their cards close to their chest.

The case study of the NDW showed that in the area in between cities projects are initiated which aim to improve the quality and identity of space. A multi sectoral project like the NDW is an opportunity to intertwine different interests and translate them in coherent plans for this dynamic region. However, to reach collective action, mobilising and programming activities are required but are difficult to execute because they entail opposing modes of interaction.

THE REGION, THE TOWN AND THE HERITAGE: FUNCTIONAL LINKAGES ON THE PERSPECTIVE OF INDIVIDUALS' SOCIAL PRACTICES[1]

Luciane Aguiar Borges and Marcus Adolphson[2]

Abstract

Improvements in regional transport infrastructure have stretched individual's alternatives in regards to places for living, working, recreating and participating in civic activities. Beyond enlarging labor markets, these improvements have also changed the social character and the spatial configuration of urban milieus affecting as well the urban heritage. This paper investigates the functional linkages between the region, the town and the heritage on the perspective of individuals' social practices. The theoretical approach hinges on two understandings (i) social and physical structures constrain and enable individual and social activities and (ii) individual and social activities are an outcome of various processes based on needs and desires, which are dependent on individual, social and physical prerequisites. Based on this reasoning the paper proposes a model that comprises the region, the town and the heritage. In depth-interviews are the sources to design three personas that belong and represent each one of these social systems. The interviews also describe personas' social practices which are the parameters to assess the functional linkages among the region, the town and the heritage. The model is tested in the empirical context of Mälardalen Region, in Sweden in which Mariefred is the town and Gripsholm castle is the heritage. The results suggest that the model is appropriate to depict the functional linkages between the region, the city and the heritage.

Key-words: regional integration, urban heritage, functional linkages

1. Introduction

Improvements in regional accessibility have changed commuting patterns and cities' demographic and social structures (Champion, 2001). According to urban economic theories one of the consequences is that there will be fewer and larger big cities and they will be further dispersed in space (Krugman, 1996). Thus while some cities will expand other cities will shrink.

The consequences of increasing regional accessibility on the internal dynamic of cities are uneven and at large extend unknown. The enlargement of job markets accessible to the population by means of better transport infrastructure might have negative effects in some cities, whereas others in the same region will benefit from the development. One result of better transport facilities is that competition between

[1] This study was financed by the Swedish National Heritage Board (Riksantikvarieämbetet – RAÄ).
[2] Royal Institute of Technology, Stockholm, Sweden. Division of Urban & Regional Studies. luciane.borges@abe.kth.se and marcus.adolphson@abe.kth.se

different localities most likely will increase, as a greater number of local places will come up for consideration when people and companies choose between possible locations. Improving regional accessibility also magnify individual's alternatives to perform their activities in different places within the region, altering thus, their character and consequently contributing to reproduce and transform the region as a whole and thus the cities which are part of it.

The intra-urban structure of cities is also influenced by improvements in regional accessibility. Taken heritage as one of the components of the intra-urban structure one can argue that the existence of heritage in a town associated with improvements in regional accessibility might influences individuals in regards to place for live. Thus, heritage might lead to urban development since it may attract newcomers. Furthermore, newcomers may imply urban expansion affecting negatively the conservation of heritage. For example, undeveloped urban areas which stand for heritage preservation might be target for development. The dual and conflicting role of heritage as an attractor and restrictor of urban development makes heritage an interesting example to discuss the effects of improvements in regional accessibility on cities' intra-urban structure.

In this sense this study deals with three different scales: regional, urban and intra-urban and focus on the functional linkages among them. Previous studies (e.g. Taylor, 2004) have dealt with urban networks in terms of volume of contacts between cities based on number of work places within firms. Others based on system theory have created linkages between urban sub systems based on flows of people, goods etc. Nevertheless, none of them have approached functional linkages based on social and system theories and on individuals' social practices anchored in structuration theory. We argue that the functional linkages between the region, the town and the heritage are product of how individuals stretch their territorial boundaries through their practices.

Therefore, this paper aims at increase understanding about the functional linkages between the region, the town and the heritage. Knowledge about these interdependences will enable estimate effects of planning initiatives in regional, local and heritage management and identify spillovers that procedures adopted in one level may have on the others. Thus, relying on social theories we design a model that assists to map the functional linkages between these social systems. Individual action is the parameter to measure these linkages. Thereby, this research contributes in improving the effectiveness in planning and heritage management.

Mälardalen region in Sweden, Mariefred town and Gripsholm castle are the empirical cases to test our assumptions. Mariefred and the nearby Gripsholm castle are of medieval origin and are today – due to transport investments in 1997 – spatially incorporated within the Stockholm labor market. Still, due to lack of knowledge regarding these interdependencies effects on the Gripsholm castle and in Mariefred from these investments are rather unknown.

In order to depict these interdependencies in-depth interviews with three individuals (the regional citizen, the local citizen and the heritage representative) are the sources to measure the functional linkages among the region, the city and the heritage. The actions performed by these individuals are what establish the functional linkages among the systems.

Following this introduction the paper is arranged in five sections. Next section presents the Mälardalen Region, Mariefred and Gripsholm Castle. Section three describes, the main theoretical standpoints used to build up the model which is explained and discussed in section four. Afterwards we present and discuss empirical evidences about the functional linkages between these social systems. Finally, section six outlines some implications for planning and also pinpoints some limitations and further developments of the study.

2. Background

2.1. Mälardalen Region

The Mälardalen Region is constituted by five counties: Stockholm, Uppsala, Örebro, Södermanland and Västmanland (see Figures 1 and 2). The biggest county is Stockholm with 26 municipalities and population of almost 2 million inhabitants. In functional terms the region is considered as the largest one in Sweden with regard to population and economic competitiveness. There are tendencies that the Stockholm County polarizes the development.

The region is surrounded by railway and motorway networks that link several municipalities within the five counties (see Figure 2). In 1997 the implementation of high speed trains (Svealands line) made possible a journey of 115 km in just one hour. One effect of these investments was the enlargement of local labour markets and population growth in the neighbouring areas. This was a consequence of increased accessibility and supporting daily commuting which has balanced the housing and labor markets. Figure 3 shows the number of local labor markets from 1970 to 2008.

Figure 1: Swedish counties

Figure 2: The railway system in the Mälardalen Region

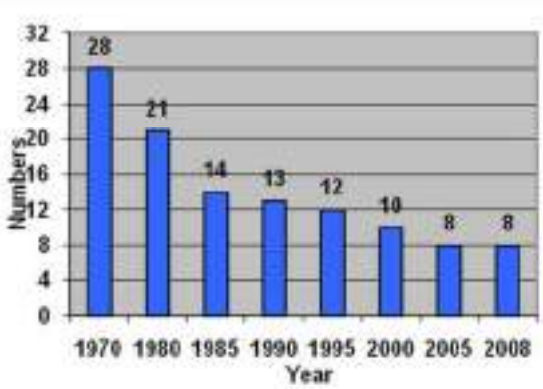

Figure 3: Local labour markets in the Mälardalen Region.

As can be seen from Figure 3 there were a quite significant number of labor markets in the region during the first 15 years from 1970. From 1985 and the following years the process of integration of labor markets decrease in general. However, the labor markets have become larger in size as a consequence of the increased commuting.

Previous studies (Copus et al, 2006; Johansson, 2009) show that even if 'regional enlargement' has increased as a function of the increased commuting, peripheral municipalities have lost in population size. On the other hand, municipalities around Lake Mälaren have experienced a favorable development during this period comparing with 1970s. The Figure 4 shows a schematic typology of the population development in Mälardalen Region 1973-1977 and 2003-2007 (Johansson, 2009). The color scale ranges from red that means a positive population development (positive net migration and positive natural population) to dark blue which depicts a negative population development.

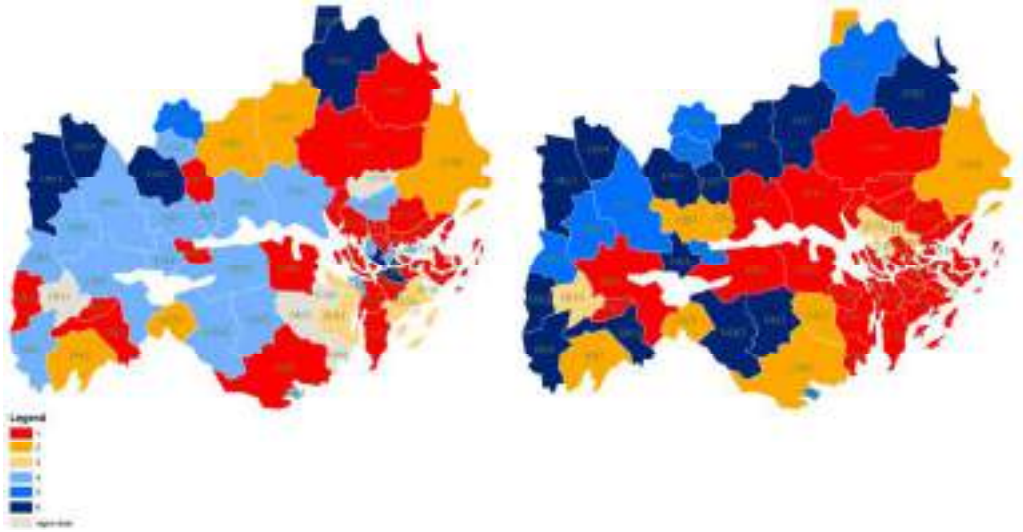

Figure 4: Typology of the population development in Mälardalen Region
Source: Copus et al, 2006; Johansson, 2009.

2.2.The context: Mariefred, Strängnäs

Strängnäs is one of the municipalities in Södermanland County and Mariefred is one of the eight towns that belong to Strängnäs. The municipality has experienced the effects of being connected through an efficient transport infrastructure. Approximately 14% of Strängnäs' population commutes in daily basis, most of them travelling to another county (SCB, 2010).

Between 1990 and 2009 Mariefred population has increased 33%. Mariefred is located 68.5 kilometers from Stockholm. Since 1997 with the implementation of high speed trains (Svealands line) the town has been seen as an attractive place for living. The Svealands line enables a trip between Läggesta (Mariefred' train station) to Central Stockholm in only 33 minutes. This fact reflects in Mariefred's commuting patterns; more than 20% of the population commutes in a daily basis: 38.9% of them to Södertälje, 25.3% to Stockholm and 13.4% to Strängnäs (SCB, 2006).

Changes in the social and demographic structure of Mariefred's population have urged urban development. There is an increasing demand on urban services such as schools, daycares, etc. as well as new residential areas. Figure 5 show Mariefred'

urban structure and the existing built environments (grey) and those which are under investigation for future developments (dash grey colour).

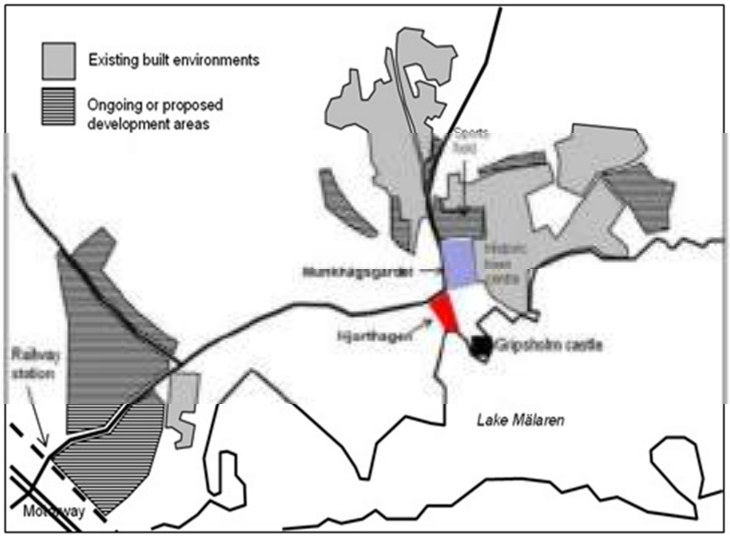

Figure 5: Mariefred and the region

Figure 5 shows that the area close to the railway station (Läggesta) is expected to expand considerably in the future. Nevertheless, the most sensitive areas for development are those close to Mariefred historic town centre where there has been a great pressure for relocation of communal activities to develop residential areas.

2.3.The object: Gripsholm castle

Gripsholm castle is one of Sweden's royal palaces. It was built as a fortress by Bo Jonsson Grip in 1380. In 1526 the King Gustav Vasa confiscated the fortress, tore it down and built a fortified castle as it stands today. Since then Gripsholm has belonged to the Swedish Royal Family and was used as their residence until 1713. The castle is now a museum and home to the Swedish national portrait collection.

The relations of production and consumption in the castle have changed along the history. The castle has functioned as fortress, residence, prison, and as museum. It means that different demands had to be fulfilled to enable these activities to take place. For example, when the castle was residence of the Swedish Royal family possibly few resources were enough to supply royal family's needs but when it became a prison there were also soldiers and prisoners who had another demands and so on. These changes in activities associated with technological changes (e.g. introduction of motorized vehicles, modernization of Svealands line) have changed the functional linkages between Gripsholmen, Mariefred and Mälardalen Region.

The castle underwent to rebuilding and redevelopment in several stages that has changed its built form and its surroundings. Nevertheless, some of them still remain the same. Figure 6 shows Gripsholm castle and its surroundings.

Figure 6: Gripsholm Castle

3. Theoretical framework

The understanding of the functional linkages between the region, the town and the heritage is theory/discourse dependent. In this paper we use basic components from system planning theory (McLoughlin, 1969) and Giddens structuration theory (1984) as the theoretical basis to design the model.

System theory contributes with a framework that explains how the region, the town and the heritage are functionally interlinked. Mariefred and Gripsholm castle are here regarded as social system that are affected by the surrounding – the region. The affect from these social systems on the region is not of concern here. Due to the need and desire for consumption and production there is a flow of goods, people, money, etc. between the surrounding and the social systems. A change in one component will imply a change in all other parts

The structuration theory contributes with a conceptual framework that integrate the individual in 'social systems' how individuals reproduce these 'social systems' (the Mariefred and the Gripsholm castle), the linkages among them and how knowledge about the society is connected to actions. A simple example of a social system could be a supermarket. Individuals go to the supermarket and buy goods, and by doing that they reproduce the supermarket every day. Therefore the supermarket is also a resource for other people, ultimately the supermarket exists because people go there and buy goods. Nevertheless, to go to the supermarket and reproduce it the individual needs to have knowledge that the supermarket exists. Thus knowledge and motivation are essential for individuals' actions, which is what reproduce and transform the social systems and the linkages among them. Hence, the structuration theory provides a framework for incorporating the individual in a social and physical context. This concept can be extended to a region, a town or a heritage.

3.1.Functional linkages

In this study a functional linkage is related to individuals' actions to supply their demands in the surrounding (region) and in the social systems (the city and the heritage).

System theory acknowledges that the town comprises a number of constituents or parts: residential areas, industrial areas, etc. Each part could also be regarded as a system. They are interconnected and interdependent since change in one part influences the other parts, affecting the entire urban system (McLoughlin, 1969). The system perspective thus provides a dynamic functional approach on the heritage, the town and the region. This approach also makes possible to integrate the heritage in the town and in the region as one of the urban component among others.

Structuration theory (Giddens, 1984) is used to understand each part – each system – and their interdependence. The theory brings in the knowledgeable reflexive individual who – by his/her activities – contributes in reproducing the society. This theory acknowledges the ongoing reproduction of the town. By performing activities individuals' reproduce their homes, work place, the food store – and the town. Thus the individual by his/her actions also reproduces resources for other people. These resources is by Giddens divided into three external 'constraints': material, regulations and institutions (patterns of activities). For instance, the possibility for an individual to perform an activity depends on the material shape of her/his home, her/his town, if roads are available, etc. Further on, also laws and rules regulates the opportunities for activities, and last the individual is also dependent on others peoples activities in maintaining for instance a shop. The individual uses memories of these external constraints as a resource in his/her internal action generating process. Other influencing factors are the individual motivations and consciousness. Examples of these kinds of resources are work places, shops, supermarket (see example below) etc. For a more detailed description see Giddens (1984) and Ritzer (2008)

In this paper the town (Mariefred) and the heritage (Gripsholm castle) are regarded as interlinked social systems that are continuously reproduced by individuals. The region (Mälardalen) is – according to the system planning terminology – regarded as the surroundings. These social systems are understood to be constituted by material, regulations and activity patterns. When people perform activities they use their knowledge – stored as internal memories – about these social systems in the action generating process.

4. Methodology

4.1.The model

The model enables to analyze the relations among the surroundings (region) and two social systems (town and heritage).The main objective of the model is to describe,

from a social perspective, the functional linkages among them in order to provide some insights about how planning at different levels affects and is affected by the other levels.

The region provides a framework that contributes to shape the town and their objects components (e.g. the heritage), physically and socially, and, at the same time, the physical and social character of the towns build-up and constitute the region. The region is understood in morphological and relational sense. In a morphological sense a region is constituted of towns which are linked by efficient transport infrastructure, that enhance regional integration. The relational aspect stands for the (functional linkages) that the physical morphology enables. An example is the circulation of flows of people, money, information, goods, etc. which is enabled by regions' physical structure and also by cooperation between individuals and/or organisations.

The towns, besides being part of the region they are the environment that contains the objects (any built form). Thus, the town is the urban settlements which contains a form and enable/constrain individuals' action. The town is a system in itself that provides the necessary resources for the reproduction of each urban object. According to system theory changes in the town also imply changes in the urban objects and vice versa. What determine the level of dependence between the town and the object (urban heritage) are their linkages, which are depicted through individuals' social practices.

The town is understood as association of two basic components: (i) the morphological, which refers to the material part (buildings, streets, open spaces, etc) and (ii) the relational, that refers to the activities, not only those embraced by buildings (residential, commercial, leisure, industrial) but also those that take place in public spaces (meetings, leisure, etc.). While the morphological part is more permanent in time, i. e., it might take a long period to change the relational component is more ephemeral and fluid because changes depending on immediate individuals' action.

In this study the heritage stands as an urban object. Nevertheless, urban objects could also be a sport field, a food store, a house, etc. They are reproduced in time and space by individual activities, and consequently they are also resources for other people (Giddens, 1984). According to system theory the urban objects are perceived to interact with each other through individuals' action which reproduce and transform them in time and space. The town is seen as the interaction among different objects. It is not our intention disregard the on-going discussion about what heritage is, but this issue is not the focus of our paper. Nevertheless, the heritage is assumed as a build-up form recognized by authorities as such. It is urban because it is an interactive part of an urban structure; it changes functionally and is dependent on appropriation by individuals. It is heritage because it is associated with knowledge, culture and identity.

The model acknowledges the individual as a key actor as she/he by her/his daily activities, of different spatial stretches and duration reproduce the social system. So the individual is the agent who, through her/his action is able to assess the functional linkages between the social systems. The individual is reflexive (has a free will) although she/he is constrained by external resources.

The functional linkages are assessed by three individuals that belong and represent each social system: the region, the town and the heritage. Their actions and the resources that they need to perform their daily activities (professional and private) describe the functional linkages between the social systems. These individuals are designed as personas. This technique is further explored in the following item. Figure 7 illustrates the model.

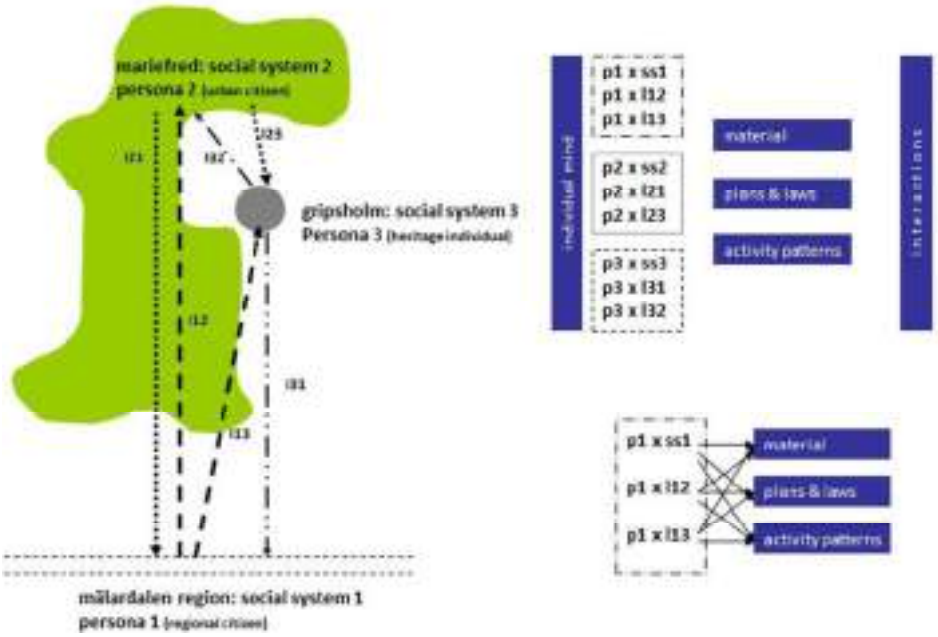

Figure 7: Model of interactions between social systems

Figure 7 shows the social systems (ss) and the lines represent the different linkages between them (l12, l13, etc.). In each social system there is a persona (p1, p2 and p3) who belongs, represents and assesses the linkages between this social system and the others through her/his professional and private social practices. For example, persona 1 (p1) is located and represents the region (ss1) since she/he perceives the region as a resource for her/his own actions. Therefore, this persona, by describing her/his actions, needs and knowledge indicates the interactions between the region and the other social systems: the town (l12) and the heritage (l13). This procedure enables to draw a functional map of interdependences between the region, the town and the heritage on the perspective of individuals.

4.2.Techniques

In depth interviews was the main resource to design the personas and to describe the functional linkages between the social systems.

Persona is a technique that was initially used for software design (e.g. Haikara, 2007). Nevertheless, its use has extended to other fields, such as travel behavior (Henriksson & Räsänen, 2010), consumers preferences (Palmgren & Zapico, 2008). These studies used personas as a means to describe patterns of behaviors and individuals' needs. The technique consists of a precise description of a user´s characteristics and what she/he wants and needs to accomplish a given task (Cooper & Reimann, 2003). A persona can be designed based on a single interview or can be a 'collage' of perspectives of many interviews, depending on the objectives of the designer in the process.

Since we focus on the region, the town and the heritage as a resource for individual's action we believe that personas technique provides a reasonable way to depict the functional linkages among them. Personas' concept is very much associated with products and services so it is our perspective about the region, the town and the heritage.

Therefore, based on in depth interviews with three individuals we designed three personas that belong and represent the surrounding and the social systems: the region, the town and the heritage. It is assumed that she/he belongs to the social system because she/he take from this social system most of resources that she/he needs for act. She/he represents the social system because she/he by acting establishes functional linkages with the other social systems. For example, an individual who works in another place in the region but lives in Mariefred is an individual who belongs to the region. Ultimately it is in the region that this individual takes her/his main resources to perform her/his activities. This individual represent the region by establishing, through her/his actions, connections with other social systems to supply her/his demands, which are not satisfied in the region. Therefore, she/he through his/her social practices is able to map the functional linkages between the different social systems.

The selection of the individuals followed some criteria: (i) their belonging to the surrounding and social systems should be explicit; and (ii) they should have a position in respective system where they have a comprehensive overview of the activities that take place in the system and the flows in both direction that link the systems with the other system.

Giddens' theory (1984) was the starting point to design the interviews, which covered questions about the individuals' mind and also about the material resources (built environment), sanctions (plans and & laws) and structural (patterns of activity). While information about the individual mind aided to design the personas, the other data helped to define the functional linkages between the social systems. In the

individual mind knowledge about normative rules, authorative and allocative resources are stored as memories. Allocative resources are the internal 'picture' of the external resources. The knowledge is also connected to degrees of consciousness. Thus is where action generating process – connected to motivations, and reflexion monitoring about actions – take place (see Giddens, 1984)

4.3.The personas

Based on Giddens (1984) and in three interviews we designed three personas: (i) Persona 1: the regional citizen. He lives and works in different cities within the region. (ii) Persona 2: the local citizen. He is manager of a hotel/restaurant in Mariefred and (iii) Persona 3: the heritage representative. He is Gripsholm's castle manager.

The regional citizen: Matts is 54 years old. He is married and has two teen ager daughters. He is from Uppsala (town close to Stockholm) but moved to Mariefred in 1989. He commutes every week day to Stockholm where he works as chemical engineering. He works irregular hours so when it is possible he takes the train to work otherwise he drives. Mariefred's' historical landscape, aesthetic characteristics and the cosy and nice atmosphere were the main motivations for him and his wife to move to Mariefred. Matts is engaged in local political processes. He is interested in the future development of Mariefred.

The urban citizen: Daniel is in his late 20's and is single. After spending some years abroad he came back to live in Stallarholmen (a small town close to Mariefred) where he was born. He was working as manager in a hotel in Strängnäs but since June 2010 he has been working as a manager in hotel and restaurant in Mariefred. He travels everyday by car to his work. He barely travels by train. He enjoys living in Stallarholmen because his family and friends live there and because it is close to the nature. He recognizes the importance to preserve Mariefred as a historical site and its importance for the success of his business.

The heritage representative: Lars is 66 years old. He comes from Vaxholm (small town close to Stockholm) but he moved to Mariefred five years ago to work as governor of Gripsholm Castle. He and his wife live in a building close to the castle. He travels by car to Stockholm for professional purposes twice a month. He is a member of Folklore society and participates in other social activities such as discussions about Mariefred development. Lars enjoys living in Mariefred because it is similar to Vaxholm and the community is very friendly. He acknowledges that the origin of Mariefred is connected to the development of the castle.

5. Analysis

Following the theoretical reasoning the analysis was divided into two themes: knowledge about what the personas know about the functional linkages and the functional linkages.

5.1.Knowledge

The theoretical framework already highlighted the importance of knowledge in order to reproduce the social systems and the surrounding. Based on the interviews we present personas' knowledge in regards to the functional linkages between the social systems and the surrounding.

The regional citizen, Mats, is aware about the dependencies between the museum in the castle and Mariefred. His main motivation to move to Mariefred was the landscape's aesthetic values. However, he has limited knowledge about the historical relation between the castle and Mariefred. He is concerned with the development of Mariefred but has mixed feelings about development/preservation. At the same time that he believes that Mariefred should grow to offer opportunities to newcomers he is also concerned with the effects of the development on the urban heritage. Mats argues that Mariefred's' historical core must be preserved but the town should expand in the periphery. In his opinion Mariefred could host activities such as advertisement, computers, and distribution hub due to its location close to highway. Nevertheless, big industries are not welcome in the town because they would compromise the town's characteristics.

Daniel, the restaurant manager is also responsive to the dependences between the museum in the castle and Mariefred. He recognizes that the restaurant and hotel would not be economically viable if the castle would not exist. Therefore, he stands for urban heritage's preservation and acknowledges the role of the landscape's historical and aesthetic characteristics as influential for the success of his business. Daniel believes that Mariefred should maintain its character of small and cosy place. In his opinion there is no place for activities such as night clubs or big shops in the town.

Lars, the castle manager, is aware about the dependencies between the museum in the castle and Mariefred. He acknowledges that Mariefred is highly dependent on the castle and vice versa but not in the same extend. He stresses that the historical process of urban formation of Mariefred was a consequence of the functional demands of Gripsholm Castle (employees, services, resources). In his opinion the improvement in regional accessibility has not influenced the number of visitors in the museum and in the castle.

5.2.Functional linkages

As stated before interviews were the source to map the functional linkages between the three subsystems. Information about which kind of resources the personas needed to perform their daily activities were classified into two categories: professional and private. Professional activities hold specialized and non-specialized services and employees, goods and customers. Private activities were classified in civic activities (participation in social organizations such as religious, political, etc.), leisure, shop of groceries (daily stuff) and more specialized goods (clothes, shoes, books, furniture,

etc.). The graph below (Figure 10) was used to plot the personas spatial footprints. It distinguishes between four different spatial levels (local, regional, national and international) enabling a visualization and comparison of the results. Even though the paper deals with the functional linkages among the region, the town and the heritage, the interviews showed that some individuals also need resources from the national and international level. Table 1 summarizes personas' spatial footprints.

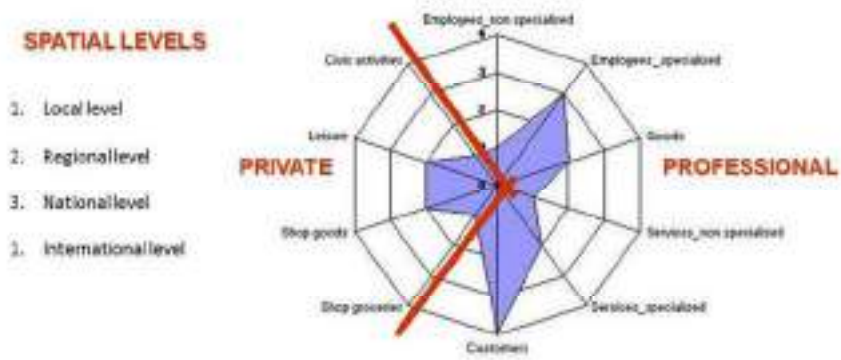

Figure 10: Personas' footprint

Table 1: Personas' spatial footprints

CHART	PRIVATE	PROFESSIONAL
	• ranges between local level (civic activities & basic goods) and regional level (leisure & specialized goods)	• Not applicable. Matts' job locates in the region thus the spatial reference of resources' provision changes in relation to Lars and Daniels' professional activities.
	• shopping (specialized and non-specialized) at local level • not engaged in any civic activity • leisure at regional level	• National customers but also few international • specialized goods and non-specialized employees at local level • non- specialized goods at regional level • specialized employees at national level

	• ranges between local level (civic activities & basic goods) and regional level (leisure & specialized goods)	• visitors from international level • specialized employees at national level • specialized services and goods at regional level • non-specialized services & employees at local level

In regards to private footprints, Lars and Matts present a similar pattern. Both of them participate in civic activities and shop groceries in Mariefred but their boundaries stretch to the regional level concerning to leisure activities and shop of goods. On the other hand Daniel is not engaged in civic activities, he shops groceries locally and specialized goods on the Internet, and therefore the spatial level was disregarded. Like Lars and Mats Daniel also performs leisure activities at the regional level.

Lars and Daniel professional footprints are almost the same, excepting for their customers that in the case of Gripsholm castle are significantly from the international level while for restaurant in Mariefred are from the regional/national level. The results also show that specialized employees such as guides for the castle and chefs for the restaurant usually come from the national level. Daniel also mentioned that the restaurant uses local products such as homemade beers and vodka but the regional level supplies the restaurant with most of the resources for food.

5.3.Results & discussion

This section summarizes the information about knowledge and functional linkages on the perspective of the personas. Table 2 provides an overview about the type of resources the personas need to perform their activities and from where they come from (region, city and heritage).

Table 2: Personas and resources for action

Persona	***Region***	***City***	***Heritage***
Matts	- work - specialised goods - leisure	- non-specialized goods - non-specialized services - civic activities - leisure	- nothing
Daniel	- leisure - non specialised goods - specialised employees	- work - leisure	- nothing
Lars	- wages - specialized services - financial resources for management	- non-specialized services - non-specialized employees - non specialised goods	- work

	- specialized employees - guidance for his work	- civic activities	

Based on the interviews Table 3 compiles the information about the functional linkages described by the model (see Figure 7). When analyzing the linkages between the region (R), the town (T) and the heritage (H) the activities/resources selected were those which fit to answer the question: what does this system provides to another? The grey color indicates that there is a linkage.

Table 3: Functional linkages

Types	***Services***		***Goods***		***Employees***		***Costumers***	***Leisure***	***Money***		***Regulations***	***No links***
Links	***s***	***n-s***	***s***	***n-s***	***s***	***n-s***			***w***	***p***		
R-T												7
T-R												4
R-H												5
H-R												2
T-H												3
H-T												4

(s) specialized; (n-s) non-specialized; (w) wages; (p) payments.

The Table 3 shows that the region is quite influential for both the town and the heritage. The strongest linkage (R-T) shows that Mälardalen complement Mariefred in regards to services, goods, employees, etc. The region also plays an important role for the heritage. It affords services, employees, customers, regulations and financial resources for management. On the other hand the weakest linkage is between the heritage and the region. The heritage provides leisure opportunities to the region and some financial resources from the museum entrance fee.

6. Discussion

The model provides a systematic way to depict the linkages between the region, the town and the heritage and shows in which way they are interconnected. In regards to planning at different scales some estimation can be pinpointed.

The interviews showed that the modernisation of Svealands line in Mälardalen region did not strengthen Gripsholm castle as social system. Even though most of visitors come from the regional/international level their visit do not depend on the capacity in the railway system. Nevertheless, Svealands line strengthens Mariefred as social system, because it attracts newcomers. Attracting newcomers implies a need for urban development, which might threat heritage as spaces close to the castle may

come up as alternative areas for urban expansion. The understanding of these implications it is beneficial for planning.

From the heritage management perspective it is worth to mention that the introduction of entrance fees to visit the museum in Gripsholm castle in 2007 caused a drop of 30 000 visitors/year. Certainly it influenced Mariefred's' local economy. This fact reveals the strong interdependence between Mariefred and Gripsholm castle and also suggests that both local planning and heritage management should coordinate their actions through cooperation. Evidences from the interviews also indicated that the castle is one of the main aspects that influence newcomers to move to Mariefred. It reinforces the dependences between Mariefred and the castle.

7. Final considerations

The paper presents a new approach to disclose the interdependences between the region, the city and the heritage. This approach considers system and social theories as the basis to envisage the interrelations between different planning scales; therefore it enables to estimate consequences of changes contributing for planning practice.

However, the study presents some limitations. A larger number of interviews would enrich the personas profile, aiding to deepen the analysis. Still, the model needs further development. The consideration of volume and intensity of flows certainly would provide a more accurately measure of the functional linkages between the surrounding and the social systems.

From heritage management and planning perspectives, the use of heritage as one of the social systems disclosed how social and system theoretical approaches could deepen the knowledge of how heritage is integrated in urban and regional contexts..

Abstract

Any attempt to use heritage in the pursuit of place planning and development objectives is bedevilled by terminological and conceptual confusion. This stems largely from the way thinking about the past in the present evolved and the resulting contribution of many different academic disciplines to the creation and application of heritage, resulting in a plurality of paradigms and quite different, even contradictory attitudes to the past and its contemporary uses. This creates a lack of understanding or dialogue between those involved and drastically reduces the instrumental effectiveness of heritage in place development and planning. This paper will explore the confusion in terminology and the concepts behind it and argue for a common, less ambiguous and logically underpinned language. The heritage phenomenon itself should not be viewed as object, artefact or site but as process, outcome and experience. As a contemporary creation in the service of current needs, the spurious dichotomies of natural /cultural and tangible / intangible are a meaningless distraction. As heritage is produced by the user of it, its values are extrinsically ascribed rather than intrinsically authenticated and thus authenticity can relate only to the contemporary consumer experience not the contributory historical resources. However this also implies that heritage is multi-used and multi-consumed, which renders its management a necessity. The role of the preservation, conservation and heritage paradigms in development will be explored and the contradictions inherent in the first two will be resolved in the third. Heritage plays many potential but quite different roles in development, including as a commodifiable resource for products and services, an enhancer of environmental amenity, a catalyst in local area regeneration and revitalisation and contributor to place image or brand. The characteristics of heritage, so defined, as a ubiquitous, flexible, and inexhaustible development instrument thus render it ideal for place management but until we resolve these terminological and conceptual issues its potential will remain largely unrealised.

keywords: heritage, paradigm, terminology

'Words are like leaves; and where they most abound,
Much fruit of sense beneath is rarely found'
(Alexander Pope, *Essay on Criticism* 309)

Pasts, presents and futures

Heritage is a process and an outcome. It is a process whereby objects, events, sites, performances and personalities, derived from the past through relict structures, memories and histories, are transformed into experiences in and for the present, with an intention of bequeathing these to a future. It is an outcome in which the present evokes imagined pasts and imagined futures in fulfillment of contemporary political, social, economic and psychological needs. The problem is that those engaged in this process and involved in managing these outcomes have varied, different and even contradictory intellectual backgrounds, approaches, motives, working methods, ethos and responsibilities. These differences are manifest in the paradigms, concepts and terminology used. The result is not just cacophony; it is a counter-productive, often fractious, misunderstanding and loss of opportunity. If the enormous, flexible, multifaceted contribution of heritage, not least to the planning and management of environments, is to be realized then at its most basic level we must begin by using the same language.

Historical paradigms

Three main paradigms have been, and are still being, applied to aspects of the relict past in the present. Each evolved its own focus, obsessions, justifications, and modes of expression not least in language (Ashworth, 1997; 2011).

The language of preservation: the absolutist paradigm.
Assigning value to the past, and even the wish to sustain elements or qualities derived from it into the present and bequeath these to a future, has a very long history and may arguably (such as by Tuan 1977) be an inherent human trait. However the idea of preserving obsolete forms for their own sake, when the functional requirements that produced them no longer exist, is much more recent. Almost every Gothic cathedral in Europe was built on the demolished ruins of its predecessor. The European cultural renaissance of the fifteenth and sixteenth centuries may have rediscovered and revalued the ideas of the classical world but was simultaneously using the surviving classical monuments as just a quarry of building materials (Larkham 1996). What Lowenthal (1996) has called the heritage "crusade" begun in the middle of the nineteenth century and has often been linked to three long-term, inter-related trends in the cultural, economic, and political spheres of Western European and North American societies. It would need a lengthy historic study (such as attempted by Lowenthal 1985 and Denslagen 1994; 2009) to trace why this radical change in thinking occurred and why it became so deeply entrenched as to become for many today effectively an unchallenged self-evident truth. However suffice it to note that the rapid economic and concomitant social changes, which are

encapsulated in the term the 'industrial revolution', accelerated the replacement of many centuries of urban evolution by new forms, spatial patterns and ways of life that in reaction fuelled a romanticism, powered by nostalgia, etymologically pain for what has been lost. This became intertwined with the rise of nationalism, an ideology necessitating the creation and propagation of the entity 'nation'. This imagined entity is bound together and separated from others, by the bonds of a collectively memorialized past, within which built environments played a major role through their very visibility and thus the raucousness of their message.

This radical change in the way historic built environments were viewed, was pioneered by crusading prophets with a near messianic fervor, focused determination and impatient dogmatism such as among others John Ruskin, Augustus Pugin, William Morris, George Gilbert Scott in England, Victor Hugo and Eugene Viollet-le-Duc, in France and Victor de Stuers and Pierre Cuypers in the Netherlands. All shared a fundamentalism based upon an unshakeable belief in their righteousness, a feeling of being alone against an indifferent or hostile majority and impatience with counter argument. All combined in the single simple message to save what can be saved before it is too late. The paradigm is a clear, obvious and unchallenged imperative expressed in the word 'save'. The main unquestioned assumption is that the past is real, it actually existed, and it can be preserved through its sites, monuments, memories and historical narratives for the present and bequeathed intact to the future. The sharp and continuing schism among preservationists revolves around the application of the action 'save'. Some, notably Ruskin (1849) would save 'as found' after time and circumstance had impacted upon the relic, others, notably Viollet-le-Duc (1858 /1872) would not only save but also 're-establish a building in its finished state, which may in fact never have existed'. The word renovation was the dividing shibboleth.

Preservation appears to be a straightforward and uncomplicated idea associated with an equally simple action, saving. It is a protective intervention to maintain the current condition of an artefact, building or ensemble. It is notable that the word 'use' has not entered into the discussion except as a potential enemy of preservation. The objective is just to continue to exist with the idea of bequest so that such existence should continue also for future generations.

The language of conservation: the planning paradigm

The seeming success of the preservationists, expressed by their obtaining effective, comprehensive, official protective legislation and a consensus of popular support at least in Western countries by the 1960s, led to an extension and modification of the preservation ideas, which became manifest in official policy documents and ultimately very similar legislation in, for example, The Netherlands (1961), France (1962) Britain (1967) and Italy (1970) (Burtenshaw et al. 1991; Ashworth & Tunbridge 1990). The focus shifted to include not only individual buildings (the 'monument') but also ensembles (the 'historic or 'heritage' district). This in turn compelled a wider approach, if only because a single building could perhaps be treated as an art object in itself regardless of its contemporary use but a whole urban historic district could not. Function had to be added to form which inevitably

involved the planners and managers of place functions and thus what had been largely the preserve of architects and art historians now became linked to policy objectives, wider than the building or site itself, which became an element in more extensive schemes of local area renovation, revitalization, renewal and regeneration. Larkham's book (1996), entitled *Conservation and the City*, which is structured by local area policy objectives rather than the historic characteristics of the buildings and areas in which they are applied, chronicled these changes in the United Kingdom. The phrase "adaptive reuse" became a mantra in planning departments of local authorities throughout Western Europe and North America (Tiesdell, et al. 1996). The critical difference between preservation and conservation however was not so much in the actions themselves as in the methods, attitudes and goals of those who were performing them.

The term conservation, used in this way rather than as used in museums as a synonym for preservation, was evolved and applied largely by place planners and managers in the context of the built environment and to them was best expressed in the phrase "preserving purposefully" (Burke 1976) where the decision to save is linked with the intention to use. The increasing involvement of politicians and government officials in a field previously the almost exclusive preserve of experts, usually architects, is related for the United Kingdom by Delafons (1997).

The language of heritage: the phenomenological paradigm

In many respects, heritage has evolved as a process of managing the consequences of the very success of previous paradigms and the heritage paradigm could be seen as a continuation of the shift in focus from object to process and outcome. Structures, sites and places are seen as vehicles for the transmission of historicity, contributing to many contemporary social, political and economic needs. It is the fashioning of some representation, a key word, of a past in the present from selected relics, memories and histories. The purpose is thus not to save anything from the past but to use the past in the present: the use determines and, in that sense, creates the resource rather than use being a subsequent action for something already preserved. As Lowenthal (1985) put it 'heritage is about creating something not about preserving anything'. A heritage approach has a significantly different way of viewing the basic time dimensions of past, present and future than does a preservation approach. A preservationist sees the responsibilities of the present as being to select and preserve aspects from an inherited past and to bequeath these to a future. The salient questions here are how is such a selection made, who makes it, on what criteria and on the basis of what authority. Preservationists seek to retain an objectivity in relation to the selection of the subject being preserved and see the process as devoid of ideological meaning. The questions about ownership or relevance are not posed or, if so, only answered by an appeal to the universal - all humanity. A heritage approach asks only what are the needs of the present that a past transformed into heritage can help satisfy. The future, when it becomes the present, will have not only its own needs but also will create its own heritage to meet those needs. If the past is treated as a resource to be activated by contemporary choice then the choice is likely to be quite different in content, criteria, agency and purpose.

This way of viewing the relics, memories and narratives of the past has a number of implications. If the process is demand driven then, at least in theory, resources will be activated as contemporary needs require and thus are mutable, ubiquitous and infinite. A major objection to the view that heritage resources are inexhaustible is that this view is plainly contradicted by countless cases around the world where demand is outstripping supply, not least the supply of space itself that is self-evidently bounded. A particular heritage site, district or city has a limited capacity to accommodate contemporary uses and users and that capacity may be exceeded causing damage to the resource itself, conflicts between users and a diminution of the quality of the user experience. However the supply of heritage in total is limited only by the limits of the human imagination to create it. Thus a local excess of demand over supply can be seen as just a result of specific time or place bound management failure to increase supply to meet the demand by shaping new heritage products and spaces (Ashworth, 2011).

The view that heritage resources are ubiquitous would also be countered by a glance around the world and the conclusion that there is just more heritage in some places than in others. This would be a misunderstanding of what has occurred. Deliberate choices were made to activate potential historic assets according to the prevalent idea of what constitutes heritage and to pursue heritage as a characteristic

element in preference to other options (Ashworth & Tunbridge, 2000). All places have that possibility: only some choose it. No place therefore is inescapably locked into, or out of, the heritage option by a fixed resource endowment.

An incomplete paradigm shift

In most sciences paradigm shift (see Kuhn 1962) is a successive challenge, conflict and replacement of one commonly accepted way of viewing and processing knowledge by another. However what has happened in the short few centuries of concern for the past in the present is that quite different paradigms have been successively introduced for use in particular areas of study or practice and instead of replacing those already in use have tended to be added to them so as to coexist simultaneously with them (see figure). There has been only a partial and incomplete paradigm shift. It is this uneasy coexistence of parallel paradigms and their languages that gives rise to confusion and many misunderstandings between those responsible for different aspects of the heritage process. A consequence of the incompleteness of the paradigm shift has been to emphasise and widen the gap between different phases and aspects of the process whereby past built and natural environments are transformed into contemporary heritage products. In particular the gap between the theorists and the practitioners may be tolerable if they operate in mutually isolated spheres. However when they come into enforced contact then this gap may have several serious consequences. Heritage place management and planning with the objective of contributing to local public policy objectives has many such contact zones (see Graham, et al, 2000).

Confusions and delusions

Values and value

Those engaged in the selection, care and safeguarding of historic resources apply a dominantly preservation paradigm in which value is assumed to be intrinsic, universal and immutable. The object itself possesses value, which although discovered and legitimated by experts is self-evidently present to all who wish to experience it and always will be. In the heritage paradigm all values are extrinsic and ascribed to the object by those who experience it. They are thus neither universal nor immutable, as different people at different times will ascribe different values. The value, and thus the heritage itself, is in this sense created by the current users in fulfilment of their contemporary needs. Heritage is a cultural creation of the present and as with all culture, is fashion driven: new presents will constantly imagine new pasts to satisfy changing needs.

What seems to have happened over time is that form, which was a direct creation of function, possessing only utility value, now becomes itself a creator of new functions and has other non-utility values ascribed to it. Thus the reversal is total. There is a direct parallel in approaches to the natural environment, which was treated for many millennia as usable space, most obviously for food production, This

was supplemented and at least partially replaced by the aesthetic concept of nature to which many non-utility attributes were ascribed (Denslagen, 2009).

The intrinsic / extrinsic distinction over value should not be confused with two other debates that involve the idea of value. The first is common in cultural studies in general and is between the 'economists' and the 'culturalists' (Klamer, 2003). The former attempt to value culture in the sense of ascertaining its worth, ideally through some comparative measure, ultimately market price, thus allowing selection, prioritisation and comparison to be made. The latter see culture as possessing non-commodifiable values that render both comparison and selection of the basis of objectively determined value all but impossible.

The second distinction is between the instrumental and non-instrumental uses of the past and its artefacts. In the former heritage is used as a means towards some other political, social or economic objective. Heritage becomes a resource for political legitimation, socialisation or an economic enterprise. However heritage may also confer non-instrumental values, in itself such as aesthetic satisfaction or just pleasure. In both of these conditions the values remain extrinsic as art appreciation is a learned, culturally specific and time bound response and the values experienced are not intrinsic to the paint, stone or musical notes.

Objects and resources

Heritage can be constructed from an enormously varied range of physical objects, sites, events, personalities, memories and cultural expressions. If the focus is upon the object then heritage could be classified according to the characteristics of that object. The temptation to do that in practice is strong if only because the expertise required in the creation, maintenance and presentation of different categories of object is itself quite different. The task of a museum curator, an administrator of a cultural performance or manager of a natural landscape or physical phenomenon requires different skill-sets. It is understandable therefore that these difference have led agencies to add the adjectives 'cultural', 'natural' and even 'mixed', to the noun heritage. Such usage has become embedded and legitimated by UNESCO in its application of the World Heritage Convention to specific sites and is echoed in numerous national ministries and non-governmental agencies around the world. From the perspective of heritage as experience such usage is in part tautological and more seriously a misleading misdirection of attention. The resources from which heritage is shaped may be categorised in this way but the heritage itself cannot, as all heritage, whether a building or a landscape, is a cultural construction. The stones and bricks, or trees and hills, are not heritage until recognised and designated as monument or park.

A similar misdirection to the resource rather than the experience is the distinction between tangible and intangible heritages, introduced by UNESCO in the interests of political balance between countries, continents and cultures in its bestowing of World Heritage accolades. Apart from its comic aspects such as French cuisine or carnival costumes at Binche, being designated 'intangible', more

fundamentally it misdirects attention from heritage, which is all inherently intangible, to the resources from which it is constructed, which may or may not be.

There is a further related source of misunderstanding concerning probably the most toxic and divisive word in heritage debate, namely authenticity. An object based preservation paradigm is dependent upon the authenticity of the object, whether this means the authenticity of the date of creation, hand of the artistic creator, or historical accuracy. Such authenticity in turn is dependent upon authentication and ultimately upon the authoritative authenticator resulting in an expert-driven, top-down validation. An experienced-based heritage paradigm however has no such dependence. This is not because heritage, as its preservational critics charge, is inauthentic and essentially false. It is because heritage relies upon the authenticity of the experience, not the object. Thus a reconstruction or a facsimile may convey more the sense of how it was, or how we now wish to imagine how it was, than some partial degraded relic however authenticated as validly of the period. Ultimately heritage relies upon a user-driven, bottom-up validation.

Objectives and outcomes

The objective of preservation is to save: the objective of heritage is to use.

The ostensibly simple idea of preservation can be logically challenged by posing the question of whether preservation, in this negative sense of protection from change, is actually possible. The preservation of physical objects created in past time can of course be attempted, as can their reconstruction. However the past is by definition not here now and a preserved or recreated historical townscape is of the present not the past, however perfectly preserved or reproduced are the physical forms of which it is composed. We cannot experience it as it was, if only because we are different.

In a preservation paradigm the subsequent uses of what is saved, apart from any aesthetic satisfaction or pleasure derived from experiencing it or just from the knowledge of its continued existence, are irrelevant to the action. First save, then maintain and only then, if grudgingly possible, reuse. This was expressed in the UNESCO so-called "Venice Charter" of 1964, whose article 5 states clearly that uses of preserved buildings would only be permitted in so far as they do not cause change to the structure or site. This idea, echoing the much earlier (1931) 'Athens Charter', became a central dogma of ICOMOS, established in 1964, and has been reiterated in all 12 subsequent such 'Charters'. The sole purpose is preservation and bequest not use (ICOMOS 1974).

The relationship of preservation as saving, to development as change, is ostensibly simple: they are opposites between which no logical compromise is possible as an increase in one inevitably causes a corresponding decrease in the other. The slogan "save by developing" is a terminological contradiction. Heritage however contains no such contradiction; indeed heritage is a development option.

As far as planning or development is concerned the saved and preserved relict historical artifacts and sites are at best irrelevant and at worst an obstacle. There are

three possible planning reactions, discounting illegal demolition. First, the spaces and buildings designated as saved are removed from 'normal' planning consideration and development occurs elsewhere. A spatial fossilization occurs as evolution and change is brought to a halt at such designated places. One practical difficulty of this is that the monumental designations contain no time limit with the preservation extending into an infinite future. Thus our built environments are increasingly cluttered with the museumified artefacts, monumentalised buildings and sacralised sites that previous societies believed were worthy of preservation for us and for future generations stretching into infinity. This may appear an exaggeration in countries yet to develop effective building preservation official structures and corresponding popular ethos. However in the countries of Western Europe a position has been reached where large swathes of most cities have been effectively fossilised and a millennium of urban development has come to an abrupt end. This raises some uncomfortable planning and management issues and there are very few precedents for de-listing or un-inscribing historic buildings or districts so as to preserve the future's capacity to make its own choices rather than to be imprisoned in the choices of the past.

Secondly, if the legislative protection permits, the preserved structures can be somehow incorporated undamaged into the development, which occurs around and even above and below them. Thirdly, the protected structure can be moved, which saves the object but divorces it from the location upon which it was built. This solution is quite common in North America, where individual buildings or clusters are relocated from the path of development. Europe, however, can be credited with devising whole concentrations of such relocated structures known as 'skansens' (a now generic term for open-air museums of displaced and rearranged buildings, originating from the location in Sweden of the first such collection by Artur Hazelius in 1891). The structural authenticity of the object is preserved at the cost of the authenticity of the ensemble, the site and the function.

A linguistic cacophony of fragmented meanings

Given the long list of the potentially beneficent characteristics of heritage it could be simply concluded that heritage is an ideal policy instrument whose benefits, of whatever sort, will accrue more or less inevitably and the only determining variable is management. However, it is not so simple and there is an inherent condition of heritage that at the very least complicates its use as an instrument of public policy, namely its fragmentation. This in turn is both a consequence of a mutual unintelligibility and also its cause.

Fragmented consumption

Heritage is multifaceted and because it can serve many purposes, it generally does. It is therefore unlikely that the utilisation of heritage for any public purpose is the only, or even the major, use of any given set of heritage resources. The almost inevitable consequence is the multi-use of the same resources, even at the same location; the multi-consumption of diverse heritages by different consumers for different purposes; and the polyvocality of the messages being conveyed and

received. The reason why this matters is that the public policy claim upon heritage is likely to have to compete with other claims.

Heritage producers, notably but not exclusively in the public sector, tend to be product driven. They focus their attention on the selection, maintenance and management of the product itself rather than upon the manner of its consumption. They see their task as being completed once the product has been made available often to a market that they only vaguely and cursorily envisage. However, heritage consumption is not only highly selective it is driven by changing trends and fickle fashions. The idea that heritage is the expression of timeless, universal, immutable value is a comforting delusion. All culture tends to be fashion driven and heritage is no exception. Thus what is today selected may be ignored tomorrow and vice-versa. The more rapid are the changes in an increasingly fluid society, then the more rapid and less predictable will be such changes in fashion.

It also needs to be remembered that all heritage is essentially individual. Each individual creates their own heritage from their own resources of personal relics, histories and memories for their own self-identification and self-positioning within society. Collective memory is not a physiological reality it is a metaphor for attempts outside the individual to add to or modify the individual's identification with ideas, places or other people. The collective in heritage is not an aggregate of the individual. It is, like the 'public interest' it is frequently called upon to serve, an abstraction useful in the formulation of public policy.

Fragmented production

To accept that public heritage is what someone has decided we collectively should remember is not to reduce it to any simplistic 'Bourdieuian' or 'Habermassian' conspiracy theory of dominant ideologies legitimating themselves through the capture of cultural capital and imposing this on the passive subordinate consumers. Merriman succinctly disposed of that simplistic idea in 1991. It is actually much more straightforward. Heritage is an undoubtedly potent instrument in the expression and exercise of ideology, power, and social control. It is not however intrinsically an instrument of any specific version of any of these. Therefore the significant questions will turn out to be, who is doing this and for what reasons. The answers are likely to be as multiple as the agencies competing in this struggle for attention and power.

Heritage is also used as an instrument of public social policy, becoming burdened by governments with many social goals and expectations. It is expected to further social inclusion by promoting social cohesion and combat social exclusion by mitigating social division (Ashworth, 2012). Assumptions are made about the unifying nature of heritage when the reality is that it is as often divisive. All heritage by definition disinherits and all heritage is dissonant to someone, which allows it to evoke feelings ranging from vague disquiet through distress to a complete cognitive alienation and rejection (Tunbridge & Ashworth, 1996). The producers of the heritage product may react by denial and claim they do no more than relate 'the facts of history' or display the cultural, architectural or technical ingenuity of previous ages. They may even claim to be fulfilling an educational role, using an imperfect

past to teach various commendable lessons for a perfect future through 'edutainment'. Both reactions are usually spurious. The point is just that heritage is not a universal common public good that automatically bestows benefit to everyone and anyone. Any use of heritage opens up a potential Pandora's box of particular and often unanticipated reactions, all of which require recognition and sensitive management.

It is often assumed that heritage is a zero-priced freely accessible public good. To many it is. However, heritage from the position of the producer, or indeed the place, is not free. To the costs of selection, maintenance, accommodating collections, promotion, interpretation, marketing and consumer site-management, must be added the opportunity costs of development options foregone. Heritage may be an instrument for some types of development but it also inevitably imposes restrictions, reflected in costs, upon many other types of development. Such costs will be paid at least in part by local communities, whether or not they are the beneficiaries of the heritage development.

Finally in this list of fragmentations and resulting cacophony of messages, there is the issue of spatial scale. Although the national scale has tended to dominate the political legitimation uses of heritage, other scales have become powerful competitors. The continental and even global scales have been recognised in policy at the European scale and at the world scale by UNESCO and its agencies. Similarly at the sub-national scale, regional and local heritage has been explicitly used in the furtherance of place identities at these scales. It may well be that these various jurisdictional scales harmoniously complement each other in a 'Russian doll heritage model' but equally they may not and may project different, distracting and even competing messages.

Does it matter?

The fragmentation in the experience of heritage evident among consumers and producers in all of the various dimensions of heritage sketched above is manifest in the deepening chasms of misunderstanding between the collective and the individual, public agencies and commercial enterprises, theorists and practitioners, the local and the global and many more dichotomies. All are expressed in mutually unintelligible terminologies derived from assumptions that are neither stated nor argued. The question must now be posed, does it matter and if so can such chasms be bridged.

A failure to respond or even to be aware of the issues of fragmentation raised here could, at the least serious, render most public heritage simply irrelevant. There is at least an arguable case that this drift into an irrelevant obscurity is already occurring. At a time when popular interest in personal heritage has never been greater, as witness the increasing interest in genealogy, and family and local history, public museums are becoming concerned about their function and a future in which they serve only an elite minority. While marvelling at the large numbers of local history activists, heritage guide purchasers, heritage trail followers or viewers of television heritage programming, we should not be blind to the even larger number

who eschew all of these activities. The overwhelming majority of national monumental buildings in most countries serve no obvious social or cultural function and a high percentage of even the occupiers of state protected monuments and areas in a recent Dutch study (Kuipers, 2005) were just unaware of the status conferred and, of those that were aware, many were indifferent to it. This popular irrelevance can descend into ridicule as the ever-lengthening heritage lists, designations and appellations are extended to the curious, ingenious and bizarre. (A reading of UNESCO's tentative list of 'intangible' heritage provokes but incredulous hilarity rather than indifference.)

The influence of public heritage policy is reduced by the multiplicity of official agencies and commercial enterprises operating in this field and the resulting unavoidable absence of coherence or consistency in the messages they attempt to project (Ashworth & Graham, 2012). In addition most public heritage producers and promoters underestimate or just fail to consider, let alone understand, the reactions of their targeted consumers. Most public heritage is not noticed and, if noticed, is ignored. Even if noticed and experienced, it is highly unlikely that public heritage will be understood in the way the producers of it intended. Such evidence as does exist suggests that consumers have conscious or unconscious strategies of resistance to the messages intentionally conveyed by public heritage. They change and adapt public heritage to conform to their much more significant private heritages, even to the extent of creating a counter-culture supported by a counter-heritage that, being unexpressed publicly, is unknown to the public authorities.

However, irrelevance is not the worst future scenario. The loss of the opportunities presented by an effective engagement with a pluralizing society is enormous. Heritage can divide as well as unite, be a source of conflict as well as harmony, can lead to social exclusion and disintegration as well as inclusion and cohesion. Many public agencies seem to be unaware of the fragmentation of the societies in which they operate, let alone set out to manage such inherent pluralism through their heritage policies (Ashworth et al. 2007). Finally heritage can be a powerful instrument for the furtherance of many laudable and increasingly necessary social goals as well as the source of much individual satisfaction and plain enjoyment. The loss of this potential, as heritage theorists and practitioners imprison themselves in their mutual linguistic solitudes, would be close to tragic. A necessary precursor of liberation would be the use of the same language. Common concepts, paradigms, theories, goals and instruments of practice could follow.

TERRITORIAL DIMENSION OF INTEGRATED DEVELOPMENT POLICY – EXPECTATIONS AND CHALLENGES TOWARDS PLANNING AND INSTITUTIONAL SYSTEMS

Tadeusz Markowski[1]

Abstract

Contemporary development faces a fundamental problem: a mismatch between the institutional system and the planning practice in the context of increasing contradictions between the dynamics of functions and petrification of spatial development. Therefore the new public intervention policy, covering development policy requires a serious reform, as well as structural and institutional adjustment to the new conditions.

At times of the global need to maintain the competitive capacity of territorial units, and the need to protect the environment, it is necessary to create new forms of multi-level decision-making system (for policy and management purposes). Such organisational system should aim at optimisation of development opportunities and reduction of social costs related to development management by highly politicised administrative structure of territorial government. This policy should use such an instrument as integrated planning and functional approach to the territories.

The ongoing debate on the cohesion policy and the nature of territorial cohesion in particular, provides such an opportunity of creating a new policy and planning model. However, the European debate mixes up the concepts of spatial cohesion and territorial cohesion and treats them as synonyms. This results in many misunderstandings.

A broad definition of cohesion put forward by the European Council of Spatial Planners (Conseil Européen des Urbanistes) states that „territorial coherent Europe can be achieved by „**The connectivity of and among Economic, Social and Physical Systems, which enhances their overall Effectiveness for Innovative Sustainable Development".** Author discuss definition territorial cohesion and put the question to what extend **„Territorial cohesion" be perceived as universal objective or even paradigm of contemporary development policy?**

Adopting such a concept of territorial cohesion means that it becomes a synthetic (macro) objective for the development policy; an objective which is reached through ensuring **social cohesion, economic cohesion and spatial cohesion which are coupled with integrated, horizontal cohesion policies; social, economic and spatial ones.**

[1] University of Lodz, Dep. of City and Regional Management, Lodz, Poland – tamarko@uni.lodz.pl

The author consider also concept of integrated planning, delimitation dilemmas of functional areas in territorial cohesion policy and functional areas (territories) as subjects of regional policies. It needs to be noted that **the approach concerned with functional areas brings about a greater probability of more effective usage of support funds with regards to achieving the objectives of pro-development policy**. What is more, this approach is also in line with the new theories on development, such as: a networking economy, an economy of flows and highly flexible, increasing role of territorial factors in competition of companies-(terriorialization of the economy), etc.

The paper is concluded with the set of recommendations and directions of activities addressed to public institutions involved and responsible for planning system.

Key words: territorial cohesion, integrative planning, functional areas.

Introduction

Contemporary development faces a fundamental problem: a mismatch between the institutional system and the planning practice in the context of increasing contradictions between the dynamics of functions and petrification of spatial development. This is a structural barrier of the contemporary increasingly more globalised economy, which is expressed in the growing market failure and governmental failure. And in consequence it leads to increasing negative effects of development, including in the form of interregional polarisation, social exclusion, growing public debt, etc. Therefore the new public intervention policy, covering development policy requires a serious reform, as well as structural and institutional adjustment to the new conditions.

The international development policy must adopt – as its overriding strategy – a constant drive towards price internalisation of externalities or, in other words, reducing market failure, since otherwise international capital flows will enhance and grounds for political corruption will consolidate (forcing regulation that enable to avoid the social costs by failure to respect the social internalisation of effects). This is encouraged by too slow changes in the local (territorial) systems of social values, loosening of the system of values by the business cycles and other disruptions of social, environmental, etc. character.

At times of the global need to maintain the competitive capacity of territorial units, and the need to protect the environment, it is necessary to create new forms of multi-level decision-making system (for policy and management purposes). Such organisational system should aim at optimisation of development opportunities and reduction of social costs related to development management by highly politicised administrative structure of territorial government. This policy should use such an instrument as integrated planning.

Integrated planning should be understood as planning covering social, economic and spatial issues, under which spatial planning acts as the verifier and coordinator of many elements in the area of effects referred to space (it is *de facto* the instrument of territorial dimension coordination and the impact of functions (activities)). Development plans have to be jointly elaborated under the multilevel and multisectoral governance system. Legal regulations are necessary as they make it possible to establish real competences to solve conflicts between territorial administration jurisdictions and governmental administration sectors.

The ongoing debate on the cohesion policy and the nature of territorial cohesion in particular, provides such an opportunity of creating a new policy and planning model. Various broadly-conceived attempts at interpreting and defining territorial cohesion bring to a conclusion that it should be, actually, treated as an important effort to find the new vision for Europe's development: "A territorially coherent Europe". We adopt a broad definition of cohesion put forward by the European Council of Spatial Planners - Conseil Européen des Urbanistes (ECTP–CEU), which states that territorially coherent Europe can be achieved by "The connectivity of and among Economic, Social and Physical Systems, which enhances their overall Effectiveness for Innovative Sustainable Development" (Vogelij, 2010, p. 1) **Hence "territorial cohesion" understood in that manner becomes an universal objective (means), or even a specific paradigm of contemporary development policy.** Territories under such policy are treated as categories that change over time and whose size is determined as a result of an agreed planning and political decision.

However, the ongoing European debate mixes up the concepts of spatial cohesion and territorial cohesion and treats them as synonyms. This results in many misunderstandings. It is our proposal to understand spatial cohesion - in reference to the definition of ECTP - as the state of spatial development (spatial, network and point structures), which enables the establishment of highly efficient connections of economic, social and spatial systems beyond administrative divisions. **Hence spatial cohesion is a means to the achievement of territorial cohesion in Europe. Thus it is not identical with the territorial cohesion and the territorial dimensions of the development policies.**

When adopting such a concept of territorial cohesion we treat it as a synthetic (macro) objective for the development policy; an objective which is reached through ensuring **social, economic and spatial cohesion which are coupled with three integrated, horizontal (cohesion) policies: social, economic and spatial.**

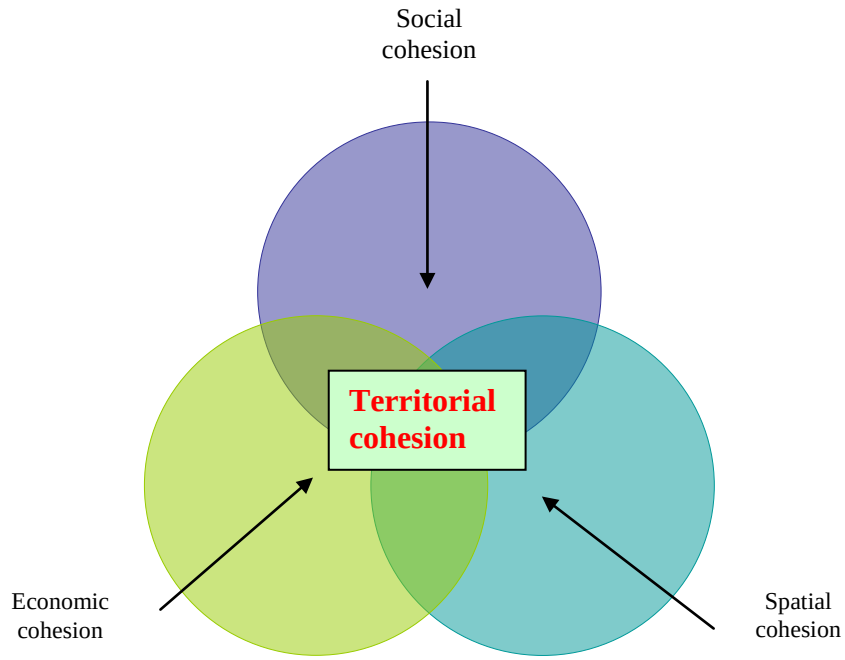

Figure 1. Territorial cohesion concept

The cohesion policy (understood as the new integrated development policy) should be conducted on and within the framework of the specified functional areas. This makes it possible to better ensure efficiency of functioning and development of social, economic and physical systems (built and natural environment). Emphasising the role of connectivity factors as well as the quality of spatial systems in the new cohesion policy means that the role of spatial planning methods will increase in importance. After all, spatial planning in its very essence was (and is) oriented towards integrating relationships between the system of functions and the forms of spatial development.

2. Integrated planning

The traditional spatial planning (physical planning in particular) was concerned with locating the functions and buildings in space. The more advanced planning methods put more emphasis on externalities caused by construction activities as well as by

technological spillover effects caused by the users of properties. Today spatial planning is oriented more towards the shaping of the natural environment as well as the anthropogenic environment in the context of sustainable development. This means an entirely different approach to planning in the entire system of development policy.

In the British concept of development planning, spatial planning is a synonym of integrated planning. This follows from the fact that in the traditions of the British local-level planning there was no such a concept until Great Britain accessed the European Union. Planning pertained to land use - Land use planning, or buildings - Physical planning. Under the influence of the continental Europe - using the English language to describe the planning system - the term "Spatial planning" in Great Britain was recognised as well corresponding to the new approach of planning for development[2].

Regardless of the final popularisation of the term applied in Europe - we refer to the integrated development planning combining in the planning process the phenomenon and socio-economic relations with the forms of spatial land development and showing the mutual relationships and dependencies determining the drafts of planning decisions and political forms of intervention. The territorial dimension of development policy means that we consider the functioning of the systems under their spatial ranges (both the factors determining their development and negative externalities) and we coordinate the sectoral policies by referring them to the functional and spatial layout, in other words, to places where it is possible to better coordinate them in spatial and thematic aspects, i.e. under a system of functional (planning) areas defined for the period of the intervention.

3. Delimitation dilemmas of functional areas in territorial cohesion policy

The functional and territorial approach can result in the greatest doubts and concerns. The more if the issues of functional connections under the territorial system are not adequately stressed. The discussions on the so-called territorial based policy highlight – and correctly so, at least in theory – that the territorial development policy must put an emphasis on endogenic factors that exist within the territorial system and that the territorial capital is the essence of contemporary development. However, the dynamic and changeable character of functional areas is not sufficiently emphasised. What is more, the delimitation of territorial units for the support policy is concerned most with solving specific problems (thematic issues). Thus two approaches can be identified in these debates:

1. An approach concerned with problems on given territories (delimited in accordance with administrative units and statistical nomenclatures), and

[2] Given the significance of the English language for the European Union it seems to be worthwhile to agree this term between Member States. To what extent the term development policy should be used and to what extent the term spatial development policy, and whether this do not give raise to interpretative misunderstanding. Whether this should be the new spatial planning or integrated spatial planning or integrated development planning?

2. An approach concerned with functional areas

It needs to be emphasized that these two approaches are not mutually exclusive. However, it needs to be noted that the approach concerned with **functional areas brings about a greater probability of more effective usage of support funds with regard to achieving the objectives of pro-development policy.** It is also in line with the new theories on development, such as: a networking economy, an economy of flows and highly flexible and increasingly important role of territorial factors in competing, etc.

Hence in fact territorialisation in the concepts of the new EU policy was simplified and presented in a rather trite manner, which may be scientifically attractive, but it remains very traditional in practice; it assumes that the administrative units which apply for support will identify and define their development potentials themselves, while public support will anyhow be concentrated on *a priori* defined problems (thematic concentration). If it turns out that under other sectoral policies, other types of intervention will take place regarding other issues, than the essence of territorial approach would cover coordination of sectoral support on the level of a territorial (de facto administrative) unit. However, the practice shows that this has not been possible so far, and that the traditional reluctance to cooperation or even mock cooperation aimed at gaining funds will not change a lot in the way that the regional policy is implemented, and conditionality principle does not help much, either.

"Place based policy" requires that many classification and delimitation criteria are applied which rather leads to another artificial division (masked with the air of scientific requirements) into groups of similar units (often dispersed in space). The politicians then assign these groups of units with the right to apply for funds in line with the so-called principle of thematic concentration, using objective (or rather mechanical) criteria. The other approach can be based on spatial and functional relationships of the socio-economic activities of man and, therefore it relies on networking criteria, where a functional area delimited according to a set(s) of leading functions (or even according to one highly specialised function) acts as an object of intervention.

The territorial system in this respect is treated as a set of interrelated functional and spatial characteristics, in which the so-called built environment preconditions the development of the functions (their efficient and competitive functioning against other entities). For example, this can be a group of gminas having a leading touristic function. This can be an area, in which there are metropolitan functions or an area, in which spatial effect of a metropolis are visible, etc.

Identification of the delimitation criterion(a) of the functional area, at the same time, implies identification of the strategic direction of intervention. This does not, however, mean that in such a functional area it is not possible to set an intervention in other spatial functions and features in line with other thematic and sectoral policies. Nonetheless, this territorial and functional approach simultaneously points

to the fact that in such an area we have to make interventions and plan development **in an integrated manner.**

Functional areas are dynamic in both time and space. Their range depends on the changeability of functions, lifecycle of products, fluctuations of the outlet and supply markets, variations as regards the number of companies, spillover externalities caused by economic activities, etc. The range of functional areas depends also on the physical features of the geographical environment, the need to sustain life, biodiversity, air purification and meeting the need of people to have contact with the natural environment, etc.

The planning practice uses planning areas which are, de facto, political areas. Their boundaries are based on conventions valid only as long as the plans are valid. Delimitation of an area requires delimitation of the intervention area. The typology of functional areas may adopt various objectives and criteria, such as: cognitive, legal, spatial externalities, multiplier (territorial) effects of development, social and political objectives, etc.

The functional and territorial approach enables greater effectiveness and efficiency of development management and is integrated into the territorial dimension of the EU cohesion policy. At the same time, it is in line with the integrated development planning, under which - in the current conditions and according to the generally accepted rule of sustainable development - the role of organising and coordinating the development factors in territorial systems gains special importance. Adopting the functional approach means that it is necessary to seek for new methods of management (and regulation), allowing true discounting of theoretical opportunities for reaching development objectives in the territorial dimension. The country's territorial organisation, local ambitions, political interests, the existing system of competences and forms of financing of the local activity are often contradictory to the functional areas (territorial) approach to cohesion.

Delimitation and policy of functional areas belongs to one of the most important forms of implementation and conduct of development policy and spatial policy accompanying it. The functional approach covers economic, social and natural areas, etc. threat going beyond the administrative borders - from the local to the national level considering the border areas.

4. Regions vs. functional areas (territories) as subjects of policies

Problems with a functional approach appear whenever questions concerning the subjects responsible for policy implementation in functional areas which go beyond the administrative borders of the country's territorial division are raised. Are we protecting anything? If so, which functions? Are we developing anything? Are we repairing anything? What are the levels of competences (of organisations) required for solving the problems of a given planning area? Will some of the contemporarily identified areas require creation of special organisational and institutional structures

in order to attain the objectives which were set for them? It needs to be remembered that in the history of several countries, including the former socialist countries, there was a time of too many special administrative divisions, which often disturbed the operation of the local administration. The memory of the negative effects of operations of the government special administration system can constitute an ideological barrier to introduction of the management structures, despite the fact that economic and system conditions have changed significantly. This concerns, for instance, the management of metropolitan areas. Yet another issue, is the matter of natural systems, separated as the planning areas. How can we interfere in such areas? In case of natural systems, people decide on their delimitation and carrying out such type of activity that will be compliant with or stopped given the expected functions of the natural system. Thus it is necessary to create an organisational and institutional system, which will ensure protection of functions assigned by the planner to the natural system. Therefore by introducing such an area, not only the law must be established but also mechanisms of its control and enforcement. If areas of risk are delimitated, it is also necessary to undertake a number of actions in such an area, e.g. prohibitive and prescriptive actions, regulations within the scope of risk insurance, forms of awarded support, etc.,

Efficient implementation of planning arrangements following from the functional approach requires seeking for objective and technically feasible criteria of geographic delimitation and consideration of dynamic changes of social and economic relationships over space and time. Therefore an important feature of the managerial approach to functional planning covers: identification of the sources of conflict and methods of achieving compromises; legal, institutional (including political), economic and financial barriers existing both in delimitation of functional areas, as well as determining later implementation of the provided arrangements and objectives of social policy (and general development policy) in the entire planning system.

We should strive for attaining the greatest possible consistency between borders of the functional regions, the borders of administrative territorial divisions and the territorial units defined for statistical purposes. Delimiting a functional area, the borders of which exceed administrative borders, has to be preceded by an analysis of existing administrative structures in terms of their co-governance capacity in the functional area. Furthermore, the necessary instruments which motivate to adopt multi-governance methods (such as economic, legal and organisational impulses) need to be highlighted. Otherwise the idea of functional planning will remain dead.

Providing support for creation of co-governance systems (idea of public governance with professional agencies acting as operators and trustees, etc.) should become the essence of implementation of policies based on functional areas rather than creating special administrative structures, which would be outside of the control of local democratic and civic local government structures.

5. Functional areas in integrated planning

Delimitation of functional areas in plans is a sign of public authorities' policy, whether we want it or not. This assumption consequently means that, the delimitation thereof, must be followed by different forms of direct and indirect impact oriented at functions under the area delimitated in the plan. The plan points to strategic areas (zones), whose borders and specificity are made more precise in further programmes and decisions on the national, inter-regional (inter-voivodeship) and inter-gmina levels.

National plans cover only such areas which, due to important national interests, are of significance for state policies. By analogy, the same is applicable to the EU level. The European development strategy should highlight the areas which are directly in the field of interest of the European Parliament and the European Commission. Identification of these areas in practice has to imply that they are (or will be) related to a specific system of regulations and financial instruments. For example, should floodlands be identified, then the minister responsible for construction should, by way of his action, introduce appropriate building standards for these areas, i.e. a requirement to construct higher foundations, provision prohibiting the construction of basements, the need of using appropriate foundation technologies, etc. Identifying mountainous areas or, for example, areas threatened with landslide, will mean that voivodeship and gmina plans will need to specify their borders more precisely and the minister will introduce regulations which will, for example, put limits on the weight on constructed buildings. It is thus imperative for the planning practice to clearly differentiate delimitation of areas (and various methods applied for this task) for cognitive and analytical reasons (studies to plan) from the final delimitation which serves political objectives (approval of the drafts of plans).

It needs to be noted that in practice, the functional dimension of spatial policy is ensured by zoning and delimiting areas also in modes other than the planning mode, i.e. by legislation approved by the parliament or regulations issued by ministers or voivodes. In case of the EU, such modes may include strategy provisions or directives. In such circumstances planning processes need to recognise these areas and treat them like any other legal or regulatory condition. However, it needs to be highlighted that planning which integrates complex aspects of planned future should also critically assess areas delimited in non-planning modes and indicate, in the plan's provisions, required changes in that respect[3].

When adopting that spatial planning serves e.g. strengthening the protection of natural systems and/or development of different functions under complex socio-economic systems operating in space, it is necessary to consider that the planning areas - regardless of the adopted delimitation criteria (these are changeable and

[3] Given the fact that zoning through statutory mode is often not implemented in Poland, the situation leads to collisions in the system of planning provisions and later results in social and political conflicts and degeneration of the planning system.

historic), are always oriented at functions[4]. Functional planning areas are therefore arbitrary areas and acts of political choice. The accuracy of choice depends on the state of knowledge, cognitive methods of the manner of their delimitation. Hence it needs to be assumed that the functional planning areas should be connected with the function of the system objective or sub-system objective and not only the morphological features. The morphology of the area is an important but only auxiliary criterion. This can raise doubts of spatial planners that aim, primarily, at shaping the manner of development and physical features of a space, and not at caring for the system organisation and efficiency of its function.

An integrated planning system includes two types of planning decisions: identification of a functional area as an object of concentrated intervention, as well as obligations to prepare indicative and regulatory plans for identified functional areas. In the former case planning instruments and other methods for delimitation of an area for intervention are applied in order to achieve the best possible concentration of means of intervention devoted to certain areas or themes (problems). In the latter case, intervention means implementation of the plan's provisions which are binding for political entities and different users of space in a functional area covering several administrative units.

In the former case, delimitation of functional areas as an object of intervention comes close in its concept assumptions to the mechanism of intervention in special economic zones. Not all functional areas will require special strategic spatial plans. Since, in many cases it is to be expected that specialised instruments of development policy will enforce integration of local spatial development plans (urban-planning). In such cases a principle of conditionality of financial support may be used in order to stimulate joint preparation of plans. This may, above all, apply to border areas and, where regulatory systems (procedural and implementation) in terms of spatial planning differ. In this case the documents supporting the management process will be prepared according to a different formal and legal mode.

It remains to be considered whether the new type of integrated development planning introduced into the EU development policy will require individual Member States to harmonise their systems of creating local spatial development planning, including the procedures for issuing building permits in the EU, ordering the implementation system of the area related to spatial development, real estate marketing, etc., in order to exclude the possibility of competition between territories by means of creating political benefits.

[4] It is necessary to ask oneself a quite straightforward question: how do we actually understand functions under planning? Starting with the systematics of the word to function, i.e. act, it needs to be stressed that it pertains to action for a given purpose. Each function (activity) is assigned objectives of action, e.g. production, logistic servicing, education, etc. The Functions (activities) create defined relationships between each other. Thus they create functional systems and sub-systems. A natural system also has a function of an objective, which can consist, for instance, in sustaining life or capacity to recreate life processes. Under the natural systems it is also possible to separate planning area: chain systems, hub systems, etc.

Integrated planning combines, at east, several overlapping dimensions (Vigar, 2009, p.1572):

- Interpenetration of and relation between strategies and polices (integration of strategic documents and actions- policy framing),
- Connecting policy and actions, as well as cooperation between actors and actions.

Integrated planning requires the strategy development processes to be coordinated in order to avoid conflicts. It also requires that the scope of issues and context of the problems covered during document preparation (formulating objectives and actions) is broadened. The process of integration includes also an equally important process of learning and developing new knowledge which is beneficial to all users. This often allows to overcome institutional failures, i.e. avoiding the fragmentation of institutional systems and established a partnership for achieving joint objectives. Of course, how the integration takes place depends on local cultural conditions, legal systems, tasks and formal competences, the planning system and all other elements which form e.g. the spatial economy system. Thus integrated planning requires a change of many legal, institutional and cultural conditions, and overcoming stereotypes of both decision-makers as well as stakeholders.

The typology and delimitation of functional planning areas for the purpose of methodological practice, and later on the implementation practice, two basic types of areas should be identified: 1) areas based on natural and physiographic features and relationships, and 2) areas based on the socio-economic features and relationships. The attempts at integrating spatial and socio-economic planning give raise to additional complications in the establishment of a functional planning model. The integrated plan covers also areas of different level of precision and changeability (blurring) of borders, which is not tolerated by the traditional spatial planning, Therefore integrated planning will include both areas with clearly defined borders - having administrative and legal effects, and also areas with blurred (approximate and arbitrary) borders. In the former case, these will be areas, where each activity within the boundaries of the zone (area) has to be subordinated to the legal regulations binding therein. In the latter case, the intervention is connected to a function, and location in a area is of secondary importance. This does not, however, mean that restrictive borders for policy purposes cannot be delimitated for them.

A new challenge for the integrated development planning, including in particular for the purposes of spatial planning, includes delimitation of a hub and networking region, in which there is discontinuity, insufficient determination and blurred nature of the borders. Such an approach is contrary to the traditional understanding of spatial development. This, however, does not release us from the search for new methodological approaches.
The delimitation of a planning area should serve for:
- concentration of actions of thematic (sectoral) policies,
- or, introduction of new rules (regulations) of used areas,

- or, confirmation of the existing regulations on the area by way of statutory acts.

Cognitive delimitation of areas of different functions in the planning process through the so-called system of overlies should be used to delimitate areas of critical and integrated intervention. When it will be necessary to establish special organisational structures to solve the overlapping and complex problems it seems justified to draw attention to two forms of intervention in space:

- **Regulation and intervention in an area** and indirectly in functions and
- **Regulation and intervention in functions in given area** and indirectly in area and its physical development.

For the purpose of the implementation and analytical practice of integrated planning: at the European, national or regional level, it is possible to use a division into strongly functional areas (in which de facto one function predominated over others) and multi-functional areas (areas of broad contradiction of functions and likely occurrence of conflict situations). This division makes it possible to show the scale of the problem related to legal tools of the planning instrument. Multi-functional areas require very complex approach and integrated inter-sectoral cooperation. For example, metropolitan areas require integrated approach to planning, system, financial, environmental, infrastructural and other issues.

6. Postulates and recommendations

- Introducing integrated development policy and integrated planning methods in individual territorial units will, undoubtedly, encounter numerous barriers. The most significant of these barriers include: barriers of political, mental, historical, bureaucratic, informational, legal, institutional and other nature.
- High dynamics – in terms of both space and time – of functional areas need to be recognised. This means that regardless of statistics carried out according to the conventional nomenclature of statistical units, there exists a need to set up minimal statistical units which are necessary for implementing effective cohesion policy on every level of intervention decision making (EU, state, administrative region, gmina). Furthermore, the scope of collected information needs to allow observing and verifying functional areas delimited according to varying criteria. These actions will create rational foundations for optimising intervention performed by the authorities. Therefore it is necessary to reorganise public statistics in the EU Member States and introduce an obligation to record externalities, including territorial distribution of externalities which are public and quasi-public in character.
- In a society of high differentiation of social systems of value (human and social capital) development policy targeted at mobilisation of social groups according to standardised methods may turn out to be of little efficiency. Hence it is not possible to apply the same instruments in the entire EU. It is necessary to identify differentiated systems of value in territorial systems. These systems should also be the subject of integrated cohesion policy. Hence there can be territories having territorial systems where externalities commercialisation strategies will prevail, and others - where the level of their

internalisation has to be lower, and yet others, where the policy can be liberal or ever restrictive, etc. As a consequence, it means economic differentiation of competitive conditions of functional areas and makes the cohesion policy pursued in the regions a more complex (sophisticated) issue. This implies that the policy will require a high level of institutional development.

- Ensuring effectiveness of the integrated policy requires creation of mechanisms guaranteeing that politicians become interested in avoiding negative externalities related to development and incorporate such criteria in their decision-making systems and political decisions. Identifying and incorporating negative externalities into the social (electoral) system of values is a prerequisite for such political behaviours (it provides an opportunity for the so-called socio-political internalisation of negative externalities)[5]. Positive externalities, on the other hand, may be regarded as means of strengthening objective foundations of a functional system's competitiveness (in other words – they allow for creating the so-called external sources of competitive advantage).
- It is also necessary to create adequate instruments, including universal instruments common for the EU and taking into account the need of creating specialised and territorially oriented instruments which, at the same time, would not violate the EU's principles of fair competition.
- Undoubtedly, the integrated planning methods need to become more widely spread, and as for planning processes it is necessary to popularise the application of similar methods for assessment of policy and planned activities impact in a territorial dimension (impact assessment methods and analysis of external, non-market effects) divided into positive and negative externalities. It is also required to disseminate the use of multiplier analyses of economic growth effects on account of the intervention in markets and resources - i.e. analyses based on the effects estimated by the markets.

7. Directions of reform of the public planning system

- It is necessary to start with a concept of integrated development planning and based on it build a rational model of intervention meeting the requirements of the economic competitiveness, sustainability and social inclusion. The above terms to some extent are combined with the traditional understanding of the regional policy objectives. It is necessary to answer the key question: should we keep the conventional regional policy model, but with emphasis on the territorial effects of sectoral policies and mobilisation of resources in territorial administration units, or should we establish a new model - an evolutionary one, which in a way covers the conventional approach, but puts more emphasis on functional areas (administrative divisions are of secondary

[5] A social system of internalising externalities is a long-drawn process and can be implemented through education of the society and sending new demand signals, for example for environmentally friendly manufacturing processes so that companies respect the principle of minimising their environmental footprints (a strategy of enforcing corporate social responsibility with regards to the natural environment).

significance) and produces stronger connections and relationships between organisations rather than highlighting the physical resources that can be used by economic activity on the markets of goods exchange. The new approach should put more emphasis on the coordination of resources, factors and products of the non-market area co-deciding on the quality of life, development sustainability and long-term competitiveness.

- Under the latter solution, the role of the international achievements and experience in the field of spatial planning will, certainly, gain in importance. Development policy objectives (the object of the intervention) cover, above all, externalities in functional areas (as a place of intervention in market failure, and creating conditions for a more efficient and better internalisation of resources and creating sustainable competitive advantages for commercial business operating in the functional areas). The role of multi-level governance becomes more important and the principle of subsidiarity on providing support has to have dynamic nature.
- It is necessary to take into account in the spatial decision-making the externalities at all levels of political decision, i.e. considering them in spatial development and adjusting development to dynamically changing functional and spatial relationships (and these are formed and disappear independently of the formal jurisdiction of the political entities).
- The new approach implies greater role of professional planning. It requires reorganisation of studies and statistics, introduction of a dynamic approach as regards application of the principle of subsidiarity in the territorial authorities organisational systems, strengthening and professionalisation of administration, new instruments for organising cooperation, adequate ways of accounting for development benefits, i.e. eliminating conflicts, prisoner dilemma and other social traps, greater trust to the co-participants of the policy and concentration of control on the results.
- The governmental institutions play an essential and important role in outlining and "enforcing" the integrated approach to planning on the regional and local level. We hope that the European Commission and the European Parliament will recognise and adopt to the practice the integrated approach and apply adequate instruments to its introduction, i.e. they will form the legal grounds for integrated development planning.

Annex

Minimum requirements for implementation of integrated development planning and management methods

- Knowledge and methodological skills;
- Adequate methods for planning development processes, including concept of observing critical provisions of a plan which allow for integrating development (the so-called critical points of political control and joint decisions);
- Introducing adequate economic stimulators targeted at stakeholders and decision makers into the functioning of the socio-economic system: the objective is to provide transparency and create awareness of economic, political, social and environmental costs and benefits of all decisions;
- Availability of analytical instruments for decision making in public and political institutions together with appropriate skills required for using them;
- Legislative support for integrated (multi-subject) planning;
- Adequate databases and monitoring systems;
- Instruments for implementation (real competences);
- Preparing and disseminating as well as observing the principles of integrated planning *(some examples of such principles include:*
    - *Using long-term, comprehensive analyses in the operating and decision-making system;*
    - *Adjusting spatial development to functional requirements (eliminating speculation);*
    - *Principle of conditionality, related not only to effects but also outlining conditions for cooperation and coordination of actions of administrative bodies as well as other structures operating in the functional area;*
    - *Principle of specificity – requiring that organisational structures are adjusted to the local context).*

AN ASSESSMENT OF THE PLANNING AND OPERATIONAL PERFORMANCE OF THE BUS RAPID TRANSIT SYSTEM IN ISTANBUL

Elif Can YÜCE[1], Assoc. Prof. Dr. Ela BABALIK STUCLIFFE[2]

1. Abstract

Bus systems are the backbones of transportation systems in cities; all cities provide their mobility with bus systems either as their main public transportation system or a feeder service for rail transit. However, conventional bus operations have been suffering from a poor public image due to their slower and lower quality service provision. Thus there is a tendency to improve the quality of bus operations in recent years, and Bus Rapid Transit (BRT) systems are getting more popular throughout the world since they combine quality of rail transit service and flexibility of buses. Today there are more than 120 cities operating BRT and bus corridors in North America, South America, Asia, Europe and Australia. BRT operations in medium-sized cities and in certain corridors in large cities can carry the same amount and even more passengers than many of the LRT lines. Since BRT provides faster transit services, reduced travel times and high quality of service with good identity and image it is believed to increase transit ridership. Furthermore, recent experiences with certain systems, such as one of the best-practice cases of BRT in Curitiba, Brazil, show that when the planning of these systems are carried out in integration with metropolitan development plans as well as local neighbourhood plans, expected benefits can be significantly increased due to high land-use impact that can in turn increase ridership.

This paper provides an assessment of the Istanbul Metrobus, the only BRT system in Turkey, which opened in September 2007. Using the lessons learnt from a number of best-practice cases in the world (TransMilenio in Bogota, RIT in Curitiba and Metrobus in Mexico City), the paper will first attempt to answer what makes a BRT system successful, and then review the following aspects regarding the Istanbul case:

- Planning background: integration into urban planning; integration with other transport modes
- Physical characteristics of the system: location, design and other aspects that may have effects on ridership
- Operating characteristics: level of service, fare schemes, etc. that may have effects on ridership
- Marketing, advertising, identity and image-building policies: operator's and/or local authorities' efforts in promoting the system, which may have an effect on ridership

[1] EMBARQ-Sürdürülebilir Ulaşım Derneği, ecan@embarqturkiye.org
[2] Middle East Technical University, Ankara, ebaba@metu.edu.tr

It is intended to elaborate how the first four aspects, ie. planning, design, operation and marketing, may have affected the ridership performance of the BRT in Istanbul. Findings are to be generalized in comparison with the aforementioned best-practice cases, and a list of possible factors will be presented for a successful BRT implementation.

Key words: BRT, planning, implementation, operation

2. Introduction

Today, the boundaries of cities enlarged due to high economic activities and in metropolitan areas population increases, thus the mobility between residential areas and job, education and public services become fundamental. Cities throughout the world suffer from traffic congestion caused by high rate of private car usage and air and noise pollution due to gas emissions led by transportation activities. In order to deal with traffic congestion, air and noise pollution problems national and local authorities started to focus on integrated public transportation activities. With no doubt bus systems are the backbones of the public transportation systems, because of being cheaper and more flexible. Rail based transportation systems are applied in most of the cities in the world, but they are expensive to implement and require long construction time. Despite being the most common type of transportation mode, conventional bus operations suffer from poor public image, lower speed, reliability and safety issues. Bus Rapid Transit systems are getting more popular all over the world both in developed and developing countries, because of having flexibility, being easy and cheap to build, which are characteristics of bus operations, and having high service quality high capacity, being reliable and safe, the well-known characteristics of rail transit.

BRT includes many components; according to budget of the national and local governments it can be implemented either partially or as a whole. The benefit gained from operation increases when all the components are implemented. There are more than 120 cities that applied BRT in their public transportation network either as the primary mode or as a feeder service to the rail transport system.

BRT system is not a recently rising public transportation trend; especially in Latin American cities it has been implemented for decades. In Turkey too, there was a separated bus-lane operation in Ankara in the 1980s; however it was abandoned in favour of an underground light rail system. Currently, the only example of BRT in Turkey is in Istanbul which is the largest metropolitan area in the country. City officials are trying to deal with traffic congestion and problems caused by this situation.

Population of Istanbul is rapidly increasing due to economic development, thus urban area is expanding. Registered private car number has increased 6 times and reached

over 1,7 million since 1958 in Istanbul. Also passenger mobility is very high. According to household survey conducted by Metropolitan Municipality of Istanbul, number of daily trips is 20,9 million, 10,3 million trips are pedestrian the rest is with motor vehicles. (İstanbul Ulaşım Ana Planı, 2010)

As it is discussed previously, rail transit investments require high investment and maintenance cost and also long investment time. Istanbul has a number of rail lines newly developed; but the city also needed a cheaper and quicker solution for transportation problem in the main arterial of the city. The corridor that BRT is implemented is one of the most important highways and surrounding areas are densely populated. One of the main objectives of the BRT project on this corridor was to provide fast, reliable and comfortable service to the users and attract especially private car owners.

Istanbul also suffers from high air pollution rates caused by transportation activities. While planning and implementing BRT in Istanbul, reducing greenhouse gas emissions was the other objective, by decreasing the number of private cars in the corridor and also reducing the number of other (low-capacity) public transportation vehicles which pollute the environment most such as low technology conventional buses and minibuses.

The first BRT corridor in Istanbul started operation in September 2007 between Avcılar-Topkapı corridor. The first phase became successful and fulfilled the objectives; reducing travel times, reducing private cars by attracting people with high quality service, via high technology buses and eliminating low technology conventional transportation modes from traffic BRT reduced CO_2 emissions.

The high ridership of the 18,2 km BRT route led new routes to be planned. Today three phases have been completed and in operation. After completion of Phase III two continents, i.e. the two sides of Istanbul, were connected through the Bosphorus with BRT line. Phase IV is under construction in the western part of the city from Avcılar to Beylikdüzü.

Figure 1: BRT System in İstanbul

3. Implementation

3.1. Phase I: Avcılar-Topkapı Corridor

The construction of the first BRT corridor started in 2007 between Avcılar and Topkapı corridor and started operation in September 2007. Total construction time of the corridor was 8 months. Total route length of the corridor is 18,2 km and total number of stations on the corridor is 16, 14 bus-stops and 2 turning point stations.

Açıklama [EBS1]: Bu aşamada olumlu değerlendirmelere girilmemeli. Daha tarafsız bir anlatım baş tarafta daha doğru olur.

Figure 2: Avcılar-Topkapı BRT Line

3.2. Phase II: Topkapı-Zincirlikuyu Corridor

One year after Phase I, Phase II started operation in September 2008. Phase II starts from Topkapı and ends in Zincirlikuyu station which is the last station in European side. Construction of Phase II was completed in 77 days. Total route length of the Topkapı-Zincirlikuyu corridor is 11,8 km and total number of stations are 12; 11 bus stops and 1 turning terminal.

Figure 3: Topkapı-Zincirlikuyu BRT Line

3.3.Phase III: Zincirlikuyu-Söğütlüçeşme Corridor

Zincirlikuyu-Söğütlüçeşme line is the 3rd Phase of the Istanbul BRT. This phase of the system connects two continents over Bosphorus. This feature makes Istanbul Metrobüs first and only intercontinental BRT line in the world.

Figure 4: Zincirlikuyu-Söğütlüçeşme BRT Line

Total route length is 11,5 km, consisting of 7 bus stops and 1 turning terminal. This phase is constructed in 5 months and started operation in September 2009. The line starts from Zincilikuyu station from Europe and ends in Söğütlüçeşme station in Kadıköy District in Asian side.

The BRT line in Istanbul has a fully segregated route along the corridor. The only place where BRT buses flow in the mixed traffic (for 3 km) is on the Bosphorus Bridge. However, in order not to compromise the speed of the system buses enter and exit the bridge on dedicated lanes, and it is the approach to the bridges that feature the worst traffic congestion; therefore the system provides a significant advantage in journey time when crossing the Bosphorus.

4. Physical Characteristics

4.1. Running Ways

İstanbul Metrobüs is running on D-100 and O-1 Highways with fully segregated median busways with 40 km route length. There is one lane in both directions and it is segregated from general traffic with physical barriers and from other BRT lane with road markings. Since the doors of the vehicles located on the right side, buses run on the left side of the traffic and counter to the general traffic flow.

Photo 1: Fully Segregated Median Busways

4.2.Stations

There are 33 stations in Avcılar-Söğütlüçeşme BRT corridor. Since running ways are limited with total two lanes, there is no passing lane at stations. Platform length is 60 m which allows two 26 m long bus or three 18 m bus to serve at the same time in the stations. Since BRT corridor is located in the middle of the highway, passengers' access to the stations is provided via under or over passes. Platforms and vehicles have the same level of height.

Photo 2: Median Station

4.3.Fare Collection

Fare collection is off-board. In Istanbul fares are fixed both in rail and bus transportation independent from the travel length. In order to decrease waiting times of buses in stations and accelerate the boarding, BRT uses same fixed tariff with other public transportation systems.

Photo 5: Off-Board Fare Collection

4.4.Service Plan

There are three lines as described before, which are operated 24 hours stopping at every station. Since the line has one lane in the both directions, there is no overtake capability of buses in the stations, thus different service types, such as express service is not applicable.

4.5.Information Technologies

Visual and audio information is provided in every bus for passengers. Real time information is gathered in command and control center. Every bus is tracked with GPS technologies and any emergency situation can be detected quickly.

Photo: GPS tracking of buses

5. Analysis

BRT system in Istanbul has all the components of classical BRT systems in the world. In this part of the study BRT system in Istanbul will be compared with three other BRT systems in the world. First best practice case is Curitiba RIT system in Brazil. Reason for choosing this case is RIT is the pioneer BRT implementation attempt starting from the 1970s and has a great success in terms of ridership and system performance. The other system is TransMilenio in Bogota in Colombia. This system is implemented at the end of the 1990s but the system coverage, ridership and performance is admirable because of its planning background. Third case is the Metrobus system in Mexico City in Mexico. This system started operation two years before Istanbul Metrobüs and more or less has same ridership with Istanbul. The population of the city, its density and increasing car usage are also similar to Istanbul,

Comparison of the systems is made in 5 categories: planning background; physical characteristics; operating characteristics; marketing, advertising, identity and image-building policies; and finally the ridership on the systems.

5.1.Planning Background

Daily trip rate is very high in Istanbul due to high population and development pattern of the city. Since there is limited area for development, the city has a linear urban form but very strong Central Business District (CBD). Although about half of daily trips are made by walking, the remaining half represents long trips between homes and working places. Passenger mobility is provided in Istanbul with road, marine and rail transport, but most of the trips are done via roads. Private car ownership is low compared to Western European cities but car usage rate is high and combined with ever-increasing rates of mobility, this causes traffic congestion in many arterials. Rail investments are present in the city, with a number of metro, LRT and tram lines, but their coverage is still limited and the completion of the full network takes long time to construct. Therefore, city officials decided to implement BRT as a cheaper and quicker solution to traffic problem.

Since the decision to implement the BRT was linked to traffic congestion and the existing mobility needs, the local government focused only on traffic issues and aimed at starting the operation in the shortest time possible. This meant that urban development plans and future development patterns were not considered; and as a result the system does not have any integration with the urban master plan, which was actually being prepared and about to be finalized at the same time with the BRT decision. Meanwhile a comprehensive transport plan is also being prepared for the city, studies for which have been carried out since the mid-2000s, again during the same time with the BRT decision. The BRT is not integrated into the transport plan either.

After the high ridership of the first phase, other corridors were implemented again without any coordination with urban master plan and urban transportation plan.

The system operates in the middle of D-100 Highway, which has already turned to an urban arterial, and thus land use pattern is mostly integrated with the road. Some of the stations in the European side are partially integrated with important nodes, such as universities, shopping malls, dense residential areas and commercial uses. These uses existed before BRT implementation; they are not a planning decision because of the Metrobüs construction. In the Asian part, the highway preserves its highway features, thus integration with land uses seems more complicated here. Since important land uses do not exist close to BRT stations (because they are at a reasonable distance to the highway), integration becomes weaker.

BRT system is also only partially integrated with rail system in the European side of the corridor. The integration is related to proximity of Metro and BRT stations only. Many of the bus and minibus operations are removed from the corridor, since Metrobüs has a higher carrying capacity. But there is opportunity to transfer to bus and minibus systems; İETT tried to integrate conventional bus stops to BRT stations. Metrobüs system is operating in the middle of highway, thus bike lanes are not applied. Bike integration does not exist; and there are no bike parking areas on the corridor. There are Park and Ride facilities in some stations. Since pedestrian infrastructure is very weak in the whole of Istanbul in spite of high pedestrian trip rates, integration with pedestrian areas and streets is also limited.

Information about the best-practice case studies of Curitiba, Bogota and Mexico are given in less detail and summarized in Table 1. Important findings of the comparison to note are as follows: all systems initiated the BRT projects due to congestion problems and high car usage rates, and therefore to improve public transport. In Curitiba, an additional aim was to control development, which is important since this leads to one of the best-known examples of integration between land-use planning and BRT implementation. In other cities too, integration with urban plans existed; and this seems to be one important shortcoming in Istanbul. Integration with other transport systems also appears to be limited in the Istanbul case. Interestingly, all systems have somewhat neglected integration with cycling, perhaps due to the low rate of cycling in these cities.

Table 1: Planning Background Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
Reasons to implement	uncontrolled development high car usage	high traffic congestion high private car ownership	poor public transport high car usage	high travel times high congestion poor public transport
Aim	integrated public transport reduced private car usage	reduce private car usage	increasing mobility reduced gas emissions	fast & economic transport solution to corridor
Integration with urban plans	yes	yes	yes	no
Integration with land use	trinary system zoning & land development policies	support long-term urban renewal prioritize walking & cycling	yes	no

Integration with rail systems	Not applicable	yes	no	limited
Integration with bus systems	yes	yes	no	Yes
Integration with Bicycle	no	partially	no	no
Existance of bike parks	no	yes	no	no
Existance of Park&Ride			no	some
Integration with pedestrians	yes	yes	yes	partially

5.2.Physical Characteristics

An important aspect that affects ridership is the physical characteristics of the systems, including location and design of the system. In this part, analysis is done in three categories. First physical components, then busways and finally stations and vehicles will be compared.

Table 2: Physical Components Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
BRT System Covarage	405 km	310 km	67 km	42 km
BRT Busways	65 km	84 km	67 km	42 km
Number of Stations	127	114	112	33
Average Distance Between Stations	600 m	790 m	600 m	1210 m
Off-Board Fare Collection	yes	yes	yes	yes
Control Center	yes	yes	yes	yes
Located Top 10 Corridors	yes	yes	yes	yes

As Curitiba is the first city that applied total BRT system, its network coverage is the highest. This is also due the feeder service network. In Istanbul there is not an official BRT feeder, thus BRT busway can be observed as the coverage of the system. But in Istanbul BRT corridor is fed by İETT and private buses, thus total system coverage is more than 42 km. In terms of station numbers and average distance between stations; Istanbul represents a faster system with much higher distances between its stations.

While determining stations' location, being a trip attraction point is an important factor, and especially in Asian side distances between stations increase.

Another important feature of BRT systems is off-board fare collection. Since it is time consuming to pay to the driver, the most effective way to decrease time needed to validate the ticket is off-board fare collection. Smart cards are also very effective to decrease time losses while boarding to the vehicle, off-board fare collection allows passengers to board vehicle not only from first door but also from all doors, which in turn decreases time needed for buses to wait in the stations. All four systems have off-board fare collection to increase the performance of the systems. Existence of control center tracking buses with GPS technologies lead to interfere to buses quickly if an emergency situation occurs. Thus, whole system is not affected negatively from the interruption.

If the system is constructed along one of the top 10 corridors, it also increases the number of the passengers using it in daily trips. Same as all three best practice cases, BRT system in Istanbul is implemented on one of the most important arterials.

Table 3: Busways Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
Busways				
Segregated Right-of Way	fully segregated	fully segregated	fully segregated	fully segregated
Alignment	median	median	median	median
Intersection Treatment	yes	yes	yes	not applicable
Passing Lanes at Stations	%20 of total	%100 of total	no	no
Station Set Back from Intersection	yes	yes	no	not applicable
Center stations	yes	yes	yes	Yes

Segregated lanes are the distinctive characteristics of BRT systems when compared to conventional bus operations. It leads buses to move quicker and not to be affected by traffic congestions. All systems analysed here have fully segregated busways. BRT system in Istanbul crosses the Bosphorus Bridge, the only place where BRT buses flow in the mixed traffic is on the bridge: that is because the property of the bridge belongs to General Directorate of Highways, and this authority did not permit reserving one lane exclusively to BRT. But buses enter and exit the bridge in

dedicated lanes, and since it is the approach to the bridge that suffers from worst traffic congestion, the BRT is not affected much by congestion.

All systems are located in the medium lane which prevents interruptions from other traffic. But Istanbul has the advantage since it runs on the highway that already has most junctions in grade-separation; and therefore the BRT does not have any at-grade intersections. There is no intersection where BRT buses have to stop for traffic lights.

Passing lanes at intersections is another feature of the system that increases the ridership. Passing lanes located at the stations prevent buses to wait for the other bus to move. Also it gives opportunity to operate express services which do not stop at all stations, just at those with higher passenger demand. Passing lanes may be one of the reasons that Curitiba and Bogota BRT systems have higher ridership than Mexico City and Istanbul BRT because this gives them an opportunity to provide higher service levels. Since the highway that the Metrobüs was implemented has a limited area, it was hard to implement passing lanes, thus system has only two lanes both in the corridor and at the stations that decreases the passenger numbers carried.

Access to the station has to be safe for passengers using the system, thus stations should be located at a distance to intersections not to conflict pedestrian movement with vehicle traffic. Since stations in Curitiba, Bogota and Mexico City are at grade intersection set back becomes crucial. Stations are located in Curitiba and Bogota at a distance from intersection to protect pedestrians from flowing traffic. But this type of treatment was not applied in Mexico City. This kind of precaution is not applicable for İstanbul BRT, because passengers can only access to stations via pedestrian overpasses.

While using median running-ways center station which serves both directions of BRT system makes transfers easier and it is also more cost-effective. All four systems have center stations.

In Istanbul buses and stations have same level, but drivers are afraid of crashing to the platform, thus they do not dock to the station. This sometimes leads passengers either to jump a long distance or step down and step up to access the vehicle. This also decreases the performance of the system. Safe and comfortable station design is the distinctive characteristics of BRT systems when compared to other bus operations. In RIT, TransMilenio and Metrobus systems, stations have safe and comfortable design. In RIT tube stations are used, in Bogota and Mexico City there are similar station design with Curitiba. This type of design provides total weather protection. Also they are safer, because they have sliding doors protecting people from stepping into the road. Despite having diverse severe weather conditions in Istanbul, weather protection is very limited, since stations have only roofs. Also neither sliding doors nor guard rails exist to protect passengers from flowing bus traffic. Especially in peak hours people wait for the bus standing on the road. Since BRT operations are very frequent in Istanbul, seating are not provided at the stations. Since off-board fare collection is a feature of BRT operation, the number of doors on buses becomes important. Passengers can use all doors, time losses decrease while boarding. In RIT system buses have 5 doors, the other three systems are using buses

with 4 doors. Frequency of BRT operation is very high especially in peak hours, thus platform length should be long enough to accommodate more than one bus at the same time to decrease waiting times of buses in each stations. There are sub-stops and docking bays in three best practice cases. In Istanbul platform length is enough for 3 buses to stop. Sliding doors have another important mission, that is to define the exact place where buses will stop and this informs passengers to wait close to the doors. Also it helps handicapped users to know where to wait to board easily with wheelchair or with special pavements blind people can be directed to the doors. Mexico City and Istanbul BRT systems do not have sliding doors.

Table 4: Stations and Vehicles Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
Platform Level Boarding	yes	yes	yes	yes
Safe and Comfortable Stations	yes	yes	yes	yes
Number of Doors on Bus	5	4	4	4
Docking Bays and Sub-Stops	yes	yes	yes	yes
Sliding Doors in BRT Stations	yes	yes	no	No

5.3.Operation Characteristics

Having good feeder services is a very important determinant that increases ridership of systems. Curitiba and Bogota systems have feeder operations to support BRT system. Mexico City and Istanbul has only BRT corridor not including an official feeder system. But these two systems have conventional bus operations to support the system which is only based on proximity of stations. Istanbul has a good conventional bus feeder operation but vehicles cannot enter the corridor. Buses discharge people to a bus stop close to BRT stations.

BRT systems have higher commercial speeds then conventional bus operations, because like rail operations they have their own right-of-way. But especially intersections slow down vehicles when they meet mixed traffic and decrease commercial speeds. All three best practice cases have at grade crossings and intersections. Thus commercial speeds are 17,5 km/h for Curitiba, 18-28 km/h for Bogota and it is less than 20 km/h for Mexico City. Since Metrobüs in İstanbul is located in the middle of highway and intersections are eliminated from flowing traffic, commercial speeds are as high as 35-40 km/h, which results in faster and more reliable operations.

İstanbul Mertobüs has the highest frequency especially in peak hours among other cases. Also off-peak intervals between buses are very short which increases total

ridership of the system. In peak hours every 15 seconds a bus leaves the station. 3 buses dispatch from terminal stations and in order to meet high demand on crowded stations some buses leave terminal stations empty. In day time, off-peak intervals are 1 minute. The system is operated 24 hours both in weekdays and weekends while this is not the case in any of the other comparison systems. It can be concluded that operating characteristics are quite superior in IstanbulMetrobüs, providing a high quality service level. On the other hand, as mentioned before, there is only one corridor in Istanbul and since there are no passing lanes it is not possible to operate express or limited services. Despite having only one corridor there are 3 different lines in the same corridor, defined by different lengths. Same electronic card is used in Istanbul for all transportation modes except for minibuses, which operate with cash payment. Same travelcards are used for Metrobüs also; this provides easy transfers between other transport modes.

Table 5: Operation Characteristics Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
Operational Mode	trunk-feeder	trunk-feeder	trunk-only	trunk-only
Commercial Speed	17,5 km/h	18-28 kım/h	<20 km/h	35-40 km/h
Peak Frequency		2 minutes	48 seconds	15 seconds
Off-Peak Frequency		6 minutes		1 minute
Hours of Operation	weekday 20 hours	weekday 5am-11pm	weekday 4:30am-0:30am	weekday 24 hours
	weekend 19 hours	weekend 6am-11pm	weekend 4:30am-0:30am	weekend 24 hours
Multiple Routes	yes	yes	yes	No
Express, Limited and Local Services	yes	yes	no	No
Multi Corridor Network	yes	yes	yes	yes
Express, Limited and Local Services	yes	yes	no	No

Fare Integration	yes	yes	yes	Yes
Automated Fare Collection & Fare Verification	yes	yes	yes	Yes

5.4.Marketing, Advertising, Identity and Image Building Policies

Stations and vehicles should be distinctive for BRT systems, because they show the customer that they provide different and higher-quality services than conventional bus operations. Since the idea behind implementation of BRT is "think rail, use buses", it should provide comfortable, reliable and frequent services like rail systems, thus it should have different vehicle and station designs like tube stations in Curitiba or Bogota. In Istanbul, buses and stations are different than conventional bus operations, but unlike other cases, stations do not provide full protection for users like tube stations do. Also for increasing ridership branding of the systems by local private or public authorities is very important. Before starting the operation in Curitiba, Bogota and Mexico City a large campaign was made to introduce BRT systems to the users. Since planning and implementation was very quick in Istanbul branding was very limited initially. But now there are some commercials for the system.

Table 6: Marketing, Advertising, Identity and Image Building Policies Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
Stations	distinctive	distinctive	distinctive	distinctive
Vehicles	distinctive	distinctive	distinctive	distinctive
Branding	yes	yes	yes	Initially limited; improved today

5.5.Ridership on the System

After presenting the features that are likely to affect the ridership and performance of the systems, in the last part ridership on systems will be discussed. As it is stated before Curitiba is the pioneer BRT system and because of its integrated planning background and high coverage, total ridership is very high with 2.26 million passengers per day. Since there are 6 different corridors and multi centered urban pattern peak hour passenger/hour/direction are only 13.000. When the only BRT

corridor of 65 km without the feeder services are taken into consideration, passengers carried per km is 34.770 in Curitiba. (Table 7)

TransMilenio in Bogota also appears to be a highly used system: 1.65 million passengers are carried daily on the corridor. In peak hours passenger/hour/direction is 34.000 on the 84 km BRT corridor. 19.047 passengers are carried per km of the BRT corridor.

Metrobus in Mexico City has ridership numbers close to Istanbul: total number of passengers is 620.000 daily on 62 km route. Approximately 9.250 passengers are carried per km. In peak hours, it carries 9.000 passenger/hour/direction.

Total number of passengers carried daily in İstanbul Metrobüs is 600.000. With 42 km route length, this amounts to 14.280 passengers carried per km. It carries 21.400 in peak hour passenger/hour/direction.

When the total ridership is compared Curitiba and Bogota has very high numbers but they have very extensive feeder services too. Despite using only existing conventional bus operations and having a rather limited integration based on proximity of stations, İstanbul BRT has a rather high ridership, higher than the BRT in Mexico City. Also Istanbul has shortest route length when compared to other systems. The reason to have high ridership for Istanbul is probably a combination of two factors: the corridor's location and high service level. It is located on one of the most demanded axis and it provides a rather fast journey with very frequent services and for 24 hours all days of the week. In addition, the system provides a relatively fast crossing across the Bosphorus, a major physical barrier for the two sides of the city. Also many of the conventional and minibus operations are removed from this corridor, thus people have to use the system. Despite having high frequency especially in peak hours, it is often reported that operation is inadequate to meet the demand.

Table 7: Ridership Checklist

	Curitiba	**Bogota**	**Mexico City**	**İstanbul**
Passenger Numbers	2,26 million/day	1,6 milion/day	620.000/day	600.000/day
Peak Hour Passenger/hour/direction	13,000	43,000	9,000	30,000
Passenger Per Km	34,770	19,047	9,000	14,280

6. Results and Conclusion

When compared to the three well-known best-practice cases of BRT, the Istanbul Metrobüs is found to have a mixed performance. Its major weakness is in its planning background: the system was developed without any integration into the urban development plan and the transportation plan of the city. This has two consequences:

- The Istanbul Metrobüs is developed with only existing passenger demand considerations; and therefore the corridor serves currently existing development areas that already have very high mobility needs. This maybe one of the reason for its high ridership. Such a strategy of serving the existing high-demand corridor may be beneficial indeed to establish the system as a success in its early years of operation. And Istanbul Metrobüs is a young system that proved to be successful in ridership figures. However, this lack of coordination between the system's planning and urban planning need to be overcome in the future in later stages since the urban plans will inevitably change demand patterns, that the Metrobüs will have to follow.
- Lack of integration into the transportation plan meant that the system was not integrated with existing metro and tram stations at all initially. No transfer stations were designed although some rail stations were in close proximity to the BRT. The same goes for conventional bus systems and stops. They were also poorly integrated although this improved in later years. The transfer stations with rail systems also improved although problems still exist. This is obviously a negative aspect in terms of planning; but it may have two very conflicting repercussions: had the system been better integrated with rail, the passenger numbers might be even higher; however, the opposite appears to be the case: the BRT system competes with the (Light) Metro system and it is stated by the Istanbul Rail Operating Agency that it attracted many passengers from the rail systems.

In spite of these apparent problems of integration, the system carries a reasonably high number of passengers. Its number of passengers per km of route is lower than the systems in Curitiba and Bogota, but higher than that in Mexico City. Furthermore, its number of passengers per km of route is higher than that of the two Metro systems of the city combined, which is about 13,500 passengers/km according to figures given by Özgür (2009). This high level of ridership shows that the level of service provided is a very important factor since this is the clear strength of this system when compared to the best-practice cases. The strong points of the Istanbul BRT can be listed as follows:

- Due to its design with higher distances between stations and full-segregation, it provides the highest speed of service when compared with the best-practice cases, and this is extremely important in a large city like Istanbul where commuting from outer suburbs to the CBD is the dominant mobility pattern.
- Furthermore, the system operates with very high frequency and 24 hour service – in both aspects, the system out-performs the best-practice cases as well as the Istanbul Metro systems.

- Moreover, the Bosphorus crossing, a condition specific to Istanbul, is a major advantage since there is no rail crossing yet and therefore this is the first rapid transit connection between the two sides of the city.
- Although it was noted that integration with other transport modes was limited, conventional buses and minibuses operating at the BRT corridor were reorganized and mostly removed, which made the BRT system the favoured choice in most cases.

Finally, the comparison with best-practice cases also provides some lessons to improve the Istanbul Metrobüs:

- Station design needs to be improved for both safety and weather protection.
- In future phases, passing lanes should be incorporated in order to allow for faster operation as well as express services.
- Integration of non-motorised modes, such as cycling and walking, should be improved.
- As already mentioned above, integration with rail systems need to be improved; and future phases must be planned in integration with the urban development plan of the city.

Historic preservation in Fast-Changing Cities - Case Study of the Hankow Historic Concession District

Cheng Shidan[1] ,Zhang Ming, Huang Lingjiang, Li kuncheng

Abstract

During the past three decades, since China's reform and opening up in 1979, there has been rapid urbanization and urban change in most Chinese cities as a consequence of economic growth. Facing the need for urban development, many local officials regard new construction as the representation of advanced and modern development as well as political achievement. Therefore there are many forces to change the appearance of the old city with consequences for historic buildings and districts which are of great cultural value but in poor condition. Although recently the concepts of historic preservation have been more widely accepted, there is still a challenge to meet the need of economic growth.

Taking the Hankow historic concession district as the case study, this paper aims to analyze historic preservation and renewal in fast-changing cities. The Hankow historic concession district was formed by Western countries' aggression in China during 1861-1898, its formation was greatly influenced by western cultures, and meanwhile it embodied the traditional and regional cultures of China. Presently this district has become an important part of the modern Wuhan's multiculturalism. The fast growth of Wuhan' urbanization has brought pressures on this district from both internal and external aspects, including local residents' urgent demand to improve their living environment and authority's expectation to maximize economic value of the land in the city center. Therefore historic buildings were once regarded as the obstacle of urban development, but in the last decade the value of the Hankow historic concession district has attracted more attention from the local authority, developers and the public.

The local authority has offered legal protection to this district at building, block and urban levels: First, regulations protect listed historic buildings; second, overall historic preservation of three blocks with a high density of well-preserved historic heritage and buildings has been undertaken; third, Hankow historic concession district has been ranked one of four urban historic preservation districts. Developers have also realized that historic buildings

[1] Department of Architecture, School of Urban Design Wuhan University, Wuhan, China ,chsd821@163.com

embody great economic value as well as cultural value, an example given in the paper shows that the integration of the old and new can create the urban place of historic and livable features as well as commercial success. Public and small enterprises were also encouraged to participate in the restoration and renewal of historic buildings by renewing internal conditions with the external appearance unchanged.
This study concludes that historic preservation and development seem now to be better balanced in Hankow based upon its urban characters and condition in the "fast changing" era of Wuhan. It also shows that the revitalizing of historic district needs both efforts and cooperation from the public and private sectors.

1. Introduction

Since the reform and opening-up in 1979, China has witnessed high economy growth, rapid urbanization as well as ever-expanding city sizes. Facing the urban growth imperative, many China officials regard development as the symbol of urban modernization and political achievements. Nearly all China cities have massive urban construction undertaken under a variety of rhetoric over the past two decades, therefore urban growth turned out to be the explosive shift only instead of conventional evolution. Many historic cities have suffered, under those drastic urban transformations, various damages, even erasement of extinction and were replaced by the universal urban style. Such development homogenization puts all cities in one appearance, and thus the urban character crisis incurred raised concerns about historic preservation in public who increasingly recognizes that historic places not only demonstrate culture heritage but also work as the basis to build up urban character.

There are few well-preserved historic towns in urban China due to weathering through the ages and continued destruction or devastation, in which case the historic areas and districts with relatively concentrated historic buildings and still with residents have emerged into the primary carrier of urban culture heritage. China started to incorporate historic districts into its historic preservation initiatives in 1986, and then a number of historic districts were registered and conserved all over the country with Wuhan among the second-round list of National Historic Cultural City. For the purpose of preservation and usage of urban historic heritage and urban cultural character, Wuhan designated 4 historic townscape area, of which the Hankow historic concession district best survived owing to its historic buildings which is the greatest in number, with the most integral and best in conditions. At the same time, 4 of the 10 historic districts of the whole city lie in the areas according to Wuhan urban preservation planning.

The Hankow historic concession district is the legacy of former western colonial powers invading China, and served as the major intermediary to usher in western civilization in Wuhan. Its urban pattern was greatly affected by western

cultures while taking shape however still beared the imprints of Chinese traditional and Wuhan local cultures, and presently has become a major part of the culture diversity of Wuhan. During recent rapid urbanization of Wuhan, the Hankow historic concession district confronted pressures from both inside and outside. On one hand, local residents are in urgent need for living improvement due to heavily deteriorated infrastructure. On the other hand, because of the scarcity of land resource, the authority and developers attempt to maximize land value of the downtown. The Hankow historic concession district has therefore long been in the dilemma of historic preservation vs. urban redevelopment. With the transition from preservation of historic building to that of entire region, the government-led historic preservation initiatives were shifted from sheer regulatory conservation to the revitalization of historic neighborhoods.

2. The Making of Hankow historic concession district

Hankow was specified as a trading port along the Yangtze River according to unequal treaties with western powers after the Second Anglo-Chinese War between 1856-1860. The concessions of the U.K, Russia, French, Germany and Japan were established one another after 1861, covering largely from present Jianghan Road down to Mayang Street and in between the Yanjiang Road to the east and the Zhongshan Road to the west, totaling about 195 ha., bringing into being a riverside development strip. Infill development took place lengthwise afterwards as the territory expanded, forming a pattern of street block fronting the Yangtze River against the Jinghan Railway line.

The internal development in each concession was totally independent including urban planning, road system, drainage system, water supply and power system planning etc. However due to the adjacence to one another, the external transport links needed to be considered. Urban district pattern appeared in the early-opened British concession. Thus the later concession developments referred to this mode which followed uniform planning rules such as wharf, warehouse and yard along the riverside area for water carriage and distribution, layout of large scale public building along the riverside main road to improve the riverside landscape. The external side of the concession was functioned as commercial area. Residential and office area were planned between Shengli Street and Zhongshan Road with other functions of embassy, bank, hospital, school, church, trading, restaurants and other public buildings and residence, villa, residential and other residence etc. Thus quiet and noisy area was distinct between internal and external of the concession area. Such layout reflected the modern urban zoning characteristics, while the urban form still followed the traditional European classical style with tall buildings at the end of the main streets, and the continuity of the street interface were paid certain attention to.

After the establishment of the concessions of the five nations, consultants of another seven nations were setup. Since then, a great number of western –style buildings appeared in Wuhan and the unprecedented construction peak occured in the Wuhan urban development history. With the rise of Westernization Movement, many modern factories, schools were then built in the concession area, including both pure Western-style and mixed-Chinese and western style, together with the modern factories, residential alleys and private villa by the public, these buildings became the symbol of the transformation from the traditional style to the modern.

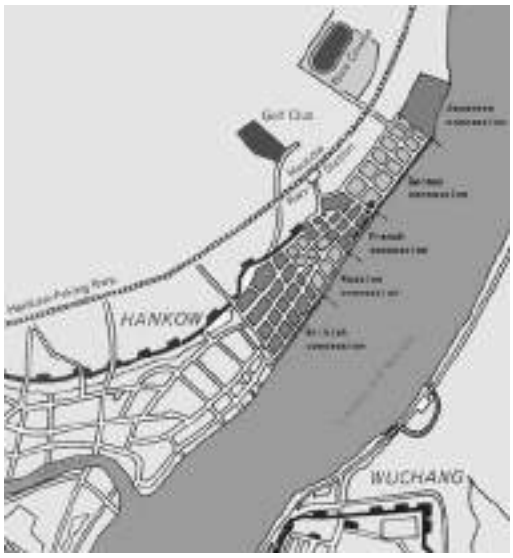

Figure 1. The Map of Hankow historic concession

3. The Present Situation in Hankow historic concession district

Urban Wuhan has changed radically since the reform and opening-up policy and in only 30 years new building made up 90% of the total in its 8,000 Km2 of region, which accelerated the disappearance of historic building in its downtown, in particular of the traditional wooden building that was left few due to its poor fire-and-erosion resistance, as compared to stone building that remains many thanks to its safety and durability, especially in the Hankow historic concession district. Nevertheless, the area is confronted with demolishment from outside and plagued with redevelopment of itself as well. In general, there are five issues in present Hankow historic concession district as follows.

(1)Damage to Historical Townscape

Due to urbanization shock, the Hankow historic concession district has also undertaken sweeping demolishment and development, especially in the north

part where few historic buildings were left and they are surrounded by new constructions. Even for the well-conserved old neighborhood in the south part, there are still some less harmonious developments resulting in serious inconsistency with the historical townscape in the aspects of the massing, color, style of new buildings. Moreover, the original spatial pattern and townscape have been damaged badly due to lots of environment variation or unauthorized constructions within their sites.

(2)Decline of Urban Vitality

The Hankow historic concession district was at one time the high-end quarter with many outstanding colonial buildings compete with public facilities and so was the place of dwelling, leisure and entertainment of the upper-middle class then. Its infrastructure got dilapidated over the time, and in addition, hollowing-out can be found downtown as its surroundings kept growing and new high-standard estates gave incentive to resettlements by downtown population. What are worse, more commercial shopping centers are settled during the period of urbanism and have a negative impact on commercial activities in the Jianghanlu Commercial Street, the symbol of Wuhan commercial hub.

(3)Deterioration of Building Quality

Many changes have been made in the use of historic buildings in the area, such as housing turning into office, restaurant, recreation and etc. Some former single family houses were shared now by multiple families, leading to overload operation. What is more, historic buildings of the area have serviced generally longer than their physical life, their safety is declining year by year and even some have become dilapidated.

(4)Underdeveloped Infrastructure

It is evident that the standards of existing infrastructure are lower than those of modern urban living. Quite a lot of old neighborhoods even lack of sanitary fittings, most existing facilities of waters supply, drainage, electricity and etc. grew physically dilapidated, and new facilities like gas and CCTV remain substandard. Many of the roads have worn down without repair for many years. The Infrastructure that cannot meet the requirements of modern cities therefore has yet to be either improved or increased.

(5)Inadequate public space

Years of unauthorized developments keep reducing the otherwise already less public spaces. The surge of private cars ownership in recent years brings about parking problems that in turn add to the decrease of public space. New developments have increased greatly, which leads to more inadequate public spaces.

4. The Preservation of Hankow historic concession district

Urban character and culture heritage gain increasing attention with people's living standard's rising over the decade, and the public come to accept the historic preservation. In the recent decade, as the increase of living standard, more attention has been paid to the urban characteristic and cultural heritage. The concepts for heritage conservation ideas were gradually accepted by the public. The preservation for cultural heritage is reinforced by the local authority, and relatively complete classification, grades, hierarchical protection system was formed the main responsibility of different protection units has been clarified.

The preservation units are classified as two types: heritage conservation units and outstanding historical building. The former is the name for the unmovable cultural relics according to the National Heritage Preservation Codes and is of the highest level of protection; the latter refers to all the listed historic buildings by Wuhan urban Cultural heritage protection regulations and managed by the local Housing Managing Bureau.

The local urban planning bureau is responsible for the preservation of urban level and related planning strategies. The preservation unit is classified as historic district and historic scene district. The former refers to the districts which reflect traditional historic scene and local characters with relatively more numbers of historic relics, sites and buildings; The latter is greater in scale and refers to districts with historic buildings, urban patterns, building type and streetscape. With the increasing awareness of cultural heritage preservation, the range of preservation work expanded and has experienced the process from the level of building preservation to the level of historic environment.

（1） The Preservation of Historic Buildings

The Hankow historic concession district preservation began with the protection of primary historic buildings in it by filing and reviewing of Heritage Conservation Unit and implementation of corresponding measures in accordance with the National Heritage Act. Heritage Conservation Unit is classified by its significance into the 3 levels of State, province and city (county) and published by governments. 34 in all in Hankow historic concession district have succeeded in the register of Heritage Conservation Units since 1982, including 4 at State level, 5 at province level and 25 at city level. The local government designates boundaries of conservation and development control, sets up protection sign, files registry, in conformity with relevant rules of the "Measures of Hubei Province for enforcement of the National Heritage Act" and "Conservation measures of Wuhan Local government for Heritage Conservation Unit". Protection limit is confined to 10 meters outside Heritage Conservation Unit whereas its counterpart of development control largely to 20 meters outside it, and within it no development or act is allowed to harm the Heritage Conservation Unit or its surroundings. The style, height, mass, color must go harmonious with those of Heritage Conservation Unit and its surroundings upon new development, major repair or reconstruction within the development

control area. The proposals of project, maintenance, or reconstruction should get permitted by corresponding culture heritage authorities and approved by urban planning authorizes before its construction.

Criteria are quite strict in the selection of Heritage Conservation Unit, focusing only on those of historical, art, scientific significance and often closely related to history events or figures, as a result of which a lot of significant historic buildings have no access to legal protection, leading to a simplistic approach to preservation initiative. The local government therefore enacted the “Measures for Conservation and Management of Wuhan Townscape area and Outstanding Historic Building ”in 2003, broadening the scope of historic buildings, which specifies those over 30 years old and of historical or cultural value as Outstanding Historic Building, and set explicitly conservation guidelines, duties of competent agencies, owners and users. On the basis of a survey by municipal housing administration department, reviewed by culture heritage and urban planning authorizes, and permitted by the local government, 54 in Hankow historic concession district are identified as Outstanding Historic Building with 8 at the first and 46 at the second class.

To advance further its regulation and rule for cultural heritage conservation, make the preservation endeavor more specific, for the ease of application, thus for better conservation, Wuhan enacted the “Wuhan Regulations for Historic Preservation "in 2007, taking it as an important agenda. Meanwhile, the authority made more commitment to it and have repaired some historic buildings, for instance, the 4 in Hankow historic concession district have been well maintained and greatly improved their conditions, guided by the principles of cultural heritage repair and technical requirements.

（2） The Preservation of Townscape Area and Historic District

Because of the prominence of Hankow historic concession district in the evolution of urban Wuhan, Wuhan Master Plan 2006 specified its south as one of the 4 townscape areas that hold the greatest amount of historic buildings and highest historical values, noting that priority should be put in maintaining the integrity of downtown characters and their continuity, appropriate designation of character-compatible area, restructure of land use, and control of population. Townscape area should protect styles of historic building, regulate those of new buildings to make them in harmony with their contexts, in principle no change should be made to existing road patterns and current names of streets and places be retained. Also, the master plan had mapped 4 historic districts within the historic concession quarter, that is, the neighborhoods between Jianghan Road and Zhongshan Road, along Qingdao Road, around venue of the “CCP August 7th Conference”, and around Yiyuan Road, each with conservation priorities.

The Wuhan Historic and Townscape Region System Planning by Urban Planning Bureau in 2009 extended historic conservation sites, adding 12 historic districts, and for the first time covering the quarter to the south of Jinghan Avenue in the north of Hankow historic concession district. To carry out historic preservation in the Master Plan 2011 and in the system planning above, explore the methods of creating Regulatory Detailed Planning concerning historic districts, and better serve urban regulation, Urban Planning Bureau is coordinating the formulation of Regulatory Detailed Planning for the 4 historic districts in Hankow historic concession district, the work of which is under review now.

Table1. Authorities for Cultural Heritage Preservation and Their Duties in Wuhan

Authority		Units(immovable heritage)	Work
Municipal Government	Urban Planning Bureau	Townscape region Historic district Cultural heritage units Outstanding historic building	Planning and administration of historic heritage, including plan creation and review.
	Housing Administration Bureau	Outstanding historic building Ordinary historic building	Administrative control of the safety, use, maintenance of outstanding and ordinary historic buildings.
	Cultural Heritage Bureau	Cultural heritage units	Administrative control of townscape region, historic heritage unit, and outstanding historic building in accordance with relevant laws and rules.

5. The Revitalization of Hankow historic concession district

How to achieve sustainable growth in historic heritage arises, as the preservation agenda in the Hankow historic concession district shifts from unit to outstanding Historic Building, and single Monumental architecture to historic district and even the morphology of entire downtown. The experiences by Shanghai, Tianjin, among others, that link historic preservation with urban growth arouse extensive attentions, and the initiative to combine conservation with re-use came to prevail in addressing historic districts. That process

developed rapidly, during the transition the government, developer and the public all vigorously provide support. As such, the Hankow historic concession district area began its recovery only several years later.

(1)Government Developing Revitalization Scheme of Historic District

Economy-oriented land use Restructure became of the priority of the revitalization undertaking in historic districts. The Hankow historic concession district used to be the upscale business center, the first agglomeration of finance and trade services in Wuhan's history second only to that in Shanghai. Based on the local government's strategy, the Urban Planning Bureau worked out the "Development Planning of Wuhan Riverside CBD "in 2008, to make full use of cultural heritage advantages of the historic concession area, and promote it as the finance and business center , creative industry base, and culture-tourism destination, 5 major strategies of modern service industry are developed to build on business headquarter economy, scale up boutique business, move forward with culture-creative industry, integrate IT industry, enhance tourism and entertainment industry. Meanwhile, various conservation models, such as priority protection, coordinated protection, and development protection, are adopted to featured locations within the historic concession area and on specific basis of different sites.

During building the Riverside CBD, the Qingdao Road region initiated the protective development agenda of Wuhan's historic concession district that has to be demolished in part because the Yangtze River Tunnel runs through beneath it. The negative effect taken as a catalyst, the area above the tunnel is being redeveloped as public space, around which a pedestrian space is under construction complete with culture-creative industry, commerce, finance, tourism and entertainment, adapting to modern needs, adopting new features, boosting vitality, and improving environment through the conservation, rehabilitation and redevelopment.

(2)Developers Shaping Mix of Old New Dynamic Neighborhood

The success of Shanghai's Xintiandi project demonstrated a new approach to Wuhan's urban renewal, i.e. linking preservation to development by converting history resource into commercial resource, which was applied once more by the developer to Wuhan Tiandi project located in the former Japan's Hankow concession in 2005. Outside the downtown conservation area, the site is allowed for massive development. Instead of scrap and build redevelopment, it kept all of the 9 historic buildings within its site that are neither Heritage Conservation Unit nor Outstanding Historic Building registered by the local government, undertook renovation and alteration work, and added new use, making the historic building radiating new unique charm, well blending in with surrounding modern buildings, creating an original Hankow-like atmosphere with retail, restaurant, entertainment, business, hotel and etc. The premise gets widely popular since its completion in 2009 and now becomes of a city branding. Its success rests not only in set of modern urban design elements like

mix-use, compact configuration, pedestrian circulation, diversified public space and etc., but more in deliberate conservation and subtle remaking of historic elements integrated into modern life, in which small fashion buildings meets old-fashioned mansion, street pool, old trees, gallery, shop, restaurant, café, and bars all come together, whereas people are exposed to the history and culture of Wuhan in their leisure-time. The project brings people about the recognition that historic preservation and urban development can get along.

(3)Partnership and Re-use of Historic Buildings

The Hankow historic concession district's preservation endeavor is increasingly focusing on the sustainable growth of historic heritage. The Municipal Housing Administration Bureau established the re-use principle of outstanding historic building, asking to make full use of value of Outstanding Historic Building and well integrate its social and economic benefits, by function replacement, interior alteration, environment making, and commercial operation, in light of the characteristics and modern function, based on retaining original style and inheriting history and culture.

Some strong enterprises began investing heavily in the renovation of Outstanding Historic Buildings to host them. The former French Calyon is repaired and rented by Agricultural Bank of China Hubei Branch. Another, Tukunshan mansion, after a massive renovation by China Oil and Foodstuffs Corporation, has become a place for dining and gathering. Those along the river within the former British concession also did it, turning into nostalgic café or bar street. Many artists also came into the quarter refitting old houses into studio, salon, gallery, and freelance artists flock around the Lanling Road, known as "artist village" within the former Russian concession.

Conclusions

The historic concession district is the shift of Wuhan urban spatial form from the traditional to the modern development. In the recent 100 years, the communication and integration of Chinese and foreign cultures have left deep imprint on the urban form etc., which are considered as the valuable for the future urban development. In the rapid growth of urbanization in Wuhan, the concession district has been in the conflicts between conservation and development and experienced the process from the sharp opposition in the beginning to the pursuit of win-win situation and this process also represents the social and economic change of Wuhan. The acceptance of the value and importance of historic preservation by the public, the authority and the real estate could promote the historic district from decline to revival. In the background of "chasing the new change" era in China, Wuhan is exploring an unique way to balance the preservation and development in the historic district. However, according to the case study of historic concession of Hankow, a number of aspects in preservation and development are in need of improvement. For example, in the aspect of historic preservation, the public resources are almost entirely focused on cultural relics protection units and

outstanding historic buildings, while neglecting of the preservation of general historic buildings, which results in the further deterioration of the overall environment of the historic districts.

On the other hand, in recent years, the re-use of the historic district which aims at revival is in the ascendant development, however with a too strong economic driving force underlying. This kind of development led to the contrary results to the basic principles of historic preservation, such as forcing relocation of local residents for the purpose of commercial development, manufacture of fake antiques to maintain the historic style of the old city etc, and it is clearly shown that historic preservation still needs research and thinking, as well as further legislative protection and public participation. Only when historic preservation is regarded as an universally shared value, could the government, developers and the public form a joint force, and promote the historic districts from decline to revival, and truly realize the sustainable development of the historical heritage.

Abstract
The ESPON Climate project is an Applied Research Project conducted within the ESPON 2013 Programme. The project can be considered as a response to the EU 2007 Territorial Agenda, Priority 5, which stipulates a need for developing Cohesion Policy with respect to territorially differentiated effects of climate change and for further development of transregrional approaches to overcome natural hazards. More explicitly, ESPON Climate also addresses direction given in EU legislation from the EU White Paper "Adapting to climate change: Towards a European framework for action" which states that strategic approaches to spatial planning are needed for territorial development.

In consideration of this policy background, the ESPON Climate project produced a Pan-European vulnerability assessment which identifies regional typologies through analysis of exposure, sensitivity impact and adaptive capacity as components of overall vulnerability. It creates a basis for tailored-made strategies for adaptation due to the regional specificity emphasised within the project. These regional responses to climate change are further addressed within the seven case studies evaluated and communicate the diversity of responses to climatic stimuli. The project provides a territorial focus which is commonly lacking in most related studies. The focus is one which addresses regions within and across European territories rather than maintaining the more commonly used sectoral focus. The project also addresses the need to consider Europe as a whole, to assess what consequences European regions will face in regard to climate change, and how this affects the competitiveness of Europe as a whole and the cohesion of European territories. Through this assessment, ESPON Climate creates an evidence base for policy through possible scenario outcomes. Though the project does not provide a clear cut forecast, it offers a basis for recommendations for policy development toward climate change adaptation.

Concluding findings of the project provide policy recommendations for the development of European regions. The analysis identifies hot spots, or areas most affected by climate change, emphasising the need for developing tailor-made adaptation strategies for example in Southern Europe and for areas such as the Alps and the Mediterranean where tourism will be greatly affected. Also identified are the challenges to spatial planning and which types of regions should be targeted in terms of increasing emission reduction measures. The analysis additionally establishes that countries which are most highly affected have lower adaptive capacity and that this is contradictory to current and future aims of territorial cohesion. These and other findings of the project assist in the understanding and implementation of context appropriate strategies. These strategies will be crucial in overcoming present and future challenges to territorial cohesion and in achieving a harmonization of territorial development.

Acknowledgement

This brief paper is derived from the more extensive literature found within the ESPON Climate Final Scientific Report (2011) and the forthcoming chapter 'Implications for territorial development and challenges for the territorial cohesion of the EC' in *European climate vulnerabilities and adaptation: A spatial planning perspective* (Greiving and Schmidt-Thomé, forthcoming). The reader is encouraged to consult these documents for further information.

1. Introduction to Brief Policy Background

The European Union is currently pressed by many challenges including unemployment, financial crisis, demographic change, movement toward a low-carbon economy and the development of strategies for climate change adaptation. Development and implementation of responses to these challenges necessitates action and initiatives within both vertical (EU, national, and regional levels) and horizontal (across sector) dimensions of governance. This is particularly the case when considering efforts within EU competitiveness and Cohesion Policy which must take into account the spatially differentiated impacts of climate change. Anticipated changes will produce significant economic, social and environmental impact which will vary largely by region, sector, and social groups. Challenges posed by these changes require a place-based approach to actions taken toward implementation of adaptation strategies. This is particularly due to the spatial variation of climatic impacts. With regard to mitigation, the Europe 2020 Strategy adopted by the European Council in 2010 provides specific energy goals toward reducing greenhouse gas emissions and increasing energy security. The Strategy additionally specifies the following priorities (COM, 2010, p. 3):

– Smart growth: developing an economy based on knowledge and innovation.
– Sustainable growth: promoting a more resource efficient, greener and more competitive economy
– Inclusive growth: fostering a high-employment economy delivering social and territorial cohesion

The Strategy also includes a 'Resource efficient Europe' as one of its seven flagship initiatives which, in combination with the above-stated priorities, contributes to both climate change mitigation as well as EU competitiveness. This is achieved through the Strategy's "smart, sustainable and inclusive growth" agenda which aims to reduce emissions and to encourage positive economic growth (COM, 2010, p. 13). The importance of this in relation to EU competitiveness is apparent in the need for reducing energy insecurity and in reflection of pledges already made for emission reductions within the 2009 Copenhagen Accord. However, even if these pledges are met, consequences for competitiveness will still be far-reaching due to the changes already underway. With respect to this fact, actions must be taken now to avoid substantially higher costs of inaction in the future (OECD, 2009). Direction for these actions has been provided within the adoption of the EU White Paper on Adaptation to Climate Change in 2009 which acknowledges the regional vulnerability of climatic impacts and the crucial role of these impacts on the future of European competitiveness. Disparities in regional vulnerability and capacities toward adaptation and mitigation are addressed in both the White Paper and the outputs of the ESPON Climate Project. The disparities highlight how economic development is often correlated with mitigative capacities. This is exemplified by regional differences such as the difference between the lower mitigative capacity and weaker performance in competitiveness indicators of South and East Europe verses that of North Europe. A further example is found within the gradient revealed between East and South Europe which additionally identifies a particular weakness of the peripheral regions compared to that of the core.

The results of the ESPON Climate project reveal that the economic sectors most directly affected include primary as well as the tourism and energy sectors, again with the periphery regions most adversely affected due to their higher vulnerability. These regional imbalances are exceptionally important when considering the impact to European territorial cohesion and are particularly important to future solidarity. Most crucial in this respect is the potential for a widening and deepening of disparities and a compounding of inequalities as a result of climatic impacts.

What these inequalities necessitate is the regular inclusion of climate change policy within rural territorial development as is required under the holistic approach of the Renewed Social Agenda in 2008 (COM, 2008). Inequalities within and beyond rural development will more specifically be affected by the potential change in frequency and intensity of natural hazards including flooding, landslide, forest fire, drought and heat waves which will significantly impact both physical and human capital. The potential loss of physical capital, such as infrastructure, and human capital, such as loss of working days and lives, can produce adverse consequences for EU competitiveness. The ESPON Climate research, however, emphasizes that some climate change impacts produce potential opportunity for capitalization toward reducing these disparities. This is an important part of territorial cohesion and is stressed within the EU's Fifth Cohesion Report (5CR).

The 5CR explicitly addresses the 'third dimension' of Cohesion Policy, territorial cohesion, introduced originally within the Lisbon Treaty (EC, 2010). In contrast to the other economic and social dimensions, territorial cohesion emphasizes the importance of "access to services, sustainable development, functional geographies and territorial analysis" and further states that climate change and energy goals require coordination at all governance levels (EC, 2010, p. 24). This is in order to prevent counteractive policies and additionally places stress on the regional, more local levels. The 5CR addresses these issues and acknowledges differences in intensity of impacts, but does not elaborate on how the variation of impacts will affect future Cohesion Policy. The ESPON Climate project attempts to remedy this gap by identifying regions which are most adversely impacted and should be targeted for financial assistance. Though this project clearly states that it does not provide a clear-cut forecast, it assists in current efforts to improve Cohesion Policy and future growth strategies toward harmonious territorial development.

2. Main Findings of the ESPON Climate Project

The ESPON Climate project conducted a Pan-European vulnerability assessment and evaluated seven case study areas. The assessment focused on five impact dimensions: social, cultural, economic, environmental and physical impact and three elements which determine the regional capacity to adapt: awareness, ability and action. These dimensions serve as an important part of the ESPON Climate methodological framework. Suggestions for policy options are based from the Massey and Bergsma (2008) classification of adaptation objectives: adaptive capacity enhancement, reduction of risk and sensitivity, coping capacity and capitalisation.

The social dimension considers the adversely affected populations exposed to heat waves, flooding, and sea level rise and tends to target adaptation policies to reduce risk such as loss of life. The cultural dimension focuses on susceptible historical sites and landscapes which are exposed to flooding and concentrates on policies toward flood risk reduction especially for the tourism sector. The economic dimension varies by sector with policy recommendations including a need for flexibility, for granting autonomy for business adaptation, and for evaluating opportunities for capitalisation especially in the tourism and agricultural sectors. The environmental impact dimension targets primarily ecosystem indicators with adaptation policies to enhance coping capacity through maintenance of ecosystem services. Adaptation policy for the physical dimension focuses on risk reduction through planning regulations and codes and capacity building of emergency services. Though it is acknowledged that the ability to address adaptation objectives is highly spatially dependent, trends can be observed within these dimensions and are summarised as follows:

- All dimensions need both short and long term adaptation planning
- Adaptive capacity enhancement: is oft a result of early warning systems, education and information sharing

- Risk and sensitivity reduction: requires revision of current and specific policies and regulations
- Coping capacity: is found within focus on response of emergency services
- Capitalisation: is very tourism centred, while few in-practice examples exist

The information provided in the assessment also highlights what can be divided into several categories of the main findings: regional consequences, challenges and typologies in the spatial context, and recommendations for development of climate change strategies[1]. This is followed by a brief section on affects to European competitiveness and cohesion.

2.1 Regional Consequences

This section is broken into three main sub-sections. The first provides the ESPON Climate project's identification of consequences using the INTERREG IV B & C programmes' 10 trans-national regions, while the second sub-section provides consequences as analysed through regional typologies. The third sub-section provides a brief explanation of mitigative typologies.

2.1.1 Consequences on Trans-National Regions Assessment

The ESPON Climate project has generated a regional analysis through identification of climate change issues utilising the 10 European trans-national regions of the INTERREG IV B & C programmes. The analysis identifies a reiteration of the following events throughout the regions: sea level increase, flooding, forest fire, drought, extreme weather conditions and events, and a potential for increased frequency for natural damages. The summary for this analysis is provided in Table 1[2]. The information in Table 1 provides each trans-national region specified by the INTERREG IV B & C programmes and includes the climate change issues identified in each region by the ESPON Climate project as well as recommended options for future programme development.

Table 1. Climate change issues identified by ESPON Climate European for each trans-national region

Region Identified	Climate Change Issues Identified by the ESPON Climate project	Options for further programme development
Northern Periphery	flood sea level rise	-Risk management for settlements potentially affected by river floods related to climate change

[1] The ESPON Climate project employs the definition for adaptation provided by the IPCC Fourth Assessment Report stating adaptation is an "adjustment in natural or human systems in response to actual or expected climatic stimuli or their effects, which moderates harm or exploits beneficial opportunities" (Klein et al, 2007, p.750).

[2] Tables within this paper are taken from the forthcoming chapter 'Implications for territorial development and challenges for the territorial cohesion of the EC' in *European climate vulnerabilities and adaptation: A spatial planning perspective* (Greiving and Schmit-Thomé, forthcoming).

Baltic Sea	storm surges sea level rise floods & flash floods changing frost changing precipitation	-Further development of Regional Adaptation Strategies related for climate change impacts on forestry -Climate change impact assessments on coastal and island areas, including tourism and water quality (algae blooming)
North West Europe	flood (river & flash) sea level rise storm surges	-Combination of flood and storm surge prevention and spatial planning as cross border and transnational initiatives.
North Sea	flood (river & flash) sea level rise storms (& surges)	-Combination of flood and storm surge prevention and spatial planning as cross border and transnational initiatives.
Atlantic Coast	flood (river & flash) sea level rise storms (& surges)	-Development of regional strategies to anticipate the impact of river floods -Development of regional strategies to anticipate the impact of storms and storm surges
Alpine Space	floods & flash floods changing precipitation	-Diversification of tourism, also interlinked with water scarcity -Integration of sustainable crossborder adaptation and mitigation concepts -Options of enhancing synergies to avoid conflicts (especially on adaptation measures) -Over regional and transnational water management approaches, especially focusing on the Alps as a "water tower".
Central Europe	floods & flash floods changing frost changing precipitation + summer days + summer temp. sea level rise	-Development of regional climate change adaptation strategies on floods, heat waves, forest fires -Development of regional climate change adaptation strategies on water scarcity -Development of regional climate change adaptation strategies on tourism -Development of regional climate change adaptation strategies for agriculture and forestry
South West Europe	agriculture forestry flood sea level rise	-Development of regional transnational climate change adaptation strategies on heat waves, water shortage and forest fires.
Mediterranean	storm surges droughts floods forest fires changing precipitation + summer days Sea level rise	-Management of public (including tourism) water demand. -Identification of possibilities to save water instead of relying on current -Water management schemes and further development of desalinisation plants. -Avoidance of mal-adaptation, e.g. transferring costs and risks from water sector to energy sector -Management of land take (urban sprawl)
South East Europe	flood sea level rise changing precipitation changing evaporation + summer days Sea level rise	-Emphasize analysis and management concepts on impacts of climate change on forestry and agriculture -Development of common (crossborder) methodology for land use restructuring, including integrated water management planning

Of the INTERREG IV B & C programmes considered, adaptation to combat adverse climatic impacts was not found to be a priority but appeared to be indirectly addressed in the majority of the programmes through efforts toward sustainable development, environmental protection and natural risk avoidance. Actions within these efforts take the form primarily of water management development and risk prevention. Aside from this observation, the ESPON Climate project identifies that when climatic stimuli are applied the most prominent impacts across all regions are found in the following order: flooding, storms, precipitation change and sea level rise.

The results of the vulnerability assessment enable a further classification of these 10 trans-national regions into three major groups which are identified in Table 2.

Table 2. Three major groups identified by the ESPON Climate project vulnerability assessment utilising the INTERREG 10 trans-national regions.

1. Regions where vulnerability is expected, as a rule, to increase at a high or medium rate
Regions: Mediterranean Region, South-Western and South-Eastern Europe **Description:** impacts accrue primarily in the environmental and economic dimension, overall growth of vulnerability related to poor adaptation capacity **Proposed solutions:** program measures addressing e.g. water management, preservation of water, forest fire forecasts, preparation for heat waves and regulation of land use would potentially have the greatest importance
2. Regions where vulnerability is expected, as a rule, to grow at a low rate
Regions: Northern Sea region, the North-Western European and the Atlantic coastal regions (includes also some Alpine regions) **Description:** increase of climate change impacts is projected primarily for the physical and social dimensions **Proposed solutions:** measures addressing natural disasters such as floods and coastal storms would have the greatest positive effects
3. Regions, where vulnerability is expected, as a rule, not to change significantly
Regions: Baltic Sea region, the Northern periphery and Central Europe (the lattermost can also be in part of the second group) **Description:** climate impacts are diverse but not extreme **Proposed solutions:** adaptation measures should stress the importance of the role of water management and prevention of natural disasters

The table (Table 2) identifies the regions in terms of the severity of change in vulnerability as estimated by the ESPON Climate project. The table further provides a description of the climatic impacts and a few recommendations as to potential solutions. What can be concluded from the table is that certain hot spots, or areas most affected by climate change, are found within the Mediterranean region, South-Western and South-Eastern Europe. This is in large part due to the poor capacity for adaptation of the region coupled with significant impacts felt within environmental and economic sectors, especially for the potential impact to the tourism industry. Forecasting, preparation and land use measures are suggested as having the greatest potential benefit in remedying adverse consequences. Climatic change is found to be significant but to a lesser degree within the some Alpine regions, the North Sea, and the North-Western and Atlantic coastal regions. Impacts within these regions tend to

affect primarily physical and social dimensions and are recommended to be addressed through measures that specifically target natural disasters including coastal storms and flooding. The last category consisting of the Baltic Sea region, the Northern periphery and Central Europe faces diverse impacts that are estimated as having no significant changes. In keeping the severity of change to an insignificant level, it is encouraged here to consider adaptation measures stressing natural disaster prevention and the importance of effective water management practices.

2.1.2 Mitigative typologies

With respect to climate change mitigation, the ESPON Climate project has identified what can be described as mitigative typologies[3].Within this identification process, the project makes use of the mitigative capacity definition as provided by the IPCC, "a country's [or region's] ability to reduce anthropogenic greenhouse gas emissions or enhance natural sinks" (IPCC, 2007, p. 818). The analysis of typologies considered social factors including educational commitment and attitude towards climate change as well as the availability and extent of the following: technology for reducing emissions, availability for non-carbon energy sources, land use type, mitigation policies, and government effectiveness and economic resources through income per capita. Four types of regions were produced as a result of the analysis:

1. regions with high capacity and low emissions
2. regions with high capacity and high emissions
3. regions with low capacity and low emissions
4. regions with low capacity and high emissions

The analysis further emphasized the importance of particularly types 2 and 4 as both indicate the most obvious areas in which action toward reduction measures should be taken.

2.2 Challenges and Typologies in the Spatial Context

Aside from the analysis provided above, the project also produces a spatial planning focused analysis generated in terms of identification of spatial typologies and the immediate challenges faced. The project acknowledges and builds off previous work by Massey and Bergsma (2008) as well as Greiving and Fleischhauer (2012) who review European spatial planning perspectives. Through the reviews, it is asserted that spatial planning is related to land use within adaptation policy development and that though its role is growing in importance this role is not well recognized (Greiving and Fleischhauer, 2012). This role is further differentiated based on the planning policies of various countries where, for example, a role is assigned in Germany, France, Hungary, a central role is played in the UK and the Netherlands, and a role is not assigned in Finland and Spain (Greiving and Fleischhauer, 2012). It

[3] The use of the word mitigation follows the definitions provided in IPCC (2007) and Füssel and Klein (2002) where mitigation is an effort to reduce climatic changes by reducing greenhouse gas emissions and through enhancing carbon sinks.

is recognised that consideration of particularly a spatial focus is especially important for adaptation at the regional level not only for political reasons, such as policy with respect to the role played, but also territorially with respect to type of spatial designation. This topic is elaborated within the next sub-section.

2.2.1 Spatial Typologies

The Pan-European vulnerability assessment recognizes and identifies variability of impact not only for specific types of regions, such as those previously mentioned from the INTERREG programmes, but also between and within these regions. This variation is spatially determined and is represented within the ESPON Climate project through regions based on spatial typologies. These are listed as follows: metropolitan/urban, rural, mountain, coastal, sparsely populated, islands, and border regions. The analysis considers the climatic impact, adaptive capacity and vulnerability and provides some policy recommendations within each typology.

The metropolitan/urban regions were found to have high impact particularly for the highly populated coastal areas, Alpine areas and especially Southern Europe. Impact is largely dependent on the characteristics of these regions such as the concentration of both people and infrastructure. The ESPON Climate analysis states that, for these particular regions, there is a need to establish a common 'spatial vision' through collaboration of both spatial planners and civil society because of the management constraints of limited space and resources. The vision must include diversity of structural sensitivities as well as system redundancy (where main elements of the system can be interchangeable) and robustness (where e.g. infrastructure and vegetation strengthen resistance to adverse impacts).

Analysis of rural regions highlights a range of low to high potential impact with particular adversities for Southeast Europe. These regions are economically not as robust as other regions and have consequentially lower adaptive capacity. To remedy this, attention must be paid especially to economic development, particularly for areas facing water scarcity.

Impact is considered medium to high for mountain regions; Southeast Europe, Spain, Greece and the Southern Alps being especially affected. Impacts are exacerbated through the inaccessibility of transport, demographic changes, and triggering of natural hazards by climate change which requires hazard assessment and risk mapping.

Coastal regions have medium to high impact due to potential sea level rise which necessitates a need for Integrated Coastal Zone Management for improving coastal defences in combination with settlement restrictions. Potential capitalisation opportunity exists with potential for increased tourist comfort in Northern Europe.

Sparsely populated regions must be considered in terms of relative and not absolute impact because there are relatively few assets within these regions which include part

of the interior of Spain, Scandinavia and Scotland. Improving accessibility is suggested particularly for the periphery regions.

Islands in the Mediterranean and Atlantic face severe impact due to their reliance on tourism and agricultural sectors combined with low adaptive capacity. Solutions proposed include diversification of economic activities especially those which conserve freshwater resources and are generally less climate sensitive.

A wide range of impacts exist for border regions due to differential sensitivities (e.g. population density, settlement patterns, economic development, and general adaptive capacity). Solutions suggested for these regions include particularly strategies balancing economic development, environmental issues, and demographic change.

Overall, the analysis of spatial typologies reveals that the Mediterranean and Southeast Europe have the highest vulnerability because of high impact and low adaptive capacity, especially those areas in the Mediterranean and the Alps which depend largely on the tourism sector. The typologies identify the vulnerability of these among the other spatially differentiated regions and suggest that each area has a different starting point for the investment and effort needed. Taking the typology analysis into consideration, it must also be acknowledged that challenges exist for the spatial approach to implementing climate change strategies.

2.2.2 Challenges for Spatial Planning

The ESPON Climate project identifies that in taking a spatial approach to adaptation and mitigation one must consider important challenges faced by spatial planning. Already existing structures are a particular challenge especially for adaptation strategies and must be considered within implementation of an RAS, or regional adaptation plan. Spatial planning is considered more relevant for still developing areas because conflicts arise between adaptation enforcement and pre-existing private property rights. To remedy these conflicts, it is recommended to avoid regulatory (or conforming) planning and to provide compensation schemes for affected private property owners.

The role of spatial planning should also be considered as it is and can be applied across sectors and governance levels, though challenges arise in that this role is not well understood, well-developed nor emphasised within strategies toward mitigation and adaptation (Davoudi et al., 2009; Mickwitz et al., 2009; Greiving and Fleischhauer, 2012). There is a need for a multi-level (vertical) and cross-sectoral (horizontal) governance approach because sectors are differently affected by climate change impacts. If the role of spatial planning follows a comprehensive planning approach to climate change strategies, this can consider both institutions within and across different levels and the involvement of multiple actors in order to establish legitimacy of recommended actions and to account for normative values (Mickwitz et al., 2009). The inclusivity of this approach is an important feature of climate change governance and has been cited within both European legislation and recent

literature as essential for effective adaptation strategy development (Ribeiro et al., 2009; Swart et al., 2009; Meister et al., 2009).

2.3 Recommendations for Climate Change Strategies

In addition to the typologies presented and the identification of particular challenges within the spatial context, the ESPON Climate project identifies specific recommendations for adaptation and mitigation strategies. The project recognises and discusses briefly the interconnectivity between the two kinds of strategies. The linkages between these strategies are acknowledged especially by the IPCC Fourth Assessment Report and described within three types of relationships (Klein et al., 2007):

- Direct relationship: involves use of the same resources (e.g. land and stakeholders)
- Indirect relationship: involves connection through budgetary allocations
- Remote relationship: involves distant connection (e.g. currency exchanges)

The project reiterates and recommends the notion that establishing an understanding of the type of relationship is crucial for developing effective mitigation and adaptation, especially in avoidance of potentially counteractive strategies. What must be further understood are the four types of interrelationships also identified by the IPCC, two of which are discussed within the ESPON Climate project: 1) strategies for mitigation which impact adaptation and the inverse 2) strategies for adaptation which impact mitigation. This occurs when, as an example of #1, mitigative reforestation efforts impact adaptation by influencing the water budget and biodiversity of a given region or when, as an example of #2, adaptation efforts require additional energy resources.

2.3.1 Recommendations for Adaptation Strategies

Specific to adaptation strategies, the project recommends more research and development for that which requires international cooperation such as forecasting systems, planning methods and knowledge transfer as well and coping strategies especially for those concerning natural risks (e.g. flooding). Within cooperation for all adaptation strategies is a need to consider multiple levels of governance because implementation at one policy level is not independent of implementation at levels both above and below. It is further recommended to take into account more social measurements including demographic changes and to encourage more concentration on integrated water management particularly when dealing with transnational prevention of flood risks. Specific to tourism and agricultural sectors, special attention should be paid to changes in availability of water as peak water demand and seasonal reduction in supply occur at the same time (Amelung and Moreno, 2009). This is especially important because of the economic role played by tourism in regions such as Mediterranean and the Alps which are even acknowledged in the EU White Paper on Adaptation as susceptible to climate change impacts (COM, 2009). It

is, however, also important to consider what the ESPON Climate project highlights as opportunities, or capitalisation, for these sectors where diversification of both industries can lead to beneficial adaptation strategies. Opportunity for capitalisation is found also within recommendations for mitigation.

2.3.2 Recommendations for Mitigation Strategies

Though substantial difficulties exist in estimating how the energy sector can develop particularly due to uncertainty of estimated impacts, the project recommends encouragement of capitalisation in current and future policy development with respect to mitigation strategies. This is a relatively new concept and takes form in mitigation strategies through opportunities in reduction of energy consumption and increase in energy production. This can additionally mean provision of market opportunities by development of carbon neutral technologies. One more specific example exists in taking advantage of favourable wind power conditions in Northern regions and connecting these to areas of high consumption. Opportunities also exist within the tourism sector, especially within the Alpine region, where development and implementation of climate neutral facilities can be encouraged through mitigation measures.

2.4 Affects to European Competitiveness and Cohesion

The analyses provided by the ESPON Climate project identified the above recommendations and regional typologies based on place-based characteristics of climate change impacts and assists in determining priorities for future territorial development. Identification and variation particularly for regions which are most vulnerable is acknowledged within the 5CR. However, the project provides some solution to the 5CR's lack of further explanation for future policy development. There is a need for a transnationally coordinated approach which must include consideration at the EU level due to nature of climate impacts where boundaries of impact are not confined to politically or administratively drawn lines. Attention at this level is important to ensure efforts are made to build capacities of the most disadvantaged regions. The role of the region is crucial in consequence of the regionally specific physical, social and economic factors which influence the severity of impacts as well as responsibilities of the region in providing utilities, emergency services and general disaster risk management.

Climatic impact to territorial development is likely to deepen already existing regional inequalities and produce a significant challenge to progress for competitiveness and general Cohesion Policy, especially with respect to the solidarity principle with respect to most disadvantaged regions. This demands that more attention be paid to how Cohesion Policy will address this challenge and how this combines with effects of existing demographic changes. The project estimates that this could expand the wealth gap in areas where greater change is expected. Attention is additionally needed for the peripheral regions that face additional challenges due to rising energy costs and substantial commuting. Policy should also

consider what is termed ‘carbon leakage’ where high emitter industries avoid costs imposed by one region by relocating to another. It is suggested that, in order to balance territorial development, climate change issues must be integrated within rural development policy. Another important consideration is the potential development opportunity for regions which rely heavily on seasonally dependent sectors including forestry, agriculture, and especially tourism. These regions face challenges especially at the local level in terms of EU policy implementation.

Through observations from discussion within the 2011 EPSON Internal Seminar, it is revealed that there are some additional challenges to implementing the Europe 2020 Strategy which must be addressed. Discussion greatly emphasized that there exists a need for flexibility in translation of objectives and targets especially at local levels because targets in their current form are unrealistic or undesirable for some regions (e.g. property rights for pre-existing settlement). Further, priorities need to be set at the regional level in order to ensure successful climate change strategy implementation especially with respect to territorial development. According to representatives of the Polish Presidency, this particular Presidency has stressed the importance of the role of spatial planning and the need for spatially specific strategies as well as the need for more local input in strategy development. This sentiment is echoed in the emphasis placed on analysis of the spatial, or place-based, context within the ESPON Climate project and is seen as an important component toward achieving the 2020 Strategy goals and implementation of current Cohesion Policy.

3. Conclusions

A number of observations, estimations and recommendations have been produced as a result of the ESPON Climate project analysis. These products stress that implementation of strategies must encourage regional and more local level involvement and multi-level governance for effective implementation. They further emphasise that the current trends indicated demonstrate a path for European regions which is contradictory to the goals of territorial cohesion and that taking preventative and precautionary actions now save substantial future costs. The analyses and understanding produced from the ESPON Climate and like projects assists in creation of tailor-made strategies which will be crucial in overcoming present and future challenges to territorial cohesion and contributes in the efforts toward harmonious development of the European regions.

THE EVOLUTION OF FAIRS, HOW FAIRGROUND DEVELOPMENT REFLECTS HISTORICAL PLANNING DISCOURSES

Rick Vermeulen[1]

Abstract

Fairs have a very long tradition within the cities of Western Europe. Medieval markets, World expo sites, early industrial facilities, venues constructed after World War Two and modern state of the art convention centers all take up a specific role in the city. By opposing a traditional and a modern discourse in urban planning, this paper argues that through the course of fair development, these venues have shifted more and more towards the modernist discourse. This has resulted in large efficient venues but has decreased direct relationships with their surroundings. The paper ends with the discussion of a recent and partial reversal of this trend and relates this development to broader shifts in the orientation of urban planning.

1. Introduction

Over the past two decades, many cities have invested in their exhibition centers. Some cities renovated their old centers that were constructed in a previous exhibition center boom in the years after the Second World War, others have built new centers at regional subcenters. The amount of newly constructed and extended exhibition centers is extraordinary and unprecedented (Fenich, 1992; Kay, 2005). Between 2000 and 2005 the number of square meter exhibition surface worldwide had grown with 40% (Wallace, 2007). This sparks an interest in the historical development of these sites and in what this tells us about current development. When we look at the longer lines of fair development in Western Europe, we see that there have been previous waves of exhibition center development in the second half of the 19th century, the 1920s and directly following World War Two (Vermeulen, 2011). This paper describes these periods of development and also places them in the light of an ever strengthening dominance of modernist values, striving for efficiency through enlargement of scale and isolation from other functions. It is argued that this is emblematic for the overall development of cities. The paper ends, however, by discussing what can be argued to be a revival of traditional urban values of diversity and small scale in urban planning. It is suggested that recent divergence in exhibition center development strategies shows on the one hand a continuing of the modernist logic and on the other hand this revival of traditional urban values.

[1] Amsterdam Institute of Social Science Research (AISSR), University of Amsterdam. [r.vermeulen@uva.nl]

To support these arguments, illustrations are given from the development history of different fairs around Europe, most notably Amsterdam, Frankfurt, Munich and Vienna. The word fair is used, even though it is in some contexts a little outdated, to indicate what has at several moments in time and place been also called expo, exposition center, exhibition center or convention center. A fairground is the broader ensemble, also encompassing adjacent outdoor exhibition terrains and complementary infrastructure like parking lots and free standing restaurants and theatres. First, two ideal typical urbanist models will be introduced, thereafter the development of fairs in different time periods will be described. The article will end with a discussion of current developments.

2. The traditional and the modern city

Before planners took over the control of the development of the city, cities developed organically. This rendered functionally very mixed neighborhoods where working, living, trade and cultural activities were spatially very close. The central squares of medieval towns where trade, religion and government were represented are emblematic for this diversity. All these combined activities ensured close relations between different activities but also produced inefficiencies, mutual nuisance and congestion. With planning and modernization came the separation of functions. As the footprint of different activities became larger and markets demanded efficiency, each function was moved to its own particular location, often to the borders between city and countryside. This functionalist logic was especially dominant in the post World War II period when specific areas for working and living were designed and developed. This period produced a massive amount of monofunctional districts and buildings. Markets were replaced by food centers, town halls by government centers, urban shopping streets by peripheral shopping malls and university campuses by university complexes and, later, technology parks. Relations with other functions vanished as these autarkic complexes housed everything that was needed for an efficient fulfillment of their tasks.

Modernist development went at the expense of the diversity and livability of urban centers. With many functions moving out, they were deprived of their diversity and functional separation, resulting in the absence of functional relations. Especially US cities were hollowed out by these processes and found themselves during the 1960s, ‘70s and ‘80s in a downward spiral (Frieden and Sagalyn, 1991). As fewer people had business in the center, this center became less attractive for business to settle. For functions traditionally enmeshed in urban centers, people now went to dedicated locations where their sectoral needs were efficiently answered.

There has always been a counter current to these developments, most famously represented by Jane Jacobs in her – scholarly (1961) and activist- work. This view on city development adheres to many of the traditional traits of urban development. They propose gradual development and transformation and, most importantly, a diversity and mix of functions. Illustrative for the influence of this strand of thought is the attention for (new) urbanity, the return of many cultural functions and small businesses to city centers and the preference of a growing part of residents for urban environments, reflected in increasing rents and property values.

Francoise Choay (1965) has termed these two different ways of urban development as cultural (culturaliste) and progressive (progressiste), we will here use the terms traditional and modern. They can be opposed and seen as ideal types for the analysis of urban development. Where modern development advocates separation, disintegration, efficiency and scale; traditional development advocates functional mix, small scale and relations.
This paper will use these two ideal types in order to typify the historical development of fairs in Western Europe. They have always largely followed the dominant discourse as they moved from very traditional to structures that can be termed very modern. At this moment, they can be argued to be at a crossroad where we see diverging development with some exhibition centers opting for a continuation of the modernistic pattern and others for more traditional values.

3. The medieval city

The first fairs originated at strong centers of production or at crossroads of international trade routes. Cities like Leipzig, Lyons and Frankfurt benefitted greatly from their central location within Europe. As centers of production shifted, so shifted the dominance of fairs within Europe. Whereas in the twelfth till fifteenth century the Flanders and Champagne fairs were dominant, this shifted in the 16th century to Frankfurt and later to Leipzig (Allix, 1922).
The first of these fairs were extensions of local markets that were held at the central squares of medieval towns. As markets became larger and more prestigious, soon arcades and covered passageways were constructed to prevent for rain and snow. Such a central location also favored local businesses, especially guest houses and inns. Not seldom, local commerce was supported by decree. In medieval Munich, a center of the salt trade, merchants had to stay at least 24 hours in the city (Schafer, 2005). In Munich, the location of the fair was the central Marienplatz, which was also the site for festivities, government and jurisdiction. The markets were held at religious holidays, thereby integrating them with religious life of the city. This integration also serves as the etymological origin for the words fair (English), Messe (German), Fiera (Italian) Feria (Spanish), which all mean religious festival.
Only at the beginning of the 19th century, the Munich fair had grown to such an extent that it could not be housed at the central square anymore. Different sites were allocated for different goods to be marketed and often some kinds of halls or stands were erected (Schäfer, 2005). The first signs of functional separation became visible, even though integration of the different sectoral fairs with their surroundings and city life was still largely in place.

4. World fairs and exhibitions

By the mid 19th century the phenomenon of the international exhibition rose in importance. The immense World Expo's that followed the 1851 World Fair in London are of course the most pressing examples but also many thematic and regional exhibitions were held (Mattie, 1998). These events marked a shift in the sense that they were no longer focused on economic exchange but rather on display and showing what mankind was capable of. This was also reflected in the venues where these events were held. Contrary to the market-like settings of earlier

exhibitions, architecturally impressive facilities were erected at international exhibitions, exemplified by the appealing and prestigious Crystal Palace of the 1851 London World Fair. Many cities followed with similar facilities like the Paleis voor Volksvlijt (Amsterdam, 1864), the Glaspalast (Munich, 1854) and the Rotunde (Vienna, 1873). The construction of new facilities and the mere size of the events often required a location outside of the city. Although the terrains were often found adjacent to the city, this provided a first stage of disintegration between the city and the fair. Nevertheless, this connection was still very apparent. Local residents visited the fairs and also side events like carnivals that were accompanying them (Bennett, 1994).

This combination was more permanently realized in cities like Munich and Vienna. In Vienna, the legacy of the 1873 World Fair had resulted in an amusement park and exhibition facilities at the Prater, which were after the fair conserved and extended (O'Brien, 1981). In Munich a 'Vergnugungs- und Ausstellungspark' was realized by the city in 1904, facilitating large exhibitions as well as a leisure environment for residents (Lauterbach, 1984). In these days, the combination between cultural consumption and exhibitions was still very common (Bennett, 1994). In Frankfurt, the Festhalle was constructed in 1909, providing a space for concerts, exhibitions and other events. Till today, this building serves as a central venue in Frankfurt and an important place for its residents (Bauer, 2009).

With early industrialization in the first half of the 20th century, the exhibition space at these fairgrounds was extended. Gradually, the architecture of these facilities became more sober and functional. As these additions served predominately to facilitate the enlargement of exhibitions, they also had a more monofunctional use.

In the 1920s, cities like Amsterdam (1922) and Milan (1923) continued this development in their new exhibition facilities (Heijdra, 1995). Those were much more functional and efficient than the earlier generation that was developed two decades earlier in Vienna, Frankfurt and Munich. They merely served the display of goods, produced by the emerging industrial sectors of the city. There was also no surrounding amusement park as the focus shifted towards mere exhibiting. This more sober layout was also inspired by the economic crisis that was hitting the world during the 1920s. Moreover, these exhibition centers were no longer developed by the municipalities themselves but by industrial sectors. The RAI exhibition center in Amsterdam was developed by the bicycle industry of the Netherlands, in its aim to concentrate dispersed exhibitions in a single time and place. As they had developed their own venue for this purpose, they soon started to sublet it to other organizations (De Jong, 1986; 1982).

Again, these new facilities were realized at the border of the then-existing city. With a physical separation from the city and a separation between cultural consumption and display and exchange, these facilities were again more functional than their predecessors.

5. The functional city

World War Two marks the further modernization of exhibition facilities in Europe. During the war, many facilities had been ceased for military purposes and many facilities, especially in central Europe had been damaged by air raids and other acts

of warfare. The exhibition centers of Frankfurt, Milan, Munich and Vienna were all to a considerable extent destroyed. Although exhibition centers were certainly not the only aspects of the city that needed attention after the war, all cities decided that their exhibition centers needed to be rebuilt. Especially in German cities, the reconstruction of the fair was seen as an important impetus for economic recovery. Although Hannover is the most apparent example of this strategy, it hosted already in 1947 an export fair for over 730.000 people in a 30.000 m2 facility, also other cities like Frankfurt, Munich and Cologne followed pretty soon (Möller, 1989).

They used the remnants and old sites of the pre-war facilities, initially by constructing temporary facilities, but later also for more permanent structures. Economic recovery led to an increasing interest in trade fairs through the 1950s and 1960s, which required again larger halls. These new facilities consumed most of the park-like environments that had characterized pre-war fairgrounds. Moreover, as industrial products like cars, building equipment and agricultural machinery required larger halls than the smaller pre-war manufactures, individual halls also increased in size (Kölbl, 1984). Functionality and efficiency replaced aesthetics and diversity. In Frankfurt, the terrains around the restored Festhalle were fenced-off to prevent people from sneaking in.

Although the extension of the city around the exhibition centers of Frankfurt and Munich made them, at least geographically, more embedded within the city, they were functionally segregated. In Amsterdam, this segregation was also geographical as the fair was again moved to the border of the city in 1961. The halls constructed here were also considerably larger than the ones at the central city location (De Jong, 1968; 1982).

The processes of enlargement and segregation can be seen as mutually reinforcing. First the growth of exhibitions required larger halls which in some situations led to the need for a new location, often out of town. Second, these larger events also produced larger crowds which produced more noise and traffic. Especially the busses, cars and taxis needed to transport visitors were in many cities seen as nuisance by surrounding residents. This, again, led to all sorts of measures to alleviate or prevent these side effects, which often led to increased separation. New parking lots were developed to prevent visitors from parking in residential areas. Often, residential streets were closed off for visitors during event days. Loading docks were covered to mitigate noise from constructing and deconstructing exhibitions. Highway exits and connections routing to public transport stops were made more efficient to separate visor flows from residents. Moreover, first the nationalization and then internationalization of fairs made that visitors came to an increasing extent out of town and, consequently, that local residents frequented their home-fairs less often. Fairs turned their back to the surrounding neighborhoods.

The continued enlargement of fairs and fairgrounds has led to a situation in the early 1980s where most fairs are now conceived as segregated and underused parts of the city where normal residents hardly ever go. The extensive use of the fairgrounds, often taking up large surfaces at relatively central locations, has led to questions of the legitimacy of this use in some cities. Neighboring residents conceive negative effects related to parking, traffic and noise over positive effects on the urban

economy. In both Amsterdam and Munich this has posed serious limitations to the extension of fairgrounds.

6. The polycentric city

It is therefore not surprising that many cities have considered the relocation of their fairs towards the urban periphery. During the 1980s and 1990s, the periphery of European metropolises has developed rapidly into an attractive environment for economic activity (Phelps and Parsons, 2003; Keil and Ronnenberger, 1994). The relocation of exhibition centers in, amongst others, Munich, Milan, Madrid and Stuttgart, has been facilitated and has strengthened this development (Jesse, 1998). New fairs are used to instigate regional sub-centers. Also the newest generation of World Exhibitions is used for this purpose as cities do not have inner city locations available of the size needed for the most current events. In Munich, a new fairground was constructed for the National Garden Exhibition of 2005. The old fairground had faced problems with extension and neighborhood nuisance since the 1970s. In Milan a new fairground opened in 2005 at a former oil refinery between the city and the airport.

This move away from the city center signifies the definitive cut between the exhibition center and other urban functions. Where modernization had already cut functional ties, relocation also separated city and fair geographically. Thereby, most fairs have become truly international places, only connected to their host city by their name, history and some spill-over effects to the urban economy. These large facilities have several in house restaurants, conference facilities and in many cases also hotels. Dedicated high speed rail stations, highway exits and convenient connections with the airport ensure accessibility and prevent the mixing of visitor flows with conventioneers. The monofunctionality of the complexes ensures that nothing different from exhibitions and conventions takes place there. This has left them far from the situation of the medieval market or the international exhibition when fairs were hallmarks on the urban calendar.

7. Back to the city.

Just when modernization seemed to have reached its final stage, consumerism and cultural economy have sparked new interest in the city (see for example Florida, 2002; Zukin, 2010). In recent years, urban centers have gained a new attractiveness and reinvigorated themselves from the derelict places they were during the 1970s and 1980s (Law, 1992). To this testify new waterfront developments (Judd, 1999) and entertainment districts (Sagalyn, 2003). These developments do not thrive on efficiency, large scale and separation but rather on the opposite: functional diversity and small-scale. Part of the revival of urban centers are, especially in Anglo-Saxon countries so-called convention centers, smaller and compact versions of exhibition centers and fairs. Hong Kong, Vancouver, Liverpool and Boston are amongst the cities that have constructed such convention centers in an attempt to add a different function and use to their waterfronts. Cities that have not removed their centers from their urban locations also cease on this opportunity. Frankfurt and Amsterdam are investing on their inner city locations. Primary reason not to move to the periphery is the synergy with urban amenities and other functions. Traditionalist urban views are

taken in consideration again and now form a serious alternative to modernist strategies.

8. Conclusion and discussion

Fairs in Western Europe started out as very traditional, diverse functions, enmeshed in urban life that developed more and more into modernist, functional facilities. Throughout the years they have increased in scale and decreased in integration with the surrounding city. Since World War Two, the fair in Amsterdam has increased almost three times in size, Munich more than four and Frankfurt almost five and a half times. In this regard, they can be argued to represent a broader shift in urban planning towards modernist principles and organization. In recent years, however, both fairs and urban planning in general is attributing renewed value to traditional urban values. This has resulted in divergent patterns of fair development with on the one hand, large scale, efficient peripheral venues and on the other hand centrally located facilities, striving for added value through a relationship with the city.

Hence, current exhibition center development reflects current ambivalence in planning where the modern and traditional discourse exist side by side. Many cities are trying to get the best of both worlds as they concomitantly strengthen and diversify their historic cores as well as develop peripheral nodes of activity. In the case of a single entity like a fair, such a balance is less easily found. Nevertheless, some cities attempt to offer both efficiency and urbanity in multiple facilities. In Paris, several central and peripheral facilities have united in a single organization offering different levels of urbanity and efficiency. In Milan, a small part of the central exhibition center was conserved as a new integrated convention and exhibition center was build outside the city.

FLOODINGS AND SOCIAL VULNERABILITY: THEIR SPACIAL EQUIVALENCE IN THE CITY OF CURITIBA, BRAZIL

Beatriz Hummell Clovis Ultramari

ABSTRACT
This is a theoretical discussion on social vulnerability and on the construction of vulnerability indexes. Empirical exercise takes place in the city of Curitiba, Southern Brazil. Article is based on both conceptual approaches revealing complexity of such topic as well as on empirical demands to establish priorities in terms of risk reduction action facing natural adverse events and distribution of resources in post-disaster recovery. Urban context is that of Brazilian cities, revealing spatial inequalities in the way inhabitants build, use, and transform urban compartments. Research presented here can be contextualized in a scenario where adverse phenomena increasingly influence the elaboration of urban public policies; its main target is to contribute to the identification of parameters to channel public resources in preparedness actions facing adverse situations.

KEY WORDS
Social Vulnerability; Natural Hazards; Vulnerability Index; City of Curitiba.

1. FOREWORD

Natural hazards represent an increasing threat to populations in all parts of the world. Historical statistics show that, since the 1950s, the number of these hazards has increased significantly (EMDAT, 2011; SWISS RE, 2011). Natural hazards may occur regardless of social stratification, and their impacts affect differently among these very same specificities, enabling to increase or diminish damages and their temporalities. Empirical and scientific observations confirm that lower income levels of the population often are repeatedly affected by the recurrent hazards, which leads to the necessary addition of social and economic parameters on the vulnerability concept. It means that similar exposures to natural hazards may generate different consequences according to social parameters. Again, we juxtapose Hewitt´s (1997) more restricted view of social vulnerability to that of sustainability restricted view of Blaikie et al (1994). By adding the complex social layers to an already wide concept such as Beck's (1992, 2006) risk society, vulnerability acts as a result of contemporary social development and discrepancies in the distribution of the outputs of this very same development. This article is based on such conceptual bias, stressing a close relation between impacts caused by natural accidents and social characteristics of those who are submitted to

them. Because of the fact that social vulnerability may be understood as a “dormant phenomenon in suspended animation till a calamity occurs,” it is more easily related to risk management situations and hardly taken as a pre-existing condition that shapes suffering and recovery ability. Case study presented here is carried out by the authors in the city of Curitiba, located in the southern region of Brazil, with 2 million people and known because of its urban management experiences and a better quality of urban life if compared with country´s average but still with deep social discrepancies. Methodology adopted in this case study overlays the most affected areas by natural hazards to the spatialization of social-economic indicators of the entire population. This methodology is pragmatically and necessarily simple to be developed based on the data available and to pedagogically and clearly distinguish a city´s district regarding their vulnerability index. It also stresses the importance of spatializing public policies, an approach rarely seen even in cities marked by social and environmental compartmental discrepancies. Longer periods of analysis would certainly provide more solid results; however, the intended time frame of 10 years had to be shortened because of data unavailability and different methodologies used to collect them. Thus, the time frame considered was limited to 2003-2008. Otherwise, this period provides rich information on the topic discussed here because it may be particularized by the occurrence of intense adverse natural phenomena in the city. Geographical scope of the research refers to the entire territory of the city (430, 9 sq. km) according to its 75 districts that represent not only administrative units but also specific territories with social and economic specificities.

2. THE CONTEXT OF ADVERSITIES

In the last 100 years, an increase in the number of natural hazard events has been noticed throughout the world. According to The International Emergency Disasters Database, the number of natural hazards in the last decades increased faster if compared with the first decades of the 1900s (EM-DAT, 2009). Other studies, developed according to different methodologies, also have stressed similar concerns. Data showing and highlighting the increase of disasters is, in fact, recurrent in the scientific production that discusses contemporary social and urban problems. The United Nations Development Programme (UNDP) states that, in the last 25 years, not only the number of reported natural disasters but also their impacts on human and economic development worldwide have increased, reducing gains obtained during a period of relatively economic success. “It is troubling that disaster risk and impacts have been increasing during a period of global economic growth” (UNDP, 2004, p.11). Similarly, Munich Re Group (2003) data show that the economic losses related to disasters also have increased since the 1950s.

Rampant impacts of natural disasters on human and economic indicators call for a combined and complex action in terms of prevention, risk reduction, emergency procedures, and reconstruction practices. They also call for a solid proposal of financial and economic sustainability for the communities involved. Globalization and regional intricacy have certainly multiplied solidarity action but, reversely, also have caused impact on communities and countries that were not primarily submitted to the natural phenomenon.

According to Nunes and Kobiyama (2006), the increase of reported disasters is caused by a number of factors, such as the population growth, social and territorial segregation, accumulated resources in danger areas, progress in communication media, and global changes. This phenomenon also can be related to the global warming process and climatic changes (IPCC, 2007). If causes are to be detected in a myriad of typologies, current scientific production seems to focus its main concern on the social factor, which is considered decisive to understand natural hazard impacts.

Yet considering the complexity involving the increasing number of accidents and the increasing impacts they impose, this paper concerns the ability of local power or cities to adopt reduction risk procedures. Indeed, some authors quote the cities' occupation dynamics and urban growth as important facts to understand the social systems and the social and environmental vulnerability related to natural hazards (Santos, 1996; Rolnik, 1997; Giddens, 2000; Hogan et al 2000; Kasperson & Dow, 2001; Mattedi & Butzke, 2001; Carvalho, 2006; Maricato, 2006; and Marandola Jr. & Hogan, 2006).

In poor countries, the intense and fast occupation of the urban territory, especially in the 1970s – 1990s, was caused by many facts such as a) mechanization of rural production procedures resulting in migration of countryside populations to cities and b) generalized crisis in the production and consumption systems with impressive layoffs and no generation of new compensatory job posts.

In fact, the expansion of Brazilian cities is basically characterized by both an impressive official division of rural areas into urban lots, reserved to those who can afford this product, an even more impressive production of irregular or illegal division of land properties or a complex process of squatting environmentally fragile urban compartments. All this forms what Milton Santos (1993) calls spread urbanization: an intricate way of building and transforming cities with fragmentation, peripherization, and dispersion.

The large number of unqualified workers available in urban centers made salaries even cheaper, working conditions precarious, and informal jobs recurrent. Generalized impoverishment pushed low-income families to distant and never ending suburbs. Despite low urban quality of these areas—in most cases, with no basic infrastructure, new comers were not able to afford the cost of the formality desired by the urban technique and imposed by municipal and federal legislations. Resulting settlements mostly characterize the entire city with an inappropriate way of occupying the territory such as riverside strips, with the reduction of essential riparian woods, environmentally protected or fragile areas, and highly descending slope areas with no proper soil engineering correction, among others. At the same time, territory in impoverished cities is improperly occupied; an almost generalized lack of basic services and infrastructures also aggravates urban dwellers´ vulnerability: if occupation occurs in improper ways, municipalities hardly consider the possibility to correct resulting risk situations. In fact, lack of basic services and infrastructure imposes an additional burden to a population already overexposed to natural and social contingencies: nonpaved road system or the lack of rain water drainage network causes or aggravates floods, lack of garbage collection services obliterates existing water and sewage pipes and natural hydrological

flows, and poor sanitary habits in high urban densities lead to alarming public health problems.

Despite recent positive changes in the Brazilian and other countries in Latin America, cities of this continent are still featured by a fast and impoverished urbanization process: "while 136 million poor people lived in LA/C countries in 1980, this number rose to 204 million in 1997. One third of all people in LA/C live in poverty, and 15 percent (90 million people) live in extreme poverty" (Duncan, 2005, p 5). The same author stresses the fact that, according to the International Labour Organization, the unemployment rate in this continent in 1999 was at 9.5 percent, higher than it was even during the worst period of the 1980´s generalized debt crisis.

Two concurrent and connected impacts in the consolidation of the contemporary Brazilian cities can still be identified: those resulting from economic crises and those resulting from a fast urbanization that certainly shaped urban settlements with hard-to-solve problems. Current urban policies in the country recognize social and financial limitations to transform entire cities and have channeled efforts to more pragmatic solutions comprehending acupunctural interventions, legalization of squatted areas, and maintenance of original people in their occupied lots (Ultramari, 2006). If this approach may be considered appropriate mostly because of the grant of legal property rights, it does not fully eliminate the submission of large groups of Brazilian urban population to the immediate impacts of natural accidents.

This occupation dynamics is largely known in large poor compartments of impoverished Brazilian cities. However, if that generalization is still valid, new economic scenarios in regional emerging markets announce new phenomena still left to be understood. Brazil, in the last five years, has embarked in a non-precedent economic recovery with immediate transformation in the way its cities are occupied. Legal land market has, in fact, boomed in Brazilian cities, following the decision of federal and local governments to launch massive low-income housing programs: lower income levels of Brazilian population, who were marginalized, are now part of the consumption market. It certainly increases pressure on the limited stock of land made available by planning guidelines. At the same time, this lack of proper urban land for occupation is now a real problem if we consider the fact that in the case of governmental programs considering the necessary removal of families from risky areas, new houses must be located not far from original areas, services, and job posts: a demand not easily to be accomplished. For the first time in recent Brazilian urban history, limitations for implementing social housing programs concern not only financial restrictions and speculative behaviors but also physical unavailability of proper land. This new situation indicates a problem that has unexpectedly forced national urban planning and management to be more "flexible" in their parameters of proper and safe land. Irony now takes place in the construction and transformation of our cities: if, in the past, they experienced risks being concretized by illegal or informal occupation, at present, this phenomenon may take place because of official determination and technical orientation.

3. NATURAL HAZARDS AND VULNERABILITY

Situation previously described confirms the idea of a wider concept of vulnerability resulting from natural accidents. Certainly, social, community, political, cultural, and economic aspects play decisive roles in its definition side by side to natural phenomena. This is, in fact, a conceptual approach already largely adopted by the scientific milieu and that has been clearly defined by the distinction between the Theory of Disasters and the Theory of Hazards. These theories attest two traditional analytical formats. The first one is mostly aware of geographic aspects, such as dimension, causes, and typologies of natural phenomena. The second one conducts its investigations mostly referring to more socially elaborated analysis to understand adverse natural phenomena. From a limited mono-disciplinary approach, the concept of vulnerability has been driven to a wider understanding, with several sciences playing a distinctive and collaborative role (Thouret & D'Ercole, 1996).

The research presented in this article is related to the Hazards Theory, considering it as its main reference and understanding urban occupation dynamics (presented above) as a fundamental factor to consider lower income levels of the population as the most vulnerable to natural disasters' effects. These populations, usually living in environmentally risk areas and relying on their low incomes, present a limited "response capacity," forcing them to depend on external agents to cope with adversities. Deschamps´ empirical research reinforces the idea that "there's a strict relation between the placement of the lower levels of the population and the areas that have adverse risk factors. The socially vulnerable populations are placed in socially vulnerable areas" (2004, p.104). This is an example of a series of studies that this present research takes part in, all insisting on the assumption that disasters are no longer acts to be understood through the lens of the natural sciences alone or even nature's will.

At this point, we should go back to the dialectics announced by Hewitt´s (1997) and Blaikie et al (1994) and the construction of the concept of social vulnerability. The origins of the concept of vulnerability may, in fact, blur the idea we have of it today. Introduced as a scientific field of research connected to the hazards and disasters phenomena, it still shifts from a more natural to a more social approach. Back in the 1970s, O´Keefe, Westgate et al. (1976) radically proposed to *take the naturalness out of natural disasters, advocating that* socioeconomic factors were the causes for natural disasters; a conclusion taken from an empirical study proving that the larger amount of human losses because of natural accidents is confirmed in the poor countries. Chambers (1989), despite agreeing with the fact that people present specific abilities to cope with exposure to natural adverse phenomena, argues that vulnerability results from both natural and social risk, opening the opportunity to accept that social vulnerability has, in fact, multiple origins in terms of scientific fields, either in social or natural sciences, and so is expected to be presented according to different approaches.

Social factors have a partial implication in the construction of the social vulnerability concept and also depend on an institutional - civil and governmental - framework and its ability to respond to emergency situations. The case study presented here describes a

city with different urban compartments according to their social indicators, with specificities in terms of community ability to react when facing adverse phenomena but with a homogeneous paid attention in terms of governmental public policy in preventive actions. If this combination of factors confirms the complexity of the social vulnerability concept, it allows a more simplified analysis of concentration of low social indicators and the number of natural accidents per district. Case study confirms too that social indicators certainly have a close relation with the compulsory choice lower income classes (have to) take for their settlements. The city of Curitiba, and other capitals in the country, suffered from huge rural-urban migration in the 1970s and 1980s; to the newcomers, improper parcels of urban land were left, both those cheaply and legally traded and those simply squatted. This situation is recognized recurrently among authors who discuss vulnerability in the context of Brazilian cities. Rolnik (2011) perhaps synthesizes these ideas by recalling that

There are ways of intervening in order to improve terrain stability, drain water, slope reinforcements, that are ways of intervening in order to improve safety and management of a certain urban so that even at risk situation deaths are avoided. But the main question is that nobody chooses to live in a risk area because he is dump. People live in a risk area because there is no other option to their income. We are talking about workers whose salary does not allow to buy neither to rent a place to live in a proper area. … There is no point in palliative measures here and there if we do not take decisive action: what are the proper areas, or what are the areas that will be designated to the poorest people? (Translated from the Portuguese).

At this point, we can refer to the pressure and release model as announced by Blaikie et al (1994) as a reformulation of that previously proposed by Turner et al (2003). The model proposed by Turner et al (risk hazard model) understands impact of hazards as a result of the exposure to a hazardous phenomenon and of the sensitivity of a community exposed; however, authors do not make clear what or how impacts of the hazard are amplified or attenuated. The model by Blaikie et al stresses the progression of vulnerability according to the relation between the four main component - three socially constructed and one naturally built: root causes, dynamic pressures, unsafe conditions, and the natural hazard itself. In the case of the city of Curitiba, these four components can be understood as follows. Root causes can be translated into the economic and demographic features of the boroughs in the city, each of them presenting specificities in their average income, unemployment rate, and demographic performance implied in the number of people per family and house density. Dynamic pressures may indicate the migration process observed in the city confirming at least three main inhabitant groups: those who arrived in the turn of the 19^{th} - 20^{th} centuries; those who arrived in the rural urban migration flux of the 1970s and 1980s and still able to afford safe but distant areas of the city or of its metropolitan region; and finally, those who still arrive, with low income, and occupying off-adequate limits of an already large agglomeration. As a rule, these two social components—root causes and dynamic pressures—present a close

relation with the distance we take from central areas: the further we go, the worst social conditions are. This is, in fact, a pattern to be taken as a rule for Brazilian cities, where central areas differ in terms of historical occupation, provision of infrastructure, urbanistic quality, and income from that occupied in the most recent decades, more precisely after the 1970s, when urbanization process boomed. Third, Blaikie et al´s component—unsafe situations—is to be observed mostly in summer time during the rainy season and the resulting floods: illegal settlements along rivers or in areas already considered improper by planning guidelines but still an affordable choice for lower income classes are among the most submitted areas to such adversity. Finally, in terms of the natural hazard itself—the four component, it is important to recall that impermeabilization of urban land in the city resulting from a demographic rate of 1.3% per year and a never seem civil construction sector boom have imposed the elimination of so far large areas of natural permeability.

It seems that models to establish components of a comprehensive concept of vulnerability and indicators to geographically measure impacts of adverse phenomena are under constant criticism and, paradoxically, an object of recurrent practice, both at public policy agencies and scientific production levels. Undoubtedly, despite conceptual limitations of these methodological tools, they remain, or should remain, a reference for public managements concerning the most sensitive groups in emergency situations. In the case study presented here, pragmatism imposed submission to data available: number of occurrences (floods) per district per year and social indicators gathered to summarize a hierarchy of income levels' emergency response ability per district. By adopting such approach, we avoid common criticism to the construction of the concept of vulnerability by adding probably more adequate indicators but with difficulty in their measurements. Besides, the approach adopted here considers the fact that statistics concerning geographical and social concentration of floods in the city of Curitiba are taken as a result of 1. Social structures and processes (either by the lack of necessary infrastructure or by the occupation of environmentally fragile areas), 2. Different responses to recovery according to different socioeconomic profiles (poorest people rely more on immediate public action than those who can afford individualized solutions), and 3. Physical features of the municipal terrain (some areas are more subject to floods than others). As a matter of fact, the case of the city of Curitiba, which could be taken as a parameter for other Brazilian cities, overlaps these three levels of comprehension: unsafe lands are primarily occupied by lower income people, both for historical reasons but mostly because of impositions of segregating practices concerning real estate values. The effort to establish a relation between these levels of comprehension is aligned to what Villágran de León (2006) considers one of the main current topics in the formulation of social vulnerability: use of models to explain it and the creation of indicators to express it over time and across spaces.

Another conceptual reference adopted in the case study presented below concerns the limited number of indicators used to determine the most and the least affected districts by adverse natural phenomena and the most and the least prepared districts to respond positively to their impacts. It contradicts other analyses such as that developed by

Yeletaysi, Sarp et al (2009), among many other authors, who works with a broader set of indicators to identify poverty. In our case, there is an assumption, based on empirical experience, where it is possible to work with combined indicators such as that used by the municipality of Curitiba to express a social condition or, what interests the most here, a hierarchy among districts of social fragility facing disasters. By proceeding this way, we avoid criticism as that recalled by Villégran de Léon (2006) who attests an intrinsic difficulty in quantifying vulnerability.

What is important for the construction of a socially sensitive public policy is the recognition that certain areas of a city are more likely to suffer from the very same adverse event than others. This results not only from different physical features but also from differences concerning its population groups. By doing so, this discussion enlarges the comprehension of Beck´s (1992) idea of risk society or even his own concept of risk: society is not only part of the "world's uncontrollability" but also capable of disaster preparedness, mitigation, reconstruction and, most important, understanding who deserves priority in actions depending on limited financial resources.

The case of the city of Curitiba reinforces these ideas and confirms the hypothesis that the higher impacts of disasters and the lowest social and economic features are expectedly and almost precisely overlaid. This article focuses on the determination of compartments that are socially and spatially vulnerable. The first compartment stresses the identification of human settlements with lower social and economic indicators. The second one focuses on where natural disasters are more likely to take place, according to physical and natural aspects. The combination of social and physical aspects reveals a conceptual concern that disasters are hard to be named either natural or human but certainly carries a combination of both (Baker, 1976; Tobin and Montz, 1997).

The understanding that natural hazards cannot be described as consequences of independent natural or human factors but, most likely, as a result of their complex and constant interaction is on the basis of what is described below.

4. ANALYSIS AND RESULTS

The method used in the case study is primarily based on the analysis of official data produced by public agencies. According to Brazilian legislation and local institutional practices, incidence of accidents must be reported, properly classified, and publicized. Despite this organizational process of collecting and making information available, as well as an increase in the number of accidents and in the number of impacted areas and people, they are not yet easily spatially understood. It means that civil defense agencies or urban management processes still resent planning tools to establish priorities in terms of city compartments and their vulnerability specificities. This absence of spatial comprehension is implied not only in a blurred and generalized view of possible adverse phenomena and their real impacts but also in difficulties to later determine the kind of action needed to each one of the urban compartments of the city. In fact, most of the Brazilian municipalities still lack spatialization of accidents data in their territories; the city of Curitiba made progress in presenting these data according to its districts; however, microspatialization is still in demand.

In terms of the variables used in the research, two are more representative: a) natural disasters (number of registered disasters between 2004 and 2008), collected by the City´s Civil Defence Agency, classified by year and type of occurrence and gathered by the city´s districts; and b) population's quality of life index (PQLI) given in percentage and synthesizing a series of education, health, housing, safety, and transport indicators. This variable was collected at the Institute of Research and Urban Planning of Curitiba (IPPUC) and refers to the year 2003.

In both cases, data used were the most updated at the moment of the research. Complementary and updated analysis made for selected compartments of the city confirm positive changes in terms of the quality of life index. However, it also confirms the persistence of spatial patterns differentiating districts and confirming a discrepancy between those with high PQLI from those with generalized critical socioeconomic indicators.

Data concerning accidents are normally classified in natural, anthropic, and combined. Despite the fact that such distinction is very subtle in urban areas and more and more difficult to be established, official data are still organized according to these three typologies. In the case of the present research, the combination of anthropic factors such as the location of urban settlements, techniques of civil construction, density categories, provision of infrastructures, and impermeabilization patterns intensely shape and graduate impacts imposed by the most recurrent natural adverse phenomenon observed in the city: intermittent floods in selected areas during the three months' summer time. Discussion presented here is limited to this kind of accident (floods) and confirms the inaccuracy in classifying accidents according to independent causes.

To make a joint analysis of the variables (recurrence of natural accidents and PQLI), they were both classified in four categories and were given numerical values. In both cases, the category with the lowest value (1) represents the worst situation; the category with the highest value (4) represents the best situation.

Table 1: Classification and Numerical Value of the Variables

Numerical Value given to the Registered number of Disasters and to the PQLI	PQLI Classification	No. of accidents Classification
1	Very Bad	Highly above average
2	Bad	Above average
3	Good	Below average
4	Very Good	Highly below average

Additionally, the analysis of the areas were floods are more recurrently observed reveals that relation between these phenomena and the density of water bodies is not equivalent; in fact, their spatial differences stress the idea that natural events may constitute a risk but not necessarily an accident: a paradoxical discrepancy that confirms conceptual differences between risks, accidents, and vulnerability.

Considering the fact that Curitiba's territory is fully occupied, although with different densities, spatial differences between indicators used in the present research reinforce the well-known idea that not all adverse natural events necessarily turn into accidents: the two North-South corridors (along the two main rivers crossing the city of Curitiba), for example, that concentrate the largest areas under historical risk of floods, do not correspond to the main areas of accidents: districts in the north, around downtown area, and those in the very south.

By analyzing the information of the two variables simultaneously according to the same scale of 1 to 4, it was possible to create another scale, now with a combined meaning but again from 1 to 4. As a result, the highest number (8) represents the best situation in both (lowest number of accidents and the best socioeconomic situation), and the lowest number (2) represents the worst situation in both variables (similarly, the highest number of accidents and the lowest PQLI). This combination made possible the creation of the so-called Vulnerability Index to be used in analytical spacialization.

After this classification, it was possible to visualize a spacialization that gathers both variables simultaneously (registered number of disasters and quality of life index) and then to establish the vulnerability index per boroughs. Such spacialization confirms that a) neighboring boroughs perform similar results, and b) distinction between central and peripheral boroughs is clearly observed.

Districts presenting a score of 8 are concentrated in the central regions (downtown areas); districts with a score of 7 are not as spatially concentrated as those with score 8 but are generally located in the surroundings of downtown area. These factors can be explained by the history of this part of the city territory, which has been occupied mainly by higher socioeconomic level populations. Safer areas were first occupied, leaving those considered under risk to migrants arriving in the 1970´s demographic boom or simply to those who could not afford overpriced urban land. It is important to stress that areas in the core territory of the city were not "made" safe by infrastructure interventions; quite the contrary, they present almost no limitations in terms of unstable terrains, slopes, or high concentration of river channels. Mostly recent occupied areas either depend on such infrastructure implemented by local government or are simply left to be occupied under risk.

Districts with scores of 3, 4, 5, and 6 or classified as "Vulnerable" and "Most Vulnerable" do not have an occupation pattern in the municipal territory.

Despite the already mentioned facts, by drawing an east-west line along the center of the municipal territory, it would be possible to observe a concentration of the higher scored districts ("least vulnerable" ones) in the upper part of the map, whereas the lower numbered ones ("vulnerable" and "most vulnerable") are concentrated in the southern areas of the city. Again, this fact may be related to the history of the territory's occupation: selection of safer and infrastructured areas by those who first settled (a long and slow process of urbanization till late 1960s) among an occupation that would sprawl to distant, improper, and metropolitan terrains (an appalling process starting in the early 1970s).

Final analysis reveals that 29 districts or 40% of the total (least vulnerable ones or adding the ones with results 7 and 8) have the best situation in both variables. Eleven districts, or 15% of the total (most vulnerable ones or adding the ones with results 3 and 4), have the worst situation in both variables.

All this facts allow the conclusion that in a great number of cases, the districts classified as having higher PQLI levels (good and very good) are related to lower registered numbers of disasters (below average and highly below average). On the other hand, the districts classified as having lower PQLI levels (very bad and bad) are related to higher registered number of disasters (highly above average and above average).

Considering these observations, it is possible to understand that the populations performing lower PQLI are more vulnerable to natural hazards than those performing higher PQLI. This information allows the return to the working hypothesis announced earlier in this article. This being confirmed was so reiterated in the final results of the research that authors now believe it would be only named assumption And, at the same time, scientific approach recurrently observed in terms of validating the priority given to social concerns in the discussion of adverse phenomena.

5. FINAL REMARKS

A conceptual review on social vulnerability and efforts to measure it are discussed in this paper; the case study presented here submits itself to explicit methodological limitations for apprehending social realities in abstract representations such as numerical indicators and maps. Despite the confirmed possibility to rely on the vulnerability index as a parameter for the development of public policies in the city of Curitiba, it leaves room for controversies concerning variables to be considered and the way they are overlaid and finally analyzed. Despite its significance for a specific urban planning, it reinforces unavoidable generalizations of specific situations (in this case, made at the district level), recalls the multitude of variables influencing final results, demonstrates recurrent ideological approaches in the selection of parameters to be taken into consideration, and confirms a submission of the researcher or policy maker to data availability. If this complex situation leads to reconsider the search of precise hierarchical definitions of spatial compartments in terms of risks, the extreme situations, those that interest us most (both very good and most critical) are believed to be detected in a more accurate way. Such contribution, made possible by the definition of a vulnerability index, also may serve as an instrument of public policies concerning different needed governmental or community actions facing risk reduction plans or emergency procedures. Despite generalizations because of the geographic scale adopted (boroughs), it may constitute a primary planning tool. Otherwise, much room is left to the investigation of particularities at a more intra-urban scale, considering existing differences inside the same district.

Results presented in this research were not expected to point out other important facts related to the concept of vulnerability, such as different capacities of the population´s territories to reduce risks and to respond to disasters according to their institutional and local organizations. Therefore, there is an assumption that it is implicit in socioeconomic

profiles described in the synthesis brought by the population´s quality of life indicator (PQLI). Constraints and distinguished abilities to establish either formal or informal civil organizations to present demands are to be differently detected in territories classified either as the most or as the least vulnerable ones. Social scenario worked in this research certainly indicates the existence of an overlay of unequal access to urban services and infrastructure (education, health, housing, safety, and transport), unequal conditions to respond to emergency situations, and unequal conditions to postulate for structural changes. If this triple overlay is somewhat a synthesis of different vulnerabilities, it still recognizes the existence of a city far from the dual visualization proposed by Castells (1989) or Mollenkopf & Castells (1991) but closer to a more encompassing one, such as that formulated by Marcuse´s quarters (1993). From a dual city of rich and poor, overlays worked in this research indicate an urban occupation characterized much more by a profusion of situations, agents, and abilities to cope with adverse natural phenomena.

If the assumption that different socioeconomic levels are affected differently by natural hazards is largely taken into consideration at conceptual discussion, urban management practices are hardly familiarized with this particularities in their own territories. It draws the attention to the fact that preventive actions are not only needed but also must adopt a profound fractal vision of the city.

Codes of research ethics : what are they useful for; and what are their limitations?

Francesco Lo Piccolo and Huw Thomas

Introduction

This paper will discuss the nature, usefulness and limitations of codes of research ethics. An awareness of the need for ethical sensitivity has been an accepted part of research practice in the humanities and social science for at least the last sixty years (Small, 2001). In recent decades the concern has taken a distinctive form, namely an increasingly prominent role being ascribed to procedural safeguards for ethical behaviour. Formal ethical approval for research proposals is now a standard requirement in virtually all disciplines in universities of the Global 'North'. Major funders of research in humanities and social sciences – for example, the Research Councils in the case of the UK – ask specifically that research they fund have appropriate ethical approval. The concern has gradually cascaded down the academic hierarchy, so that by now it appears to be commonplace in planning schools in the UK and elsewhere to require ethical approval of any significant piece of formal research even by undergraduate students[1].

Ethical approvals for research proposals are also required in some of the Southern European university systems, such as those of Portugal and Spain. This can extend to the training of the next generation of researchers. Despite the substantial lack of awareness in PhD programmes which was described by Mello (2009) in reference to many European university systems, in 2011 the Portuguese National Ministry for Education and Science issued a Guideline of Ethical Issues which has to be considered by all applicants; consequently, PhD researchers are asked to complete a questionnaire concerning ethical issues. In Spain, the National Law 14/2011 established (Title I, art. 10) the National Ethical Committee on Research; among its duties and commitments, there is also that of producing a code of ethics. At the local level, as a consequence of the National Law 14/2011, many universities have established ethical committees, issuing ethical protocols and guidelines. Although most of the concerns regard bio-medical and natural sciences research, in both countries some attention is paid to ethical issues arising in social research, in reference to those activities which involve the treatment of personal data or the engagement of children or adults unable to give informed consent.

Italy provides a rather different, but instructive case. In Italy codes of ethics represent a very recent initiative undertaken by universities, and the concern of Italian universities' codes of ethics is on the independence of research on the one hand and on integrity in the staff recruitment procedures on the other (thereby recruiting the right kind of ethical individuals). These concerns reflect the particular political and socio-cultural circumstances of Italy,

[1] This statement is based on personal experiences and anecdotal evidence.

reminding us that in relation to ethical judgement, especially, cultural inflection is inevitable. The focus on the independent responsibility of the researcher, on the other hand, is common to most discussions of ethics, and ethical codes: the implication is that in essence ethical behaviour is an individual accomplishment in an imperfect and impure world.

We previously discussed how most of the debate on research ethics and the principal concern of codes of ethics focus on individual behaviour, tending therefore towards a view of ethics as heroic endeavour (Lo Piccolo and Thomas, 2009). Small (2001, p. 390) highlights that the radical assumption that ethics is "an immediate relation between the individual person and moral values, without the mediation of a social group as a source of either understanding or motivation (…) leave the public dimension of ethics in darkness". We suggested (Lo Piccolo and Thomas, 2008) that ethical sensitivity is developed by researchers as part of a social practice, through communal activity; in order to demonstrate this assumption, we used the notion of social practice, as developed by MacIntyre (1985), which places the individual's acquisition and development of moral perception and judgements within a social context.

Nevertheless, individual responsibility is sill the basis of approach to most ethical issues in planning research (and practice). In fact, in most of the examples discussed in the literature, which regards planning research as well as planning practice, the autobiographical approach is (still) the most common: personal experience, and the ethical dilemmas which were faced, are the base for a more or less (self)reflective interpretation of more general issues. Codes of ethics *for individuals* reinforces this individualistic framing of the ethical landscape of research, including planning research.

Some commentators have drawn a distinction between a procedural approach to research ethics and reliance upon a code of research ethics (Guillemin and Gillam, 2004). The prime example of the former is a requirement to seek formal ethical approval of a research proposal. This approach, it is suggested, attempts to address all potential ethical issues involved in research ahead of time, and checks that the researcher's espoused belief about how s/he will react to such issues is acceptable. The latter, on the other hand, involves drawing up a code which gives advice on good conduct in research, and allowing individuals to interpret the code within the context of their particular research as it progresses. It should be noted that though the code has to be interpreted, its contents – what count as ethical considerations – are laid down within it for the researcher. There is undoubtedly a difference of approach being identified here, but its significance is over-stated. In practice, applications for research ethics approval will often contain a reference to an appropriate code of research ethics, usually one from an academic discipline within which the research proposal is framed. Second, and more importantly, a procedural approach and the reliance on a code share a significant similarity which marks them as very different from the approach to research ethics that once prevailed in planning research. Use of either a code or formal research ethics approval suggests that it is not safe to allow researchers to simply get on with their research project and exercise individual judgement in the field (even after suitable training, which could include a period of supervised research for example). In addition, and related to this focus on anticipating what researchers will encounter, both approaches assume that their framing of the ethical landscape within which the proposed research will take place by codes or approval

procedures is accurate, and will be uncontested by the researcher, even when s/he encounters the day to day realities of the research project. A discussion of the usefulness and limitations of codes of research ethics will therefore identify some considerations which also apply to a procedural approach to regulating researchers' behaviour.

This chapter will begin by discussing why concerns might arise about the ethical conduct of research, and in particular how such concerns are shaped by how research is conceptualised. It then examines the nature of codes of ethics, especially what they might typically contain and hope to achieve. Finally, it considers whether the content of codes of ethics are intelligible outside specific ethical traditions. In each section, the implications of the discussion for the kinds of use researchers can make of codes of ethics are drawn out.

Why regulate research?

Research is a social practice which finds its definition and rationale within a particular way of conducting, and ordering, social relations and institutions more generally –ie a way of organising social life. While curiosity, learning and teaching, and social differences which are at least in part based on some conception of possession of greater or lesser knowledge or understanding may be widespread in human societies, research as the kind of activity conducted in contemporary universities is distinctive of a certain kind of post-Enlightenment society. As Weber knew, science as a vocation becomes possible only when certain political-economic and institutional structures are in place. It is because research has become a particular kind of social practice that it comes to be argued that it requires formal regulation – in which a code, or codes, of research ethics may play apart.

Regulation of a practice can become attractive for many reasons; in the case of academic research a number of these have coincided. From outside a practice, demands for regulation arise when the practice has the capacity to cause widespread and possibly serious harm, and when there is a possibility that those involved in the practice may be so wrapped up in it that they lose their sensitivity to broader value concerns. This is particularly likely when a practice becomes institutionalised and a significant divide – in terms of social identity and outlook – arises between practitioners and others beings and objects which are caught up in the practice. From within the institutionalised practice, on the other hand, the key question will be who undertakes the regulation. It is a mark of the power, and status, of those engaged in a particular practice that they be allowed to regulate themselves, as in the case of some professionalised occupations (Johnson, 1972). Even for practices/occupations which are not entirely self-regulating, having aspects of regulation such as a code of ethics can provide an additional (albeit small) marker of distinctiveness for the practice, as it does with professionalised occupations (Bickenbach and Hendler,1994). Even in professional codes we can find an attitude towards the accountability and legitimation of the social status of a profession (and its members), which is prevailing compared to the aim of regulating the ethical conduct of the members in their professional activities (Moccia, 2011).

We would suggest that it is significant that the rise to prominence of regulation in general, and codes of ethics as part of this, in social science research has coincided in many countries with a number of related phenomena. Prominent among these is the increased emphasis on the importance of research as an activity which defines a university and is also a major source of revenue (Collini, 2012). Secondly, there has been an acceleration of research, with minimal teaching, as a career path – both for established faculty, who may simply relinquish other duties – and for newer faculty, who are recruited as researchers and intend following, if possible, a research career. The research-based PhD has become almost universally required as a qualification/apprenticeship for academic life. Running alongside these developments, social research institutions have continued, perhaps intensified, their roles as authoritative producers of knowledge, particularly for policy development that professes to be based on evidence (Allen and Imrie, 2010; Thomas, 2010). So, universities and research institutes are doing more research, are claiming it is important, and more and more academics are thinking of themselves primarily, or at least in large measure, as researchers. It is in these circumstances that it can seem attractive and appropriate to devise and subscribe to a code of research ethics as part of a tacit professionalising of the researcher's role and practice. It is arguable that Planning still has an insecure place in the Academy, and for such a discipline a clear commitment to ethical self-regulation, including adherence to a code of ethics, can be an important part of the continuous assertion of academic legitimacy. Some arguments are discussed by Stengers (1987) on the process of 'soft' sciences in order to become 'harder' in order to acquire broader recognition. The process of 'hardening' a discipline comes from the need of gaining broader social legitimation and reaching an upper status for its members. Even the establishment of professional codes of ethics is a step towards this direction.

In large measure, the practice and understanding of research in contemporary universities is modelled on the experimental sciences (for example, if the underlying rationales for research assessment exercises are ever persuasive then it is in relation to these disciplines (Collini, 2012)). Yet, the metaphysical underpinning of experimental science, its ontology and epistemology, is only one way of seeking an understanding of the world. Within social science, positivism, which is an approach framed by the same metaphysics as experimental science, is fiercely contested (eg Flyvbjerg, 2001). Values are central to various (different) critiques of positivism within social science. Thus, it is criticised by some for ignoring, and having no resources to address, the value-context within which social scientific problems/issues are framed and pursued (Flyvbjerg, 2001). Others suggest that to make sense of individual and social activity, social science must understand the systems of meaning (and values) within which individuals and groups make sense of the world and generate reasons for acting (Winch, 1958). Conceived in this way, social science and the Humanities might be characterised as activities which seek understanding rather than seek knowledge (Collini, 2012). And undertaking them might sometimes involve feeling one's way into sets of values and ways of life which have ethically questionable dimensions. At the same time, knowledge produced by planning research is influenced by the local power-relations and the hegemonic policy discourse (Thomas, 2010). In many cases (and more often in recent times, due to the position of the contemporary entrepreneurial universities), planning researchers are looking for institutional requests and commitments, with significant ethical implications. Thomas

(2010) has discussed how planning research can be helpful to those who would promote and sustain hegemonic policy discourses and that legitimacy is acquired through claims to a particular kind of rationality and objectivity. In other words, planning research as it is developed in universities – as a product of institutional requests – may have as a result the university's standing as the guardian and constructor of (a supposedly neutral and objective) knowledge, justifying and sustaining any given set of governance arrangements.

One might expect a code of ethics to have something to say about these matters. But as Christians (2000) points out, codes of research ethics developed in the context of positivist, 'value-free', science. This has shaped their form and content. One consequence is that the nature and purpose of research as a practice is usually not alluded to in the codes – it is assumed to be socially beneficial and value-free (as natural science is widely considered to be). The codes focus on the day to day practice of research itself, and within that, the researcher is viewed as detachable (including ethically detachable), at least in principle (and ethically) from that which is being researched.

This is particularly inappropriate for research such as planning research which involves, of necessity, an engagement with the value-saturated world of public policy. For example, if planning is about a dialectical relationship between knowledge and action (Friedmann, 1973, 1987) then those who claim to produce planning knowledge will inevitably be implicated in the moral landscape of practice. As we know, most of the practice requires to face ethical judgements and dilemma; as Kaufman (1993, p. 113) highlights, "much of the behaviour of planners reflects both ethical choices and carries with it ethical consequences. Ethical judgements are involved, sometimes explicitly but more often implicitly, in many planning activities including collecting and analyzing data, forecasting, cost-benefit analysis…". So, if we consider and recognize the pervasive ethical dimensions involved in planning work (Kaufman, 1993), ethics is a relevant, even if not particularly discussed, component of planning research, which mainly derives from the continuous involvement of planning researchers into practice. Although the utilitarian approach implies that the choice of good or ends come from a political process beyond the scope of the planner-as-scientist, which is responsible just of the choice of means (Harper and Stein, 1992), we all know that this division does not occur in reality. Planning practice is inherently political, denying the rhetoric or stereotype as a value-free means-technician who deals with "factual data but avoids the value questions of defining these objectives" (Klosterman, 1978). In those circumstances, good researching is partly defined by sensitivity to politico-ethical implications of the research (Flyvbjerg, 2001).

What do (and could) codes of research ethics contain?

In discussing professional codes of ethics for planning, Taylor (1992) rehearses a distinction which also appears regularly in discussions of research ethics (eg Small, 2001): is a code a set of ethical guidelines which could apply to any occupation, or at least any professional occupation, or does it identify challenges and issues which are particularly pertinent to

particular kinds of activities? The appearance of virtues such as honesty, objectivity and respecting confidentiality (eg Resnik, nd) in research ethics codes illustrates that to a large extent what is being asked of researchers is that they simply be of good character as they go about their work (Thomas, 2009). Yet, it is certainly the case that different kinds of research tend to bring distinctive challenges and dilemmas. The case-studies in Lo Piccolo and Thomas (2009) illustrated ethical challenges which had resonance for researchers into planning, but were likely to have little or no resonance for researchers in experimental science. For example, at the core of Porter's (2009) concerns is exploring the feasibility that a non-indigenous researcher researching the lives and views of indigenous peoples can free herself from the objectifying imperial gaze that has structured (and defined) indigenous/non-indigenous relations over centuries. She is rejecting the research position of the experimental researcher on ethical grounds.

It follows that codes of ethics which is sensitive to the circumstances under which particular occupations or activities are undertaken are likely to be more useful. In the case of research, appropriately different codes will be needed by researchers engaged in activities involving people, other sentient beings, other organisms, or objects, for example. Different codes may also apply to people engaged in activities which can potentially cause widespread harm; and these are just some examples of differences which many would regard as warranting special mention in a code of research ethics. Researchers who wish to avail themselves of guidance from a code need to unearth one that is appropriate for their kind of research, therefore. It should be noted that what counts as a significant difference between types of research is itself an ethical judgement ; so, for a group of people to agree about even the need for, and broad lineaments of, a code, they must already share significant ethical perspectives.

This consideration has a bearing on another of Taylor's points. He argues that central to a code of ethics must be a vision of what the activity (eg planning research) should be, a vision of what MacIntyre might refer to as the characterisation of excellence in that activity[2] .

Such visions are contestable. This is not always obvious because often discussions of research ethics focus on the minutiae of day to day research activity, at its worst reducing the ethical implications of research to a kind of soap-opera of inter-personal relations which happen to take place in the research field. It is certainly the case that inter-personal relations are as important an issue in research ethics as they are in ethics in general, and researchers must be sensitive to factors such as the power-relations bound up in social relation. The research activity itself can create distinctive kinds of social relations which will have their own power-dynamic, and at times one that is questionable (eg Porter, 2009).In addition, those engaging in research, in any capacity, are inevitably embodied and socially located (in terms of gender, or class, for example) as they engage in the research process. As Sayer (2005) has argued persuasively in relation to social class, these characteristics, and their associated hierarchies, can have a moral dimension because they have judgements of personal worth bound up with them.

[2] Hendler (1990), too, notes the significance of ideals of excellence in relation to codes of ethics.

Important as they are, these kinds of issues associated with the conduct of research do not comprehensively define the ethical landscape for the researcher. Flyvbjerg (2001) points out that social research practice is itself enmeshed in webs of power-laden social relations which constitute a particular kind of world with a particular kind of trajectory. The practice of social research will either consolidate or change the world. He argues that the kind of practical knowledge which is required for researching human social life is itself a capacity which will allow the researcher to judge the ethical import of the research being undertaken and to act so as to make the world better. There is no choice in this matter, in that research which is not self-consciously set on improving matters will either be self-consciously avoiding doing so, or be poor research because ignorance of the import of research betrays a lack of the phronesis needed to undertake insightful research into human social life.

Harper and Stein's (1992) argument for a reunion of ethical and planning theory makes a similar point in relation to planning research, on the grounds that planning can not be considered a technical, value-free activity. Moving beyond this consideration, we could add that is not possible to justify the goals of (public) planning research without appeals (possibly explicit) to normative ethical theory. In most planning research we will not find references to ethics and ethical theory, but implicit interpretations of and references to public ethics, as inherent in planning as a public (political) activity: issues as cultural heritage, environment and public health, social justice and equal opportunities are common examples. Most planning research (especially when intended to directly inform practice) does not make any reference to any sort of ethics or ethical theory. This does not imply that there is not any (normative) ethical theory at the base of the research, but just that it is implicit (and sometimes at a non-cognitive/conscious level). It would be a significant advancement in our research to make these implicit normative ethical foundations explicit. However, an ethical code alone will not impel researchers in this direction.

Research is intended to make us understand the world better, and hence differently. In planning, this cannot but have normative implications, because understanding the world a certain way suggests ways in which it can, and should, be changed. Seeing people a certain way is part and parcel of behaving towards them in given ways; the two are inseparable. This implication of research is so, whether one is taking oneself to be de-mystifying power-relations in a major planning project in Denmark (Flyvbjerg, 1998) or exposing the failure of planners to grasp the concrete realities of the communities they were affecting with their policies as Jacobs (1961) and Dennis (1970,1972) did in their different ways. In these cases, Geertz (1988) argument that a process of persuasive interpretation of circumstances is central to ethnographic research rings true. But even self-consciously dispassionate studies such as Forsyth's (1999) account of struggles over urban expansion in Sydney, or Le Goix andWebster's (2008) theorising of gated communities still invite us to understand the social world in a certain way, and that way will be shot-through with values. This is impossible to capture in any code of ethics, for the latter's bullet-points can get little beyond 'don't lie; don't fabricate' and the like; and that is not what is going on when research is being written up. All writing up of research intends to persuade the reader of that of which the researcher is

already persuaded. But in writing up planning research, like any social research, the commentary (like the study itself) has within it a picture of humanity, a picture that is inevitably normative.

Codes and ethical traditions

As noted earlier, codes of research ethics tend to contain a core set of concepts. Central to most are integrity and respect for persons. The current UK Economic and Social Research Council framework for research ethics identifies what it calls 'six key principles' (ESRC,2010, p3). These highlight the significance of:

- Integrity, quality and transparency
- Informed consent
- Confidentiality
- Voluntary participation
- Avoidance of harm to participants
- Independence/freedom from partiality and/or clear declaration of interest/partiality

Small (2001) points out that the kinds of concepts listed above gain their meaning within an ethical tradition or theory which will itself have metaphysical underpinnings. Underlying the significance of informed consent and voluntariness, for example, is a liberal notion of respect for persons, which views the person as ontologically and morally more basic than, and prior to, any social entity. But liberal conceptions of what is meant by 'respect for a person' simply cannot be transplanted unchanged into, say, the kind of feminist perspective on life which emphasises the significance of our social being in constructing our individuality. As he says, applying the notion of respect to social groups is not simply an extension of the Kantian notion of respect for individuals, but a different idea entirely. This kind of conceptual revision, and argument around it, is central to ethical life. It is an unavoidable part of the way in which we construct our social existence, and moral concepts have to be understood within these forms of life (MacIntyre, 1998, 1– 4).

Small (2001) suggests that as a consequence, ethical codes are simply compromises between groups with fundamentally different ethical perspectives, a kind of lowest common denominator that all can live by. Not surprisingly, he goes on to argue that developing ethical behaviour among researchers should not focus on codes of ethics but on how to discuss ethical issues and reach agreement on ways forward. If one follows MacIntyre's approach, even a lowest common denominator will be illusory – for the terms used will have been ripped from the context which gives them their full meaning. As a consequence, they will either be applied in ways which will seem arbitrary, even when agreeable to all; or, at other times, their application will be embroiled in irreconcilable conflict (eg in relation to research involving human embryos; or research which involves contact with largely undisturbed peoples) as concepts are interpreted within different ethical traditions. Codes of ethics are

mainly related to procedures and (individual) conducts; nevertheless, there is a substantial difference between substantive ethical theory and procedural ethical theory, the latter making "recommendations about the process which should be followed in deriving and justifying ethical principles, and arriving at ethical conclusions" (Harper and Stein, 1992, p. 106). For their nature, codes of ethics are mainly related to procedural, and not substantive, ethics.

These considerations suggest that central to ethical research will be the development of a community of researchers which shares an outlook on what matters, and what the place of human life (including practices like research) is in relation to what matters. Within this community there will be shared terms of reference and vocabulary which allows principled, but constructive, discussion and disagreement about research ethics. In particular, it allows constructive discussion about why, when and how research may be appropriate. Within research communities, codes of ethics may have a role as rules of thumbs, or reminders of key dangers to researchers' integrity. But not as answers to day to day issues that arise in research.

ONLINE INTERACTIVE LEARNING TUTORIALS: ADDRESSING ACADEMIC INTEGRITY AND REFERENCING

Ann Peterson[1], David Neil[2] Clive Warren[3], Deidre Seeto[4], Dominic McGrath[5]

Abstract

Academic integrity and good practice are central to student learning, and student success requires flexible delivery of critical concepts in interesting and interactive formats. Two online tutorials were developed and successfully implemented in the planning program at The University of Queensland, Australia. The Academic Integrity tutorial clarifies aspects of good academic practice, including why it is necessary to cite sources and how to acknowledge them, explains the difference between collaboration and collusion, examines the seriousness of misconduct and demonstrates good habits for avoiding plagiarism. The Academic Referencing tutorial addresses the concepts of referencing and why it is important and clarifies the key elements of citations using the Harvard and Chicago styles. Planning students require basic information on institutional and workplace expectations in relation to plagiarism and referencing to enable them to effectively assess information, work within teams, and communicate in an age of expanding technologies and information.

The seamless design of the tutorials incorporates linear navigation, meaningful contexts, learning by doing and a thorough testing of concepts. Students interact with a series of real world scenarios and respond to case studies and questions which test their understanding. Learning is promoted by extensive feedback and multiple attempts, and users' progress and outcomes are recorded in a database. The needs of diverse learners were considered, by incorporating a range of cultural backgrounds in the examples, ensuring all visual information represented in text was suitable for visually impaired users, incorporating the use of screen readers, and designing the flash demonstrations to reduce cognitive overload. Extensive evaluation has indicated a significant improvement in student knowledge of what constitutes plagiarism and an enhanced understanding of the seriousness of plagiarism and its consequences. Students and staff focus groups indicated that the key strengths of the tutorials are their clear and relevant information on referencing styles, collusion, collaboration and plagiarism, their good design, relevant language, ease of operation and the sense of relief that students now understood how and when to reference and what is and is not good academic practice. The Academic Integrity tutorial has won international acclaim for its high quality design and effectiveness.

Keywords: plagiarism, online learning, academic integrity, referencing

1. Introduction

There is no doubt that some students plagiarise (James et al., 2002; Park, 2003; Sutherland-Smith, 2008; AUQA, 2009; Curtis and Popal, 2011) and that some professionals in the workplace plagiarise (Roberts, 2008; Shrimsher et al., 2011). These findings have relevance for both planning educators and employers. Our research team in the School of Geography, Planning and Environmental Management (GPEM) at The University of Queensland (UQ), Australia began a proactive approach to move from a regime of punishing students who were found guilty of academic misconduct to one of providing relevant information in an engaging and interactive manner. In response we developed a range of tutorials. In this paper we examine the key features and effectiveness of the *Academic Integrity* and the *Academic Referencing* online tutorials. The former has been in place within GPEM since 2006 and was later redeveloped and deployed university wide in 2010, while the latter was completed in 2012.

We begin with a review of the recent research addressing academic integrity, then an overview of the two online tutorials, followed by a brief explanation of the technical and pedagogical principles that underpin them, how they are delivered, and finally brief evaluation results. Our research indicated a significant improvement in students' level of understanding of academic integrity and referencing and very positive student and staff responses to the design and delivery of the tutorials.

2. The nature of the educational problem

Plagiarism is the act of misrepresenting as one's own original work, the ideas, interpretation, words, images, designs, or creative works of another (UQ, 2008). Examples of plagiarism include: direct copying of paragraphs, sentences, a single sentence or significant parts of a sentence without appropriate acknowledgement; a 'cut and paste' of statements from multiple sources; and simply rearranging another person's words or ideas without changing the basic structure and/or meaning of the text and without appropriate acknowledgement (Warren et al., 2012).

The literature cites many reasons for academic misconduct among students, including: time pressures; inexperience; immaturity; personality; cultural practices; the pursuit of good marks and the associated belief that this will assist in gaining employment in harsh economic times (Harding et al., 2004); increasing class sizes, with reduced access to staff; staff setting similar assessment tasks and student's increased reliance on past student work (James et al., 2008). Students also are learning from their peers through group work, online discussions, and interactive activities (McLoughlin and Lee, 2011), and some may not fully understand the complexities of collusive activities. For professional planners this can be potentially problematic as many will work in interdisciplinary teams. In addition, students may view information on the internet as public knowledge and thus free from intellectual property rights (Schrimsher et al., 2011) and some will download academic papers for free or for a small price (Evans, 2000; Thompson et al., 2002). Faced with an

explosion of information, issues of plagiarism and collusion are problematic in many educational institutions and professional workplaces.

Academic misconduct is a problem that seems to be on the rise in most countries (Larkham et al., 2002; Carroll, 2004; Park, 2004; Roberts, 2008). The Australian Universities Teaching Committee (AUTC) (2008) indicated that while it is impossible to determine trends in the incidence of plagiarism in higher education institutions, it appears to be widespread, and occurs across a range of disciplines (Peterson et al., 2009a,b). The incidence of plagiarism and the perception among students that poor academic practice and plagiarism are tolerated in universities has been an issue raised by the Australian Universities Quality Agency (AUQA) in a number of its audits of Australian universities. In the 2009 audit of UQ the agency observed that the university needed "to address a concern held by students in some schools that plagiarism or copying is tolerated" (AUQA, 2009). Other research (AUTC, 2008) indicated that many cases of alleged misconduct could be attributed to misunderstanding and ignorance among students about why they should avoid plagiarism and how they can do so. Hence it is evident that students, particularly beginning students, may not have the necessary academic skills (O'Donnell et al., 2009) to perform well and avoid academic misconduct. In fact they may have to unlearn certain practices (Johnson and Watson, 2004). However, to complicate this situation, staff may overestimate students' abilities in key areas (Tobell et al., 2008) and thus fail to provide the necessary information and guidance.

Instances of students, including planning students, in GPEM demonstrating poor academic practice were long recognised by our research team. The reporting of suspected plagiarism cases increased following the introduction of plagiarism detection software and in response the School introduced procedures to identify and categorise the seriousness of the alleged plagiarism, and to process allegations of misconduct. This was efficient, but not totally effective. A frequent student defence was, "… I didn't know this was plagiarism". In 2006 we changed direction and decided it was necessary to increase out students' awareness of the meaning of academic integrity and how to avoid it.

In GPEM, 472 students, including students in a large first year planning course, were invited to participate in an online survey addressing student understanding and attitudes to academic integrity. Thirty-three percent (157) responded. Most students agreed that plagiarism included paraphrasing or summarising someone else's work and not citing them as the source. However, 21% believed that it was acceptable to use someone else's ideas, to express them differently, and not acknowledge the source (4% didn't know). When asked about using elements of a design from a third party and incorporating these into their work, 85% did not consider this to be plagiarism. Almost 50% believed that it was acceptable to submit, without acknowledgement, an assignment for assessment that was previously submitted in another course. Almost 30% were neutral on the issue of copying information because of time demands and 10% disagreed or did not know that this was plagiarism. Over 30% believed that it was acceptable to be a member of a group

undertaking a group project, to work less than other members in the group and to claim equal contribution to the project. About 10% of students could not correctly identify examples of collusion. In terms of seriousness: plagiarism was viewed as moderately serious by 19% of students (81% very serious or serious); collusion as moderately serious by 27%, (44% very serious or serious); and 20% believed that cheating on an exam was not very serious. In an age of easy availability of information from the internet, students were asked if the use of text that was cut and pasted from websites was a serious plagiarism issue and 27% did not consider this to be serious, with a further 13% not knowing.

When examining the causes of plagiarism, almost 20% of students believed that they could 'get away' with plagiarism in their courses and that their peers thought it was 'OK' to plagiarise. Almost 40% believed it was easier to plagiarise than spend time undertaking the work properly; and over 10% believed it was appropriate to 'make up' information in a bibliography. In relation to referencing skills, most students were unable to correctly reference information using a recognised referencing style, and. Students also showed little understanding of the consequences of plagiarism. However, nearly 80% believed that plagiarism detection software encouraged them to correctly cite information.

Our results provided clear evidence that universities and their component programs (including planning programs) must ensure that their students are adequately skilled in the concepts of academic integrity and referencing to ensure that collusion and plagiarism are avoided. Pecorari (2003, p.317) agrees stating that "the focus on preventing plagiarism [should] be shifted from post facto punishment to proactive teaching" and a Stanford University student survey also indicated that students "wished faculty would clarify their expectations for academic integrity" (Schrimsher et al., 2011, p.10). Curtis and Popal's (2011, p.30) longitudinal research about the perceived seriousness of plagiarism and its causes indicated that "plagiarism may be reduced by means of educational programs that promote the perception of plagiarism as a serious academic integrity issue".

In order to narrow the gap between student expectations and course, program or institutional expectations, we developed and implemented an online tutorial about academic integrity (including referencing). Our need for a new approach took us on journey to evaluate what was currently being used in other universities and workplaces, both in Australia and internationally. Nothing suited our needs as most instruments focused on repeating institutional policy and instituting punishment regimes. In 2006 we developed our first tutorial about academic integrity and referencing. The final product was piloted and implemented with first year undergraduate and postgraduate students in GPEM. Our three year evaluation of the tool highlighted its effectiveness (refer section 4). At this time, the findings of the AUQA (2009) audit in relation to UQ were released, highlighting the misconceptions of students as to the nature of what constitutes plagiarism, and this resulted in new institutional policies and procedures in relation to academic misconduct, based on increasing staff and student awareness of the key issues. One of the decisions of the

university was to invite our research team in 2010 to re-develop our existing tutorial for university wide deployment. This resulted in the *Academic Integrity*: *referencing and avoiding plagiarism* online tutorial and the excision of information about specific styles of referencing into a new tutorial called the *Academic Referencing* tutorial.

3. Design elements

The Academic Integrity tutorial aims to ensure that students develop a sound understanding of key issues so that they can apply and demonstrate academic integrity and good practice. It encompasses four sections: S1 "Academic Integrity" clarifies aspects of good academic practice; S2 "Working Together" explains the difference between collaboration and collusion; S3 "Misconduct and Consequences" examines the seriousness of misconduct; and S4 "Good Writing Habits" demonstrates good study habits for avoiding plagiarism, including time management and note-taking. From 2011, the tutorial must be completed successfully by all commencing UQ students. A university-wide evaluation of the effectiveness of the tutorial began in 2012 and will be completed by the end of 2013.

While issues related to referencing were included in the original tutorial, its redesign for institution-wide deployment resulted in the removal of information specifically addressing referencing styles. In response, we developed a separate tutorial to complement the Academic Integrity tutorial and its focus is when and how to reference. It has four sections: S1 "Introduction to Referencing" addresses core concepts of referencing and why it is important; S2 "Elements of Referencing" clarifies the key elements of citations and provides detailed instruction for a range of sources (e.g. books, book chapters, journals, web sites, government reports, personal communication etc.); S3 "Harvard" referencing; and S4 "Chicago" referencing provide information on how to format elements of referencing for bibliographic and in-text referencing for an author-date and footnote systems of citation. It was piloted in 2012 and will be implemented fully within our School in the latter half of 2012.

The technical and pedagogical design issues are explained in this section, including information on the administration of the tutorial. The target audience for both tutorials is undergraduate and postgraduate students at UQ. The Academic Integrity tutorial is compulsory for all students at the university (about 45,000 students), while the Academic Referencing tutorial is implemented in GPEM (about 2,000 students). The tutorials are completed by both domestic and international students.

3.1 Technical design

The tutorials interface seamlessly, although ideally the Academic Integrity tutorial would be completed first. They have a similar clear and refreshing design, with appeal primarily to university students, due to the images and contexts that are used (Figure 1). For example, the tutorials are personalised with images of young adult students, who have been selected to reflect the age range and cultural diversity of the

students within our institution. The layout is uncluttered with interesting text to engage the reader and yet maintain a serious tone reflective of the issues being presented.

Figure 1. Example of the Academic Integrity tutorial design encompassing interesting layout, colour and style

Information is presented mainly by means of a two-part screen, with stimulus material (e.g. information and demonstrations) on the left, and instructions and interactive activities on the right (Figure 2). Thus different sections of the screen are assigned to specific purposes (Alessi and Trollip, 2001) and this remains consistent in both of the tutorials to facilitate student interaction and ease of use. The screen separation also assists sight-impaired users.

Figure 2. Screen layout, incorporating resource information (left) and instructional and interactive exercises (right)

The content of the tutorials is identified on the log in page and they each have four self-contained sections. These sections also are clearly identified at the top of the

screen, with a 'mouse over' facility to identify the key content areas in each section (Figure 3). The Academic Referencing tutorial incorporated a progress line at the bottom of the screen for ease of navigation, allowing students to slide the bar to highlight relevant parts of the particular section (Figure 4).

Figure 3. Incorporation of a 'mouse over' facility enables the detailed content of each section to be identified.

Figure 4. The slide bar at the bottom of the screen enables students to quickly manoeuvre between various components of each section of the tutorial.

The tutorials' content incorporates visually stimulating images, and the examples used for instructional purposes reflect the cultural diversity within the university. There is sufficient, but not excessive, instructional text and clearly indicated transitions between sections and screens. For example, navigation within the tutorial is by consistently placed icons, indicating the 'next' and 'previous' screens (Figure 4). The language is geared to appeal to university students from a variety of discipline areas.

The tutorials' linear navigation allows students to complete each exercise, receive immediate feedback with a learning focus, and have multiple attempts at the exercises until the correct response is achieved. Students must successfully answer

each question in order to proceed and hence a 100% success rate is required to complete the tutorials.

The tutorials are self-paced, allowing students to enter and exit at any time. An underlying database records and saves users' progress, meaning that students can continue the tutorial from the location they left. Once questions have been answered correctly a 'skip' button appears (upon return to the particular question). This enables students to review questions and move quickly between questions that have been correctly answered on a previous occasion. The pedagogical purpose of this linear navigation is to build on the concept taught, apply concepts, and test concepts.

The web advantages of the online tutorials allow users secure access, any time and any place. A lightweight html based design minimises download size, improving the speed and experience of all users particularly students accessing the tutorial on low-bandwidth connections. Tutorial content is stored in database tables separating the content from the presentation level. This separation enables additions and modifications to the tutorial without the requirement of technical expertise and upgrades and modifications to the presentation level without the requirement to re-enter or change the content.

Each response provided by students is logged with a timestamp. Analysis of these logs enables reviewers to consider which questions take students longer to answer, are more likely to have students leave the tutorial, or are more likely to have students choose incorrect options. The total time and number of logins is stored per student providing an overview of how students use this system. A report of student competitions is generated on request for administrative systems to track compliance with university requirements. Student data is stored for 12 months and to manage data storage and student privacy, official completion details are transferred and stored in administrative systems.

3.2 Pedagogical design

The tutorials employ two key categories of affordances of e-learning, namely static/instructive learning opportunities (e.g. definitions and explanations), and productive learning (e.g. "learning by doing") (Bower, 2008). Several key principles of effective instructional design (Carrol, 2002; Anderson and Elloumi, 2004), which facilitate learning, are reflected in the design of the tutorials including the following (Peterson, Jordan and Neil, 2010; Peterson et al., 2010, 2011):

a) Relevant contexts to help learners construct new knowledge from existing knowledge
   The authentic/real world contexts (e.g. exemplars from student work and their practices) employed in the tutorials, link the current student experience with future real-world work experiences and activate learners' schema – the "structures that permit us to recognise objects and other entities" (Sweller, 1999, p.10), thus reducing cognitive, working load stress. Due to the diversity of students at our institution, broad themes are used in the examples (e.g. environment,

sustainability, climate change), along with common student contexts (e.g. related to assessment and group work).

b) New knowledge is demonstrated to the learner
In general all key concepts are defined and illustrated through examples and/or animations to minimise confusion (Klausman, 1999). For instance, learners are provided with information about the conventions of referencing, they read the specific requirements (e.g. use of author names, or how to reference a quote), and then view it in a stimulus text, where it is highlighted, often using flash technology.

c) Learning is enhanced by doing
The principle of 'learning by doing' is based on the notion that active learners learn best and thus reinforce their learning (Dewald et al., 2000). Students are compelled to think and in practical terms, the learners must demonstrate knowledge or understanding by choosing the correct response to questions. They then receive feedback for both correct and incorrect responses.

d) Self-paced learning
The students are able to work through the on-line tutorials at their own pace and in their own time, thus more appropriately matching the learning style of the student. The tutorial can be used as an on-going resource for students to refer to as the need arises. Hence, its flexible delivery enhances student engagement, as does its good design, layout and ease of use.

e) Students are required to apply the new knowledge
Learners are required to demonstrate their new understandings in their assessment tasks and other activities. For example, GPEM course profiles, which outline student obligations and assessment tasks, include reference to the need for students to undertake and pass the tutorials. All staff (including tutors and markers) are trained in the tutorials and reinforce the standards and expectations established in the tutorials. The tutorials' on-going availability to students also assists in embedding the key concepts.

4. Evaluation

To date, only the Academic Integrity tutorial has been comprehensively evaluated and this has centred on assessing the effectiveness of the tutorial in raising awareness of academic integrity, its key components and the serious of academic misconduct.

There were several components to the evaluation of the tutorial:

a) A three year evaluation within GPEM (2007-2010) involving 157 students. This included a pre- and post-survey (i.e. about 6-8 months after completion of the tutorial) and in-depth focus groups.

b) Observations of how 25 students manipulated and navigated through the tutorial within a controlled computer laboratory prior to the university-wide roll out of this tutorial (2010). The evaluators observed student progression through the tutorial, noting whether students were reading the text or merely clicking buttons, and how long the tutorial took to complete. Students also were

interviewed to assess the relevance, interest, effectiveness and user interface of the tutorial.

c) All UQ academic staff were informed of the tutorial and invited to provide comments and feedback to the project team.
d) Pre- and post-surveying of all UQ students who undertake the tutorial. To date approximately 600 students have completed the pre-survey (data has not yet been analysed).

The online survey canvassed student responses to several issues including:

a) why it is important to engage in good academic practices;
b) what constitutes plagiarism;
c) the seriousness of several practices (e.g. copying information from the internet/books/journals/designs, failure to correctly reference, unintentional copying, cheating on exams, collusion, and auto-plagiarism);
d) factors influencing plagiarism (e.g. time commitments, lecturer inaction, real-world pressures, peer pressure, difficulty in detection);
e) sourcing information, which addressed author-date in-text referencing and constructing a bibliography, and when to reference (e.g. use of common knowledge, quotes);
f) differences between collusion and cooperation; and
g) penalties in relation to the seriousness of plagiarism.

Qualitative responses were analysed using Leximancer to identify key themes, and relational responses were analysed using Nvivo software.

5. Results and discussion

The results indicated improved student knowledge of what constitutes plagiarism, when and how to cite sources (Peterson et al., 2009a), the seriousness of plagiarism and its consequences. They also had an enhanced understanding of collusion.

a) Importance of citing sources
Students were asked to indicate three reasons why it is important to correctly cite information. About 25% of students said that it was necessary to acknowledge the work of the author or demonstrate respect for the author (6%) (Figure 5). Enhancing the credibility of the student/writer's work was also important (16%), as were a range of value-based responses, particularly that of fairness (11%). Other criteria included abiding by rules (either to ensure compliance or through fear of censure) as well as this being a sign of good practice, enabling the tracing of cited information.
b) Meaning of plagiarism
Following completion of the tutorial, students displayed improved understanding of plagiarism and considered that it included the following: failing to correctly cite information; 'copying and pasting' information from the internet without acknowledgment; and auto-plagiarism. They also had raised awareness of the

need to acknowledge the work of designers (e.g. planners). Students generally understood, both before and after completing the tutorial, that the failure to correctly reference images, maps or diagrams, and paraphrasing without acknowledging the authorship constituted plagiarism.

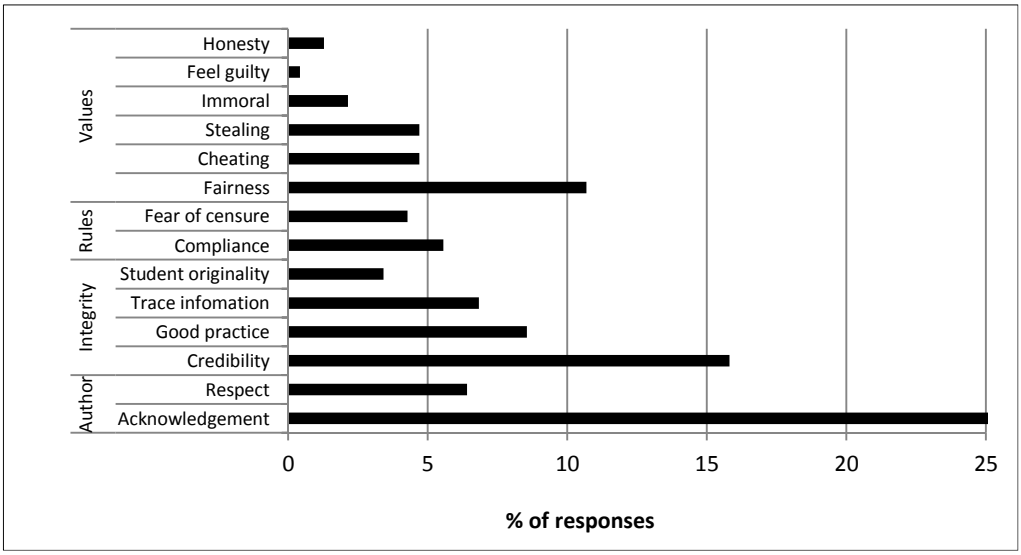

Figure 5. Student responses to why it is important to correctly cite information

c) Referencing skills

The ability of students to correctly in-text reference and create a bibliography significantly improved following completion of the tutorial (Figure 6). The greatest change was in relation to a basic in-text Harvard referencing style where students were asked to consider the author/date order, and in this instance, success improved from 46% to 81%. Students were generally much better able to cite quotes and to detect inaccuracies in-text referencing of information obtained from the internet and in understanding bibliographic referencing.

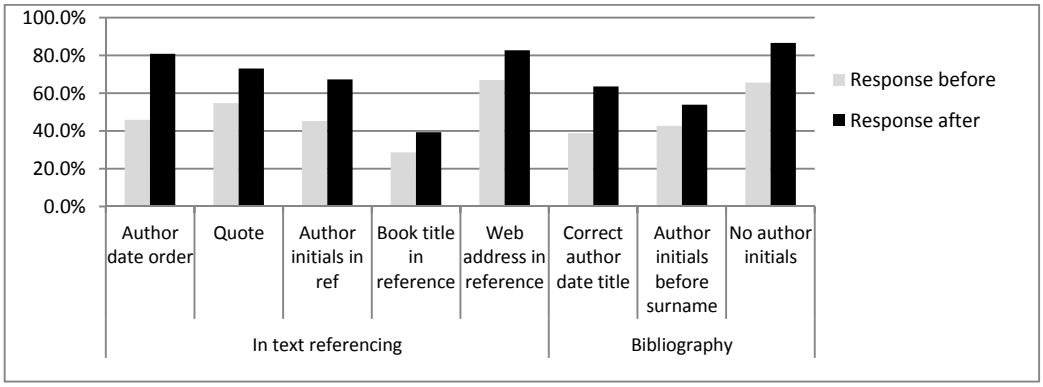

Figure 6. Percentage of correct student responses to in-text and bibliographic referencing questions, before and after completion of the Academic Integrity tutorial

d) Seriousness of plagiarism

Almost all students (97%) viewed cheating on exams and plagiarism as either serious or very serious, both before and after the tutorial (Figure 7). The greatest percentage change in awareness (14%) was in relation to copying images from the internet (from 71% - 85% of students perceiving this to be serious or very serious). There was a 14% improvement in relation to auto-plagiarism (78%-92%), 11% for copying text from the internet (85%-96%), 10% for collusion (69%-79%), and 8% for copying a design (86%-94%). There was a 3% change in relation to copying from a journal (78%-81%).

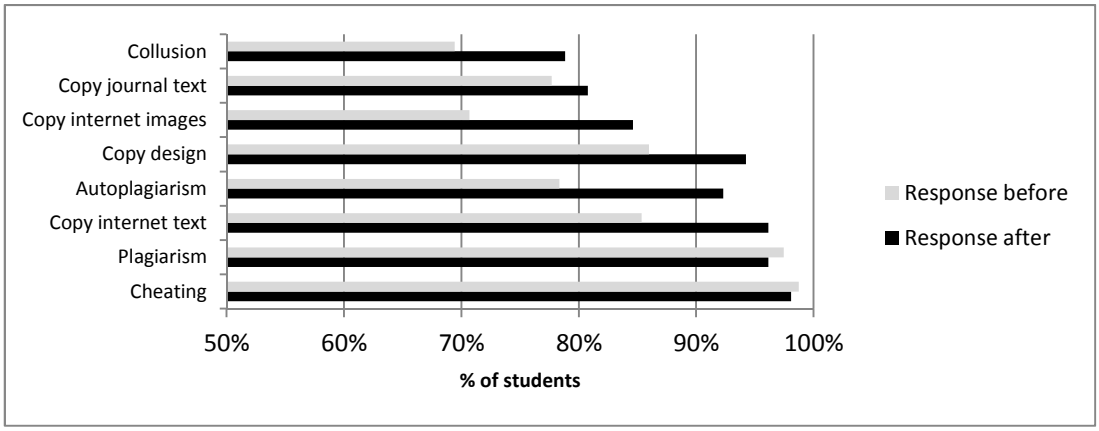

Figure 7. Percentage change in student perceptions of the seriousness (both very serious and serious) of various aspects of plagiarism before and after completion of the Academic Integrity tutorial

e) Causes of plagiarism

Several researchers have identified a range of factors that contribute to poor academic practices (refer section 1). Our results indicated that the highest positive changes in student perceptions of plagiarism, following completion of the tutorial, were in relation to: the opinions of peers, with students believing that their peers did not think it was acceptable to plagiarise; that plagiarised information is not better than the work the student can produce; plagiarism detection software is a disincentive to plagiarise; plagiarised information does not provide a competitive advantage; information is not freely available on the internet without acknowledgement; the pressures of course demands, and time limitations should not be used as an excuse to plagiarise; and that it is not easy to 'get away' with plagiarism (Figure 8). Hence the tutorial was effective in positively changing students' perceptions particularly in relation to the social norms affecting behaviour.

Both before and after the tutorial, students generally did not believe that: plagiarism was acceptable, merely because you could get away with it (89%-92% overall disagreement); cheating was acceptable and that plagiarism was not looked on unkindly in the 'real world' (92%-94% overall disagreement); others' expectations placed pressure on students to plagiarise (91%-89% overall

disagreement); it was acceptable to contract and pay someone else to research and write their assessment (94%-100% overall disagreement); they would purchase an assignment from the internet and change it slightly (94%-94% overall disagreement); and the benefits of cheating outweighed the consequences of not cheating (92%-92% overall disagreement).

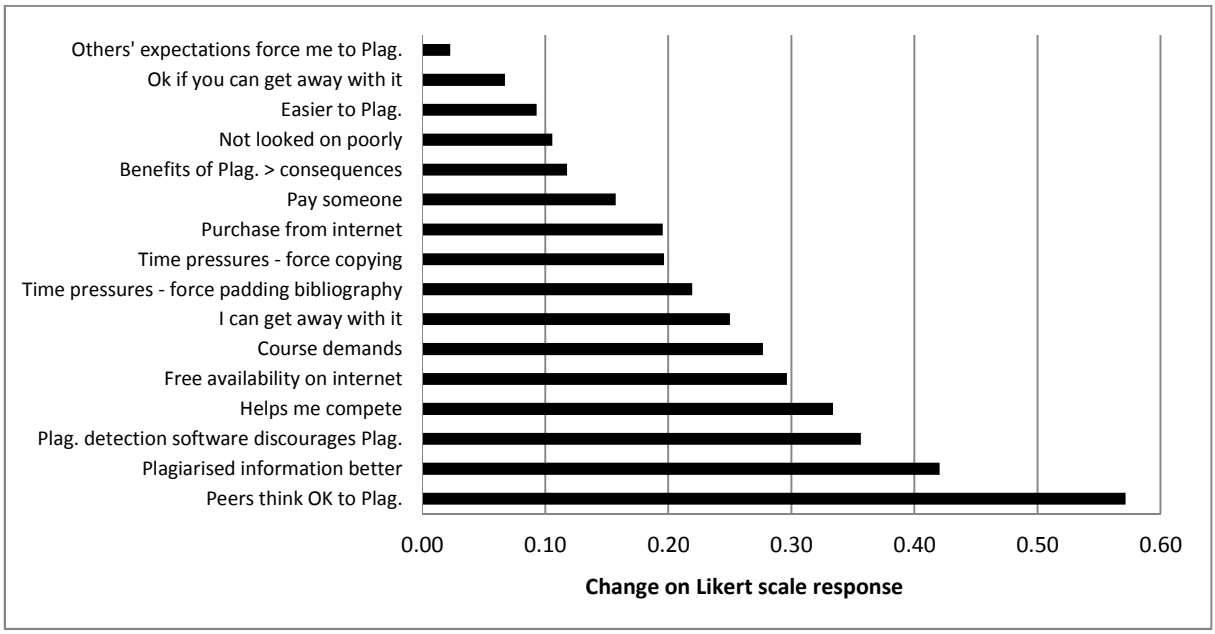

Figure 8. Changes in students' perceptions of what constitutes plagiarism following completion of the on-line tutorial (based on a 1-5 Likert scale response)

Following completion of the tutorial, more than 60% of students indicated that cheating, plagiarism, auto-plagiarism and copying text from the internet were very serious. Issues perceived as being less than very serious were copying designs and images, copying text from a journal and collusion. There were also marked improvements in their understanding of the implications of poor academic practices, although the relatively poor results in relation to collusion indicate an area to be addressed in subsequent versions of the tutorial.

Student Focus Groups identified the key strengths of the tutorial as its clear and relevant information on referencing styles, collusion, collaboration and plagiarism, its good design, relevant language, ease of operation and their sense of relief in now understanding how and when to reference and what constitutes good academic practice.

Academic staff from UQ also were invited to test and comment on the tutorial. Comments from staff included:

> ".. I think it's great, especially the section dealing with collusion over group work – an issue that is not well understood by many students. Also

> fantastic that it points students at the resources that will help them if they are under assessment pressure and tempted to plagiarise. It will help me a great deal that there is such a tutorial in place and that it is compulsory for students to complete ...".
>
> "I have just worked through the new academic integrity tutorial and it is great … it will really help to emphasise ethical practice… I … understand how confusion about plagiarism is both widespread and currently difficult to overcome without use of significant class time - which of course cuts into tuition of other issues. The tutorial's design allows students to really think through and engage with authentic problems, which we all know is the most effective means of teaching, so it will make an impact. I sense among many students a real desire to understand these issues more deeply and also a strong commitment to ethical practice. So, this is fantastic…".

6. Conclusion

The widespread and rising incidence of plagiarism were the stimulus for our team to develop the Academic Integrity and Academic Referencing online, interactive tutorials. These are central to student learning and provide a sound foundation for professional practice, particularly regional and town planning. The tutorials are designed to support student learning in several contexts: new information is presented in meaningful ways through the use of real scenarios and real academic texts, which help to construct and build learners' understanding; interactive exercises are provided, which require active user engagement with the learning material; an assessment process is applied whereby learners are able to re-try exercises, after responding to extensive feedback until they submit a correct response; and once the tutorials have been completed, users can access them as an information resource.

The tutorials have successfully raised awareness of the meaning of plagiarism (including collusion) and its seriousness, and enhanced students' skills in referencing, including the citation of written material, images, and maps, and how to correctly reference in-text material and to develop bibliographies. These skills provide life-long advantages for our students, many of whom will move into professional practices as planners, and the tutorials set a consistent standard for all students and hence greater equity in relation to assessment procedures. Additional efforts are needed at the institutional level to embed good practice, ensure equitable processes in the detection and processing of students alleged to have plagiarised and thus to demonstrate to students that plagiarism is not something that they can easily 'get away with'.

CONFLICTS IN PLANNING PROCESS OF LOCALLY UNWANTED LAND USES (LULUs): A CASE STUDY IN İZMİR

İlgi Atay Kaya [1], Nursen Kaya Erol [2]

Abstract

Land use planning is a both technical and political process in which many different groups with multiple interests are affected by planning decisions. While every land use planning problem has a potential of creating conflicts Locally Unwanted Land Uses (LULUs) are the most conflict facing subjects in urban land use planning.

Locally Unwanted Land Uses are land uses which may be regionally or nationally needed or wanted but are considered objectionable by many people who live near them because of their negative externalities. Land allocation for LULUs is usually problematic and usually a threat for the whole planning process. A site selection decision for a LULU becomes more difficult when there is a NIMBY (not in my backyard) movement against the LULU. It is opposed by interest groups with various reasons such as health effects, economic costs, harms to environment. The possible relation between the conflicts about land uses and its decision making process should be discussed.

This paper focuses on the need for understanding and evaluating the planning processes of LULUs. The paper is based on a research examining the planning processes of a LULU in İzmir, Turkey. The case study is examined to demonstrate;

- the whole process followed for the land allocation of the LULU,
- the conflicts and the reasons of conflicts,
- interest groups involved and conflicting interests,
- solutions searched or proposed by planning authorities or related institution and,
- what might be done for a more smooth process and formation of a consensus base

To understand the reasons of conflict and to highlight the potentials that planners should seek would be a step for solutions.

Keywords: Locally Unwanted Land Uses (LULUs), Land use planning, Conflicts in planning process

1. Introduction

Land use planning, as a process affecting various interests groups, faces with conflicts especially while dealing with locally unwanted land uses (LULUs). The aim of this paper is to emphasize the importance and difficulty of site selection processes of LULUs.

The research involves two main parts. The first part includes a short review of literature related with LULUs, their decision making process, conflicts and conflict resolution techniques.

The second part includes a case study about site selection process of solid waste disposal area in İzmir. The case study aims to demonstrate the conflicts, the conflicting interests, the movements against site selection decision in an ongoing process and the actions taken and proposed by the responsible institution to solve the problem. Finally the paper discusses reasons of conflicts, and possible solutions to conflicts.

The data for the case study is gathered from the archives of local institutions and newspapers. The plans analysed are obtained from İzmir Metropolitan Municipality. The web-based archives of two national (Milliyet and Hürriyet) and a local newspaper (Yeni Asır) including news since 2004 are searched. 417 news from three newspapers are searched and 93 related news are found in the period between 09.03.2009 and 19.02.2012. Additionally a city planner from the Planning Department and an environmental engineer from the Department of Solid Waste Facilities of İzmir Metropolitan Municipality are interviewed.

2. Planning for Locally Unwanted Land Uses (LULUs)

2.1 What are LULUs?

LULUs are described as development projects that are predictably objectionable to many of their neighbours (Popper, 1983), a set of technologies with the potential of creating major environmental or social perturbations (Nordenstam, 1994), potential threats to the environmental safety and the economic value of property to adjacent communities (Peyton, 2007), and land uses which may be regionally or nationally needed or wanted but are considered objectionable by many people who live near them because of their negative externalities such as being noisy, dangerous, ugly, smelly; polluting; increasing traffic; and lowering property values (Popper, 1985; Nordenstam, 1994).

There are various examples of LULUs given in the literature. These are energy, waste, industry, transportation, housing, health, and crime related LULUs. Energy related LULUs are nuclear facilities, power plants, refineries, mines and electricity generating facilities, and so on. Waste related LULUs are solid waste facilities, hazardous waste facilities, landfills, incinerators, and so on. Factories are industrial

LULUs examples. Airports, highways and other transportation infrastructures are LULUs related with transportation. Housing related LULU examples are low income housing, slums, shelters for the homeless, housing for the mentally ill and so on. In addition, there are health related LULUs such as rehabilitation clinics, drug treatment centres and mental health facilities. Prisons and detention centres are also noted as LULUs related with crime. There are also other LULUs such as red-light districts and military installations.

2.2 Decision Making for LULUs

Local level has more importance in decision making of LULUs than other various levels (such as territorial, national or global) of environmental problems (Peeples, 2000). There are post-siting effects of the LULU decision making process (Been, 1994). Classical location criteria are not suitable for decision making of LULUs, rather multi-criteria undesirable facility location model is needed (Colebrook and Sicilia, 2007). Also, there should be an integrated framework guided by a multi-disciplinary approach in LULU decision making (Nordenstam, 1994).

Various interest groups are affected by decisions of land use planning. These groups include different levels and departments of government, representatives of special interests such as neighbourhood preservation, environmental conservation and minority groups, and market oriented groups including private sector land owners, developers and builders, local residents and other members of the public, and finally land planners (Kaiser et al., 1995).

2.3 Conflicts in Planning LULUs

Urban land use planning process faces with conflicts about various topics because urban environment itself includes various people with multiple interests. Therefore, every land use planning problem has a potential of creating conflicts. LULUs are one of the most conflict facing subjects in urban land use planning. Land use planning process deciding a site selection of LULUs becomes more difficult when there is a NIMBY (not in my backyard) movement against LULUs. NIMBY is described as mobilizations to oppose the siting of LULUs. It is opposed by interest groups with several reasons such as health effects, economic costs, harms to environment, and so on.

One point of view demonstrates that LULUs are located in economically deprived or racially and ethnically minorities' neighbourhoods and the lack of equity in these kinds of site selection decisions are seen as reasons of LULU conflicts (Minchart and Neeman, 2002; Rootes and Leonard, 2009). On the contrary to the view describing siting LULUs as racist and classist, Been (1994) discussed the possibility that neighbourhoods surrounding LULUs may become poorer and become home to a greater percentage of people of colour over the years following the sitings.

2.4 Conflict Resolution for Land Uses

Several strategies to solve land use conflicts are proposed in literature. Participatory planning (Magigi and Drescher, 2010), mediated negotiation strategies describing various roles for planners such as mediator, resource, regulator, negotiator and process manager (Forester, 1987), dispute resolution techniques (Dorius, 1993), decision making processes considering local community perspectives (Nash et al., 2010), and to sum up the need for alternative planning processes with more public participation than planner-centred planning is underlined by various studies.

Collaborative planning which seeks to bring together major stakeholders to build consensus rather than use majority rule, and also generates commitment to commonly accepted objectives and fosters commitment to implementation is one of these alternative planning approaches (Healey, 1997; Margerum, 2002). It engages stakeholders in interest-based negotiation to reach consensus agreement on plans. There are both advantages such as avoiding win-loss outcomes and improving stakeholder relations; and limitations of collaborative planning such as powerful stakeholders' possible reluctance to participate (Cullen et al., 2010). Also, there are several recommendations for collaborative planning such as including full range of stakeholders and participation on an equal basis and full information (Margerum, 2002).

3. Case study: Land Allocation Process of Waste Disposal Sites in İzmir

3.1 Waste Disposal Sites

İzmir is the third biggest city in Turkey with a total population of 3 948 848. Total amount of waste collected in İzmir in 2010 is 1 685 659 tons/year. It is almost 7 percent of total waste of Turkey in the same year. Almost 77 percent of the collected wastes are disposed in controlled landfill site while others are disposed in dumping sites of municipalities in İzmir in 2010. Composting plants have been used for waste disposal until 2008 (TurkStat, 2010), but these facilities located in Uzundere and Menemen in İzmir are not active today (Özen, 2011) because of revision studies (CEE, 2009).

There are 41 municipal waste landfill sites in Turkey in 2009 (MEF, 2009). Two of these landfill sites are located in İzmir: Harmandalı and Foça. Foça Solid Waste Landfill Area is constructed in 1999 for Foça, Bağarası, Gerenköy and Yenifoça Municipalities (MEF, 2008). Harmandalı Solid Waste Landfill Area is constructed in 1992 by İzmir Metropolitan Municipality (MEF, 2008). It is the first regular waste disposal site in Turkey. It has 90 hectares of area. It is 25 km. far from city centre. It has run out of its temporal capacity of 15 years (İDA, 2008).

Almost 3000 tons/day of waste is collected in this area everyday. There are three types of waste collected in this area: domestic waste, industrial waste with domestic characteristics and medical waste (Figure 1). Oozing water from the collected waste

is transferred to sewage system and refined in Çiğli Waste Water Refinery. Harmandalı Solid Waste Landfill Area serves all settlements within the boundaries of İzmir Metropolitan Municipality. The capacity of this facility is increased in 2007 (Özen, 2011).

Figure 1. Disposal areas for domestic waste (left), for industrial waste with domestic characteristics (middle) and for medical waste (right) in Harmandalı Solid Waste Landfill Area (İWSMGD, 2010)

The boundaries of İzmir Metropolitan Municipality is enlarged in 2004 due to the Law of Metropolitan Municipalities (No. 5216). 24 of the 26 irregular waste disposal sites in new added settlements are closed and 2 of them are going to be closed after construction of new waste transfer stations. The wastes from these settlements are being transferred to Harmandalı Solid Waste Landfill Area. There are transfer stations in Halkapınar, Gediz, Kısık, Gümüldür, Karşıyaka, Selçuk, Torbalı, Foça and Urla (Figure 2). In addition, the site selection and project preparation processes are continuing for Türkelli and Kemalpaşa Transfer Stations (Özen, 2011).

Figure 2. Waste Transfer Stations in İzmir (Özen, 2011)

3.2 Site Selection Process of Waste Disposal Sites

The legislation related to the waste disposal sites in Turkey includes fundamental right of living in healthy environments in Turkish Constitution, 6 laws about environment, municipalities, metropolitan municipalities and penal code, almost 15 regulations about waste processes including incineration, disposal, control and so on,

almost 21 circulars about waste disposal facilities, implementation projects, management plans, permissions and so on, and other related notifications. While the related laws regulate the general rights and rules, the regulations specify the type of waste such as oil, vehicles, batteries, construction wastes and so on.

The Department of Solid Waste Facilities in İzmir Metropolitan Municipality is the responsible institution for preparation of plans, projects, adjudication documents and Environmental Impact Assessment (EIA) reports, and control of these processes. Location decisions are taken by this institution. An environmental engineer from the department explained the process they followed for site selection: First they use several criteria to select a location, produce alternatives according to these criteria, choose the most suitable alternative and start the land allocation procedure. Then they call for a bid for EIA report preparation. Afterwards, they report the selected location to the Department of Planning so as to make the decision added to the plans. Sometimes Planning Department report negative opinions to the selected locations depending on planning principles but they do not take part at the beginning of the process. The Department of Solid Waste Facilities considers plans while studying the criteria before proposing alternative locations. That means plans are included in the process, but planners are not.

The criteria in the site selection process of waste disposal sites considered by the Planning Department are as follows:

- Space requirements
- Distance to settlements
- Distance to agricultural lands
- Distance to olive groves
- Land use capability classes
- Distance to industrial zones
- Distance to conservation sites
- Distance to military zones
- Distance to natural lakes
- Distance to dams
- Distance to rivers
- Distance to drinking water wells
- Distance to 1st degree highways
- Distance to 2nd and 3rd degree highways
- Distance to railways
- Slope
- Elevation

Minimum or maximum values are determined depending on existing regulations and legislation for each of these criteria.

The processes about transfer stations are not so different; however, there are fewer criterions for site selection. Accessibility and the availability of roads for trucks are the most important criteria. Also, minimum space requirement is specified as 6000-

$8000m^2$. First, the department proposes a site for a transfer station considering these criteria. Then, EIA Report is prepared. Documents that state "EIA Report is not needed" is also valid. After the EIA process, geologic situation of the area is analysed for development and construction; and finally the implementation projects are prepared. The project is sent to the Planning Department. If there are objections to the selected site of the project, alternative locations are searched. For those alternative locations the opinions of several institutions are taken (İMM, 2008).

3.3 Planning Decisions on Waste Disposal Sites

Plans with upper scales in İzmir include decisions about waste disposal sites. 10 waste disposal sites are shown in the Manisa Kütahya İzmir Environment Plan (Figure 3). This plan proposes strategies to minimize the pollution depending on solid wastes. The main suggestion of the plan is that there should be infrastructure unions in which the solid waste problem is solved for a region including several settlements instead of solving the problem for each settlement. The location criteria should include geographic structures of the land. It should serve the whole city. Regional solutions are needed.

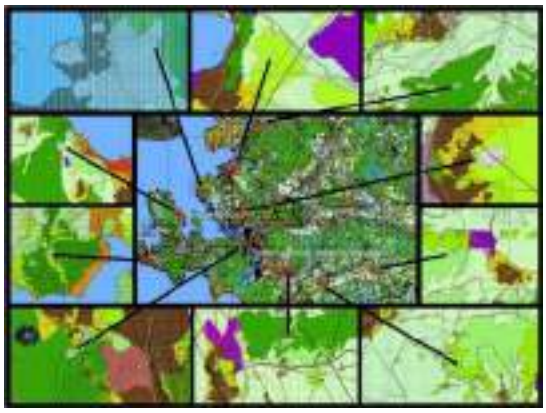

Figure 3. Solid Waste Landfill Areas in the boundaries of the city of İzmir shown in Manisa Kütahya İzmir Environment Plan with 1/100 000 scale (webpage: gisapl1.cevreorman.gov.tr/cdp/)

İzmir Development Plan approved by İzmir Metropolitan Municipality shows several waste disposal site decisions (Figure 4). The plan proposes a total area of 237,2 hectares of solid waste collection and disposal areas. The plan includes Solid Waste Disposal Areas in Harmandalı (existing 107,1 ha, proposed development 147 ha, conservation zone in a buffer of 1km), Konak Uzundere (8,2 ha and conservation zone in a buffer of 1km), Foça (4,8 ha), Torbalı (43 ha), Mordoğan (5,9 ha), Urla (12,5 ha), Yelki (1,5 ha) and Gümüldür (0,4 ha), Solid Waste Transfer Areas in Buca (6,1 ha), Karşıyaka (5 ha) and Menemen (6,1 ha), Kemalpaşa (4,1 ha), a rubble disposal area in unused area of stone mines in boundaries of forests in Bornova (50 ha), renewal of the irregular waste landfill in Aliağa and transform of it to a regular solid waste landfill area (4,3 ha). The plan includes requirements about solid waste

landfill areas. First obligation is EIA. Second, waste collection is not allowed in 1st and 2nd Zone Resource Conservation Areas. Finally, the Environment Law (no. 2872) and related regulations including Solid Waste Control Regulation should be considered in all solid waste facilities.

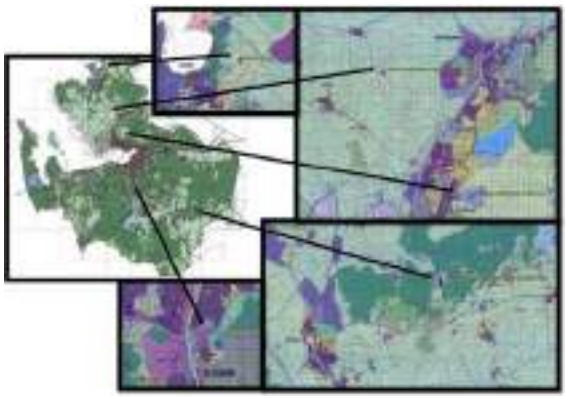

Figure 4. Some of the Solid Waste Landfill Areas in İzmir Development Plan with 1/25000 scale (3D City Map of İzmir Metropolitan Municipality)

3.4 Search for a New Site for Waste Disposal

The site selection process of solid waste landfill areas in İzmir is a difficult decision making process facing with conflicts depending on negative opinions of some institutions and objections of nongovernmental organizations and local people.

As Harmandalı Solid Waste Landfill Area has completed its capacity and, as the city grows, this facility becomes so near to the residential areas (The proximity can be seen in Figure 5). İzmir Metropolitan Municipality tries to find a new site for waste disposal. The Department of Solid Waste Facilities plans to construct a Solid Waste Assessment Facility for effective and efficient assessment of solid waste, separating recyclable waste from others, producing electrical energy from organic waste and composting wastes (Özen, 2011).

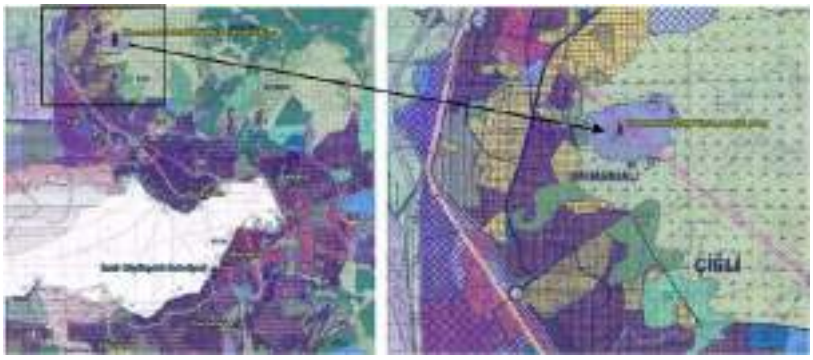

Figure 5. Harmandalı Solid Waste Landfill Area in İzmir Development Plan with 1/25000 scale (3D City Map of İzmir Metropolitan Municipality)

According to the Action Report of the Department of Solid Waste Facilities (2008), a new regular landfill area is planned in the southern part of the city. First, several alternative areas in Torbalı are proposed. After a series of cancellations for most of the sites because of objections of several institutions, an area of 168 hectares is selected. The prior authorizations are taken from Forestry General Directorate. The area is approved by Local Environment Committee. Map preparation and then, EIA report preparation and planning processes started. The new solid waste facility is added to the İzmir Development Plan, and then the institution opinions are collected for plans with lower scales (İMM, 2009). The project was planned to be finished until 2010 (İMM, 2008). However the actual process was not same as predicted in the Action Reports.

In 2009 the mayor of the Metropolitan Municipality announced the plans to close the existing disposal area in Harmandalı in the following 2 years and to select a site for a new facility. There were two possible lands for an Integrated Solid Waste Facility including collecting wastes, composting or incinerating them and producing energy. First one was in Torbalı and the second one was in between Bornova Gökdere village and Buca Kaynaklar village (M, 09.03.2009; YA, 07.10.2009). This announcement started the discussions with several conflicting opinions.

The first responses were from the majors of the municipalities of Buca and Bornova. They did not want the facility in the boundaries of their municipalities. Also, the Minister of Environment and Forestry were opposed to the type of facility. He explained that incineration facility which was planned to be constructed was not appropriate to the existing conditions and budget of the country. Depending on these objections, Metropolitan Municipality gave up the project in that location (YA, 31.03.2010) and discussions continued on the alternative proposals for Torbalı, Menemen and existing Harmandalı sites (Figure 6).

Figure 6. Locations of existing Harmandalı Solid Waste Landfill Area and proposed Solid Waste Landfill Areas in Torbalı and Menemen (image from 3D City Map of İzmir Metropolitan Municipality)

For the Torbalı proposal an objection came from the Provincial Directorate of Agriculture as 47 hectares of the total 168 hectares of proposed area contained olive

graves (Figure 7). This problem was overcome by decreasing the site to 121 hectares (YA, 31.03.2010).

Figure 7. The Proposed Site for Solid Waste Disposal Area in Torbalı Taşkesik (YA, 06.05.2010)

Then many objections came from different individuals but more from local or central authorities, NGOs, representatives of political parties and groups of local people who were usually activated by professional chambers. They showed their protests in municipality councils, through press releases, going to court or collecting signatures by door-to-door visits. The majors of the Chambers in Torbalı including Chamber of Commerce, Chamber of Agriculture, Chamber of Tradesmen, and Chamber of Drivers worked in a union to prepare a report about the problems of Torbalı including the location of solid waste disposal area. They visited the Minister of the State, Vice-Prime Minister and deputies from the three major political parties, and presented that report to them (YA, 04.04.2010).

Beside objections there were few supporters of the proposal. The director of the Provincial Directorate of Environment and Forestry supported the mayor and criticized the people saying "not in my town" that they did not learn the type of facility, its technology or its quality (YA, 05.06.2010; M, 06.06.2010). Also, some newspaper writers reminded that there were several institutions giving positive opinion to this site such as Regional Directorate of Forests, Institute of Mineral Research and Exploration, Ministry of Environment and Forestry, General Directorate of State Hydraulic Works, Provincial Directorate of Agriculture, Gediz Electricity Distribution Company and other related institutions (M, 06.06.2010; YA, 09.06.2010).

The mayor of the Metropolitan Municipality visited the proposed site in Torbalı and faced with protests (Figure 8). Almost 70 villagers from 3 villages met in the area, stopped the bus of the Metropolitan Municipality, booed, showed banners writing “We do not want İzmir’s waste in our region”. Some of them showed their land titles to the mayor and said that the area was theirs. Some of them loudly asked the mayor why he did not ask them while making this decision. The mayor tried to explain the process, told that their opinions would be taken in two or three meetings after the EIA report and suggested them to come to the meetings and to tell the reasons of not wanting. The headman of the village told that they gave petitions against the decision but did not get answers. The mayor told that telling opinions was their right, however

the decision would be taken depending on science and if there were no legal constraints then they would locate the facility in this area. The villagers shouted him down and then he got angry and left the area (YA, 04.06.2010; M, 05.06.2010).

Figure 8. The Protests against the Decision of a Solid Waste Disposal Area in Torbalı (photo on top left from YA, 04.06.2010; other photos from M, 05.06.2010)

Following these protests Metropolitan Municipality organized a trip to Germany to show good examples to interested people or groups. Some of the interest groups decided not to attend the trip as a response, while some others decided to participate to learn so as to oppose better and consciously. 32 people including some villagers, people from central and local government, representatives of universities, chambers and other nongovernmental organizations attended to the trip and gained positive opinions about constructing the similar in İzmir (YA, 20-23-25.09.2010; M, 23.09.2010). The trip included technical observation in Münster Mechanic-Biologic Processing and Regular Disposal Facility and Vereinigte Ville Regular Disposal Facility in Cologne (Figure 9).

Figure 9. The Participants of the Technical Trip to Germany (left photo from YA, 25.09.2010; right photo from M, 23.09.2010)

The people objected the solid waste facility in Torbalı established a Nongovernmental Initiative Group against Waste in the coordination of Torbalı

Chamber of Commerce. The group included participants from political parties, nongovernmental organizations, unions, headmen of villages, and representatives from 25 institutions (Figure 10). They organized meetings and discussed possible movements against waste. They decided to sign a declaration, distribute hand-outs including this declaration, announce by newspaper advertisement, tell the possible harms and bad effects of the facility to the villagers, make a press release in Harmandalı waste disposal area, start legal fight, visit the institutions in the EIA process, organize an exhibition in Torbalı centre including the photos of Harmandalı waste disposal area, stop waste trucks and stay in tents in the proposed waste area (YA, 28-31.10.2010; M, 30.10.2010).

Figure 10. The Participants of the Nongovernmental Initiative Group against Waste in Torbalı (left photo from YA, 28.10.2010; right photo from YA, 31.10.2010)

While discussions were continuing for Torbalı, in a press release, the mayor of the Metropolitan Municipality announced a proposal for a secondary waste disposal site in the northern part of the city too (YA, 3.11.2010; M, 04.11.2010; H, 04.11.2010).

On the other hand, people living near the existing solid waste landfill area in Harmandalı also started to take actions and organize meetings to force the responsible institutions to find solutions as soon as possible (Figure 11). The headman of the Cumhuriyet Quarter in Harmandalı applied to the Human Rights Committee of İzmir Governorship, Environment Commission of İzmir Bar Association and Provincial Directorate of Health. His applications were based on the 56th sentence of the Constitution which guarantees the right of living in healthy environments for everybody. He complained about the environmental problems and health risks caused by waste disposal, but the authorities from Metropolitan Municipality Water and Sewerage Management General Directorate rejected the claims and told that there was no risk of explosion, no stored gas, no leakage of polluted water (YA, 05.12.2010). The people from Harmandalı explained their decision to go to the European Human Rights Court. The mayor of the Metropolitan Municipality supported this decision and told that they were right (YA, 05.10.2011).

Figure 11. The meetings of the people living near the existing solid waste landfill area in Harmandalı (left photo from M, 09.09.2011; right photo from M, 13.09.2011)

The news about the movements against the existing condition of the solid waste landfill area in Harmandalı increased the movements in Torbalı (Figure 12) (YA, 06.12.2010). The first legal action of the Nongovernmental Initiative Group against Waste in Torbalı was going to the court with an aim of cancellation of the Manisa-Kütahya-İzmir Environment Plan claiming that the proposal for a waste disposal area in Torbalı was on contrary with the 20th Sentence of the Law about Rehabilitation of Olive Production and Vaccination of Wild Olives with No. 3573 (YA, 28.12.2010; M, 29.12.2010).

Figure 12. The Meeting of the Participants of the Nongovernmental Initiative Group against Waste in Torbalı Taşkesik (YA, 06.12.2010)

The group organized a meeting, invited first the Minister of Environment and Forestry, then organized another meeting, invited the Minister of Culture and Tourism and presented reports including their opinions against waste facility in Torbalı. Both of the ministers said that Torbalı is not appropriate for this facility. The mayor of the Metropolitan Municipality told that if any other more appropriate area was possible the Metropolitan Municipality would change the decision (YA, 01-02-03-04.04.2011; YA, 03.08.2011).

In the following days the EIA report for the area in Torbalı was completed. It was found that the ground was permeable and also there were underground water resources. Therefore, Metropolitan Municipality announced that the area was not suitable for any waste facility, rejected the possible proposed methods using impermeable membrane in the ground of the facility, and the process of searching a

new area for the facility was continuing (Figure 13) (YA, 27.08.2011; M, 29.08.2011).

Figure 13. Villagers of Taşkesik and members of the Nongovernmental Initiative Group against Waste in Torbalı Taşkesik celebrating the decision of Metropolitan Municipality not to locate waste disposal area in Taşkesik (YA, 27.08.2011)

With a majority of votes the Council of the Metropolitan Municipality decided to transform the existing compost waste facility to a new more technological one on an area of 203 acres in Menemen. The facility would not be for storing waste but for separating it and producing energy and raw materials for industries (M, 16.10.2011). The mayor of Metropolitan Municipality organized a press release, explained the details of the project and the reasons of the selection of the area. He added that there would be another solid waste disposal area in an unused area of stone mines in the southern part of the city (YA, 05.10.2011; M, 28.10.2011).

The people against the solid waste disposal area in Menemen came together to show their response. The mayor of Menemen Municipality organized a press release and told that the decision was not appropriate to the Development Plan and the Environment Plan. He emphasized that the economic structure of Menemen depending on agriculture would be affected badly with this land use decision (M, 26.10.2011; YA, 28.10.2011). The mayor of the Metropolitan Municipality responded to the oppositions by explaining the reasons of site selection as the area was far from settlements, it was near to highway, using the existing facility and renewing it would be more feasible, and there would be no odour and no stored waste after the process which had a high technological design (YA, 06.11.2011; M, 07.11.2011). However the movements of people from Menemen continued with a meeting of representatives of several chambers, City Council and Profession Organizations Platform of Right and Left Coasts Irrigation Associations (M, 13.11.2011). They protested the decision by showing agricultural products (Figure 14). The head of Left Coast Irrigation Associations told that they went to court to cancel the project (YA, 15.11.2011) to protect the neighbouring agricultural lands and water resources (M, 16.11.2011). The protests were supported by the representatives of the political parties, nongovernmental organizations and lots of farmers (M, 17.11.2011). The nongovernmental organizations in Menemen also went to court to cancel the project (M, 08.12.2011).

Figure 14. The Meetings of the People in Menemen to Protest the Decision of Solid Waste Disposal Area (left photo from YA, 15.11.2011; right photo from M, 17.11.2011)

İzmir Metropolitan Municipality sent the proposal for Menemen solid waste disposal area to the Provincial Committee of Soil Conservation. The committee investigated the site and reported that the area was agricultural land with quality (Figure 15) depended on the Law about Soil Conservation (no. 5403) (YA, 30.12.2011).

Figure 15. The Existing Waste Facility in Menemen between Agricultural Lands with Quality (YA, 30.12.2011)

In the following process the Metropolitan Municipality is going to approve for 'public interest' decision in the area to the General Directorate of Local Administrations in the Ministry of Internal Affairs (YA, 30.12.2011). If it is not possible to get this decision for the additional area, the existing area of 65 acres will be used (YA, 12.01.2012; M, 13.01.2012). According to the mayor there is no need to take EIA report again, because it was taken before for the existing facility. On the other hand, according to the head of Left Coast Irrigation Associations, EIA for the existing facility was given in 1995 and it is not valid in 2012; therefore a new EIA process is needed (YA, 16.01.2012). That shows signs that the following process will go on with conflicts.

4. Discussion: Conflicts in the Process and Possible Solutions for a Consensus Base

The problem of site selection of a new solid waste disposal area in İzmir remains unsolved. Analysis of the process may be of help to understand the reasons of the problem and learn lessons for a smoother process.

There are several actors involved in this site selection process. These actors may be grouped as; (I) public institutions including İzmir Metropolitan Municipality and host municipalities, ministries and their local directorates, (II) local people and their representatives, (III)non-governmental organizations such as chambers of various professions, environmentalist groups, political parties and so on, (IV) universities, and (V) private companies including possible investors of the facilities.

Most interested and involved actor groups are public institutions and local people groups. The first group is the responsible institution that makes the decision. Second group involves the people who are living close to the proposed area and think that they would be directly affected by the decision. This group is usually supported by various actors from the third group. These groups are the main stakeholders of the site selection process. They are conflicting with each other and among themselves. While the people living near the existing disposal area in Harmandalı take actions to call the attention of metropolitan municipality to the completed capacity of the area, on the other hand, the people living near the proposed disposal areas in Torbalı and Menemen move against the land use decisions and organize meetings to make the metropolitan municipality to change the location of proposed solid waste disposal area.

The other groups are less interested. These are the institutions that give/or not give permission to the project, the groups with political interests, and so on. The examples in İzmir showed that the groups with political interests oppose to the project to make the municipality unsuccessful and that their approaches are not for solving the problems but for inciting the conflicts.

The types of responses of the second group to the decision are several. The most popular response is verbal notification of the opposition. There are group based responses such as organizing meetings, going to the site, stopping the bus of the municipality, booing, showing banners writing negative opinions to the decision, preparing reports including the reasons of ‘not wanting’ the facility, collecting signatures against the facility by door-to-door visits, signing a declaration, distributing hand-outs including this declaration, announcing by newspaper advertisement, telling the possible harms and bad effects of the facility to the villagers, making press releases, visiting the institutions in the EIA process, organizing an exhibition of the photographs showing the situation of the existing solid waste landfill area, stopping waste trucks, showing agricultural products to protest the decision of solid waste area located in agricultural lands, camping in the proposed area, calling all people living in host settlement for action against the

decision. The Nongovernmental Initiative Group against Waste in Torbalı also invites the Minister of Environment and Forestry and the Minister of Culture and Tourism. Some members of the council of metropolitan municipality show responses by leaving the council chamber. Legal movements are also seen such as giving petitions against the decision, working with an environmentalist lawyer and going to court. There is an application of the headman of the Cumhuriyet Quarter in Harmandalı to the Human Rights Committee of İzmir Governorship, Environment Commission of İzmir Bar Association and Provincial Directorate of Health. Also, the people from Harmandalı explain their decision to go to the European Human Rights Court. One of the extreme responses is from the preceding mayor of the Torbalı Municipality. He explained his will that his name would not be given to any place in the settlement after his death if this waste disposal area decision is implemented in Torbalı.

The objections to the proposals stems mainly from environmental concerns, traffic problems, image of the town and political reasons. People emphasize the health effects, natural, economic and social harms and traffic congestion. The olive groves next to the proposed area in Torbalı and the absolute agricultural lands next to the proposed area in Menemen are listed in the reasons to oppose the waste facilities. One of the reasons of the cancellation of the area in Torbalı is written as the existence of underground water resources in EIA report. Is it a sign that the metropolitan municipality skipped the site selection criterion about distance to the underground water resources? Are there variations in the thresholds of the criteria? Isn't it interesting that the metropolitan municipality learned the underground resources from the EIA report? Well designed processes in which analyses are fulfilled and site selections are depended on these analyses would not face with this kind of results.

The decisions of existing plans of the settlements are also considered as a reason of opposing the waste facilities. Both the opposing and the supporting groups use this subject in their speeches in Menemen case. The opposing groups say that the facility is not appropriate to the İzmir Development Plan, while the metropolitan municipality says that it is appropriate. In fact, the proposed area for waste facility is shown in the plan between absolute agricultural areas and also the plan notes give permissions to the new solid waste disposal areas without a need to review the plan if there is a public interest and need for public investment.

The manager of the Department of Solid Waste Facilities explained two major reasons of the conflicts about site selection processes of waste disposal sites of İzmir. First, "the problems of the existing waste facility cause a negative public opinion and people need to see good examples". Second, there is a lack of trust to public institutions responsible for organization, management and control because these institutions failed to fulfil their previous promises about the environmental investments such as waste disposal facilities. Then what might be done for a more smooth process and formation of a consensus base? What are the ways to minimize or overcome the conflicts?

The metropolitan municipality tried to change the perspectives of the opposing groups by showing good examples in a trip to Germany. The technology and quality of the visited facilities without odour and harm to environs was useful to make people think that similar would be good for İzmir. However, what about the people denying to attend to the trip? A trip to show good examples abroad would be a solution to conflicts just with a limited success. The attempt with much possibility of success is to show the local good examples. In Menemen case, the mayor gave the example of purification facility 2,5km far from the proposed waste disposal area in Menemen and told that the new facility would be as unproblematic as that. This is much meaningful because the management of this good example is in their responsibility.

One solution proposed by the metropolitan municipality was an additional tax. It would be useful to make host municipalities to support the site selection process, but what about the local people? They would be forced to pay extra for the facility that they do not want. The support of the host municipality is not enough to solve the conflicts as seen in Torbalı example. On the contrary, the opposing people blamed the mayor of the Torbalı Municipality not to be against the waste facility.

An important requirement for a process with minimum conflicts is that the locations of LULUs such as solid waste disposal areas should be decided with a comprehensive approach while deciding all other land uses and planning the whole city or region. These decisions are sometimes skipped or postponed in the planning process and they are handled when there is an urgent need. This is resulted with inconsistency between planning decisions. The environmental engineer from the Department of Solid Waste Facilities told that there would be better site selection processes if there was cooperation between their department and the planning department. Joint works of experts from various professions would be better. Experience is also important in this process. They solve problems easier than the process of their first waste disposal site proposal. She told the possible strategies that could be used. She gave the example of making investments to villages with no water purification facilities. If these kinds of villages are chosen for waste disposal sites, the villagers will gain a water purification facility. She also gave example from Japan. She told that there is a mutual gain system in waste disposal site selection processes in Japan because they construct public swimming pools in the settlements in which they plan to locate a waste disposal site. She thinks that trying this kind of solutions would be a chance to solve problems about waste disposal sites in İzmir.

For a more smooth process, first the responsible institution should select a process which is technically and scientifically proved. The previous solid waste landfill site selection cases should be considered and their proposals should be modified to the conditions of İzmir. For example, several multicriteria analysis methods, combination of the multicriteria analysis and geographic information systems (GIS), combination of the analytical hierarchy process and GIS, adding remote sensing methods to these two techniques, the Analytic Network Process, combination of

stakeholder analysis and spatial multicriteria evaluation are used in various cases (Vasiloglou 2004; Banar et al., 2007; Chang et al., 2008; Schumati et al., 2008; Ersoy and Bulut, 2009; Wang et al., 2009; Aragones-Beltran et al., 2010; Ekmekçioğlu et al., 2010; Şener et al., 2011; Geneletti, 2010). If the responsible institution uses such a method to select a location for solid waste disposal areas, it would be easier to persuade the opposing people. To consider various interests including local interests would increase the possibility of better solutions and focusing on reasons rather than insisting on positions would also be useful for opposing groups.

5. Conclusion

The results of this research indicate that the process has conflicts in which opposing groups could not propose an alternative solution and the metropolitan municipality could not ensure trust because of doing technical mistakes and unkept promises. This lack of trust causes people not to believe although there are scientific data and evidence.

Planning LULUs requires a carefully designed decision making process. The responsible institution should ensure trust by finding solutions to minimize negative externalities of LULUs, choosing scientific and applicable methods to select a location. However choosing a location with technically appropriate process is not enough. There is also a need to maintain a fair process, considering all interest groups. To solve or minimize conflicts depending on local interests the reasons of conflicts should be carefully analysed. The conflicts can be solved by changing the site selection method. Site selection process of LULUs should not be handled incrementally but should be solved comprehensively. In addition, planning practices for LULUs should give more attention to local level than the other land use decisions.

BEE or not to be.
LINKING BUILT ENVIRONMENT EDUCATION AND PARTICIPATION IN PLANNING PROCESSES

Anna Juliane Heinrich[1], Angela Uttke[2]

Abstract

The paper reflects in practice and theory on the link between built environment education and youth participation in urban planning processes. The discussion is based firstly on an evaluation of the EU-project "Fantasy Design – Children in Community (2009-2011)". The project explored innovative ways of design education in four countries focussing on participatory design processes involving young people in design projects. Secondly, the paper is based on an analysis of results of the youth workshop "Young Cities Now! Youth.City.Laboratory". The workshop invited adolescent who participated in different urban development projects all over Germany to reflect upon their experiences. As a result the young participants formulated a manifesto.

Taking into account further empirical knowledge on linkages between built environment education and youth participation the case studies show, that built environment education is an important way to qualify current practice of participation. Strong linkages between education and participation seem to be evident but further investigation is necessary. The authors will argue that a deliberate integration of the two fields can be very productive.

1. Introduction

Children and adolescents have a vital understanding of spaces, buildings and neighbourhoods. They are experts for their needs. They will be "framers" and decision makers in cities of tomorrow. Hence, the participation of children and young people in planning processes receives more and more attention in urban planning. Planning cities for children and young people today still means planning for a largely unheard section of society. There is a rising acceptance and willingness to seriously let young people and children participate and collaborate with adults to discuss, plan and implement improvements in their cities and neighbourhoods. At the same time the participation processes place enormous demands on young people.

[1] Berlin University of Technology, Berlin, Germany – juliane.heinrich@isr.tu-berlin.de

[2] Berlin University of Technology, Berlin, Germany – angela.uttke@tu-berlin.de

Educational processes that focus on design and planning skills help children and young people to form a stronger and more reflective voice when it comes to formulate their spatial needs. Built environment education is such a multifaceted and interdisciplinary way for young people to learn about their own environment and gain necessary skills in designing it.

The obvious overlapping of built environment education and community participation could qualify both. In order to initiate a debate on linkages between youth participation in community and built environment education this paper introduces both concepts and afterwards discusses practical experience from two projects which worked on the interface between the two fields, meaning: the both presented participation processes were also aimed to be educational processes. The examples will be reflected in the light of the existing theoretical debate.

2. Youth Participation in Planning Processes

Communities face today manifold challenges of organisational, economic and social nature. The creation of youth- and child-friendly cities and neighbourhoods involves a complex and difficult process of negotiation. An important basis for this is a broad and inclusive decision-making pattern, which engages stakeholders with different backgrounds, motivations, opinions and resources and makes also the voices of young people and children heard. Through the participation of the civil society, planning processes and their outcomes can acquire higher quality and efficiency as well as broad acceptance. One important way to broaden participation and to move to a more generationally inclusive city is the involvement of youths (cf. Bertelsmann Stiftung, 2007, pp. 7 and 78-80; Meinhold-Henschel, 2007b, p. 221; Mullahey et al., 1999, p. 5). "From the perspective of community planning, influential youth participation occurs when:

- actions aim to intervene in existing conditions
- involvement is part of the public dialog and decision making
- engagement is influential and changes are significant" (Mullahey et al., 1999, pp. 3-4).

Characteristic of community participation is that young people act as stakeholder in the political arena and not in a pedagogical environment (cf. Knauer, Sturzenhecker, 2005, pp. 19-20). But looking at current participation processes young people identify problems, they analyse causes and resources in order to solve these problems, mobilise other stakeholders, they formulate goals and design action plans, they implement actions and evaluate their outcomes (cf. Mullahey et al., 1999, p. 5).

A typology of different kinds and levels of participation is provided by Hart's ladder of young people's participation (first published in 1992; see figure 1) which is based on Arnstein's seminal ladder of participation (1969). The ladder distinguishes non-participation and divers degrees of participation. The different degrees describe grades of "agency or participatory engagement by young people" (Hart, 2008, p. 23). In 2008 Hart wrote a paper reflecting on the ladder of youth participation and its

manifold interpretations since its publication. He concludes that the ladder metaphor is unfortunate because it suggests the assumption that the higher rugs of the ladder are necessarily superior to the ones beneath. He stresses that this is not the case. Rather do the rugs describe the different roles adults have in youth participation and the degree of agency by young people (cf. Hart, 2008, pp. 20-24).

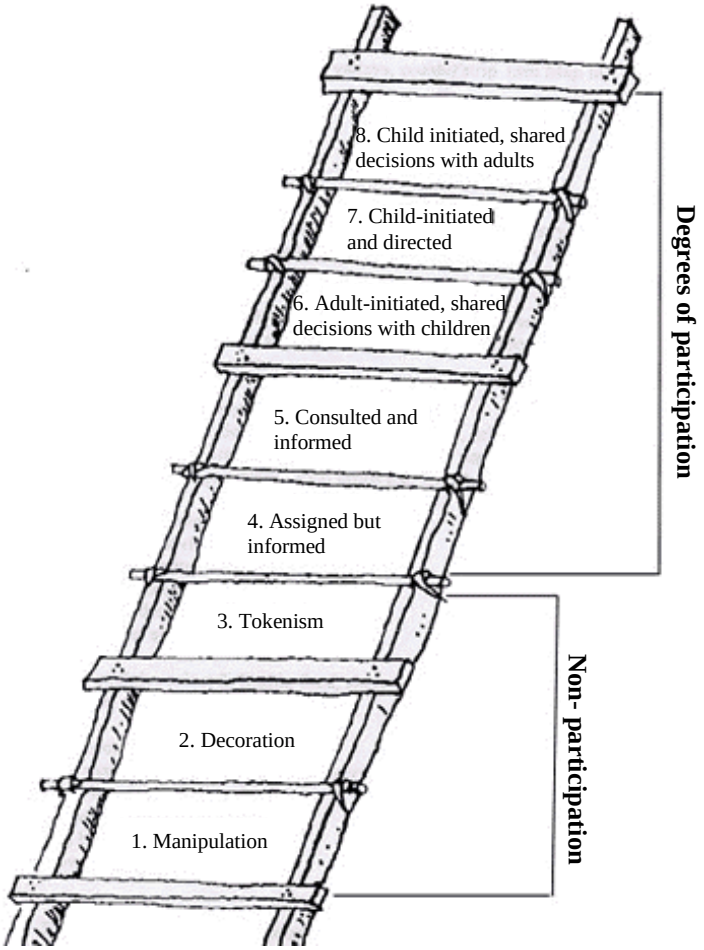

Figure 1. Hart's Ladder of young People's Participation
(source: modified figure based on Mullahey et al., 1999, p. 10)

Within the five degrees of participation different forms of participation can be distinguished. While there is a high diversity of methods Stange (2008) gives an overview summarising different categories of participation methods:

- advocacy representation of youth's interests,
- youth participation in institutions of the adult world,
- selective participation,
- everyday participation,
- representative participation (e. g. children and youth parliaments),
- Open forms and forums, and
- project approaches to participation.

Within this categorisation the first aspect describes “policies for young people”, the second to fourth point define “policies with young people” and the last three categories outline “policies by young people” (cf. Moser, 2010, p. 212).

The justifications for youth participation are divers and refer e. g. to civil law, democratic and political theory, educational, ethical and moral theory and service orientation (cf. Betz et al., 2011, p. 3). The most important legal point of reference is The United Nations Convention on the Rights of the Child (1989). It discusses children’s and adolescent’s right to participation as one of its main topics. Thereby it contributed to an appreciation of youth participation in many countries (cf. Meinhold-Henschel, 2007a, p. 9). Furthermore, the United Nations action plan for sustainable development, namely Agenda 21, and its Local Agenda 21 processes strengthen the of role major groups in development processes including the role of young people (cf. Hart, 1997, p. 23). In Germany, an important motivation which drives youth participation in communities is the common goal to be family-friendly and thus to attract families and enterprises (cf. Meinhold-Henschel, 2007a, p. 12).

Despite these legal foundations of and motivations for youth participation, adolescents are generally not integrated in traditional planning processes of urban development in Germany (cf. BMVBS, 2010, p. 10). Participation is often part of project work at most. So far, youth participation is neither a cross-cutting issue in urban development nor is it part of planning culture (cf. Moser, 2010, p. 19). Additionally, the quality of participation processes is often poor (cf. Meinhold-Henschel, 2007a, pp. 12-13).

3. Built Environment Education (BEE)

Educational activities related to the built environment incorporate a broad field of activity focuses and approaches to education such as architectural education, design education, (visual) arts education and environmental education. “The common ground of all these various types of learning activities for children and young people is the use of buildings, places and spaces as a context for learning” (cf. Uttke, forthcoming). Built environment education (BEE) is conceptualised as a cross-cutting subject which utilises the built environment as a learning resource taking into consideration cities, towns, villages, buildings, landmarks and public spaces. Common BEE activities are e. g. school visits to certain places, school-projects supervised by design professionals such as architects or urban planners and participatory school design processes. Furthermore, BEE can thematise the relation between people and the built environment or the design of spaces in order to trigger learning processes (cf. Engaging Places network, 2012a).

Built environment education is multifaceted and interdisciplinary. It incorporates aspects of architecture, urban design, city and regional planning and landscape design. Consequently, educators from these different fields cooperate in projects and programmes of BEE. Furthermore, schools and teachers, parents, education

authorities and governments can be partner (cf. Uttke, forthcoming; Engaging Places network, 2012a).

The different approaches to BEE are all forms of cultural education and share common aims (cf. Uttke, forthcoming). Objectives and learning targets of BEE are amongst others:

- to develop awareness and understanding of the local environment and appreciation for architecture and design
- to learn about stakeholders, rights and responsibilities in the design of the environment and possible careers in the built environment
- to support the development of responsibility in view of contributions to society and sustainable development
- to broadens personal, learning and thinking skills such as creativity, confidence, self-management, team-work, critical reflection and judgement, participatory and communicative skills
- to experience analytical and conceptual working methods (cf. Engaging Places network, 2012b; UIA, 2008, p. 5).

The development of concepts and ideas for BEE has increased in the past 20 years and receives growing attention nowadays. International networks, have been installed in the last years to discuss, promote and support BEE. Examples for this are amongst others PLAYCE (www.playce.org), the Engaging Places network (http://www.engagingplaces.org.uk/home) and the International Union of Architects (UIA) Built Environment Education Network (http://uiabee.riai.ie/index-en.html).

4. Linking Built Environment Education and Youth Participation in Planning Processes

"It is noticed that – at least in Germany – there is a growing importance of linking education and participation" (Uttke, forthcoming). The linkages between built environment education and youth participation in planning processes seem to be particularly evident. On the one hand one of the central motives of community participation is the assumption that participation entails a great variety of educational and socialisation processes (cf. BKJ, 2009, p. 31; Knauer, Sturzenhecker, 2005, p. 3; Mullahey et al., 1999, p. 3). Key qualifications such as self-reliance, communication skills and the development of own viewpoints shall be strengthened (cf. Winklhofer, 2008, p. 72; Knauer, Sturzenhecker, 2005, p. 3). On the other hand, BEE shall "inculcate […] a desire to participate in the complex and magical process that constructs the house, the town and the region" (UIA, 2008, p. 4). BEE promotes abilities which are relevant for decision making and participation and besides arouses interest in urban development and the built environment. Accordingly, BEE can be a starting point for further participation in the community (cf. Uttke, forthcoming; Räsänen, 2006, p. 14).

In practice the linkages between built environment education and youth participation are evident in concepts for both alike. For one thing participation places high

demands on young participants and thus qualification and education are regarded as a necessary component of participation processes (cf. Adams, 2006, p. 9; Bertelsmann Stiftung, 2009, pp. 60-61; Knauer, Sturzenhecker, 2005, p. 20). For another thing BEE is supposed to be participatory in order to engage young people in local development processes (cf. Kapanen, Svinhufvud, 2011, p. 9). Despite these linkages practical concepts of BEE and participation rarely focus on mutual references and strategic links between one another.

The described first glimpses on the linkages between built environment education and youth participation in planning processes ask for proof and furthermore raise many questions. What are in detail the interfaces between BEE and community participation? What exactly do young people learn in participation processes? Does experience from BEE indeed influence future commitment? How do BEE and participation complement each other and were do the two approaches aim for contrary goals?

In the following, practical experiences from the authors will be presented in order to shed light on the linkages between participation and education and to give first answers to the posed questions.

4.1 Practical Experience in Linking BEE and Youth Participation

As an approach to a deepened understanding of the linkages between participation and built environment education, the authors practical experiences from projects at the interface of the two fields will be described and analysed in the following.

First, findings from the EU project "Fantasy Design in Community" will be summarised. The project was designed to promote built environment education and focused on participatory design with young people. Therefore, it allows many assumptions on the linkage between participation and built environment education. Basing on a professional evaluation the results can be classified as practical experience from a scientific viewpoint.

The second example of practical experience presents an attempt to incorporate the viewpoint of adolescents. The findings are derived from the youth workshop "Young Cities Now!" which was conducted with young people who participated in divers planning processes all over Germany in 2009. One result of the workshop was a manifesto drawn up by the participants.

4.1.1 Fantasy Design – Children in Community

In the EU-project "Fantasy Design – Children in Community" innovative ways of design education were explored between 2009 and 2011. "Fantasy Design is a design education initiative […]. Its core idea is to give children and young people an opportunity to work with designers and to display their own design thinking in an international exhibition" (Kapanen, Svinhufvud, 2011, p. 9). The project focused on participatory design processes involving young people in design projects, solving

problems of their own environment and everyday life and discussing these issues in an international community (cf. Uttke, Heinrich, 2012, p. 18). Uttke/Heinrich conducted in 2011 the evaluation of this EU-project.

"Fantasy Design – Children in Community" was realised by partners from four different countries: Design Museum Helsinki (Finland), University College Sealand (Denmark), Design museum Gent (Belgium) and National Museum of Decorative Art Madrid (Spain). The Fantasy Design (FD) project consisted of central activities and components on national and international level. Local design projects of different tasks and scales working with designers and other professionals were conducted in all four countries (cf. Uttke, Heinrich, 2012, pp. 17 and 21). In total Fantasy Design consisted of 18 local projects in Finland, Denmark and Belgium and 12 workshops in Spain (cf. Kapanen, Svinhufvud, 2011, pp. 113-116). An international web site (http://www.fantasydesign.org/fd/) was used for the documentation of the projects, for compilation of information on design education in general (e. g. learning material for teachers) and communication within projects and amongst different projects. Throughout the process two international conferences were held. An international touring exhibition presenting design processes and products was both highlight and closing event of the project (cf. Uttke, Heinrich, 2012, p. 21).

Figure 2: "Fantasy Design in Community" local youth project in Gent (Photograph: A. Uttke)

The project was based on earlier international design educational programs: the first „Fantasi Design" (engl. Fantasy Design) project (1998–2000) and the second „Fantasy Design – Children and Young People as Designers" project (2003-2006)

(cf. Uttke, Heinrich, 2012, p. 14). Those first two Fantasy Design (FD) projects mainly focused on product design (cf. Uttke, forthcoming, p. 3). "Fantasy Design – Children in Community" (FD 3) retained key ideas and factors of success of the first two FD projects. Furthermore, deficits of the former projects were compensated and new components were added to the concept (cf. Uttke, Heinrich, 2012, pp. 57-58). One of the most important innovations of FD 3 was the explicit focus on community aspects and the built environment, such as

- „looking at design as a tool in building a sustainable and socially inclusive environment,
- working in collaboration with local authorities of planning and environment,
- including trans-sectoral aspects in local work; e.g. collaborating with social and health sectors, culture
- and administration,
- creating an European design community within the project" (Application Form to the EU Culture Programme / Education and Culture DG application FD 3, p. 8).

Figure 3: Testing and prototyping in the Fantasy Design project "Outdoor Artwork" (Photograph: E. Vasu, available at http://www.fantasydesign.org/fd/content/building-recycled-artwork, accessed 7 May 2012)

The spectrum of realised projects under the umbrella theme "Fantasy Design in Community" was very broad. Projects included re-designing of central spaces in communities, such as school yards, parks, youth houses and spaces for the youth,

community centres and neighbourhood spaces. Other projects focused on a communicative and collaborative process in product design discussing the needs of participants and clients in a community. Within the local design processes designers and educators with different professional background as well as local actors were partners. They assisted the children and adolescents acting as designers (cf. Uttke, Heinrich, 2012, p. 8).

Within the various projects different methods and principals were applied: young people worked as designers in teams, collaborations with local partners were built up and open design processes were created. As a design education project, supporting learning with design and promoting design methods in education was one of the main principles. All projects should trigger learning processes through personal experience and should allow exploring creativity and innovation through "real" design projects (cf. Application Form to the EU Culture Programme / Education and Culture DG application FD 3, p. 8).

An evaluation of the EU-project "Fantasy Design – Children in Community" was conducted by the two authors of this paper. Aim of the evaluation was to reflect on outcomes of the project. The methodology of the evaluation included a workshop with the four national coordinators of the project, face-to-face and e-mail interviews with several participants such as educators and designers, desktop studies of the Fantasy Design web site and documents as well as self-evaluations of the national coordinators and finally a visit to the international Fantasy Design touring exhibition in Gent (cf. Uttke, Heinrich, 2012, p. 12).

Figure 4: "Fantasy Design in Community" touring exhibition in Gent
(Photographs: A. Uttke)

Benchmarks for the evaluation were the project's objectives as described in the project application:

a) "to deepen and to extend the collaboration with central organizations in design education,
b) to promote contents and activities of innovative design education in Europe,
c) to create for children and young people a framework for informal learning and networking in local communities through real design tasks,

d) to use the possibilities of digital media (interactive web site) for collaboration and cross-cultural dialogue between children, young people, designers, educators and other stakeholders" (Uttke, Heinrich, 2012, p. 11).

As a participatory design project Fantasy Design and its local projects operated at the interface of (built environment) education and youth participation. Particularly important for the examination of linkages between the two issues is the third goal which addresses the framework for informal learning and networking in local communities. The evaluation stresses how closely related the aspects of BEE and participation are. Often education and participation are hardly separable within a project for both are fundamental for a successful process and high quality products.

Each local project of FD 3 proceeded from a "real" design task such as the (re-)development or (re-)design of a certain place within the community or existing needs from local stakeholders. This relation to young people's own environment and daily problems and needs gave the projects high authenticity. FD was originally conceptualised as an educational project. The task to engage in community design was used to give the young people the opportunity to directly participate in urban design processes involving local politicians, architects and urban planners. Instead of "just" learning something about design in community in theory or exercising design projects completely detached from the current local development, the young participants were able to actually implement own ideas and thus to influence and change their local environment. This practical and participatory component gave the young people a high motivation to learn about design because they were eager to realise own high quality projects. Accordingly, project components such as visits of local design museums were appreciated by the young participants. The young people obviously interpreted educational components as necessary prerequisite for their own design processes (cf. Uttke, Heinrich, 2012, p. 40-45).

Furthermore, being empowered to actually change the own environment gave the young people a strong feeling of appreciation and acknowledgement. They experienced how they can influence their surrounding and implement own ideas. The approach of learning-by-doing triggered their creativity and allowed them learning about design by playful means. This created not only feelings of success but was for many participants overall a formative experience (cf. Uttke, Heinrich, 2012, p. 44). This could be important for future participation and commitment in community development because the participants were very positive and motivated at the end of the project and inhibitions for participation processes were overcome through the projects. Statements from youth workers from Finland support this assumption. They report that since the involvement in Fantasy Design young people as well as youth workers are for example no longer "interested in just buying new furniture for the yard when they can make it in a more special way by building and recycling" (Kapanen quoted from Uttke, Heinrich, 2012, p. 44).

4.1.2 Young Cities Now!

An important aspect of the discussion on youth participation is the viewpoint of young people themselves. They are experts for their needs and should thus be allowed and encouraged to discuss and formulate their claims in view of youth participation. This is not least the case because young people's perspective on participation is highly relevant for a realisation of successful youth participation (cf. Bertelsmann Stiftung, 2009, p. 19). Therefore, young people's ideas and criticism in view of community participation will be considered in the following. As will be seen, young people do strongly link the issues of participation and education.

The workshop "Young Cities Now! Jugend.Stadt.Labor" (Young Cities Now! Youth.City.Laboratory; www.youngcitiesnow.de) was conducted in Berlin, Germany by the non-profit organisation JAS Jugend Architektur Stadt e.V. (Youth Architecture City) in November 2009 (Heinrich, 2010, p. 15). One of the authors was herself one of the project managers who conceptualised and conducted the workshop. The other author accomplished a scientific analysis of all material concerning youth participation which was produced during the workshop (Heinrich, 2010).

"Young Cities Now!" was a project within the research field "Adolescents in Urban Neighbourhoods" of the German Federal Institute for Research on Building, Urban Affairs and Spatial Development. This is one of the research fields within the research programme "Experimental Housing and Urban Development" of the German Federal Ministry of Transport, Building and Urban Development. Aim of the research field is to develop methods and strategies for youth participation on different levels of urban and neighbourhood development. In the long term the projects within this research field shall support the establishment of a youth participation culture and thus contribute to the creation of youth-friendly cities (cf. Heinrich, 2010, pp. 15-16; BBSR, 2009b, pp. 21-22; BBSR, 2010a).

In May 2009 a call for projects for the research field "Adolescents in Urban Neighbourhoods" was launched. 25 projects all over Germany were chosen from 220 applications. The range of applied methods and conducted projects was very broad – the adolescents used new media, made films and composed songs, they created art initiatives and festivals. Additionally, "Young Cities Now!" was selected as an add-on project inviting two representatives of each of the 25 pilot projects to a common workshop. Aim of this workshop was to give the youth ambassadors the opportunity to reflect, discuss and communicate their different experiences. As a result a manifesto should be written in order to set an impulse for the qualification of youth participation in planning processes (cf. BBSR, 2012; BBSR, 2010b; Heinrich, 2010, p. 16; BBSR, 2009a, p. 29).

In total 42 adolescents age 12 to 22 joined the three-day workshop in Berlin. The major topics they discussed were

- participation,
- communal life and neighbourhood,

- sport and action,
- chill out,
- art,
- music, and
- mobility (cf. BBSR, 2010b).

First a world café allowed all youngsters to share experiences, ideas and criticism on all of the seven main issues. In the further course of the workshop small groups focused on one topic each. After deepened discussions they formulated paragraphs and catchy slogans for the manifesto and created illustrations to underline their statements (cf. BBSR, 2010b; Heinrich, 2010, pp. 16-18; JAS, 2009).

Figure 5: Group discussion at the "Young Cities Now!" workshop
(Photograph: A. Meichsner)

In total the manifesto consists of eleven statements under the title "Live your city – bringing forward something new together. A manifesto for youth-friendly and liveable cities" (http://youngcitiesnow.de/manifest/). The first statement is entitled „Future is Youth – Trust us!" and addresses youth participation. The adolescents criticise the lack of confidence in the abilities of young people which reduces their opportunities for action and participation. As one solution to this lack of confidence and the consequential lack of participation the adolescents consider empowerment and education. The young people suggest projects, seminars and workshops as possible formats of education. The value they see in an aimed empowerment is

- a strengthening of interest in and motivation for youth participation and voluntary commitment amongst adolescents,
- a growth of confidence of adults in adolescents,
- an improvement of the quality of living in cities, and
- an acquisition of soft skills and key competences (cf. JAS, 2009).

The working material of the small group which explicitly concentrated on the issue of youth participation stresses this again and goes further into detail. The analysis of the working material was focused on four main issues:

- conditions of youth participation,
- formats of youth participation,
- motivations for youth participation, and
- topics and choice of topic for youth participation (cf. Heinrich, 2010, pp. 27-28).

All written documents (posters, index cards, text blocks) from the small group working on participation throughout the workshop were analysed via content analysis. Additionally, an expert interview was conducted with the supervisor of the working group (cf. Heinrich, 2010, pp. 21-22 and 24-25). The mass and diversity of points of discussion which could be identified from the working material shows how complex and intensive the adolescents discussed the issue of participation (cf. Heinrich, 2010, pp. 32-35). Furthermore, the analysis stresses that the young participants linked the subjects of education and participation in all four dimensions of the analysis although education was not a topic brought up by the supervisors.

Figure 6: Visualising their demands for the "Young Cities Now!" manifesto (Photograph: A. Meichsner)

The young participants interpret education as a necessary prerequisite and condition of participation. Within processes of participation the adolescents expect support from adults, especially from politicians and the administration. They summarise the expected with three key words: guidance, competence and learning. They describe

that they want to be supported developing certain skills. On the one hand they want to adopt those skills through participation and on the other hand they feel they need to be trained for participation. They link this qualification closely to the matter of trust. „Trust us" is the most prominent claim of the youth's manifesto. Obviously the adolescents gain self-confidence from the empowerment and they hope to be able to enrich planning processes in a way which builds up a certain trust in youth in general (cf. Heinrich, 2010, pp. 36-39; JAS, 2009).

In view of the forms of participation and education the adolescents discussed two major issues: Firstly, they claim the application of participatory methods which guarantee an individual support of all youngsters. Secondly, they address youngsters and ask them to support each other within participation processes. They do not necessarily link the issue of education to adults and supervisors. They see a high potential in learning from one another (cf. Heinrich, 2010, p. 39; JAS, 2009).

Figure 7: Final presentation of the "Young Cities Now!" manifesto to representatives from the Ministry of Transport, Building and Urban Development (Photograph: A. Meichsner)

The third dimension of the analysis was the motivation for youth participation from different viewpoints. As an overall societal reason for participation the adolescents see a possible strengthening of society through participation because of the many educational effects participation incorporates. From their own perspective they also value participation because of its educational effects but again stress that participation necessarily needs educational elements as precondition for a high quality (cf. Heinrich, 2010, pp. 40-41; JAS, 2009).

In view of topics and choice of topic for youth participation the youngsters state that generally they want to be allowed to participate in all contexts and discussions, not only those directly relevant for themselves. Issues they name specifically are amongst others competencies they would like to strengthen such as media usage and to learn to do interviews (cf. Heinrich, 2010, pp. 41-42; JAS, 2009).

In line with these findings the German Federal Institute for Research on Building, Urban Affairs and Spatial Development draws the following conclusion from the pilot projects of the research field "Adolescents in Urban Neighbourhoods": "Teenagers must be empowered in order to tap their potentials. Therefore, foundations must be laid to enable them to formulate their interests. For this purpose, knowledge must be conveyed and technical languages translated or learned. Based on this, teenagers are given the possibility of becoming independent players in the quarters themselves" (BBSR, 2012).

4.2 Lessons Learnt from the Practical Experience

The EU-project "Fantasy Design in Community" started as built environment and design education project. "Young Cities Now!" however was conceptualized as a participation project. Both projects nevertheless emphasise a close connection between BEE and participation.

The evaluation of "Fantasy Design – Children in Community" shows that projects on the interface between built environment education and participation attain very high quality. The young participants had a strong motivation to learn about their environment and design because they realised that the gained knowledge and skills could help them to realise projects of high quality. The youths considered it appropriate and purposeful to integrate learning processes in their projects and accordingly had a high level of motivation and willingness to learn. The young people enjoyed learning because it was meaningful and the educational components of the projects made the youths knowledgeable participants with increased self-confidence. The participatory component in turn increased the authenticity of the project, as projects were involved in real community development processes. The opportunity to implement own ideas in their local environment made the projects beneficial for the young people and at the same time expressed appreciation of the young people's commitment. The expression of appreciation is again a crucial factor within participation processes as the example of "Young Cities Now!" shows. Altogether, the evaluation clearly shows that one factor of success of Fantasy Design was indeed the linkage between built environment education and participation.

The analysis of the workshop „Young Cities Now!" and the resulting manifesto reveals adolescent's viewpoint on participation and education. All participants were representatives of youth participation projects that focused on urban development. Based on their experience with community participation the adolescents clearly expressed that participation and built environment education are inseparable. Youth participation should be designed as an educational process which allows the

participants to learn from adults and from each other alike. For one thing the youths interpret BEE as necessary prerequisite and condition of participation because of the high demands placed on participants. For another thing they see BEE as a means to support individuals throughout participation processes and thus to strengthen the society as a whole.

4.3 Theoretical Discussion on Linkages between BEE and Participation

The theoretical discussions on built environment education on the one side and youth participation in community on the other are poorly linked. So far, there seems to be general agreement that participation automatically implies educational processes (cf. Düx, Sass, 2005, p. 397; Winklhofer, Zinser, 2005, p. 72). "Through first-hand experience [in participation processes], young people are building self-reliance, connecting with others, and learning about their inner resources and their own creative potential to forge a new sense of what is possible. They are transforming ideas into pragmatic proposals for action and advocating solutions to the urgent problems confronting their communities, their country, and their world" (Mullahey et al., 1999, p. 1). Nonetheless, the assumption on this connection between participation and education lacks empirical evidence (cf. Prein et al., 2009, pp. 530-531; Düx, 2005, p. 397).

A strong focus in research regarding these educational processes so far is on participation as an experience and training ground for democracy and civic education (cf. Hafeneger, 2005, p. 27; Knauer, Sturzenhecker, 2005, p. 11). In this sense, empirical studies proof a strong connection between education and participation in the way that an increasing level of education increases the general political interest, trust in social institutions and participation in organisations (cf. Winklhofer, 2008, pp. 77-78). "Young people need the experience of genuine participation and knowledge of the responsibilities of real citizenship to become effective decision makers. [...] A community planning process can serve as a springboard to actualize democratic citizenship" (Mullahey et al., 1999, p. 6).

First findings on educational effects of participation in general are presented in the investigation by Düx and Sass (2005). They analyse informal learning in the youth age in settings of voluntary commitment. Their results base on 72 face-to-face interviews with adolescents and young adults who are or have been voluntarily active. Furthermore, the data basis includes standardised telephone interviews with 1,500 persons who were engaged in voluntary activities as adolescents and 500 persons who did not engage in community commitment in their youth. The interpretation of the empirical material suggests that young people's commitment in the community leads to a development of skills which meet the conflicting demands of modern society. Skills such as personal, social and technical skills, responsibility, democratic participation and moral values are promoted (Düx, Sass, 2005, p. 398 and 408). On top of this, a recent review of international research on issues of acquisition of competencies and learning through commitment and participation can be found in Lerner et al. (2007) (cf. Prein et al., 2009, p. 532).

Starting from the discussion on education in general and built environment education in specific there seems to be general agreement on the insistence that meaningful education needs to be participative (cf. Kapanen, Svinhufvud, 2011, p. 9; Winklhofer, Zinser, 2005, p. 73). Despite the debate on educational effects of participation and participatory approaches to education there is little discussion on a purposeful integration of education and participation. Scientific research so far lacks investigations and discussions on the high demands on youths within participation processes and the questions what kind of education participation thus requires.

5. Conclusion

The theoretical discussion on linkages between built environment education and youth participation in community shows that it is generally assumed and partially proved that meaningful education needs to be participative and that participation automatically implies educational processes especially in view of civic education. The two practical examples introduced in this paper – "Fantasy Design in Community" and "Young Cities Now!" – added a further aspect to the current scientific debate on participation and education. While youth participation and built environment education are mostly considered apart in theoretical and empirical studies so far, the practical experience emphasises that an integrated consideration is productive.

Based on the findings from "Fantasy Design" and "Young Cities Now!" the authors strongly recommend expanding the occasional educational processes within participation processes through a deliberate integration of built environment education. BEE should be an integral part of participation processes. Gained skills could improve process and product quality of youth participation. This would make participation a positive and formative experience and young people more knowledgeable participants. Furthermore, having participated in a successful project once, the young people would more likely participate in future projects.

Hart's ladder of youth participation introduced different degrees of participation. Hart stresses that a higher rug of the ladder of participation is not necessarily the better one but that the degree of participation simply needs to suit the respective project. Nevertheless, it seems obvious that the higher the rug and thus the higher the degree of agency by young people, the more demanding and challenging youth participation becomes for young people. The authors conclude that a debate on the inclusion of BEE in participation processes is necessary to enable young people to participate on the higher rugs of the ladder of participation. The discussion on linkages between the two fields of education and participation should definitely take into consideration the different degrees of participation and the arising need for support and education in projects of a higher degree of participation. This enriches the on-going discussion on whether children and youths are able and capable to truly participate in community planning (cf. Christensen, O'Brien, 2003, p. 10).

Despite the presented recommendation to link built environment education and youth participation in planning processes the authors are aware of the risks and problems this might incorporate. “Young people's work that focuses on individual learning and development, rather than on changing their surroundings, is not real participation” (Mullahey et al., 1999, p. 4). In this sense, Knauer and Sturzenhecker (2005) come to the conclusion that by definition youth participation is not pedagogical because here youths act as political actors and policy-maker. But because this seems hardly manageable without certain knowledge and skills, coaching and training should be integrated in participation processes (cf. Knauer, Sturzenhecker, 2005, pp. 19-20). Participation processes must not be instrumentalised as pure educational processes but it seems necessary and productive to integrate educators and built environment education in youth participation.

THE CONUNDRUM OF A STATE SPATIAL PLAN IMPLEMENTATION: THE SPATIAL PLAN OF THE REPUBLIC OF SERBIA (2010)

Miodrag Vujošević [1], Tamara Maričić [2]

Abstract

Political changes in Central and Eastern Europe, initiated with the fall of the Berlin Wall (1989), had immediate and strong impact in Serbia. However, economic and political reforms of post-socialist transition in Serbia, followed with the dissolution of Yugoslavia at the beginning of 1990s, have been going through a number of "ups and downs". One of the causes lies in the fact that majority of those reforms have been imposed on the society at large by the political and economic elites, almost without any broader public dialogue undertaken about the main directions, content and implementation means of such reforms. The current socio-economic situation of Serbia is poor, mainly taking the form of a "growth without development". While facing a number of difficulties, Serbia also fails in institutional and organizational adjustments, to cope with the predictable bleak future development prospects.

The former *Spatial Plan of the Republic of Serbia* from 1996 defined a very complex set of implementation measures and support, which was stipulated for further elaboration, via a particular implementation programme. However, this programme has never been worked out. For the newly adopted *Spatial Plan* (2010), the *Programme for implementation in the period 2011-2015* has already been adopted, but there are still many obstacles in the current system and practice of spatial and environmental planning, which represent a mixture of old habits and substandard approaches, with only some adjustments to current EU legislation and good practice introduced. Therefore, the main worries remain – will it be possible, and how, to reverse the existing institutional and organizational solutions and practices, in order to implement at least the majority of strategic aims from this leading strategic document, on the one hand, and thereby to support the renewal of strategic research, thinking and governance in Serbia, on the other.

Key words: national spatial plan of Serbia, implementation, post-socialist transition, collapse of strategic thinking, research and governance

1. Introductory notes on post-socialist transition in Serbia

The collapse of communist/socialistic system in Central and Eastern European countries has induced different reactions from their political and economic elites. Success of the ways those governments and experts tried to solve these new challenges are still much reflected in today's economic and geo-political position of their countries and wellbeing of their nations.

[2] IAUS - Institute of Architecture and Urban & Spatial Planning of Serbia, Belgrade, Serbia - tamara@iaus.ac.rs

For its specific socialistic/communist (self-governing socialism) and political heritage (a part of both the East and the West), Serbia holds the distinct position regarding the process of socio-political and economic transition. Since the 1950s, the Yugoslav version of a Bolshevik ideological paradigm, i.e. "self-managed socialism" has been developed as quasi-market and quasi-liberal, but at the same time it was also quite opened to the economic, political and cultural influences from the "West", the so called "Third world nations" and the "Socialist block" (Vujošević et.al., 2010). This period was characterised by an enormous economic and overall development, but already experienced a crisis in the middle of 1970s and finally collapsed in the early 1990s after the fall of the Berlin wall.

The unstable political situation (civil wars for Yugoslav secession started in 1991) and deep economic crisis directed Serbia towards rather bleak development prospects. Therefore, the initial phase of transition period (1991-2000) or the so called "blocked transformation" (Lazić and Vuletić, 2009) has been devastating for Serbia. For the period of more than ten years the country was isolated from the mainstream trends of European integration and convergence.

Serbia's comparative advantages and competitiveness have worsened in two key aspects: firstly, in terms of its structural qualities, and secondly, in terms of its territorial capital, whereby Serbia's "endogenous capital" and competitiveness lost a large part of their previous value and potential. Especially has worsened the so-called "soft territorial capital", together with the weakening capacity for strategic research, thinking and governance. (Vujošević et. al., 2012, and Vujošević et. al., 2010).

After the political changes in October 2000, substantial economic, material institutional and organizational progress has been accomplished in the subsequent period. Though, that wasn't enough to satisfy the expectations of the overwhelming majority of the population. The economic recovery from 2000 onwards, while fairly dynamic (by the average annual GDP growth of almost 5%) has still been insufficient and more or less assumed the form of a "growth without development", as well as a long unsustainable development. Although transition reforms in Serbia have progressed, their political legitimacy is rather poor, since veritable societal dialogue has not been established so far, nor has societal consensus been reached on the most important issues. The country is still among the least developed ones in Europe (a part of the "inner peripheries of Europe", Göler, 2005) and faces a vast number of very complex developmental problems and also many challenges. Its development prospects, at least over a mid-term period, are not bright. The global and national economic crisis, as from 2008 onwards, has only worsened the existing conditions and future prospects.

In the sequel of this paper a short account of the different institutional, economic, social and environmental changes and adjustments is given. This is followed by a brief overview of planning and governance system and practice. The comparison of the latest (2010) and previous (1996) Spatial plan of the Republic of Serbia and their implementation measures and support will also be presented. Finally, some conclusions regarding possible development prospects of Serbia, and renewal of strategic research, thinking and governance in Serbia are given.

2. Collapse of planning system and practice

Although more than two decades have passed since the process of transition from socialism to capitalism started in CEE countries, Serbia is still in a phase of post-socialist "proto-democracy", where institutions of market economy, civil society and representative

democracy are only basically developed. While the "good" parts of the Yugoslav self-management system have been abandoned and almost forgotten, its bad parts, e.g., paternalism, manipulation, clientilism, etc. are still being kept.

Serbia has now found itself in a deep crisis, which is even more emphasized by the ongoing world economic crisis. The current economic development of Serbia is poor, mainly taking the form of a "growth without development". The new dilemma that emerged in front of Serbian elites reads: "What would be a successful development path for the Serbian society today?" As only recently (in March 2012) it finally received a status of candidate member of European Union, Serbia has been trying for so long to "Europeanise outside the EU", which has put forth additional challenges to its development. Today, after many years of reforms, with some ups and downs, a lot of people in Serbia are the objective losers due to an application of contemporary models. The main economic consequence of this period is a stunning redistribution of a social wealth, followed by a total destruction of the former economic system and formation of new interest-groups in this isolated semi-martial economy. Since 2000 there have been attempts to improve that new and unjust economic distribution by measures like a tax on extra profit, but they mainly remained unsuccessful due to absence of other measures of political transition, like reform of the security sector, reform of the tribunal and prosecution, restitution and denationalisation, etc.

From the beginning of the post-socialist transition, one of the most radical changes in Serbia was attempt to create a new balance in the state (power) – market – planning – privatization quadrangle. This "search for a new balance" has a great influence on development planning and governance system and practice. However, there has been a retrogression of strategic thinking, research and governance in last two decades or so. Planning system, and particularly planning practice have not been developed in accord with the "asymptotic ideal" of a democratic, participative and emancipatory-modernising model, but rather manipulation, clientelism and paternalism dominated in practice. After many years when an eminently anti-planning and anti-developing attitude dominated among the elites, a large number of development documents (strategies, plans, etc.) have been adopted in recent years at various governance levels (state/national, regional, and local), totalling many hundreds of the kind.

In terms of institutional and organizational arrangements in planning, in parallel two tendencies took the place: on the one hand, a number of old "institutional zombies" have been kept; on the other, "management agencies" and similar organizations have been introduced at large. The latter proved of almost no use to cope with the key development problems and challenges Serbia has been facing for a longer period now. In sum, the legitimacy of planning is relatively low, while planning practice represents a mixture of elements from different "models": planning as crisis management; planning as a mechanism for support of "uncontrolled privatisation and wild marketisation" (with domination of big projects instead of strategic development programmes); and, the least practised but mostly needed, planning where institutional framework is accommodated to the needed social, economic, cultural and environmental transformation of Serbian society (see Vujošević et. al., 2010).

3. Old and new Spatial Plan of the Republic of Serbia

In the last 20 years there have been two attempts to redirect the existing, undesirable direction of development from the spatial and environmental perspective, and provide a common strategic framework for the coordination and integration of different and multi-levelled

development policies, viz., *Spatial Plan of the Republic of Serbia* from 1996, and *Spatial Plan of the Republic of Serbia 2010-2020* adopted in 2010.

When *Spatial Plan of the Republic of Serbia* was adopted in 1996, Serbia (at that time part of the Federal Republic of Yugoslavia) was first among the post-socialist countries that have had a newly prepared and adopted national spatial plan. The *Plan* consisted of a large number of basic reference points, strategic commitments and general goals (English version, 1997:9-12), viz.:

- A higher degree of functional integration of Serbia's territory;
- Better communication and economic links between Serbia and its neighbouring and other European countries;
- More balanced regional development (decreasing regional disproportions);
- Improvement of life quality in macro and regional centres;
- Effective introduction of the principle of polycentric development;
- Developing rural areas as multifunctional production, social and cultural entities;
- Priority development of insufficiently developed border and mountain areas;
- Introduction of rigorous location, technical, techno-economic and environmental criteria in investment and decision-making procedures;
- Careful management, rational use and protection of natural resources, and protection of natural and cultural heritage;
- Priority protection for best-preserved and most valuable ecological areas, and those with best prospects for sustainable development;
- Providing the timely reservation of space in the corridors of technical infrastructure;
- Combating illegal construction and un-planned space utilisation; etc.

The intention was to produce a strategic document to be "more than a plan", i.e., to instigate a number of legislative, normative, institutional, organisational and other changes in the planning system and practice. The *Plan* encompassed a very elaborate system of implementation measures and support. Those measures were stipulated to be elaborated in detail in the particular implementation programme, which, however, had never been made. It has turned out that one of the main problems lied in its implementation and coordination, or, as Anker (1998) had noticed: "there is a need for further coordination of the proposed concepts over the medium term with other policies and development measures".

No systematic monitoring or *ex post* evaluation of the implementation of the *Spatial Plan of the Republic of Serbia* (1996) has ever been carried out, but it could safely be concluded that the majority of its provisions have never been carried out. Apart from a number of some mostly exogenous factors (viz., international sanctions and isolation of the country, slow pace of transition reforms, NATO bombardment in 1999, etc.), a lack of effective political will played key role for its poor implementation. Only the preparation of spatial plans at lower planning levels was more successful, as well as an indirect implementation of some of its propositions via spatial and urban plans at sub-national planning levels. In sum, the realisation of a few elements of the *Plan* turned out to be erratic and accidental, more as an outcome of non-coordinated activities of some individual actors, than resulting from the organised and systematic efforts of key institutional actors (Vujošević, 2010).

Similarly, the new *Plan* (2010) has replicated the ambitions, approach and structure of the former *Plan* (1996). As its precursor, it has also demonstrated an ambition to be "more than a mere spatial plan" at the national level, apropos, it has introduced a number of measures and

instruments targeted at broader reform of systems, approaches and practices in the sphere of sustainable spatial planning and governance. Alike to the previous *Plan*, this new *Plan* also defined many different propositions (as a part of different categories), which will probably prove unmanageable due to the poorly developed planning culture and capacity, as it has happened with the strategic document from 1996. Even more than the former *Plan*, the new *Plan* insists on adequate implementation of key sustainable spatial development propositions, also by realising the Programme of implementation (2011) which has been elaborated and adopted one year after the *Plan* itself. Some other differences between these two strategic documents include:

- The new *Plan* devoted more space to novel categories from the European planning discourse (e.g. "territorial cohesion", "social inclusion", "territorial capital", "urban-rural cooperation", etc.);

- Not having been daunted by the existing poor development conditions, the authors of the new *Plan* envisaged the "long term vision of spatial development of Serbia" imbued with further "boosterism" like: "In the future Serbia should be territorially defined and regionally well balanced, competitive, socially coherent and stable with sustainable economic growth, proper infrastructure and good transport accessibility, preservation and protection of natural and cultural heritage, enhanced environment and functionally integrated with neighbouring countries and regions''. (*Spatial plan of the Republic of Serbia 2010-2014-2020*, Abridged version, 2010: 9);

- The new document has paid, at least nominally, more attention to spatial development scenarios. Two basic scenarios have been defined – "scenario of recessive growth with the elements of crisis management" ("predictably not to last more than 3-4 years"), and "scenario of sustainable spatial development", to emulate the above defined vision and subsumed key strategic goals in the sectors comprised by the *Plan* (*Zakon o Prostornom planu Republike Srbije od 2010. do 2020. godine*, 2010:31-35);[3]

- For the monitoring and *ex post* evaluation of the key strategic propositions of the *Plan* an elaborate list of indicators has been defined and further elaborated in detail in the *Programme of Implementation of the Spatial Plan of the Republic of Serbia from 2010 till 2020* (2011);

- The broader contextual factors that influence the implementation of the new *Plan* (2010) are in many respects different as compared to those pertaining to the implementation of the former *Plan* (1996). Regarding the effective manoeuvring space of the planning authorities at various governance levels, this has even narrowed in three key aspects: misbalances are worse, the macroeconomic situation is worse, and the foreign debt has reached a multi-ten billion of €, altogether crippling the effective capacity to introduce more redistributive policies, which are however an imperative vis-à-vis ever enlarging territorial misbalances and social differentiation and polarization; and

[3] Within the latter, a number of reform steps have been stipulated with regard to the following "frameworks": legal and institutional; market, economic and development; macroeconomic; demographic; social; ecological; and spatial-urban. This scenario contemplates four specific sub-scenarios ("variants"), viz.: "negative economic growth and disintegrated spatial system" (1); "negative economic growth and integrated and partially regulated spatial system" (2); "positive economic growth and disintegrated and partially regulated spatial system" (3); and "positive economic growth and integrated spatial system" (4), all under different assumptions regarding the pace of intensity of the integration of Serbia into the European Union.

- The utmost limit to the *Plan's* implementation is stemming from a predominant compartmentalization of development policies in Serbia. The work of ministries is extremely competing and uncoordinated, as being mostly managed under the auspices of political parties as their "feuds", under the circumstances of prevailing "partitocracy", as the current state of political governance of Serbia is depicted by the majority of most authoritative commentators. Under such circumstances, it can be hardly expected that new *Plan* will act as strategic framework for integrating specific (sector) approaches and concepts, i.e., combining both spatio-ecological (environmental) proper, and broader economic and development concerns; etc.

4. Concluding remarks

Paralleling the collapse of strategic thinking, research and governance, lasting now for more than 20 years, there has been a lack of effective and implementable strategies in Serbia for resolution of its key developmental problems, and some necessary strategies are still missing as well. Despite the fact that in recent seven or eight years several hundred strategic development documents have been adopted (at various governance levels), an overall "exit strategy" is missing to cope with the prolonged crisis, for which reason some commentators have been pointing to a "developmental schizophrenia" (Vujošević, 2010). This also applies to the *Spatial Plan of the Republic of Serbia 2010-2014-2020*, which was adopted in 2010. Within the overall strategic framework, this document contains a number of various sector conceptions. The enclosed implementation means, however, have not been formulated so that they could effectively support the implementation of the respective sector concepts, vis-à-vis disposable financial and other resources. Similarly, existing institutional and organizational arrangements, which have recently been introduced, do not properly reflect the differences between various regional areas, especially vis-à-vis the concentration of activities and population in the metropolitan area of Belgrade and Novi Sad ("Serbian spatial banana"), and concomitant lagging behind of majority of other regions of Serbia. This could be improved via the *Plan's* implementation programme, which ought to be coordinated with other strategic frameworks, both overall and sector-wise. They should altogether focus on the key developmental problems of Serbia, always keeping in mind that the disposable resources are scarce vis-à-vis the predictably prolonged economic crisis (1) and, also predictable, "long and difficult Europeanization of Serbia outside the European Union and with its limited financial and other support" (2). Within the overall strategic framework, this document contains a number of various sector conceptions, also comprising those of balanced regional demographic development. However, for the effective implementation of overall and sector development concept, now a clear political will to define implementation means and mechanisms will have to be demonstrated. Particularly, new institutional and organisational arrangements are needed for the strategic governance in the Belgrade and Novi Sad metropolitan area. In addition to this, a new approach is also needed with regard to the utilization of territorial capital of Serbia, this being a relatively new thematic issue in European spatial planning, also addressed in Serbia only as from very recently. The *Spatial Plan of the Republic of Serbia 2010-2014-2020* represented a first attempt of the kind, i.e., to address this theme in a strategic document at the state (national) level, paralleling few regional plans also comprising this issue in a more significant way. Apart from dealing with the geographical and traffic position of Serbia, some other aspects of overall territorial capital of Serbia have also been taken into account. However, the approach and defined concept have been applied rather rudimentary and insufficiently, especially vis-à-vis implementation of the

Plan and concomitant institutional and organisational support, either at the state (national) or at the regional governance levels.

INTELLIGENT PLANS FOR INTELLIGENT CITIES

Jorge Batista e Silva[1],
José Antunes Ferreira[2], Beatriz Condessa[3], Isabel Loupa Ramos[4]

Abstract

The concept of digital city has been evolving since the 1990s towards the formation of a knowledge society enabling the exercise of citizenship through different types of participatory processes and levels of involvement in city planning. This is made possible by the amazing volume of information that is now available to all, supported by Information and Communication Technologies and the growing field of Intelligent Systems. The concept of intelligent cities (IC) is related to the notion of collective urban intelligence that can be enhanced through different factors: learning, innovation, organizational capacity and leadership or creativity and competitiveness. The four challenging topics of evaluation, governance, intelligence and complexity are used to introduce the concept of intelligent plan (IP) as a cornerstone to IC. Using a three level approach (planning process, plan and territory) crossed with the planning evaluation timeline (*ex post*, ongoing and *ex ante*), the authors argue that the Intelligent Plan should take advantage of ongoing evaluation and monitoring, should preserve memory, have ability to display visions into the future and allow for strong interaction between local authority (the plan owner) and urban actors. Applying the attribute "intelligence" to cities and urban plans and its quasi personification as autonomous and living entities, which do not necessarily presuppose automation, is seen by the authors, above all, as a way of instilling reflection.

The article seeks to explore the attributes of IC, bringing new digital "faces" for IP and its future contribution concerning planning challenges derived from IC. Such a plan is highly dependent on Information and Communication Technologies (ICT) and Web-based-GIS which are seen as important drivers for enhancing interactions between citizens, planning process and city governance, improving a participated policy making and urban design and the effectiveness of plans and planning according to the intents of an increasing intelligent city that continues evolving and adapting.

1. Introduction

'Intelligent Cities' and 'Smart Cities' are the present concepts that succeed to 'virtual cities', 'digital city', 'informational city', 'wired city', 'telecity', 'knowledge-based city', 'electronic communities', 'flexicity', 'teletopia', 'cyberville', among others, covering a wide range of electronic and digital applications related to digital spaces of communities and cities.

The label 'smart city' is used by the World Foundation for Smart Communities (http://www.smartcommunities.org/) to address the 'smart growth' issue. Here development is based on ICT and 'Smart Communities' are communities that have made a conscious effort to use information technology to transform life and work within its region in significant and fundamental ways. The concept of 'smart city' turned out to be popular and has been generally adopted by many cities, business industry and urban marketing, having had echo in the scientific literature of urban and regional studies and policy development, even in the EC and OECD initiatives. There have been some relevant efforts to address the concept (VUT, 2007) - structured on smart economy, smart mobility, smart environment, smart people, smart living and, finally, smart governance - anchored to traditional regional and neoclassical theories of urban growth and development, competitiveness, transport and ICT economics, natural resources, human and social capital, quality of life, and the participation of society members in cities.

Intelligent cities (IC), (communities, clusters, regions) were defined as multi-layer territorial systems of innovation (Komninos, 2009) that bring together: a) knowledge-intensive activities (the intelligence, inventiveness and creativity of the individuals who live and work in the city, widely explored by Richard Florida (2002)); b) institutions for cooperation in learning and innovation (the collective intelligence of a city's population allowing capacity of human communities to evolve towards higher order complexity and harmony, through differentiation and integration, competition and collaboration. (Atlee and Pór, 2006); c) and digital spaces for communication and interaction (the artificial intelligence embedded into the physical environment of the city and available to the city's population) in order to maximize the problem-solving capability of the city. Komninos (2002, 2009, 2011) states that the distinctive characteristic of an intelligent city is the high performance in the field of innovation, because innovation and solving of new problems are representative features of intelligence.

Smart city literature and research seem to put more emphasis on embedded systems (Steventon and Wright, 2006), sensors and interactive media, while intelligent cities rely more on collective intelligence / collaborative intelligence, innovation systems, and web-based collaborative spaces. In literature the concepts of smart and intelligent tend to overlap and try to integrate the three dimensions of urban space (physical, social, and digital), thus having strong similarities. Some authors sustain that 'smart city' is still quite a fuzzy concept (Caragliu et al, 2011). In addition, the

issues associated with Urbanism, Planning and the physical organization of the city and territory have not been properly considered. Likewise, the future shape of planning tools that currently do not address the increasingly digital dimension of urban space has been out of the scope of the literature. There is an apparent lack in smart city literature concerning the physical side addressing urbanism and planning functions. Hollands (2008) report some problems: the splintering urbanism (fragmentation and polarization, economically and socially); growing contrast between creative classes and IT illiterate sections of the population; social inequality and urban gentrification; conflict between environment sustainability and economic growth. Hollands argues for a more progressive smart city that might use ICT to enhance democratic debates about the kind of city it wants to be and what kind of city people want to live in – a type of virtual 'public culture'.

In general, this debate has gone alongside planning practice and plans ignoring its influence in urban development. In all countries urbanism and urban planning have their own idiosyncrasies and go side by side with the legal system of planning in force. In Portugal it is well rooted in both public opinion and the media that urban planning (and in general spatial planning) is a problem that remains unsolved. In many countries, the plan is still an important instrument in the practice of planning, guiding private and public initiatives and more recently supporting public participation and strategy building, in spite of many criticisms that have forced a progressive shift from planning to process and to the improvement of city governance. And the question remains: What is the role for urbanism, urban planning and plans regarding the future IC?

Rephrasing Hollands' statement concerning the need for a 'virtual public culture', we would appeal for a 'virtual planning culture' enabling a more progressive intelligent city that links urban planning and society. This would mean also a less pro-business city, with smart (quick) and traditional reactive attitude from policy makers but a city that has a medium- and long-term policy agenda. For our purpose this is a good reason to differentiate smart city from intelligent city.

This requires different planning practices but also a different planning product (a different Plan) better adapted to an increasingly digital urban infrastructure that here and there is already including some smart devices embedded in the urban environment (e.g. the Intelligent Transport Systems), but also an increasing amount of urban information made available online and instantly – the ubiquitous city (U-city) - where virtually everything is linked to highly connected information systems (see Choi, 2010).

Within this paper we intend to explore and discuss a new type of plan for cities - we have called it an 'Intelligent Plan' (IP) - as the cornerstone for the future Intelligent City.

2. Four challenging topics for the planning process - evaluation, governance, intelligence, complexity

This notion of a new plan format better adapted for intelligent cities is our provocative starting point that triggers, at least, two questions. The first is "Does the Intelligent City need a plan?" and the second is "If the Intelligent City needs a Plan, what type of plan is it?".

In fact, we believe that an intelligent city still needs a plan. Or better than this, it still needs planning. And planning process should give form to urban development strategies. It is important to state these strategies and, sometimes, to give them an urban form, usually with some rules and to promote public participation and public agreements with stakeholders and community. So, we need to express all this in a plan that acts as a public contract. We also need a plan to promote public participation and to assure transparency to planning process. However, in the context of intelligent cities, this plan should be more interactive, informative and self-explanatory. We have considered four topics that should be the basis for the discussion about the intelligent plan: evaluation, governance, intelligence and complexity.

2.1 Evaluation

There is an extensive literature concerning evaluation in planning (Oliveira & Pinho, 2010) that has been giving useful insights to improve plan making. The traditional timeline of evaluation - "*ex post* evaluation" (what has been done, how, why, by whom), "*ex ante* evaluation" (what should be done considering what is going or is expected to happen), the "ongoing evaluation" (a type of evaluation that takes advantage of plan monitoring and that allows for changing the course of things in time) – can be a first framework to consider. Lessons learnt from *ex post* evaluation practices (Lichfield & Prat, 1998) put the accent on the preservation, as complete as possible, of planning process memory, including previous plans, strategies, options, their implementation and results. *Ex ante* evaluation, the most and more widely explored type of plan's evaluation, puts the accent on the ability to anticipate change allowing for the *a priori* evaluation of the plan and its components. Finally, ongoing evaluation (or "*in continuum* evaluation") and monitoring (Silva, 2006) place the emphasis on the planning process that produces and takes advantage of information (that is being produced and stored, namely through monitoring indicators) and has the ability to process that information in order to give inputs to plan improvements and adjustments in the course of plan implementation.

Conformance and performance principles (Mastop & Faludi, 1997) should also be considered. The first uses a framework of explicit intentions and plan objectives that should be structured in order to be compared with results that are being obtained. The performance principle is better oriented to plans with a strategic dimension and uses different criteria to assess the plan success, such as the utilization of the plan by the community and as a frame of reference to decision making. Planning rights, explored

by Alexander (2002, 2007), are dependent on a specific institutional context but should also be considered as important key-points to ensure a lower threshold of quality to plans, namely as far as public participation, non-discrimination, human dignity and social and distributional justice are concerned.

In a few words we would say that the intelligent plan has to consider the rationale for what, and for whom, it will be evaluated on its own course of implementation favoring an ongoing evaluation process, by planners, politicians and the community.

2.2 Governance

Governance has been an issue of strong debate and has an extensive theoretical literature on which to draw. According to Santinha & Anselmo de Castro (2010) this has led to several reforms in public administration and in the delivery of public services. The growing awareness that governments need to interact with society at different levels in order to tackle the emerging challenges has enabled city governance to involve all informal and formal actors in policy design, decision-making and delivery, with high levels of interaction with citizens, socioeconomic agents, and other public institutions. The emphasis has moved from the power to decide to the power to transform through an active multilevel cooperation. Within this process ICT may have an important role to develop innovative solutions and improve governance mechanisms to reduce deadlocks, conflicts of interest or differences in attitude arising among stakeholders, which are very common in territorial arena. Van der Meer & Van Winden (2003:412) describes 'e-governance' as "the capacity of local administrations, in a dialectic exchange with social organizations, citizens and firms, to deploy ICT to achieve urban policy goals" and discern that access, infrastructure and content form a 'local digital flywheel' for the local information society.
Santinha & Anselmo de Castro (2010) present four levels in ICT use by local/ regional governments in their governance mechanisms: a) passive and unidirectional provision of web information – the technology is used as means to facilitate information delivery, namely cartography or land use plans, and other services of general interest located within its geographical area, namely in the field of health, education and tourism; b) ICT use for interaction and transaction purposes with citizens and other institutions, namely the submission of forms, payments, or the issuing of licenses and permits; c) the use of ICT in promoting interaction with citizens and other institutions so that full participation in policy design and decision making is granted; d) ICT used to bring many participants into the public policy domain not only in providing all technological and organizational means available for the full participation of citizens and other institutions, but mostly in developing complementary initiatives to provide people with, on the one hand, the necessary know-how to understand the utility of and have the willingness to participate in public policy design and decision making and, on the other hand, the needed mechanisms to organize collectively and therefore increase their capacity for participation and mobilization towards collective aims and interests. The same

authors have analyzed three Portuguese case-studies that can be located at the third level, being the fourth level the most difficult one to achieve.

2.3 Intelligence

Considering the urban planning context, 'intelligence' is derived from 'information' and "planning intelligence is strategic decision-support information that enables the planner and the community to identify, understand, and deal with new and trying situations" (Kaiser et al, 1995). Its foundation is an information system, which rapidly evolved with computers to what is known as Planning Support Systems (PSS) (Geertman and Stillwell, 2003; Batty, 2007). The massive use of GIS and Web-oriented ICT had also an outstanding development. Google Earth and systems alike boosted the 'virtual city' concept. Visualization and web based contexts are viewed as the future driving forces for PSS (Batty, 2007). Systems of Monitoring Indicators had a huge improvement in last years to monitor urban change and assess policies, planning and plans (Innes and Booher, 2000; Hoernig and Seasons, 2004; Wong, 2006) improving access to data, to its meaning and to better urban knowledge. As mentioned by Santinha & Anselmo Castro (2010:82), "if knowledge is the engine and information the fuel of economic development, ICT can be seen as driving the innovation process".

The intelligence of cities is intrinsically linked to data and information which are increasing in quantity and quality. Intelligent cities tend to require more collaborative and collective intelligence and new discussions concerning spatial intelligence are being presented in literature (Komninos, 2011). In any case, cognitive psychology could give good insights to discern about the intelligent city.

The future format of plans for cities will be digital and web based. And the main interrogations concerning plan making will be centred on tools made available to increase and develop that collective intelligence and on their different attributes and dimensions, to improve a more participative attitude, on information to trigger urban creativity and on governance tools to explore artificial intelligence and modelling.

2.4 Complexity

Cities and society are complex by nature. Recent developments concerning complexity theory try to uncover its mechanisms: urban long term evolution, path dependence, emergence, feedback, self-organization, resilience-adaptation among others. The main efforts in different scientific areas concerning the complexity of cities are centred on understanding fundamental principles governing global behaviour of these urban systems, expressed in terms of many dimensions (namely physical, ecological, economic and human) related to interactions and resulting patterns and structures that collectively define system responses. There have been many studies interested in local interaction between parts giving rise to an emergent global order, "the order out of chaos". This recognizes, somehow, the virtues of bottom up dynamics that have led to enhance participation in planning and the use of

collaborative planning practices as a means to reinforce the self-organization and self-adaptation power of cities. But in our point of view this is illusive if we think that those practices can lead to waive the plan, as a planning tool to organize cities. Alexander, Mazza and Moroni (2012) explained recently very well why we still need rules, and consequently, why we still need plans. Portugali (2011) also stated that the notions of complexity and self-organization are not in opposition, as apparently they seem to be, with the notions of planning and urban design, highlighting the importance of spatial cognition where planning can be at once a cognitive capability of humans as individuals and collectivities.

We are certainly far from the time when the Intelligent City would resemble a self-planned city, expression used by Portugalli (2011) which would require a new and different structure of planning and perhaps new planning authorities. But we cannot continue to ignore the role of models, simulation, technology, information and multiple types of communication in the organization of the city, which do not fit in the traditional and common format of plans. The "Intelligent plan" can be a first step to recognize and start to deal with the complex nature of cities in spatial planning.

3. What can be an Intelligent Plan?

Our problem to be investigated is centered on the fact that the present format of plans to cities does not match with the future intelligent city and it does not take advantage of ICT and digital space in urban societies. Despite having evolved into more dematerialized versions, made available on the Internet, these formal plans remain stuck to the traditional paper format. They remain static, generally blind without visual representations of the planned reality, rigid in time, with low interaction with people after plan adoption and difficult to interpret concerning the proposed changes to the antecedent plans. Therefore, the challenges are to design a new plan framework that can be adopted and web based, taking advantage of three types of Intelligence – Human, Collective and Artificial - in order to prepare better adherence/adaptation to the future Intelligent City.

This new plan format – the Intelligent Plan (IP) – is a challenge to scientific research because it seeks to overcome different problems. In the scope of intelligence we can devise the problem of information systems (openness of data access to different users and applications, uniqueness of digital applications and fragmentation of planning activities, tools to automate urban analysis and management). In the field of evaluation in planning there is the problem of structuring and preserving old plans, past planning options and policies, results, practice and urban change (spatial memory). Looking to the planned city there are problems such as those of visualizing intermediated stages of city being changed and simulating the planned city that is being built to evaluate its performance (self-explanatory power). Complexity leads us to understand the long-term evolution (memory) of the city and implies paying attention and favor bottom-up emerging behaviours from citizens and organizations which, in turn, recommend us to create mechanisms for communication and public participation. From the governance side different problems emerge: the interaction models between urban actors/ population and decision makers and planning

authorities to be embedded in IP; the automation of approvals and authorizations of land use changes and its public disclosure through the IP; the creation of automated tools to monitor policies, namely through monitoring indicators, dashboards and management tools.

The almost personification of the IP as an autonomous and living entity will be used in the context of this paper to help us think about its meaning, functions and main attributes.

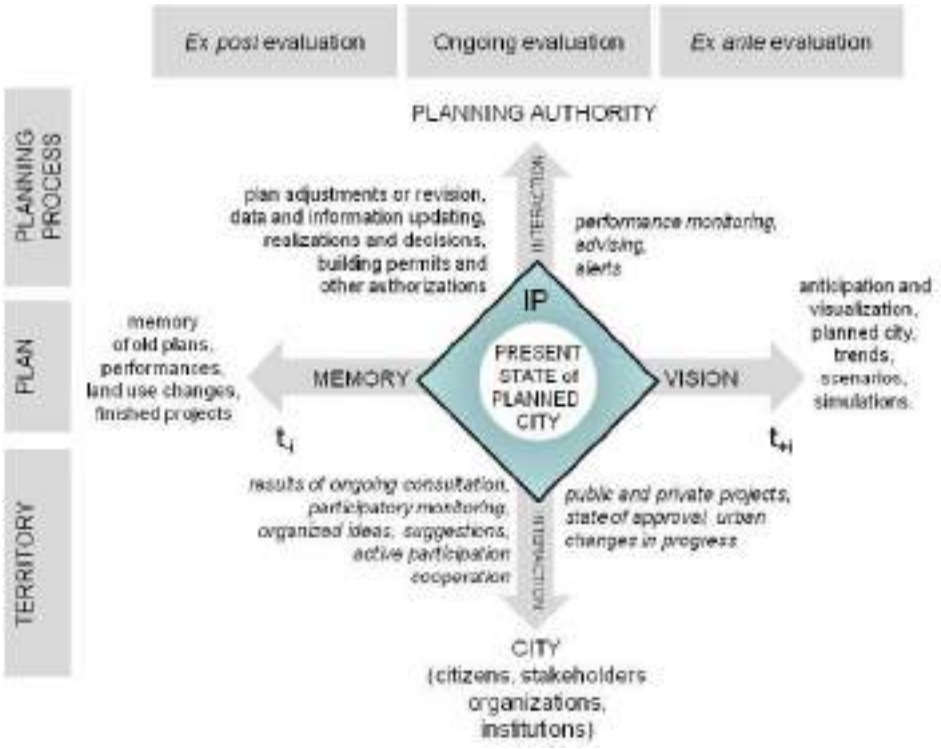

Figure 1 – the Intelligent Plan (IP) as a communication tool for planning authority and for urban actors concerning the past, present and future state of the intelligent city.

The attributes of the IP represented in Figure 1 cross the traditional timeline of evaluation types (*ex post*, ongoing and *ex ante*) with three evaluation levels – the Planning Process with strong interaction with the planning system - styles of planning, legislation, planning authorities and planners – with the formal Plan itself and the Territory (the city) that receives the influence of the Plan but has its own behavior and transformation mechanisms.

A second line of thought (Table 1) will try to link the IP with the idea of an IC which is expressed in Table 1. The attributes identified on the first column are based on extensive literature produced about IC and cognitive psychology, taking into account that the intelligent city is a collective and evolving body with similarities with human

intelligence attributes. In the second column we try to expand potential contributions that IP can give to IC. The type of IP considered here is based on the common functions envisaged for urban planning to structure, organize and prepare cities for future times.

Table 1 – Contributions from the Intelligent Plan to the Intelligent City

Attributes of the Intelligent City	Intelligent Plan
Intelligence (collective) / Education	
• Urban Knowledge and Learning • Problem solving and the construction and use of urban tools • Collective thinking (reasoning) • Mental representation (abilities of abstraction, generalization, interpretation concerning city)	• Repository of old plans, preservation of memory related to past planning process and past performance and evolution of city • Self-explanatory power (language) concerning policies, planning options and measures adopted • Takes advantage of Internet and augmented (mediated) reality through ICT devices to show urban changes (land use change, new public projects or private buildings) in progress or planned for the city. • IP has enhanced capabilities of representing virtual city being changed and planned, relating urban models, structures and abstractions to land use maps and proposals.
Communication	
• Takes advantage of digital infrastructure (ICT), physical space (public space, sustainable mobility) and public services (sustainable transportation) to fuel quality of life for all and develop human and social capital; • Urban open systems (available formats and open data to the creation of apps) and sensor networks • Ensures access for all social groups and organizations and enabling wide interactions • Stimulus to simplification, transparency and new public e-services; • Enables the relational capital of cities (among citizens/organizations and between cities).	• Offered as an ICT technological platform that relates local administration to citizens/organizations/ companies • Promotes and organizes public participation to different planning purposes (auscultation, hearing, partnership, collective deliberation, etc.) • Requires integration with urban planning and local urban management services (e-governance). • Gives and collects data that can be used and interpreted by urban actors • Displays benchmarking data, performance indicators and comparative analysis between cities on the course of plan implementation
Relational capability	
• Promoting human and social capital enabling social relationships among citizens and the expression of their emotions concerning city and urban life • Ability to relate to other cities	• Integration on (or integrating) local social networks
Creativity / Innovation	
• Entrepreneurial capabilities; • Inventiveness of individuals, organizations, institutions and companies • Openness to experimentation	• Providing office spaces, support services, financial backup and urban environments to nurturing creativity and innovation • Launching challenges and interpellations trough the plan to the community to solve problems or uncover solutions • Acceptance of temporary (non definitive) or

Biçimlendirilmiş: Girinti: Sol: 0 cm, Asılı: 0,25 cm

	experimental solutions by planning and planners and its formal inclusion in the plan
Healthy growth	
• Promotes a balanced metabolism and sustainable growth (production and consumption of resources and energy, green and social economy) • Ability to care for itself (social inclusion, territorial cohesion, preservation of social/ common services and supporting deprivation) • Balancing competitiveness/collaboration • Balancing differentiation/ integration • Seeking diversity (in all dimensions) • Capacity of adaptation (adaptability/ resilience) • Ability to reproduce itself.	• IP includes knowledge about the urban metabolism and measures of its evolution • Promotes diversity of urban typologies and urban ambiances • Promotes diversity of housing solutions for different social groups, taking into account the lifecycle of families in neighborhoods • Anticipates the risks and develops contingency programs and solutions • Enhances adaptability (resilience) of city and avoids a complete allocation of uses and a total definition of land use, accepting uncertainty and bottom-up initiatives. • Promotes city growth by multiplication, not by increasing its size, developing cities within the city and polycentrism within the system of cities.
Self-organization and wise management	
• Rules and self-control • Self-evaluation, monitoring and warning systems • Leadership and democratic governance • Stimulation for public participation • Enables an organized participation	• IP includes more flexible regulation, more agile in changing (improving) planning rules and developing stochastic norms that are triggered when a certain condition is met • IP offers information and interactive tools to more knowledgeable governance about population needs and desires. • Feeds leadership allowing for a participative monitoring • IP can open decision spaces to public discussion and deliberations • IP can offer some automation concerning mature methodologies of urban management (e.g. Urban Development Charges, land taxation, etc.).
Intentionality	
• Ability to develop common understandings and a collective consciousness (social, cultural, environmental and urban) • Structure future intentions, policies and take action • Ability to progress for long term planning (sustainability)	• Shows clearly the intent structure and how the objectives and strategies evolve in time with the successive revisions/ alterations of the plan (conformance) • Can automate (performance) levels of participation/interaction and how the IP is acting as a reference system to decision making • Can include monitoring dashboards, and offers simulation tools to anticipate configurations/ visions for future states of the city and its *ex-ante* evaluation.
Finality / Purpose	
• Creating citizens and develop citizenship, which allows collective thinking about the future of their city, what and how can be achieved and developing common strategies to get there.	• The IP should feed citizenship

It is our conviction that such IP should have, at least, the main following attributes (Figure 1):

Memory - preserving old/previous versions of plans, their objectives, options, realizations and performance and also previous images of city and its past transformation.
Vision – powering to anticipate urban change and visualize the future planned city, its trends and visual simulations concerning strategic projects.
Interaction capability – interaction with the city actors promoting consultation, enabling active participation individually or collectively organized, allowing to post individual initiatives or even private projects in order to an automated preliminary approval; interaction with the planning authority and the planning process in order to make possible plan adjustments or revisions, updating data concerning administrative and management decisions or including performance results using dashboards and monitoring indicators.
Self-explanatory power – presentation of an updated view of current state of city and all data/ information related to approved land use changes and building permits; showing an updated image of the virtual city that is being built which should be available to all the community; including clear explanations and justification of planning options using ICT concerning urban design, urban structure and regulations.
Reasoning – allowing collective thinking which may include graphical representations and mathematical formulations, capabilities of urban modelling (and some sort of artificial intelligence) in order to anticipate impacts from private actions or from public decision making and warning systems, namely those alerts concerning performance of plans and their objectives/ targets.

Vision and *Interaction* are in line with the two main performance strategies to increase the success of plans, following the main functions that plans should fulfill (Needham et al, 1997): the "vision model" where the attractiveness of the design is crucial but have to be perceived visually in all its multiple dimensions; the "consultation model" – a two-way participated process of plan-making. Visioning the virtual city being built or the planned city and scenarios are crucial to formulate and validate urban policies (Ramos, 2010). *Interaction* is a means to allow public participation in plan making and plan implementation. *Memory*, like in humans, is considered essential to build a sense of collective intelligence. The *self-explanatory power* is here assimilated to human language and can be explored in different ways by an IP. The *reasoning* ability pushes the IP to include models and artificial intelligence tools allowing some automation capabilities to support governance and interaction.

4. Conclusions

In Portugal every 308 municipalities have a master plan (Plano Director Municipal-PDM) for their territory and some cities have a land use plan (Plano de Urbanização). A high percentage of them (Santos et al, 2012) use GIS and the presence of the

municipality on the Web is widely observed. E-government had an increased development in Portugal at central and local levels which is internationally recognized - Portugal ranks first in the European tables for the sophistication and availability of its online public services (EC, 2010).
In general, local plans are still produced in paper format but many municipalities offer dematerialized versions in common digital formats (pdf, jpg). The General Directorate of Planning, responsible for the registration of all formal plans in Portugal, has moved to dematerialization and made available all plans in digital versions through SNIT (National System of Territorial Information, www.dgotdu.pt), which was a strong enhancement to the planning system.

Possible evolutionary steps could be, as proposed, to move from simple dematerialization to a plan format implemented as a technological platform, a true e-planning service with tools in front-office available to community and tools in back-office available to local authorities and planning departments. Therefore, the plan would become: interactive; acquiring and storing data from many sources, integrated with municipal planning systems; with memory concerning the succession of plans; embedded with monitoring indicators that would enable its multi-level ongoing evaluation; serving as a platform of collective communication tool for discussion of "collective hopes" and creation of visions for alternative scenarios and future development; displaying visualizations of the virtual city being planned and built and of the trends of the evolving city and its future configuration; enabling cooperative mechanisms regarding the process of finding and developing solutions; having tools to promote an organized participation process among citizens, public and private organizations; a plan that would promote high levels of transparency, advising and alerting.

An improved digital ICT has strong challenges to urban planning and plans: information asymmetry between citizens and administrations, access of the population to the web, different digital skills and economic and educational levels among the population. The more dynamic nature of such IP may present difficulties to its juridical side where the stability of plan regulations is considered important for the confidence of economic agents. Even the issue of transparency has its limits concerning some aspects of negotiation involved in the planning process. But other challenges related to this transfer from the traditional paper format to the web will have clear positive impacts on collective intelligence and on the planning culture of the city, as many other aspects of the information and knowledge society had in the last two decades.

THE MEANING OF BIOMASS IN LANDSCAPE MANAGEMENT AND ENERGY PLANNING: UNDERUTILISED OR OVERESTIMATED?

dr. ir. Janneke E. Hagens[1], prof. dr. ir. A.J.M. Smits[1]

Abstract

A team with representatives of private and public sectors deals with the spatial organisation of Dutch river region WaalWeelde. They care about landscape management of the river flood plains, which takes in maintenance of nature areas and water safety measures. The team calls for improvement of landscape management, due to financial cuts and inefficient practice. The concept of ecosystem services is considered as a promising concept for changing landscape practice. Biomass resulting from landscape management can be considered as one of these prospective benefits. Whereas nowadays practitioners handle organic material mainly as a cost, in future it can be handled as, for example, a renewable energy resource. Notwithstanding this promising outline, some people are cynical about the feasibility of using biomass. What is the meaning of biomass, as ecosystem service, to improve landscape management in the WaalWeelde case? In this paper, we consider biomass as a 'matter of concern' (after Latour). Biomass is a physical 'matter' that can be valued from diverse perspectives, for example, in energy potential. Moreover, the meaning of biomass in practice depends on the 'concerns' of organisations involved in landscape management: their drives, instruments, rules and boundaries define to what extent biomass can really matter. A literature review shows that the value of biomass 'matters' in the WaalWeelde case is relatively limited but can increase. For example, harvest can expand by more active management, which also increase other spatial qualities. Moreover, cooperation is useful to bundle both biomass and ambitions. Spatial planners can play a key role in organising this cooperation. Then, an impression of actual 'concerns' of key landscape managers in WaalWeelde shows a vital challenge for spatial planners. Namely, hegemonic practice, rigid legislation and prevailing habits hinder change in the field, notwithstanding sustainable initiatives around biomass and willingness to cooperate.

1. Introduction

"Because the Waal belongs to us all!"[2]

Various private and public organisations are involved in the spatial organisation of river Waal surrounding in the Netherlands. River Waal is an important transport river of the Netherlands, part of the extensive Rhine Delta in Western Europe. In addition

[1] Faculty of Science, Department for Sustainable Management of Resources (DSMR), Institute of Science and Society (ISIS), Radboud University Nijmegen, the Netherlands, j.hagens@science.ru.nl

[2] Vision WaalWeelde (Project WaalWeelde 2010, p.2)

to their individual spatial practices, organisations cooperate under a program called WaalWeelde, directed by the province of Gelderland (www.waalweelde.nl). 'Waal' refers to an 80 kilometres long Waal section, from the German border to the castle of Loevestein in the middle of the country, part of the province of Gelderland. 'Weelde' means richness, referring to shipping, nature, rural functions and an attractive environment for housing and business. These various spatial functions need to be preserved, utilised and managed (Project WaalWeelde, 2010) but have diverse physical and social dynamics and are organised by different owners or institutions, each having specific practices and standards.

Landscape management: financial cuts and fragmentation

Whereas many teams under the WaalWeelde program are concerned with spatial visions and implementation of projects in view of *realising* spatial quality, one team is concerned with management in view of *continuing* spatial quality. This team is 'taskforce river flood plain management', concerned with maintenance and exploitation of WaalWeelde's flood plains. Management in WaalWeelde is based on water safety, transport standards (e.g. line-of sights), ecological norms (e.g. Natura 2000), as well as agricultural practice and recreational needs. In this paper we focus on land-based management (i.e landscape management), with special focus on vegetation management.

In general, landscape management in rural landscapes is crucial for sustaining natural and cultural values (Naveh, 1994). Surprisingly, landscape management is mostly neglected in Dutch comprehensive and communicative spatial planning approaches ('hidden responsibilities', Beunen & Hagens, 2010), though most space is subjected to management rather than to new development. Moreover, Dutch national government (i.e. 'Rutte cabinet' 2010) made large financial cuts in nature policy, including landscape management; meanwhile, decentralisation of nature and spatial policy from ministries to provincial authorities started, which still causes an unsure situation about tasks and possibilities. Furthermore, landscape management of Dutch river areas needs to be improved due to inefficient practice (Bureau Stroming, 2011). Landscape management in river flood plains is hindered by fragmentation of property and responsibility[3]. This 'practical' fragmentation comes together with discursive and institutional fragmentation. Namely, stakeholders have various viewpoints on the function or functions of Dutch river floodplains (Jacobs & Buijs, 2011; Fliervoet, 2012). Likewise, river flood plain management in the Netherlands has been dominated by a battle between technocratic (i.e. safety and agriculture) and ecological (i.e. 'dynamic' nature) approaches (Van der Brugge et al., 2005), notwithstanding spatial concepts intended to integrate various functions and implemented in practices ('Plan Stork' by Van Nieuwenhuijze et al., 1986; 'Cyclic

[3] For example, Rijkswaterstaat (i.e. the executive arm of the Dutch Ministry of Infrastructure and the Environment) is a key organisation in river floodplains. Its task concerning landscape management is manifold: DG water management is, overall, owner of the river shores (i.e. summer bed to river groins); contracting authority for water and vegetation management of the river shores; sometimes owner of other parts of the river floodplains, which are mostly put out to lease; temporarily owner of project areas, which are transferred to managers after completion; always responsible for permits concerning vegetation management, based on water safety and shipping rules, in the flood plains (interview RWS, 2012).

Floodplain Rejuvenation', Baptist et al., 2004). The challenges of finances and fragmentation also apply to landscape management in WaalWeelde's floodplains. Stakeholders and experts tackled these challenges during a two-day conference in June 2011. The conference was the start of 'taskforce river flood plain management' and resulted in three innovative scenario's for future landscape management for WaalWeelde's floodplains.

The potential of ecosystem service biomass
An important direction in each WaalWeelde scenario for future management, developed during the June 2011 conference, is to make better use of the socio-physical values of the river region. In other words, people concerned with management of WaalWeelde are encouraged 'to cash' material and cultural ecosystem services (cf. Melman et al., 2010), like sand for infrastructural works or an attractive environment for recreation. In addition, regions are forced to become less dependent on standard 'central' resources and find place-related 'decentral' resources (Pinto Correia et al., 2009). During the conference, scenario-makers mention residual biomass resulting from landscape management, wood and grass, as a promising 'new' ecosystem service. Namely, nowadays, Dutch practice mostly handles organic material from landscape management as a cost, whereas it can be handled as a source for renewable energy or other high-quality products. Moreover, using residual biomass from landscape management on local-regional scale can contribute to a very small but ecologically sustainable biomass supply for a national-international bio-based economy (Ros et al., 2012). However, knowledge about energy-flows in ecosystems and energy-conscious spatial planning, especially on the regional scale, is limited (Stremke & Koh, 2010).

'The tragedy' of ecosystem service biomass?
The idea of 'cashing biomass' from landscape management, instead of considering it as a cost, will overcome a 'tragedy of ecosystem services' (Lant et al., 2008). In line with the familiar 'tragedy of the commons' about over-exploitation of an environment by misplaced investments, a 'tragedy of ecosystem services' concerns under-exploitation by 'misplaced' (i.e. *non*placed) investments (ibid). Notwithstanding a promising plea to make better use of biomass in WaalWeelde by dedicated conference participants, other participants were more cynical about the feasibility of using biomass. To better understand this struggle between 'optimism and pessimism' as well as the actual situation, we study the potential of biomass for improving landscape management in the socio-political context of WaalWeelde. The main research question is: what is the meaning of biomass, as ecosystem service, to improve landscape management in the WaalWeelde case? In other words, is the potential of biomass underutilised or overestimated?

2. A realistic approach to the meaning of ecosystem service biomass

Ecosystem service contextualised: a theoretical reflection
Starting point of improving landscape management in Dutch river region WaalWeelde is, in this paper, the use of ecosystem service biomass. Starting from a

physical issue (i.e. an ecosystem service) is a sensible step in spatial planning since the future of our landscapes is a central task of planners (Perry, 2003); nevertheless, 'landscape' itself has been narrowed down in planning theory (Graham & Healey, 1999) and is overruled by theories about procedures. The key, then, is to *contextualise* ecosystem services and to understand *why* spatial planners deal, or do not deal, with specific ecosystem services (cf. Allmendinger 2002). An ecosystem service refers to "the benefits people obtain either directly or indirectly from ecosystems" (Millennium Ecosystem Assessment in Lant, et al. 2008, p.969). People only benefit if a service is made operational: recognition of its value, incorporation in policy practice and paid for (Daily et al., 2009). The possibility of 'cashing' an ecosystem service depends on individual, market and state engagement; this engagement implies clarifying and organising 'new rules' between 'buyers' and 'providers' of a service (Vatn, 2010). Such engagement and 'new rules', however, are difficult to realise.

Change, as engagement with a 'new' ecosystem service biomass in WaalWeelde to improve landscape management, is sensible in nowadays political-economic situation (section 1, this paper; cf. a 'trigger event': Kingdon, 2003). It may not only deliver financial support for landscape management but may even 'mobilise power' and create new coalitions of individual, market and state (Healey, 2006), which break through rigid spatial planning (Hajer & Zonneveld, 2000) and fragmented landscape management practice (section 1, this paper). The use of ecosystem service biomass on regional Waalweelde scale fits in a prospective energy perspective on planning (Stremke & Koh, 2010) yet needs to battle against existing hegemonic nature and safety perspectives (cf. Disco, 2002). Likewise, change depends on the flexibility of existing structures and procedures, as well as the will of existing authorities to release power if necessary (Moulaert et al., 2007; cf. 'fallacy of centrality', a lack of curiosity and ignorance of new ideas: Westrum, 1982; cf. 'self-referential' systems, in reference to Luhmann: Van Assche, 2007). In order to get a realistic picture of the meaning of ecosystem service biomass in WaalWeelde we accordingly need to investigate 'new' power and ambitions in local-regional spatial practice in relation to hegemonic planning practice.

Biomass as a 'matter of concern': an analytical framework

In this paper, in line with our theoretical reflection, we study an ecosystem service as a 'matter of concern' (after Latour, 2004). An ecosystem service is a physical 'matter' that can be valued from diverse perspectives, for example, in financial terms, energy potential or cultural significance. Moreover, the meaning of an ecosystem service in practice depends on the 'concerns' of owners, landscape managers, users and organisations involved (i.e. its system); their drives, instruments, rules and boundaries define to what extent a service can really matter. For example, organic material from landscape management was often categorised as 'waste' by legislation and needed to be dealt with accordingly (Senternovem, 2005; see www.agentschap.nl for new European Waste Legislation). And, for example, logging techniques in relation to accessibility of a site define the actual availability of biomass (Kuiper & De Lint, 2008).

For a realistic picture of the meaning of biomass in river region WaalWeelde, we study the *combination* of matters and concerns. For simplification, though, we sketch four -theoretical- possibilities, based on a combination of scores for 'matters' and 'concerns' (see table 1). Ecosystem service *matters* hover between little and high potential, taking in socio-physical values of the service. Ecosystem service *concerns* refer to the effort and input of people and related institutions to 'cash' a service (cf. Vatn, 2010), which hover between passive (i.e. ignorant, prioritising other issues) and committed (i.e. eager, capable, organising) systems.

Figure 1 The meaning of an ecosystem service in practice

The meaning of an ecosystem service in practice Hagens 2012		**'matters'** potential, including values	
		little	**high**
'concerns' efforts & input	**passive system**	A. unfeasible	B. underutilised
	committed system	C. overestimation	D. feasible

Four -theoretical- scenarios emerge:

A. *Scenario unfeasible*: the amount and value of biomass is limited and the system is reluctant to use biomass for, for example, energy-production (i.e. a dark scenario);
B. *Scenario underutilised*: the, hidden, potential of biomass is considerable but has little meaning since individual, market and government are not willing or capable of utilising its potential;
C. *Scenario overestimation:* the expectations and willingness to participate in the exploitation of biomass are high but the actual amount of biomass is of little value;
D. *Scenario feasible*: both the potential biomass and the possibility and willingness to invest in using biomass are sufficient (i.e. an ideal scenario).

With these framework, we can specify two mediocre scenario's of an ecosystem service, which are essentially different in problem and solutions, being either an 'underutilised' or an 'overestimation' scenario.

The case of biomass in WaalWeelde: research material
We investigate biomass 'matters' in the context of landscape management in WaalWeelde by literature review (Spijker et al., 2007, Kuiper & De Lint, 2008, national explorations; Stroomlijn, 2011, a study about cost-effective management in Dutch river regions). Detailed research into the availability of biomass in WaalWeelde's floodplains, in an ideal scenario, is ongoing (Caspers, 2012). We

investigate biomass 'concerns' in the context of landscape management in WaalWeelde by interviews with representatives of key organisations in landscape management, as well as additional literature.

3. The results of a 'matter of concern' analysis of the meaning of biomass in Waalweelde

Basic material: biomass 'matters'
Biomass in flood plains comes, of course, from the vegetation present. According to succession models, vegetation development on exposed bars in temperate European river areas is initiated by pioneer species, followed by willows and poplars, and potentially converting to oaks (Francis et al. 2008). In a landscape mainly dominated by river dynamics, diverse development stages can be found at the same time (Geerling et al. 2006). The vegetation nowadays present in the flood plains of the Waal river is defined by Dutch history of civil engineering, manifested in dike building and cut off of river bends, in relation to creating a safe environment and economic development. Moreover, vegetation is defined by nowadays policy decisions and approaches in landscape management (see section 1, this paper). Overall, five main categories of habitats are related to floodplains of the Waal river (Bureau Stroming, based on Schipper & Siebel (eds.), 2009). These categories take in both vegetation and management characteristics (see table 1).

Table 1 Habitat and management characteristics in WaalWeelde's floodplains (based on Schipper & Siebel (eds.), 2009 & Bureau Stroming, 2011)

Habitat category	Typical vegetation	Spatial and management characteristics
River- and wetland	grassland, wetland vegetation, alluvial wood	- Influenced by flooding - Dynamic landscape - Grazing
Wetland	grass, reed, reed grass	- Transition stage, from water to land - Dynamic water level is essential - High water quality is essential
Herbaceous and fauna-rich grassland	grass with herbs and mosses, brushwood, shrubs	- Extensive land use - Often a temporarily situation
Oat grassland	oat grasses, flowers, a diversity of herbs	- Landscape with gradients (elevations) - Rare habitat; habitat of European importance - Mowing regime; clippings is removed
Grasslands of overwintering birds	grassland	- Productive landscape - Foraging area - Nutrient rich grass land

Various issues define the amount of organic material available in WaalWeelde's floodplains for products instead of 'waste'. Firstly, the total production depends on physical issues: the area and rate of growth of vegetation present (Spijker et al., 2007; Kuiper & De Lint 2008). Consequently, harvest out of the total production is defined by some practical and strategic issues (ibid). Namely, in case of Dutch river floodplains, management is mostly defined by water safety and ecological targets

(see section 1, this paper). In general, water safety promotes harvesting, whereas ecological targets can either promote or restrict harvesting (e.g. Stroming, 2011). Moreover, in the Netherlands, harvest by sometimes remains on spot, especially in forests, due to nature conservation legislation and is, therefore, unavailable as biomass (Kuiper & De Lint 2008). Another issues that influences harvest of organic material is grazing; by grazing, vegetation is transformed into another ecosystem service as meat. That is, in the case of WaalWeelde, 'wild' horses and cows (Stroomlijn, 2011). Furthermore, accessibility of sites and harvest techniques define the amount of organic material (Kuiper & De Lint, 2008). The current harvest is not equal to the potential harvest: there is organic material that can be 'activated'. For example, in case of Dutch wood from forest and landscape elements about a quarter of potential harvest that is not yet harvest in current practice (Kuiper & De Lint, 2008). Spijker et al. (2007, p.12) estimate that in the Netherlands in total "an annual amount of 1.9 million tons dry matter biomass can be harvested in nature by 2020, based on the current management practices". In the case of WaalWeelde's floodplains, a preliminary estimation is that 'natural floodplains' can produce, in an ideal scenario, 31937 tons dry matter per year (Caspers, 2012). That will, then, be a small 2% of the national amount of biomass from nature in the Netherlands (as presented by Spijker et al. 2007).

Only part of the vegetation harvest is, in the end, suitable as biomass that can be transformed into useful products. There is a difference between the biomass-chain of wood on the one hand and grass and reed on the other hand. Stroming (2011) presents an optimal scenario for landscape management of alluvial wood (taking in 400 present hectares plus 200 future hectares of alluvial wood, of almost 9000 hectares river Waal floodplain's). In this scenario, landscape management is cost-effective, provides sustainable energy, advances biodiversity, within water safety targets (ibid). Of course, the feasibility of this scenario depends on the willingness and necessity to change of current organisations (see 'concerns' in this section, this paper), as well as market prices, market development and governmental subsidies (Spijker et al. 2007). In many Dutch studies, wood from landscape management is related to energy; these studies follow a national 'energy agenda' with reduction of greenhouse gas and promotion of sustainable energy (e.g. Spijker et al. 2007). However, part of wood can be used in a more effective way; that is, with smaller amounts, one can produce more high-quality products in, for example, the forestry industry (in line with the 'cascading principle', e.g. Kuiper & De Lint 2008).

Organic material harvested from natural reed and grassland is mostly used as cattle feed, dried, or composted (Kuiper & De Lint 2008). Experts estimate that about a third of reed and grass harvest is treated as waste. The use of grass and reed for bio-energy is very limited in the Netherlands (Spijker et al., 2007). Logistics are complex since there are only two cutting-moment per year, which requires pre-processing and storage (Kuiper & De Lint 2008). Moreover, due to the chemical composition of grass it is, until now, still difficult and expensive to convert it into bio-energy (Spijker et al., 2007).

An impression of biomass 'concerns'
The potential value of biomass 'matters' in WaalWeelde is also defined by existing 'concerns' around landscape management and biomass (section 2 & figure 1, this paper). Therefore, we explore the practices of key organisations in landscape management in WaalWeelde's region, floodplains and surrounding, taking in their habits, ambitions and structures concerning removal and use of biomass. The impression of 'concerns' is based on interviews with representatives of four key organisations: Rijkswaterstaat (i.e. the executive arm of the Dutch Ministry of Infrastructure and the Environment), Staatsbosbeheer (i.e. Dutch National Forest Service), Agricultural Nature Management Organisations of the WaalWeelde river region (organised in 'SpAN') and Waterboard Rivierenland of the WaalWeelde river region. Interviews were held in February and March 2012. The description of 'concerns' of key organisation is based on these interviews, as well as other references (mentioned in the text).

The role and position of Rijkswaterstaat in floodplain management is major but diverse (see footnote 3, this paper). For Rijkswaterstaat, water safety and shipping conditions are leading objectives in management (e.g. reducing hydraulic resistance and clearing line-of-sights, by the removal of vegetation). The actual management is, in the case of river Waal, mostly carried out by a large contractor, based on multi-annual management. On 'top level', sustainable processing of biomass is promoted though not primary. A focus on biomass is absent 'in the field'; above all, management needs to be feasible and affordable. Likewise, management decisions and activities are mostly focused on a 'short term' efficiency philosophy, rather than on a sustainable but unsure 'long term' philosophy. A shift towards sustainable management requires a huge and difficult cultural shift within Rijkswaterstaat (cf. Van den Brink 2009). Similarly, a 'financial' argument for sustainable management will make more sense than a 'green' argument. Interestingly, a small team of Rijkswaterstaat developed a 'self supporting river system' scenario for the Dutch IJssel river. Self supporting implies a low-cost form of management, by new coalitions, using ecosystem services as 'blue energy', recreation values and biomass (Hamilton-Huisman et al., 2011). The concept of 'self supporting river system' is an ambitious but unusual plan within the technical practice of Rijkswaterstaat. In the 'self supporting river system' scenario, biomass is considered a substitute for petroleum-based materials, instead of a cost (ibid). This idea, however, cannot catch up with the actual planning and implementation of urgent 'Streamline' program of Rijkswaterstaat, which is designed to realise removal of vegetation that hinders straightforward river runoff. The actual owners and managers are responsible for implementation of 'Streamline', like Staatsbosbeheer, being another key organisation in landscape management of WaalWeelde's floodplains.

Staatsbosbeheer is the Dutch National Forest Service; it is an independent administrative body, privatised but commissioned by the government (http://forestportal.efi.int). Staatsbosbeheer is manager of about 60% of the area in Dutch floodplains designated as Ecological Network (i.e. nature policy; that is about 25% of floodplains covered with vegetation, i.e. about 17% of total floodplain area in

the Netherlands). Thereby, it is considered as a major landscape manager in floodplains, together with major player Rijkswaterstaat. Staatsbosbeheer has a pragmatic or adaptive approach to its management task: notwithstanding its main focus on nature, it connects with other land use functions that are 'on the agenda' and accordingly cooperates with other players in spatial policy. In the case of WaalWeelde, recreation, nature and water safety targets are combined. With regard to processing of biomass, Staatsbosbeheer can be considered as an experienced player. Staatsbosbeheer has considered biomass as a product of its main task instead of as a waste for years. Biomass, wood and grass, has accordingly 'a positive value'. For example, wood is used in wood products as paper, as well as sold for the production of bio-energy (www.staatsbosbeheer.nl). Staatsbosbeheer has a subsidiary company, Biomassa BV and is also involved in BioEnerco BV (www.staatsbosbeheer.nl). These companies facilitate agreements between wood supplier and processors, taking in mostly Staatsbosbeheer's wood but also wood from 'third parties' to fulfil agreements. In line with legislation, Energiehout BV has restricted its transactions of wood from 'third parties' (ibid). This restriction will be supported by entrepreneurs in the Dutch wood sector (www.avih.nl); however, this restriction may complexify the possibilities of cooperation with other, smaller, biomass suppliers. An example of a small biomass supplier are farmers.

Dutch farmers involved in landscape management often cooperate in Agricultural Nature Management Organisations; in river Waal region, these organisations are in turn organised in a support centre (i.e. 'SpAN'). Farmers can deliver biomass from maintenance of landscape elements in WaalWeelde floodplains, as well as from horticulture and arable crops in WaalWeelde surrounding. The total amount of biomass, however, will be restricted in comparison to other suppliers. In WaalWeelde's farming practice, organic material is collected by contractors, against payment. In part of the river region, willow material is collected by people from the regional zoo, for free. The willingness of farmers to change this practice into a more sustainable and efficient way is limited. A practical restriction is the actual small amount of biomass. Moreover, it is difficult to compete or connect with larger biomass suppliers as they have binding agreements with other companies. A possible scenario for farmers in WaalWeelde is to focus on high-quality products, as aspirin from willows, rather than on energy production; this scenario requires innovative techniques but small amounts of biomass. Finally, the Agricultural Nature management Organisations will be inspired or assisted by innovative initiatives concerning sustainable processing of biomass by other landscape managers. An example of an innovative initiative is the 'Energy Factory' concept of Waterboards.

Dutch Waterboards are owner and/or responsible for management of a network of waterways and embankments, roadsides and dikes. In the specific case of WaalWeelde's river floodplains, Waterboard Rivierenland is responsible for management of river dikes. Normally, management is outsourced to contractors; contractors, thereby, become holder of organic material. These contractors are not yet bounded to rules about the processing of organic material; however, setting green conditions is a sensible possibility. Contractors mostly compost green material; wood

is processed as either waste or in the wood industry. Waterboard Rivierenland is not directly intended to build digesters herself; the private sector needs to take the lead, in line with Waterboard's public -therefore restricted- function. This caution to extend its function is led by risks in legislation and investments. Companies are willing to produce energy and contact Waterboard Rivierenland but most initiatives do not succeed. Nevertheless, Waterboard Rivierenland joins some regional digesting initiatives, as cooperation with farmers (e.g. providing manure as essential adding to organic material in digestion). Transport is considered as a possible breaking point of regional initiatives, trust as a requirement. Moreover, Waterboard Rivierenland investigates sustainable methods for processing its 'green flows' as an alternative to conventional methods; this exploration is rooted in a climate and energy agenda but mostly led by financial drives. Finally, in contrast to its reserved attitude towards new functions, various Waterboards have the ambition to realise sludge digesters in combination with sewage water treatment (i.e. an 'Energy Factory', an idea rooted in a challenge of the Dutch Association of Regional Water Authorities, Kiestra et al., n.d.). Accordingly, Waterboards will become energy producers (ibid). Biomass other than sludge, however, does not play a key role in the Energy Factory concept.

4. Conclusions & discussion

Limited 'matters'

WaalWeelde's biomass 'matters' take in wood, grass and reed. Preliminary results show relatively small amounts of potential biomass in WaalWeelde (Caspers, 2012). However, studies show that current harvest of biomass from nature and landscape in the Netherlands can be increased by different, more active, management (Spijker et al., 2007, Kuiper & De Lint, 2008). This is an interesting assertion in the light of WaalWeelde's spatial qualities: different management can increase biomass harvest, as well as improve landscape quality and water safety (cf. Stroming, 2011). Moreover, part of biomass harvest in the Netherlands is still treated as a waste (Spijker et al., 2007, Kuiper & De Lint, 2008). In theory, biomass is processed in an optimal way if one follows the cascading principle, striving for 'high-quality' products. In practice, 'low-quality' product bio-energy is on the Dutch policy agenda, whereas the actual market, logistics and techniques are still negative. In the end, in the light of making landscape management in WaalWeelde more efficient, it is crucial that profit is invested in landscape management and not lost 'outside'. Overall, we indicate the total value of biomass 'matters' in the case of WaalWeelde, at the moment, as *little* (figure 2). 'High potential' can be reached by improvement in logistic and energy-processing techniques. In addition, cooperation between various landscape managers within WaalWeelde's floodplains (as 'taskforce river flood plain management'), as well as on regional WaalWeelde scale (cf. Stremke & Koh, 2010) can bundle biomass value and push WaalWeelde's position in comparison to other Dutch regions. The willingness and necessity of landscape managers to cooperate depends on the 'concerns' of organisations involved.

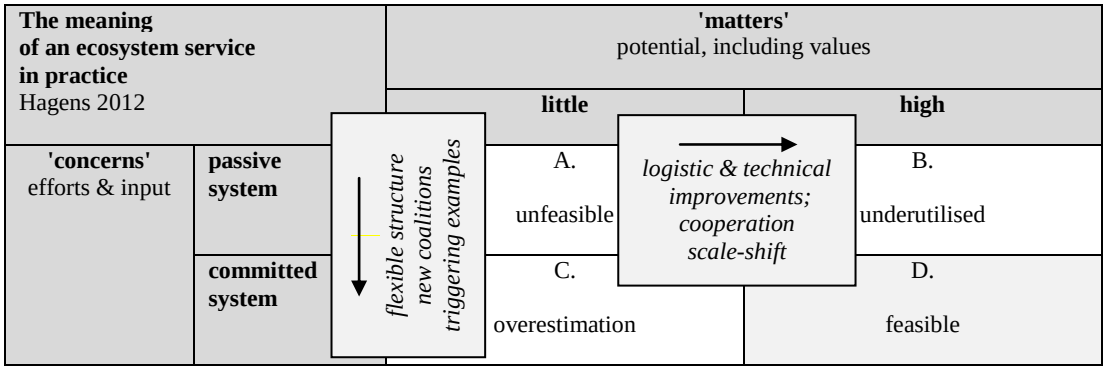
A hesitant system

Participants of WaalWeelde's river flood plain management conference were enthusiastic and had ideas about the use of biomass to improve landscape management (see section 1, this paper): they had high expectations, though some were cynical. Then, a more detailed analysis of the 'concerns' of key organisations involved in WaalWeelde's landscape management shows a more complex reality. Each organisations is willing to use biomass in a more sustainable or cost-effective way. These ambitions, however, are not easy to realise. For example, initiatives risk stranding on 'top level' (case of Rijkswaterstaat). Other ideas are often too 'small' to compete with other initiatives (case of Agricultural Nature Management Organisations & Waterboard). The willingness or necessity to cooperate is sometimes hindered by legislation or binding agreements. Likewise, change is difficult if practices have strong but inflexible structures and discourses (cf. Moulaert et al., 2007). In the case of landscape management in WaalWeelde, a 'biomass and energy' discourse is inactive and overruled by the hegemonic battle between 'nature' and 'water safety' discourses. Overall, based on the impression of 'concerns' of key landscape managers, we define a small part of the system as *committed* due to some biomass initiatives but most part of the system as *passive* due to rigid structures in practice.

Spatial planners and ecosystem service biomass

The current meaning of ecosystem service biomass is, without change, *unfeasible*. Directions towards a feasible scenario are summarised in figure 2.

Figure 2 The meaning of an ecosystem service in practice: towards a feasible scenario



In short, a feasible scenario requires cooperation between both old and new planning participants. Spatial planners can play a key role in organising this cooperation. Likewise, they are essential in realising a feasible ecosystem service. Starting point is to relate the potential of ecosystem services with nowadays planning problems. Moreover, planners need to show how existing structures can be 'opened up', without losing functional power.

Discussion
Is it right to explore, market-based, alternatives for governmental financial cuts in landscape management? Likewise, does a 'utilitarian calculus' neglect esthetical and ecological perspectives (cf. Spash, 1997), which are vital to beautiful and sustainable landscapes? Is it right to promote 'green energy' from biomass, which may not be the most sustainable solution? As spatial planners, in research and practice, it is our job to present and discuss 'unthinkable' alternatives. The meaning of ecosystem service biomass in the case of WaalWeelde's management seems limited but the exploration in fact shows vital conditions for making other ecosystem services operational in dealing with planning challenges.

Making scenarios for nature policy in the Netherlands

Ed Dammers, PBL Netherlands Environmental Assessment Agency
Arjen van Hinsberg, PBL Netherlands Environmental Assessment Agency
Janneke Vader, LEI, part of Wageningen UR
Wim Wiersinga, IMARES, part of Wageningen UR

Abstract

The *Nature Outlook 2010 - 2040* was produced by applying the scenario approach. The outlook explores some alternative directions in which nature policy may evolve in the long term and the implications of this for nature policy in the short term. The subsequent building blocks of the scenario study enable policymakers to gradually gain insight into alternative desirable future states of nature and alternative policy-strategies to realize them. This is further stimulated by the character of the scenarios, which contain not only qualitative storylines, but also concrete images and quantitative information. In order to build such scenarios various methods were applied, like model calculations, scenario workshops, and design activities. By participating in the scenario study, policymakers not only provided valuable insights but also became more receptive for the results.

1. Nature Outlook as a source of inspiration

Recently, the PBL Netherlands Environmental Assessment Agency published the *Nature Outlook 2010-2040* (2012). The main objective of this scenario study is to inspire the present political and societal discussion about nature policy in our country. After some decades of ongoing efforts for developing a national ecological network, consensus has recently eroded. Nature policy is criticized now as being too much technocratic and legalistic and too little responsive to other societal interests, like outdoor recreation and building of industrial estates or roads. There is a lot of political and societal discussion now about a new direction of nature policy. This discussion is not only fed by the budgets which are cut in response to the economic crisis. Policy objectives are also under discussion. Furthermore, the government started a deregulation and decentralization program of nature policy (Wieringa and Van Oostenbrugge 2010).

The nature outlook intends to inspire policymakers and stakeholders involved in nature policy to think not only about policy-changes in the short term, but also about policy development for the long term (PBL, 2011). This happens among other things by presenting several alternative futures of nature and alternative policies to realize them. This is relevant for nature policy for various reasons. First, it's important to

avoid policy-decisions, which may later only be corrected at high costs. An example of this is building in natural areas that are important for biodiversity. Second, some decisions must be made now in order to realize desired results in the long term. For instance, it can take a few decades before a newly developed natural area is fully grown. Natural processes can indeed be slow and policy-making and implementation may also take some decades, particularly if land must be bought for nature development. But in the long term nature policy can be questioned again and the policy impacts may be uncertain (Van Asselt et al., 2007). Desires regarding the natural environment dominating society and politics today may change again. The same is true for the context of nature policy. This is clearly illustrated by the economic crisis and the radical budget cuts for nature policy in reply to this event. It's uncertain now how the economy will evolve in the next decades and which impacts this may have on nature policy.

This paper describes how the *Nature Outlook 2010 – 2040* was produced. First, it explains why scenarios were built (section 2). After that it describes the scenario parts that were made (section 3) and the methods that were applied (section 4). The paper will also explain which choices were made and which impacts they had on the results of the outlook. Finally, some lessons are drawn from the nature outlook that might be relevant for other scenario studies (section 5).

2. Nature Outlook as a scenario study

Various methods are available to help policymakers and stakeholders to better deal with the uncertainty regarding the future, such as trend extrapolations, computer simulations and creative brainstorming (Wright and Goodwin, 1998; IKR, 2005). Figure 1 gives an overview of the main *types* of methods. The degree of uncertainty of the future course of political or societal trends about which statements are made is decisive in this respect.

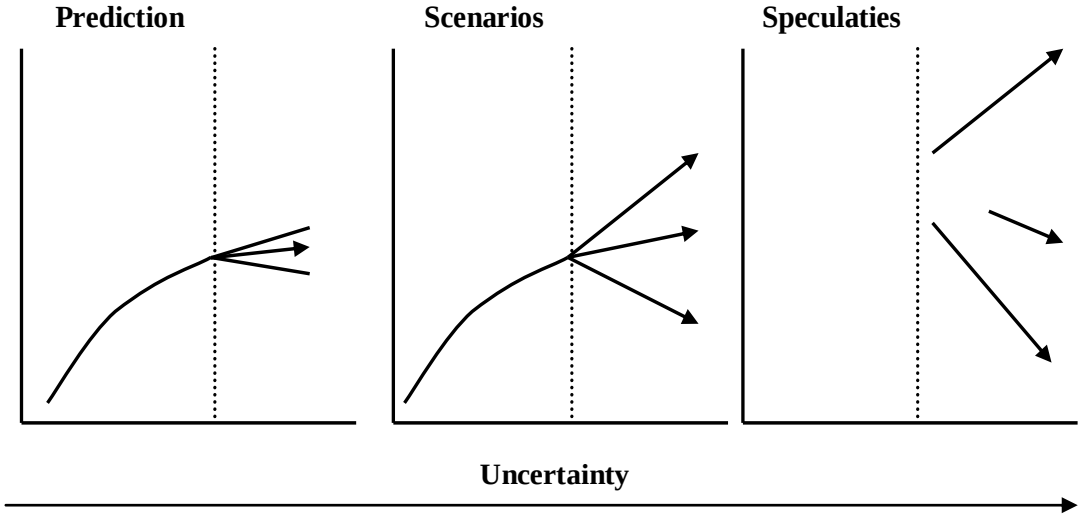

Figure 1. Prediction, scenarios, and speculations

A prediction provides a statement about a future trend, which is based on knowledge about that trend in the past and which is meant to be as accurate as possible. Since the future is always uncertain to some extent the statement is accompanied by a confidence interval, indicating an upper and a lower limit within which the trend may evolve with a specified probability. A prediction is made if the uncertainty regarding the future trend is limited. This may be the case if the trend is expected to be relatively stable or if the period which is taken into consideration is relatively short (Dammers, 2000). A statement about the expected climate change within ten years is an example of this.

Scenarios are narrative descriptions of possible or desirable futures that focus attention on causal processes and decisions (Kahn, 1965). They consist of statements about several alternative courses of future trends or other developments, based on knowledge about them in the past and the present. Scenarios are built when the future is uncertain, but not as uncertain as in cases in which speculations are made (see below). This is for instance the case if a development is known to be dynamic but not chaotic or if the period which is taken into consideration is long but not extremely long. The *Nature Outlook 2010 – 2040*, exploring alternative futures of nature and alternative policies to realize them, is an example (PBL, 2011).

Speculations provide statements about several alternative futures based on creative ideas or images about how these futures might look like. Usually, there is no link with a past or present trend or other development. Speculations are made if the uncertainty regarding future developments is large. This may be the case if the course of the development is expected to be chaotic or if the period which is taken into consideration is very long. An example of this is the possible development of the knowledge-based economy in the next 100 years.

Scenarios have an advantage over predictions because they can provide more inspiration. The reason for this is that they explore different directions in which nature policy may develop in the future, for instance in the direction of realizing several large scale natural areas or in the alternative direction of a great amount of parks and other green areas in urbanized regions. In addition, scenario's do more justice to the uncertainty regarding the long term future since they explore alternate directions in which political, societal and physical developments with an impact on nature may evolve. Scenarios have an advantage over speculations because the statements about the future they provide are more substantiated. Moreover, they offer more insight into the ways in which desired future states could be realize. As a result, scenarios provide policy recommendations that are more practical and concrete.

3. Building blocks of the Nature Outlook

Scenario-building is an eclectic activity, applying various methods like scenario workshops, essays, designing or computer models, and using various knowledge sources like expert judgments, literature review, imagination, and quantitative data. It's rather a global approach than a well-defined method (Dammers, 2010). Therefore, it is not self-evident that all building blocks of a scenario project that can be distinguished in theory are always made in practice. In the *Nature Outlook 2010-2040*, we have done this though. This scenario study consists of a scenario base, policy scenarios, context scenarios and policy messages.

The *scenario base* gives a description of the present situation of nature and nature policy in our country and how this situation has arisen from the past. The scenario base was made, because it provides a starting point to define the policy scenarios. The various images about nature that for many years now play a role in the political and societal discussion about nature policy provide a basis for the policy scenarios. In addition, the scenario base provides the possibility to compare desirable or possible futures of nature and nature policy with the present situation and thereby to indicate the required policy changes more clearly. Furthermore, the scenario base makes it easier to derive policy messages from the scenario study. For this requires not only that imaginable futures of nature and policy are taken into consideration but also the present situation.

Describing the past and present situations of nature included the identification of various policy problems. Important problems that were identified are decline in biodiversity, shortage of 'green' amenities, unsustainable use of natural resources, and hindrance of building activities by nature policy. Part of the analysis of the past and present nature policy was to make the various motives of people for being involved in nature conservation or development explicit. Important motives are the intrinsic value of nature, the esthetic quality of nature, the sustainable use of natural resources, and the utility of nature. By doing this the scenario team intended to inspire the present discussion about the direction of nature policy. A comparison of the problems and the motives provided four challenges for nature policy. These were in turn used to define four policy scenarios.

Policy scenarios describe alternative desirable futures of nature and alternative policies to realize them (figure 2 provides an overview). The challenges for nature policy, derived from the comparison of the bottlenecks and motives, were taken as a starting point. "Vital Nature" meets the challenge of improving internationally relevant biodiversity, "Recreational Nature" the challenge of improving the accessibility of natural areas and the esthetic quality of the living environment, "Functional Nature" the challenge of using natural resources, like CO_2 storage or biomass production, in a sustainable way, and "Flexible Nature" to reduce the costs related to nature development and the hindrance of other land-uses by nature. Policy scenarios are

normative since what nature an organization or group desires depends on its values (WRR, 2010). Each policy scenario describes how the challenge can be met and is also assessed on the degree to which it meets the challenges of the other policy scenarios. This makes the scenarios comparable and helps to derive policy recommendations from them.

Figure 2. Overview of policy scenarios

Context scenarios were developed in order to explore to what extent the policy scenarios can be achieved under different circumstances. These scenarios are descriptive (Becker et al., 1982). They explore in an integrated and coherent way some alternative future directions of economic, societal, physical and other trends with an impact on nature and nature policy (compare Wack, 1985). In addition, they explore how big the challenges mentioned before may become in the future, for instance, improving biodiversity in circumstances of high or low dynamics in land-use and environmental pollution. Furthermore, they explore the opportunities and threats for nature policy, for instance, in terms of the availability of public and private money.

Policy recommendations provide strategic points of interest to policymakers and stakeholders involved in nature policy. Recommendations are focused on the short term, formulated from views on the long term. Some recommendations were derived by comparing the policy scenarios with one another. On this basis, suggestions were made to combine parts of the scenarios, such as large natural areas which are made accessible for extensive recreation. Other suggestions were derived by comparing the policy scenarios with the scenario base. This makes the consequences for the current

policy clear, for instance, that there is always an important role for public organizations in nature development even if the market is highly involved.

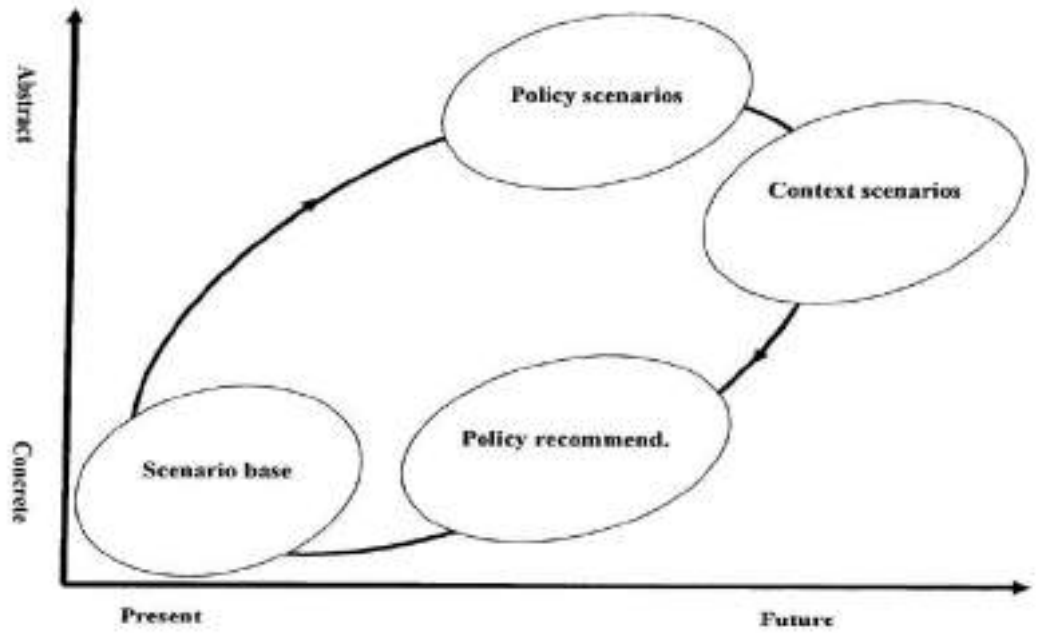

Figure 3. Building blocks are connected in a cyclical way

The building blocks just described are connected in a cyclical way (see figure 3). First, there is a cyclical movement in time. The scenario base focuses by definition on the past and the present. The policy scenarios and context scenarios explore desirable or possible developments in the long-term. And policy recommendations focus on the short term since they are formulated for current policymaking. Second, there is a cyclical movement in the measure of elaboration. The scenario base is relatively concrete since usually a lot of knowledge about the past and the present is available. The scenarios are necessarily more abstract since we know much less about the future, particularly about the long term. And policy recommendations are formulated in a more concrete way in order to provide policymakers and stakeholders strategic points of interest that are useful for them.

4. Applied methods

The building blocks can be developed in different ways using various methods. Each method has its strengths, but also its weaknesses (Dammers, 2010). Scenarios which are developed by model calculations often provide specific insights, because many variables and relations are made explicit and quantified. But the scope of these scenarios is usually limited, since variables and relations that cannot be quantified are excluded. Scenarios developed by designing are often very inspiring, because they present visionary images about the future. But the insights these scenarios provide

are often not very specific since they remain rather sketchy. Scenarios developed by workshops offer the possibility to let policymakers and stakeholders participate and thereby to mobilize a lot of practical knowledge. But the insights that workshops provide are usually less specific than those generated by model calculations since hardly any variables or relations are quantified.

Producing the nature outlook, the scenario team found it a challenge to apply the methods just mentioned in a combined way. By doing this, the team tried to exploit the strengths of the methods and to compensate their weakness as much as possible. Figure 4 provides an overview of the methods that were applied for each building block; the sections below provide an explanation.

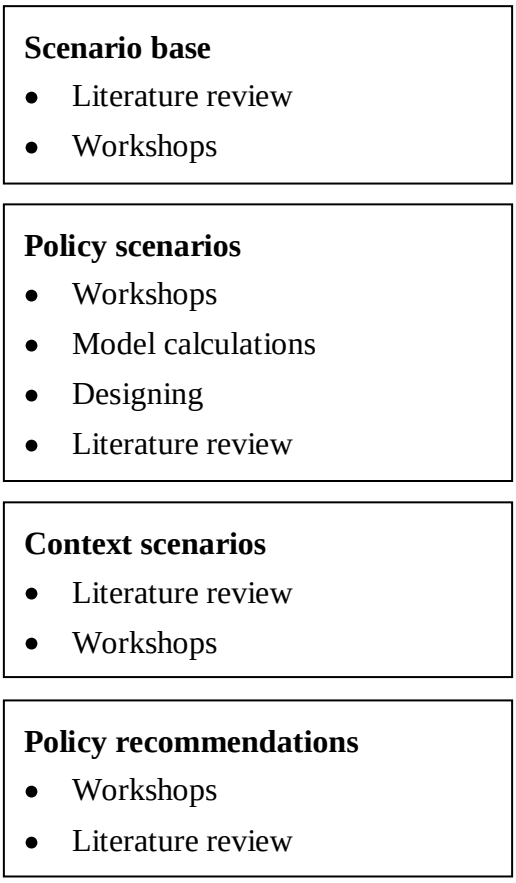

Figure 4. Methods applied for each building block

Scenario base

The scenario base was made by doing a literature review on the past and present situations of nature and nature policy. The developments, including the policy problems they generated, were mainly derived from the *Assessment of nature*, an evaluation study published every two years by PBL, and the *Assessment of the environment* (PBL, 2010), in which the assessment of nature is now integrated. In order to find the motives of organizations and groups a study was carried out into the history of their

involvement in nature conservation and development and into the changes that occurred in nature policy (Klijn, 2011).

The results of the literature review were checked by and discussed with experts on nature policy during workshops and interviews. These experts were employees of departments, provinces, municipalities, nature organizations, knowledge institutions and private companies. During the workshop the experts pointed to some aspects of nature and policy that should be taken into consideration, for instance, that natural dynamics at the local level (which is important for biodiversity) decreases and that the relationships between public organizations and citizens are important for the effectiveness of nature policy. These aspects, were included in the scenario base.

From these outcomes the scenario team derived the four challenges for nature policy. The team especially took policy problems into consideration that already exist for a long time and motives that organizations and groups already have for years. The policy challenges differ clearly from one another and therefore appeal to various organizations and groups: preserving and restoring internationally important biodiversity, making nature more accessible and perceivable, using natural resources in a sustainable way, and utilizing nature in a profitable way while reducing the hindrance for other land-uses. These challenges were presented to the participants of the above-mentioned workshops. This gave, however, no reason for adapting them.

Policy scenarios

The challenges were then used to define the policy scenarios. They became the most important building block of the nature outlook. The reason for this is that the political and societal discussion, as mentioned before, is focused on a new direction of nature policy and that the nature outlook is produced to inspire this discussion. For this building block also most methods were applied.

Four workshops were organized for making the policy scenarios: two workshops on terrestrial nature and two on maritime nature. The aforementioned experts participated in the workshops. The main criteria for their participation were: having much expertise about nature, being able to reflect on the long-term future, being able to think beyond the limits of one's own professional domain, and together represent a great variety of viewpoints on nature and policy (Dammers, 2010). The application of these criteria contributed to a rich harvest of ideas. Additional workshops were organized with experts from the Government Service for Land and Water Management (DLG), the recreation sector and building companies.

During the first workshop for terrestrial nature and for maritime nature the contours of the policy scenarios were drawn. This happened first by asking the participants to generate a large number of so-called guiding ideas about the future of nature in our country. Examples of generated ideas were "nature near home", "natural recycling",

and “interwoven nature”. Subsequently, the guiding ideas were clustered on the basis of their substantive consistency and the participants were asked to work out the ideas both in keywords and in sketches. In this way, the first rough versions of the policy scenarios were constructed.

The additional workshops with employees of DLG helped to work out the policy scenarios for various regions in the country and to make them more concrete. More than in the other workshops the focus was now oriented on policy strategies. For each policy scenario it was explored in which regions it could be realized and what measures would be required to do this. The workshops with the recreation sector and the building companies yielded additional information, e.g. about opportunities for extensive recreation in large natural areas and on the possibilities to achieve more nature in the living environments.

Interviews were conducted with experts who were underrepresented during the workshops, including experts from water boards and from the agricultural sector. These interviews also yielded new information, for instance about the fragmentation of land-use, generating high costs of water management and about the larger role that farmers could play in nature management if they were addressed as entrepreneurs instead of subsidy recipients.

The scenario team analyzed the results of the workshops and the interviews, clustered them into the four policy scenarios and elaborated them into storylines. The story lines represent the essence of the policy scenarios and integrate the many insights they contain in a meaningful way. This is important for the usability of the scenarios, since storylines are often easier understood and remembered than equations and graphs (Schwartz, 1991). Each storyline responds to a challenge that was defined in the scenario base.

During the elaboration of the story lines two criteria were applied: maximum consistency within the policy scenarios and maximum contrast between them (Van der Heijden, 1996). This contributed to the plausibility of the storylines and their imaginativeness. During the workshops also the names of the policy scenarios were defined: “Vital Nature”, “Recreational Nature”, “Functional Nature”, and “Flexible Nature”.

In the second workshops for terrestrial and maritime nature the results of the analyses and the elaborations were presented to the participants and discussed with them. The experts did various suggestions, for instance, to pay more attention to cultural history and to gradients from salt to fresh water. These suggestions were integrated in the further development of the policy scenarios.

Initially, the policy scenarios only had a qualitative character. Model calculations were done in order to quantify them. For each challenge it was calculated which solutions were possible. In addition, models and data were used to make the first sketches of the scenarios more concrete and realistic. For "Vital Nature" the Meta Nature Planner was used to calculate which environmental conditions had to be improved for creating favourable conservation status of species and habitats (Reijnen et al., 2007). Habitat suitability maps, based on soil conditions and current land-use, were used to determine where the relevant types of nature should be realized to improve biodiversity. For "Recreational Nature" the Hotspots Monitor (Sijtsma et al., in press) was used to calculate what existing nature should be preserved to maintain the experience quality and accessibility of nature. Experience GIS was also used to identify the locations where landscape should be improved. And AVANAR (De Vries and Goossen 2002) was used to calculate where deficits of hiking and cycling trails occur and extra recreational area is needed. Hiking and cycling are the most popular activities of outdoor recreation in the Netherlands. For "Functional Nature" various ecosystem models were used to determine, for instance, in which locations what type of nature is optimal for capturing CO_2 or for countering water floods. And for "Flexible Nature" the RuimteScanner (Hilferink and Rietveld 1999) was used to calculate where nature will disappear if other land-uses become more dominant.

Model calculations were not only done to make maps of the policy scenarios, but also to assess them. The Meta Nature Planner was used to assess the effects of all policy scenarios on biodiversity. AVANAR was applied to indicate which part of the future population in 2040 would be confronted with deficits of walking and cycling trails in their living environment. Information from the Hotspots Monitor was used to explore the experience quality of the policy scenarios. The LEI Cost-Effectiveness Instruments (De Koeijer e.a. 2006) were used to calculate the economic costs and benefits of nature development and management.

For maritime nature no model calculations were done, because suitable models were missing. There were, for instance, no allocation models to calculate the most optimal locations for functions, such as aquaculture, wind energy, and sand extraction. And the use of models for the assessment of the policy scenarios on biodiversity was limited by the large spatial variation and temporal dynamics of ecosystems in the sea and the lack of understanding of the sensitivities of the ecosystems and the dose-effect relations. Therefore, the elaboration of maritime nature in the scenarios relied on expert judgement and simple techniques, such as a comparing a map indicating future uses of the sea with a map indicating the locations of ecosystems.

Design activities played a role in making maps for the policy scenarios. These activities were closely interwoven with the model calculations. On the one hand, the sketches made during the workshops were the basis for the maps that were calculated. On the other hand, the results of the model calculations were modified into simplified maps. For terrestrial nature the detailed model calculations were simplified

via GIS analyses. In this way the scenario team tried to prevent users from interpreting the policy scenarios as blueprints (Van Hinsberg et al., 2011). The simplified maps express the essence of the scenarios by indicating in a rough way what types of nature can occur on which locations. The simplification also made it possible to integrate the maps of terrestrial nature with those of maritime nature. These maps were immediately displayed in global way since no model calculations were done for them. Drawings, sketches, and photographs were used make the scenarios more imaginative.

The policy scenarios were further elaborated by literature review. This was especially true for those parts of the scenarios that could not be calculated since data on the national level were missing, such as the locations of parks and green working environments. With this information the storylines were further improved. The policy strategies for terrestrial and maritime nature were also further elaborated by literature review (Bolman and Goldsborough, 2011; Verburg et al., 2011). Research publications, scenario studies, policy documents and other literature was used to gain knowledge of important aspects of policy strategies, such as coalition formation, strategy development, policy measures, financing, et cetera.

On the basis of literature and through logical reasoning, the scenario team constructed a specific strategy for each policy scenario. Each strategy can be considered an example of how a desired future regarding nature could be realized. “Recreational Nature”, for instance, could be realized by provinces taking the lead in regional policy networks, by putting co-designing into practice, by combining public and private financing in regional funds, et cetera. And “Functional Nature” could be implemented by public and private organizations and research institutes cooperating in innovation networks, by providing freedom to experiment with new ecosystem services, by establishing regional business enterprises et cetera. During the construction of the strategies principles of the welfare theory were applied, e.g. principles regarding public goods, external effects, market forces, and coordination issues (Stiglitz, 1988; Kuiper and Evers, 2011). The results of these activities were also discussed with experts during the workshops. Suggestions made by the experts, for instance, to pay more attention to new coalitions for nature development and to new arrangements to finance nature development were helpful to further elaborate the strategies.

Context scenarios

The context scenarios were developed by doing literature review and organizing workshops. The scenarios were based on the existing scenario study *Prosperity, welfare, and quality of the living environment* (CPB et al., 2006). This study contains four context scenarios: “Global Economy”, “Transatlantic Market”, “Strong Europe” and “Regional Communities”. Only the first and the last mentioned scenario are include in the nature outlook, because they explore more or less the highest and the lowest dynamics in demography, economy, and other trends in the coming decades. As a result they roughly represent the largest and the smallest pressure on nature in terms of environmental pollution and land-use. Because of that, they suffice to ex-

plore the possibilities and limitations for realizing the policy scenarios under different circumstances. Moreover, to inspire the political and societal discussion about nature policy it's important not to make the scenario study more complicated than necessary. Furthermore, the policy scenarios and not the context scenarios are the most important building block of the nature outlook.

From both scenarios only trends with an impact on nature and nature policy were selected to be included in the nature outlook, such as economic growth, food production, and energy supply. For some trends the scenarios had to be updated, since they were no longer plausible in the light of present knowledge. Because of the expected food crisis in the world, for instance, agriculture can no longer be expected to be subordinate to other forms of land-use in each scenario (Stegeman et al., 2011). In addition, sustainable energy policy is more ambitious now than expected in the scenarios. The reason for this is that only measures that the Government had officially decided on at the time of publication were included in *Prosperity, welfare, and quality of the living environment*. Two trends were added in the nature outlook which have an impact on nature and nature policy but receive little attention in the former scenario study: the changing attitudes of people towards nature and the changing institutional setting, i.e. the relations among public organizations and between public and private organizations, including the EU. These trends were explored by literature review and by expert judgement. Because of these amendments the scenarios were renamed into High and Low scenario.

The scenario team summarized the results and presented and discussed them with the experts. This happened during the second workshops for terrestrial and maritime nature. The experts stressed, for instance, that a distinction should be made between people's attitude towards nature and their attitude towards nature policy. They also informed the team there that several studies on future oil and gas exploration at sea were available. These reactions were particularly important for exploring trends with an impact on maritime nature since these trends are not included in *Prosperity, welfare, and quality of the living environment*.

The context scenarios were used to explore to what extend the policy scenarios could be realized and what resources and efforts would be required for that. The available budgets of the national government for nature policy in the context scenarios, for instance, were compared with the costs related to the realization of the policy scenarios. This provided information about the recourses that should be generated by other public organizations, nature organizations, business, et cetera. In one case, the context scenarios provided input for the model calculations that were done to elaborate a policy scenario. In "Flexible Nature" the land-use demanded for building houses and offices in green environments was derived from the context scenarios (Van Hinsberg et al., 2011).

Policy recommendations

The policy messages were based on the workshops and literature review. Three workshops were organized in which participants could derive ideas for policy messages from the scenarios or come up with their own ideas. In two workshops ideas about parts of the policy scenarios that can or can't be combined were generated. The combination of "Vitale Nature", "Functional Nature", and "Recreational Nature" in the coastal zone may improve biodiversity, recreation and water safety. But agriculture in a peat meadow area can't be combined with CO_2 capture since the latter requires a much higher water level. In the third workshop the participants could generate ideas about themes for the policy recommendations. Examples were "nature in the heart of the economy" and "diversity of nature types caused by diversity in urbanization".

The scenario team selected and checked the ideas that were generated during the workshops. A criterion for selection was that the ideas should focus on themes that were also explored in the policy scenarios. But this didn't withhold the team from adding themes to the scenarios that were mentioned in the workshops. An example of this were ideas about the added value of financial arrangements, like regional funds, over separate financial flows. The ideas were checked for their relevance for nature policy by comparing them with the results of the literature review and by expert judgement.

5. Lessons for other scenario studies

This paper described the way in which the *Nature Outlook 2010 – 2040* was produced, the choices that were made during the production, and the impacts of the choices on the results of the outlook. In this final section we draw some lessons from the scenario study that might be relevant for other scenario studies. The policy scenarios were defined by taking nature images that already play a role for years in the political and societal discussions as a starting point. The advantage if this was that truly different policy directions could be explored and that various organizations and groups involved in nature policy can easily identify with them, as was apparent from the workshops.

The nature outlook includes all building blocks that can be distinguished in a scenario study. Therefore, it provides policymakers and stakeholders using the scenario study the opportunity to explore the alternative policy directions as well as their implications for current nature policy step by step and thereby to learn from them.

Various methods were applied to produce the building blocks: workshops, literature review, designing, and model calculations. Because of that, the scenarios contain not only qualitative storylines, but also visualized images of the future and, where possible, quantifications. Besides, more knowledge resources were mobilized than had been possible if only an individual method was applied.

Policymakers and stakeholders were actively involved in the production of the building blocks. This enhanced their receptivity for the scenarios, as contacts with them indicate. The reason for this is that they consider the scenarios not as being produced by other people but as produced (among other people) by themselves.

There are also lessons that can be drawn from some suggestions to improve the nature outlook. In the context scenarios trends in food production and energy supply were updated by expert judgement. Updating these trends by model calculations would make it possible to quantify them and would thereby be helpful to better test the policy scenarios in different circumstances, defined by the context scenarios.

Besides, more attention could have been paid to the design activities. It would be easier for policymakers and stakeholders to imagine the policy scenarios if they were more visualized by showing more concrete situations of how nature might look like (e.g. by making sketches or manipulated photographs), by providing more symbolic representations of land-use by nature, and by showing the differences with the present situation more explicitly.

Furthermore, the methodology for deriving policy recommendations from the policy scenarios could be further elaborated. This was more or less done in an ad hoc way. Doing this in a more systematic way could be helpful not only for the scenario team but also for the policymakers and stakeholders who want to derive more recommendations from the scenarios by themselves.

RIVER AGREEMENTS: A STRATEGY FOR DE-GROWTH? COLLABORATIVE WATERSHED MANAGEMENT TOWARD RENEWED ECOLOGICAL RELATIONSHIPS.

Giusy Pappalardo[1]

Abstract

Contemporary strategies and practices for environmental management are not always able to improve healthy ecosystems. Pollution, landscape degradation and resources' crisis are crucial issues not only for scientific community; they are also common topics among laymen and activists involved in various associations. After the Rio Declaration on Environment and Development in 1992, for almost 15 years Sustainable Development paradigm seemed to be a suitable path to regeneration of local contexts taking into account global challenges. Then, some questions arose about the concept of Sustainable Development itself, about its outcomes and real effects on ecological matters, thinking ecology as a complex system of exchanges among humans organizations and their environment of life (Bateson, 1972).
Sustainable De-Growth is coming up as a possible alternative, with a variety of theories, hypothesis and discourses about it, inspired by groundbreaking thinkers like Georgescu-Roegen, Gorz, Illich, and Latouche (Martínez-Alier et alii, 2010). Beyond scholar debates, some people are starting to change their vision, expectations, and behavior, participating in "De-Growth inspired" movements in different parts around the world. The First International Conference on Economic De-Growth, held in Paris on April 2008, was a milestone about the topic: in its Final Declaration, it is underlined the needs for transition toward renewed ecological relationships, whose core can be synthesized through what Latouche calls "the eight R program": re-evaluate; re-contextualize; remodel; relocate; redistribute; reduce; reuse; recycle (Latouche 2007). Innovative strategies are required to accomplish this transition, starting from spontaneous movements already existent, but also interesting and involving people who are not inside De-Growth discourses, and above all, affecting institutional structures and decision-making processes.
Assuming that watershed management is a central issue for humans organizations and their environment of life, watershed policies and programs can be an opportunity to verify how De-Growth can be translated in practical experiences. A shift of paradigm is required: from a technocratic approach, to the active involvement of laymen, with their peculiar knowledge and their proposals about everyday life (Gorz,

[1] Giusy Pappalardo, PhD student, Regional and Urban Planning - Architecture Department, University of Catania - Via Santa Sofia, 64 - Città Universitaria - 95123 Catania . Tel (+39) 3479461112
Fax (+39) 095 330309 - giusypappalardo83@gmail.com

1975). In Italy, there is a school of avant-garde scholars that is experiencing watershed management through participatory processes and collaboration among associations and institutions: these processes are called River Agreements (Pizziolo&Micarelli, 2011).
This paper discusses if a River Agreement can be a De-Growth strategy, and how; it presents a body of literature to identify which families of practices can be considered "De-Growth River Agreements", and why. The paper is also a working tool to reflect about an ongoing Participatory Action Research project in the widest watershed in Sicily, the Simeto River process, led by a partnership between the University of Catania, Department of Architecture, and a network of grassroots associations (Saija, 2011).

1. Introduction

"[…] The creature that wins against its environment destroys itself. […]"
Gregory Bateson (1972), Steps towards an Ecology of Mind.

The last part of Bateson's milestone is named after *Crisis in the Ecology of Mind* (Bateson, 1972). According to the author, ecology is a matter of complex relationships among human beings, communities, and their places of life. The crisis regards these relationships, and it is related to the concept of hubris, i.e. the extreme feeling of powerful that lets humans act as dominant beings, when they have a strong faith in their technological capacity in order to control other humans, other living beings and nature. In the section called *The Roots of Ecological Crisis*, a bill is reported. The bill was presented in 1970 to face Hawaii's environmental problems related to DDT's use; it describes how unaware human actions are able to affect ecosystems hardly, leading to the annihilation of the species if human arrogance is not stopped. To escape the crisis, the bill asked for institutional commitment in changing, involving all the community's members in a deep debate about their common future. This is just an example of a lot of documents, essays, research, that came out during the 1970s; they all were worried about the destiny of Earth and its ecosystems, trying to deal with possible solutions. That decade was the starting point of a debate that lasts nowadays: even if some conditions have changed (like the DDT's issues), the ongoing global crisis is still related to environmental degradation, persisting inequity between northern and southern countries, plus the recent trouble of economic recession and financial bubbles.
Bateson pointed out that a crisis can be an opportunity to re-think relationships inside communities, and to re-adapt them in a co-evolutionary and regenerative sense. Even Rifkin (1980) underlines the necessity of new organizational structures for societies that have to face their lack of resources; he describes the history of mankind as a sequence of entropic watershed, critical moments when communities have to re-think their institutional structures if they want to survive.
The 1970s were also the decade when Sustainable Development came out: the Club of Rome's *Limits to Growth* (1972), highlighted the need of a regulatory framework in consuming resources that were about to be exhausted in the short-medium run, according to its previsions. It opened the way for different policies and strategies in

order to allow development inside some limits defined by carry-on capacity indicators. In the meanwhile, ten years before Rifkin, Georgescu-Roegen had already introduced the concept of entropy inside debates on resources' management. *The Entropy Law and the Economic Process* (Georgescu-Roegen, 1971) underlined the necessity to change direction in the mainstream economic schemes of maximizing production-consumption, as this mechanism cannot last forever in a finite world that is regulated by the second principle of thermodynamics. Georgescu-Roegen's positions were more radical than the Club of Rome's ones, asking for a deep change of direction that was identified with the label of De-Growth. Even if Georgescu-Roegen and the Club of Rome had some contacts points (Levallois, 2010), Sustainable Development and De-Growth followed two different paths: the first one was recognized as the feasible one in the dominant culture, through a system of technological solutions and incentives, while the second one remained just a marginal hypothesis of changing economics organization.

Beyond the controversy about these two approaches (Kallis, 2011), and the disputes about GDP/GNP as proper indicators for well-being (van den Bergh, 2010), Sustainable De-Growth discourses are coming up again, at a scholar level, as well as at a grassroots level, with international conferences (Paris 2008; Barcelona 2010; Montreal 2012; Venice forthcoming), and international networks among people who are trying to explore and experience practices to overcome the crisis line. It is too general talking without entering a specific context, with its preconditions and characteristics, but it sounds reasonable to say that societies are still stuck on the line of an entropic watershed, at the global and at the local scale; so De-Growth movements are questioning how to reorganize life-styles around the idea that human beings cannot deplete resources more and more.

In this framework, urban and regional planners have the responsibility of rethinking the use of territories as an opportunity to regenerate communities. Following this perspective, rivers' ecosystems may be a test-bed to understand how to move practically toward renewed ecological relationships inside communities, and between communities and the environment. The choice of focusing on watersheds is related to the importance that water resources have for human life, culture, rural economies, and to regenerate healthy landscapes; the Bioregional Movement (Aberlay, 1993) had already identified rivers as the vital circulatory system of Earth; furthermore, in the last years, international governmental and non-governmental organizations are increasing the attention on water, asking for an equitable and sustainable use of it.

2. Planning to Sustainable De-Growth? Some lessons from the current debate.

A recent article (Limburg et alii., 2011) on *Fisheries*, the Journal of American Fisheries Society, reports the necessity in stopping the depletion of water's ecosystems in order to protect the growing number of threatened or endangered aquatic species. Authors well explain the relationship between economic growth and the progressive decline for fishes and fisheries in the world, entering the debate about limiting the levels of growth. Authors ask for a "framework to assist society at large in re-directing lifestyles and satisfaction away from a consumptive perspective

toward a sustainable perspective". In this hypothesis, it is central the role of laymen and NGOs, as well as institutions, in order to work on the cultural improving of behaviors, paying attention to social justice, corporate responsibility and ethics. Coming back at the 1970s, even Gorz (1975) had already underlined the necessity to approach ecology through practices deeply connected with people's living and behaviors, rather than a technocratic way to eco-compatibility.
Furthermore, Kallis (2011) well focuses the importance of changing the collective vision toward less-consuming lifestyles; Jackson (2011) highlights the necessity of a cooperative approach, instead than a competitive one; Daly (1995; 2005), in his ecological economics perspective, underlines how stopping growth does not mean stopping development, rather it is necessary a qualitative improvement of the economic process toward efficiency, justice and sustainability. In general, there are different ways to embrace Sustainable De-Growth discourse, and Martinez-Alier et alii (2010) well trace the current articulation of the debate.
Besides different positions and labels, it is possible to point out some elements as raw indications to trace a planning approach, in order to overcome the limits that have characterized a failure in facing ecological crisis since the 1970s.
According to Gorz, the first step moves from the local knowledge, i.e. the system of values, memories, skills, hopes that people have about environment: if sustainability has to be an effective path, it is important to involve laymen (with their direct experience of their life places) in debates, working actively to improve everyday life-style and common imaginaries.
This fact leads to the necessity of collaborative practices among different members of a community, like laymen (and their different kinds of associations), researchers, experts, practitioners, administrators, and so on. Institutions like schools, universities, municipalities, public agencies, and environmental boards, play an important role to trigger and to speed up a democratic and constructive dialogue to reframe environmental management day by day, at a local scale, as well at a broader one.
The current debate also reminds that equity and quality of life are indefeasible characteristics toward the path of sustainability: it does not matter if GDP/GNP increase or not, or if other indicators for well-being are more precise, but it does matter if all the members of a community, and among different communities, develop their life-conditions, using resources in a responsible way; of course, differences between rich and poor contexts (in terms of personal income thresholds) have to be taken into account in a global justice perspective.
Lastly, Latouche (2007), with the "eight R program" (re-evaluate, re-contextualize, remodel, relocate, redistribute, reduce, reuse, recycle), inspires another important R: re-thinking urban and regional planning paradigms, policies, strategies, and tools, in order to renew ecological relationships.

3. How to re-think planning? Rivers Agreements as an opportunity for Sustainable De-Growth.

The paper's research question deals with the possibility of applying Sustainable De-Growth discourses (as they have been traced in the last paragraph) in practical

experiences related to an aware use of rivers' ecosystems in a specific context. In Italy, these experiences are defined as River Agreements, i.e. collaborative strategies among laymen, NGOs, experts, researchers, institutions, in order to start a community approach for watershed management. They come out after some European Conventions and Directives, like the *European Landscape Convention* (Florence 2000), the *EC Water Framework Directive* (2000/60/EC), and the *Strategic Environmental Assessment* (2001/42/EC), whose core is the active involvement of citizens in public processes, in order to define which plans and projects are really able to revitalize landscape, according to inhabitants' visions and needs.

An example of a River Agreement is the Panaro River Landscape Contract, Modena-Italy: it is an open and evolutionary path that is built day by day thanks to the input of different actors (inhabitants, associations, researchers, administrators, and so on), leading to complex and articulated systems of proactive actions, organized in a structure labeled as a 'beehive'; this name underlines the relational character of all the actions (it is well known that everything is related to each other in ecosystems), and also the fact that every participant is asked to be active and to collaborate with others. The river is the central core of the Contract: it means not only working on projects for water quality, but also realizing a system of sustainable projects to enjoy the landscapes, to promote wholesome rural productions, to host visitors interested in the local cultures through a fair touristic network, and so on. It is a way to sustain a slow use of territories, to improve the quality of relationships among its users, and to enhance the 'genius loci', i.e. the soul and peculiarities of the context (Norberg-Schulz, 1979; Pizziolo & Micarelli, 2011). This example suggests some key elements: the participatory process, as a way to define what inhabitants really want to do with their places of life, takes advantage from supportive institutions, in order to realize concretely inhabitants' willingness; the active role of each participant means not to delegate, but to work concretely for a specific action; every small action, as a part of the complex 'beehive', takes actually benefits thanks to the fact of being part of the system.

Focusing on the participatory approach, research shows the importance of stakeholders' involvement in watershed management issues: through a variety of case-studies, the work of the Nobel Prize in Economics Elinor Ostrom, *Governing the Commons* (1990), proves that a collective action may be able to change institutional structures in order to reorganize common goods' management, like rivers or forests. When there are some litigations related to a lack of resources or problems into the management system, partnerships can be an effective way to reframe and to improve the organization, but they have to be established under some important conditions, like inclusiveness and a deliberative character of the democratic process (Fisher, 2000; Leach, 2006). Other scholars (Mirghani & Savenije, 1995; Dube & Swatuk, 2002; Lennox et alii., 2011) have demonstrated the overall importance of stakeholders' involvement through widespread participatory practices in order to better distribute water benefits. It is not just a matter of water: all the connected activities take benefit from a genuine community-based watershed management. For example, agriculture moves toward a better quality production if it is located in a healthy watershed; of course it is necessary to pay attention to the

nutrient load that goes into the water courses: Amate & de Molina (2000) show how an organic and local farming system can avoid this problem, and become a key element for sustainability.

In synthesis, it is possible to define a 'River Agreement' as a system of collaborative practices among different stakeholders, inhabitants and institutions, established through participatory processes with the aim of improving local watershed and ecosystems. River Agreements can be a way to experience Sustainable De-Growth discourses practically, if they come out from the same perspective of enhancing local resources in an equitable way. It is the concept of applying the R-program to territories and lands, using derelict areas as an opportunity to test Sustainable De-Growth hypothesis.

In order to lead planning and environmental management toward this directions, institutions (like Universities and Public Agencies) are compelled in reframing policies, strategies and tools toward more inclusive and democratic practices, working actively with local inhabitants, with their local knowledge, and visions for the future. Someone can argue that it is obvious underlying the importance of collaboration among stakeholders, and inhabitants' participation into the decision-making process, since the aforementioned European Directives were passed, or the elder *UNECE Aarhus Convention on Access to Information, Public Participation in Decision-making and Access to Justice in Environmental Matters* (1998) was ratified, as institutions are forced to involve laymen in their planning processes. Even the *Rio Declaration on Environment and Development* (1992), that contains the principles of Sustainable Development itself, underlines the vital role of local communities in environmental management "[…]because of their knowledge and traditional practices. States should recognize and duly support their identity, culture and interests and enable their effective participation in the achievement of sustainable development[...]" (Principle 22). Evidence suggests that this is still not completely acknowledged in some contexts.

An innovative aspects of emerging Sustainable De-Growth discourses is related to a deeper attention for everyday lifestyles thanks to the input received from grassroots movements (Martínez-Alier et alii, 2010); the forthcoming Third International Conference on De-Growth, Ecological Sustainability and Social Equity, is indeed paying attention to listening at territories' stories through activists' voices (www.venezia2012.it).

Besides these innovative discourses, and some avant-garde institutional processes, it has been shown (Gravagno et alii., 2010) that the direct involvement of local communities is not going to happen in contexts like Sicily, where the planning process is still anchored to a technocratic approach, and participation processes need to be explored much more. The proposal for a River Agreement in Sicily comes out from this necessity: it is a practical experiment to understand if it is possible, and how, to modify the ordinary planning procedures toward an effective collaboration among inhabitants and institutions. This paper tries to verify if the River Agreement can happen in a Sustainable De-Growth perspective, as a an opportunity to experience if a community is really able to take care of its place of life, to regenerate its ecological relationships and its economies, through a deep change in everyday life.

4. The long and passionate road toward the Simeto River Agreement.

To enter deep inside the practical experience in a specific context with its peculiarities, it is now presented a Participatory Action Research project, i.e. a research conducted through a mixed and open group that includes scholars and other different participants, in order to empower the local community (Whyte, 1997), revitalizing the spoiled context of the Simeto River Valley, Sicily-Italy.
In 2008, the partnership was established between the University of Catania – Department of Architecture, and a network of grassroots associations called ViviSimeto; since 2011, the partnership is enlarging through the involvement of municipalities and other institutional agencies in charge of regional planning, and it is leading a process toward a strategy for sustainability, called the Simeto River Agreement.

4.1 Methodology.

The partnership is led by a mixed research group, with researchers and activists as catalysts of the process, and open to different inputs from local people. Some scholars (Lewin, 1946; Whyte, 1989) have shown the validity of these groups that contribute to build collective innovative processes, linking research deeply with the context, and producing changes into the context. This is suitable for researchers to enter inside practical problems and evaluate their hypothesis during the action; and for participants to get capabilities in raising problems and building strategies. This research strategy is recognized as Participatory Action Research with a Service Learning perspective (Reardon, 2003; Gravagno et alii, 2010).
Service Learning is an opportunity for University in order to apply its theoretical skills and to contribute directly to local development; for Associations, in order to learn and to improve their action; for Institutions, in order to innovate themselves.
As research is connected to a practical experience, researchers themselves are active participants, not just observers: according to the complexity theory (Morin, 1994), they influence data during the action, and they are also influenced from the action.
All participants are invited to reflect and to reframe their issues and visions (Schon, 1994; Schon & Rein,1995). Results are evaluated during the action, too; they are deeply connected to what is currently happening during the process, and they are subjects of discussions, focus groups, and public debate.
This paper, after contextualizing the research, presents some steps of the participatory process, with two milestones toward the Simeto River Agreement: the Community Mapping Project, and the Institutional Turning Point. The process is analyzed to answer the research question about preconditions and characteristics of a River Agreement as a Sustainable De-Growth strategy in a specific context. In order to evaluate some preliminary results, interviews in-depth have been conducted. Interviews in-depth are conceived as a tool for a self-reflective moment in order learn from the past and to understand how to go on, highlighting crucial issues.

Key-actors are identified as the 'passionate participants': they have been selected for their important inputs to the process, with their lives, stories, emotions, perseverance; the interaction among researchers and activists has been based on intense empathy, sharing the common feeling of working to improve the native context. According to Fisher (2009), this emotional dimension has to be highlighted to explain well the deep motivation of participating in an unusual end experimental processes in a challenging context like Sicily.

4.2 Snapshots from the context.

The local context is a rural area where the most important river of Sicily flows, the Simeto River (113 km/70 mi long; 4182 Km^2/1614 mi^2 watershed). This place is very rich of biodiversity, traditions and agricultural productions, but it is losing its original characters due to a lot of factors. The local community calls the middle course of the River as the Simeto River Valley.
With five municipalities in two different Provinces along its path, plus eight more close to it, it is a significant area due to some features: rare elements of wildlife still existing; historical and cultural heritage places; peculiar farming systems (with some high-quality products into a fascinating rural landscape with ancient buildings and infrastructures, from different époques starting from Neolithic, continuing with Greeks, Romans, Arabic, Normans, Bourbons); a lot of springs from Mount Etna (rich groundwater system).
But there are also a lot of disturbing factors: water and ground pollution (cities' depuration plants do not work; inefficient waste management system, illegal water pumping and chemical pollutants by some farmers and industries); derelict lands (young generations move from rural places into the cities and no one is taking care of fields anymore); inefficient and useless hydraulic infrastructures (artificial banks and dykes); so the context is badly changing and biodiversity is decreasing. For these reasons, it could be defined as an ecological challenging context.
Furthermore, there is a long-lasting crisis for the local agricultural market and rural economies, with few institutional plans and no well-defined visions to empower local communities. Different local agencies do not share land management information and, in general, laymen, associations, and institutions are not used to work in a collaborative way, as it is even difficult to say who is the local community. Moreover, political patronage is quite common and young generations suffer unemployment problems (they do not believe in better changing so they often go away from Sicily).
In the meanwhile, there is an active network of grassroots associations that wants to promote strategies and projects to revitalize derelict areas though responsible fruition and practices. They want to encourage public debate about these issues, with institutions playing their part in a responsible way.

4.3 Steps toward the River Agreements.

In 2008, partnership started from a specific need: defending a Special Area of Conservation (SAC Pietralunga) from the building of a big incinerator, that laymen

perceived as very dangerous for them, for ecosystems and for the economy of their life place. This incinerator was part of the Regional Waste Plan of Governor Salvatore Cuffaro in 2002 (some years later he was convicted of mafia affair), so that regional institution was perceived as an enemy to fight.

Laymen started organizing in grassroots associations that were able to affect decision-making process thanks to mass protests, for example mobilizing more than 5000 participants for a march, and also legal actions supported by some experts (Gravagno&Saija, 2008). Even if the fight against incinerator was successfully, it was not enough: partnership knew that NIMBY approach was not a proper way to face the question (Fisher, 2000), so researchers and activists started reflecting on a complex and more holistic level. It was immediately clear that the entire river system needs to be revitalized from deep changes, long-terms strategies, new and respectfully relationship human-environment.

The partnership highlighted some goals: promoting an inclusive debate about the environment, starting from local knowledge and common experience, involving also laymen that are outside grassroots associations; affecting decision-making process, building a community strategic plan as a tool for a meaningful dialogue with institutions; trying to overcome advocacy toward a shared responsibility, i.e. a process in which different actors play their part with their skills. The partnership was therefore starting to trace a collaborative strategy for watershed management improving renewed ecological relationship. It is reasonable to say that these goals are inspired by discourses about sustainability. The partnership never faced the debate 'Sustainable Development' vs 'Sustainable De-Growth', but the common issue was clear: how to make the Simeto Valley a beautiful place to live, for present and next generations, learning from the past ones? More than theories, the debate focused on practices: which could be suitable paths toward sustainability?

The first step was defined as the 'Community Mapping Project', built in a specific way suited to the local context, interests and needs. It explored the awareness to be part of an ecosystem where inhabitants share a 'common home' and its resources with other living being. Inspired from Bioregional practices, it focused the importance of mapping to create a community sense related also to natural environment, giving up a 'city-centered' vision to move toward a wider one, with the central role of rivers as symbols for respectful ways to live together (Aberlay, 1993); furthermore, it was a way to explore allocation and management of resources through an easy way of understanding land's features, as experienced in Participatory Rural Appraisal (Chambers, 1992). But the 'Community Mapping Project' was also something more. It was a simple and direct action able to put different people together in front of a huge map (1:10000 scale with the all river path, in a 3 m height, 10 m weight wall) and reflect together about future of their land. A 'serious play' was invented, without rigid rules, but just some guidelines, to sharpen 'mapper's' interest and action. In four months of work (carried on in four different cities), the partnership was able to involve 500 active participants (farmers, tourism operators, students, inhabitants, workers, users of the valley, and so on), plus some institutional representatives. This number is quite minor comparing with 5000 people involved into the protest against incinerator mentioned above, because it was more difficult moving 'from NO! to YES!', i.e. from the protest level to the proposal level. By the

way, the Map collected a lot of interesting contributes about the past, the present and the future of the river valley in its complexity, with a particular attention on water resources. After a 'Three Days Community Design Workshop', called 'ViviSimeto 2010' and focused on some topics arisen from the 'Community Mapping', a document was realized, with a system of values, wish and, above all, with a system of actions: something like a participatory strategic plan. Participants evaluated this phase as successful through public appreciations and the willingness to continue working together.

When the partnership focused which pilot actions and projects could be the starting point of practical landscape transformation and regeneration, it was immediately clear the necessity to start from derelict areas, places that are not currently used, apart from being illegal dumps. Two of them were chosen, where the partnership experienced a community design approach to build collective knowledge (Raciti, 2012): one near the river, to revitalize through planting trees and natural open furniture, promoting a responsible use and care of a fragile ecosystem characterized by peculiar birds; the other one inside a city in a poor neighborhood, to revitalize through a creative school-community garden, promoting intergenerational exchange between old people and young students, with experiential forms of education. These two experiments showed two critical points: voluntary action was too weak; institutional support was not effective. Reflecting during the action, the partnership focused the importance of an Institutional Turning Point, i.e. a more organized structure made of a deep collaboration among associations and institutions.

Synthesizing, in order to build the River Agreement, the Community Mapping Project was the first milestone as a voluntary experiment carried on by the partnership among associations and institutions, with its good results and some failures related to the pilot actions. In the meanwhile, the partnership decided to enlarge itself, enclosing different institutional representatives, with the aim of building a frame defined as a Community River Statement, the baseline for the River Agreement. This is still a work in progress, but it is possible to trace its characteristics. It is about to be realized by mixed work groups, with the institutional representatives as newcomers, and the purpose of clarifying the Simeto Community's system of values, common rules, and landscape managing. The process of realizing the Statement is a way to let institutions and citizens collaborate around the common issue of revitalizing their place of life. It is going to be structured like a 'puzzle', where different actors do what they can (and want) to do, in order to contribute and to exchange with others. For examples, old people want to explore the topic of memories and transmission to young generation; some institutional representatives want to exchange data and expertise related to the river system; farmers and touristic operators want to realize networks and promotional strategies for a sustainable rural economy; some activists and researchers want to continue a 'listening process', like the one started with Community Mapping Project, going deeper inside stories of people who live the river. All different contributes are going to compose the puzzle, if every participant does not delegate, but takes own responsibility of a small action for the large collective project. After this phase, expected results are related to obtain a mature process to build the River Agreement, with the crucial challenge of defining the 'stickiness factor' (Gladwell, 2000).

In which sense this process is going toward a sustainable de-growth perspective? To answer the question, interviews in-depth have been conducted, as exposed in next paragraph.

4.4 Evaluations from passionate participants: some preliminary results.

Four people have been listened to discuss paradigms, results, and next steps of the River Agreement process. They all are activist of ViviSimeto, and they represent four different points of view, that can also be assumed by other participants, but cannot exhaust the variety of points of views. According to the classification matrix of Deming&Swaffield (2011), this research strategy is subjectivist, i.e. knowledge itself is the product of a particular way to look at society where researchers are merged, and samples are not representative of general laws, but they are related to specific situations and contexts. The interviews are a tool to verify if the Simeto River Agreement can be an opportunity to experience De-Growth discourse, reflecting with people who are directly involved working actively into the process. Their lives are deeply related to their answers, so four stories are synthesized, together with their reflections.

More than 10 years ago, the President of ViviSimeto has been also the mayor of Paternò, one of the municipalities along the River; after that experience, she worked actively for the River, from the very first moment when ViviSimeto arose against the incinerator, till the ongoing process. Her point of view is very close the an institutional perspective, and her sustainability idea is related to promote a plain life-style and a responsible use of resources, consuming less and improving local economies. To her, the River Agreement has the potential to become a strategy for sustainability, but two preconditions have to happen: the first one is the ability of its promoters to affect the political sphere, transforming the Agreement in an effective tool for environmental management; the second one is the capacity to start the cooperation among different rural producers, in order to revitalize the socio-economic context via best practices for the environment. She is concerned not only for the natural ecosystem, but also for unemployment plague that is affecting the local context.

With her, another activist has already been involved in governing the Paternò's Municipality some years ago, and he also followed her into the ViviSimeto adventure. He declares not to be inside the De-Growth/Sustainable Development debate, but he has a clear idea: it is necessary to reduce consumption of resources and to improve the relationships between communities and their local context. For him, first of all there is a problem of democracy and values: it is central to start public debates in order to go deep inside the concept of community, to create the sense of community, and to highlight which values a community wants to share, with the awareness that the current direction will lead to destroy peculiarities and the real wellbeing of the context; he also underlines the central role of agriculture, reframing it toward a multifunctional conception. So, the River Agreement has to be an opportunity to enter this path.

They both sustained the Community Mapping Project (even with some preliminary doubts), and now they are very passionately involved into the Institutional Turning Point.

An organic farmer is an activist of ViviSimeto, too. He experiences De-Growth discourses in his everyday life, thinking De-Growth as a change of direction, from the obsession for quantitative development, toward the relaxed search for equitable quality. He was one of the passionate promoters for the Community Mapping project, hosting some public meetings into his rural farm (and house, that he calls 'La Casa delle Acque' – tr: 'The Water House', paying extreme attention to this important resource), while he is doubtful regarding in the Institutional Turning Point. He was enthusiastic for the working method used during the Community Mapping Project: it was led by an open group that met frequently in order to design and to organize the process, exchanging ideas in a very friendly way, and according to him, this exchange made the Community Mapping an original practice, rich of a variety of inputs. He believes in the strength of networks, at a local and at a global scale, so he is part of a lot of 'De-Growth' inspired networks, like the 'RESSud - Fair Economic Southern Network', based on the mutual support and trust among different producers and consumers. He supports De-Growth practices and tools, like the Participatory Guarantees System, to certify good organic productions through a community process of control, and he is aware of the importance of a rural network for the Simeto Valley. He sees in the River Agreement an opportunity to sustain these networks, if they are spontaneous, not addicted to fundraising, and composed of innovative farmers, who link agriculture with hospitality and, above all, with the aim of taking care of the land, transforming derelict areas in regenerated ones.

A Bioregional activist was one of the main promoters of the Community Mapping Project. He is very familiar with De-Growth discourses, that he started deepening during the Earth Summit in Brazil, 1992. He experienced fair and ethic economics systems, like the Time Banking and, at a certain point of his life, he decided to live very close to the Simeto River, as a sort of 'River Caretaker', with a very essential lifestyle, believing that rivers are the most vital part of earth. He was part of ViviSimeto while he was living his deep connection with the river ecosystems, being genuine concerned about its future. He knows that saving the earth is a matter of deep awareness inside every inhabitant, and of willingness in living like a community: it is a matter of ecological relationships. He thinks that the institutional support can be important, but before it is necessary to build a community sense, to build healthy relationships among people. Otherwise, according to him, it is like 'having beautiful cut flowers without a vase to contain them'. His dream would be to continue being a 'River Caretaker', with other young people as facilitators to renew ecological relationships. Institutional support can be useful in organizing the 'River Caretakers', so the Agreement can be an opportunity toward this direction.

These two last participants are inside De-Growth discourses more than the first ones: they were passionate promoters of the Community Mapping Process, and they are

not deep inside the Institutional Turning Point like the first ones, but they both hope it can happen as a useful frame for De-Growth practices.

5. Conclusions and discussion.

Beyond labels, Sustainable De-Growth is perceived like a feasible perspective in the Simeto Valley. Discourses about GDP/GNP, or decreasing production, are never been faced by the partnership, but it is shared the idea that local community has to rethink its economic system toward an aware and responsible use of resources. It is widely accepted that the sense of community has to be improved, and that ecology is not just a matter on healthy natural relationships but, above all, of healthy social relationships.
The Simeto River Agreement is coming up as a strategy to organize spontaneous De-Growth practices already existing, to speed up innovative practices, and to allow young generations revitalizing spoiled contexts, with a multifunctional approach to agriculture. Collaboration among laymen, association, experts, and institutions is necessary to improve a holistic sense of community; furthermore, institutional support is important in order to introduce effective changing in environmental management.
As this is still a work in progress, a question is open: how is the Institutional Turning Point going to end? Future development of this research will be related to explore the practical experience of building a Participatory River Statement, and to define concretely the River Agreement at a more advanced status.

6. Acknowledgements.

I feel grateful to every person I met along the Simeto River. Besides, this paper exists thanks to those ‘passionate participants’ I interviewed, and it is full of inputs received during discussions with my advisor, Prof. Filippo Gravagno, University of Catania; my co-advisor, Laura Saija, Researcher and Marie Curie Fellow, University of Catania – University of Memphis. Special thanks to Antonio Raciti, Visiting Professor – University of Memphis, for the practical experiences and efforts in our common fieldwork for one year. I also want to acknowledge professors and students I met, as a short term visiting scholar, during my research exchange at Mississippi State University, Landscape Architecture Department, Mississippi Water Resource Research Institute, and College of Forest Resources – Wildlife, Fisheries & Aquaculture: far from my river, close to other rivers, I have the opportunity to refocus some points of my work, and to look at the international debate from another meaningful perspective.

FEEDING THE CITY: HISTORICAL EVOLUTION OF THE FOOD SUPPLY AND ITS TERRITORIAL PLANNING IMPACTS END 18TH CENTURY - END 20TH CENTURY

Sabine Bognon[1]

Abstract

Cities do not produce their own food and that is why they are an interesting starting point to study food policies evolution, regarding territorial and urban planning and concerning food supply.
Feeding a city depends on procedures settled since its founding. But food supply results from a sequence of complex and rather unknown mechanisms. Unfortunately, knowledge is fragmented whether (or both) by disciplinary shackles or (and) historical periods boundaries.
The theoretical and analytical framework of territorial ecology provides a way to think historically the co-evolution of the urban food hinterland and its governance. It helps tracing past social and territorial conjectures in order to provide new inputs for a prospective debate on the current changes in urban food supply arrangements and its consequences in terms of urban and territorial planning.

A historical scan will embrace the connected evolution of the Parisian hinterland and the governance of its food supply. Since the end of the 18th century, food supply experienced progressive liberalization. Technical changes in farming and transport released most of the natural constraints that featured the pre-industrial food system; whilst feeding Paris remained and important issue for both the city and the French state, justifying the existence of a public supply policy, at least up to the World War II. Simultaneously, the agricultural policy (at regional, national or after WWII European scale) had large consequences on food production that had as well many consequences on hinterlands and especially on rural areas that surrounded Paris (where they added to urban pressure, especially from the inter-two-wars on). The metabolic links between Paris and its surroundings became very thin. This ongoing configuration led to agrifood business, large retailing and mass consumption development although almost hegemonic, the resulting food system has been challenged from the 1970s on.

Based on a multidisciplinary bibliographic approach, this paper aims at better characterizing this long-term history. We are indeed convinced that it is a necessary step to a comprehensive analysis of urban-rural trajectories and the intertwined

[1] Paris 1 Panthéon-Sorbonne University – ADEME, Paris, France – sabine.bognon@gmail.com

questions of space (rural and urban) and flows (of food) underlying some great planning issues.

The findings expected in this article are twofold.

First, the center of Paris metropolitan area's is an illustration of the co-evolution of the hinterland and the multiscalar governance of food stream, from the late 18th century to the early 1980s. The case helps to understand the processes and agents' networks that govern upstream of urban metabolism, in terms of food supply.

And second, as expected, agent's governance and the management of a food hinterland involve consequences in terms of territorial and urban planning. The case offers a way to analyze those consequences retrospectively and maybe foresee new perspectives regarding recent movements of food system "relocalization".

1. Introduction

Resource scarcity and global change confirm the relevance of considering the city as endowed with a systemic metabolism. It has a stock, it is supplied by material and energy streams, it produces excretas, and it is sometimes even able to recycle some of these resources. The city thrives on exterior territories since it is not intended to produce its food. As renewed policies think on money saving and flow management efficency, food supply is being challenged by movements aiming the relocation of food strems provenance.

The analysis of the food system and its recent changes may lead to its spatialization. The metabolism territorialization takes place through the concept of hinterland. Literally "backcountry", the hinterland is defined by the American geographer Van Cleef as "the area adjacent to a trade center (extending to and including its satellites) within which economic and some cultural activities are focused largely on the primary center" (Van Cleef, 1941, p.308). The hinterland, from the perspective of urban metabolism and in our globalized societies, involves non-contiguous territories, and it is the result of food upstream management. The "natural" hinterland, as reffered (in other words) by those who claim for a territorial bond between production and consumption, can be defined as "the valley of the river on which [the city] is located or even of the drainage basin of the river. [Or as] the region readily accessible from the [city] or as the terrain tributary to the [city]" (Van Cleef, 1941, p.308).

At a metropolitan scale, the food system is now global, but it has not always been so. History is used to understand how the Parisian hinterland has become global and what the socio-spatial path that led to pleading for the relocation of the food supply areas is[2].

Feeding the city is a public policy concern since the urban population, concentrated and plentiful, is capable of a certain political power. However in Paris (and in some other global cities), the governing who cared greatly for the livelihood of citizens under the *Ancien Régime*, now seem to be almost entirely excluded from food supply management decisions. A retrospective review of the stakeholders and their involvement in the food supply system is needed to understand their path, their political chronicle. It leads to the causes and consequences of a public withdrawal, to the study of agents today in power, and to the implications of relocating the hinterland in terms of food flow governance.

This study is mainly bibliographic. It seeks to gather in a synthetic way, much scientific work concerning the subject. So the material basis is deliberately eclectic and multidisciplinary.

One goal of this paper is the decompartmentalization of disciplinary approaches: planning is a field that, although denying it, remains dominated by sectoral thinking. We aim to bring together a broad and transverse thematic corpus, and by that to embrace the diversity of approaches tackling spatial planning and food.

[2] Relocation involves a come-back to a nearby supply, reached one day and now lost.

The bibliographic material is essentially made of secondary sources: reports, monographs, articles, theses… but we also wanted to compare some of these documents to their sources, in order to reveal their richness.

Here, time slicing is driven by the evolutions more than by the historical accuracy or an academic relevance. The study investigates the periods of time in order to understand the transitions between each of them. Thus, we focus on the end of the *Ancien Régime* (second half of the 18th century) because it carries the unprecedented changes and announces the upheavals of the Industrial Revolution. The following period covers the 19th century and the first half of the 20th century. This combination is used to treat the process of long-term Industrial Revolution: the successive innovations as taken one by one are not the point here. This long period allows us to read the political-economical and socio-technical trajectories of the food system. Finally, since World War II (WWII), the period stands in one block because it seems that we are still evolving within it.

As a first step, we analyze each period independently. We study the co-evolotion of of the food flow governance, the scale of the Parisian food hinterland, and land management and urban planning. The results of this bibliographic investigation are presented as answers to two main working hypotheses.
a. Public authorities are sidelined in terms of food supply. How did it come to such marginalization? What were the keys of a public food policy and in which directions were they replaced?
b. The inner metropolis of Paris allows us to observe the combined evolution of the hinterland and a multiscalar governance of food flow. How city and regional planning are keys to understand this co-evolution? What are the spatial implications of political and economical choices for food supply?
At last, the interest of that work is that its timeline is deliberately long. Our hindsight highlights different stable periods and their transitions. It sheds light on actual claims for the relocation of the hinterland.

2. Analysis

2.1 Ending the *Ancien Régime*[3] (last 18th century): the State governance of Paris food-stream landscapes a "natural" hinterland.

Social stability and the basis of power are only guaranteed by the insurance of a consistent, affordable and regular food supply : administrators keep in mind the political disorders caused by food scarcity and famines. Paris is even more strategic as it is the capital of France: the population is high[4] and represents a risk of urban uprising (that finally turned out to be at the end of the period!).

[3] *Ancien Régime* is the French term that refers to the polital system established before the French Revolution, including monarchy and aristocratic society.
[4] Lepetit (1995, p.93) notes that there are approximately 510 000 people at the edge of the eighteenth century and 620 000 by the Revolution (1789).

Royal power is directly involved through the supply police (*police de l'approvisionnement*). It ensures consistency, quantity, quality and prices' relative stability (Kaplan, 1988). The monarchy controls many different places, but the police is mainly operational on markets. All transactions must take place there, where the supply police overcomes and moralizes trade. The market provides a bridge between the interests of the "sovereign [State] responsible of the exchange" (Clement, 1999, p.8) and those of the society, against the principle of market economy[5] (*principe de marché*).

Following this principle, the market economy is completely freed, on property and self-interest bases. Facing this thinking trend, the state fears the monopoly and the power or merchants that may now speculate on famines to increase their profit. Preventing that kind of speculation is also a way to guarantee State incomes: "tax interest came in large part in the measures taken, arguing to ensure supply and to fight speculation" (Bureau de l'Approvisionnement, 1889, p.11). The principle of market economy leads private interests, as the market is the material place of sales that supply police can look after and rule.

In the middle of the 18th century, French economists stand up for liberalization. They recommend freed exchanges, guided only by the rules of offer and demand, out of all socio-political considerations (Clément, 1999). On the eve of the Revolution, supply police is quite contested since it sets against the liberal claims of the merchants.

Ending the 18th century, all believe in a social justice that allows everyone to get food according to one's needs, without yet accepting the State as a market ruler. Whilst the debates among economists are reflected on the merchants' claims (Clément, 1999), in fact, according to Kaplan's expression, supply police and food supply are "an inseparable pair". French society, and particularly Parisians, is gifted with a strong political culture: the State along with the police keeps legitimacy to rule the market until the end of the *Ancien Régime*.

Whereas Abad (2002) and Kaplan (1988) respectively spot successive "circles" or "rings" centred on Paris, we rather stand with a slightly flat characterization of spaces[6].

Abad (2002) shows the contribution of all the French territory to provide varied foodstuffs. Other authors (Billen et. al., 2011) balance these contributions by their nitrogen value, but agglomerate at the same time the types of food. The following maps (figure 1) combine those works : they do not exclude some provinces even if they are lightly contributing to Paris hinterland in caloric terms.

[5] "System of relations in which, whereever the transaction takes place, the impersonal forces of offer and demand determines the prices that preside the allocation of resources, incomes and productions" (Kaplan, 1988, p.16)

[6] The contributions of these authors are relevant in their argument (typology and sectorial features of each areas). But here, this representation is superfluous and may even suggest an application of the Von Thünen model – although Abad (2002, p.802) defends itself in the way that territorial specialization does not match the type given by the German economist.

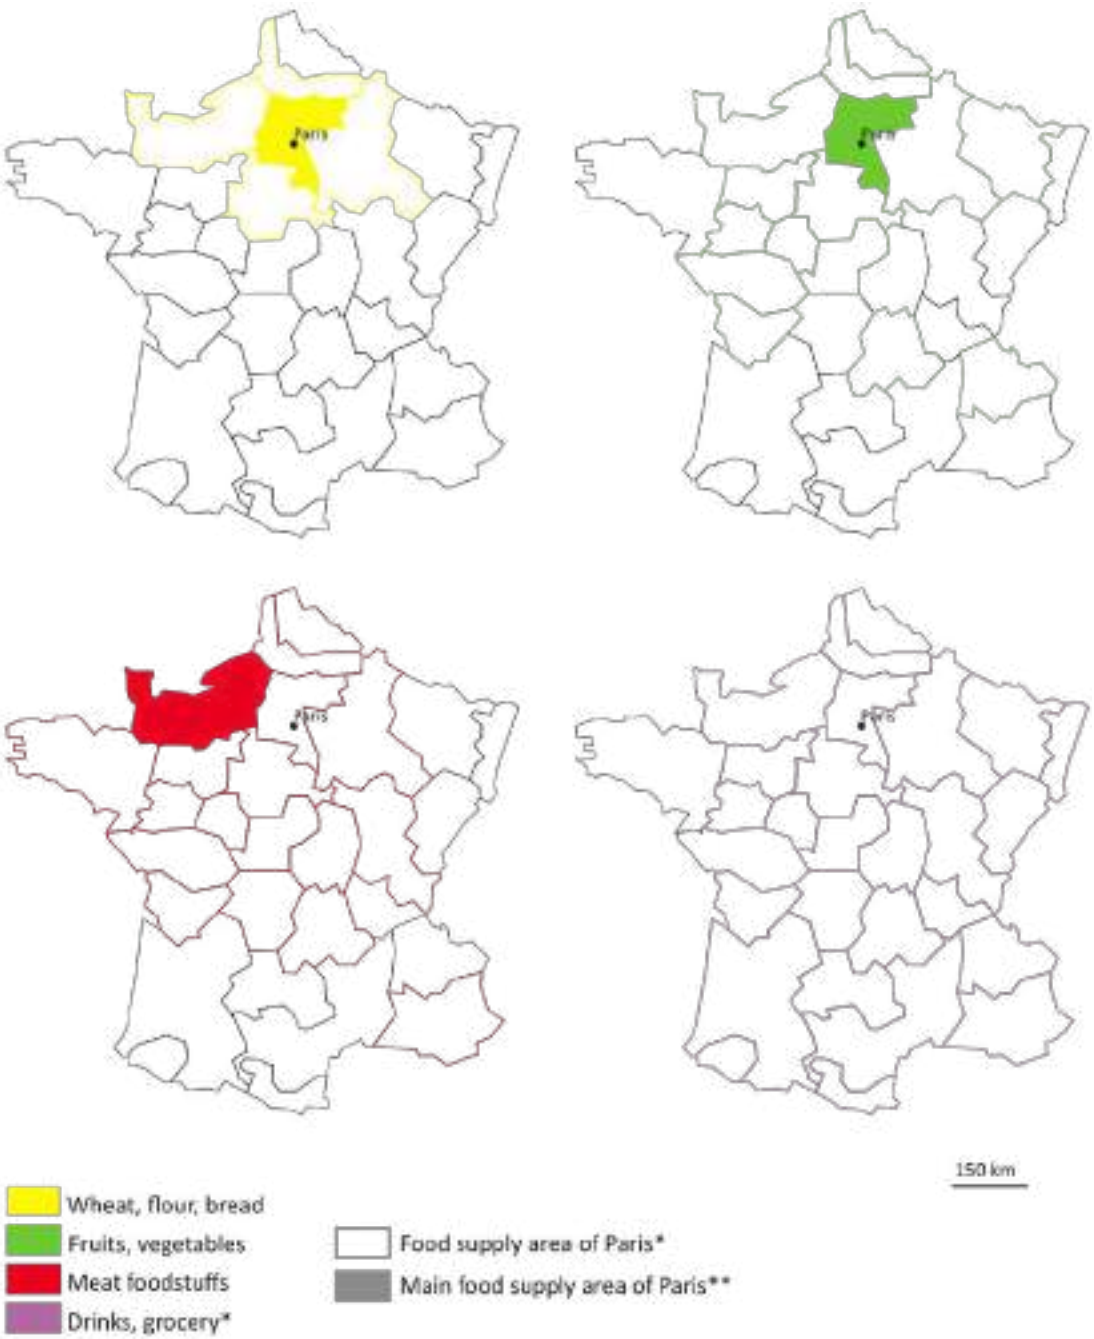

Figure 1. Paris food hinterland, ending the Ancien Régime

From Abad, 2002 ; Billen et. al.,2011

** data exclusive Abad[7] - ** data exclusive Billen et. al.[8]*

[7] Although way more fragmented, we have regrouped some datas to ease their overlaying.

[8] We have only selected the upper class of statistical quantitative typology because this assessment does not necessarily represent at best the reality of the Parisian hinterland of the *Ancien Régime*. The unit that bases these thresholds is the amount of nitrogen in each food family. Our study does not attempt to assess the contribution of nitrogen flow in the territories, which may also skew the results for the products that contain little (fruits and vegetables). The representation of the upper end of this territorial classification allows here to prove the quantitative weight of some territories.

Ending the *Ancien Régime*, the food hinterland of Paris is national: all the provinces contribute. International trade is negligible, as it concerns very few volumes, and exotic foodstuffs that are reserved to the wealthier[9]. The quantitative results (Billen et. al., 2011) show an origin area centred on Île-de-France (Paris province) and Normandy. Even if the whole French territory feeds its capital city, it seems that the watershed of the Seine-river downstream from Paris, is the "natural" hinterland, as defined by Van Cleef (1941; see introduction of this article).

Both cause and consequence of what we achieved to demonstrate, Paris is conceived as the core knot of the national transport system. Numerous streams pass through the city that concentrates financial capitals. Concentrating the national infrastructure is a typical concern of the monarchy.
Created ending the 15th century[10], postal roads (*routes de poste*) founded the national road network. Built on a radial scheme around Paris (figure 2), they guarantee a decentralised royal power throughout the country. The merchants nevertheless neglect road supply, because road network is not very attractive. On the one hand, foodstuffs are not necessarily produced nearby the main roads, and on the other hand, transport conditions are much poorer than by waterway. Waterborne shipments are favoured (Abad, 2002): it is more profitable (opportunity to move more important volumes, with less workforce), and the network is already well extended. Rouen and Le Havre ports are the sea doors to Paris. The Seine-river watershed's mesh is important and bonded to the Loire-river watershed since the beginning of the 18th century. Let us note that the Canal du Midi, which construction started ending the 1660s, can bring to Paris southern and Mediterranean foodstuffs, via Bordeaux and Nantes, without passing through the Strait of Gibraltar (figure 2).

Important infrastructure work, ending the *Ancien Régime*, gives Paris privileged access and fluidity: "a very large part of the communication network has been conceived to allow Paris to soak up the whole kingdom production" (Abad, 2002, p.15).

[9] Abad (2002) quotes citrus and dried fruits from the Mediterranean basin, almonds, capers and olives from Spain, Japanese pistachios, spices from colonial trusts, coffee from Arabia, tea from China…
[10] Their purpose is the availability of mounts for the messengers of the kingdom.

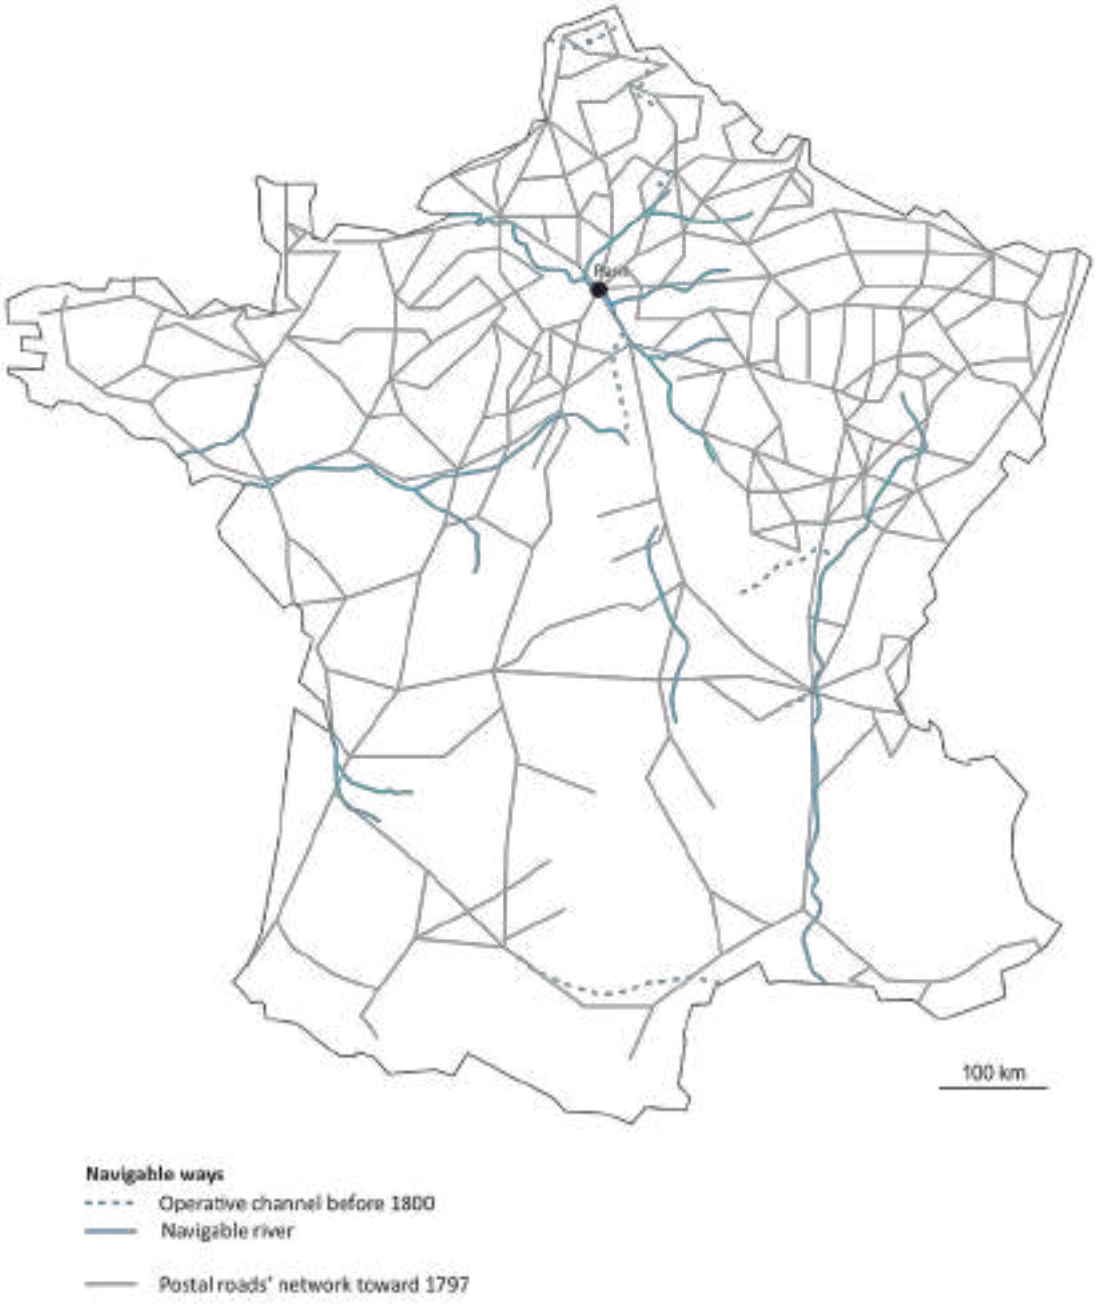

Figure 2. Paris as a transportation node for roadways (*) and waterways (**).
From (*) Saint-Julien, 2000, p.77 ; (**) Saint-Julien, 2000, p.23

2.2 The Industrial Revolution and its consequences (19th century – inter-world-wars period): innovations improve the transportation infrastructure network and provide a wider hinterland

One revolution after another, the French Revolution gives place to the Industrial Revolution. Technical improvements cause great changes into the food-system. The documentation concerning this period increases: primary sources become reachable due to thriving national statistics. And those sources are often the basement of the secondary sources of our demonstration.

Paris keeps its capital city status: its population is far superior to that of other French cities and is growing fast, particularly in the second half of the 19th century (Dupâquier, 1995). At a national scale, the urban population increases by 155% between 1831 and 1911. The main causes are industrialization (which attracts rurals) and the intensification of international commercial relations (which attracts immigrants).

Still central to the concerns of public authorities, social order[11], tax collection and thus food supply are among the causes and consequences of enhancing the polarization of transport networks around Paris.

The road network is growing. The whole territory is now covered even if the north of France, and especially around the capital, is more densely equipped. A nodal network of cities is born, creating as many regional relays for the delivery of provincial goods between these secondary cities and to Paris.

Figure 3 shows the road network in 1820: differences in meshes are still significant. Even if the gaps tend to disappear throughout the period, the road network remains differentiated in favor of the capital city area.

Waterways, always playing a part in food supply capital are also improved and increased throughout the 19th century and the first half of the 20th[12] (figure 3). The watershed of the Rhine and the Rhône are connected to that of the Seine to facilitate international trade with Central and Southern Europe and with the Mediterranean ports.

[11] Attracted by the cities, the working masses increase the vulnerability of the State against potential episodes of food insecurity.

[12] Ther modernisation (1879-1914) is mainly due to Freycinet, French ingeneer and public Works minister, than *Président du Conseil* (Saint-Julien, 2000, p.77)

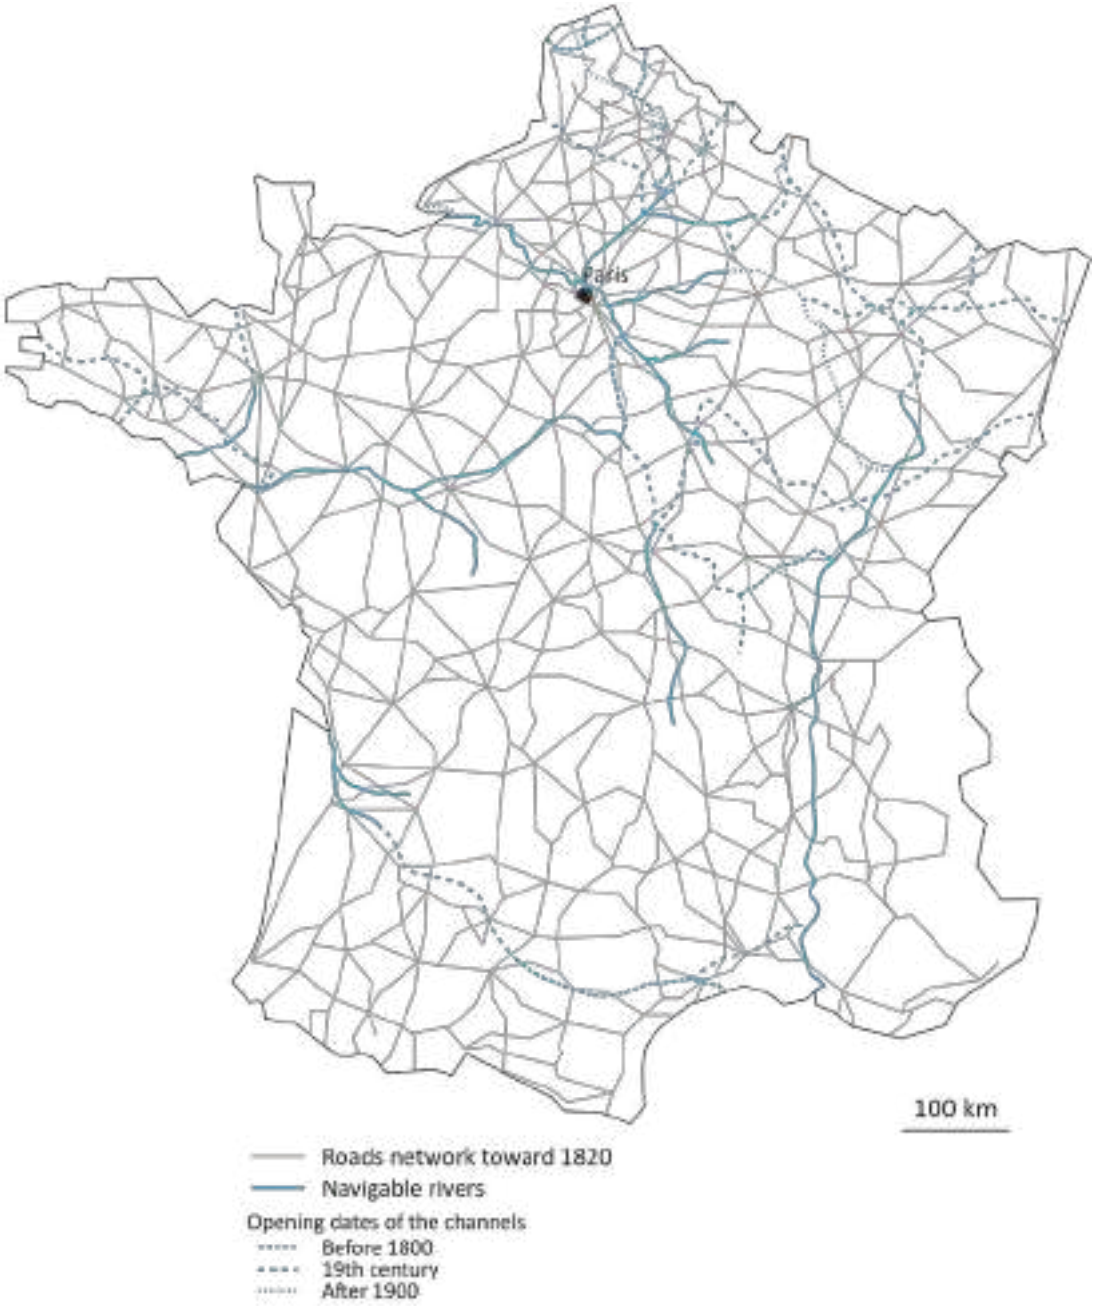

Figure 3. Main roads network toward 1820 (*) and navigable waterways (**)

From (*) Saint-Julien, 2000, p.23 ; (**)Saint-Julien, 2000, p. 77

The advent and growth of the railway contribute to strengthening the central location of Paris since the network is heavily polarized by the capital (figure 4). In the first half of the 19th century, it seems that the rail has a mandate for international transport. The trend is reinforced in the second part of the period with new links created to the Mediterranean (present Italy and Spain) and the multiplication of tracks towards Prussia and the Netherlands.

Figure 4. Railroad network emprovement.
From Saint-Julien, 2000, p.45.

The origins of the products are known by the accounts held by the authorities. For this period, we have two specific dates (1896 and 1910) to which the Prefecture of the Seine (Bureau de l'Approvisionnement, 1897 ; Bureau de l'Approvisionnement, 1911) gives the origin of the products sold in Paris.
More than the previous period, the *Départements* (designation of the provinces since the Revolution) are requested. Their ability to meet this demand is made easier by the constant improvement of transport and technical progress in the primary sector. The widespread agricultural intensification contributes to higher yields[13] and at the end of the period, and the mechanization of farming increases productivity. These volume gains are reflected in the participation of all *Départements* to supply Paris.

[13] The fallow fields are reduced to leave room for legumes plantations (nitrogen-rich fertilizer) and the stocking density increases (producing quantities of manure suitable for fertilization). (Billen, et. al. 2007)

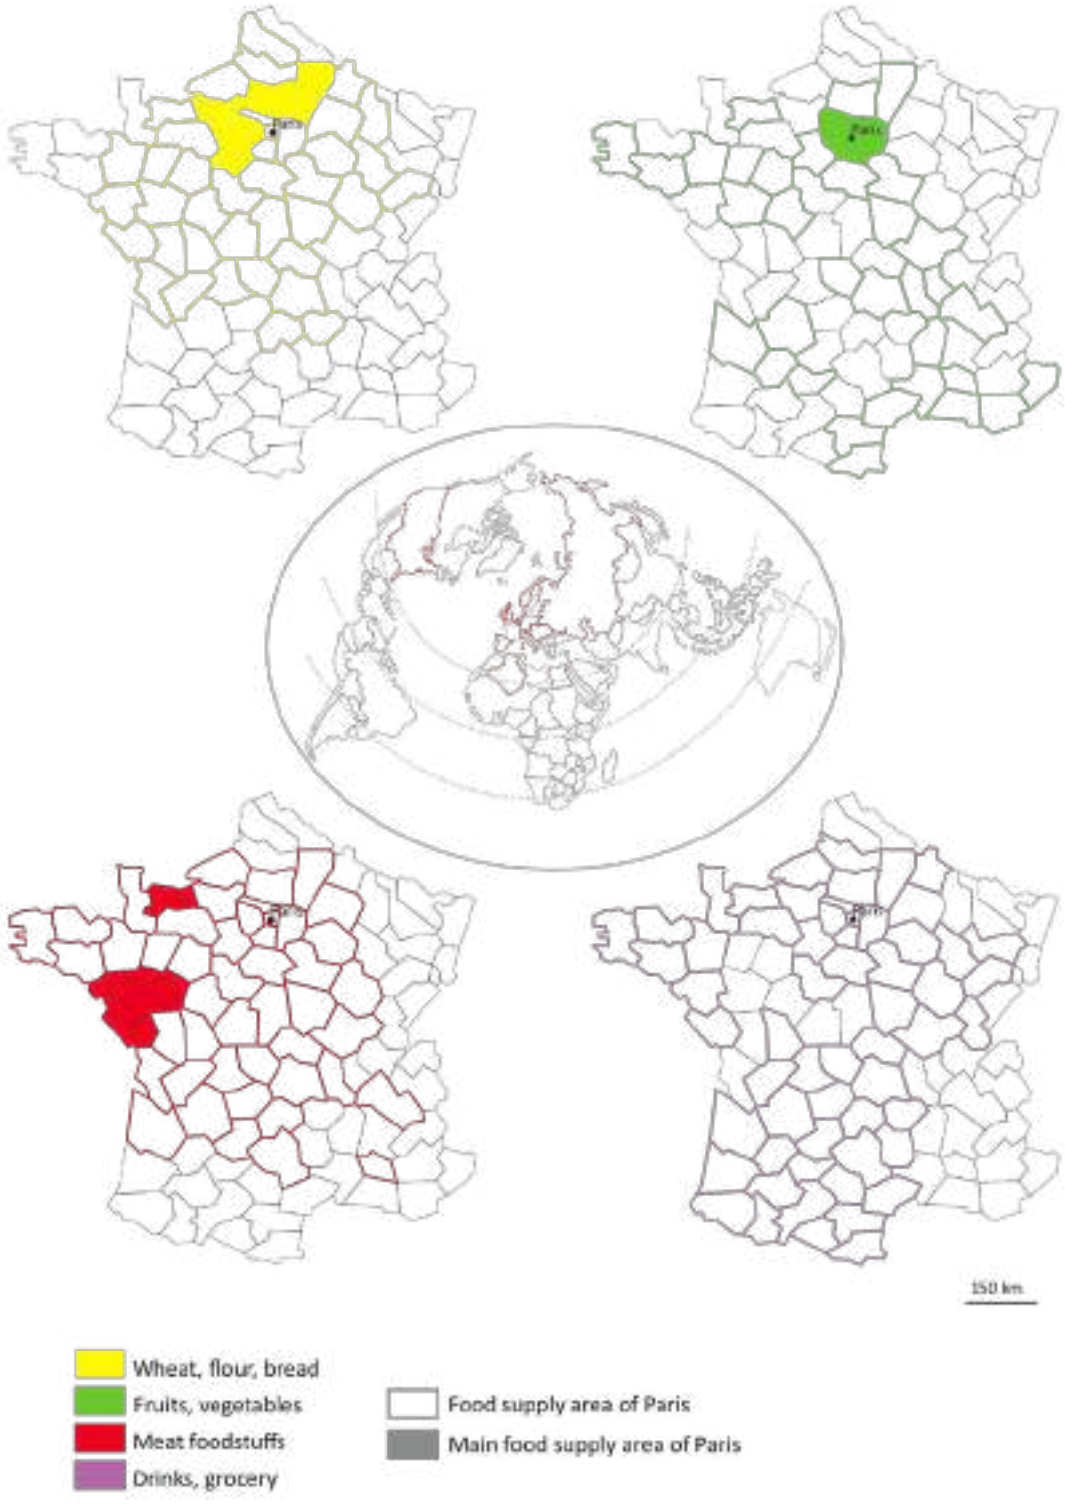

Figure 5. Paris food hinterland in 1896

From Bureau de l'Approvisionnement, 1897 ; Billen et. al., 2011[14]

[14] We have not found data detailed enough to compare them with those presented by Billen. As in Figure 1, we have retained only the higher level of its quantitative classification to account for the majority of grain origins.

On figure 5 the year 1896 is represented because it is one for which we have the largest number of corroborating reports. The natural hinterland from the late 18th century now seems challenged. All *Départements* are still involved in supplying the capital, but some regional specialization of production is at work. The privileged area of origin of animal products (meat and fish) moves to the west of the country and Algeria takes a relatively large share in the supply. Only 5% of animal products are imported from abroad, but most of Europe contributes. Marginally more in 1896 than in 1910, the import of meat from North America (and later Southern America) is gaining importance, especially because of the technical progress in shipping refrigeration means (Pedrocco, 2005).
Fruits and vegetables come mostly from the crops in the surrounding suburbs of Paris, while many other *Départements* contribute. The increasing importance of Mediterranean products (citrus and other fruits) and the significant contributions of Algeria as well as Spain and Italy, should be noted. The improvement of transport conditions is the cause (shortening time, preservation techniques): products previously reserved for wealthy people (exotic or extra seasonal consumption) become more and more affordable (Péhaut, 2005).

Les Halles Market case study

The dichotomy centralization / co-operation between public and private sectors can be explained with the case of Les Halles Market. Governed, according to the period, by the State or the City, but daily managed by merchants, this central market is only dedicated to the supply of fresh food in Paris.
Under the *Ancien Régime*, Kaplan (1988) describes it as a state-market (*Etat-marché*) in which each corporation rules its law, while subordinated to the public authorities. The transition from the revolutionary period occurs only in the last years of the First Empire (1810's). A dual public authority governs Les Halles Market. The *Prefecture de Police* (police headquarter) makes it accessible, ensures internal and surroundings security, healthiness of the products and the places of sale. The *Prefecture de la Seine* (city authority) monitors all economic transactions (fees and sales taxes collecting, price control by following prices trends, anticipation of speculation by prohibiting storage). Driven by economic interests above all, merchants are responsible for daily management of the market: they ensure the cleanliness of their storefront and update the register of financial trends of the products (enabling control by the *Prefecture de la Seine* and justifying prices' increases and decreases).
Les Halles Market, sometimes nicknamed the Belly of Paris (*Ventre de Paris*[15]), supply the capital city since Louis VI (12th century) who had launched an initiative to the site (Chemla, 1994). The upgrading will, expressed at the end of the *Ancien Régime*, was taken over by Napoleon. Haussmann, prefect of the Seine *Département* commands the main arrangements. He mandates the architect Victor Baltard to conduct works from 1853 to 1868, building ten pavilions on two blocks, connected by a glass roof.
The works increase tenfold the space occupied by Les Halles under the *Ancien Régime* and the neighborhood is greatly changed, especially to facilitate its access by

[15] For a romantic and realistic portrayal of Les Halles market, see Zola (1873)

various transportation modes, since the barriers and railway stations. "[...] the whole neighborhood was redesigned, upset. The breakthrough streets [...] [made] away much of the old market district [...] the result of those new streets was a profound and radical change in the neighborhood, making a clean sweep of the past [...]."(Chemla, 1994, p.39). The State's goal is to provide a centralized food supply for the capital region, "the new pavilions were not only an architectural work [resulting of technical progress of the Industrial Revolution, particularly in regard to light metallic structures and large glazed areas], they had to fulfill their daily essential function, that of providing the regular supply to the inhabitants of Paris and the Seine *Département*, but also to cities and outlying regions" (Chemla, 1994, p.40). The ten pavilions house the goods according to their nature. Outside, the fairground hosts the storage of all goods that do not fit in or do not find their way to their proper pavilions (figure 6).

In the early 20th century, access to the pavilions is more and more difficult[16]. The commercial intermediaries create their market niche by taking advantage of these obstacles and the multiplication of retailers scattered in Paris. They are remunerated by commission (thereby increasing significantly the price of food previously traded in direct circuit), a service provided to the seller and the buyer who now meet less directly. This new link in the chain of food distribution reveals the economic liberalization of the markets.

[16] The fairground's gradual spatial conquest causes a congestion that will bring the government to reconsider the location of the market after WWII.

Figure 6. Pavilions and fairground of Les Halles Market towards 1986-1875 (*) and in 1903 (**)

From (*) Chemla, 1994, p.58 (pavilions in 1869) and p.75 (faiground in 1875) ; (**) Chemla, 1994, p.88.

2.3 Contemporary period (post WWII – end 20th century): privatizing the food governance leads to a globalized and rather unknown hinterland, while State planning of the food supply becomes obsolete

The food industry dominates the production of foodstuffs and gradually becomes the origin of most of the products consumed. Indeed, the industry is involved in agricultural activities (production rationalization, use of chemical inputs, mechanization...) and productivity increases despite the decreasing number of farmers (rural exodus) and land availability (urban growth) (Malassis, 1994). The transition from a society of "mass poverty" to a society of mass consumption, and the globalization of the food economy is effective. Thus, it causes the expansion of an agribusiness food system. Supply is changing since the destination of the agro-industrial production is mainly supermarkets. In the 1950s, the original aim is to bring closer the consumer and the producer by combining interrelationships into the hands of intermediaries (distributors), in order to reduce the prices (figure 7).

B : potential buyer – P : producers – I : business intermediaries
No intermediary: **BxP**
5 producers and 10 potential buyers: 5x10= **50 interrelationships**
Availability of intermediaries between producers and consumers: **PxI+IxA**
2 producers gather the previous offer in one place: 2x5+2x10 = **30 interrelationships**
In this example, one loses almost a third of interrelationships. Here, the efficiency appears as particularly reliable for both the producer and buyer.

Figure 7. The efficiency goal of the mass distribution
From Dioux, Dupuis, 2009

But this demonstration does not take into account the margins released by the intermediaries, nor the pressure they may have on suppliers to ensure an affordable price to the consumer.
That distributor is buyer then seller of goods: its economical reason to be is therefore limited to (co-)pilot the households supply. From an economic perspective, food supply of Paris merges with the supply of consumption units that compose it (households, communities, businesses...). If the distribution circuits have always existed[17], modernity invents logistics. In the 1960s, it is about the logistics of means (freight management). Then in the 1980s, the concept of supply chain provides retailers the opportunity to drive the supply from beginning to end. Therefore, the distributor ensures a continuous flow of goods and makes reliable the corresponding information flows (creating databases that allow the exchange of computerized data throughout the distribution process[18]), dealing with making the service efficient and responsive to consumer expectations. It is in fact a tool of flexibility and constant adaptation of supply to demand. Finally, in the late 1990s, supply chain management becomes a unit of profit, an activity in its own, that distributors include (or not) in their supply activity.

[17] i.e. since concentrated populations need to by supplied by tradable goods.
[18] "By 1988 [Wall Mart] had the largest privately owned satellite communication network in the US and its central database is second size only to that of the Pentagon". (Morgan, et. al., 2006, p.180)

The backbone logistic tool of the mass distribution is the central purchasing body (CPB). To strengthen their relationship with suppliers and external purchasing companies, major retailers have formed oligopolistic and in-house CPBs, for their own use. They are intermediaries between farmers and agri-food suppliers; and although there are only few companies, they gather the large majority of turnover. This is the proof of the unequaled success of the large retailing companies.
The links between public authorities and the people become distended on food. The convenience prevails over the quality and quantity, considered as the primary givens of the food industry. From the perspective of consumers, the state is less involved, and it should, because food is a matter of individual choices (Chabrol, D., 2008). Public power is gradually but completely delegating the food supply governance to the business world. After WWII, supply control is provided by private companies, dominating a booming consumer society that chooses to accept and undertake the direction it is orientated.

The hinterland is reset by the plans of the agribusiness. The decrease of transport costs enables the outsourcing of production to countries with cheaper workforce. The hinterland is becoming global in consistency with new consumer habits: seasonality is no longer a price criteria and exotic products are made affordable for all. Consequently, the supply of Paris (as the supply of other cities in rich countries) is from more and more remote provenances. The hinterland is therefore largely and intensely internationalized. On the one hand, the potential provenances of products have increased. And on the other hand, territorial logics of supply have excluded State planning. Specialization of productive areas is guided by the agribusiness, and transport infrastructures created by the State in order to manage the supply nationally are being exploited by private companies.
It is difficult here to produce a map of the hinterland. First, although the food system is relatively stable since the 1960s, fluctuations in the hinterland are such that it is impossible to give a fixed vision. Moreover, the origins are skewed by the blurring of sources: food companies, CPBs, and large retailers communicate very little about the exact origin of the products they sell. And finally, the circuits of production and distribution have become so fragmented[19] that the origins obtained by the databases of the Customs can only account for the last (or penultimate) stage stop of the products.

In the 1950s, three reasons push the State to transfer the activity of the Halles Market on the outskirts of the capital city (Chemla, 1994). First, location is no longer appropriate, because of the city center traffic congestion, bad working conditions for the merchants, and the impossibility to extend despite the high population growth. Second, the occupational structure of the market is changing due to progressive emptying of the wholesalers that go to outskirts warehouses, and the emergence of polyvalent buyers for whom access to various buildings is complicated by the morphology of the market. Finally, the urban supply is changing with the progressive domination of the supermarkets.

[19] About this fragmentation, see the travel of a strawberry yogurt before one can eat it (Böge, 1993).

The State therefore wishes to create a new logistic platform that would be accessible, flexible and extendable. In 1962, Rungis is chosen because it is located close to functional transport infrastructures (main roads around Paris and Orly international airport). The market opening is in 1969. Forty pavilions, sectored according the traded goods, form a regular alignment and are separated by parking areas and arterial roads for internal circulation. A goods station completes the 230 ha of the National Market (Marché d'Intérêt National, MIN). Management is entrusted to SEMMARIS, a semi-public company that is technically and economically responsible of the MIN.
Rungis is one of 16 MINs in France. It is the one that has started the State dynamic of formalization of wholesale markets supplying large urban centers. Gradually becoming outdated (competition with agribusiness), the MINs were reformed in 2004, giving local communities greater autonomy for their management.
However, the evolution of consumption has profoundly affected the success of Rungis. The domestic market has not been responsive to the development of new products (frozen, freeze dried, processed...) that pass through major retailors and their central purchasing bodies. The sizing of the MIN becomes too important for the use made of it. An international dimension emerges. First, the goods passing through the marketplace are intended to supply cities abroad (London, especially for products of southern Europe). And a consulting firm offers the expertise of the SEMMARIS agents on management and development. Moreover, an office of the *Rungis* brand was exported to London (Covent Garden Market) and a close collaboration is born, including the sharing of experience.
Away from the outgoing logic (state control of local trade and national), Rungis is now in decline. The diminishing importance of national production (subsistence agriculture) led the wholesale markets to restructure. The international opening and the creation of parallel professional branches (marketing, consulting ...) illustrate the attempt of the MINs to be maintained, in urban contexts, however, more favorable to the extension of the commercial network of the supermarkets.

3. Results

3.1 The path of the governance: from centralized State to relegated State

From the end of the *Ancien Régime* to the present day, governance of the food supply has been reset continuously. From a centralized state that managed all matters concerning the supply of the Parisians, the food system has now passed into the hands of the private world of business.

At the French Revolution, the depletion of populations' amount differences between Paris and other French cities is partly due to the diversification of the supply means: it is the "revenge of the merchants' profits onto the tax levy, [the revenge of the] openness onto the world of earthly society, [the revenge of the] the market economy onto the state administration" (Lepetit, 1995, p.94). But according to Kaplan (1988), modernization of the supply means does not fundamentally change consumer attitudes against the State. The progressive globalization of the economy

(internationalization of economic relations, including the intensification of inter and intra colonial trade) puts forward the principle of market economy to which population and public authorities oppose the superiority of social demands. The trend is probably twofold. Market and principle of market economy are therefore political positions borrowed alternatively by governments and merchants.

However, the Industrial Revolution has led to technical progresses that have impacted all key areas of the food system. First, producing and routing facilities are systematized and streamlined. The responsibility now rests on private and public trusts. These companies first concern transportation (rail, initially) and then gradually handles the other components of the food system. The industry comes into production (improved farming techniques, farm businesses in the "new world") and distribution (rationalization of distribution and concentration at Les Halles Market).

This privatization trend has been continuing to this day. After WWII, the State is still relatively strong and highly centralized. Nevertheless, the priorities of government deviate from Paris food supply. Indeed, the material reconstruction of the country, the management of urban growth (shift to a service economy, rural exodus and international migrations) as well as considerations for international politics (decolonization and repatriations management, construction and development of a European Common Agricultural Policy) lead the public authorities to a withdrawal from food governance. Still in charge of quality control of foodstuffs (public health) and the balance of goods in transit on the domestic territory (customs), the role of the State is gradually becoming marginal to the omnipotence of agribusiness companies.

3.2 Spatial and urban planning at the heart of food supply concerns

During history, food supply has been a crucial issue for the authorities. They made of the capital city an essential node which polarizes the whole territory. This is obvious in terms of transportation: infrastructures were designed radially and concentrically around Paris; natural routes were arranged so that all can converge toward Paris. The urban site is fully optimized since the foodstuffs can reach from around the world.
It is the same inside the city: the facilities are designed to rationalize the supply. Initially, the concentration on a market was for the State to control transactions, but this structure has persisted because it allows an orderly supply. Haussmann's urban restructuration has optimized the supply, at least for a moment. As well, Les Halles Market's transfer to Rungis, closer to the national and international transportation infrastructures is the same movement: on the orders of public authorities, Paris relocates one of its functions outside its own territory, and further accentuates its functional influence on the national territory.
The privatization of supply did not reverse the trend. Instead, the companies responsible to route the food to Paris use the access roads provided by the State. As Rungis Market, CPBs of large retailers are excluded from inner Paris area, and their location depends more on the reported profitability and on land freight rates than on the consistency of proximity to the city.

The extension of the supply area of Paris is obvious. The international opening has been a milestone since the end of the *Ancien Régime*. International trade and technical-industrial revolution of the 19th century are the basis of this configuration of the hinterland. This is not a matter of planning, the specialization of agricultural areas is part of a global mechanism due to various factors (economical, financial, commercial, historical, climatic, diplomatic…).

4. Conclusion

History enlights a view over the periods that preceded us and the transitions that accompanied them. Nowadays, the relocation of the hinterland is a burning issue: it mobilizes a growing number of stakeholders and challenges the foundations of the global and privatized food system that governs us since the 1950s. On behalf of sustainable development, some say we should at all costs overcome this system. Indeed, it abolishes all values of equity (unfair trade), viability (mismatch between economic development and ecological enhancement of territories) and bearability (inadequacy of chemical-technical industry with public health priorities). This historical synthesis offers a reading key for the evolution of our food system: nothing was done without transition. No rupture is possible with the food system that rules us. But it seems likely that we live in a period of transition. Paris is an example of one of these rich cities that include some of the citizens and politicians to question the hegemony of the private and global agribusiness system. Emerging initiatives suggest that the invective of sustainable development has entered the common awareness. The shortening of some delivery circuits (direct sales) and the enthusiasm to go "back to the land" (community gardens, intra-urban or suburban productive areas…) can be plotters, leading signals suggesting that the food system is changing.
In France, and in Paris, this relocation will appeal (without using those terms specifically) to the proximity of a natural hinterland once optimally located on the outskirts of the city and that no longer exists. Supporters of this relocation are probably tagged by over a century of suburban legend, colored by the theories of the German economist Von Thünen and the utopia of the British urban planner Howard. Following the findings of this paper, the natural hinterland is to be relativized. First, no backtracking is possible in the the current system. Changes, if they are perennial, will be due to the innovations and to adaptation of some already known but renewed processes. Furthermore, we demonstrated that the natural hinterland, as defined in the introduction, has never matched the ring road of Paris. In his most spatially concentrated, the Parisian hinterland corresponded to the downstream of the Seine-river's watershed. But our demonstration helped to see that for over three centuries, Paris food needs polarize ad minima the whole country.
The importance of considering spatial and urban planning to gather consumption and production areas, is to be found in the principles of territorial ecology. This scientific field, under construction, considers a territory, together with the flows that supply it (and the ones it generates) and the actors who govern it. This set should be taken into account in any sustainable attempt to relocate the hinterland. Indeed, localism and proximity are two concepts, not to be confused. The first attempts to impose by whatever means the notion of local, which can lead to ideological dangerous shifts

(national or local fallback, borders glorification, excessive protectionism, "food fascism"…). Instead, the idea of proximity enables a step by step reflection, without giving limits for the relocation, and considers values of *rescale, respace* and *reconnect* (Kneafsey, 2010).

DEVELOPMENTAL STATE, NEOLIBERAL PRINCIPLES, TRANSFORMATION OF PUBLIC HOUSING POLICY IN SINGAPORE

Jun Wang[1]

Abstract

Among studies on variegated neoliberalization, a great deal of attention has been directed towards the Asian Tigers, where the neoliberal logic lands in a territory previously dominated by Developmentalism. Empirical studies unveil such an unstructured pattern of variegations that fuel the debates on the frictions between neoliberalism and state-led developmentalism. Situated in this concern, this study attempts to examine the frictional process through a longitudinal study on public housing policy transformation in Singapore, with the focus on the pathway revealed by successive rounds of neoliberal regulatory experiments.

Singapore might offer an interesting laboratory for studies on this topic for the following two reasons: a) TNCs dominate the economic life of the city-state, and the city has always ranked high on the Index of Economic Freedom by the Heritage Foundation; b) the Singapore party state not only plans and intervenes in the country's economic development, but also appropriates the state apparatus such that a number of scholars classify its model as State Capitalism. Open economy and state dominance seem to co-exist shoulder-to-shoulder for decades in the city-size country, and thus, the intensified conflicts between developmentalism and neoliberalism might inspire studies with either empirical or theoretical endeavors. The study examines the transformation of public housing policy and schemes from 1979 to 2011, identifying two stages. During the first stage, a series of market-oriented regulation relaxation and financial liberalization have been carried out, with the main drivers more than often domestic in origin. The second stage is featured by active involvement of international capital, which pursues a ticket to penetrate the domestic market that was dominated by the Government-Linked Corporations and to participate in the decision-making process that was confined to the state and its arms. This is a non-linear path, while the latest scheme of DBSS splits the two sides of

[1] Hong Kong Baptists University, Kowloon Tang, KL, Hong Kong - Jwang312@hkbu.edu.hk

public housing sector, with one side opened wider to the private sector for capital accumulation whist the other side as a governable space reclaimed by the state.

1 Introduction

Among studies on variegated neoliberalization (Peck and Theodore, 2007, Brenner et al., 2010), a great deal of attention has been directed towards the Asian Tigers, where the neoliberal logic lands in a territory previously dominated by Developmentalism (Weiss, 2004, Ong, 2007, Park et al., 2012). In concept, the two utopian projects of Neoliberalism and Developmentalism clash at their ideological cores which, guided by different norms, serve to justify interests of different social forces and power relations (Chang, 1999, Ong, 2006, Park et al., 2012). In empirical, studies on developmental states have unveiled either varied, hybrid modalities or mobile, and dynamic processes that tend to portray an "unstructured" pattern of variegation (Brenner et al., 2010). The conflict in ideology and deviations reported in empirical studies fuel continuous debates on the friction between Neoliberalism and Developmentalism (see Weiss, 2004, Park et al., 2012).

In a very concise sense, neoliberals put "egoism" as the basic law of society (von Hayek, 2005). Advocates of neoliberalism act wisely when they frame the discourse based on "individual liberty and freedom as sacrosanct" (Harvey, 2006a), which makes the removal of any constraint used to embed the Keynesian capitalist system necessary. Neoliberalism, therefore, is in fact a political project that restores the power of economic elites and reestablishes the condition for capital accumulation by naturalizing and legitimizing the idea of a free market. The neoliberal political regime embarks on institutional reforms featured by privatization, marketization, and commodification. Moreover, the requisite for the construction of a competitive market and a free economy is extended to social society, which must be economically and socially attended by the state (Peck and Tickell, 2002).

On the other hand, Developmentalism advocates Confucian values and collectivism. One must trace back to the original historical setting of Japan at the time of the Meiji Restoration to understand the rationale of Developmentalism (Chang, 1999, Hill et al., 2012). Facing the intrusion of the liberal model brought about by Western military conquests and the economic domination by foreign companies, the Japanese government was in urgent need of instant economic growth. The Japanese government resorted to Confucian values, in which the collective interest supersedes individual ones. A strong state, which represents the general will of the entire nation as one person, is thus claimed to be the leader of economic change through a full-fledge exercise of government instrumentality. Correspondingly, public ownership and strategic planning are institutional means to best achieve national economic development. The State-led Developmentalist model soon thereafter spread in Asia, being adopted by South Korea, Hong Kong, and Singapore, and recently by other countries, such as Malaysia and China.

Given the conflicts at their normative orientations, the current occurrences in developmental states in the global tidal wave of neoliberalism become interesting. Studies have reported diverse opinions. Market-oriented regulatory reforms are generally acknowledged, but scholars disagree with one another in terms of whether market-oriented regulatory changes are defined as transformation or cooperation, are driven by international forces or proactively taken by the state in response to changing circumstances, or by liaised inside and outside forces (Weiss, 2004, Ahmed, 2009, Stubbs, 2009, Park et al., 2012).

Aihwa Ong calls for a wider order of theoretical structure, in which Asian countries are perhaps "an extreme case," or "variants of the (global north), based on historical and geographical contingencies" (Ong and Zhang, 2008). Following Foucault's (1991) theory of governmentality, Ong (2006) goes to the abstract level to introduce her concept of "neoliberalism with a small n" for Asian developmental states, which triggered heated contestations in theorizing neoliberalization (Brenner et al., 2010, Peck, 2010). Scholars in the governmentality approach conceive neoliberalism as a technology of rule (Rose, 1999, Ong, 2006). The state imposes the idea to the ruled that " 'we' – the universal and undifferentiated subjects of the present – have entered the sunny uplands of liberty and human right" by shaping the discourse on freedom (Rose, 1999). Therefore, it is the call from the new era, in which self-enterprising and self-managing subjects live, that "places the ground upon which government must enact its practices" to remove impediments to free market (Rose, 1999).

The severest critique to the governmentality approach might come from Brenner, Peck, and Theodore (2010). They argue that the over-emphasis on instability, hybridity, and contextually specific presence fails to explain the "inter-jurisdictional family resemblances, interdependencies and interconnections" (206-207). Brenner et al. reiterate their theory of variegated neoliberalization, namely, the systemic production of geoinstitutional differentiation, by which they stress that "neoliberalization processes are simultaneously patterned, interconnected, locally specific, contested, and unstable" (185). The methodological flaw in the governmentality approach, as explained, is the lack of a broader view on the "context of context - specifically, the evolving macrospatial frameworks and interspatial circulatory systems in which local regulatory projects unfold." Local areas are not isolated from wider transnational political processes espoused by transnational corporations (TNCs), liberal intellectual elites in educational institutions and think tanks, and international financial institutions, such as the International Monetary Fund and the World Bank (Harvey, 2006b, Peet, 2007). Neoliberalization relies on the dialectic among different spatial scales of economic and political organizations and the mutual constitution of structure and agency across different levels (Cox, 1998).

The interactions between inherited institutional landscape and neoliberal experiments are agreed to matter in the transformation of an institutional framework (as constellations of normative orientations and organizational arrangements) (Weiss,

2004), but the question contested is how much is the room for the state to maneuver as a component of the regime.

Singapore offers an interesting laboratory for studies on this topic for the following two reasons: a) TNCs dominate the economic life of the city-state, and the city has always ranked high on the Index of Economic Freedom by the Heritage Foundation; b) the Singapore party state not only plans and intervenes in the country's economic development, but also appropriates the state apparatus such that a number of scholars classify its model as State Capitalism (Rodan and Jayasuriya, 2009). Open economy and state dominance seem to co-exist shoulder-to-shoulder for decades in the city-size country, and thus, the intensified conflicts between developmentalism and neoliberalism might inspire studies with either empirical or theoretical endeavors. The sector of housing development belongs to the latter category, which has been gradually pried open by international forces after 1997. Parallel with the state-led urban landscape beautification process for a post-modern cosmopolitan image, the long suppressed desire of (transnational) private developers for a bigger role has started to bear fruit.

Enveloped within this concern, this paper attempts to examine the frictional process between Neoliberalism and State-led Developmentalism through a longitudinal study on the public housing policy changes in Singapore, with a focus on the transformation of institutional framework as constellations of normative orientations and organizational arrangements. Particularly, the period under examination of this study is from 1979 to 2011. Through the experimental and frictional processes between the two forces of neoliberal globalization and the authoritarian state, this study attempts to shed light on studies regarding neoliberalization in developmental states.

2 Singapore in the context: Strategic pragmatism

Unlike the other developmental states of Japan and South Korea, Singapore's economic life is unique in the degree to which national economic growth has been so heavily reliant on international capital (Schein, 1996). Given the absence of a strong domestic bourgeoisie class and a colonial legacy that has contributed to the openness of trade (Rodan, 2004a), the resolution of an export-oriented manufacturing base run by foreign investment seemed natural. Articulated in support of national objectives, numerous policies are promulgated in favor of the interests of Multinational Enterprises, such as removing impediments to free trade and open economy. Nevertheless, efforts to attract foreign investment are not indiscriminate. What distinguishes Singapore is what Schein (1996) termed as the "strategic pragmatism", characterizing the working style of the Singapore Economic Development Board (EDB), which was a statutory board set up in 1961 to attract foreign investment. By strategic pragmatism, Schein highlights that the state picks "targeting industrial sectors" by plan and indulges them in globalization-oriented free market (Pereira, 2008). In other words, sectors not on the list of targeted industries are living on the flip side of an open economy, that is, state dominance. This condition is particularly

true for several key sectors with close linkages to the domestic market, such as media (Ibrahim, 2007) and land development (Lee, 2010).

Starting from Singapore's self-rule, policies on land-based development aimed at centralization of control. Through a series of measures, such as compulsory land acquisition assisted by the Land Acquisition Act, land reclamation, and land-lease legislation, the state became the primary landowner in Singapore, directly or indirectly owning approximately 80% of the land. The land, after acquisition and amalgamation, is either allocated to its arms, such as the Housing and Development Board (HDB) for public housing, or leased to the private sector. Through this mechanism, the state plans and tracks land released into the public and private sectors on the basis of projected demand (Lee, 2010). The control of land allows the state to influence the proportional share of private and public housing sectors. Sitting on the allocated state land parcels that are cautiously planned in the master plan, public housing easily gained popularity for its lower price, better locations in infrastructure terms, among others. Within a relatively short time, public housing has become the "common bond for all," accommodating approximately 85% of the whole population.

3 Stage One: liberalizing the resale market of public housing

Singapore's public housing is in ownership terms, with the Home Ownership Scheme (HOS) introduced in 1964. At that time, worries that public housing might become a vehicle for speculation restricted the liquidity of these assets. Hence, ownership rights were initially limited by numerous regulations concerning eligibility conditions for purchase, resale, subletting, and housing loans. Since the 1980s, a series of events related to regulation relaxation and financial liberalization reshaped public housing into a liquid asset, the value of which lies in the resale market.

Over decades of explorations and experiments, the state and its arms, including the HDB, Government of Singapore Investment Corporation (GIC), and Central Provident Fund (CPF) Board, have formed an almost closed loop of capital flow in public housing production and consumption (Figure 1). In the circuit, the scheme of CPF is a crucial financial tool through which individual savings are channeled to the largest single pool of investable funds. The mobilization of CPF money not only makes construction of public housing at a massive scale possible at the macro level, but also boosts housing ownership consumption at the micro level.

Established as a pension plan in 1955 by the colonial government, the initial objective of CPF was to provide social security for the working population in Singapore. For individuals, CPF accounts are compulsory savings accounts to which both employers and employees make monthly contributions at specified rates. Two years after the implementation of the HOS scheme, public housing consumers are allowed to withdraw money from their CPF accounts for down payment. By selling Singapore Government Securities (SGS) to the CPF Board, GIC - a subsidiary of the

Ministry of Finance - absorbs this increasingly large amount of forced savings and redirects part of them to HDB through schemes of Annual Grant and Development Loans. Sitting on this financial support and cheap state-owned land, HDB is able to invest on public housing development and sell the dwellings at a price lower than that in the private market. Individual consumers, the actor at the other end of the circuit, may apply to the CPF Board for a deduction of down payment from their personal CPF accounts. Moreover, after receiving another financial support called the Mortgage Finance Loan from the government, HDB also plays the role of a commercial bank, offering HDB mortgage loans to consumers for 80% of the total property value. In this way, national saving accounts are productively employed to finance housing development at the macro level, as well as housing consumption at the micro level.

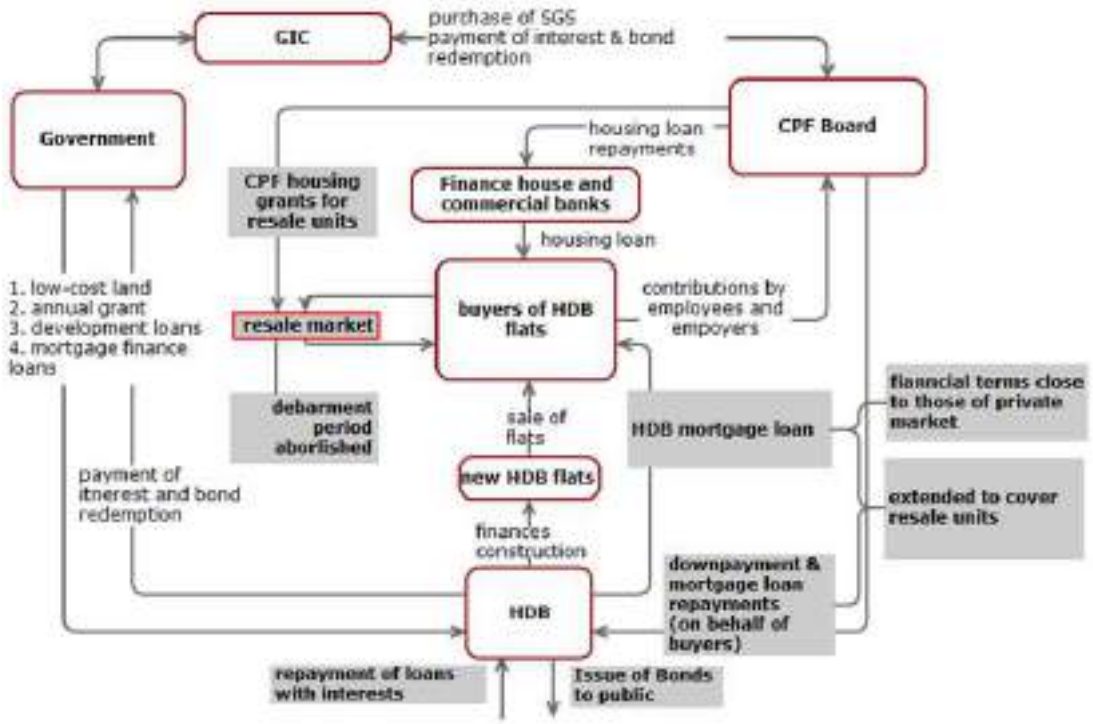

Figure 1: Financing public housing (developed upon the diagrams by Ng, 2000; and Phang, 2001)

Also within this framework, carefully timed measures are introduced to liquidize the asset of public housing on the resale market by replacing coercive rules with new financial technologies. The resale market, although in place as early as 1971, was constrained by many conditions. Among these regulations, the debarment period is a great deterrent for households considering the sale of their flats. Under this condition, the seller was debarred from applying for another public housing unit for one year. This largely limited volume of housing stocks that were placed in the resale market. Hence, 1979, the year in which the debarment period was demolished, is referred to as a turning point for a conceptual shift from public housing as a means to attach

people to the land, as claimed by Lee, to public housing as a liquid asset tradable on the market. In 1979, the regulation on the debarment period was replaced by a new scheme in relation to a resale transaction levy, which was further replaced by a graded levy system in 1985. In 1993, the HDB moved its mortgage financing terms for resale units closer to market practice by granting loan financing of up to 80% of the current valuation or the declared resale price of a housing flat, whichever is lower. In 1993, the CPF Board also began to allow withdrawals of CPF savings to be used to meet interest payments on mortgage loans for resale units. One year later, another scheme for resale units called "CPF Housing Grants" was announced, extending subsidies tied to new flats to resale flats. The subsidy is deposited into the CPF account of the eligible household upon application. Under the scheme, the government provides the eligible applicant household a grant of SG$30,000, with the figure increasing in 1995.

The threshold line for people to become eligible resale unit consumers has been lowered to accommodate permanent residents and the local economic elite in 1989. On one hand, access to subsidized public housing is offered as carrot to lure foreign professionals in exchange for their applications for permanent resident status. On the other hand, the relaxation indeed enlarges the pool of potential consumers, which is more critical when we consider the socioeconomic characteristics of these two population segments, which were private housing market residents with apparently higher purchasing power.

As a result, the resale market of public housing blossomed in a relatively short time span, the operation of which showed close correlation with the private housing market (Tu and Wong, 2002). Not only did the volume of transactions go up, but the fluctuation of transaction prices also resembled that of the private market closely (see Phang, 2001). The market-oriented institutional reforms resemble several features of neoliberalization, but all regulatory restructuring were driven by governmental forces and were constrained in the state-centered organization structure. What makes the case of Singapore different is the almost closed circular loop of capital flow, along which interests of the networked government and its associates are channeled with the assistance and intervention of financial tools.

4 Stage two: prying open the big cake of the public housing market

4.1 The context of context

The Asian financial crisis of 1997 significantly affected the island-state's economy and brought about fear of insecurity to its party state, which appropriates economic growth as one most important source of legitimation (Castells, 1992, Low, 1998). Afterwards, the anxiety rose to a new level because of Singapore's worst economic recession in 2001 and the economic stagnation in Southeast Asian region. Criticism of state capitalism from the international business community became powerful, something that was conspicuously absent in previous decades under the authoritative

state. Instead of requesting for a mechanism of a liberal market for it has been operating in Singapore, what international capital pursued was a ticket to penetrate the domestic market that was dominated by the GLCs and to participate in the decision-making process that was confined to the state and its arms. International capital aimed to eventually find a way by which to tear open the closely knitted network of the state, the GLCs, and the state capitalist class (Rodan, 2004b).

4.2 Participation of the private sector in decision making

The authoritative state of Singapore puts on a humble face, introducing the gardener analogy to illustrate the new role that government would play, a "catalyst that allows all kinds of organisms to thrive in a cooperate setting" (Ong, 2005). The government, unprecedentedly, also acknowledges that the process needs help from the private sector, who knows better how to cater to the market needs and the rising aspirations of the affluent.

The channel for communication between the state and the private sector is a new committee called the Economic Review Committee, which, as suggested by the CSC, should incorporate representatives from the three major sectors, namely, government, unions, and private entities. Under the sub-committee on Taxation, Wages, CPF and Land, the Land Focus Group is convened to review all policies, schemes that are related to land development. Influence from the private sector, especially transnational corporations is obvious. Of the 11 members of the Land Focus Group, three are senior managers of TNCs[2], three are from Singapore-headquartered Multi-national Corporations (MNCs), and two are from GLCs, whereas the remaining members are government officials. The private sector's long-suppressed desire for more participation has gathered momentum. Planning laws, such as the Land Title (Strata) Act and the Planning Act, along with many other regulations, such as the Controller of Housing regulations, were identified by the committee as "rules, regulations, and practices that needed immediate review" (Land Working Group, 2002). The government was urged to minimize its participation in the market, but encouraged to initiate infrastructure construction for land value creation and institutional reform to reduce the cost to investors.

4.3 Introducing private developers to public housing

Under this circumstance, public housing development in Singapore turns to a new chapter, especially in terms of the relationship between the state and the private capital. New schemes were announced, such as the Selective En Bloc Redevelopment Scheme (SERS), Executive Condominium (EC), as well as the Design, Build, Sell Scheme (DBSS). Although the first scheme allows private capital to participate sporadically through outsourcing, the latter two schemes offer private

---

[2] TNCs include: Hewlett Packard Asia Pacific Ltd, Knight Frank Pte Ltd, and Exxonmobil Chemical Asia Pacific; MNCs include: Fraser & Neave Ltd, Wing Tai Holding Ltd and YCH Group Pte Ltd; GLCs inlcude: Capital Land and Singapore Airline Ltd.

developers more significant autonomy. These two schemes have many commonalities. First, under both schemes, the government auctions state land on a 99-year leasehold basis to developers, who are granted freedom to design, build, and sell housing stocks at a price comparable with those in the private market. Second, target customers of the two schemes significantly overlap, that is, the new rich who desire something more than the standardized ordinary public housing but find private market housing out of reach for the time being.

Since the inception of the EC scheme in 1996, a total of 21 projects have been completed. The field has clearly been dominated by GLCs, the mergers of which in later years merely resulted in the concentration of EC properties in giant government-linked conglomerates. According to the data, 15 out of all 21 projects were developed by GLCs and their subsidiaries. For instance, nine estates, such as the pioneer project of Chestervale, were developed by subsidiaries of either Pidemco Land Ltd or its shareholder, Singapore Technologies Properties Pte Ltd (STP), a subsidiary of Singapore Technology Group (ST) that encompasses critical sectors of national significance, namely, aerospace, electronics, land systems, and marine systems. After acquiring 24.6% of Development Bank of Singapore (DBS) Land, STP, which was then the shareholder of both Pidemco Land and DBS Land, urged a merger of the two. This merger resulted in the birth of the giant developer Capital Land in 2000.

In comparison, the GLCs' influence on the DBSS scheme evidently declined, the form through which the state and the international capital participate became indirect. . Since 2005, 13 land parcels have been put on sale for DBSS development, of which 12 have been awarded, nine to private developers and three to a joint venture. For instance, one big winner under this scheme is the consortium comprising Hoi Hup Realty Pte Ltd and Sunway Developments Pte Ltd. Hoi Hup is a well-established local developer that owns many properties on freehold land, and Sunway is the Malaysian conglomerate that forged strategic partnerships with global investors, such as GIC, Malaysian Provident Fund, Kuwait Finance House, and Goldman Sachs. Meanwhile, several private developers also managed to expand their business from humble beginnings as builders or building material traders to property developers. Such is the case for six out of the total eight developers. Sim Lian Land (SLL) is an example that continues its exploration in the public housing sector, developing one EC project and three DBSS projects. Thus far, the claimed business-friendly environment for all organisms to thrive seems emergent. This environment might be more evident from a closer examination of the geographical distribution of these projects, given that location is always at the core of real estate development.

4.4 Preserving the authoritarian state

The fundamental difference between the EC and DBSS schemes may lie in the official categories where they belong. In a concise sense, the EC is taken as private development at its final stage, whereas DBSS is envisaged as public housing. Public housing in Singapore might be an excellent case to demonstrate Foucault's (1991) concept of Governmentalization of the state. As illustrated by Rose (1999),

"invention and assembly of a whole array of technologies that connect calculations and strategies developed in political centers to those spatially scattered points where the constitutional, fiscal, organizational and judicial powers of the state connect with endeavors to manage economic life…and habits of the population." This change in the property manage sector reclaims the power of the state over the DBSS community, which is a governable space where a series of institutions have been set up over the years to shape, guide, and direct the conduct of community members. Nevertheless, DBSS residents are not exactly the same as the remaining members of the public housing community; on average, they paid significantly more for their flats. Complaints on the sky-high prices of DBSS projects are gaining momentum, triggering heated debates on the DBSS profit margin. In response, the ethos of neoliberalism as a technology of governance was employed.

On 24 June 2011, an article entitled "Time to slay the DBSS 'monster'" on "The Straits Times" triggered a stir in media (24 June 2011). The reporter reminded the public that, "Today, the 'monster' is rearing its ugly head – in the form of a record-setting SG$880,000[3] three-bedroom flat" in the Central 8 project developed by Sim Lian Group. Under this program, the reporter wrote, "developers profiting from high premiums slapped on homes and buyers seduced by unrealistic expectations of capital gains." Several days later, an article entitled "Profit margins for DBSS developers 'look high'", was published on "The Business Times" (30 June 2011), estimating that developers may make a gross profit margin of 20% to 33%, with that of the Central 8 project by the Sim Lian Group rising to an eye-catching 76% compared with an average 30% to 40% profit margin in private developments. The extreme case was immediately corrected by government officials, that is, the Director of Housing at the Ministry of National Development (MND), who published an article that highlights the errors in calculation on "The Business Times," as well as the Minister of MND on his blog, new entry of which has always been reported by the mass media like the several main TV channels. The government clarified that the margin of the Central 8 project had been exaggerated, and the press had to apologize. In another blog entry by the minister, Khaw, in fact, acknowledges that the price has caused discontent of the public, who requested the MND to step in and regulate. However, Khaw reminds the public that the power is at their hands, their power as consumer and their consumption behavior in the market will affect pricing. In contrast, any intervention by the state, that is, by MND, will only "damage Singapore's reputation as a business hub, with severe repercussions". In other words, self-enterprising behavior requires non-intervention of the government because only in the mechanism of a non-interrupted market can consumer preference become a determinant of price.

[3] Prices of ordinary new three-bedroom public housing are pegged from SG$116,000 to SG$188,000 in the year 2010 (HDB, 2011).

5 Conclusion

Analyses on public housing institutional restructuring in Singapore, while shedding light on neoliberal regulatory experiments in the developmental states, might generally have broader aspirations on theorizing neoliberalization.

This study uncovers an experimental process with trial and error. Basically, two stages with distinctive features are identified. The first stage, from 1979 to 1996, witnessed a series of market-oriented deregulation and liberalization initiatives that boosted the resale market of public housing. Since 1996, the regulatory restructuring of Singapore's public housing entered a new stage, in which state dominance was pried open to allow (international) private capital to join as a new player in the public housing sector. At the core of the developmental state of Singapore might be the organizational structure, which explicitly defines who are members and who are not. Meanwhile, the normative orientation of Developmentalism, that is, Collectivism, does not seem to resist the neoliberal principle of the free market. Hence, (international) private capital, at the time of the economic crisis and stagnation, aims at prying open the tightly woven net of the state, its statutory boards, and GLCs that used to dominate the domestic market of non-targeted industries, land-development in this case, as well as the decision-making process at the policy level.

The EC and DBSS, implemented in 1996 and 2005 respectively, are instructive in illustrating the dynamic and frictional negotiations between the authoritarian state and private capital. Although the policy of EC implies a more complete withdrawal of the state and its arms, possibly a hasty attempt to pull the public housing market out of the doldrums, the DBSS is a modified version that takes better care of both state and private capital interests. DBSS splits the two sides of public housing sector, with one side opened wider to private sector for capital accumulation whist the other side as a governable space reclaimed by the state. The case of Singapore's pubic housing might put us to another reflection on the neoliberal statement of "individual liberty and freedom as sacrosanct", which places neoliberals on the moral highland (Harvey, 2005). Importantly, transnational forces which urge for neoliberal regulatory reforms may be only partially or periodically attracted to individual liberty so that to differing degrees, these reform pressures can be accommodated by authoritarian regimes.

Urban strategies and post-event legacy: the cases of summer Olympic cities

Dr. Yawei Chen MSc, Assistant Professor

Department of Real Estate and Housing, School of Architecture, Delft University of technology, Delft, the Netherlands

Email: y.chen@tudelft.nl, 00 31 15 2781272, 00 31 639251385

Abstract

Mega-event strategies and their impact on host cities have drawn increasing interest, as organising large-scale urban events has become part of a deliberate urban policy strategy to promote local economic growth, improve the city image and put the host city on the world agenda. Most cities stressed exploring city marketing and reimaging effect of these mega events, like the construction of iconic flagship projects or large scale facilities and infrastructures; however, limited attention has been paid towards what legacies these strategies have created on host cities' long-term development, like the post-use of event venues, facilities and related infrastructure. Even less attention was paid toward the long-term effect of these mega-events on host cities' economic growth, social development and environmental upgrading.

This research critically examines the use of mega event strategy in urban development process in the Summer Olympic host cities since 1992 and the legacy left after the Games was over. Data has been collected through fieldwork and literature review. The research identifies urban strategies different host cities have adopted on program definition, organisation structure and development process and evaluate their effect on post-event legacy. This paper suggests that, although host cities may emphasize one particular perspective, it is important for host cities to take a more integral approach to guide the whole process from pre-event preparation and event hosting to post-event development. Such approach may take more care of the balance development of the host cities in economic, social and environmental perspectives and have better chances in sustaining mega-event impact. In particular, urban strategies should pay attention to the establishment of economic functions, social integration and sustainable re-use of post physical legacy in the long-term.

Keywords- Summer Olympic Games, urban strategy, post-event legacy, Barcelona, Beijing

Introduction

The Olympics is one of the world's great 'mega-events'. The Games' five-ring symbol alone can be recognised by approximately 90% of the world's population. Given the event's significance, studies have paid increasing attention to the Olympics in recent years. A large-scale undertaking such as the Olympics can act as a catalyst for local – and even regional – economic development, attracting mass investment, tourists and the global media to the host city. Indeed, host cities generally attach great importance to factors such as the Games' economic implications, event-related income, and the development of tourism. A number of studies have looked at the economic implications of staging the Olympics for host cities. Most studies attempt to identify the economic benefits, either measuring the extent to which such benefits offset the costs, or the extent to which such benefits can be sustained in the long term (Preuss 2004; Austrian and Rosentraub 2002; Kasimati 2003; Gratton et al. 2006; Whitson and Horne 2006). Others, meanwhile, focus on the development of Olympic tourism (Pyo et al. 1988; Higham 2004; Gotham 2005; Weed 2008; Van den Berg et al. 2002). In addition to the economic implications, a number of studies have drawn attention to the Games' likely social-cultural and environmental impact. With respect to social factors, there has been particular interest in the Games' social impact on local communities. It has been found, for instance, that while such an event may engender a local community's sense of self-worth or stimulate participation in sport at the community level, hosting the Olympics can also have negative social effects, particularly on housing and tenants' rights and processes of social gentrification (Jones 2001; Olds 1998; Waitt 2003). From an environmental perspective, the relevant studies have not only focused on the technical details of the International Olympic Committee's (IOC's) environmental requirements, but also increasingly link these to the issue of sustainable development.

Although the Olympic Games usually have a great impact on a host city's spatial structure, due to the IOC's requirements regarding the construction of gigantic sports venues and facilities, studies of the Games have been largely concerned with cities' economic or social motivations for hosting the event. In recent years, the Olympic Games have increasingly been viewed as a means of stimulating urban development processes, on the grounds that the erection of landmarks, the development of infrastructure, and urban renewal processes frequently transform an urban space (Chalkley and Essex 1999; Roche 2000; Gold and Gold 2006). The Olympics' role as a catalyst for urban development and regeneration was first identified in a bidding document in 1992, when Barcelona was preparing for its Olympics. Owing to its use of the Olympic legacy, increased capital flows and its improved attractiveness as a city, Barcelona was able to boost its economic growth, enhance its image, and transform itself into a

globally competitive city. Barcelona's success is one indication of the significance that the Olympic Games can have for urban development practices and urban policy in host cities, and equally, the importance of understanding the Olympic Games from an urban development perspective.
With a view to this, the objective of this paper is to review the existing literature on cities that have hosted the Summer Olympic Games, from the perspective of urban development. In doing so, this paper attempt to draw links between the Olympic Games and urban regeneration practices, in terms of motivations, development strategies, and post-event legacy. This paper does not, however, attempt to draw any conclusions as to how cities should capitalise on hosting the Olympic Games, nor does it propose the best strategies for interlinking the Olympic Games with legacy. Instead, the objective of this paper is to provide an overview of the different approaches adopted by the host cities, their underlying motives, and the expected or actual legacy.

The article is structured as follows. It begins by explaining the context of the Summer Olympic Games, and what motivated the cities to make such enthusiastic bids to host the Games in the context of globalisation. It then examines the various urban development strategies that were used to translate the host cities' visions and goals into reality. In the next section, post-Games legacy were examined, followed by the synthesis on the interrelationship between strategies and legacy in the years following the Games. We finally conclude by presenting the results of the literature review. We highlight the contrasts and contradictions provoked by the strategy of using the Summer Olympic Games as a catalyst for stimulating both urban development in host cities and, ultimately, sustainable development.

Hosting the Olympic Games in the context of globalisation

The interrelationship between the Olympic Games and urban regeneration in host cities is often addressed from two distinct angles: those of the Games as a global phenomenon, and their local aspects. The reason for this is that the Games are a global event that unfolds in one particular place (Short 2008). Mega-events such as the Olympic Games have often been described as one of the primary expressions of the globalisation of culture; or, as Roche puts it, as "large-scale cultural (including commercial and sporting) events, which have a dramatic character, mass popular appeal and international significance" (Roche 2000). Roche argues that that such an event's ability to support and adapt to the time structure helps "to coordinate intergenerational cultural, political and economic flows and networks" at the global level (2003, 119). Moreover, the unique feelings of being in a 'global village' and 'one world awareness' that are provoked by the Games have been further strengthened by the emergence of

globally-mediated television broadcasting and advances in communications technology. Horne and Manzenreiter (2006), for example, suggest that exposure to vast global audiences allows a sport-media-business alliance to benefit from the promotion and association of business with sport. In this way, argues Roche (2006: 30), the Olympic Games have become “an element in the development of global culture” on local soil.

A number of factors can shape a city’s motivation for hosting the Games, including its circumstances prior to the Olympics, the key challenges that it faces, and its vision on how the Games can contribute to urban regeneration. With a view to this, studies have often positioned host cities, especially western industrial cities, in the context of deindustrialisation (Gratton and Henry 2001; Surborg et al. 2008). Prior to hosting the Olympics, many of the cities in question had ceded their roles in traditional industries to newly industrialised countries, and were facing significant challenges in the form of local economic depressions, unemployment and urban decay. Recognising the growing importance of the service sector and the creation of new leisure and consumption spaces in the post-Fordist urban economy, these cities chose to host the Olympic Games as a strategy for facilitating urban restructuring and transformation processes (Surborg et al. 2008; Hannigan 1998). Among the host cities since Summer Olympic Games 1992, as Table 1 has summarized, Barcelona, Athens and Beijing the initial motives for the Summer Olympics host cities. For cities, hosting the Games provides an incentive and opportunity for city elites to restructure their cities in an increasingly competitive environment.

Table 1 Olympic host cities: initiatives

City	Initiative stakeholders	Goal	Objectives	Integration with urban vision
Barcelona 1992	Local municipality Leadership under the mayor	New Barcelona	Adopt global opportunities; solve economic crisis; incorporate long-term development projects	Very strong
Atlanta 1996	Private party: Billy Payne and “Crazy Atlanta Nine’	International recognition	Establish a higher international profile; invest in deprived areas, revitalize inner city	weak
Sydney	Central government	Global	International tourism; Attract business and	Moderate

2000	and state government of New South Wales	positioning	investment; Green Games	
Athens 2004	Central government and municipal government	Put Athens back on the world map; restore Olympic value	Reurbanise the city; link ancient and modern culture; boost business and tourist market	Strong
Beijing 2008	Central government and municipal government	International recognition; national promotion	Modernization; economic restructuring; Greening the city	Very strong
London 2012	Non-profit organization BOA, supported by municipality government and supported by the Mayor	Create city spectacles	Regeneration of East London;	Strong

In the early days, hosting the Olympics meant little more than assuming responsibility for providing the necessary venues and accommodations for competitions. These activities inevitably led to a stimulus of the local construction industry, employment boost and a tourist boom. Over the time, the Olympic Games grew bigger and larger. The host cities hope to use the adoption of larger, more spectacular and inherently more expensive stadia to make statement about the technological progress and modernity of the host nation (Gold & Gold 2007). Given the Games' multiple dimensions and the broad range of actors involved, the Games' potential legacy can give a city a wide range of motivations, from the economic and the social, to the spatial and the environmental. Baim (2008), for example, distinguishes four primary reasons for host cities to place a bid for the Olympic Games: enhancing tourism; promoting more rapid infrastructure investment than would occur without the Games; promoting entrepreneurial goals; and gain recognition as a global city or nation. Baim also points out that, although no former host cities have exclusively

aimed for only one objective, all cities since 1972 games in Munich emphasized one of these goals more than other.

The Olympics and its catalyst effect of on urban regeneration

When Barcelona seems successfully transforming itself in a short time “from a ‘gray’ industrial city in the midst of a deep economic crisis to an international successful story a decade later” (Calavita & Ferrer 2000: 793), their mega-event–driven urban regeneration strategy became particularly popular. Host cities have routinely integrated the Olympic development with host cities’ long-term strategic planning and hope to result in a package of benefits. These benefits include boosting the urban economy, permanently repositioning the city in the global tourist market, promoting regeneration, allowing the revamping of transport and service infrastructures, create vibrant cultural quarters, and establishing a network of high-grade facilities that could serve as the basis for future bids (Gold and Gold 2008).

While the Olympic Games promise each host city “fast track urban regeneration, a stimulus to economic growth, improved transportation and cultural facilities, and enhanced global recognition and prestige” (Chalkley and Essex 1999), different host cities have taken different approaches to implementing urban regeneration programmes. Some of the main urban development strategies of the six host cities (1992-2012) that are relevant to post-event legacy can be summarized as following in table 2. In comparison with the abundant literature on the legacy of the Olympics, our knowledge of urban development strategies that are able to bridge the gap between vision and reality is rather fragmented. While many studies examine individual cases in particular host cities, only a few offer more general insights into urban regeneration or urban renewal strategies. Chalkley and Essex (1999) identify a general transition in urban development strategy, from an early emphasis on constructing gigantic sports facilities and urban infrastructure, to a much broader notion of urban regeneration and urban restructuring programmes that sees the Olympic Games as a catalyst. In the case of Berlin (1936), Rome (1960) and Tokyo (1964), for example, the host cities reconstructed and expanded existing facilities, constructed landmark buildings, and generally improved existing infrastructure in order to achieve urban upgrading. In the case of Montreal (1976) and Seoul (1988), meanwhile, Chalkley and Essex explore the role of the Olympics as a vehicle for urban change via the development of the Olympic venue. In these two cases, the sports facilities and Olympic Villages were developed in combination with urban renewal, and schemes for “improved traffic management, the enhancement of cultural facilities, an environmental beautification program and actions to ensure

health and hygiene standards throughout the city" (Chalkley and Essex 1999). Furthermore, the development of Olympic sites has been increasingly integrated into host cities' larger-scale urban development plans, enabling such sites to become sport and recreation complexes, harbour developments, housing, and tourist accommodation, once the Olympics have taken place.

Table 2 Main urban development strategies in Olympic host cities

City	Integration with urban program	Infrastructure upgrading	Post-use legacy strategy	Economic development	Social development
Barcelona 1992	Integrating Olympic plan with long-term spatial planning; Transforming 4 key location, including the redevelopment of the coastline and upgrading of deprived districts; New identity by creating new landmark, improved public space and facilities; Mixing function in land-use	Constructing major ring road and other transportation infrastructure;	The Olympic stadium has been used by a local football club; the stadium is used for hosting mega events; the game training venues were used for public use.	Enhancing tourism throughout the region through rebranding and tourism planning;	Providing housing for different income group

Atlanta 1996	Developing the Olympic Park at a central gathering point; redesigning the street corridors	Expansion of the airport; the MARTA rail system, road network and renovating bridges, telecommunications and sewage systems	The central positioning of the Olympic park aims to create post-use of Olympic venues and facilities; The Olympic stadium would transfer to the new baseball stadium for the Atlanta Braves; Olympic villages would be transferred to become a dormitory for a local university. Tourism strategy to ensure tourism expenditure; Improve skill level of local workforce;	Olympic trust to offer young people and diverse community the opportunity to fully participate;

Barcelona (1992) perhaps offers the most developed example of how the Olympics can function as a catalyst for urban development. Not only was Barcelona's urban structure modified through the development of four Olympic sites in different types of location (such as a low-income neighborhoods, a declining industrial site, and a waterfront area), but many programs that had already been proposed, such as the creation of public open spaces, the general improvement of public transportation, the opening of the city to the sea, the renovation of the city's cultural infrastructure, the landscaping of squares, and the commissioning of new sculptures, could finally be realised; programmes that

might otherwise have suffered long delays, or might have been cancelled altogether (Chalkley and Essex 1999; Marshall 2000, 2004; Monclú 2007; Coaffee 2007). Building on the so-called 'Barcelona model', Sydney (2000) continued the trend of integrating Olympic facilities with the city's Brownfield redevelopment (Chalkley and Essex 1999; Lochhead 2005; Lenskyj 2000). Sydney applied a detailed set of 'green guidelines' to the design, layout and construction of the Olympic facilities in the regeneration of a notorious polluted industrial site for redevelopment into the Olympic park (Chalkley and Essex 1999; 389). Sydney also attempted to achieve long-term vibrancy and variety in the area by mixing functions in its Olympic site development, providing sporting, entertainment, exhibition, commercial and residential facilities in the Homebush Bay. London (2012) uses the Olympics as a force for regeneration of the poorest and most deprived East London. The Olympic site was built on a 600-ha brownfield that has problem of contamination and toxicity,

An important but less well-examined issue is that of Olympic host cities' social regeneration strategies. While some identify the importance of community spirit, and suggest that participation is an essential means of improving community self-esteem and creating social coherence, other see social regeneration in terms of community empowerment, arguing that equipping people with skills through training and education (especially those in marginalised groups) will strengthen community development (Long and Sanderson 2001; Owen 2002; Waitt 2003; Regan 1999). In addition, a number of studies highlight the strategies that local communities can use to harness critical resources. The Games can function as an opportunity for job creation, the development and operation of leisure and recreation service opportunities, the upgrading of open spaces, and improved levels of public health and participation in sport. The existing literature is deeply inadequate when it comes to relating social development to spatial planning or urban renewal, however. The numerous studies on the Barcelona model are an exception in this respect, in that they look specifically at the social aspects of preparations for the Games, in term of housing for low-income groups and community participation (Marshall 2004). This particular strategy focused on how to benefit local communities and increase the welfare rights of low-income- and other vulnerable groups within local communities (such as housing and tenants' rights, job opportunities, and so forth). It is possible that this particular approach was the result of a number of factors, including: the leadership of the Community Party in local government, which stressed social welfare; the relative strength of neighborhood associations in the wake of the Franco regime; and the latter's direct involvement in decision-making processes, representing their own interests.

While most ambitious Olympic hosts use the Games as an opportunity to bring forward long-term plans, to accelerate the pace of change, or to introduce new planning concepts, using major events to achieve long-term urban goals has proven to be a difficult task to manage and implement. Since the end of 1980s, the transition towards a form of governance that gives greater weight to private sector leadership has greatly influenced the organisational structure of mega-events and the ways in which the various stakeholders collaborate. The involvement of the private sector in organising the Olympic Games in Los Angeles (1984) and Atlanta (1996) not only demonstrated the economic benefits and professional knowledge that the private sector could bring to the Games, but also necessitated a more collaborative way of working (Burbank et al. 2002). A number of studies identify particular configurations of public, private, and non-profit sector actors and coalitions that set a city's medium- to long-term urban governance agenda (Surborg et al. 2008). In Barcelona, for instance, a more business-like and less controlled urban intervention approach was introduced to deal with the city's exceptional circumstances, using public capital and a joint venture between local and central government to lure private investment (and especially foreign investment) (Brunet 2002). Acknowledging this trend, Smith (2001,180) notes the irony that in such cases the government, which is meant to be serving the public interest, negates broad social goals in order to focus on entrepreneurial and corporate interests.

The Olympic Games can function as powerful tools for developing cities as brands (Smith 2001; Van den Berg et al. 2002; Surborg et al. 2008). The development of sports facilities, for instance, may provide a city with important visual symbols, provoking memorable and positive images in tourists' minds (Smith, 2001, 136). The media and Games-related publicity may highlight improvements in a city's urban environment, transportation system and general level of organisation, attracting both sports tourists and a more general audience, such as companies, investors and conference delegates. In addition to the new physical icons and transitory spectacles that were intended to rebrand their cities, for instance, both Barcelona and Sydney used broad promotional campaigns that combined place marketing and tourism promotion with business networking (Ward 2007; Waitt 1999; Hall 2001; Yu 2004).

Post-Games legacy

The Summer Olympic Games "allows a rare opportunity for a major restructuring of the built form, a major economic boost, an increased global connectivity, and a profound change in the global image of city" (Short 2008, 339). Host cities

generally experience a number of direct or indirect benefits, but may also suffer from various potential downside.

Potential benefits

Regarding the tangible results generated from hosting the Olympic Games, Sakai (2006) suggests that hosting mega-events stimulates governments to invest heavily in the construction of event venues, tourism facilities and other forms of infrastructure over short time periods. In recent years, the construction of Olympic venues and facilities has been seen as a process of forming urban spectacles, through the creation of new, iconic stadiums and the construction of landmarks (Gotham 2005; Coaffee and Johnson 2007). A number of Olympic stadiums, like Munich's Olympiastation, Sydney's Stadium Australia or Beijing's Bird's Nest Olympic stadium, have since the Games become new landmarks for their host cities. The development of sports facilities may provide a city with important visual symbols that create memorable and positive images in tourists' minds (Smith 2001, 136). Furthermore, at the urban level, the Olympic project is increasingly used to facilitate the creation of new urban centers with mixed-use service, leisure, business and residential functions. This has resulted in a form of comprehensive strategic planning that combines Olympic site development with the provision and improvement of infrastructure, tourism facilities, the creation of high-quality public spaces, tourism planning and general urban regeneration programs, so as to maximise urban impact. Although a majority of past transportation infrastructure construction has been on roads, host cities and regions have also spent considerable sums on airport construction as well as on the renovation and construction of public transportation systems (Essex and Chalkley 2004). Investment has also been made to building modern telecommunication capacity in Atlanta or renovate the existing telecommunication system, as is the case in Los Angeles.

However awe-inspring during the Games, many of the heavily cost venues created or modified for the Olympic Games later falls into disuse or are used sporadically without generating a profit and many Olympic Parks remains largely empty and unused. This common problem occurring after the Olympic Games is the creation of the so-called "white elephants" –facilities that are built at great cost and after its initial use for a particular event become less and less used and therefore the cost of it out-scales what it give back to society (When host cities deliver venues or urban areas that are not or under- used after the Game, host cities.

Host cities can expect tangible economic results that are directly related to the Games. The host city can profit from television rights, sponsorship, ticketing and merchandising that is directly related to hosting the Games (Horne & Manzenreiter 2006; Gold 2008). It is suggested that an average of 5.1 million tickets had been sold for the past six Summer Olympic Gamesto local residents and visitors, generating substantial spending in the lodging, food and beverage sector (Zimbalist 2010: 8). Furthermore, host cities also receive a substantial income from the selling of Olympic television rights, special marketing measures such as sponsoring, licensing and merchandising (Preuss 2004). Preuss (2004) and Gratton et al. (2006), for example, also suggest several important economic aspects of holding the Games, such as those relating to employment, revenue, investment, real estate, tourism and the Organising Committee's expenditure. Increasingly, host cities are gearing themselves towards more long-term, more intangible economic approaches that are intended to sustain such cities after the Olympics have taken place. A substantial number of studies, meanwhile, focus on the development of Olympic tourism and the creation of new business opportunities (Kasimati 2003; Weed 2008).

Although the Olympic Games are often viewed primarily in economic terms, in almost every case, the Games have a significant social impact. Much of the concern expressed in the literature is related to the Games' effects on local communities. This is due to the fact that not only is community support an essential aspect of a successful mega-event, but also that community groups tend to be more vulnerable to, and more affected by, Olympic-led development. Jones (2001) suggests that hosting the Olympics leads to wider participation in sport and greater community access to improved sports facilities. Long and Sanderson (2001, 189) list a number of community benefits that may motivate host cities, including: enhanced confidence and self-esteem; empowerment of disadvantaged groups; improving a community's capacity to take the initiative; increased social integration and co-operation; the promotion of a collective identity; and increased cohesion. The Games not only offers an opportunity to physically renew but also a rare opportunity to re-brand a city, while providing valuable promotional opportunities for both cities and regions (Short 2008). The global media and the general publicity surrounding the Games can be used to highlight improvements in a city's urban environment, transportation system, and organisation, attracting both sports tourists and a more general audience, such as companies, investors and conference delegates.

Potential downside

Despite the important economic impact that sport events can have on their host cities, evaluating this impact remains a complex undertaking (Baade and Matheson 2002; Owen 2005). In general, direct economic cost-benefit

calculations take into account the host city's investment in the building of sport venues, media centres, accommodation, relevant infrastructure, and other tourism-related facilities. This may place an enormous financial burden on the host city and its taxpayers. Poynter (2006) suggests that it is perhaps useful to distinguish the financial costs and benefits derived from staging the event (the 'one-time', primary Games-related impact) from an evaluation of the longer-term structural economic changes that are derived from investing in transport infrastructure, telecommunications, environment, social and sports facilities, and housing (the secondary impact). Ingerson (2001) also suggests that economic impact studies of sporting events should take two key elements into account: the costs and revenues for the event's organisers, and the event's impact on the area in question. As far as the latter is concerned, attention has mainly been paid to the event's effectiveness with respect to job creation, tourism revenue, local real-estate market growth, and local income flows (Gratton et al. 2006; Jones 2001; McKay and Plumb 2001). Furthermore, there is the question of how to justify using taxpayers' revenues to subsidise private enterprises on economic grounds. On this point, Chanayil (2002) considers the evidence to be inconclusive, at best. Gratton and Henry (2001, 311) suggest that many studies had political motives for justifying expenditure on new facilities, and that "the validity of many of the results is questionable". Indeed, in some cases, "such studies have often been methodologically flawed, and the real economic benefit is often below that specified in such studies" (Crompton 2001).

A number of studies have assessed the social impact of hosting the Olympic Games in recent years. While the Games can have a positive social legacy, there is no compelling evidence to suggest that individuals and groups in host cities' local communities receive a just share of the rewards. Despite the fact that community support is vital for staging successful Games, community involvement in the early planning stages seems to be largely lacking. As Horne and Manzenreiter (2006, 13) argue, "sports mega-events have been largely developed by undemocratic organisations, often with anarchic decision-making and a lack of transparency, and more often in the interests of global flows rather than local communities". Furthermore, some analyses suggest that city elites tend to steer the Games towards corporate rather than social goals, thus undermining the social impact on local communities. Olds (1998), meanwhile, draws attention to the importance of guaranteeing housing and tenant rights, particularly for low-income groups, through specific, target-oriented housing programmes. Like all such mega-events, the Olympic Games are an almost exclusively urban phenomenon, requiring high levels of public and private investment, and offering opportunities to both governments and corporations to forge mutually beneficial alliances. As a result of investing scarce resources in Olympic projects, the government may make drastic cuts in health, education or

social housing budgets in order to reduce the level of public debt. The private sector, in turn, may benefit both from a growing market and from public subsidies linked to the Games. This trend, along with "the pursuit of enhanced, or even 'world class', status by politician and businesses, raised questions for some analysts about the social distribution of the supposed benefit of urban development initiatives" (Horne and Manzenreiter 2006, 8). Moreover, "which social groups actually benefit, which are excluded, what scope is there for contestation of these developments, and how can social equality be measured are three important questions that are often ignored" (Horne and Manzenreiter 2006, 8) For example, evidence suggests that Olympic developments in Atlanta led to the displacement of homeless people (Whitelegg 2000); and that in Sydney, low-income households, suffering from rent increases in the historically cheap housing area neighbouring the Homebush Bay Olympic site, were forced to move away (Hall 2001). More research is needed into the social value of such events, in order to understand exactly how communities benefit, and how they can use the Games to their advantage.

In terms of the governance of mega-event development, a key challenge is the increasing contradiction between the ideal of an open, collaborative and democratic process, and the reality of a process that is dominated by elite alliances. On the basis of case studies of five European cities, Van den Berg et al. (2002) conclude that mega sports events can be powerful tools for developing a city's 'brand', as is demonstrated by Barcelona's experience, but that such success requires strong, creative leadership. Burbanks et al. (2001) stress the crucial role that can be played by external actors operating at an international level, whose interests might conflict with those of the city. Roche (2000, 126), meanwhile, argues that mega-events are typically conceived and produced by powerful elites, with little opportunity for locals to contribute democratically to policy-making processes. Such conditions can lead to deeply ironic situations. For example, despite the fact that Sydney had embraced the notion of a 'Green Olympics' and adopted sustainable development as a governing principle, in order to provide certainty for developers and meet planning deadlines, the local government went so far as to issue new legislation to relax planning processes. This meant, for example, that environmental impact statements for Olympics-related developments and local community participation in decision-making processes were not required – simply to ensure that most of the facilities would be ready almost twelve months in advance of the opening ceremony (Owen 2002, 332).

Discussion

Sport is increasingly seen as a central strategy for cities to promote their image and global position, undertake regeneration and tackle problems of social exclusion" (Herring 2004). The Olympic Games are particularly attractive to cities, due to the unique impact that the intense media interest associated with the Games can have on a global audience. Existing research acknowledges the complex challenges associated with bidding for and staging the Olympic Games (Emery 2001). The issues examined in this review of the relevant literature can help us to better understand the relationship between the Olympic Games and host cities' urban development practices. Since the Games are tightly interwoven with urban economies and urban (re)development schemes, how cities indeed harness the Games and create their own Olympic legacies can best be understood by looking at their motivations, the kind of Olympic legacy that they anticipate, and the implementation processes that connect the vision with the expected results. By posing questions such as what motivates cities to stage the Olympic Games, how urban development strategies are formulated and organised in different cities, and the Games' true impact on a city, we have been able to identify the various approaches taken by different cities to staging the Games. The literature indicates a clear relationship between a city's motivations, urban development strategies, and expected results (impact). Whilst much is known about the event's impact, however, there are considerable gaps in our knowledge about the event's legacy and its social-economic effects. Along with disputes regarding methodology, this means that we lack persuasive evidence to support the claim that the Olympic Games bring social benefits to host cities.

It is also evident that different cities have adjusted their approaches to fit particular circumstances, particularly with a view to temporal demand, purpose, political agendas, and the locality in question. Thus the 1996 Atlanta Olympics, the 1992 Barcelona Olympics, and the 2000 Sydney Olympics had fundamentally different aims and objectives, and took different approaches. Atlanta set out to deliver a commercially successful event at no cost to the tax payer. Barcelona, in turn, aimed to regenerate the city and assert its Catalan identity. Unlike Barcelona, meanwhile, Sydney was not facing an economic crisis, but it did need to find a niche in order to defeat its fierce competitor in the bidding process, Beijing. Sydney thus appealed to the IOC's concerns about sustainable development, and aimed to achieve an environmental legacy.

Whereas every host city expects to experience some form of short- and long-term impact, or the so-called legacy, it is however difficult for most host city organisers to think beyond the Games in any systematic fashion due to the pressing nature and planning complexity. Therefore, although the post-Games period is by far the longest period that stretches for decades after the Games to

affect a host city, it is “clearly the least-planned period” (Cashman 1998). City leaders may well view the Olympic Games in strategic terms, as an opportunity to gain regional, national and international exposure at a relatively low cost. City leaders also face a gigantic and complex task in addressing financial, spatial and temporal challenges prior to and during the Games, however, not to mention the enormous investment of resources needed, and the large number of actors involved in the development process. Subject to time pressure and without careful consideration of the long-term impact, Olympic venues may become ‘white elephants’ after the Games have taken place, isolated in their city landscapes (Furrer 2002; Cashman 2002). In such situations, rather than economic benefits, the host city may be left with huge debts that take many years to repay. Moreover, the promises of social benefits made to local communities may well prove to be empty, with the circumstances of vulnerable groups potentially worsening, rather than improving. The contradictions and controversies surrounding the Summer Olympic Games may thus have significant implications for the lives of people living in host cities, and are therefore worthy of increased attention on the part of policymakers and planners.

Planning to Achieve/Planning to Avoid

Helge Fiskaa:

The high ambitions of Norwegian Planning

Abstract

Traditionally the Nordic countries have many similarities in their administrative and planning systems, more or less different from other European countries due to common historical and cultural heritage and long lasting cooperation. They have all revised or replaced their planning (and building) acts during the last few years (Finland in 2000, Denmark in 2007, Norway in 2009, and Sweden and Iceland in 2011). This paper questions if the Norwegian planning system has become more unlike the other Nordic countries' systems, and if the ambitions have escalated beyond the limits for what planning can or should overcome.

Over years, Norway has extended the ambitions for planning, last by the implementation of the new Planning and Building Act. This relates to the act's requirements to the comprehensiveness and content of plans, and the plans coordinating and controlling function. Based on studies of some countries' planning and administrative systems the paper examines some features of the prevailing planning system in Norway compared with to the Danish, Finnish and Swedish systems (Iceland is not included due to practical reasons), and demonstrates that Norwegian ambitions for planning is far beyond the other countries'. The concluding discussion questions if the ambitions are realistic and what way Norwegian planning may take in the years coming.

Firstly, the Norwegian act's requirements to objectives, tasks, and considerations imply a nearby all-embracing social planning, including physical, environmental, economic, social and cultural development in regions and municipalities, which is far beyond the physical planning stated in the other countries' acts. For example, the municipal master plan shall include a social part dealing with all municipal activities and development in total. The ambitions bring Wildawsky's (1973) question "if planning is everything, maybe it's nothing" in mind.

Secondly, dealing with such comprehensive planning the act requires thorough coordination and collaboration among public sector authorities at different administrative/political levels, which is a complicated task. As municipalities perform most planning and Norway has strong traditions for local self-government, the challenge is how to coordinate sector bodies at state and regional level with municipal interests. On one side, municipalities can not instruct state or county agencies, and on the other side, use of the act's rather strong means for central control of local planning will often meets political resistance.

Thirdly, a question is about the ambitions of public control when private actors exert strong influence in community development. As in most western countries, public-private cooperation has emerged as the ordinary means for plan preparation and implementation in Norway. The Planning and Building Act underlines public bodies' responsibility for securing common interest. However, a special Norwegian right for private actors to promote plans may squeeze the public control. As in addition, negotiations on development agreements can take place parallel to the plan preparation the content of plans may be more or less determined in forehand of public participation and political treatment, and thus short-circuit the democratic planning process. The other Nordic countries have kept their hands on the steering wheel by maintaining the public planning monopoly.

Key words
Planning systems, Planning ambitions, Nordic countries.

Introduction

A country's planning system is rooted in its particular historical, legal, physical conditions (Cullingworth and Nadin, 2006, p. 10), geography and settlement structure (Böhme, 2002, pp. 43ff), and cultural traditions (Knieling and Othengrafen, 2009, p. 39). Countries with long-lasting close political, economical and cultural relationship have influenced each other and thus probably having similarities in their systems, though specific national features may cause more or less differences.

Supported by among others Zweigert and Kötz' (1987) investigation and classification of five legal/administrative "families" i Europa, and based on EU's surveys of planning systems (EC, 1994; EC, 1997), Newman and Thornley (1996) have pointed out five "planning families" in Europe. That means groups of countries having more or less similar planning systems and styles in the perspective of legal and administrative principles. They define a British, a Napoleonic, a Germanic, a Scandinavian or Nordic, and an Eastern-European "family".

Figure 1. The five planning families in Europe (After Newman and Thornley, 1996, p. 29).

Previous surveys of planning in the Nordic countries indicate traditionally many similarities in their planning systems and praxis (Lemberg, 1981; Hall, 1991; Jerkø, 2004) which is highly understandable due to historical and present close political, cultural and economic interaction. They have a common cultural heritage, and there is a strong Nordic identity and cooperation, which traces its roots back to earlier centuries (Böhme, 2002). The languages of Denmark, Norway, and Sweden retain a close resemblance. An indication of this is that most Icelanders can understand these three languages while many Finns are able to grasp at least Swedish. There are well-established forums for cooperation between the Nordic countries, such as e.g. the Nordic Council and Nordic Councils of Ministers.
Although several differences exist, the investigations confirm the interpretation of Scandinavia as a planning family. The differences to other European countries are most evident with respect to the British system which, for example do not include legally binding plans, but are less distinct from the rest of Western Europe (Newman and Thornley, 1996, p. 34).

Over the last few years, all Nordic countries have revised or renewed their planning and building acts; Finland's planning and building act date back to 2000, Denmark revised their act in 2007, Norway decided upon their new act in 2008 (the building part in 2009), and so did Sweden and Iceland in 2010. A question is whether these revisions have lead to evolved differences between the systems or not and what important differences may be. Based on recent studies of planning and administrative systems in several European countries (Fiskaa, 2011) this paper concentrate on what ambitions for planning are embedded in the planning acts in four of the Nordic countries and discusses in what degree the Norwegian ambitions are realistic or not.

This paper gives at first an overview over the development of Norwegian planning act and system focusing on the widening of the planning ambitions over time, with some comparisons to the other Nordic countries investigated. Then a discussion set a critical eye on the present act's ambitions, illustrated with some examples of planning cases and planning processes studied. The conclusion is that the ambitions seem very difficult to fulfil.

From town planning to comprehensive planning

Building acts in the first half of the nineteenth century embedded the early regulations for Norwegian planning in for the cities in the form of pure physical planning, first of all regulating streets and buildings. The motives for planning were first of all the need for communication lines, fire protection, and establishing of healthy living conditions. Only one type of plan, town plan (byplan), which was a rather detailed plan for the whole town's area, existed according to the act. Later on, the act gave legal basis for voluntary planning also in villages and built up areas in rural municipalities, stated in The Building Act of 1924.

The renewed Building Act of 1965 introduced a more ambitious planning (Fiskaa, 2009), but still concentrating on physical planning. First of all mandatory planning also in rural areas was implemented. All municipalities had to prepare and decide upon plans. For the second a hierarchical system of plan types should contribute to coherence in the development at regional, municipal and very local level, in line with the state's policy. Thus the act introduced *regional planning* in the form of plans for two or more municipalities. The region plan should be a plan for *"coordination of land use and for joint solutions of questions concerning projects and arrangements for meeting common requirements"* in the region. (Translated by the author). The region plan should give guidance to the municipalities' planning, but not in the form of binding regulations. After some years one experienced poor results of this planning which, in 1973 led to replacement of region plans with *county plans* (fylkesplan) for *"coordination of the state's, the county's and the municipalities' planning when it comes to utilization of natural resources in a county and for other issues of common interest for promoting economic growth and well-being…"* (Translated by the author). The plan should include main features in utilization of natural resources, goals for population development and settlement pattern, assessment of labour situation and economic life, public projects and other arrangements, and economic assessment and priority of public projects.

In the municipalities, a system of *general plan* (master plan) embracing the whole municipality's area and *detailed plans* (zoning plan/reguleringsplan) for designated areas should make public control over land use and building possible, both in coarse features and more detailed. The master plan should be a plan for *"land use in a municipality and for solving questions concerning projects and arrangements for meeting common requirements in the municipality."* (Translated by the author). Emphasis should be on building areas, agriculture and forestry, natural areas, roads and other communication projects, and water and sewage installations. Also the need for different kinds of public service etc. was natural elements of common requirements. Based on recommendations from the ministry many municipalities implemented in their general planning a system of defining *common plan premises*, based on among other things prognosis for population and business life, for giving a dimensioning basis for the physical plans. Several general plans included some kind of economic plan for investments and public operations. By this the requirements to and ambitions for planning was increased but still within the frame of physical planning. The main purpose of plans was still preparation for future development on one hand and control over land use and building on the other hand. However, especial social scientists criticized planning for not solving the urgent problems, and argued for the introduction of other kinds of planning. Thus they challenged the physical planning approach (Skjeggedal, 2005, p. 739).

Planning practice and discussions about the purpose of planning, the content of plans, and planning process led to adoption of the Planning and Building Act in 1985. By this the ambitions for planning increased further. Firstly, the act introduced an objects clause stressing coordination of national, county and municipal activities, balancing considerations to use and protection of resources. Planning should contribute to land

use and building benefiting individuals and the society. By this, the act strengthened the requirements to coordination and collaboration between public administrative levels and sectors and private actors. Secondly, the act introduced rules for the state's possibilities to give instructions to county and municipal planning, and even to prepare and decide upon land use plans. Thirdly, the requirements to content of county and municipal plans expanded, and should include *physical, economic, social, and cultural issues*, and later on also *aesthetic regards*. Particularly planning should safeguard good growing up conditions for children. Fourthly, *municipal master plan* replaced the former term general plan, which indicated requirements for a more comprehensive planning than the previous physical planning.

The municipal master plan should include a *long-term part*, dealing with goals for development and guidelines for the sector authorities' planning, and a land use plan. The *short-term part* should contain an integrated action program for the sector's activities in the nearest years coming. This system was in line with Etzioni's (1967) model for a mixed-scanning approach. By this the municipal master plan should idealistic include most local development and municipal activities. The act introduced further a new type of detailed plan, *building development plan* (bebyggelsesplan) in addition to the former zoning plan (reguleringsplan). This comprehensive escalation of the planning ambitions occurred at a time when neo-liberalism and demand for deregulation influenced politics strongly, which seems paradoxical.

All-embracing planning?

After several revisions of and amendments to the act through the 1990s and many years of preparation work the planning part of the recent Planning and Building Act came into effect in 2009. The act has mainly kept the belief in strong public planning and synoptic ideals (Jensen, 2011), and extended the planning ambitions further (Kleven, 2011). In the following, the ambitions are discussed in comparison with the other Nordic countries' acts and illustrated by the results of some surveys. The discussion concentrates on the comprehensive ambitions expressed in the act, the plan system and relationship between plan types, the ambitions of coordination and collaboration between public sector interests, and the dilemmas concerning governing public-private cooperation and need for public control.

The fundamental purposes of planning are land use control, land use plans and central control (Newman and Thornley, 1996, p. 42). Planning systems consists of three elements: the plan-making function, the developmental function involving such issues as land assembly and servicing, and the regulatory or control function (Healey & Williams, 1993, p. 702). In line with this, planning traditionally is about physical planning, for the most performed by municipalities within more or less fixed frames given by the state and/or regional authorities. As described, gradually the requirements to content of planning and planning process in Norway have extended beyond the traditional.

The prevailing Norwegian Planning and Building Act's requirements to objectives, tasks, and considerations in planning imply a nearby all-embracing planning. Promot-

ing "*sustainable development in the best interests of individuals, society, and future generations"*, is the paramount objective. There shall be emphasis on *long-term solutions, and environmental and social impacts*. The principle of *universal design* shall be taken into account. Planning shall facilitate the *coordination of central government, regional and municipal functions* and provide a basis for administrative decisions regarding both *use and conservation of resources*. Planning shall ensure *transparency, predictability and public participation* for all affected interests and authorities.

This leads to numerous tasks and considerations planning shall take into account according to the act. In addition to *physical, economic, social, and cultural development*, the planning shall deal with *environment protection, public health and safety, natural resources, cultural and landscape values,* and *Sami interests.* Planning shall take the *climate* into consideration*, counteract social and health-related inequalities, promote societal safety* and *prevent crime, facilitate good surroundings, good housing and childhood environments and good living standards in all parts of the country*. At the same time planning shall *facilitate value creation and industrial and commercial development,* and *promote coherence between sectors, functions and interests.* By these requirements, planning has moved beyond the origin of regulating land use and building and undertakes the complex and contradictory task to influence people's life stile and socioeconomic behaviour in sustainable direction (Kleven, 2012, p. 49), which may be goes beyond what planning can do very much about.

However, according to the act planning shall be based on financial and other resource-related prerequisites for implementation and shall not be more exhaustive than necessary. This statement may indicate that the legislative authority is doubtful to the realism in thus comprehensive approach to planning. As planning is about future control and consequences of actions the question is how to obtain sufficient causal knowledge to control all implications and effects of contemporary proposals and decisions (Wildavsky, 1973). The comprehensive requirements will in many cases lead to disagreements and call for thorough balancing and coordination of divergent views and interests and conflict solving, which is discussed in a subsequent section of the paper.

Nor has Denmark, Finland, or Sweden near to corresponding statements in their acts. The *Danish* act's objects clause is concentrated on *physical planning* with respect to *sustainability* and *coordination of social interests in land use* with respect for *peoples living conditions* and keeping *fauna and flora*, production and protection of *valuable settlements and landscapes* and prevention from *pollution*. Similar the main purpose of *Finish* planning is to regulate *land use and building* for creating conditions for *good living environments* and promote *ecological, economic, social, and cultural sustainable development*. The act's name, *Markanvändnings- och bygglag* (Land Use and Building Act) indicates clearly that the ambitions for planning beyond physical planning are limited to taking societal considerations into account. According to the *Swedish* act's introductory clause planning is about *land, water and building*. Under consideration of *individuals freedom* planning shall promote societal development with

equal and good social living conditions and *sustainable living environment* to day and in the future.

Sustainable development is the superior objective for planning in all countries, leading to long term considerations. However, the Danish, Finnish, or Swedish acts don't require a comprehensive social planning like in Norway. However the planning must of course be accordant to superior goals and prognosis for several needs and coordinated with plans for various tasks, but not in the Norwegian way of ambitions of an all-embracing planning. This seems to be in line with the former Norwegian set of common planning premises.

A wide-ranging system of plan types

A wide-ranging and complicated system of plan types defined in the Norwegian act also indicates expanding planning ambitions. Figure 2 gives an overview over the plan types at state, regional (county) and municipal level stated in the four discussed countries' acts. It shows up that Norway has the most comprehensive and ambitious system, especially at the municipal level.

Level	**Denmark**	**Finland**	**Norway**	**Sweden**
State	- Report on national planning - Overview of the state interests in municipal planning - Rules for governing and the content of planning	- National land use objectives	- National expectations regarding regional and municipal planning - Planning guidelines - Planning provisions - Central government land-use plan	- National environmental objectives (+ Provisions in the environmental code)
Region/ county	- Regional spatial development plan	- Regional scheme - Regional plan - Regional development programme	- Regional planning strategies - Regional master plan - Regional plan provisions	- Regional plan - (Regional development program)
Municipality	- Strategy for municipal planning - Municipal plan - Plan for special topics or areas - Local plan	- Planning review - Local master plan - Partial local maser plan - Local detailed plan - Separate plot division	- Municipal planning strategy - Municipal master plan - social element - long term - implementation - land use plan - Municipal sub-plan - Area zoning plan - Detailed zoning plan	- Master plan - Detailed development plan - Area regulations

Figure 2. The plan types at state, regional (county) and municipal level.

In all countries, the State shall give some kind of superior guidelines *for local planning*. In Norway, the ministry in addition can intervene in local planning and even prepare and decide upon land use plans in order to secure national or regional interests, and give rather concrete instructions for planning. State's sector bodies, as for example the road authorities, have a right to prepare and promote zoning plans and having them treated in the municipal council. State and regional bodies have a right to object on local plans and thus bring the final decision over to the ministry. At regional level, the counties shall have a *regional planning strategy* and a *regional master plan*, and can give *regional plan provisions* concerning land use.

The most complicated and may be confusing system of plan types is to be found at the municipal level. First of all, there shall be a *planning strategy* as a superior document, comprising *"the strategic choices related to social development, including long-term land use, environmental challenges, sector activities and, an assessment of the planning needs."* This is more or less in line with the other countries requirements except for Sweden where a strategy plan is not mandatory.

Further, the *municipal master plan* is more wide-ranging than the other countries' equivalent plans comprising a long-term *social element,* an *implementation element*, and a *land use plan*. The plan shall *"cover all important goals and functions in the municipality"* and *"determine long-term challenges, goals, and strategies for the municipal community as a whole and the municipality as an organization. It should comprise a description and an assessment of alternative strategies for development in the municipality."*

The social element of the municipal master plan shall *"serve as a basis for sector plans and activities in the municipality. It shall provide guidelines for how to implement the municipality's own goals and strategies in municipal activities with participation from other public bodies and private bodies."* A municipal sub-plan may be prepared for specific areas, topics or areas of activity. The implementation part *"shall form the basis for the municipality's prioritization of resources and planning and cooperation functions, and clarify measures within the municipality's financial framework."* The *economy plan*, which has its legal basis in the Local Government Act, may be included in the implementation part, but not necessarily.

The land use plan shall cover the municipality's entire area and point out the main objectives and areas requiring special consideration in relation to the use and conservation of land. The municipality may also prepare land use plans for designated parts of the area in order to specify land use in more detail.

The act descries two types of detailed plans, *area zoning plan* and *detailed zoning* plan. The area zoning plan is meant for large areas while the detailed plan is intended for small areas, often single properties and tied to concrete projects. The requirements to content and planning process are the same for this plan types. The act definite a system of specific land use objectives, commonly for all plan types.

Several questions concerning municipal plan system can be asked. One is about the difference between the master plan's requirement for *alternative strategies for development in the municipality* and the planning strategy's *strategic choices*. Another is about the relationship between the master plan's land use part and the strategy's *long-term land use*.

Secondly, questions are about the social part of the municipal master plan, which is a quite different requirement than the other Nordic countries' master plans' concentration on land use and physical issues. The Norwegian act's description of what the social part should embrace is limited to the general statements mentioned above, and so far no precise guidance for this type of planning exists. Contrary, the act gives exhaustive instructions about the land use plan, and so do the ministry's guidance. The municipalities are doubtful how to handle the requirement to a social element of the plan, but are familiar with the land use planning. The importance of different municipal planning efforts according to the act of 1985 has been examined by asking mayors and chief executives in several municipalities (Falleth and Stokke, 2001). Shortly summarized the survey demonstrates that the economy plan and the land use plan are regarded as far more important documents for the municipal's future development than the municipal master plan's objective part, which is much the same as the present act's social element.

Thirdly, the wide-ranging system of land use plans may be confusing to operate. In worst case, one has to work out four plans for an area – the municipal master plan, a sub-municipal plan, an area zoning plan, which may be fairly similar to a sub-municipal plan, and a detailed zoning plan. In the city of Trondheim only two out of total 84 zoning plans decided upon according to the new act are area zoning plans. 77 are detailed zoning plans, and five are not specified. This indicates that the specific area zoning plan type is not very relevant. The act's intension is to establish a flexible system useful for different planning situations. However, the other Nordic countries' systems are not less flexible as the different plan types can be more or less detailed and cover larger or smaller areas, equivalent to the Norwegian system before 1985.

The ambitions of coordination

For dealing with thus comprehensive requirements to planning thorough coordination and collaboration among several state, regional and municipal bodies, private organizations and institutions, developers and the public at large is requisite. One must ask if and how the act's ambitions for coordination are possible to achieve. Questions to rise are about the system, planning process and political will for coordination between public bodies, collaboration with private sector, and public participation.

Practice demonstrates that planning often implies dealing with conflicts between sector interests and/or administrative levels, which can be challenging to overcome. One can differentiate between, relationship conflicts, conflicts about facts, interest conflicts, and value conflicts. Relationship and value conflicts may be difficult to solve as they are about personal feelings, perceptions and attitudes. Data and interest con-

flicts may be easier to overcome by bringing supplementary information and reasons for differing interests on the table for discussion and negotiation, which is the customary way to handle disagreements and conflict in Norwegian planning.

Coordinating public sector interests

First of all, decentralization is a superior objective in Norwegian as in most European countries' planning (Newman and Thornley, 1996, p. 40 ff.). This implies that the municipalities perform most planning and public bodies at state and regional (county) level are participants in the planning process by presenting their views and interests. Long traditions for local feeling and self government in Norway, make it political difficult for the state or county to instruct municipalities and overrule local decisions. Decentralisation implies fragmentation of responsibilities (op. cit. p. 67), which may counteract planning's intentions of and requires instruments for coordination.

One aspect of coordination is the effect of approved plans. As the social element of the municipality master plan is not binding correspondently to the land use plan and the zoning plans, it can only function as a guideline for further planning and decisions, usually legally based on other acts than the Planning and Building Act. When sector acts and state provisions regulate most public actions and activity, the degree of importance of the social element of the plan depends on the involved actors willingness and ability to coordination.

According to Mintzberg (1979) one can distinguish mechanisms for coordination in five categories: 1) mutual adjustment, 2) direct supervision, 3) standardization of the working process, 4) standardization of outputs, and 5) standardization of skills. Mutual adjustment means that autonomous sector bodies and actors discuss and adjust their stands. Even if actors may have more or less corresponding rationality they cannot achieve consensus in all cases, and instruments for conflict solving are needed, for example mediations or state's approval of plans. Instruments for supervision might be right for public agencies to object on plans or instruct local planning. Standardization of working process may exist in the form of planning procedures, and standardized requirements for outcome may be in the form of norms or recommendations for content of plans. Standardization of skills means participants in the planning process having equal competence.

The main legal means in Norwegian planning is traditionally a combination of mutual adjustment and direct supervision (Holsen et al., 1998), more or less like arrangements in the other Nordic countries. The Planning and Building Act expresses a strong belief in consultation, participation, coherence, and consensus building in planning processes (Kleven 2012, p. 49). Public agencies at state and regional level have both a right and a duty to participate in local planning work and thus contribute to mutual adjustment. However, the formal means for governmental supervision in the form of instructions, preparing land use plans themselves, setting aside local plan decisions etc. seem

stronger in Norway than in the other Nordic countries. The state has the last word if conflicts arise in plan matters (MD, 2001, p. 33), but traditionally instructions from a higher level are most often politically acceptable only in questions of major national or regional importance. Some standardization of working process exists in the form of general planning procedure rules, and to some degree standardization of outputs like standards and recommendations, partly settled in other acts, and professional traditions etc. exists. As several public agencies are involved in planning, probably having different experience and competence in planning, one can hardly assume high degree of standardized skills.

Although the duty to contribute in local planning, lack of coordination between different state agencies seems to be the most problematic which, is underlined in the preparation work for the new act (MD, 2001, p. 24), and have motivated the strengthened requirements for coordination and collaboration. Even if the new act has delimited the legal right for public bodies to object on plan proposals, conflicting interests and opinions, and different professional skills among participants in the planning process often causes problematic and time consuming planning processes. Even more problematic may the situations be if central sector agencies give instructions which, do not fit with other sector authorities interests and/or the local policy and plans. Over the last years, the number of public sectors' objections to plan proposal has raised (Falleth and Hansen, 2011, p. 8), which cause more plans to be scrutinized and finally decided upon by the ministry.

Municipal bodies seem to have better routines and ability for internal coordination (Holsen et al., 1998), but have of course no means for coordinating or instruct state or county agencies. An essential question then is how to force state agencies to cooperate with each other and with the municipalities and counties. The means for coordinating and forcing state sector bodies are rather weak. A solution to the coordination problem might be clearer statutory basis for departmental instructions to state sector agencies, which is controversial according to traditions of strong public sectors, often supported by politicians.

Public private cooperation and public participation

The second question concerning coordination and collaboration is about the relationship between public bodies, private interests and people in general. The shift from governing to governance during the neo-liberal period implies emerging of public-private cooperation, which is going on in most parts of the advanced capitalist world (Geddes, 2006, p. 76). This implies a number of dilemmas about the purpose of planning and the public's and the inhabitants' role in community development. As a fundamental purpose of planning is about safeguarding those matters and public interests that market forces do not take care of, the motives are to provide for what is desirable and to hinder unfortunate side effects of individual and private actions (Vigar et al., 2000 p. 7 ff; Røsnes, 2005, p. 34). Those two aspects of planning are often contradictory, and cause conflicts.

On one hand, planning must be sensitive to changes and flexible (Thornley and Rydin, 2002, p. 10). On the other hand, there are reasons for a removal beyond a project-based approach and restoration of the formal importance of plans (Newman and Thornley, 1996, p. 248). Developers request flexibility, in order to respond rapidly to changing circumstances (EC, 1997, p. 45), but at the same time a strategic framework in order to reduce uncertainty (Newman and Thornley, 1996, p. 249). Neighbours and other affected people look to protect their own interests and demand certainty (Alfasi, 2006, p. 558). And of course, developers' paramount motive is a most profitable development.

In Norway, private actors have a general legal right to provide detailed zoning plan proposals and having them political treated, in contrast to the other Nordic countries which have retained the public planning monopoly. The municipality may transfer the responsibility for preparing also area zoning plans to private actors. Most of the detailed plans are provides by property developers, and also many area zoning plans. Private developers first of all influence detailed plans, but have by their planning initiatives a considerable influence on master planning as well (Røsnes, 2008). Although public bodies decide finally upon plans, the public-private cooperation raises questions if close ties between developers and planning authorities hand power over to private developers in a way and a degree that may threaten public interests and the civil society's influence (Fiskaa, 2005).

When private developers prepare plans, the planning authorities' role is limited to negotiations over plans and control according to formal rules. Planning authorities have the primary contact with developers who only to some degree communicate with, and become influenced by affected persons and organisations. A start-up meeting between the developer and the planning authority for clarifying frames for a possible plan is the only statutory arena for direct communication in a planning process stated in the act. Inhabitants have a right to advance their views as response to announcement of start of a planning work and during the public inspection of a plan proposal, most often to late in the process to have decisive influence.

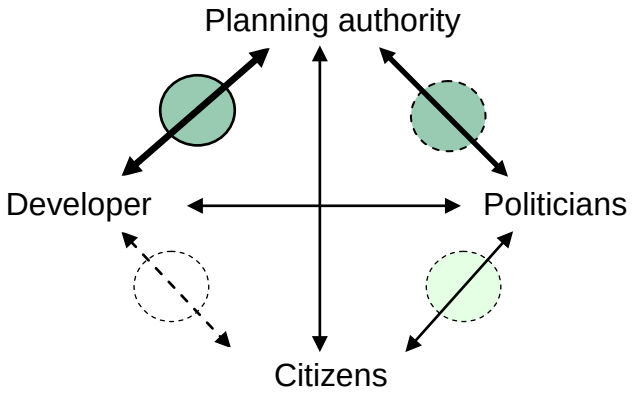

Figure 3. Actors in the planning process for a private promoted zoning plan. Full circle indicates formal statutory meeting and dotted circles eventual meetings. The thickness of arrows indicates the strength of contacts between actors.

Similarly, negotiations on development agreements between municipality and developers, which have substituted the traditional public responsibility for preparing project implementation, may threaten public interests. Crucial questions are about the transparency in the process and if negotiations can take place parallel to the planning work. Parallel and closed negotiations, and may be lobbying as well, may lead to early informal decisions on plans and thus short-circuit the planning process (Garnåsjordet, 2000, p. 31). Thus, negotiations upon plans and agreements for plan implementation may lead to pre-binding and exclusion of lay citizens and third parties from information and influence in an early and decisive stage of a planning process until the final hearing of the proposal (Røsnes, 2005; Falleth and Hansen, 2011). It seems clear that the performance of governance has given private developers a stronger position in planning and development than in the other Nordic countries at the sacrifice of public control and third parties influence. Falleth and Hansen's (2011) investigation concerning planning processes for detailed plans in several Norwegian municipalities supports such a suspicion showing generally a shortage in third party's influence.

As zoning plans are legally binding for land use and projects, and prepared through a comprehensive planning process, on should expect the plans to be followed. That is not necessarily the case. A study from 1987, when public planning monopoly still was in force, documented that only three out of 61 detailed plans in Trondheim was implemented completely according to the plan. In many cases, the responsible part was not able to fulfil all elements of the plan, and in other cases, revised solutions were worked out (Fiskaa and Røsnes, 1987).

Figure 4. The approved zoning plan to the left and actual implemented project to the right. Positioning of a buildings, the design of outdoor areas etc. are altered. Example from the survey 1987.

Especially one should assume privately prepared plans to be more in line with the developer's wishes and capability. A recent study demonstrates that it is not necessarily

so (Kristiansdottir, 2009). In all six cases investigated, the implementation was more or less different from approved plan. Both surveys demonstrates that in many cases "soft elements" like play grounds, foot-paths etc. were not constructed, which may be a sign of lack of attention to common interests and needs.

Figure 5. Overview of deviations in the planning area Hårstadmarka. Example from the survey 2009.

Conclusions

One must conclude that Norway over the years, not least by the Planning and Building Act of 2008, expanded the ambitions for planning beyond what is the case in the other Nordic countries. The ambitions drown planning in well-meant wishes and contradictory requirements (Sunde, 2000).

First of all the increased requirements for what planning in Norway shall embrace is in contrast to the other ones, which have on the whole held on the traditions of physical planning. The comprehensive and complicated system of plan types, especially the social part of the municipal master plan, is a part of this picture. In practice, most planning concentrates on land use and physical issues, and will probably do so also in the future.

Secondly, the ambitions for coordination and collaboration among public agencies at different levels seem out of range practically and politically. Especially a sectorial state is a problem as municipalities cannot force state bodies.

Thirdly, the special Norwegian right for private actors to prepare zoning plans, and thus having their hands on the steering wheel, may have weakened public authority and affected inhabitants' influence in planning, which is opposite to the ambitions of broad coordination, cooperation and participation in order to secure common interests.

Bibliography

Abstract
The paper presents the results as well as the considerations of a research project [2009-2010] concerning the future of international building exhibitions [IBA] as a tool of urban and regional revitalization. As a largeformat of urban and regional development – not directly comparable with other European formats due to different regional and national parameters – especially the IBA Emscher Park is highly reputed worldwide and viewed as an example to be followed in tackling restructuring processes (Reicher et al. 2011, p. 16). The positive reputation domestically as well as

abroad leads to believe that there are IBA-typical features which could be implemented in other formats concerning urban projects on the one hand. On the other hand, the research project gained experiences from the view on IBA similar formats in different European countries. It is necessary to discuss the experiences' value concerning IBA's future in Germany (Niemann et al. 2011, p. 314) and its implications in the European context.

1. International Building Exhibition [IBA]

International building exhibitions [IBA] are a largeformat of urban and regional development. They have become a trademark of German planning culture by being a field for experimentation marked by their openness towards innovation and goals. IBA-exhibitions take place within a time space of a century without a fixed annual schedule, set of rules or standardized quality criteria. Starting as an architecture exhibition in 1910 nowadays IBA is a highly reputed unique label dealing with social, economic and ecological aspects and the quality of processes and participation. IBA-exhibitions have to redefine themselves constantly by dealing with the real challenges of urban and regional society and urgent current problems. Due to these functions IBA are more than architecture exhibitions according to their title. (Durth et al. 2010, p. 66-70)
Especially by comparing the IBA-format with several European formats of urban and regional development, IBA-typical features and recommendations for both upcoming IBA-exhibitions and different European formats can be identified.

1.1 Retrospective:

In Germany, International Building Exhibitions have a long tradition. The first IBA took place in the city of Darmstadt in 1901. This IBA generated the exemplary artist colony of *Mathildenhöhe*, which was created in Art Nouveau Style (Durth 2010, pp. 19-20). The following IBA provided contemporary answers to urgent urban development questions (Durth 2010, p. 18). >New Objectivity< has been the central theme of the IBA Stuttgart in 1924. Architects from all over Europe developed new styles and forms of housing and presented upcoming considerations concerning constructional engineering and economy (Durth 2010, pp. 19-23).
The first IBA after World War II was located separately in both West [1957] and East Berlin [1951]. This IBA can be seen as a competition of the two rivaling political systems. West Berlin put the focus on the international tendencies of modern architecture by following the guiding principle of urban landscape, trying to propitiate both city and nature. Instead of building block of flats various types of construction should have been integrated into a park landscape. In the eastern part of the city IBA has been focused on the *Stalinallee* with its monumental architecture. (Durth 2010, pp. 23-26)
The following IBA was located in Berlin again. This IBA can be seen as a contemporary and sceptical answer to the developments of the IBA Interbau 1957. A shift of paradigm provoked contradiction. The tendencies of housing sprawl led to

the demand condensed housing again and implemented a discussion concerning city center revitalization. (Durth 2010, pp. 26-27)
While the range of tasks became broader the intervals between particular IBA-exhibitions became shorter after IBA 1984/87 Berlin. The following IBA started only two years later in 1989. The well reputed IBA Emscher Park took place in a timeframe of an entire decade between 1989 and 1999. The IBA Emscher Park has been the first IBA putting the focus not only on one city but rather on an entire region in transforming processes. It initiated regional projects and can be identified as a source of inspiration for ideas and development processes in different ways (Reicher et al. 2011, p. 16-22). Within the decade, 19 towns and cities as well as a large number of initiatives and business enterprises realized over a hundred projects (ib.). Those projects are seen as a model approach to deal with the physical realities of the region and its economic framework conditions (ib.). IBA has changed the image of the entire Ruhr Area and the way of identification by its inhabitants. Especially the conservation of former industrial buildings and their transformation into accessible cultural monuments is a considerable reason for IBA Emscher Park's high reputation worldwide. Nowadays IBA Emscher Park is viewed as an example to be followed in tackling restructuring processes (Reicher et al. 2011, p. 16) due to its characterization as an inspiration space, a demonstration space, a reflection space, a projection space and a space for encouragement (Kunzmann 2011, p. 168).
IBA Emscher Park can be seen as a model for the IBA Fürst-Pückler-Land, located in the federal state of Brandenburg surrounding Berlin. This IBA took place between 2000 and 2010 and put the focus on restructuring processes as well as the IBA Emscher Park. The IBA Fürst-Pückler-Land is located in a former lignite-mining area close to the polish border. Its projects re-developed the scenery by creating a wide lake landscape. This IBA also saved former industrial monuments by integrating them into both a new cultural and scenic context. IBA Fürst-Pückler-Land had its final year of presentation in 2010 as well as IBA Stadtumbau, located in the federal state of Saxony-Anhalt. Demographically changing and a huge rate of shrinking lead to the IBA Stadtumbau. 19 towns of the state proposed to find solutions concerning their structural renovation under shrinking conditions (Prigge 2008, p. 18).
During the last century the intervals between IBA-exhibitions still became shorter. Between 2000 and 2010 two individual IBAs were running simultaneously. Nowadays five IBAs are taking place at the same time located both in Germany and its neighboring countries Switzerland and the Netherlands.

1.2 Current and upcoming IBA-exhibitions:

Nowadays IBA-exhibitions are taking place in cities, city regions, federal states and tri-national regions. The IBA Hamburg [2007-2013] aims to realize a large city development project dealing with the cities' multi-cultural *backyard* district of Wilhelmsburg (Hajduk 2010, p. 12). The IBA Basel 2020 is the first IBA located in a border triangle containing parts of Switzerland, France and Germany. The IBA Heidelberg aims to position the city as a model city of science (City of Heidelberg ed. 2012, p. 7). And finally the IBA Thuringia – taking place in the entire federal

state – puts the focus on demographic and environmental aspects related to its financial situation (IBA Thuringia ed. 2011, p. 5-7). The first IBA abroad is located in the city region Parkstad Limburg in the most south-eastern part of the Netherlands, flanking Germany directly.
The enormous number of current IBA-exhibitions, the considerations about further IBA [Berlin 2020] and finally the positive reputation of former IBA domestically as well as abroad, lead to believe that there are IBA-typical features which could be implemented in other formats concerning urban and regional projects. IBA-typical recommendations can be useful for Europe-wide forthcoming formats of urban and regional development. Putting the focus on IBA's future in Germany, there are also experiences selected from IBA-similar formats abroad which are defined as possibly learning effects for IBA itself.

2. The research project >The future of International Building Exhibitions<:

Conducted in the context of a constantly increasing number of IBA-exhibitions in short time intervals the project >The future of International Building Exhibitions< [2009-2010] discussed the development of the IBA-format focused on two research elements.
The first element – the international project research – was aimed at enriching the discussion concerning the format's future with an international view (BMVBS ed. 2011, p. 7). Considering 80 formats and finally ten case studies [including Manchester's Urban Renaissance Program; Expo Milan 2015; Floriade Venlo 2012; …] of urban and regional development within the scope of the research project, several IBA-typical features have been defined and evaluated.
The second research element was focused on developing a monitoring system for an internal self-evaluation of future international building exhibitions as an instrument of quality assurance. That element of the research work consisted of two steps and included an analysis of the functional logic of an IBA and the development of recommendations of action for future exhibitions (BMVBS ed. 2011, p. 8).

2.1 Essential results of the international project research:

- Although IBA similarity of the international case studies has been a guiding principle for the research project, there are no formats directly comparable with IBA. For similar requirements different projects and formats are being applied (BMVBS ed. 2011, p. 7).
- Many strategies and projects combine the pure process of building with soft strategies of distinguishing sites either trough the arts, communication or events (BMVBS ed. 2011, p. 7).
- Unique characteristics of an IBA like the linkage of a top-down and bottom-up approach, the admission of experiments and of openness towards innovation and goals have been identified by only a few examined projects. (BMVBS ed. 2011, p. 7).

- Only a few projects work under lab conditions and a bottom-up approach at the same time (BMVBS ed. 2011, p. 7).
- Comparing IBA with different European formats a tendency towards regionalization can be detected and the areas of reference become broader (BMVBS ed. 2011, p. 7; p. 17).
- Instruments of analysis and quality control have only been developed in few examples abroad despite an obviously increasing complexity and need for reflection resulting from this fact. In some countries guidelines and *Baukultur* institutions (i.e. institutions for a better built environment) exist, already established in the area of quality control of strategies and projects with IBA-like aspects (BMVBS ed. 2011, p. 7)

2.2 IBA's functional logic

Considering the second research element the project was focused on developing a monitoring system for an IBA internal self-evaluation as an instrument of quality assurance. Neither has there been a monitoring process that can be generalized for the IBA, nor has there been a systematic research for a functional logic which is an essential prerequisite. Based on a case study dealing with the functional logic of the IBA Fürst-Pückler-Land in the federal state of Brandenburg, the research project defined mechanisms of functioning. Therefore partially structured interviews with the protagonists of this IBA-exhibition were a central instrument for the empirical survey. The structure of the interviews was worked out on the basis of the already existing knowledge on international building exhibitions and similar formats (BMVBS ed. 2011, p. 8). Finally four phases including several recommendations have been identified:

<u>Phase 1: pre-IBA-phase</u>

- Defining the urgency of implementing an IBA instead of using conventional planning instruments for structural problems by local actors and stakeholders. Therefore the protagonists need to discuss IBA's admission of experiences and its openness towards innovation at two levels; on the one hand innovation aspects concerning the local and regional development, on the other hand innovation aspects dealing with building and planning culture itself. (BMVBS ed. 2011, p. 7; p. 46)
- Furthermore the pre-IBA-phase requires political support, the debate of a stable IBA-idea, the definition of the area of scale and reference and the exchange of experience. (BMVBS ed. 2011, p. 47-48)

<u>Phase 2: starting phase</u>

- Developing a sophisticated structure of communication in order to assure IBA-project's approval by the local population. (BMVBS ed. 2011, p. 48)
- Institutionalizing the capacity to act concerning both financial and organizing resources. (BMVBS ed. 2011, p. 49)
- Stabilizing the network of experts and extending the structures of participation concerning IBA's projects. (BMVBS ed. 2011, p. 49)

<u>Phase 3: project phase</u>

- Emphasizing the extraordinariness and the "relative alienation" of IBA's projects. (BMVBS ed. 2011, p. 50)
- Strengthening the network of projects and sponsors. (BMVBS ed. 2011, p. 52)
- Integration into an international networking process (BMVBS ed. 2011, p. 52)

Phase 4: final phase

- Assuring institutional sustainability by defining forthcoming approaches and revoking the IBA-trademark while establishing self-supporting structures simultaneously. (BMVBS ed. 2011, p. 52)

The listed phases represent the ideal type of phases that were identified out of an abstraction of the information obtained from the IBA Fürst-Pückler-Land. The process of current and upcoming IBA-exhibitions does not follow rigidly this scheme of phases but show overlaps, parallel developments and also regressions to previous phases. (BVMBS ed. 2011, p. 8)

2.3 IBA-typical features / recommendations:

Approving IBA's functional logic – structured by phases – the research project extracted general IBA-typical features that are meant to be recommendations for both forthcoming IBA-exhibitions and different projects of urban and regional development. Based on the unique IBA-characteristics there are features considered as being typical for IBA. Initiated by an IBA validation workshop in 2010, the following IBA-typical features were filtered and emphasized (BMVBS ed. 2011, p.8). Therefore, IBA-typical features are:

- the specific innovative character of the idea of the IBA that cannot be realized with conventional instruments and formats,
- the degree of "relative alienation", meaning external influences and expertise when organizing and realizing an IBA-exhibition,
- a finely divided communication strategy,
- visionary project ideas that are initially created apart from hard calculations,
- the temporary lack of triviality and daily routines,
- the creation of degrees of freedom to allow experimental action and
- the definition of a mission for the future that can serve as a basis for planning at the end of an IBA exhibition (BMVBS ed. 2011, p. 8)

3. The future of international building exhibitions – experiences from abroad

Based on the analysis of IBA's functional logic and its typical features the research project defined – as previously listed – unique characteristics of the IBA like the linkage of a top-down and bottom-up approach, the admission of experiments and of openness towards innovation and goals. These characteristics are IBA's main potentials (Niemann et al. 2011, p. 322). Comparing IBA with different European formats of urban and regional development there are a few aspects that should be considered regarded to the future of international building

exhibitions. The key-topics in the context of possible learning effects for the IBA can be highlighted in the sense of a cross-sectional view: reason for urban development chains, scale and area of reference, identification of aims and topics, conditions for innovation/funding of innovation, quality of process, communication and image, quality assurance, functional chains and improvement of continuity (BMVBS ed. 2011, p. 7). Regarding the experience out of the international building exhibitions, the following recommendations and conclusions can be drawn for forthcoming IBA:

- IBA should provide clearly defined requirements for sophisticated analysis of the processes. Every IBA is related to specific spatial conditions and unique stakeholder, therefore the processes of following the different aims is important.

- IBA should have the view from outside. Being strongly involved in different internal problems make it necessary to have an ingenuous and sovereign view from an external perspective.

- IBA should encourage participation. The success of every IBA depends on participating the stakeholders and the concerned population.

- IBA should strengthen communication both internally and externally. Discussions in public about the projects, the aims and the successes of the whole process are import to get support from institutions and attention in public.

- IBA should implement (self-) reflective moments. As the process of nearly every IBA is flexible and determined by different decisions the moment of overturning the guidelines is a condition for being successful.

- IBA should examine mechanisms of continuation. As every IBA is running during a limited space of time, it is important to establish structures and conditions to continue the improvements.

- IBA should establish an international exchange of experiences. The format of the International Building Exhibition is getting more and more international related to the sites of the exhibition and is regarded more and more as an instrument to head urban development, therefore it is necessary to learn from each other and to profit form the different experiences.

At this moment, when the IBA format is getting known and discussed as an interesting format for initiating urban development, the research about the results should be intensified. If the Ruhr Region considers “Cooperations and networks have evolved that are now being continued on the basis of inter-municipal cooperations between the towns and cities involved… Other regional activities or the application as European Capital of Culture, would, as they stand, not have been possible without

the IBA, either on the cooperation level or in terms of the vision of seeking to create something jointly together for the region." (Reicher et al. 2011, p. 17) the question is obvious: How can this link in a chain of effects be used for restructuring the process of urban renewal?

CITY: GROWTH, IDEOLOGIES, POWER AND VIOLENCE - SEMINAR

Markéta Březovská [1], Jan Kristek [2]

Abstract

Our paper presents a theoretical framework, content and methodological format of a newly established seminar on modern history and theory of urbanism at the Faculty of Architecture, Brno University of Technology in the Czech Republic. The paper deals with our concrete experience as educators and creators of the conception and teaching methods of the seminar. First objective of the seminar titled *City: Growth, Ideologies, Power and Violence* was to acquaint students with the theory of our field. This implies relations between cities and technology, economy, politics and culture, various approaches to urban planning, ideologies, urban growth and problems of cities since the first Industrial Revolution until today. Reflecting the interdisciplinary discourse, we have welcomed lectures and discussions with professionals from external urban studies fields. Students themselves were asked to read, understand, graphically represent to others and in the end rewrite theoretical texts by experts of different backgrounds, all dealing with cities: sociology, economics, geography, philosophy, urban anthropology or cultural ethnography. The course content was divided into three blocks. The first one, called *Growth*, addressed analyzing the development of the city in terms of current theories. The second one, *Ideologies*, summarized important approaches to urban planning, understood as a response to stimuli coming from the period discussed in the first block. The third block, *Power and Violence*, outlined the city as a medium and space for exercise of power. Apart from our effort to deliver this specially tailored content to our students, we have also devised specific ways of teaching in order to improve students´ ability to use critical theory as an essential part of their future work – our second main objective. In that respect, we have introduced a participative method involving students actively in the course of each lesson, in order to help them find their own beliefs and ways of thinking, rather than offering them ready-made interpretations and instant arguments. In a broader sense, we have tackled a question what role should we play as educators in such a complex field with so many elusive factors that architecture and urban planning stands for.

Keywords: seminar, teaching theory, critical thinking, ideology, city

1. Introduction

Academic and professional sphere of architecture and urbanism are experiencing a pressure as never before, there are new factors acting on them. These forces include globalization, accelerating development of new technologies, extremely fast urbanization in developing countries of emerging economies, and new energy (de) regulatory policies. Our paper addresses an important question of today's architectural education: How can architecture schools train accountable professionals to successfully contribute to present situation? Within architectural education, we decided to focus on one topic only, which, we hope, will engage in meaningful debate. The issue covered is: How to teach urban planning theory under-ever changing conditions?

Although we[3] are examining a broader question here, this paper is very much based on one concrete example: In autumn 2011, coming back from studying and working abroad, we were asked to conceive and teach a new seminar on a modern history and theory of urbanism at our alma mater – the Faculty of Architecture of Brno University of Technology in the Czech Republic. Since the very beginning we had quite a strong idea what to teach our students and how. Rather than putting the emphasis on purely ´architectural´ analysis, we stressed out the importance of understanding links between the physical substance of cities and the technology, economics, politics and culture. The title of the course was *City: Growth, Ideologies, Power and Violence.* The course covered development of modern cities since the industrial revolution until today, based on precisely selected theoretical texts. Conceptually, we have been drawing from experience gained during our studies at the Institute of Art and Architecture at the Academy of Fine Arts in Vienna and at the Bauhaus Academy in Dessau. Therefore we would like to thank here our teachers, namely Gabu Heindl, Francoise Fromonot, Regina Bittner, Peter Trummer, Chantal Mouffe, Markus Schaefer and Wouter Vanstiphout, who have been a great source of inspiration and knowledge for us.

The given task was specific in several ways. The realm of modern history and theory of urbanism is broad enough to accommodate wide range of topics on one hand, delimitated by demand for innovation at the Brno Faculty of Architecture on the other. At the first place we have tried to understand who our audience will be. A) Although most of the students have a substantial knowledge on various topics concerning theory of urbanism, it is often fragmented gained via vicarious sources and potentially inaccurate, misinterpreted or covered with prejudices. B) The students had gained most of the knowledge passively and often have problems with interpreting it and applying it in practice. Therefore we introduced an underlying concept of thinking and talking about history and theory, rather than updating curriculum with the "latest stuff". We had decided to teach the

[3] We = MB and JK, both absolvents of the Faculty of architecture, Brno University of Technology and Academy of Fine Arts in Vienna. MB also studied at the Bauhaus Academy in Dessau. Currently, we are both working on our PhD thesis in Brno.

course in a form of a participatory seminar instead of giving lectures in order to actively involve students into its structure. As for the content, we aimed to create a bundle of "must knows" - relatively wide in range but condensed in composition. The name of our seminar, *City: Growth, Ideologies, Power and Violence*, was also the basic structure of it, which was accordingly divided into three thematic blocks. Both, the specific format of the seminar and its content will be examined in this paper.

Our departing assumptions for the overall conception were based more on personal estimates than anything else – later on, they proved to be right, measured by high attendance and interest of students. The seminar was created as a compulsory optional subject for 5th-year students, but opened to everyone. Finally, it was attended by around 40 students of both, Bachelor and Master program, from 1st to 6th year. The accent on theory as fundamental basis for practical work – theory perceived as an inseparable part of the dialectics of theoretical and practical work of an architect, rather than to be there just for corroborating a "good culture of architectural profession" – is not groundbreaking, especially thinking of other disciplines falling into category of urban studies. It was particularly our personal involvement and experience confronted with the environment of the technical university that were crucial in delivering the selected content and developing specific teaching methodology of the seminar.

Our paper presents the very concrete case of our personal experience with teaching concrete students in a particular time at the concrete location. It is not meant to be an overall manual on "how to teach". However we believe that our experience can serve as a good reference to anyone who is concerned with urbanism and teaching in general.

2. Analysis

2.1 Content of the Seminar: the Bundle

The name of our seminar, *City: Growth, Ideologies, Power and Violence,* stands for the content itself, giving it a framework of three thematic blocks. In the first block, *Growth,* we have dealt with the historical facts and their interpretation of development of modern cities since the industrial revolution until today, based on precisely selected texts. As a backbone of this block we adopted a point of view represented by Czech sociologist Jiří Musil, in which the beginning of urbanization coincides with industrialization (2002). Not being purely technocrats or culturalists ourselves, still, we found the news in technology and changing demography relevant for defining different historical eras in order to frame the topics of the first block. We talked about industrial revolution, fordism, postfordims, globalization or shrinking cities.

The second block named *Ideologies* was closely interrelated with the first block, in terms of both, the time span and the context. Here we have summarized the

most important approaches to urban planning, understood and interpreted as particular modes of thinking with their own history and context. The word "ideology" itself does not represent pejorative connotations such as closeness, unilateralism, propaganda and other irrational features in a form of political theory or utopian architecture. For us, it stands for a coherent system of ideas, attitudes, values and evidence as an intellectual framework enabling modus operandi of practical work. Our goal was to introduce to students to historical and contemporary approaches to urban planning as openly as possible, still, based on categorization by two French historians and theoreticians of architecture in different times - Françoise Choay (born 1925) and Françoise Fromonot (born 1958). Furthermore, we focused on contemporary consumerist tendencies in society and their consequences for the city.

The third block, *Power and Violence*, outlined the city as a medium and space for exercising a power. We understood power as an ability to enforce own will against abilities and will of others, making it often a source of conflicts. Conflicts have always been an obvious aspect of forming and shaping cities and modern societies, where the coercion is monopolized by the national state, multinational corporations, politics, economics, but also by culture. We addressed violence in/against the cities, not only in the form of war or terrorism - urbicide, but also violence and conflicts of power, related to the various crises and further with concepts of an unobtrusive control in the city.

2.1.1 *Growth*: The Industrial Revolution

Our lessons have begun with the so-called industrial urbanization of the late 19th century. Jiří Musil, the Czech sociologist, dealing mainly with housing and urban sociology, considered the beginnings of urbanization being this period of time, especially due to the growth of urban population and spread of the urban way of life (2002). We addressed the rapid expansion of cities in the period of coal and steel and examined the concentration effects of steam as drivers of these elementary processes. Our foreign guest Michael Reuss, a German environmentalist and urban historian, spoke on changes in living conditions and infrastructure in the time of industrial revolution.

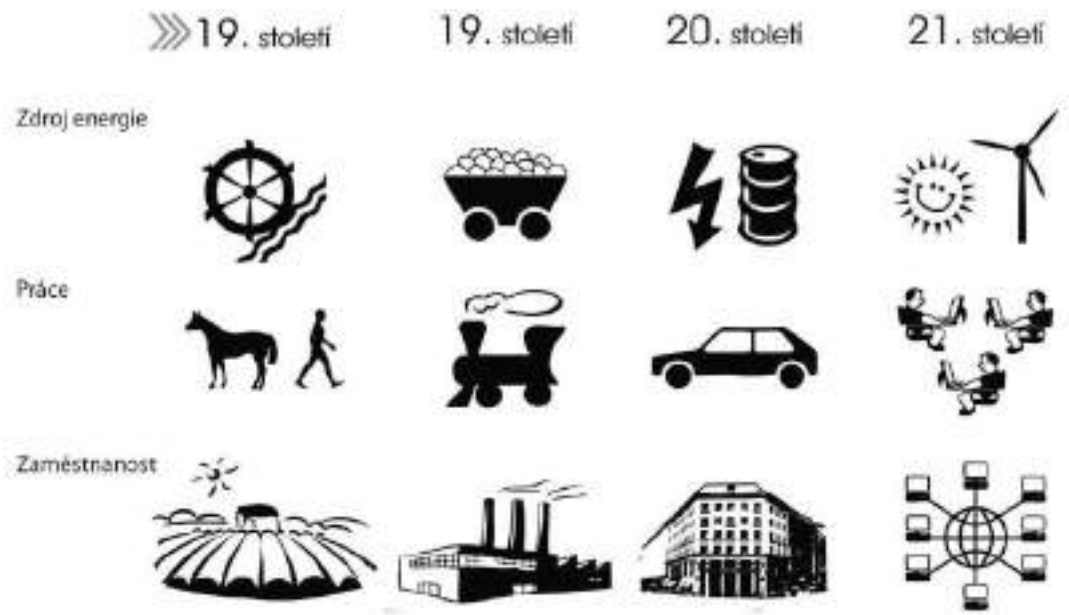

Figure 1. Classification of urbanization periods according to a participating student Zdenka Sedláková, based on the text by sociologist Musil (2002: 7 - 53). Source: Archive of the authors.

2.1.2 *Growth*: Fordism

Rationalization of production in the form of a moving assembly line introduced by Henry Ford caused the establishment of a new economic order of mass production (Garreau 1991). One of its consequences was for instance a general motorization (Jacobs 1962), acting as one of the main factors in the development of suburbia. In addition to Charlie Chaplin's film Modern Times (1936), we also watched the original documentary about the famous social project of that time – the Frankfurt kitchen by Margarete Schütte-Lihotzky (1928).

2.1.3 *Growth*: Postfordism

The rise of the middle class coincided with the advent of economy of flexible accumulation (Harvey 1994) and culture of mass consumption of goods, cities, and lifestyle. Western countries entered the post-industrial period, which we discussed with a landscape architect Daniel Matejka. Revitalization of post-industrial landscape recorded also a Josef Pleskot's documentary film *Lower Area of Vítkovice* (2011) about a Czech industrial and postindustrial city of Ostrava and its contemporary issues on redevelopment and revitalization.

2.1.4 *Growth*: Globalization and Megacities

Aspects of today's globalized world and its problems with growth (Burdett, Sudjic 2007), continued de-industrialization, migration, economic (dis) equilibrium

(Sassen 2002), the ubiquitous anonymous individuality of mass consumption (Figure 2) and attempts to escape this consumer culture (Palahniuk 1996).

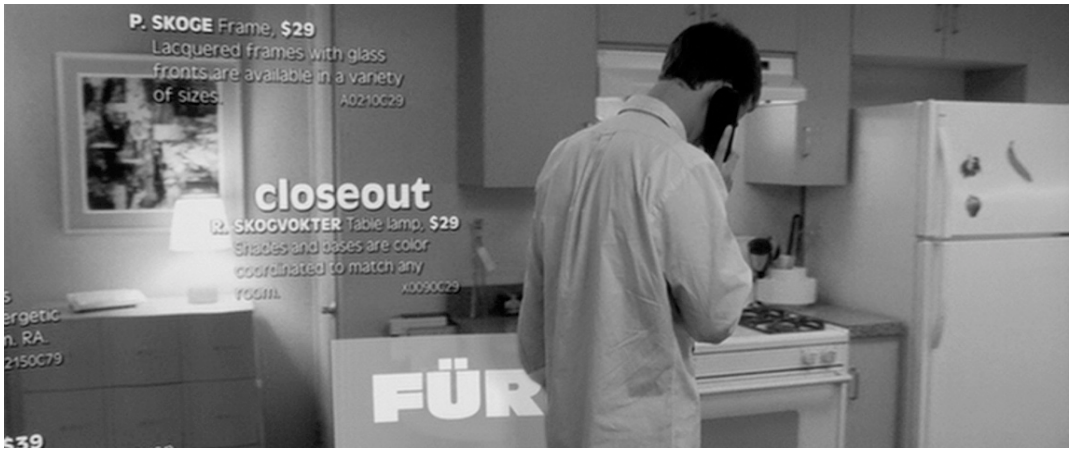

Figure 2. “Like everyone else, I had become a slave to the IKEA nesting instinct. If I saw something like clever coffee table sin the shape of a yin and yang, I had to have it. I would flip through catalogs and wonder, what kind of dining set defines me as a person? …I had it all. Even the glass dishes with tiny bubbles and imperfections, proof they were crafted by the honest, simple, hard-working indigenous peoples of wherever.” A clip from David Fincher’s film Fight Club (1999), based on the novel of the same name by an American postmodern writer Chuck Palahniuk (1996).

2.1.5 *Growth*: Shrinking Cities

Shrinking Cities - a term coined by the German architect Philipp Oswalt (2005) at the beginning of the new millennium - has been a problem for many cities around the world, and society reacts to it differently. For example, by the German video game Demolition Company (2010) as the opposite for the US video game SimCity (1989).

2.1.6 *Ideologies*: Categorization by Françoise Choay

Choy, born 1925, divides the ideological approaches to architecture and urbanism to 1) the naturalistic one - represented by F. L. Wright (and his plan for a city for a new community, 2000) for instance, 2) the progressive one - such as modernism represented by LeCorbusier and 3) the culturalist one, with suggestions of ideal garden cities (Howard 2011). We discussed the background of creation of individual ideas, their possible realizations and welcomed the lecture by the philosopher, director, scriptwriter and educator Jan Motal on dissolving the myth of modernity in the city.

2.1.7 *Ideologies*: Categorization by Françoise Fromonot

One generation younger Fromonot, born 1958, applies a slightly different classification to existing ideas, though again with the division into three groups: supermodernism (Koolhaas 1995), metamodernism (Spirn 2000) and postmodernism, represented by Jencks and Krier.

2.1.8 *Ideologies*: The City as a Product

Our guest in this session was a sociologist Slavomíra Ferenčuhová, who questioned „in what sense are the cities for sale“, when, how and why has developed the city branding and place marketing, how to create an attractive identity and image of the place/city, and whom are the cities as products primarily intended to serve. According to Jayne (2006), the cities are not only places of consumption, but also objects of consumption, and so we got to Disneyland (see Fig. 3) and Disneyworld (Zukin 1993) and urban activities of the Nike company (von Borries 2004).

Figure 3. Disneyland symbolizes the domination of space through the tools of architecture under the auspices of multinational corporate patronage. The world of joy and happiness became the visual landscape of consumerism representing a shift to a society of consumption. Source: STEROW © Stephen Rowley 2011.

2.1.9 *Power and Violence*: Crisis, War, strategy, terrorism and control in the city

Cultural anthropologist Petr Gibas, gave us a lecture on the Prague metro, the fear of (Cold) war and how it was reflected in the socialist city, both on the material plane as well as ideological and imaginary one. We also discussed issues of geopolitics, security and control in public space (Norman 2009) and the extent, to

which a war strategy (Weizman 2007) can influence the perception and the use of urban environment and architecture.

2.2 Format of the Seminar: the Method

"Imagine it, you're sitting in your living room, which you know so well; this is the room where the family watches television together after the evening meal. …And, suddenly, that wall disappears with a deafening roar, the room fills with dust and debris, and through the wall pours one soldier after the other…" (Weizman 2007).

Eyal Weizman's text was one of many read by students of the seminar. The text deals with strategy developed by Israeli military in a course of Operational Theory Research Institute (OTRI), where several thousands of soldiers were moving not through corridors of streets but through tunnels broken through walls and ceilings of houses of dense urban fabric when attacking the city Nabulus in 2002. "We interpreted the alley as a place forbidden to walk through, and the door as a place forbidden to pass through, and the window as a place forbidden to look through […]. This is because the enemy interprets space in a traditional, classical manner, and I do not want to obey this interpretation and fall into his traps," sayid Kochavi in one of the interviews (Weizman 2007). Co-director of OTRI Shimon Naveh claimed their theoretical background as being based on the texts of architects such as Christopher Alexander, John Foerster or Gregory Bateson or anti-imperialist texts of Situationsts or philosophers Deleuze and Guattari.

Although the aim of Israel military are in contrasts to often humanistic attitudes of architects, the pragmatic way of implementing critical theory illustrates its mastering as an intellectual tool. In the similar way, besides imparting the necessary knowledge of the theory, our main goal was to teach students how to use the theory for their own advantage. However we didn't aim to train students in a bare logical argumentation with the acquired theoretical ammo – a kind of academic sophism. Our goal was to relativize and in certain way undermine their way of understanding and to train them in a *strong-sense* critical thinking (Paul 1995). Similarly Shimon Naveh said: "We employ critical theory primarily in order to critique the military institution itself – its fixed and heavy conceptual foundations" (Weizman 2007).

This aim was particularly reflected in the format of seminar and the way we have worked with students. A typical lesson consisted of two up to three students´ presentations, one guest lecture, and several short screenings, always accompanied by discussion. The core of each lesson was built up on students' presentations. Each presentation was based on assigned theoretical text and it was understood as a little personal research project. In that sense, before students presented it to others, they had to have discussed it with us - in terms of accuracy of facts, relevancy of chosen material, language, correct sourcing and also means of graphic representation. Therefore, the considerable part of our teaching took place outside the seminar room – in the form of personal consultations, during

which we have intensively discussed with each student how to approach the topic, how to argue correctly about his/her findings and how to present it in appropriate way. At the classroom then, after each presentation we have critically analysed every student's work and eventually pointed out shortcomings or inaccuracies in his/her argumentation. We have also addressed various complementary or opposing points of view on the presented topic inducing students to actively participate in discourse. So at the end, it was students too, who have helped to create the content of the seminar, accompanied by our selection of screened clips from popular and/or documentary movies, series, videogames or computer games, comic books, characterizing the period, opinion or idea being discussed. The whole framework was complemented by guest lectures.

In such a scheme, a tutor operates as a discussion moderator rather than guru broadcaster. By already mentioned intensive tutoring and consultations of students' presentations/texts, we aimed to help students to deliver meaningful results in order to maintain the coherence of the whole seminar. This was possible with a great enthusiasm and engagement of students. Even if there were always some improvements possible, the problems and the following analysis carried the same importance within the lesson as the presentations themselves. To enable this participatory and informal scheme to work, we had to adjust the set up of the physical environment of the seminar room as well. At the first place we have rejected representative but proscenium-like aula and insisted on a rather smaller space. Getting one of such, we have organized its tables and chairs into a neutral O-shape, which made an informal face-to-face discussion possible.

Time restricted slide presentation of a text is already itself its reinterpretation requiring a deep understanding of the context and research on the topic. Furthermore it mobilizes conceptual and syntactical skills of a student. Based on this experience, in the second stage, students elaborated on their studied topics further by writing their own texts. We asked them to apply the newly gained knowledge on a personal experience, project or observed phenomenon of their choice. The output of the seminar is a book of students´ critical texts.

An important part of the scheme was a reflection of the interdisciplinary discourse in the form of lectures and interviews with external experts dealing with the city - from the fields of sociology, economics, geography, philosophy, cultural anthropology and urban ethnography. Besides complementary information on the topic, they have brought to discussion their own characteristic language - typical for methods and patterns of thoughts in their specific field. We have perceived this fragmentation - a consequence of the collage of the chosen texts, guest lectures and movies, which built up the content of the seminar, as an advantage – as a inseparable part of the concept, allowing students to relativize their own thinking. But, it was not enough for us to introduce students to the current expertise and to provide them this interdisciplinary context involving external professionals. Our main goal was to teach students to use the knowledge they have gained, to think critically, argue passionately, and independently express

their opinion, and by that we tried to reinforce their capacity of asserting themselves in order to be able to influence the field itself.

2.3 Results

The seminar was attended in average by forty students (which was four times more than the number of students originally officially inscribed) from 2nd to the 6th grade, both Bachelor and Master programs. The general interest of students was immense; some show broader interest in seriously deepening their knowledge in theory in the future. The methodology itself proved to be working well in terms of format and content as well. In the weekly two-hour lessons we managed to discuss the fundamental topics as the basis for our eventual future work with students to build upon. The format, dense and demanding, still appreciated by students has had a considerable outcome: valuable presentations and 3 to 12 pages long texts written by students, which we perceive as a challenging success and motivation for further work for them as well as for us. All submitted texts are now being published in a seminar proceedings book carrying the same title, *City: Growth, Ideologies, Power and Violence.* Within lessons, we contrived to encourage everyone, external guests, internal teachers and our students to interact within each other.

The conception of our seminar became a part of the Operational program "Education for Competitiveness" for the period 2007-2013, directed by The Czech Ministry of Education, Youth and Sports and founded by the European Social Fund (ESF). We have also presented the content and methodology of the seminar at the PhD conference at the Technical University in Brno in January 2012, receiving a very warm reception and feedback by both, students' body and the faculty, inspiring us for further work. We also obtained an invitation to attend and present our teaching experience at the International scientific conference "Veda vo výstavbe / Science under Construction" in Bratislava, Slovakia in September 2012.

Since we were offered to continue teaching this kind of seminar in the future, looking back, we would like to implement some improvements. This time, we have let students working on their own writings first in the second half of the semester. Today we think that a continuous work on the texts since the very beginning could bring even better results. Considering the individual consultations before presentation or final submitting with each student, the shift to collective discussion comes here into question, allowing other students to listen or interact already during a concept polishing process.

3. Conclusions

The only thing constant is change itself, (Heraclitus in Mansley Robinson 1968: 91), and as well as rapid the world changes, changes the approach to teaching.

The pilot of the seminar on modern development and theories of urbanism titled City: Growth, Ideologies, Power and Violence took place in the winter term of academic year 2011/2012. The seminar was created as a compulsory optional subject for 5th-year students, but opened to everyone. This option chose students of both, Bachelor and Master program, from 1st to 6th year. We have dealt with the development of modern cities since the industrial revolution until today, based on precisely selected theoretical texts. The whole course was divided into three blocks. The first one, called GROWTH, addressed analyzing the development of the city in terms of current theories. The second, proceeding block called IDEOLOGIES, summarized important approaches to urban planning, understood as a response to growing complaints from the period discussed in the first block. The third block, POWER AND VIOLENCE, outlined the city as a medium and space for exercise of power.

After having the clear content structure, we have focused on our main goal and how to reach it. The main goal was to acquaint students with the basic historical and theoretical concepts, and, especially, to teach them to apply the knowledge they have gained in practice, to discuss ideas properly and master the principles of presenting complex topics. To some extent, it seems like the lack of discussion in the urban planning seminars at the FA BUT came from its format. If we really wanted to

introduce turbulence into education, we needed to structure it differently, to explore new formats. We have come up with a participatory method, when moderated and tutored students presentations built up the lessons of the seminar. Students have carried a part of responsibility in imparting ideas contained in theoretical text assigned to them. Each student has had to read, understand, assess and then process it in a clear graphic presentation to introduce the main idea to others. Then we have discussed the given issue sitting in a non-hierarchical face-to-face setup circle. The final output of each student's semestral work was an own critical text, which applied the acquired theoretical knowledge on a personal experience, phenomenon or project of his or her choice. We have insisted that students always explore relations to other issues, historical, geographical situation and relate it all in time and place. They had to rethink their way of presenting things and asked themselves: which theory are we talking about, at which time, on which place, mobilized in which direction?

As from students' side, it was demanding in terms of deep studying, understanding, and presenting the assigned topics. From the teachers side, the scheme was time demanding and challenging in terms of intensive individual consultations and personal involvement in students work, in order to uncover their potentialities, rather than letting them cover done deals. Together, we have prepared the lessons in close relation to the last and the coming one. Further on, the role of us as teachers in the classroom was rather a role of discussion moderators and when necessary correctors than the role of speakers. We have found this scheme, not commonly used for teaching theory, successful in accomplishing our goals mentioned above.

In number of lessons we have welcomed external lecturers dealing with the city - from the fields of sociology, economics, geography, philosophy, cultural anthropology and urban ethnography. The texts from our reading list were accompanied by screening of clips from popular and/or documentary movies, series, videogames or computer games, comic books, characterizing the period, opinion or idea being discussed. One could easily admit that this is not architecture education; this is not urban planning education. We have shown students that to think "what if yes?" is possible, to relativize stereotypical opinions is healthy, and to look around to perceive everything is necessary.

Within this dynamic process of going beyond the definition of "urban planning seminar", we hope we have reached new attitudes to teaching.

"Our unique mission is to move beyond the highest level of professional training to open a creative space within which the discipline can rethink itself, a space of speculation, experimentation, and analysis that allows the field to detour away from its default settings in order to find new settings, new forms of professional, scholarly, technical, and ethical practice."[4]

4. Acknowledgements

At the first place we would like to thank our students, who significantly contributed to the final picture of our seminar.

Special thanks go to Karel Havliš, Head of the Ústav navrhování V (Department of Design und Urban Planning) at the Faculty of Architecture, Brno University of Technology, for inviting us to teach this course in Brno.

We were strongly inspired by Gabu Heindl's seminar "Cities, Growth, Politics and Power" at the Academy of Fine Arts in Vienna in 2008/2009.

Next to Gabu Heindl, who nurtured our interest in theory and whose way of teaching we took as a reference, our thanks go to Francoise Fromonot's theory lectures, Wouter Vanstiphout's lectures on "violence and the city", Peter Trummer, Chantal Mouffe and Markus Schaefer, all from the Academy of Fine Arts in Vienna, and Regina Bittner's lectures at the Bauhaus Dessau in 2010/2011.

LIVEABLE LANDSCAPES: A key value for sustainable territorial development

Gemma García-Blanco [1], Efrén Feliú [2]

Abstract

The development of territorial cohesion policies in EU has become a very powerful tool for the implementation of European political guidelines. Besides, with regional policies in EU increasingly focused on harmonious territorial development towards sustainability, highly inspired by the European Landscape Convention (ELC, 2003), the elaboration of landscape plans and calling for its integration within spatial planning has become a potential asset in regional development towards sustainability.

Within this context the landscape has become a key territorial value where analyses and assessments could become important elements which could enrich and improve integrated spatial planning and urbanism in different ways, and be seen and used as an asset for economic and territorial development. But with the European Union characterised by varying, historically developed governing and planning systems in relation to both landscape and spatial planning, the process of reaching such a goal is not a simple task. The differences in land use decision processes due to different patterns of legal, constitutional and administrative frameworks have obvious impacts on the concept of landscape and practices in relation to landscape management and planning. It seems clear that the linkage between territorial development strategies and landscape planning is a political priority.

The paper presents the LIVELAND project, an ESPON 2013 targeted analysis running from March 2012 until April 2013, which focuses on policy making for liveable landscapes. In particular it aims to explore practices of landscape planning and regional territorial strategies. By means of policy analysis and exchanging experience, among landscape planners and policy advisers, comparisons are drawn on the content, methodologies, processes and procedures of policy making for landscape. The identification of successful approaches in combining landscape management and socio-economic development will constitute a basis of this comparison, and based on evidence, advices will be made on 'planning for liveable landscapes' in the form of guidelines and policy recommendations. In the proposed LIVELAND project these objectives and aims are addressed by including six case examples studies across Europe, each representing a different planning culture and different levels of competences and territorial scales of landscape policy making.

[1] Tecnalia Research & Innovation, Bizkaia, Spain – gemma.garcia@tecnalia.com
[2] Tecnalia Research & Innovation, Bizkaia, Spain – efren.feliu@tecnalia.com

These 6 cases serve as examples to: get an insight of the current practice of landscape policy making, and of implementing European landscape policy in particular (without pretending a complete overview of European practice, because this targeted analysis is a bottom-up initiative); it is expected that common denominators will be identified such as terms, concepts and practice that are shared among the landscape policy makers who are included in this project. The participant regions and cities are: The Basque Country (Spain), The City of Ljubljana (Slovenia), Midden-Delfland (The Netherlands), Navarra (Spain), Thy National Park (Denmark) and the city of Offenburg (Germany).

Key words: Landscape, Spatial Planning, benchmarking, policy making, territorial cohesion.

1. Introduction

Competitiveness and attractiveness of regions have become important aims of regional, territorial and environmental policies of the European Union, particularly as contributing to harmonious territorial development.

The European Landscape Convention states that landscape "*constitutes a resource favorable to economic activity*" and responds "*to the public's wish to enjoy high quality landscapes and to play an active part in their development*" (Council of Europe, 2003).

1.1 Concepts and approaches

It is embedded in European concepts of landscape that, as people, we do not simply live in a physical reality of 'areas' or 'territory' but mainly in our perception of such areas: in landscapes (Moore & Whelan 2007). 'Landscape' includes the physical and the mental, the natural and the cultural (COST, 2010). Landscape is a common good that visibly and invisibly frames everyday lives.

In recognition of a multifaceted aspects of landscapes, the European Landscape Convention (Council of Europe, 2003) recognizes landscape as having "…an important public interest role in the cultural, ecological, environmental and social fields". Consequently, improving the understanding of the outcomes of landscape planning decisions is of high political priority (European Union, 1998), a conclusion which is followed up in the European Landscape Convention (ELC) stressing the importance of stimulating the elaboration of landscape plans for the considering of landscape as a key territorial value (Council of Europe, 2000). The Convention recognizes landscape as having "…an important public interest role in the cultural, ecological, environmental and social fields, and constitutes a resource favourable to economic activity and whose protection, management and planning can contribute to job creation".

This need of developing a definition of landscape as an asset in regional development towards sustainability is fully recognized by ESPON, emphasizing among other things the need for a: “Balance between landscape protection and social welfare and economic development” through an “Improvement of governance and participation of key actors and stakeholders in the planning process”, and furthermore “Assess, evidence based, how to consider landscape planning in the framework of territorial cohesion policies”.

Within the LIVELAND project:

- Landscape is recognized as “whatever part of the **territory as conceived by the population**, which character results from the action and interaction of natural and human factors”.

- Landscape is also recognized as an essential element in the quality of life, expressing a common natural and cultural heritage, and contributing to the configuration of the territorial identity.

- It is also a dynamic element which reflects the relationship between the population and its territory along time, and therefore, its conservation should focus on maintaining and improving its quality and diversity, integrating new elements and uses.

- Land use strategies increasingly emphasise multifunctionality. The landscapes of the future will have to serve, simultaneously and in integrated ways, a number of different functions (Haber, 1977). These functions are employed for analysis and policy proposals in this project:
    - ecological (as an area for living organisms and natural environments), (Daily, 1997)
    - economic (as an area for production and reproduction),
    - socio-cultural (as an area for cultural actions and identification),
    - historical (as an area for settlement, memory and identity),
    - and aesthetic (as an area for shaping and experiencing).

- “Multifunctional landscapes” refers to areas serving different functions and combining a variety of qualities, i.e. that different material, mental, and social processes in nature and society take place simultaneously in any given landscape and interact accordingly. Multifunctionality in landscape, therefore, means the co-existence of ecological, economic, cultural, historical, and aesthetic function. (Zebisch et al, 2004).

- Balance between landscape protection and social welfare & economic development is possible and wanted.

- Landscape approach (evaluation and planning) could enrich and improve integrated spatial planning and urbanism

- The evaluation of the landscape requires a global vision of the land throughout a multi- scale approach, going beyond the local interest and point of view.
- The identification of landscape objectives can be the support to motivate the improvement and development of poorer or abandoned areas.
- The assessment of the landscape can contribute to the process of making decisions about the most sustainable way to use the land.
- Improvement of governance and participation of key actors and stakeholders in the planning process

2. Project objectives and aims

The LIVELAND aims at exploring practices of landscape planning and of regional territorial strategies. By means of policy analysis and exchanging experience, among landscape planners and policy advisers, comparisons are drawn on the content and landscape analysis and evaluation methodologies, processes (public participation / institutional coordination), procedures of policy making for landscape (protection figures, planning instruments) and performance monitoring. The identification of successful approaches in combining landscape management and socio-economic development will constitute a basis of this comparison, and recommendations are made on 'planning for liveable landscapes' in the form of guidelines and policy recommendations.

Specific project aims are as follows:

- Developing a **definition of landscape as an asset in regional development towards sustainability.**

- With this project ESPON will have made a first systematic analysis about landscape protection and development in European 'planning systems'

- **Identifying good and best practices** in the stakeholder regions, with regard to **landscape and spatial planning**, and of their impact on regional development.

- Identifying specific **actions or measures** in the stakeholder regions which have proven to be successful in implementing combined landscape protection and socio-economic development.

- **Benchmarking** of the methodologies for analysis, content and procedures to improve the processes and performances of planning in the involved regions.

- Scientifically assess how landscape approach (analysis and assessment) and landscape planning could enrich and **improve integrated spatial planning and urbanism**

- Defining **criteria for the integrating** of landscape and regional strategies. Assess, evidence based, the consideration of landscape planning within territorial cohesion policies.

- Analyse available **ESPON data and results** from previous and also current projects that could be used to reinforce the consideration of landscape as an asset for territorial development.

3. Case studies

In the LIVELAND project these objectives and aims are addressed by including 6 case examples studies across Europe, each representing a different planning culture and different levels of competences and territorial scales of landscape policy making.

Table 1. Case studies in LIVELAND project

Case study	Overview
The Basque Country	Is revising its Spatial Planning Guidelines and a proposal for a Landscape Law is under development inspired by the ELC with the aims to integrate landscape planning in other planning instruments
The city of Offenburg	Has recently made a landscape plan and seeks to develop and protect landscapes under urban pressure. Offenburg belongs to "Eurodistrict Strasbourg/Ortenau", so there is already exchange on European scale. A new "Landschaftsplan" is nearly done. Concerning landscape planning, the municipality is interested in improving and learning from the experience of other European regions and municipalities, particularly with reference to successful execution of recommended measures.
Midden-Delfland	Landscape development plan already exists and actions in partnership with the surrounding urbanised municipalities are currently being implemented. From regional perspective, the interest is how to stimulate project development and landscape monitoring. Local and regional governments work close together.
Government of Navarra	Wants to prepare a new landscape plan for the region, based on European experiences. To date, many formal regulations and informal actions exist which now should be articulated and improved by the new plan. The Government of Navarra is especially interested in the specification of the envisaged results concerning the "the guidelines for the elaboration of landscape plans and their implementation". These guidelines will be used for the design of the landscape plan of Navarra.
Thy National Park	Is challenged by the question of enabling a planning process involving all relevant stakeholders in order to obtain a coherent landscape development.
The City of Ljubljana	Is interested in methodologies for the identification of landscape potentials and the development of guidelines, aimed at bringing new arguments in the stakeholders´ dialogue for the development of the Ljubljana and its surroundings. European exchange of experiences is an important motivation.

4. Scientific approach and methodology to be applied

A common framework has been established aiming at exploring good practices of landscape planning and regional territorial strategies in the stakeholder regions and to benchmark the content and procedures between regions.

The following sections describe the main issues, from abstract concepts to planning practices, which will be applied as cross-cutting and transversal issues all along the project tasks.

4.1 Parameters of analysis

- **Methodologies for the evaluation of landscape**

The project should assess the different methodologies that are being used for the evaluation of landscape: data used, landscape elements and methods of valorization, establishment of objectives and also methodologies for the application of landscape concept into practice: protection, conservation, management.

The analysis of the plans will focus on:

1. ***Landscape or spatial structures and appearances***: This includes areas defined through major environmental features (as natural patterns like rivers), and man-made objects and patterns (such as settlements, power-grid lines etc.) These patterns, in their appearance in maps and plans, are not only defined through their "locus standii", but also on their coverage and their density within the appropriate area unit.
2. ***Functional features***: This defined through environmental features such as Biodiversity and Productivity; socially such as Place to live, work, visit temporarily or more frequent through second homes; economically through Production and Reproduction. Identification of functions is important when dealing with general area characteristics, and especially important when dealing with multiple functions/multifunctionality across sectors as a key concept in relation to for instance urban sprawl, homogeneity and heterogeneity of land use.
3. ***Values or qualities:*** the 'quality' or 'value' of space / landscape is an important issue of planning. Beside the function often the natural, economic, cultural and recreational value is mentioned on maps and plans.
4. ***Future developments and scenarios:*** the future spatial developments (trends and scenarios) are often analysed to develop goals and strategies for also to develop 'desirable / advisable' measures for protection, development and management of space and landscape.
5. ***Drivers of change in functions and values***: For instance socio-economic driving forces such as: Land ownership; Land management practices; Land use patterns; Landscape/Land cover; Aesthetics; Biodiversity; Productivity of

ecosystems; Forestry; Agriculture, or institutional driving forces such as regional, national, or EU regulations.

- **Planning processes & participation**

Process understood as governance and sequence of planning, including formal and informal methods and practices

  - Planning and planning processes at different administrative levels (here local and regional authorities with political power to guide developments as well as protection of certain values);
  - Planning and planning processes in different sector settings (as nature, recreation, agriculture, urban dwellings, etc.) that can generate developments and investigations;
  - Planning and decision taking procedures ('good governance' and participation) in relation to landscape and territories.

- **Planning procedures & decisions**

The procedures, including the administrative requirements to be fulfilled following specific legal frameworks will be other very relevant parameter to be considered in our research.

The local and regional plans for landscape and place are often made with participation of stakeholders. It is important to analyse which procedures of decision taking have been followed: such as hierarchical / bottom up / top down / stakeholder driven / administratively organized etc.

- **Actions and measures of local / regional government**

The analysis should also addressed which actions and measures have been incorporated, whether it could be formal as part of a regulated procedure, or informal, for landscape management and planning at different levels of competence.

- **Impact measurement: monitoring indicators and systems**

It is important finally to identify which monitoring systems are in place, for measuring the territorial impact of the actions incorporated in the planning instrument with regard to landscape management and planning.

4.2 Multilevel/Multisector/Multifunctional approaches

The project will apply a multiscale and multisector approach in a transversal way all along the project development.

Although the participant stakeholders represent different administrative levels and competences, both local (represented by the cities of Offenbourg, Ludjlbiana and Midden-Defland and Thy National Park cases) and regional (Basque Country, Navarre), the project will look at the coordination of different levels of planning and also the implications of cross-sector planning. With this regard is remarkably important to address the implications that regional landscape planning will have at local level.

As planning and policy making is often done by a variety of different authorities including experts with different backgrounds the impact of local, regional and national differences should be clarified before examples of planning practice are compared. These include state planning agencies, environmental and nature protection agencies, cultural agencies and authorities for monument protection, regional planning offices, nature park administrations, local administrations; private planning consultants may be called in for support. By comparing approaches taken, by different organisations representing different levels in the planning and managing landscapes, a set of common quality standards might emerge.

Another issue appears when looking into the above described approaches, namely that sectoral differences are another important quality that should be reflected and enables consistence when used across different sectors.

The expression multifunctionality, and more specific “multifunctional landscapes” refers to probably the most important contemporary challenge when dealing with the concept of landscape, namely that areas increasingly serves different functions and combines a variety of qualities, i.e. that different material, mental, and social processes in nature and society take place simultaneously in the landscape and interact accordingly. Multifunctionality in landscapes, therefore, means the co-existence of ecological, economic, cultural, historical, and aesthetic functions. Although there are different ways to classify landscape functions, all lead to the same conclusion that landscapes are multifunctional.

As a cornerstone of the project is the comparing of examples from different regions, and therefore with concepts and conceptual frameworks with historical differences in both definitions and practices, the project needs to get an overview of as well the current approaches to practice of landscape policy making, and of the implementation of landscape policy in particular, whereby common denominators such as the identification of terms, concepts and practice shared among the landscape policy makers who are included as stakeholders in this project enables comparability, and at the same time contribute to how landscape approach (analysis and assessment) could enrich and improve integrated spatial planning in different ways and be seen and used as an asset ensuring that assessment of the landscape can contribute to the process of making decisions about the most sustainable way to use the land, improve the governance and participation of key actors and stakeholders in the planning process, and finally contribute to the assessment of how landscape planning can be considered in the framework of territorial cohesion policies.

4.3 Stakeholder involvement

As a project within the framework of ESPON Targeted Analysis Based on User Demand, the question of stakeholder involvement is crucial. Practitioners are both contributing to defining the demands that has led to the call, but are also to be integrated throughout the project as supplies of more detailed information and practical know-how. In that connection they are expected to be critical in the process of outlining new understanding and perspectives in relation to future development opportunities and challenges, but at the same time also active in relation to the outlining of actions and potential new projects. Two groups of contributors are identified: First of all the professionals on space and landscape from the stakeholders, but in addition a group of experts who have been – and are – practitioners in relation to dealing with the problems outlined throughout the project, who, due to communality to the case study practitioners, constitutes a "legitimate peripheral participation" (Wenger et al., 2002) are able to supplement the stakeholder's involvement with additional input.

With a goal of bringing up the specific approach of landscape and territorial planning of each region through the exchange of experiences and giving feedback to the involved regions, the involvement of the stakeholders include five components:

1. The stakeholder's involvement is essential throughout the project and starts off with the definition and development of the specific theme for the targeted analysis.
2. The stakeholders will provide input and play an active role by delivering strategies, plans, spatial data, cases and measures and other relevant information about their regions;
3. A comparison between the practices of different administrative territorial entities (planning agencies of the involved local and regional authorities) in order to identify examples of good/best practices will be tested and responded to from both individual stakeholders as through a more general responses from the whole group of stakeholders.
4. A series of workshops will serve as a tool for discussions among the stakeholders and the research group to compare the region's performance at three levels:
    a. Internally, aiming at providing a comparison between different practices (methods, operations and procedures) of landscape and territorial planning within one's own organisation;
    b. Intermediate by evaluating own practices against the other cases and thereby acquire an important contribution to internal knowledge generation;
    c. Externally through evaluating the potential usability of the best practices for generalizations beyond their own situations.
5. Finally their comments to the generalizing of experiences and best practices of landscape and territorial planning and their impact on

sustainable development in relation to future planning approaches will be important.

The precise involvement of experts has not been decided on at this point of time, but it is expected that the option of involving one or a few experts with both practical as well as more overarching experiences within the integration of landscape and territorial planning would be included in the workshop activities.

4.4 Benchmarking

The benchmarking is based on the baseline analysis of the regional planning practices and case studies of plans, where the policy contexts (European and national), spatial planning systems, methodologies of analysis and studies, processes, procedures, challenges as well as needs are outlined for each of the regions. Out of this an analytical framework for the benchmarking procedure is generalized. In addition to the case studies "learning cases" will be taken into account which may provide longer traditions of including landscape plans in territorial planning may be included as well. Similarly input from the first stakeholder's workshop will provide important input to this activity.

A second step in the procedure include the identification of similarities and differences between the planning practices– territorial as well as landscape wise - and thereby enabling a categorization of the case studies according to similarities in planning systems, practices and planning tools. Emphasis will be on local and regional plans, which may provide guidance to future spatial measures of protection, development and management of space and landscape. The comparison will be structured through a set of indicators which enables a comparative presentation of practices and plans. We intent to use the same scheme as in the baseline analysis of cases in stakeholder regions:

- Analysis of space / landscape and future developments
- Problems and challenges
- Objectives and targets
- Actions and measures of government
- System of monitoring
- Impacts.

The results of this comparison will be presented through a draft version of"Guidance in benchmarking best practices".

A third step will be the second stakeholder's workshop which is intended to serve as a key meeting place between practitioners, selected experts and the research team. The workshop will be a learning experience between practitioners and experts from the case regions by being a meeting between three different knowledge components: the practical experiences of stakeholders, the input from the group of experts as well as input from the research team.

To guide the learning process and the targeted output from the workshop an agenda will be made aiming at prioritising the discussion items in order to keep a feasible 'work load' of a workshop of maximum two days. An important item for the 'agenda' will be the question of which practices (kind of spatial problems and type of plans) are comparable, and which kind of learning processes could be promoted. Generally spoken professionals ('plan makers') could learn from each if, at one hand:

- Their problem statements and challenges are comparable (like high urban pressure versus 'shrinking' depopulating regions; rich versus poor economic performance);
- Their scale of working is comparable (regional, abstract strategies versus local, implementation programmes).

And at the other hand:

- Their methods and cultures of planning are different (e.g. ways to analyse the spatial development, kind of goals and steering strategies; methods of participation).

Popular formulated: it is interesting to talk with each other, when we consider having the same problem, but working on different solutions and also in a different way.

Based on the above, two outcomes are target: on one hand a refining of the "Guidance of benchmarking best practices" will take place, which will be presented for the stakeholders at the third stakeholder's workshop. And on the other hand the overall results of the stakeholder involvement and the benchmarking exercise will provide messages and recommendations on how to integrate 'landscape' in European territorial cohesion policies and national spatial strategies. It will further deliver recommendations for future benchmark procedures.

4.5 Policy recommendations

The diversity of her landscapes is widely appreciated as on of Europe's major assets. Consequently, the wise management of landscapes and their special character leads to adopting generally accepted ways of landscape policy making. Pertinent recommendations are provided through this LIVELAND project. The first set of recommendations lists strategies that are designed to overcome current policy making challenges. The second set includes ideas for a contingency planning. The overall strategy would be to build up better levels of understanding of regional cultural differences referring to landscape and to concepts of landscape, and to build strength on the basis of the potentials that cultural and landscape diversity offer.

Since a number of different policy sectors (organisations, government, and non-government) are engaged with or directly/indirectly affect landscape, strategies are developed for these sectors to **engage in communication over landscape and landscape policy**. Suggestions are provided for 'good communication' across different sectors, levels of decision making, authorities and NGO, and private consultants. A suitable terminology is needed. Included are common understandings of the 'concept of landscape', of shared ideas about 'liveability of landscapes',

agreements on definitions of landscape as an asset in regional development, and as an asset that is important to lead the way towards sustainability. Encouragement is also given to allow for a common understanding of landscape that relates to the variety of concepts that exists and yet would connect different disciplines. The overall aim of this strategy is to try and reduce risks of misunderstanding each other (different disciplines, different points of view of different organisations, etc.).

On the foundation of 'good communication' strategies are recommended for different policy makers to assume **trans-sectoral perspectives on landscape**; for example, between those in environmentally / ecologically based administrations / professions and those arising from social sciences and the humanities. The overall aim of this strategy is to try and reach a common understanding not only of what landscape is, but also of the services that are expected of landscapes to provide (referring to so called 'ecosystem services', 'cultural services', and other 'services' that are essential for people's health and wellbeing, including the need for identity, for restorativeness, and many others). The overall aim is for policy makers to start and bridge the gaps that exist due to landscape issues being scattered across different segments of government and administration, and to de-fragmentise landscape policy making activities (including landscape and territorial planning).

Strategies are also needed for **developing pan-European perspectives on landscape**, instead of separating regional / local from European views / scales. Policy makers are advised to try and build on European networks of regions, professionals, etc. The overall aim is for policy makers to take advantage of opportunities that focus on landscape as it is cherished as essential to liveability of every region, and to link liveability to competitiveness and attractiveness of regions. From here, links are to be made to aims of regional / territorial / environmental policies of the European Union, particularly as contributing to harmonious territorial development and towards sustainability. Cultural landscapes, 'liveability', 'regional identity', human health and well being all refer to important aims of regional / territorial policies at the European level. Policy makers are advised to implement these general policy goals at regional and local levels.

As 'landscape' is considered an integrated concept it is also very much suited, in policy making, for achieving sustainable development. Recommendations are given that calls for policy makers to **stimulate knowledge based planning and the elaboration of landscape plans** in particular. Landscape planning, management and protection should be done in integrated ways, referring to indicators and to good and best practice examples (as provided by this project). The elaboration of landscape plans also calls for the integration of their policy output into spatial planning, for policy makers to be considering landscape as a key territorial value.

Recommendations are given for policy makers to agree on management structures for **planning processes that are inclusive and assume an outcome oriented approach** (instead of 'plans only'), referring to the liveability needs of all who live, work and recreate in a given area, their landscape. Forms of decision making are

advisable that are open to all segments of society and respectful of principles of good governance. By involving all interested parties, and their perceptions and interpretations of landscape, the development of landscape quality objectives is much enriched. The use of public participation in the identification and evaluation of future landscapes is seen as being crucial to informing decision makers. In this context it is important to accurately represent and describe the range of landscapes and landscape types experienced by members of the civil society; these might include cities, peri-urban areas, coastal zones and sites of mobility (some of which might otherwise be neglected if policy advising is done by experts only). It is important to choose approaches that help make policy makers understand what it is in people's surroundings that they cherish, now and in the future.

Furthermore, policy making is advised to consider to what extent landscape-relevant and politically important issues will need to be thought of with reference to the generation-gap (different views and values with every new generation), to demographic change and migration, climate change, lifestyle changes (relating to landscape use and preferences), etc. These are considerations that are referring to the future and thus directly relate to sustainable development. In this context it is also important to make decisions on the involvement of stakeholders, especially on how to include not only persons who have specific rights such as land owners, but also to involve representatives of temporary users such as tourists and second home owners etc., and even future 'claim holders' such as young people and children.

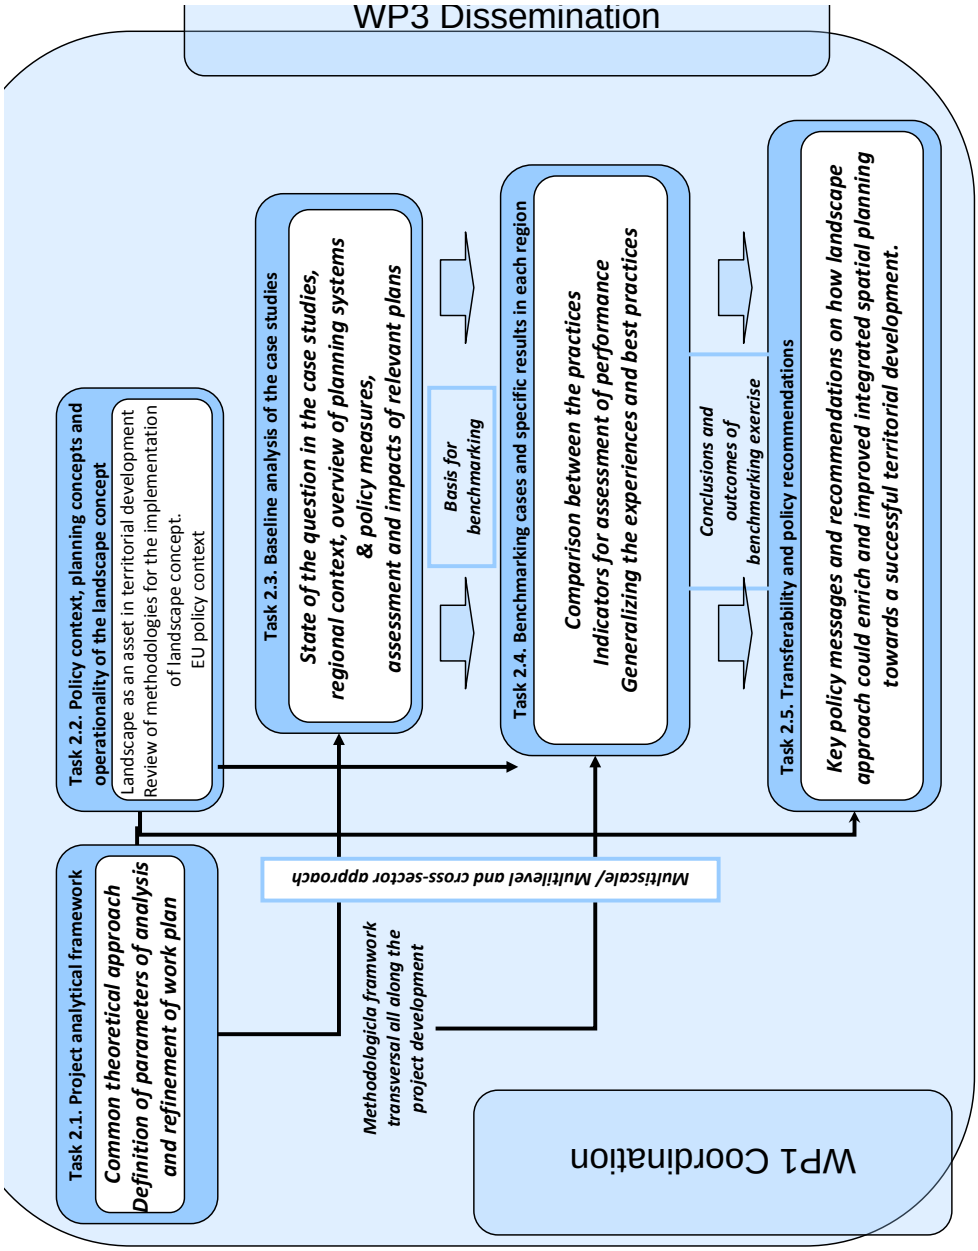

Figure 1. The LIVELAND project work flow.

5. Conclusions and expected results

Addressing the objectives and questions described above, the proposed LIVELAND project will strive to answer the following key policy questions

- Developing a definition of landscape as an asset in regional development towards sustainability. With this project ESPON will have made a first systematic analysis about landscape protection and development in European 'planning systems'.

- Balance between landscape protection and social welfare and economic development.

- How landscape approach (analysis and assessment) and landscape planning could enrich and improve integrated spatial planning and urbanism in different ways:

    - The evaluation of the landscape requires a global vision of the land throughout an multi- scale approach, going beyond the local interest and point of view.
    - The identification of landscape objectives can be the support to motivate the improvement and development of poorer or abandoned areas.
    - The assessment of the landscape can contribute to the process of making decisions about the most sustainable way to use the land.

- Improvement of governance and participation of key actors and stakeholders in the planning process.

- Assess, evidence based, the consideration of landscape planning within territorial cohesion policies.

The project is envisaged to deliver the following results:

- An overview of the EU policy context and the context of relevant national planning systems and traditions for an integration of landscape planning and territorial development

- Insight on the way landscape planning relates to economic development and land use pressure (urbanisation and agricultural intensification) including possible causal relations

- Methodology of analysing 'good practice examples' and benchmarking of the content and procedure (governance aspects) of landscape plans and their impact on the sustainable development of the case regions, and

choosing best practice in discussion with professionals and experts of planning from the stakeholder regions

- Examples of 'good & best practices' of landscape planning and the way they relate to regional territorial planning in the stakeholder regions
- Recommendations to professionals in the stakeholder regions to improve their processes and performance of landscape and territorial planning
- Policy messages for the relevant European (EC and CoE) and national authorities, to encourage the incorporation of landscape in the territorial cohesion and territorial planning policies
- Assessment on the use of ESPON data, objectives and results from relevant projects and studies. Identification of knowledge gaps to be covered by future ESPON projects

6. Acknowledgements

The would like to thank HHP+ Hoppenstedt Partners (Germany), Alterra (The Netherlands), Nasurvisa (Navarra) Nordregio (Sweden) and REC (Slovenia) as members of the transnational project group that will be undertaken the research activities for their involvement in the project configuration.

INDICATOR ANALYSIS ON THE ISSUE OF TRANSPORT ENERGY CONSUMPTION

Jian JIANG[1], Yasutsugu NITTA[2] and Hiroto INOI[3]

Abstract

The issue of transport sustainability is drawing more and more attention from related researchers all over the world. In this domain, as one respect, the restriction of energy consumption in transport sector is crucially important to a certain extent. There are many ways for analyzing the factors of the superfluous energy consumption in transport to give reasonable interpretation for the incentives of it. In recent years, factor analysis related method such as decomposition analysis and data envelopment analysis are used in literatures in order to catch the principal factor that leads to the consumption. But it remains a problem that why the very factors are selected for the analysis instead of others, and there is no convincing evidence given by the analyzers. This paper introduces the method of indicator analysis rather than generally used factor analysis to make the analysis afterwards more reasonable. Indicator analysis considers the possible factor to be candidate indicator and evaluate them in advance based on the criteria of indicator selection. The criteria are developed for the application in the transport domain and classified into three categories which named representation, operation and policy application. The scoring standard for evaluation is also given in detail in order to get impartial result. Fuzzy functions are also introduced for joint consideration of indicators.

1. Introduction

Sustainable development is considered to be a permanent topic around the world in recent years. The basic sprit of sustainability is to meet human being's needs as well as preserving the resources and environment of the world, so that the needs of human can be met not only at the time being, but also in the future for next generations. Sustainable is the systematically combination of environment, economic and social. Based on this spirit, we have to take more consideration on sustainability as well as economic development. Transport activity effects the environment, economic and social very much, therefore it is very important to trace the activity of transport for the research of activity. In this paper, we focus on the domain of the energy consumption in transport factor. It shares about 20% by the transport sector in the total all over the world, and the absolute amount is increasing generally, which is rather a crucial part.

Japan confronted a boom of economic development after the World War II, and is becoming one of the most advanced countries all over the world. At the same time, the consumption of energy in Japan is growing up steadily, which most of the energy consumed is non-renewable resources such as coals and oil. It is not considered sustainable for the ratio to consume so much non-renewable resources especially after the experiences of the oil crisis. And now, the accident of the Fukushima Daiichi Nuclear Plant makes the public uneasy for the safety of nuclear power particularly for the places where suffers from natural disasters easily. Other means of clean energy is restricted by the nature conditions crucially and the cost remains high. Overall, there is a long way for the development of the renewable resources. Therefore, it is more important to reduce the amount of energy consumption particularly in Japan which is not a country abundant in energy (Agency for Natural Resources and Energy, Ministry of Economy, trade and industry. 2008).

There are many ways to analyse the change of the consumption of the energy consumption for further policy suggestion. The most usual one is to analyse the factors which lead to the change of the total amount of consumption. Due to the method of factor analysis, we can find out the importance of each factor and can give corresponding suggestions on improvement. For instance, we can calculate the

proportion of each factor introduces by the method of decomposition analysis (Ang,B.W.,Zhang,F.Q.,2000.). However, the problem is that the selection on the choosing of factors does not have certain criteria at all. It will lead to totally different result of analysing based on different selections of factors. Corresponding references are listed for the issue in detail. Please refer to references C.Bockstaller and P. Girardin, 2003; Peter Hardi and Juanita Ama DeSouza-Huletey, 2000; Todd Litman, 2011 and United States Environmental Protection Agency, 1996.

In this paper, we introduce indicator for the analysis of the energy consumption in transport sector rather than common factor analysis.

2. Indicator analysis for the issue of energy consumption

Indicator is defined as a substance used to show visually the condition of solution with respect to the presence of a particular material by the Webster's dictionary. In the field of abstraction, it would give out invisible implications with the function as a maker or sentinel, indicating the presence or absence, a measurement tool, indicating variations along important dimensions of phenomenon, a decision support tool allowing taking certain action, or the combination of the above.

As indicators have the function to indicate the phenomenon of transport production, on the issue of energy consumption, we should analysis it in order to grasp the nature of the change of energy consumption for policy suggestions. The rest of the issue relies on the selection from factors into indicators.

According to the reference the criteria of indicator selecting can be defined as follows as most researchers agreed. We also believe that the three categories with ten criteria are the most reasonable ones as follows at the moment.

Table 1. Selected list of criteria (Jourmard and Gudmundsson 2010)

Category	Criteria	Definition
Representation	Validity	Actually measure the issue or factor it is supposed to measure
	Reliability	Give the same value if its measurement were repeated in the same way at almost the

		same time
	Sensitivity	Be able to reveal important changes in the factor of interest
Operation	Measurability	Be straight forward and relatively inexpensive to measure
	Data availability	Based on input data that should be readily available or made available at reasonable cost and time
	Ethical concerns	Comply with fundamental human rights and require only data that are consistent with morals, beliefs or values of the population
Application	Transparency	Feasible to understand and possible to reproduce for intended users
	Interpretability	Allow an intuitive and unambiguous reading
	Target relevance	Measure performance with regard to articulated goals objectives, targets or thresholds
	Action ability	Measure factors that can be changed or influenced directly by management or policy action

In the literature, based on the ten criteria above, the factors which want to be indicator have to be evaluated one by one. The evaluation method used right now is to score the ten criteria from level 1~4, which shows that the indicator candidate satisfies the criterion poorly, limitedly, well and excellently. After that, the score is added together to show which ones are apparently better than others and choose the better ones as indicator.

However, the literature assumes that all the ten criteria are of the same importance as they share the same value, at the same time, the evaluation of each criteria are almost decided subjectively, and the variance of the scores cannot be controlled, too. In fact, these ten criteria may be not of the same importance; therefore, the result of the scoring would not be so precise for us to select. In order to solve this problem, we

introduce the fuzzy functions for the comprehensive evaluation of the candidate indicators.

First, we lay out the candidate indicators that may be the one affects the energy consumption of transport crucially according to Peter W.G Newman, Jeffery R. Kenworthy, 1989. Notice that some factors are applied on the macro analysis all over a region while some factors are only applied on cities. It is important to tell them apart on the choice of factors into candidate indicator.

- Passenger trips per person
- Energy use per passenger km
- Length of road per capita
- Vehicles per km of road
- Urban density
- Vehicle ownership
- Model split
- Road parking
- Income
- Employment density
- Average speed of transport system
- Gasoline price
- Vehicle fuel efficiency
- Population
- Gross domestic product
- Passenger trip per vehicle km of service
- Lifestyle and tradition/culture

From the example factors introduced above, we notice that the factors are not all in the same field as every analysis concerns; therefore, we would like to analyze the fitness of factors into indicators by criteria according to the problem we are facing rather than putting all the probable factors into consideration.

Now we introduce the fuzzy functions for the ranking of candidate indicators, generally speaking, fuzzy functions are meant to build a mathematics function to describe the membership of each candidate indicator for the criteria, yet there are several characteristics for each criterion .For instance, some criteria cannot be described into figures so we cannot calculate its membership for that criteria .In this

case, we use relative and are classified as follows (Here we assume I_{qc}^{t} is the evaluation of this candidate and x_{qc}^{t} is the value of the candidate):

1) Ranking the candidates:

$$I_{qc}^{t} = \mathrm{Rank}\left(x_{qc}^{t}\right)$$

2) Standardize the candidates:

$$I_{qc}^{t} = \frac{\left(x_{qc}^{t} - \overline{x_{qc}^{t}}\right)}{x_{qc}^{t}}$$

3) Categorical scales:

$$I_{qc}^{t} = \begin{cases} 0.25 \text{ if } I_{qc}^{t} < p_{0.25} \\ 0.5 \text{ if } p_{0.25} < I_{qc}^{t} < p_{0.5} \\ 0.75 \text{ if } p_{0.5} < I_{qc}^{t} < p_{0.75} \\ 1 \text{ if } I_{qc}^{t} > p_{0.75} \end{cases}$$

4) Distance to a reference:

$$I_{qc}^{t} = \frac{x_{qc}^{t}}{\overline{x_{qc}^{t}}} \text{ or } 1 - \frac{x_{qc}^{t}}{\overline{x_{qc}^{t}}}$$

5) Percentage of annual differences over consecutive years:

$$I_{qc}^{t} = \frac{x_{qc}^{t} - x_{qc}^{t-1}}{x_{qc}^{t}}$$

6) Some other shape of function f(x) links from 0 to 1:

$$I_{qc}^{t} = f\left(x_{qc}^{t}\right) = \begin{cases} \frac{x_{qc}^{t} - b}{a - b}, x_{qc}^{t} \le a \\ \frac{x_{qc}^{t} - c}{a - c}, x_{qc}^{t} > a \end{cases}$$

Based on these calculations, we can deduce the evaluation of each candidate easily and lead to further results. For example, in order to judge how an indicator candidate satisfies the criterion “data ability”, we can use the ratio that available data accounts for in the number all data required as the one for calculating and use criterion number

1 above to evaluate. The characteristic of the indicator candidate should be taken into consideration on which criterion is used yet the score should be standardized for equality on all candidates.

3. Applications and Conclusions

Based on the fuzzy functions introduced to the evaluation of the candidate indicator, more convincing evidences are shown for the insurance of the indicator selecting. As stated at the beginning, the method of decomposition analysis and the DEA method can be used convincingly to describe the phenomenon. As a result, reasonable result would be got for the policy implication. Here we show the application of indicator analysis on the method of DEA.

Data Envelopment Analysis (DEA for short) is considered to be a useful operational research tool and becoming more and more popular on the field of evaluation analysis. It comes out to be a linear programming methodology to measure the efficiency of multiple decision-making units when the production process presents a structure of multiple inputs and outputs. DEA method is first proposed by Charnes, Cooper & Rhodes at first and developed into some other models with the years went by and is basically used to empirically measure productive efficiency of decision making units. Now it is spread and used widely in many fields for efficiency evaluation. Therefore, it can be also adopted for the evaluation of the efficiency by environmentally sustainable transportation policies.

DEA method focuses on the evaluation given some input variables and output variables. There is no need to set weight on each variable initially which may be difficult to grasp, and only consider the mathematical relationships of the variables. It can be used for both production and cost data. Utilizing the selected variables such as unit cost and output, DEA method searches for the points with the lowest unit cost for any given output, connecting those points to form the efficiency frontier. It is also useful because it takes into consideration returns to scale in calculating efficiency, allowing for the concept of increasing or decreasing efficiency based on size and output levels. A drawback of this technique is that model specification and inclusion/exclusion of variables can affect the results.

In the literature by Yoshino D., Fujiwara in 2010, DEA method was used for the analysis on the environmental efficiency. Population density, road length per capita, private car ownership per capita and public transport serve length per capita are selected as input variables for analysis without further explanation for the reason. And the result will be totally different if other variables are selected. Although the choice in the paper sound reasonable in certain degree and the result is very useful and robust, had the method of indicator analysis been introduced in, the analysis result would be more convincing. We do not know those candidate indicators they initially intended to introduce so we cannot give the table for calculation, yet the method in this paper may be a good approval on the decision.

An Advanced Systems Approach for Planning Practice in Complex Cities – Anticipating emergence through citizens' participation Explained on the example of Central European cities in transition

With increasing global interdependencies our cities become more and more complex, challenging planning methods and practice over and over again. Foreseen and unforeseen hazards of, e.g., climate change or global economic crises require to safe-proof our cities against uncertainties. Dynamic processes in cities worldwide, be it emerging cities in Asia or cities of Central Europe in transition, call for new, less rigid planning approaches.

Let's consider the example of the Central European second tier (i.e. non-capital) city in transition with its specific material and social structures developed through time. Growing from a medieval core the Central European second tier city went through a phase of rapid urban growth in the 19th and early 20th century. It has then been further influenced by national independence following World War I and substantial population shifts during and in the immediate aftermath of World War II. Finally, the communist regimes left their mark on the Central European second tier city which now has redeveloped it's urban functions during the past two post-communist decades.

These "inherited urban structures" (Turnok 1989, p. 151) from the medieval core to the communist blocks of flats influence today's social and, in turn, material form of the Central European second tier city through complex interdependencies. Having already gone through several steps of development, much more seems to lie ahead still – and uncertainty about what will emerge next is great. Since it is in transition still, the Central European second tier city is best characterized by processes instead of conditions. Some of these transition processes are framed by the inherited urban material and social structures. Others are triggered by national and supra-national processes or conditions. The intertwined transition processes are not easy to overlook.

Is the complex situation of the Central European second tier city reflected in current urban research and development approaches? In fact, it is not, since mainly isolated facets of urban development are considered today, often tackled by "best-practice" which is simply imported from elsewhere. What would be needed, instead, is a consideration of the interdependencies of intertwined processes and structures, both the inherited ones and the newly emerged ones. An approach to urban research and development must consider interlinked aspects, cross-disciplinary or cross-domain issues and it must make use of a framework to cover the actual urban processes and structures comprehensively.

A potential answer to this kind of challenges of urban systems under dynamic and uncertain conditions lies in the application of systems approaches. Such system approaches are of great help in planning practice, since they provide several methods for the understanding of urban complexity. Well known urban systems approaches have been introduced by Forrester (1969) and Vester (1988), where Vester's biocybernetic approach relates to and extends the system dynamics approach by Forrester.

The biocybernetic approach makes use of system diagrams in which (directed, weighted) relations between elements of the system under consideration are depicted. It reaches beyond pure system dynamics in so far, as it introduces eight biocybernetic principles and seven domains of natural and man-made viable systems to assure wholeness in systems models. Also, insights about system properties are gained by analyzing the sensitivity of system elements and by simulating scenarios in which the impact strengths of selected elements is altered.

The approach of Vester has been applied regularly in urban and regional planning. However, at least two reasons call for a revision of this seemingly established approach. First, when looking at recent-years' applications of the biocybernetic approach (see, e.g., Cole 2007), it becomes clear that Vester's original approach which intends to assure wholeness in the system analysis is not being followed any more. The eight biocybernetic principles and the seven domains of natural and man-made viable systems are regularly disregarded. Instead, recent applications only make use of the system diagram and tools for its analysis.

Second, Vester's (and Forrester's) urban systems approach is rooted in the research of the 1960s and 1970s, mainly highlighting feedback and relational characteristics, omitting more recent findings about urban systems, such as resilience and emergence (see, e.g., Deppisch and Schaerffer, 2010) as well as self-organization (see, e.g., Portugali 1997).

While resilience might be a secondary system effect, a result of feedback interaction within the urban system, and self-organization a result of random changes governed by the existing urban structures and processes, I suggest to consider emergence as a first system principle. Other first principles are the just mentioned random changes (also called mutations or fluctuations), the ability of a system to recreate itself, usually termed autopoiesis, and of course interaction of any kind. As outlined above, of these four system principles, the focus of systems approaches applied today is on the last one.

Subsequently, I will focus on the system principle of emergence.

1 Starting points of urban development matter

It is interesting to observe in literature about the Central European city how urban researchers and practitioners try to apply the same categories known from western cities to the Central European city. It appears to me that an almost marxist idea of a determined, inevitable transformation towards a capitalist urban society is guiding such thinking. That is why there is an almost desperate search for evidence of what are considered the downsides of a market economy, e.g., urban poor, spatial segregation, and bottom up driven urban revitalization ("gentrification"). For example, Kunzmann (2006) notes:

"In gentrified inner cities, attractive suburban communities and in leisure regions the nouveau-riche upper class is showing its wealth. In contrast, those who did not succeed in benefiting from the new market economy are forced to remain at the urban fringe of agglomerations, in the run-down pre-fabricated social housing schemes where Western supermarkets and fast food chains absorb their small incomes" (p. 21).

However, such a transformation of the Central European city towards a (anyway rather stereotype) western neo-liberal place is now highly disputed, because the unique starting points of market-development matter. Pichler-Milanovic (2005) observes:

"In the 1990s it was rather assumed that transition […] would project cities in Central and Eastern Europe rather uniformly along a linear trajectory, which would result in their convergence […] with those [cities] in Western Europe. Such thinking, however, was not only naïve in the light of subsequent reality, but was often based on a lack of understanding […]. [C]ities in Central and Eastern Europe are »path dependent« on their pre-socialist as well as their socialist-period legacies."

For example, let's have a look at the "run-down pre-fabricated social housing schemes" from the 1960s and 1970s. Such large scale housing was built both in former communist cities and Western cities. The learning from the Western societies is clear: The 1960's high rises of Chicago's Robert Taylor Homes and Cabrini-Green settlements had become social hot spots and were eventually torn down. The high rise neighborhood of Köln Chorweiler, finished in 1972, is notorious for its social problems, high unemployment rate and large share of migrants. And the *banlieues* (suburbs) of French cities are similarly infamous for their social problems. In the West, the large scale housing estates are associated with crime and people living from social transfers.

Quite in contrast, more than twenty years after the fall of communism, the *paneláky* (blocks of flats in colloquial Czech) "are, for the most part, still stable social areas" (Grossmann and Steinführer 2011, p. 24). The apartments in the communist blocks of flats are still "sold and bought at good prices on the free market. Their social mixtures determines these estates not to be regarded as derogatory in terms of social prestige, as they more typically are in Western Europe" (Vais 2009).[1] Instead, rather unexpected from gentrification experience in Western cities, it is the old towns, especially the apartment houses from the late 19th century, that in some cities have become the place to live for the uneducated, unemployed.[2]

Hence, the starting points matter. Do we known which other distinct structures – material and societal – will emerge from the Central European second tier city?

2.A Urban self-organization is, in principle, predictable

Much of the change that occurs now in the Central European second tier city has been or could have been foreseen. Common tools to derive development scenarios are system models based on Forester's or Vester's work (see above) and agent based models simulating the (spatial) interaction of agents given a set of human-like behavioral rules.

By modeling interaction based on a given set of entities and rules, agent based approaches are, e.g., suitable to model spatial arrangements of people, revitalization of the old towns, or the appearance of shopping malls. The outcome of those tools – as of any (mind) model – however, is limited to such states which are within the *a priori* known space of states. The "unknown unknowns" cannot be modeled, as explained in the subsequent quote (Black Swan Theory):

"More generally, decision theory, based on a fixed universe or a model of possible outcomes, ignores and minimizes the effect of events that are 'outside model'. For instance, a simple model of daily stock market returns may include extreme moves such as Black Monday (1987), but might not model the breakdown of markets following the September 11 attacks of 2001. A fixed model considers the 'known unknowns', but ignores the 'unknown unknowns'."

[1] The quoted author refers to the situation in Cluj and cites Murie et al. (2005).
[2] See, e.g., Kabisch and Sagan (2011, pp. 95-96), referring to Polish cities.

In other words, the results of our models are within the limits of what we can expect as effects of the parts that make up the model. If we have people who move between neighborhoods, who give birth and die, who start commercial activities and buy, then we can imagine (and simulate) various distributions of residential and commercial areas, and the evolution of these over time. This evolution can be based on initial and learned behavior of the people (agents in simulation jargon), and on random changes (fluctuations, mutations) of behavior. If we start with a spatial distribution of agents with some behavior, then the output will be a spatial distribution of agents with some behavior. The simulation tells us something within the known coordinates, in this case the spatial distribution after a certain time. From such simulations we can learn a lot about self-organization, but less so about emergence.

2.B Emergence of urban phenomena is unpredictable

Some of the recent developments in Central European second tier cities could not have been predicted. An example of such an emergent development is that of the Hungarian city of Pécs, which became a "City of Lovers" by the symbolism of its "Love Locks", as described by Hammond (2010):

"Thousands of metal padlocks have transformed this East-Central European city. […] Often inscribed with initials and dedications, the locks are rumored to represent young paramours' hopes far the longevity of their passions" (p. 181).

The city has integrated the Love Locks into its cultural and marketing image, and "travel websites […] describe Pecs as a 'City of Lovers'" (p. 181). Now that it has emerged, this phenomenon impacts on the image of the city, urban life, the touristic development and, through the latter, the wealth of the city and its citizens.

But who could have predicted this development which, before it happened, belonged into the realm of the "unknown unknowns, […] things we do not know we don't know" (Rumsfeld 2002), but which had a tremendous impact on the city? Who could have predicted that from somebody adding a first padlock onto a gate, a bottom up process would lead to the emergence of new cultural and image aspects of the city, of new possibilities of urban marketing, tourist attraction, history telling? "[T]he newly emergent entities […] introduce new possibilities" which were formerly unpredictable (Popper and Eccles 1977, p. 30). Or, in the words of Hammond (2010):

"What the locks do offer is a radical aesthetics of interruption, which, even in their recuperation, are an indelible trace of how cities emerge through oppositionality. …

they are the telling detail which has the potential to unravel the image as a whole" (p. 192).

As a more general example, the emergence of urbanity seems to me a good example to distinguish predictable self-organizing phenomena from unpredictable emergent ones. Who could have described urbanity before it appeared? Still today, we only try to understand that what makes a place urban. If the interaction of people and streets, places and public infrastructure etc. make a city, what else is it that makes the city urban? How did the Central European cities manage to become urban again after communism, when urban centers had become «void», deprived of urbanites (Schlögel 1996, p. 229)?[3]

Real emergence, not just self-organization, is that which transcends the *a priori* known space of states of its elements. Emergence leads to "real novelty … much that was not foreseeable, at least not for human knowledge." As Jaques Monod put it for the emergence of life: " … we were unpredictable before we appeared" (Popper and Eccles 1977, p. 16). Emergence happens, when we require new words to describe the new phenomenon.

Likewise, urbanity is something more than the sum of its parts, i.e. more than a number of people in a built up environment. It is not simply an unknown state of known phenomena (e.g., people, behavior, spatial arrangements). It is a new phenomenon which emerges from the elements we deal with. It's not only unknown to us in what way the elements are going to arrange in dimensions we know, it is the occurrence of something which we wouldn't naturally expect from looking at the elements alone. No computer simulation can tell us when urbanity emerges from the interaction of people in space. Neither can we determine which quality in which quantity leads to an emerging phenomenon. We are also unable to rebuild the emergent phenomenon elsewhere.

3 Planning emergence in the urban context?

Now that we have had a look at emergence in the urban context it should have become clear that emergence of urban phenomena cannot be predicted, nor can the factors which are eventually leading to the emergence of a phenomenon be determined. Or, if they could be separated in one case, the insight would be of no great use since any other case would be much different anyway (different place, different time).

---

[3] Original reads: "Die »Leere« der städtischen Zentren … spricht vom Verschwinden der städtischen Urbevölkerung … des Stadtbürgers."

However, urban planners would sometimes like to trigger desired emergent phenomena in cities. For example, town planners often hope that by physically structuring a neighborhood, a certain type of society will emerge. But while we can copy the physical elements of a successful urban area somewhere (and, to a certain extend, also try to get the "right" people in, e.g., the now fashionable "creative class"), we can only hope that the implementation of these structures (the elements) will lead to the emergence of a vivid, urban, thriving, etc. neighborhood (the whole) elsewhere.

Planning is an essentially top down process – it sets the frame for development (this is true even if during the planning process people were engaged bottom up). In contrast, emergence is both a top down *and* bottom up phenomenon: While natural and man made systems may frame developments of the entities within, those entities (in cities usually the people) may trigger their own new phenomena, e.g., the Pecs' Love Locks. Or, while planners might plan new towns (like the above mentioned Köln Chorweiler) according to their best practice, they cannot plan social and cultural behavior (emergent or self-organized) which might thwart the original good intentions. Planning is often carried out involving or avoiding factors of which we don't know the emergent effects. Does urbanity really die from increasing social segregation? Will urbanity survive much more greenery in the center?

4 Planning under uncertainty

The planning situation is, however, not entirely hopeless. But we need to learn much more about the peculiarities of the cities we are developing. And we need to enlarge our tool base.

Which fate would our experience and our models have predicted for the Eastern European kiosks twenty years ago? It doesn't seem unreasonable to assume that from our predictions they would have vanished by now, or at least been marginalized by large supermarkets. This fate has not come true. Instead, the kiosks can still be found in many cities across Eastern Europe today.

Although the kiosk example is one of self-organization and not of emergence (the survival of the kiosk was a predictable scenario within the known space of states), it shows how much we need to understand about the cities and how limited the transferability of knowledge, let alone "best practice", from elsewhere is.

Looking at emergent phenomena, the uncertainty of planning gets even worse. As described above, we are stuck with the coordinates we know, our models cannot transcend the dimensions for which they are set up. Yet the key question for urban development under uncertainty remains: what's going to emerge next? What is going to have tremendous impact, although from where we are now, with the knowledge that we currently hold, we cannot simulate, foresee, predict it?

Which new structures – material and societal – may emerge in the Central European second tier city under its specific conditions of deregulation, limited public financial resources, and fast growing economies? The Central European city has shown its ability to adapt rather well to changing conditions although municipal governance was usually weak. Schlögel (1996, p. 232) even argues that the Central European city "doesn't need top down organization any longer, it organizes itself."[4]

Who could have told about a re-emerging coffee shop culture in Central Europe? This hasn't happened because it was planned, and it wasn't anticipated either. In addition, the new coffee shop culture is not uniform across all Central European cities. While Budapest and L'viv – to pick just two examples – have experienced a revival of their historic coffee shops (it might, hence, be arguable whether one could talk about an emergent phenomenon), in other cities a clearly distinct coffee shop scene has emerged. For example, in Poznan, small and uniquely furnished coffee shops of a style unknown before mushroom around old town square, and also in Košice some alike coffee shops can be found.

Hence: How can we handle emergent behavior in the city?

I would like to suggest one possibility to widen the scope: involve citizens. How do people see the future developing around them? We might get ideas about what may be the next big thing. People are early "seismic" indicators for emerging phenomena – they won't predict, but they can provide a feeling for what has most recently emerged and might subsequently grow. To a certain extend, they might even anticipate what may come, i.e. they generate emergent thoughts. In a sense, this approach is a simulation of emergence in an interactive setting.

It is important to note that the suggested approach is different from participatory approaches applied today. In the participatory approaches common today, people are basically asked for their wishes. In the approach suggested above, asking people is to get knowledge about how the city works, about latest developments, and even about things that emerge (in people's minds).

5 Conclusion

What should have become clear by now is that every city has grown unique, producing its own emergent phenomena. Some cities, like those cities in transition in

[4] Original reads: "[Die Stadt] bedarf der Organisation von Oben nichtmehr, sondern organisiert sich selbst."

Central Europe, are especially prone to surprise, since their very situation of being in transition means that their structures – physical and societal – are not stable, but changing. They might more likely produce new phenomena than other, more stable cities. From emergent phenomena, opportunities may arise, like the "City of Lovers" image of Pécs. For such opportunities we need to embrace emergence, although we can hardly get a grip on it. Also, improved understanding of the cities is a precondition to informed decision making.

With cities being unique, and self-organization and emergent phenomena being produced by unique cities, it becomes clear that a simple "copy and paste" of "best practice" from elsewhere will hardly produce best results.

Have you ever heard about the Košice IT valley? Or other clones of the Silicon Valley, the thriving region south of San Francisco? People around the world are trying hard, for decades, to figure out the success factors of the Silicon Valley. They try to copy this success and bring it into their own countries and regions, around their own cities. How many copies of the silicon valley can you count around the world? And which of these, often funded with a lot of public money, is coming close to the original one? Who can tell the success factors? Today, dozens of Silicon Valley copies around the world simply won't thrive as the original place does.

Where local, bottom up forces of self-organization and emergence are at work, the conditions change fast and are never the same for any two cities. The setting in time and space is always different. A "best practice" from somewhere, yesterday, is unlikely to be adapted in the very same way elsewhere, today.

Instead of copying what worked somewhere else (for often unclear reasons), we should allow ourselves to be surprised by emergent, bottom-up phenomena. We may try out different things in the city, set impulses and test their effect, and we might not want to suffocate bottom-up organization and emergence through too strict top-down conditions (regulations, subsidies, levies etc.). The concept of emergence in urban systems is important, because it opens our eyes for the yet unknown and lets us refrain from simply copying best practice. It also leads us to embrace uniqueness. In emergent phenomena lies the source of cities' *unique* potentials – much more than in copying what has been done elsewhere before.

We need to observe: What will emerge from the many subsystems in transition in Central European cities? And in order to anticipate emerging phenomena, we need to involve citizens as outlined above.

PLANNING AND DESIGN CRITERIA TO MAKE URBAN TRANSPORT MORE SUSTAINABLE: THE CASE OF BAKU

Gülnar Bayramoğlu

(B.Arch, M.C.P.Urban Design; METU)

ABSTRACT

Since the industrial revolution, technological developments and increased population have caused environmental damages. To protect the nature and architectural environment, firstly, green architecture, ecological architecture and then sustainability occurred. This term has been proposed not to be a new term but a response to environmental disturbances caused by human activities and it is re-conceptualization of architecture. Sustainable architecture or sustainability is lot more extensive than ecological and green architecture. It contains the imbalance between environmental problems which is natural environment and consumption that occurred all around the world.

An important part of sustainability debate focused on urban planning and design for more sustainable forms and patterns. In particular it is discussed that planning and design of urban areas have a major effect on transport and therefore can help reduce car usage, emissions, global warming and climate change. There are many planning and design approaches and movement that introduce certain criteria and strategies to prevent car dependency and encourage people to use public transportation and walking. However, when review the literature, it is seen that planning movements, such as New Urbanism and Transit Oriented Development originated and were implemented mostly in West European and North American Cities. The purpose of this study is to find out whether all those criteria, principles and strategies are also relevant planning approaches for more non-western cities like Baku which has a very different planning background and therefore possibly different urban form and transport issues. In order to answer the abovementioned question, planning and design approaches in the literature and in these recent planning movements were studied and a check list was formed which indicate planning and design approaches that can help attain a more sustainable transport outcome. The checklist was then applied to the case of Baku.

1. INTRODUCTION

There is a vast literature about sustainability, sustainable development and sustainable transportation. All those issues have an impact on urban form and design. There are several planning and neighborhood design movements today that have their own strategies and principles which have common ideas to create more sustainable urban areas, particularly to create sustainable urban transport system that is not car-dependent. The other common feature of those movements is that they all studied and were developed based on the West European and North American cities. This situation brings the question of whether all those principles are universal or not. In other words it should be clarified whether these approaches and principles can also

be valid planning tools for cities in "non-western" countries, such as those in developing country cities in Asia. In order to attain the main aim and to answer the main research questions some objectives and further research questions were identified. For this purpose, Baku was selected as a case study because it has a different planning background because of its Soviet history, which is much different than Europe and North America. Baku urban planning has never been analyzed after the independency of the Azerbaijan although it has a very consuming planning history at the beginning of the 19th century. In fact Baku did not produce a Master Plan after the 1987 plan. This brings the question of whether they continue to apply the principles of the old urban plan strategies, whether this old planning strategy include the sustainable urban design principles or not. The research question specific to Baku is whether planning and design principles for creating more sustainable transport outcomes can be a valid and useful guideline for planning in Baku or whether the specific planning background and resulting urban and transport structure in Baku make these design guidelines inapplicable or unnecessary in this city's context. These two basic questions make Baku an appropriate case study for this thesis in the concept of sustainable urban development principles.

2. LITERATURE REVIEW

2.1. URBAN DESIGN AND SUSTAINABILITY

Sustainability simply means in the global context the development that should improve economically and socially without harming environment. It is related with many disciplines and professions which has therefore developed many complexities (Newman & Kenworthy, 1999, p. 1).

'***Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs***' (Brundtland Report, 1987)

When we ask under the heading 'what is to be sustained' there are three major categories identified; nature, life support systems and community which has the intermediate categories of each such as earth, environment and cultures. The question of 'what should be developed' has again three ideas which are; people, economy and society (Robert, Parris, & Leiserowitz, 2005, pp. 8-21). All those instructions conclude of the same three pillars of the Sustainable Development which are economically, socially and environmentally sustainable developments, Figure 1.

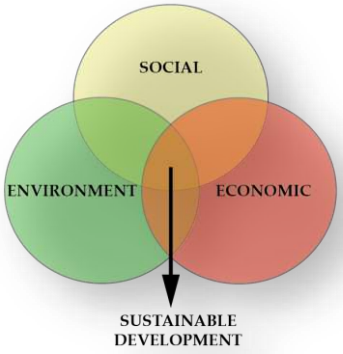

Figure 1: Three Pillars of Sustainability

Automobile usage increased over the 20th century parallel to the growth of income per capita. Both the increase in automobile usage and the division of land use functions caused the low density and fragmented land use development. As a result, a problem occurred as a planning issue known as urban sprawl. Today urban sprawl is a major source of environmental degradation. To solve the problem, many planning concepts have been introduced such as smart growth, transit oriented development and the most popular new urbanism.

When all these concepts are analyzed basic sustainable urban area planning and design principles can be summarized under four main areas which are, Land Use Management, Transportation, Social Interaction and Environment, Figure 2.

Figure 2:Sustainable Urban Area Principles Relation with Four Pillars

Sustainability is a concept that was discussed after the world war to create livable urban areas. All those discussed urban principles and trends designed to reduce the distances within and between communities. Walking and cycling can be viable options only in reduced distances, while urban sprawl with increased distances results in car-dependent lifestyles. Therefore the purpose is to reduce the travel distances between the daily facilities while saving time, design more green and walkable spaces and present quality of life by reducing traffic and accordingly reduce stress. Besides, to complete the sustainable urban idea, designing sustainable building is also thought. All written and discussed literature about the sustainable urban or city has a common approach which is Land Use Management. Land Use Management became important to succeed social, economical and environmental actions such as closer activities, more accessible centers, time saving from travelling, mixed-use neighborhoods, walkable communities. However; to achieve successful

Land Use Management there should be successful transportation system. If an efficient transportation system is not designed, land use management will not properly work. As a result, to achieve a sustainable urban area we should make the transportation infrastructure more sustainable too.

2.2. SUSTAINABLE TRANSPORTATION

Sustainable transportation is the expression of the Sustainable Development concept within the transport sector and it refers to any kind of low impact transport which includes walking, cycling, transit oriented development, green transportation and fuel-efficient transport systems. Sustainable transportation has positive effects on the environmental, social and economical sustainability of the communities they serve. (Schafer, 1998).

Transport is one of the major global consumers of energy, currently representing between 20% and 25% of aggregate energy consumption and CO2 emissions (World Energy Council, 2007). According to the IPCC Fourth Assessment Report (Transport and Its Infrastructure), in 2004, transport was responsible for 23% of world energy-related Greenhouse Gas (GHG) emissions with three quarters coming from road vehicles. Over the past decade, transport's GHG emissions have increased at a faster rate than any other energy using sector.

The social and environmental costs of transport include road accidents, air pollution, physical inactivity, lack of livability of areas. Traffic congestion also causes economic costs by wasting people's time and delivery options of goods and services. The real purpose of transport planning should be accessibility, access to work, education, goods and services etc., instead of improving mobility for vehicles. Communities which are successful in improving the sustainability of their transport network can achieve sustainable urban development (Litman, 2011).

There is a vast literature on the use of urban planning and design tools to make transport systems more sustainable. How we plan the macro form of cities, how we plan different lad-uses and densities, how we design neighborhoods have an effect on travel behavior. A set of planning and design criteria can change people's decisions on whether to make a journey by car, public transport, bicycle or walking.

For the strategies of New Urbanism, Smart Growth and Transit Oriented Development to be successfully implemented, the transport infrastructure must support sustainable transportation. When we focus on the question of "how can a sustainable transportation network be created?" it is seen that strategies fall under four categories:

- Improving and investing in public transport
- Improving and encouraging walking and cycling
- Restraining private automobile
- Supporting clean energy in public and private vehicles

All those principles related to the strategies and policies of sustainable transport, but to encourage more usage of public transport, walking and cycling needs more than that. None of these policies can be effective if an urban area has developed extremely car-oriented with low density and sprawl because public transport usage, walking

and cycling cannot be effective alternatives in long distances. This brings us back to the policies and strategies of sustainable urban design which help to create public transport friendly and walkable cities that are not automobile-dependent.

To summarize, policies for sustainable transport can be categorized under four headings as mentioned above. One of the most important aspects is to implement urban planning and design approaches to encourage more usage of public transport, walking and cycling. Hence; transport policies can make the transport infrastructure more effective, but transport policies alone cannot change travel behavior and create more sustainable travel patterns. For sustainable transport, land-use and urban design have to support public transport and walking and cycling. Transportation policies can work effectively only after such a management of the land use. Considering the review of the literature described throughout this chapter, it can be concluded that for achieving sustainable transportation, creating a sustainable urban form and therefore planning and neighborhood design are extremely important. This means that for sustainable urban areas, the operations must be performed in three scales of planning and urban design that can be classified as Macro, Mezzo and Micro scales (Table 1)

Table 1:Design Approaches for Sustainable Urban Form

SUSTAINABLE URBAN DESIGN INDICATOR		
MACRO SCALE	**MEZZO SCALE**	**MICRO SCALE**
▪ Compactness; Mixed-land-use, high density and Non-sprawl ▪ Existence of sub-centers ▪ Public transport infrastructure	▪ Mixed-land-use ▪ Grid system plan ▪ Well served public transportation ▪ Pedestrian friendly –walkable development	▪ Intensity of street network ▪ Mixed-use ▪ Well served with public transport ▪ Grid system plan ▪ Pedestrian friendly and walkable street sections ▪ A hierarchy of narrow streets, boulevards and alleys ▪ Interface with Parking ▪ Neighborhoods accessible on foot ▪ Car-free public areas

These principles are derived and originate from studies and planning experiences from the West European and North American cities, and this situation brings the question of whether all these principles are universal or not. A primary concern of this study is therefore to explore whether the abovementioned planning and design principles for creating more sustainable transport outcomes can be a valid and useful guideline for planning in developing country cities too. Such cities often have already high development densities but also they face with sprawl problems and increasing car-dependency. However with their much different planning backgrounds and different urban structures can these cities in developing countries also benefit from these design principles?

3. METHODOLOGY

3.1. AIM AND OBJECTIVES

With respect to the main focus are of the thesis, which is the sustainable development, there occurred three main questions which are tried to be answered:

- What are the key elements to make an urban area sustainable?
- What are the planning and design principles to make urban transportation more sustainable?
- Can those principles be a framework for all the countries in the world (or can those principles be considered as universal)?

One particular point of discussion was raised: all these sustainable urban design and sustainable transportation principles originated from experiences in the American and European countries.

The underlying objective is to examine whether the above framework of criteria is applicable to a city like Baku, which has a different planning history and background compared to North America and west European cities.

An expected outcome of this analysis is whether this framework of criteria can be a mainstream checklist or guideline or whether there are certain cities, due to their own context, history and background, where these guidelines become inapplicable.

Depending on these arguments main tasks of the study are listed below;

- Application/assessment of the above criteria for the case of Baku to examine whether such plan and design approaches are relevant to this City
- Through interviews with experts from Baku planning agencies, assessment of planning and transport problems and potentials in Baku
- Assessment of issues specific to the Baku context with a view to explore whether they can be addressed by the above mainstream criteria or approaches

3.2. CASE STUDY SELECTION

Baku was selected as the main case study. It is important to examine whether the planning and design strategies and guidelines for making urban transport more sustainable are relevant and applicable for cities with an entirely different context and planning background. Baku is a city that has a different planning and development background because of its history.

Azerbaijan, strategically located between Europe and Asia, has significant natural resources particularly oil and gas. The oil and gas sector has been consistently leading all other economic sectors. The non-oil sector -led by construction, services and agriculture - has also been growing but at lower pace. Today, the expanding range of economic activity and increasing cultural strength is increasing the region's popularity. Baku Metropolitan Region (BMR) is confronted with a number of challenges in order to maintain its livability.

There is a high employment rate. BMR is an internationally connected region, integrated with global markets and equipped with a world-class infrastructure in all

sectors. BMR is a leading centre of education and training in transport, a centre of excellence, within the region. Environmental awareness, health and safety, are high among residents, public authorities and the private sector (Strategic Transportation Plan, 2010);

Baku was the ancient city of the Soviet Union and has a variable history. Azerbaijan that lived under four states;

- 1918 Tsarist Russia
- 1918-1920 Republic of Azerbaijan (Mehmet Emin Resulzade)
- 1920-1991 The Union of Soviet Socialist Republics
- 1991 Republic of Azerbaijan (Heyder Aliyev)

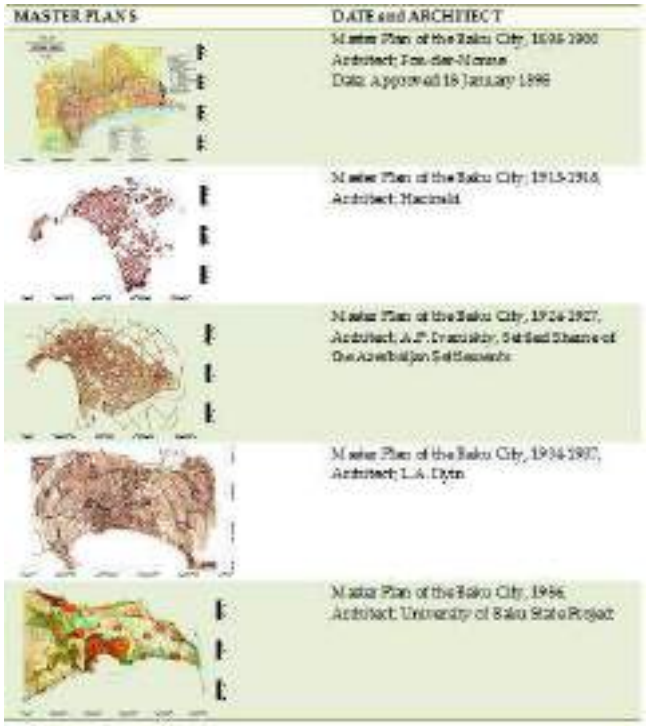
As a result it has a different urban planning history. The main Master Plan of the Baku is taking a shape according to the plan that was approved in 1987. Up to 1987 plan Baku had 5 different Master Plans,Table 2;

- A. İvaniski 1927
- V. Semyenov 1932
- L. İlyin 1937
- Bakqipogor 1954
- Bakqipogor 1986

3.3. METHOD FOR DATA COLLECTION

In this study, the data for Baku Urban Planning was considered a primary source. To access these data and documents, interviews were conducted with the Professors in Baku Architecture and Construction University, Department of City and Regional Planning and Department of Architecture and also Architects and Urban Planners in The State Committee on Urban Planning and Architecture and also the experts in The State Statistical Committee. Aim of these interviews was to get the correct information about the Baku Urban Planning Strategies with the experts and the academicians. Besides, individual analyses were also made by field trips around the selected there main study areas in the city, and sketches and photographs were taken.

Table 2:Master Plan Development of Baku



4. HISTORY OF BAKU URBAN PLANNING

4.1. BAKU URBAN PLANNING BETWEEN 19TH AND THE BEGINNING OF 20TH CENTURIES

Baku was the ancient city of the Soviet Union. Baku the capital city of the Azerbaijan settled on the west coast of the Caspian Sea. The specialty of the Baku was its thin and long streets within the wall of the Castle. Baku was the biggest industry and economy center of the Caucasian with its architecture and city planning. After discovery of the oil deposits in Absheron, Baku became the most important center for the Russian Empire during the second period of the 19th century. Lots of foreigners came for that oil deposits. Area of the Baku started to grow with the developments of industry and economy. With respect to those improvements; monuments, boulevards, and squares began to be built (Fatullayev, 1986).

When Baku entered under the protection of the Tsarist Russia, the city came out of the Castle walls/borders in 1806. It was geographically important because of the sea port that it had the trade route passing through Baku between Russia and Iran. After 1840, the highway developed and connected with all roads of Absheron Peninsula. Intersection of those roads created a square and around that square there were caravanserais and one-two storey houses which created a trade street under them. With those developments, traders and artisans began to arrive to the city and population grew. Growth process of Baku started therefore in 1806 when the city entered under the protection of Russian Empire and continued till 1914 and it was actualized in 4 phases. The first phase was in 1843, the second was between the years of 1843-1878, the third growth phase was from 1878 to 1900 and the last one was in

between 1900 and 1914 (Fatullayev, 1986). The sea side in front of the castle was used as a warehouse for the port. Sea shore/port became used as a trade center. It was growing through the east and pedestrians were not allowed to enter the sea shore. Although the plan drawn in 1854 was designed in rectangular/grid form, with the beginning of the use of sea shore, plan was designed according to the coast line (Fatullayev, 1986).

Population was increasing while the city was growing and port was getting more important because it allowed the transition between Iran and Russia. After that government took the control of the unbounded ports and in 1858, harbor/port city was designed in Bayıl District. According to the plan, there were shops, stores and lodgings. The area was 4 km2 and the plan was designed in a grid form and all the streets were open to the sea side. (Fatullayev, 1986). The biggest development of Baku was the openings of the oil factories. At the beginning oil factories and deposits were built unplanned. After 1870, because of the air pollution, government decided to collect them in one place. As a result, Qara Şehir/Black City was constructed. In 1876, no one could build an oil factory anywhere else except Qara Şehir/Black City. Like Bayıl, stores, shops and residential buildings were again designed in a grid plan (Fatullayev, 1986). In 1878 a new plan started to be developed. The new plan consisted of 3 parts which were Bayıl the port/harbor town, city itself meaning the castle and the area around it, and the Black City, the oil town. Although the area of Bayıl and the area of the Black City were located in a contrary side of each other, there were highways planned for the connection/transition. The 300 m swamp area in the sea side was designed as a promenade. In 1880 the first railway station was designed and constructed. It was located on the intersection point of the all roads of Absheron and also it connected with the three main areas of the Baku which were Bayıl, City Center and Black City (Figure 3) (Fatullayev, 1986) .

Figure 3:General Plan of Bayıl, City Center and Black City, 1878 (Fatullayev, 1986)

New towns were designed wider because the city was getting crowded and again the grid plan was used for their design (Figure 4). The main consideration was the wind of the Baku while planning those areas. As a result, all the buildings were located

facing the south. During the time period, when those towns started to connect with cities, street design and relationship between residential areas and railway system became an important issue. The main important issue considered was the topographic contours while planning. City center became the center of shops, stores, hotels, clubs, education and palaces of both foreign and local people (Fatullayev, 1986).

Figure 4:Expansion Plan of Baku (Fatullayev, 1986)

In 1908 Hacinski with his new plan development opened a water channel 190km far from Baku and this effected the industrial and economical developments of the city. Moreover drainage and green area developments of the city also changed. With this plan, a tram project began to be constructed and 270 ha new development areas were planned. Grid plan form was used from north to south and he developed narrow and uneven streets and inadequate green areas.

Figure 5:Baku Plan, 1918 (Fatullayev, 1986)

City assimilated its developments from 1806 to 1918. All political and economical situations affected those developments in each time. As a result there were ups and downs during the improvements. After all those developments and expansions Baku became one of the most important cities of the Russian and Caucasians while it was a

significant city for only Caucasians during the first half of the 19th century (Fatullayev, 1986).

4.2. BAKU URBAN PLANNING THROUGH THE SOVIET AZERBAIJAN

In the Soviet Period planners enhanced the grid system of current master plan and achieve the 1924 Master Plan by infill development of the non-designed plots as showed Figure 6.

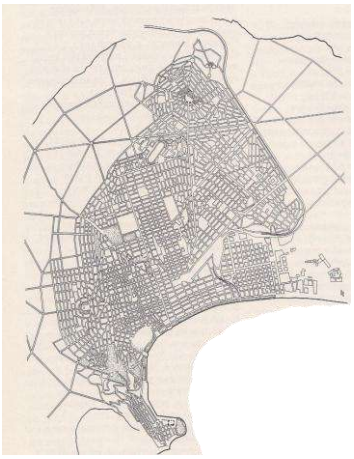


Figure 6:Baku Planning Design, 1924 (Efendizade, 1986)

According to that plan, architects developed the city borders to the natural borders of the amphitheater, in other words main Baku borders. This plan was 13 300 hectares and consisted of the sea in the south, 'Yasamal' hill in the west, great 'Shor Lake' and 'Oil' area in the east. It mainly had two areas, center and the industrial area which had its own residential districts/quarters. This land use plan was protected in the other Master Plans. Besides those land use planning, there also designed highways that appropriate to the lands infrastructure to make a connection between the other regions and industrial area. Planner also gave importance to grow green areas, by designing parks and leisure spaces. As a result boulevard which is 3 km length and 68 m wide was designed as a leisure and commercial area in 1967 (Efendizade, 1986). In the current situation, 2011 Boulevard is still 3 km length but it is approximately 170 m wide and it is the most important leisure place of Baku.

Figure 7:Plan in 1909 and View of the Promenade/Sea Side in 1910 (Fatullayev, 1986)

Planners started to use the current plan and developed the areas which are not designed of that plan schema. There were designed neighborhoods, streets and architectural buildings. The main idea of the planning system, as seen in the Figure 8, is to create streets and clusters which have courtyard in between.

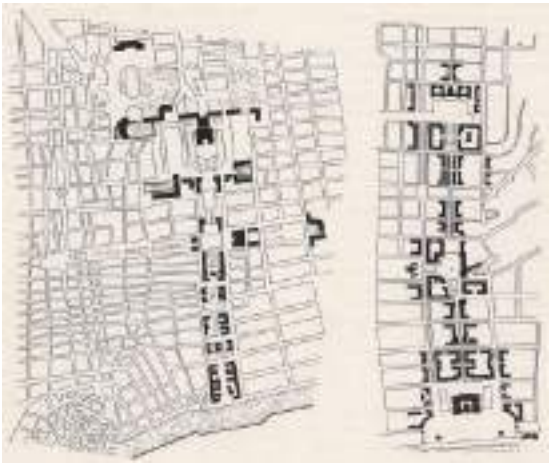

Figure 8:Baku Downtown Layout, 1932 and Baku System of City Centers, 1937 (Efendizade, 1986)

In 1950s architect M. Huseyinov made the revision plan as shown in the Figure 9. He planned the different functional building like as, administrative buildings, social buildings, cultural buildings as theaters and residential buildings along the main streets. This attitude made the Baku center multi-functional use.

Figure 9:Baku Layout of Main Ensembles (Efendizade, 1986)

Planning system of Baku will continue to with those aspects which gave the importance to the multi-functional use of the land, highways and main street layouts to make a connection between regions within and outside of the city.

5. ANALYISIS OF BAKU IN TERMS OF SUSTAINABLE DESIGN AND TRANSPORT

In this chapter of the study, the selected case area, Baku, is analyzed with regards to the approaches of sustainable planning, design, and transport that were discussed in the literature above. In particular, the relevance of approaches, such as new urbanism, smart growth, etc., is to be questioned in the context of Baku. The case area is studied in three scales of urban design which are macro, mezzo and micro scales. For the macro and mezzo scale analysis interviews were conducted with the urban planners, urban professors and architects to understand the design idea of the Baku urban planning. Experts from City Statistical Committee helped for the some statistical data's and also map analysis are done. For micro scale analysis three selected routes were analyzed by walking trips with drawing sketches and taking photographs. The main idea is to understand how Baku performs in terms of the criteria of creating a sustainable urban form and pattern; whether Baku has a problem in terms of unsustainable forms, design and transport; whether it can benefit from the approaches such as new urbanism, or whether such approaches are irrelevant in the case of Baku. In order to make a conclusion, all three scales were studied according to the principles which had been studied in the literature.

Baku, being 2130km2, has started from the intersection of the three main highway of Azerbaijan; Sumgait Highway, Shamakhi Highway and the Silk Road.

Figure 10:General Map of Baku Relation with the Main Road System of the Azerbaijan

Baku has 11 administrative regions. The population of Baku is said to be 2 246 000 with refugees but the experts said that the actual population is approximately 4 million. Baku consists of three main zones. The first one is Absheron district which called Great Baku, the second one is Baku administrative which occurred with industrial, residential and administrative areas and the last zone is the Private Baku which was designed as a residential area but currently has a huge mixed-use development. In this thesis these three zones were used as a reference for the three main scales of analysis.

Figure 11:Three Zone of the Baku Region

5.1. MACRO SCALE ANALYSIS

In this part of the analysis Great Baku was examined to find out the compactness of the city. The analysis of macro-scale criteria regarding sustainable form and transport reveals a mixed performance for Baku. According to Macro Scale Planning Policies planning for sustainable city and sustainable transport outcomes requires three main approaches (criteria): Compactness and prevention of urban sprawl; existence of sub-centers that can provide a mix of different land-uses and hence reduce the need to travel or reduce the distances to be travelled; and an extensive public transportation system.

- In terms of compactness, there is a mixed performance: the city used to be compact with a high density; however, it is experiencing sprawl now and compactness cannot be preserved as well as before.
- Sub-centers can help creating a mix of different land-uses and this issue is recognized as an important strategy in the plan document as cited above. On

the other hand, these are not implemented yet; and the existing city center of Baku is still extremely strong where most residents travel to work.

- The city performs well in terms of public transport infrastructure. It has a good metro system and extensive bus services and they are studying to develop the transportation infrastructure to make it more sustainable.

It can be said that all these macro scale policies are important and relevant issues that should be considered in the planning of Baku. Apart from the transport infrastructure, the city does not perform that well in terms of the two issues regarding compactness and sub-centers.

5.2. MEZZO SCALE ANALYSIS

Figure 12:Amphitheater Plan Scheme of the Baku, 1927

Baku is evaluated against the mezzo scale criteria and policies as shown in Table 1. Accessibility is high due to the extensive metro and bus network. The grid plan system also increases pedestrian accessibility. Mixed use development is encouraged and grid system is a positive feature of the Baku development pattern since it supports walkability. In terms well served public transportation, as there are at least two modes of transport stations around the neighborhoods or activity areas, there is an effective public transportation system. All those modes are close enough to walking, for example there are bus stations in each 350 m, and all designed pavements provide the needs of pedestrians by being at least 5 meter wide and divided with the green borders from the roads (as described below in the Micro Scale Analysis). Therefore it performs well enough in the aspect of the pedestrian friendly and walkable development.

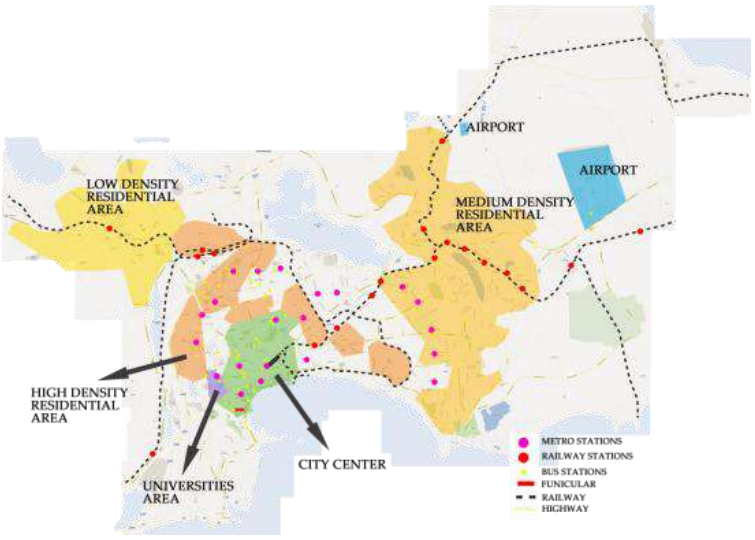

Figure 13:Accessibility of Transportation Modes of Baku

5.3. MICRO SCALE ANALYSIS

In this part of the analysis Baku Center is examined. Private Baku or Baku Center is the oldest development area of Baku.

For a more comprehensive study, three routes were selected for an in-depth analysis as shown in Figure 14. The first route is a trip going through the old residential area, Yeni Yasamal. The second route starts from a new residential area towards the city center and the last route starts from the main railway station and ends in the city center. Areas were analyzed according to the sustainable urban design indicators that were studied before. The study tries to answer the following questions: how is the intensity of the street network; is there an approach on mixed-use area development; is the area well served by public transportation; is there any awareness regarding pedestrian friendly design; how is the interface with car parking handled; is there a grid system plan to enhance connectivity for pedestrians; are there any car-free pedestrian areas and is the majority of the city walkable?

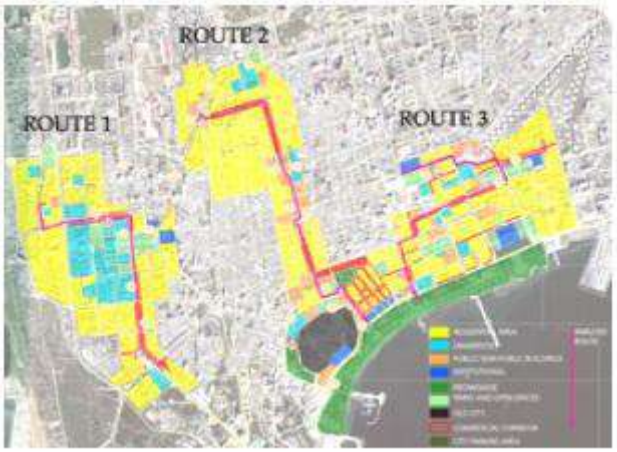

Figure 14:Three Route for Analysis

5.4. MAIN FINDINGS FOR THE CASE STUDY OF BAKU

The findings of sustainability analysis of Baku showed that Baku has retained its original development pattern which was based on grid and provided walkability as well as good public transport accessibility to a certain extent. The main findings are as follows:

- Baku has a **mixed-use development**. In earlier plans the city had a distinct zoning of residential areas and industry. However; there have always been local services and amenities within the residential developments. In addition, there has always been residential areas within the city center and administrative core area. Even within the castle there are both commercial and residential uses. After city began to grow it continued to consist of industrial areas, educational areas, business areas and institutional areas, recreation areas in close proximity to each other and in a mixed-use pattern.
- Baku traditionally had very **high density development** and this can be seen in both the city center (82,6 person/ha) and the housing areas (Yasamal District 115,7 person/ha). On the other hand, both experts interviewed and the Strategic Transportation Plan indicates that the currents trend is for low density housing and that low density development at the outskirts of the city is a major problem. Therefore; in terms of the density analysis, it can be said while Baku has a fairly high density built-up area in its inner city sections, the new developments at the fringes suffer significantly from low density growth. Nevertheless; the overall average density of 82,6 person/ha for the whole metropolitan regions is still higher than the 35 to 40 person/ha threshold suggested by Newman and Kenworthy (2006) and Banister (2008) as described earlier in the literature review section.
- Baku has an **effective public transportation system**:
    - It has had an electrified railway system since the 1960s (it is used as railway today) and it has been operating an underground subway (metro) since 1967. The metro system, which has 23 stations and 34.6 km length, efficiently serves the Baku administrative. Today, the government developed a new strategy for Great Baku by planning another 45 stations.
    - It has also an effective and extensive bus system as there are stops in every 350m approximately.
- In planning of the Baku street layout there is a concern for the **pedestrian friendly design:**
    - All pavements are wide enough for walking and separated with green border from the vehicle road.
    - There are commercial and leisure activities along the streets which encourages the walking.
    - Even though there are huge boulevards formed by the intersections of the main axes of the transport infrastructure, huge public spaces as cultural activities and parks and underground passages reduce the negative effect of those boulevards.

- Baku has had the **grid plan** system which is often described as one of the most important approaches for the sustainable urban design form. The city has had this approach since the 1898 Master Plan and protected its grid plan approach while enhancing the plan.
- All neighborhoods and special development areas like educational areas have at least two kinds of **transportation modes** like bus stops and underground subway station **close enough to walk**.
- City center layout is designed well enough to walk. Indeed three routes for the case study which are 2km long were analyzed by easily walking.
- There are huge pedestrian areas like boulevards and Tarqovı Street as leisure and commercial areas. These areas are completely **car-free areas**.

After an in-depth analysis of Baku, the following results can be shown:

Table 3:Analysis Result of the Baku Case

MACRO SCALE ANALYSIS	
Compactness of the urban form in metropolitan scale (restraining urban sprawl, setting growth boundaries, growth management, etc) and prevention of sprawl	+/-
Existence of sub-centers (a polycentric form that enables a mix of land-uses at macro scale and eliminates the need to travel to the city centre for daily needs or even for work purposes)	+
An extensive public transport infrastructure: efficient public transportation system	+
MEZZO SCALE ANALYSIS	
Mixed-land use	+
Pedestrian friendly, walkable development	+
Well served public transportation: efficient public transportation system and urban development focused on public transport stations	+
Grid system plan (to ensure high connectivity and walkability in the micro scale)	+
MICRO SCALE ANALYSIS	
Intensity of street network (to ensure high connectivity)	+/-
Existence of local services and amenities (mixed use)	+
Areas being well served with Public Transport	+
Grid Plan for high connectivity	+
Pedestrian friendly and walkable street sections	+
A hierarchy of narrow streets, boulevards and alleys	+/-
Interface with parking: parking areas should not be barriers for pedestrians	-
Having majority of the neighborhood accessible on foot	+
Car-free public areas	+

6. CONCLUDING REMARKS

According to this analysis, it can be said for certain planning principles and approaches, that Baku always had adopted those and preserved them, and therefore has a relatively more sustainable urban form and transport system. For example, mixed use development has always been an important strategy, and throughout its planning history, new developments in Baku have always been planned with their local services and amenities. In addition, boulevards with large sidewalks and protection of pedestrian pavements from the traffic with landscaping and green belts have been a long-lasting approach in planning in Baku. The adoption of grid-street patterns in most neighborhoods was another advantage that increased the

interconnectivity and walkability, although some residential areas such as Yasamal which were designed in the period of Soviet Azerbaijan had less connectivity with large mass-housing style parcels and plots.

From all these perspectives, it could be said that the new urbanism, transit oriented design and similar approaches are not as relevant to Baku as they are to the cities of North America because Baku planners have always been aware of the advantages of these approaches and implemented them throughout the planning history of the city. On the other hand, there are certain criteria or approaches that the analysis showed to be important for Baku:

Although development until recently has been in high-density, this is changing with the low density development in new residential areas. Hence there is the problem of sprawl; and therefore growth management should be an important strategy for Baku. The Transportation Strategic Plan also emphasizes this. In addition to that the interface of parking with sidewalks and pedestrians is a huge problem in Baku.

There are many large boulevards in the city and the city centre remaining from the Soviet period which are being further invested in today with fly-overs and junctions to create better accessibility for cars. Hence there is the danger of creating a car-dominated system in spite of the advantages of the current urban form and design.

Car ownership and usage are high as described. Car owner ship ratio is growing day by day because of the cheap sales of car industry. The city centre is not designed in a car oriented way and this is a positive thing. However, there are not enough traffic management approaches to prevent cars entering the city centre. Therefore in spite of the good design of the urban core, congestion and traffic problems are increasing. As a result, approaches, such as growth management and the design of car parking areas may be important and relevant strategies for the Baku case.

What the Baku case shows, however, is that with the strong planning background of this city, planning and designing the city to make it more public transport friendly or walkable is not the priority. The city is already like this. It is the lack of any control on car traffic that is the problem. This problem can be solved with further design and pedestrianisation actions, but also with good traffic management including traffic calming measures.

However; sustainability is a much extensive issue as it is related to economy, environment and social life. As a result to achieve sustainable urban area, there need be sustainable in all three pillars of sustainability. But, as cities are the core areas of the development, in the first step, they need to be designed according to the sustainable urban design approaches. There is a vast literature, again, about that issue and the transportation is the key element to design a city. Although there are many policies to achieve more appropriate and sustainable transportation they are not well served if there is not an appropriate urban planning and design approach that encourages the use of sustainable modes of transport, such as walking, cycling and public transport.

NEW STRATEGIES FOR RISK COMMUNICATION AND KNOWLEDGE: THE EXPERIENCE OF THE E-LEARNING TOOL OF THE EUROPEAN RESEARCH PROJECT ENSURE

Giulia Pesaro[1]

Abstract

The essay offers a synthesis of the activities developed into the ENSURE European project in order to build the planned e-learning tool.
The basic assumption of ENSURE is that our ability to better understand and evaluate different types of vulnerabilities and resilience to hazards constitutes a crucial tool to strengthen communities in the face of disasters due to extreme events and climate change. Improving the understanding of the factors that make a community more vulnerable from the one hand and more resilient from the other is therefore extremely important.
Into such a framework, the e-learning tool has been regarded as a new communication and knowledge strategy for achieving two main goals. The first one is the better dissemination of the project results, which enclose the proposal for a specific model to assess the vulnerability and resilience of a territorial area. The second one is more general and regards the improvement of knowledge and communication for what concerns the complex matters of vulnerability and resilience to natural and na-tech hazards and their assessment.
The tool has been organized as a course without external assistance, available in a website free on internet, and has been designed to reach and involve a variety of students, practitioners and other technicians as target users.
The e-learning path offers a sequence of themes, theories, methodologies, tools, and case studies the users can browse and experience. All learning materials come from the ENSURE project activities, which made it necessary to revise and "rework" the documents produced by the ENSURE partners during the research activities to adapt contents to the e-learning uses.
The essay offers a description of the activities and choices made by the working group to obtain the learning path and materials and to design the architecture of the website. This having in mind the need to develop a communication strategy able to introduce users to the importance of vulnerability and resilience matters and to capture them with interesting and appealing contents.
The following points will be discussed: main goals, main problems, the concept of the e-learning tool and the design of the website architecture.

[1] Diap Politecnico di Milano, Milano, Italia, giulia.pesaro@polimi.it

1. Introduction

In Ensure Project the research activity has been focused on the analysis of the vulnerability of territorial systems to the consequences of natural and na-tech disasters. Consequences like economic and social damages, loss of natural environments and cultural heritage, up to large death tolls. Losses which should be regarded as losses of territorial resources and of values for present and future development. It becomes therefore very important to better identify and measure in which way and to what extent a territory is exposed to certain types of hazards. Which means to better understand which elements, systems, subjects and areas are most likely to suffer from catastrophic events like earthquakes, floods, droughts, landslides. Improving the understanding of the factors that make a community vulnerable or resilient is therefore crucial.

Addressing the enhancement of knowledge and practice of vulnerability and resilience assessment as the main overall objective, the ENSURE Project set three working goals. The first one was the operational character of the tool to be developed. This is the reason why the project attempted to build on previous knowledge, taking advantage of what has already been accomplished in the field, trying to embed available results of risk and vulnerability assessment experiences as much as possible. The second general objective, responding to the need for operationalization, was to provide an interpretation of the relationship between vulnerability and related concepts (resilience, adaptation, coping capacity, etc.) within a framework strongly targeted towards prevention. The framework had to provide a sort of guideline to assess vulnerability before an event strikes, helping decision makers and even lay citizens take appropriate mitigation and anticipatory measures. The third, more specific, goal was to provide an updated picture of what is already available in literature, in previous studies, and in applications worldwide. We may count already a growing number of proposals concerning indicators, parameters, measures, related to physical, systemic and social aspects of vulnerability. These have been analyzed and a selection of the most advanced or appropriate ones were proposed as part of the tool for vulnerability assessment.

Into such a framework, the e-learning tool has been regarded as a communication and knowledge strategy to enhance the set of goals introduced above and to better exploit the project outcomes.

The website would like to invite users to make a journey into the vulnerability and resilience matters, offering a tool to directly experience the research results obtained during the Ensure Project work. Here it is therefore possible to find some theoretical and operational tools related to vulnerability and resilience assessment which could help in better understanding and evaluating different interpretations of the concepts and ways to operationalize them.

The rationale behind the architecture of contents and their organisation into the website meets two main purposes. The first one is the better dissemination of the project results. These enclose:

- the proposal for a specific integrated and multi-scale model to assess the vulnerability and resilience of a territorial area;
- a review of the investigations and reflections on vulnerability and resilience that led to the development of the evaluation framework;
- the consequent application of the assessment path into different case studies.

The second one is more general and addresses the improvement of knowledge and communication for what concerns the complex matters of vulnerability and resilience to natural and na-tech hazards and their assessment.

The e-learning tool, organized as a course without external assistance, aims at introducing users to the vulnerability assessment model proposed in the ENSURE project, specifying procedures, criteria and parameters to make it operable within a given territorial or cultural milieu. Case studies at local scales and within regional contexts complete the picture, proposing an approach for better understanding the articulated nature of the concept of vulnerability (i.e. physical, economic, cultural, social and systemic) at different spatial scales (regional and local), useful for exploring the integration and connections of different types of vulnerability and resilience and for developing assessment processes and future scenarios.

The learning path has been obtained from the project contents and results and offers a sequence of themes, theories, methodologies, tools, and case studies the users can browse and experience. The choice for the contents and the design of the learning sequence required a careful review of all the project documents produced and specific work to adapt them for use on a website. This adaptation was necessary because of the complexity itself of the subject matter – vulnerability and resilience to hazards – and because of the need to simplify such complexity into a clear and useful learning path.

The website has been developed to reach and involve a variety of students, practitioners and other technicians as target users. Generally speaking, each target group has different learning and knowledge needs or goals and the different categories of users are treated differently. However, in this case the e-learning tool has to be mostly regarded as an additional method for disseminating the project's results to a wide group of users, therefore documents and activities offered on the e-learning platform are generally aimed at all users. With this in mind, the website has been designed to be as attractive as possible, where the contents are interesting and appealing to many users, offering a variety of examples and case studies developed by a multimedia approach (texts, hypertexts, images, videos, links to other websites) and embracing interdisciplinary approaches, theories, methodologies and tools.

Conceived for both communication and knowledge enhancement, after the learning modules, users can find a module of activities, designed to self-test the achieved learning outcomes. Also these activities have been designed to be suitable for different target groups and mainly aim at making users aware of their capability to deal with the project issues and the use of the assessment methodology.

2. The concept of the tool

Great attention has been paid to the continuous connection between the e-learning site and the ENSURE project itself. Aiming to enhance the dissemination of the project results and products from the one side and to make users aware of the opening of the e-learning site from the other side, the e-learning tool has been linked into the ENSURE project website as one of the pieces of the starting puzzle in the home page (www.ensureproject.eu). Moving the opposite direction, in the opening page of the e-learning site (http://ensure.metid.polimi.it) a clear link to the main project site is available. The *continuum* between the two sites is also obtained by the use of graphic elements. The opening page of the e-learning tool maintains the same colours and some visual effects of the ENSURE Project website, while the graphic elements and the organization of the pages are of course different.

The contents of this e-learning tool, in a general perspective, is not so different from more traditional learning tools, the main requirements being:

- the identification of the “key learning goals”;
- the selection of the main learning contents, which will be offered on the e-learning platform in terms of “learning packages”;
- the project design of the learning path, which means the sequence of the themes, theories and methodologies, statements, tools, examples, best practices and case studies;
- the selection and/or building of reference documents;
- bibliography and literature references;
- selection and design of activities or exercises for the enhancement of the learning process and as a mean for a self-evaluation phase;

The choice for the contents and the design of the e-learning tool of the ENSURE Project required a careful review of all project documents and a specific work to adapt them for use on a website. This adaptation was necessary because of the complexity itself of the subject matter – vulnerability and resilience to hazards – and because of the need to simplify such complexity into a clear and useful learning path. Moreover it was not possible to just upload the deliverables as they have been developed. Deliverables had mainly been conceived to communicate with the European Commission and to disseminate both research results and the new methodology to the European experts, scholars and academics, even if with a great attention to the needs of practitioners. The learning goals require a different approach and a reworking, in order to obtain new materials for learning purposes.

In the light of such elements, the concept of the ENSURE Project e-learning tool is the result of the reasoning around the following points:

- the learning path itself, that is the selection of learning contents and the sequence in which they are organized;
- the building of a friendly approach to main topics as well as to the learning path, in order to attract potential users and push them to enjoy the whole of the learning offer and site contents;
- the building of specific learning materials, different from the ENSURE Project final deliverables, needed to better support the users inside the learning environment;
- the offer of some activities to self-test the learning progress.

About the learning path, the following elements have proved to be particularly important in order to obtain the final scheme (see the next paragraph about the architecture of the site):

- to offer a clear and simplified framework of the concepts and main theories and methodologies concerning the assessment of vulnerability and resilience to hazards;
- to outline in a clear way the goals of a "vulnerability assessment" and of a "resilience assessment" (or of other typologies of assessments around hazard evaluation and management) in a certain territorial system;
- to draw attention to the passage from theory to practice, in particular in terms of information collection and processing for building assessment parameters. This also refers to the need for working on territorial complexity and "solve complexity" to both obtain clear and useful vulnerability and resilience assessments and better face hazard management and mitigation;
- to draw attention to the "scale approach" or spatial dimension in the analysis, that is the observation/analysis of territorial areas at the different territorial scales at which vulnerability and resilience assessments can be developed (from urban-local to regional). This also means to build working skills in order to better take into consideration the specificities of territories at different levels, with their institutional frameworks and organizational resources and bodies;
- to draw attention to "time", defining phases or sequences of events, analysis, interventions which can be reflected in the "history" of an event and of all what follows (impact, emergency management, recovery, prevention and mitigation policies and interventions..);
- to make links between vulnerability assessment and other dynamic elements like impact, emergency and recovery management. This also with reference to resilience and mitigation of risk/damage matters;
- to identify what learning elements can be considered central for enhancing the capacity of territories to face the sequences of: hazards knowledge, potential damage impacts, emergency planning, events, post events, damage assessment and accountability, reconstruction;

- to draw attention to the importance of “learning from case studies”, which also means to outline questions that “should be asked to the case study” to extract the main elements and information from the experience.

Concerning the need for obtaining a friendly approach to the learning environment, the learning activities have been organized in a sequence of thematic chapters in which the user can find contents at three different deepening levels. This allows users to choose their main interests and/or work only on some issues but, at the same time, makes it easy to browse other, enlarged, contents. Strictly linked to this comes the point of the building of specific learning materials.

First the users can find a brief description of some main elements and concepts, just to be introduced by a first glance to the “great world” of the activities around the vulnerability and resilience matters and assessments.

Then they can deepen their knowledge selecting from a list of more specific contents and documents expressly produced for the e-learning tool. A part of these documents has been obtained from the deliverables, selecting contents and rebuilding the texts of the final products. Others are summaries of activities and documents produced from the ENSURE Project partners during the working period: slide presentations from the project’s meetings, schemes, maps, images, case studies and shorter versions of official documents, modified to be more suitable for the e-learning platform goals. The written texts in the opening pages of each module have been conceived as constituting the thread of the work.

All these will address to the ENSURE official final documents and publications by the project partners: the third learning level. As an example, if the user is reading about the central importance of time and territorial scale in vulnerability assessment, it is every time possible to trace the deliverable and the chapters in which the specific item can be found. Moreover references remain in the final deliverables, so that user will have at least to open them if they are interested in the literature, giving deliverables themselves a better visibility.

Of course basic elements like definitions, approaches, possible assessment methodologies and other elements alike have been specifically elaborated further in an e-learning perspective. For instance the users can find a list of basic keywords with a brief definition.

3. The architecture of the e-learning site

The learning menu is composed of four main modules. Two learning modules are devoted to theoretical and methodological issues related to *Vulnerability and Resilience Concepts* and *Vulnerability and Resilience Assessment*. The third module is devoted to the *Analysis of Case Studies* and the last one contains final self-evaluation activities referring to the whole proposed learning contents.

A fifth and last module contains the ENSURE Project final deliverables, the final booklet, the references of articles written by the research partners as an outcome of the project and some useful links to other websites.

In each module the user can find a brief introduction text and files containing the specific learning contents. Activities and examples useful to check the learning level obtained are all included in module four.

3.1 The home page of the e-learning tool

In the home page a presentation text introduces the ENSURE E-learning platform, explaining the main purposes of the tool and the main dissemination and learning goals (fig.1).

Figure 1 – The opening page of the ENSURE Project e-learning tool

This text is important as it must attract people to enter into the “operational part” of an e-learning tool concerning a particularly complex matter as vulnerability and resilience assessment can be. A video with a presentation completes the opening page, explaining the key contents and the meaning of the learning offer. These elements are very important as the e-learning content is offered to a huge public variously interested in the matter. Moreover some elements make the difference from other e-learning experiences and courses related to natural and na-tech hazards research, management and prevention:

1. the e-learning website has been conceived to be a tool to better diffuse the ENSURE Project integrated multi-scale vulnerability approach, together with all the documents and products available as the result of the overall project, which

makes this tool really different from all other experiences. For these reasons, just after the introductory text there is a link to the ENSURE project website;
2. The e-learning tool entails knowledge enhancement goals but in absence of direct interaction with a teaching team. This calls for solutions able to make users understand the meaning and the goals of the on-line course, what they can obtain from this particular sequence of learning contents and the meaning of the activities to self-evaluate knowledge enhancement results;
3. The access to all contents is free(similar to the tool NAHRIS, but here enriched by self-test activities), differently from other university or institutional e-learning courses (for instance the tools e-Scenario or GEOG105 Lab Programme). In the home page an "autologin" routine is available to users to simply and immediately register to the website. The registration will be used to identify users (number and some simple characteristics).

A second page contains a tutorial for the use of the e-learning tool. Here users find information on the learning object and goals, together with some instructions on how to use the platform and the contents. A menu allows to enter into the learning modules and in the module containing the ENSURE project deliverables and other products.

3.2 The organization of the learning modules

The three learning modules are introduced by a brief text summarizing the main learning elements and introducing to the use of the materials available. From the operational point of view, the contents are organized in folders and subfolders, in order to obtain both a clear learning sequence and a system of homogeneous learning units. In each folder users find the "learning files", materials especially developed for the e-learning tool starting from the final deliverables of the ENSURE project and from other documents prepared by the partners during the research working period. These files are numbered to simplify their identification and use.

3.2.1 Learning module 1 – The Vulnerability and Resilience concept: "a journey into definitions, approaches, and tools"

In this module users find definitions, concepts and evaluation methodologies useful in vulnerability assessment and management. The module is meant to summarize the main theoretical and methodological elements in vulnerability assessment and management as elaborated and proposed by the ENSURE project working teams.

Here the ENSURE partners would also like to introduce both the importance of definitions themselves and the importance of the selection made during the working period. The huge variety of approaches, methodologies and assessment tools available in literature and practice requires a preliminary analysis to make it clear all the implications of such definitions in addressing assessment issues and activities: from the identification of hazards, the selection of indicators, the data collection and the elaboration of knowledge to the interpretation and evaluation process itself.

The following table 1 shows the organization of folders and subfolders.

Table 1 - Folders organization and files in module 1

🗁 *Lm1.1 Vulnerability: concepts and definitions* – what "do you need to know" to develop a vulnerability assessment?
🗐 *F02_An introduction to vulnerability definitions*
Lm1.1.1 Vulnerability in time and space
🗐 *F03_Vulnerability in time and space*
🗐 *F04_Vulnerability in time*
🗐 *F05_Vulnerability in space*
🗐 *F06_Scale factors in vulnerability analysis: multi-scale and cross-scale analyses*
🗁 *Lm1.2 Vulnerability and resilience* – what is a resilience assessment and what do you need to know to develop one?
🗐 F07_Vulnerability and resilience
🗐 F08_Resilience and vulnerability
🗐 F09_The resilience concept
🗁 *Lm1.3 The objects of a vulnerability and resilience assessment: structural, territorial, social and economic systems* – what territorial elements should we take into consideration and in which way? Which indicators should we identify and measure to obtain a valid image of such territorial elements and their dynamics?
🗐 F10_Vulnerability of socioeconomic systems
🗐 F11_Social and economic vulnerability_2 case studies
🗐 F12_Social vulnerability and resilience_the actors
🗐 F13_Territorial vulnerability and territorial capital
🗐 F14_Vulnerability of socio-economic systems. Concepts and definitions from a theoretical and research perspective
🗐 F15_Structuring social and economic vulnerabilities
🗁 *Lm1.4 Vulnerability, resilience and natural hazards* – which fundamental relations are there between a vulnerability and resilience assessment and the type of hazard? What are the roles of time and territorial scale when working on different types of natural hazards?
🗐 *F16_Concept of risk in volcanology*
🗐 *F17_State-of-the-art on territorial vulnerability and natural hazards. Lessons learned*

Definitions are crucial for building the general framework of each issue and for answering questions like "how can we find the vulnerability profile of a certain territorial area?", "which kind of vulnerability are we exploring?", "which kind of territorial subjects and objects are exposed?", "which are the main consequences in

terms of expected damages?", "how can we find the resilience profile of a certain territorial area?".

3.2.2 Learning module 2 – The Vulnerability and Resilience Assessment

The main purpose of this part is to make users experience the assessment process developed by the ENSURE research group. This is a particularly important and delicate issue as here the specific methodology developed by the ENSURE Project partners is introduced and explained from both a theoretical and operational point of view.

Users experience the sequence of elements and activities which drives from the territorial analysis to the vulnerability and resilience assessment. They can therefore find brief introductions to models, tools and techniques for the recognition of territorial elements and dynamics which explain different levels of vulnerability together with the operational definitions and applications of vulnerability and resilience assessment processes. Here it is moreover suggested to pay attention to some particular elements like: scale, time, indicators and data organization, knowledge building, territorial subjects and objects exposed to hazards.

After these, users find elements to identify the goals of a "vulnerability assessment" (or of other typologies of assessments around hazard evaluation and management) in a certain territorial system. The sequence of the learning contents will therefore drive the attention to the passage from theory to practice (in particular in terms of information collection and elaboration for parameters building): for instance the importance of "time", defining phases/sequences of events/analysis/interventions which can be reflected in building a certain sequence of activities (analyzed through examples of applications and case studies in this and in the following module). Users will have to pay attention to differences concerning different tools coming from different approaches and follow the discussion which led to the specific ENSURE Project integrated multi-scale approach to vulnerability and resilience assessment.

The final section explores the use of vulnerability and resilience assessment results as an important basis for the design and implementation of possible policy tools for hazard management. Users therefore find elements to connect vulnerability and resilience assessments with impact, emergency and recovery management. This working at different institutional levels for a better governance and management of "the cycle of disaster" and for enhancing prevention and mitigation matters.

The following table 2 shows the organization of folders and subfolders.

Table 2 - Folders organization and files in module 2

🗁 Lm2.1 Vulnerability and Resilience Assessment Tools – from theory to practice: the steps and the tools of a vulnerability or resilience assessment.

- 🗐 *F18_An overview of vulnerability assessment concept*
- 🗐 *F19_Examples of methodologies assessing territorial vulnerability*
- 🗐 *F20_Some key elements for vulnerabilities assessment with respect to complex hazardous events*
- 🗐 *F21_Relationships among vulnerabilities and resilience: an assessment perspective*
- 🗐 *F22_Tools for vulnerability analysis and representation*

🗁 Lm2.2 Territorial elements and dynamics – the importance of the local territorial scale and of the knowledge of specific characteristics and dynamics territorial elements

- 🗐 *F23_Structuring the relations between physical, social and economic vulnerabilities: an introduction*

🗁 Lm2.3 Vulnerability and resilience assessment – How to build a vulnerability or resilience assessment procedure and which elements have to be taken into account to develop the assessment process

- 🗐 *F24_Vulnerability operational concept and measurement*
- 🗐 *F25_Transfer of vulnerability across time and space_a case study*
- 🗐 *F26_Models and methodologies for socio-economic vulnerability assessment. A theoretic and research perspective*
  - 🗁 Lm2.3.1 Indicators
    - 🗐 *F27_Indicators for a vulnerability and resilience assessment: an introduction*
    - 🗐 *F28_Indicators/parameters of socio-economic vulnerability. A theoretic and research perspective*
    - 🗐 *F29_Data availability and indicators in vulnerability assessment*
  - 🗁 Lm2.3.2 Organizing knowledge
    - 🗐 *F30_Organizing knowledge for vulnerability and resilience assessment: the set of matrices developed within the Ensure project*
  - 🗁 Lm2.3.3 Interpretation: the vulnerability and resilience assessment
    - 🗐 *F31_Methodological framework for an Integrated multi-scale vulnerability and resilience assessment*
    - 🗐 *F32_A synthesis of the whole ENSURE method for assessing vulnerability and resilience*
    - 🗐 *F33_Vulnerability analysis and assessment of cultural heritage*

🗁 Lm2.4 Facing and managing vulnerability – Which connection between vulnerability and resilience assessment and impact, recovery, prevention and reconstruction management? Once knowledge is available, which actions or tools could a territorial system explore and implement to better manage hazards?

- 🗐 *F34_Does reducing vulnerability always lead to enhance resilience?*
- 🗐 *F35_Strategies, approaches and practices to decrease socio-economic vulnerability and to increase resilience*
- 🗐 *F36_Emergency planning in Vulcano*

3.2.3 Learning module 3 – Case studies

This section would like to introduce users to the reading, comprehension and building of case studies in vulnerability and resilience matters. Learning from case studies means also to outline questions that should be asked by the case study analysis. This, among others, means to apply “a certain level of abstraction” for a more effective description of reality and to extract the main elements and information from the experience.

A review of case studies is here proposed, in order to make users understand which are the most important knowledge elements which should appear in an assessment activity and how to build the sequence of working steps leading to an effective result. This can also be considered as a reading scheme to extract and learn from existing case studies as much as possible both of the experiences themselves (type of risk, country, vulnerable elements of the specific territorial system, selected tools to face and manage vulnerability..) and of the particular application of the tools for the building of the case study. “History” of an event and of all what follows (impact, emergency management, recovery, prevention and mitigation policies and interventions..).

The following table 3 shows the organization of files.

Table 3 – File organization in module 3

🗁 Lm3 Vulnerability and Resilience Assessment Tools – from theory to practice: the steps and the tools of a vulnerability or resilience assessment.
🗐 *F37_Hazard-specific case studies of inter-relationships between social vulnerability and economic vulnerability*
🗐 *F38_Structuring the relations between physical, social and economic vulnerabilities: applications to different natural hazards*
🗐 *F39_Applying the concept of vulnerability: the case of Negev*
🗐 *F40_Vulnerability in time: case studies*
🗐 *F41_Vulnerability in space: case studies*
🗐 *F42_Applying the ENSURE methodology for vulnerability assessment: the case of Ilia forest fires*
🗐 *ENSURE Del5.3.1 - Development of the Integrated Approach on the Ilia case study*
🗐 *ENSURE Del5.3.2 - Development of the Integrated Approach on the Negev case study*
🗐 *ENSURE Del5.3.3 - Development of the Integrated Approach on the Vulcano case study*
🗐 *ENSURE Del5.3.4 - Development of the Integrated Approach on the Ethiopian, Istanbul and Corvara case studies*

The selection of case studies tries to call attention to differences of approach, media, territorial analysis process and knowledge building tools like, for instance: type of document – written, images, video –, type of assessment tool, indicators selection and processing methodologies, knowledge building according to real needs, territorial features, scale and time, type of target communities of the document, subject asking for the assessment. Moreover, some elements already discussed in the previews modules are underlined, to make it clearer the transition from theory to practice: territorial scale of the analysis, time, sequences of events/analysis/interventions and time related matters, selection and processing of different kinds of indicators, building procedure for the vulnerability and resilience assessment (emphasis on the sequence of the activities).

To make users better understand the process, in this section both elaborated files and the four ENSURE Project final deliverables on case studies are available.

3.3 The activities to self-test the knowledge achieved

This section is meant to be a place where to test the acquired knowledge and as a mean for a self-evaluation of knowledge level about the specific subject of vulnerability to hazards.

The external intervention not being previewed, the exercises are organized with answers and the indication of theoretical and methodological knowledge references into the e-learning site.

The activities have been developed according to the main knowledge goals of the ENSURE Project and try to retrace the contents from an operational perspective. The user is then asked to try to develop actions like:

- “to identify and find essential elements in order to obtain a first knowledge picture of the specific territorial system”
- “to recognize usable information/knowledge from images, maps and other visual documents describing natural and na-tech hazards”
- “to select key territorial subjects in order to organize the vulnerability assessment activity”
- “to assess the quality of data”
- “to organize indicators and build up assessment tables”
- “to develop a vulnerability and/or resilience assessment”
- “to put in evidence the main results of the assessment process”
- “to suggest some possible vulnerability management suggestions to local subjects”

The architecture of these activities also aims at introducing users to the knowledge building needs and to the sequence of actions required to autonomously develop an assessment process.

Table 4 – Example of an activity in module 4

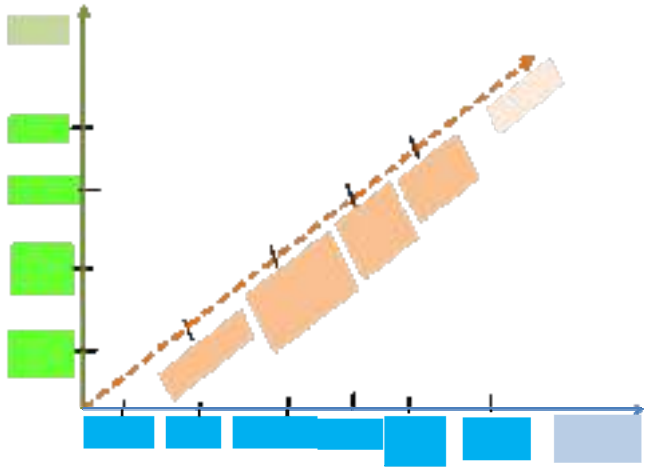
Working with indicators

This activity aims to help you achieve a better understanding of this important matter.

The use of indicators is one of the core activities in any assessment process, regardless of the specific field of application. As well introduced by file F28 in module 2, “Indicators are qualitative or quantitative parameters that describe features of a certain, often complex and ill-defined, phenomenon and communicate an assessment of the phenomenon involved (Dopheide and Martinez, 2000). The latter implies that, although indicators can be either descriptive or normative, they always have implicitly or explicitly a reference to a norm. This makes indicators clearly different from simple measurements”.

This means that the selection and quality of indicators define the quality itself of information. Quality which means completeness, usability and clarity of information describing a certain matter or phenomena or territorial area: information needed to develop any vulnerability and resilience assessment.

1. The following figure can be found in module 2 and shows “Criteria to identify and select vulnerability indicators”. Are you able to fill the coloured areas with the right contents?



To help you remember that criteria are grouped along three main axes:

- On the x axe, the inherent characteristics of indicators are addressed;
- On the y axe, the characteristics of the data to be used to assess the indicators value in a given place are shown;
- On the z axe, the usefulness of indicators is appraised.

2. To develop a vulnerability assessment you need some categories of data/indicators: which ones?

To understand which sources are needed we have to make reference to the definition of vulnerability. You can find useful elements in files F02, chapter 3, and, mainly, in file F29.

3. Once data have been processed into a vulnerability assessment, it is important to organise them into tools for vulnerability analysis and representation. Tools must be able to transmit information and communicate about the vulnerability profile of a territorial area, becoming supports for decision making processes. Which instruments for the data visualisation can be found in the ENSURE documents?

Exercises are of course based on the materials available on the website and try to use a variety of elements and media to make activities more attractive and diversified. Finally, as the e-learning site should function as a tool for the dissemination of the results and documents produced by the ENSURE Project, activities have been designed to invite users to browse all the knowledge contents and to make reference to the complete work developed into the ENSURE Project. Table 4 shows an example of activity.

3.4 Module 5 – The final ENSURE Projects products

The final module in the e-learning site offers a collection of documents and publications produced by the project partners.

Here it is possible to find the whole set of deliverables of the ENSURE Project from which the specific learning files have been obtained. There are constant cross-references between files and deliverables, in order to invite users to deepen their knowledge beyond the educational contents which have been expressly composed for learning purposes. For the same reasons this module offer is enriched by the final booklet *Enhancing Resilience of Communities and Territories Facing Natural and Na-tech Hazards,* a list of the references of the publications prepared by the project partners and a list of links to interesting websites.

4. Conclusions

The e-learning tool of the ENSURE Project may be seen as an attempt to widely diffuse both a research project results and a methodological/operational practice contributing to the offer of instruments to be used in the field of natural and na-tech hazards vulnerability and resilience assessment.

The concept and the architecture try to respond to a double challenge. From the one hand there is the need to offer contents directly coming from a recent and innovative research work. The selection and elaboration of the e-learning contents should therefore be able to adequately explain and diffuse the products of a very rich analysis and discussion regarding the existing approaches and practices in vulnerability and resilience assessment and the new operational integrated multi-scale ENSURE methodology. From the other hand this can be regarded as a new offer of an easy-to-use course on a very complex matter like vulnerability and resilience assessment to a wide audience of students, professionals and practitioners.

To draw concrete conclusions on the performance itself of the tool we will of course have to wait some more time, as a real evaluation of the results will be possible only after at least a year from the finalization of the website and the diffusion of information about its availability. The work of conceptualization and the production and organization of the learning contents has anyway highlighted some important elements for future developments.

A first issue is the use of English as the working language (see Lienert at al. 2009). This of course opens the tool to a really wide audience but, on the other hand, could represent a constraint to the diffusion towards practitioners and technicians in public and private local bodies. In future it will therefore be important to understand whether and in which cases it could be useful an effort of translation, taking into account the emerging of costs which may be high.

A second point is the capability to offer approaches and methodologies from both a theoretical and operational point of view. Operational tools are of course very important but in time they can change. A course like this one have to make users aware of the importance of theory and methodology beside practice. What changes only a little is the capability to build the knowledge needed to develop a certain sequence of actions to obtain an effective and useful vulnerability and resilience assessment, apart from the use of one specific model.

The final point is the need for contents able to offer a wide variety of operational experiences in many different regions and in presence of different hazard typologies. This is way the ENSURE Project tool put so much emphasis on case studies, a result achieved by involving many scientists from different countries working with different disciplinary approaches. An great effort during the research period but a great richness in terms of knowledge production.

ABSTRACT
Istanbul undertakes half of the imports and exports of the country which has been increasing importance as it is the most developed city in Turkey with a population reaching up to 13.255.685 people (2010) consisting of %17.98 of the national population. Conspicuously, the service demand and the commercial real estate production are expected to be high together with the Istanbul's rising position in the globalization process, which can be observed from construction statistics that are published by the Turkish Statistical Institute under the published categories of 'Hotel and etc constructions', 'Office, Wholesale and Retail Commerce', 'Traffic and Communication Buildings', 'Industry and Storage', and 'Public, Entertainment, Education and Hospital'. Considering main theories about the world city/global city concept that have played a major role in understanding the emergence of global command centers and strongly influenced on the world city literature belonging to John Friedmann, Saskia Sassen and Castells, Istanbul is relatively of the earlier stage of globalization process and with respect to these major theories; developments in respect of globalization process of the city can be expected in the direction of the formation of world city as defined in line with the Friedmann's theory regarding the city's buildings for service sector activities and industrial real estate production at the investigated period. It is expected that global city functions will develop as world city functions consolidate in Istanbul. Therefore, the commercial real estate production is expected to be more rapid and more in line with the growth of world city functions in Istanbul, compared to two other most developed cities of Turkey which are Ankara and Izmir.

Keywords: World City/Global City, Istanbul, Commercial Real Estate, Globalization Process

1. INTRODUCTION

1.1 AIM OF THE STUDY AND RESEARCH QUESTIONS

Indeed, the substantial result of the globalization process is the exceeding of the global capital among the boundaries and their movement between countries. Therefore, the country cities have differentiations in attracting the global capital, and the global cities are expected to have the capacity of attracting the global capital. Turkey's international impression in respect of investment dispersion is determined according to the diverse market opportunities in both domestic and export-oriented way which Turkey offers. As regards, Istanbul is expected to attract global capital at most in the country.

1.2 METHOD OF THE STDUY

In order to figure out the developed sectors of Istanbul, the construction statistics according to the construction permits data of Turkish Statistical Institute (TUIK) are compared with the construction statistics of each sector of Ankara and Izmir that are the second and the third most developed cities in Turkey. Thus, the comparisons of total floor areas show how afore is Istanbul in Turkey among the global sectors both industrial manufacturing and service activities.

1.3 CONTENTS

The world-city literature has been developed in parallel with the economical downturn in the 70s and the emergence of a globalized economical system, when the traditional pattern of separated national urban systems was made obsolete for a relevant analysis of inter-city relationships. In understanding the emergence of global command centers, John Friedmann, Saskia Sassen and Castells's hypothesis and theories played a major role and strongly influenced the world city literature.

Moreover, in the framework of the 1980's reforms towards economic liberalization, Istanbul, designated by the Government to become a 'global city' attracting foreign capital. The city is the primary gateway of Turkey to the global economy. Thus, international firms prefer to locate and more than half of the exports are made from there. Since the beginning of the 21st century the city has been well ranked in academic rosters of world cities (Beaverstock, Taylor et al., 2008) however; its position in famous business city rankings is not yet clearly established.

The data for the research of globalization process of Istanbul is the new and additional constructions with provincial and municipal boundaries, including the buildings for Hotels , Offices, Wholesale and Retail Commerce, Traffic and Communication, Industry and Storage, and Public Services, Entertainment, Education and Hospital that shapes the demand in the globalization process are investigated.

2. THEORETICAL FRAMEWORK

During the globalization process after the 1970s, there have been many theories regarding the world-city literature and there are several major ideas that directed the concept of the world city/global city. According to these major hypotheses,

Istanbul's position will be analyzed and the main findings of the thesis will be presented.

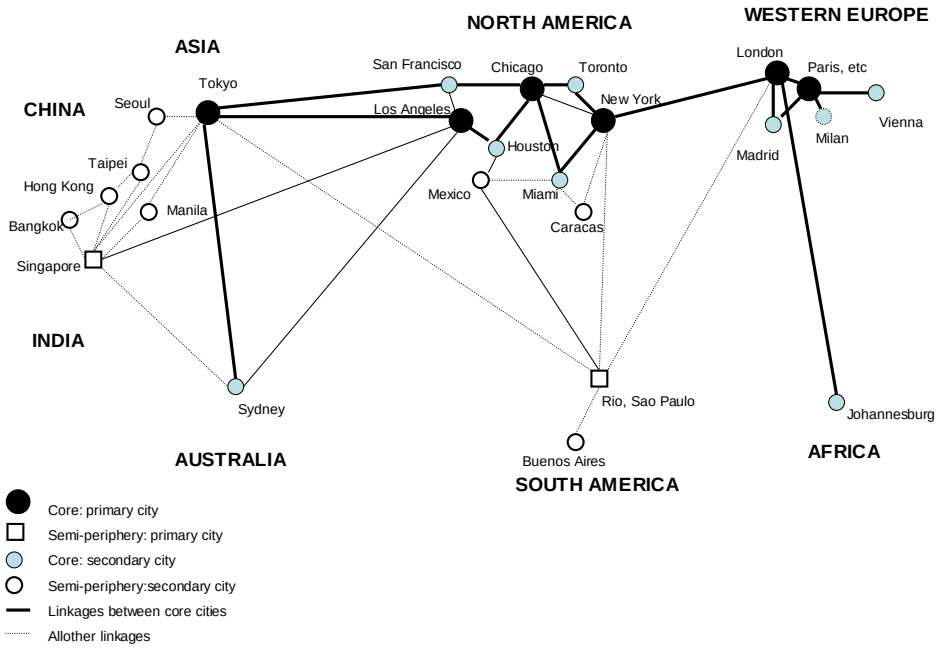
2.1 THE CONCEPT OF THE WORLD CITY

The major hypotheses about the emergence of global command centers that influenced world city literature belongs to John Friedmann, Saskia Sassen, and Manuel Castells.

2.1.1 John FRIEDMANN's "Word city Hypothesis"

Friedmann (1986) explained 'world city' concept with regards to the global economic forces as the global accumulation centers that direct the global economic system. That is to say, they are the origins of the global capital that orientates the investments and the market cities as being the command centers of capital in the new international division of labor. According to Friedmann, there is a hierarchy determined by the investment flows and the support services including advertising, accounting, insurance and legal services. Furthermore, the control center cities articulate larger regional, national and international economies in respect to flow of money, workers, information, commodities, etc beside articulating to the global economy or space of global accumulation of surrounding fields or regions and the space of accumulation represents both the national and regional capital accumulation.

Friedmann defined the process of connection to global economic forces by 'seven theses' depending on functional, hierarchical and global-local thesis. These functions are the headquarters functions, financial centers and 'articulator' cities linked a national or regional economy to the global economy. The hierarchical thesis comprises the 'basing points' of capital in the inter-city relations that resulted in a 'complex spatial hierarchy', and the hierarchy is organized by the city as a finance center, corporate headquarters, international institutions, business services, manufacturing, transportation and population size.



The world city hierarchy (from Friedmann 1986)

2 Figure 2.1 The World City Hierarchy (Source: FRIEDMANN John (1986), 'The World **City Hypothesis')**

2.1.2 Saskia SASSEN's "Global City" Concept

Sassen develops Friedmann's hypothesis instead emphasizing on the production of finance and services. Sassen defined the Global Cities as global service centers more than simply command centers including dispersed economic activities, specialized service firms, information database for the current industry sector, cross-border city-to-city transactions and the social discrimination between specialized professionals. Sassen has six hypotheses in the Global City approach including economic activities location choices, increasingly headquarters of large global firms, the specialized firms, headquarters' outsourcing increase, the need of the specialized service firms, and the spatial and socioeconomic imbalance in the Global Cities increases.

2.1.3 Manuel CASTELLS's "Space of Flow" Concept

In Castells theory, a 'new social morphology' of the society is cited as a social study regarding 'informational age' (Castells 1989). He developed the 70s and 80s elementary human framework of reference in the new information and communication technologies as 'space and time'. Castells explained spatial logic, places as the flows, which represent the informational exchanges orientated by social actors, and their frequency in receiving or production of information.

Furthermore, his aspect diverges with Sassen's idea that a network cannot be assumed as a traditional hierarchical pattern. According to his idea, in respect to interacting in one global network, the spatial domination cannot be considered in any traditional urban system pattern. Hence, the 'space of flows' becomes material thing

by its flow's own spatial arrangements in addition to its diffusion all over the world. The 'space of flows' can be interpreted by the material architecture and it is consisted of three 'layers' which are the circuit of electronic impulses, the hubs and the dominant and managerial elites' the spatial organization.

2.1.4 Evaluation

First, a city should comprehend the characteristics of world city in order to be a global city. Istanbul is relatively at the earlier stage of globalization regarding to have the world city qualifications in respect of finance, production, firms, administration, proficiency services, etc. According to Sassen, proficiency services are the fundamental aspect that should service internationally. In respect of the industry-storage, hotels, production wholesale and retail commerce production sectors, Istanbul seems to have the view of Friedmann's theory. So, it is expected to find developments in the direction of creation in the formation of world city as defined in line with the Friedmann's theory. The global city functions will develop as world functions consolidate Istanbul and in this stage, it is expected to find the final developments more in accordance with the growth of the world city functions compare to global cities.

On the basis of the short review of the three fundamental theories about global cities, the measurement and rankings of global cities can be aligned as follows.

2.2 GLOBALIZATION AND WORLD CITIES STUDY GROUP'S METHODS

In respect of studies about globalization and world city concept, The Globalization and World Cities Study Group and Network (GaWC) is a group of scholars who study the concept of world city and generated two different methods of ranking in respect of two different theoretical frameworks. The first method is proposing world cities as the concentrations of expertise and knowledge supporting and completing the job of transnational corporates and the second method depends on the 'space of flows' concept of Manuel Castells that comprehends the measure of interrelations in a network of global cities which are also accepted as process rather than places.

2.2.1 Measuring the 'world-cityness'

With respect to Saskia Sassen (1991), led by Beaverstock, Smith and Taylor, the global capacity of cities regarding services they provide were searched out, and an inventory of world-cities according to their advanced producer service level was taken. According to the data of the office distributions, information concerning 74 companies of advanced producer services in 125 cities have been collected and 55 cities have been defined as world-cities on the basis of the number, size and the importance of their offices. With regards to the research, there are three main stages which are first, the global competence of service firms in terms of the geographic location in cities, second, centers of the global services for a given sector to locate in the aggregated cities, and third, service centers' agglomeration creates the city and world cities of different degrees of overall corporate service provision are clarified.

In the research, three levels of world cities are identified in the 'roster of world-city' depending on the ranking of 10 Alpha world cities, 10 Beta world cities and 35 Gamma world cities.

More comprehensive inventory than 2000 and 2004's data collection about World Cities was taken by the Globalization and World Cities Study & Network at Loughborough University in UK within the same methodology and analysis in 2008 (http://www.lboro.ac.uk). With this respect, a roster of hundreds of world cities at 5 levels with 40 Alpha cities appeared besides the only two rankings with A++ New York and London.

2.3 ISTANBUL: A CITY HIGHLY CONNECTED TO THE NETWORK OF GLOBAL CITIES

Istanbul shelters a built environment and an imperial history that influence its position in the world system. According to the city's geography and centrality in two of the world's most important empires, and including two continents, Istanbul has the potential of being a 'global city' on the condition that the potential is actualized.
Istanbul is included in the ranking of GaWC study group as an 'Alpha Global City' in the 28th position (2008). Besides, Istanbul is the only city in the group in respect of global city in the region West-Asia, North-Africa.
Istanbul has 'global cityness' mainly in banking and financial sector. Istanbul is a highly connected city as being 35th position in the 'high-connectivity gateway' global ranking and the city can be accepted as a well connected city between the local and the global economy that the city is preferable for the firms in order to profit from the surrounding regional markets. Moreover, in the 'Global Cities Index 2008' and its global ranking, Istanbul is determined as the 8th position regarding its political engagement, whereas the 13th position in respect of good human capital.
Moreover, Taylor contradicted that Istanbul is articulated to the East European Countries better than to Middle-East and Western Asian countries which means, the city has the potential of being also a regional center besides being a gateway.
Lastly, according to Loughborough Study's research, among a network analysis of European world cities, Istanbul is an outer part of cities comprising a strong 'world city' characteristics regards to primitive service sectors. However, this will constrain its linkage to core European cities, so regarding to the city's various connections, Istanbul has better maintain and strengthen position in terms of articulating to the Middle East Black Sea and Central Asia Region as well (Foreign Economic Realtion Board, 2009).
Also, Istanbul is attraction and cultural center for many tourists. In addition to many awards, the city is declared as 'European Capital of Culture' in 2010 by the European Commission. Besides, Istanbul undertook house ownership of Olympics bids, conferences such as Habitat II in 1996 and the World Water Forum in 2009.

2.3.1 The Rise of Foreign Capital Investment in Istanbul

After the liberalization policies in 1980s, the foreign direct investments (FDI) began to increase and in 2008 Turkey became the 13th in the world and fifth among emerging markets in the ranking. Also, Turkey had the 17th largest economy and the

6th largest in the EU in 2006 within 7.4% of GDP growth which is one of the highest levels among the continent (Foreign Economic Relation Board, 2009). Moreover, Turkey ranked 23rd in the world and 9th with respect to the emerging markets according to the United Nations Conference on Trade and Development (UNCTAD). Moreover, in Ease of Doing Business Rank of the World Bank Turkey ranked 59th out of 181 economies, in Forbes Doing Business Index 41st out of 121 economies and in UNCTAD's World Investment Prospects Survey 2008-2010 15th regarding to the attracted economy for the location.

2.3.2 Foreign Companies in Istanbul and their International Network

The research of Service Sector of METU MATPUM Study Group, Istanbul's structure of economics, industry and services have analyzed among other official data without informing the employment and office numbers and their change during the years.

According to the 2000's year employment data of Istanbul obtained from the population census of TUIK, the number of employed people consists of the 34.6% range of the total population. There is a permanent decrease after 1970 and in 1980 and 1990, 51% of the total employment and 53% in 2000 consist of service sector which is pretty low regarding to other major metropolitan cities.

Regarding the employment structure of European metropolitan cities, Istanbul indicates a different structure where the industry share stays between 12% and 16%, whereas service sector has more than 80%. In South Europe cities like Barcelona, Madrid, Milan and the third world metropolitan cities, industrial activities keeps its significance and a big pie in the employment. However, due to the restricted land problem, manufacturing industry cannot be developed in the city center in Istanbul that leads same decrease in the share of this sector.

Moreover, as to the compared data with North Europe metropolitan cities, Istanbul again pretends differentiation in respect of existing structures of economic and employment and keeps its importance in manufacturing (Source: IMP Studies, *Office Cantonal de la Statistique (OCSTAT), 2004; The Swedish National Labour Market Adm. (AM), 2001;Oslo's Improvement and Dev. Agency and the Information Section of the Chief Commissioner's Department, 2002; Frankfurt Economic Development; City of Helsinki, Treasury, 2000; Statistisches Landesamt, 2005*)

Besides, service sector will develop but not rapidly. Total number of the employments of service sectors in 1985-1992 and 2002, there is dramatic increase, especially in financial institution's offices (Source: TUIK).

The global activities' developments are in respect of Friedmann's theory in line with financial institutions, insurance, real estate and commerce sector considering these years.

This case indicates the similarity with the other metropolitan cities over the world and shows the tendency of Istanbul to be a finance center. Furthermore, these data

can be commented on the Friedmann's world city concept regards to the sectors and their development. However, 50% decrease in the share of the public services, social and personal services between the years 1985 and 2002 is a negative aspect as a metropolitan area with lacking of public services. Regarding the data between the years 1985-1992, the ratio of the employment increase to population increase is 8.8%, whereas it increases to 39.6% in 1992-2002. (Source: TUIK)

ITO data also confirm the analyses as though the registered firm numbers to Istanbul Chamber of Commerce (ITO) and number of companies have rapidly increased since 1992. Despite of this, firm numbers depend on individuals stayed almost the same between the years 1989 and 2003.

Foreign capital companies in Turkey were 10,769 in 2005 and 65.3% of them located in Istanbul. Foreign-owned manufacturing companies in Istanbul are 969 and 118 of them are 'direct foreign investment' while 851 of them are multi-national capital investment companies.

According to data of ITO, in 2007, 3071 foreign investors founded company valued 410,315,784 TL capital. In 2010, 2044 foreign investors founded company valued 823,352,513 TL capital, whereas in 2011, 4639 foreign investors founded 1,735,399,674 TL capital with a 52.40% increase of investor number.

The number of International capital investment companies in Istanbul in 2011 is 15,692 and 5,634 of them are in wholesale and retail commerce sector, 2,700 are in manufacturing industry and 2,366 are in real estate renting and work activities sector.[2]

Subsectors' growth rates of sectors that are influenced directly by the population change in the structure of the population increase in the income and consumption patterns; such as commerce, hotel and restaurant are higher than the population growth. Therefore, there is no direct relation within public services and population growth due to the differentiation in the supply of public services and the least influence of the service subsectors belongs to construction and public works due to the effects of the dynamics in economics and disposal-expense equilibrium (ITO).

2.4 THE IMPACT OF GLOBALIZATION ON SOCIAL STRUCTURE AND OBSTACLES IN ISTANBUL

Many sociologists including Çağlar Keyder cite that neoliberal capitalism effects and articulation of Turkish economy to the global markets improve the social structure of Istanbul and globalization plays active role in spatial organization, within obstacles.

[2] (ITO, 2010-2011 *Registered Foreign Investors' Census and Foreign Capital's data*).

2.4.1 Social Polarization: a consequence of the entrance in the globalization process

Internal migration influences the population growth of Istanbul that increased from 1.16 million in 1950 to above 10 million people in 2000. Population growth is faster in Istanbul compare to Turkey after 1965. Regarding OECD countries, Istanbul is in the first in the ranking of OECD metro-regions between the years 1995-2002.

2.4.1 2.4.2 The Obstacles for a Broader Integration in the Global City Network

Istanbul has big potential to become a highly globalized city in case of reflecting this potential. However, the city does not perform satisfied due to its existing critical structural problems. The problems of Istanbul evaluated by Foreign Companies located in and out of Istanbul in line with the survey for checking out the problems that is conducted by the academicians in METU (ERAYDIN, A., GEDİKLİ, B., SUTCLIFFE, E., TÜREL, A. (2005), Yabancı Sermaye ve Istanbul; Istanbul'daki Yabancı Sermayeli Firmalar ve Bu Firmaların Kentle İlgili Değerlendirmeleri). Besides, there is the survey of 500 major European firms' chief executive officers about the main the European Business Centers by private consultancy agency Cushman & Wakefield since 1990 that indicates most of the firms think traffic conditions, transportation facilities are problematic, housing and living conditions are below the standards compare to global cities, prices for office and production units are high and not affordable for foreign investors, beside the environmental conditions and cleanliness and the number of NGOs and their activities pointed below 50%. This study will interpret the vision of European CEO in Istanbul that is generally in a low position comparing to the other 33 cities. Major advantage of the city regarding the other European cities is the cost competitions such as low prices for office rents/property and labor.

3. ANALYZING THE DATA

In order to become a world city, the city should first pretend as a world city in respect of finance, production, proficiency, etc before to be globalized. When the situation of Istanbul is considered, the city is relatively of the earlier stage of globalization process which is to have the characteristics of being world city. According to these aspects, the attribution of Istanbul has similarity with Friedmann's (1986) 'world city' vision. Thus, it can be expected to find developments in the direction of creation in the formation of world city as defined in line with the Friedmann's theory. The global city functions will develop as world city functions consolidate in Istanbul.

With respect to this aim, total floor areas of buildings related to each sector are compared among Izmir, Ankara and Istanbul between the years 2002 to 2010 by the TUIK's construction permits data in order to identify major differentiations of the commercial real estate production for each sector and year among each province (Figure 3.1-3.7). Second, those statistics are compared in respect of their increased populations between the years 2002 and 2010 (Figure 3.8) aiming to see the

increased shares for each city. Third, total floor areas are standardized to 1000 population for each sector and year in order to identify the supply amounts for the same population size (Figure 3.9-3.15).

In the real estate development, construction permits are regarded as representing the supply, whereas occupancy permits the demand for real estate.

3.1 SPECIFYING THE COMPARED CITIES

Istanbul is the most crowded metropolis in Turkey with more than two times greater population than the 2nd and 3rd developed cities in the country that are Ankara and Izmir. (Table 3.1). Moreover, these three cities' populations accelerate also with the contribution of migrations that shows the attraction of the city. Hence, entrepreneurs also become willing to invest to the city that improves the global capital accumulation and the connection to global economic forces of the city (Friedmann, 1986). These are such control nodes of the global economic system in the new international division of labor as the necessity of 'world cityness'.

3 Table 3.1 Total Populations of Izmir, Ankara and Istanbul Provinces

Total Population	**Izmir**	**Ankara**	**Istanbul**
2000	3.370.866	4.007.860	10.018.735
2001	3.422.817	4.074.666	10.305.451
2002	3.475.568	4.142.586	10.600.371
2003	3.529.133	4.211.637	10.903.732
2004	3.583.523	4.281.840	11.215.774
2005	3.638.751	4.353.213	11.536.747
2006	3.694.831	4.425.776	11.866.904
2007	3.751.774	4.499.548	12.206.511
2008	3.809.596	4.574.550	12.555.836
2009	3.868.308	4.650.802	12.915.158
2010	3.948.848	4.771.716	13.255.685

3.1.1 Total floor areas of Construction Permits for Commercial Real Estate in Izmir, Ankara, Istanbul

According to the TUIK's construction permits data, the development level and competitive potential of Istanbul for the 'global cityness' is examined. With regards to the comparison, Istanbul can be seen as the leading province in the Table 3.2.1 and the total areas of each sector are cited in Table 1 that show the highest demand of the sectors in Istanbul and its capacity of the global specialty.

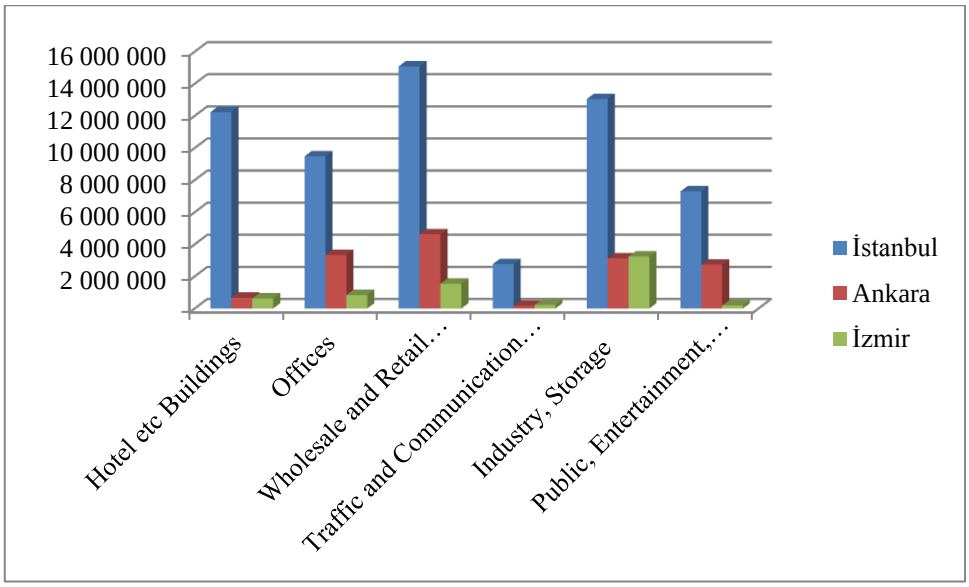
4 Table 3.2 Total Floor Areas of Construction Permits between 2002-2010 in the three developed cities of Turkey (m2)

2002-2010	Hotel etc Buildings	Offices	Wholesale and Retail Commerce	Traffic and Communication Buildings	Industry, Storage	Public, Entertainment, Education, Hospital
İstanbul	**12.230.346**	**9.476.929**	**15.077.604**	**2.762.362**	**13.048.945**	**7.293.354**
Ankara	674330	3325127	4620445	160160	3122401	2734476
İzmir	629530	834079	1537740	210140	3233147	181768

Source: TUIK: Annual Construction Statistics; 2002-2010

According to Sassen, proficiency services in respect of serving international level are the major indicators in the global network. With regards to the activities in Istanbul, the dominant sectors appear as wholesale and retail commerce, industry and storage, hotels and that indicate there is not only service sector development, but also command and manufacturing sectors as Friedmann's theory. In Istanbul, there is also a high increase in public, entertainment, education, health sector to develop the city in social aspect.

Istanbul is in the furthest among the other two cities in respect of the sectors in the globalization process.

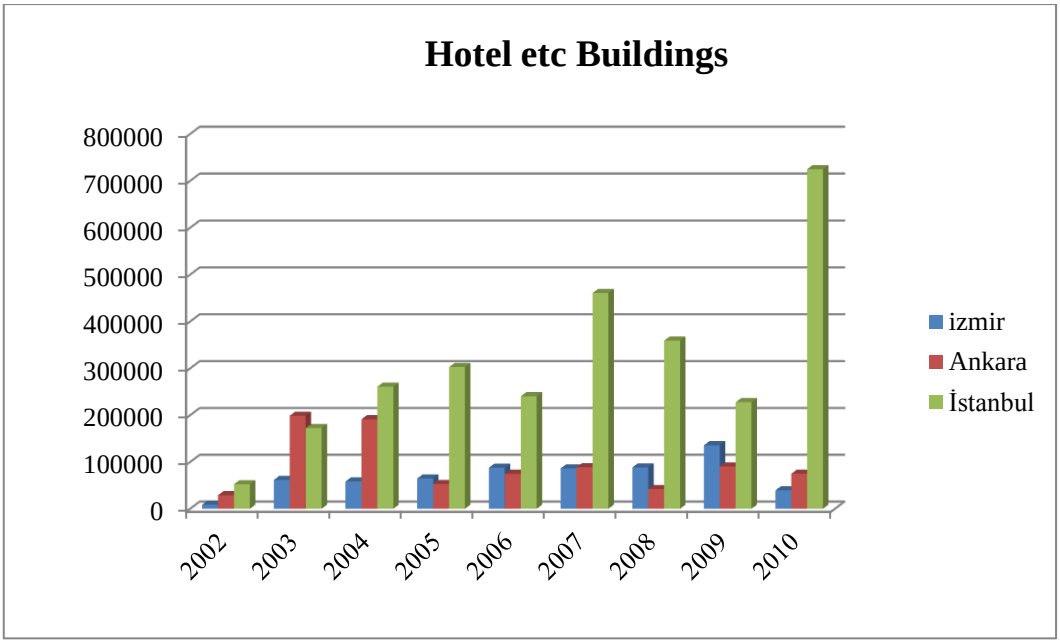


5 Figure 3.1 Total Floor Area of Construction Permits by Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

3.1.2 Analysis of the Comparison of Izmir, Ankara and Istanbul by each sector for each year (2002-2010)

When the trends of each sector are analyzed by each year from 2002 to 2010 according to the construction permits data of TUIK, it can be observed that there is a general increase up to 2008, due to 2008-2009 global financial crises there is decrease among the sectors especially in Istanbul since its articulation to the global economy and in 2010 there is high increase again.

In Hotel etc Buildings sector, Istanbul's historic architecture and geographical location attract touristic attention which improves tourism sector and hence increases the demand and supply for hotels etc buildings. Building starts in those sectors have significant developments and total floor area value increased from 52.403 in 2002 to 724.870 in 2010 in Istanbul whereas Ankara stayed in 74687 and Izmir in 3930 in the latter year. Istanbul's international articulations beside its national and local interactions provide the city new incomers due to foreign companies, conferences, tourism, etc and this requires more hotels and related buildings that increase the demand and the investment for the sector in the city.

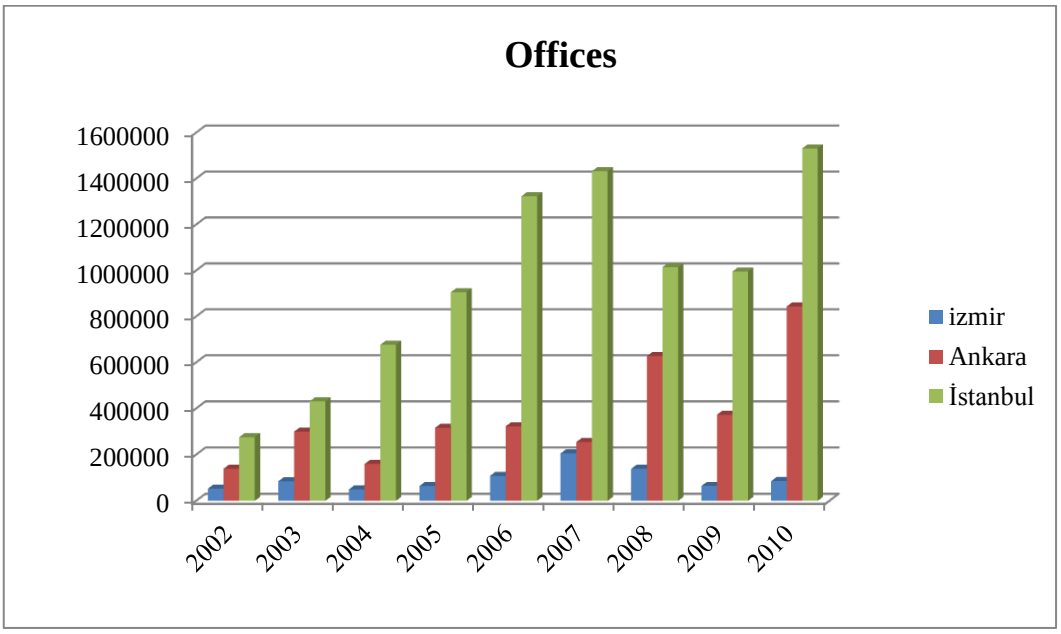


6 Figure 3.2 Total Floor Area of Construction Permits by Hotels etc Building Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

In Office Sector, during the years from 2002 to 2010, each city shows fluctuation. As a growing finance center and increasing the number of foreign capital firms lead to the rise in demand for headquarter and other office buildings these are the primary reasons for the high level of supply for offices.

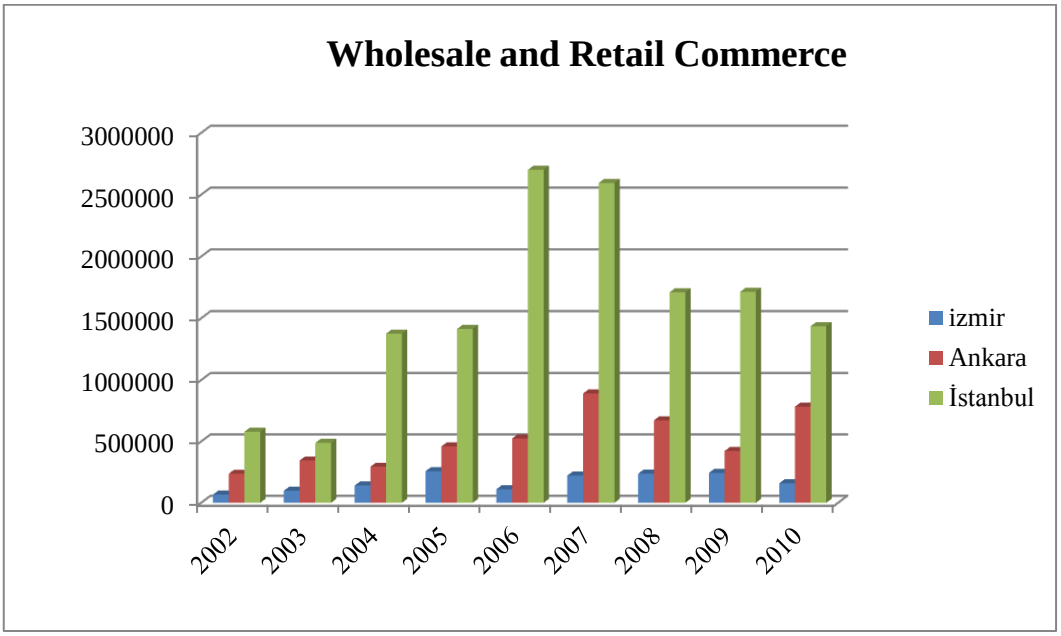
With the exception of the crisis year of 2008 and 2009, there has been increasing trend of office building supply in Istanbul.

In 2010, Istanbul has the highest level in the sector which equals to 1.531.152 m2 whereas Ankara has 843.439 m2 and Izmir has 85.457 m2. Istanbul and Ankara have relatively increased in the sector due to their effective roles in finance sector and demand for new foreign investments that contributes to their globalization process.



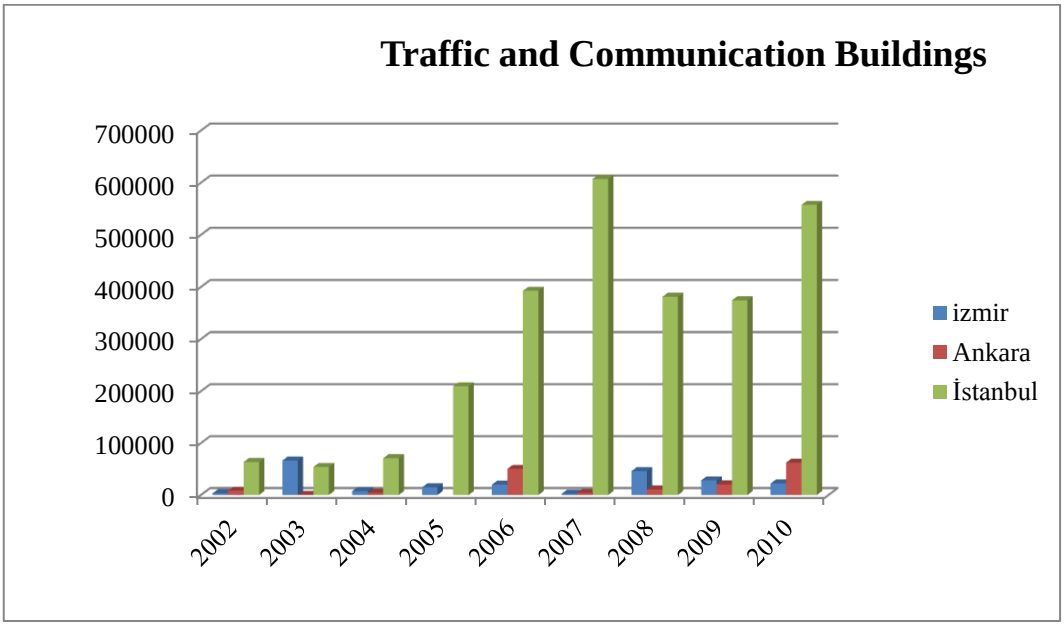
7 Figure 3.3 Total Floor Area of Construction Permits by Office Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

In Wholesale and Retail Commerce Sector. In comparison with the all three cities, Istanbul has always the highest area in the sector and investments for shopping centers are the domains of global capital. Nonetheless, after the peak in years 2006 and 2007 in Istanbul, there is recession tendency in the sector, probably due to the land shortage problem and the saturation of the market.



8 Figure 3.4 Total Floor Area of Construction Permits by Wholesale and Retail Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

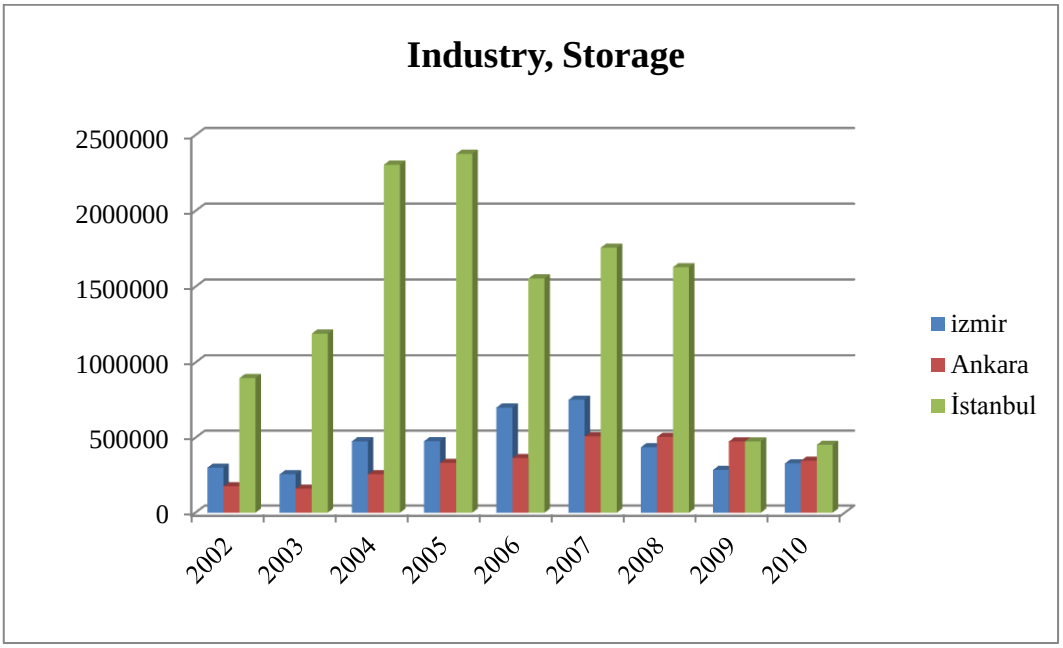
In Traffic and Communication Buildings' Sector, after 2005, emphasis on the infrastructure investments increases, particularly on communication sector. In total, the highest level in 2007 with 607122 m^2 and it decreased to 557374 m^2 in 2010. Developments in these sector, particularly in communication infrastructure is one of the major indicators of the consolidation of relationships with the world.



9 Figure 3.5 Total Floor Area of Construction Permits by Traffic and Communication Building Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

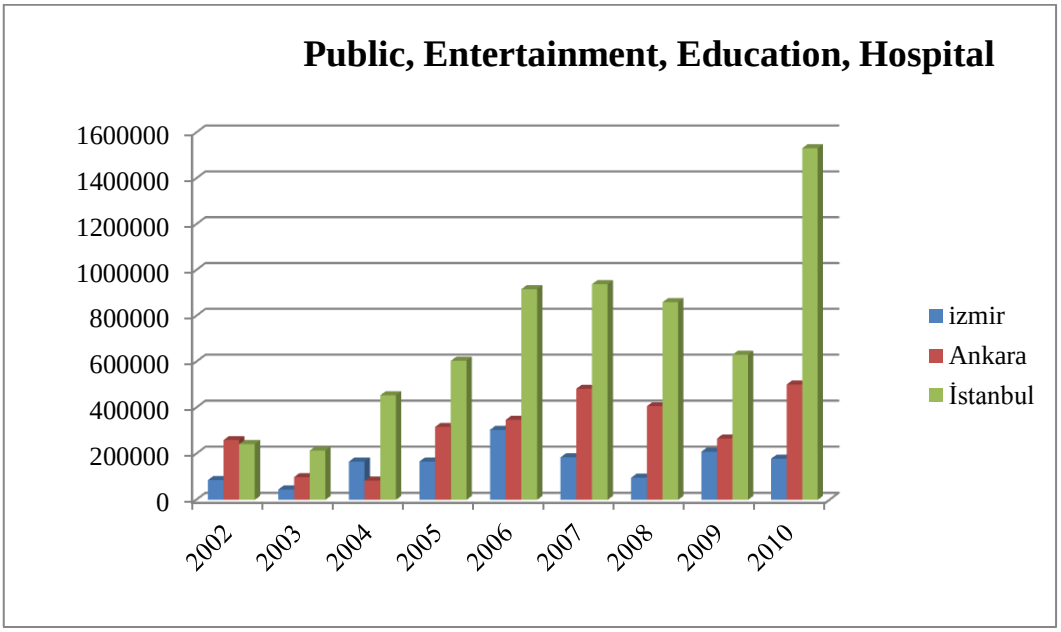
In the Industry and Storage Sector, the supply in Istanbul was high until 2008, then the amount of the increase is reduced. Besides the 2008-2009 crises, the decentralization policy for the industrial zones has impacts on the decrease. In the new plans, industry development, new as not included in the boundaries of Istanbul Metropolitan Municipality in line with the decentralization of the industry sector and increase in service sectors. Moreover, shortage of land in Istanbul is a factor that affects the fall in the development of industry. Hence, industry moves to the fringe as well as beyond the boundaries of Istanbul due to the decentralization policy and the availability of low cost land there is an increase in industrial building starts by 2004, and a sharp fall in 2009 that continued in 2010.

The trend in the development of the sectors in Istanbul between 2002 and 2010 indicates the process in lines with the world city concept of John Friedmann. There is not only proficiency services as Saskia Sassen mentions, but also there are developments Istanbul in industrial production, administration, finance and commerce in Istanbul.



10 Figure 3.6 Total Floor Area of Construction Permits by Industry, Storage Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

Lastly, in Public, Entertainment, Education, Hospital facilities, although Istanbul mainly is the most developed city in the country, nevertheless, in respect of the per capita areas of education, hospital etc Istanbul is backward compared to the country average. However, deficiency of the public services appears to be overcomed as investments increase in entertainment and health services that started to serve to foreign citizens as well. Health services gained importance in recent years, hospital becomes health proficiency service attribute, yet not only related to Sassen. With respect to accessibility, service qualification and the price, Istanbul is a very convenient city in Europe consolidate Friedmann's thesis. The sector has a massive increase in 2010 and reaches to 1.531.720 m^2 floor area in construction permits.



11 Figure 3.7 Total Floor Area of Construction Permits by Public, Entertainment, Education, Hospital Sectors in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

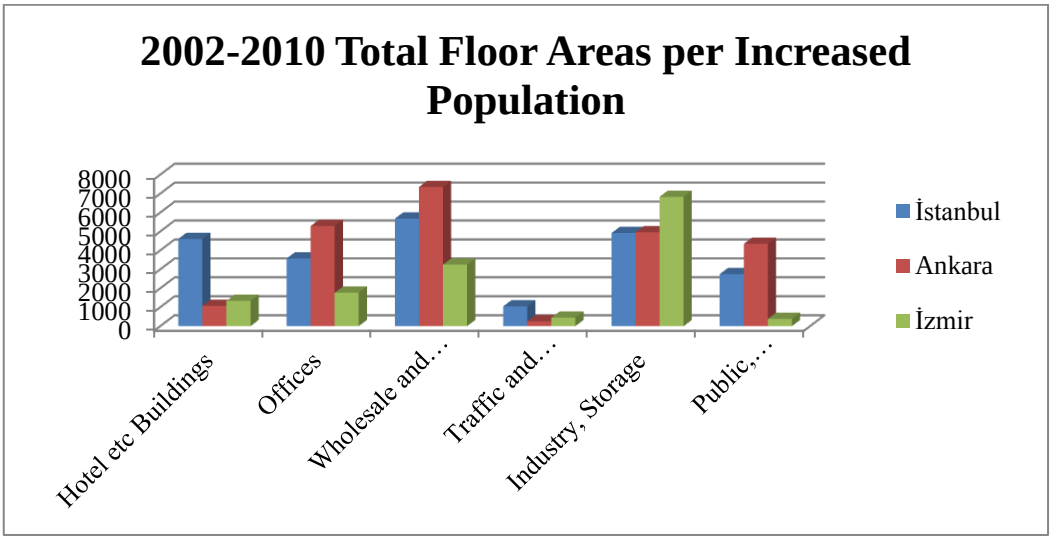
Regarding Friedmann's seven theses in terms of the process of the connection to global economic force, Istanbul's potential can be cited among the tables in addition to the ranking results among the previous studies. Istanbul has functional and hierarchical articulation to the world economy as well as global-local interaction when considered its pioneer up position in Turkey.

According to Friedmann's hierarchical thesis, it can be said that Istanbul's finance center, corporate headquarters, international institutions, business services, manufacturing, transportation and population size are the dominant aspects that has the basis in order to have global linkages in the 'complex spatial hierarchy'.

3.1.3 Total floor areas are compared in respect of their increased populations between Izmir, Ankara, Istanbul

According to the increased populations, total construction statistics of each sector of Izmir, Ankara and Istanbul are compared between 2002 and 2010. Then, within the every sector's construction statistics, the differences with the total development in the sectors for each three cities are analyzed. With respect to the total, Istanbul is ahead as an attraction center compared to two other cities in Turkey. Industry and storage sector have importance in the dispersion, in spite of the discourage policies promoting the idea of Istanbul's relative position of the globalization process.

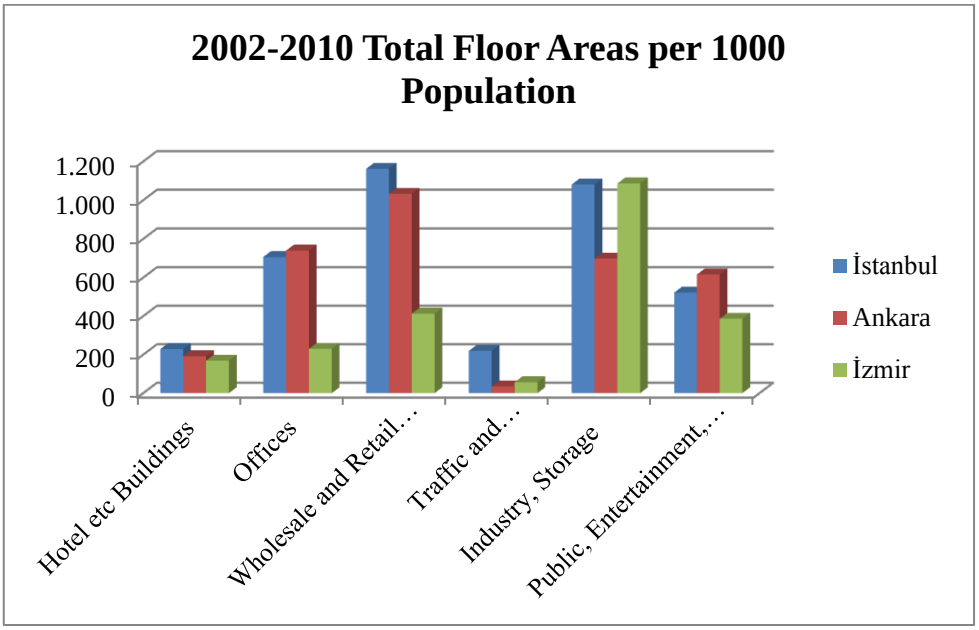
In respect to the Graphic 2, demands are higher mostly in Ankara and Istanbul. Ankara shows more rapid development in own scale. However, in compliance with the total populations and the total areas (m^2), Istanbul keeps its leading position.



12 Figure 3.8 Total Floor Area of Construction Permits per Increased Population in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

3.4 Areas Compared in respect of Standardized 1000 Populations between Izmir, Ankara, Istanbul

In the investments of global capital, differentiation between the standardized investment amounts (it is standardized to 1000 population) shows the row of inland regional functions and the attraction of global capital in comparison with the other cities again in order to observe the change in the qualifications of regional hinterlands.



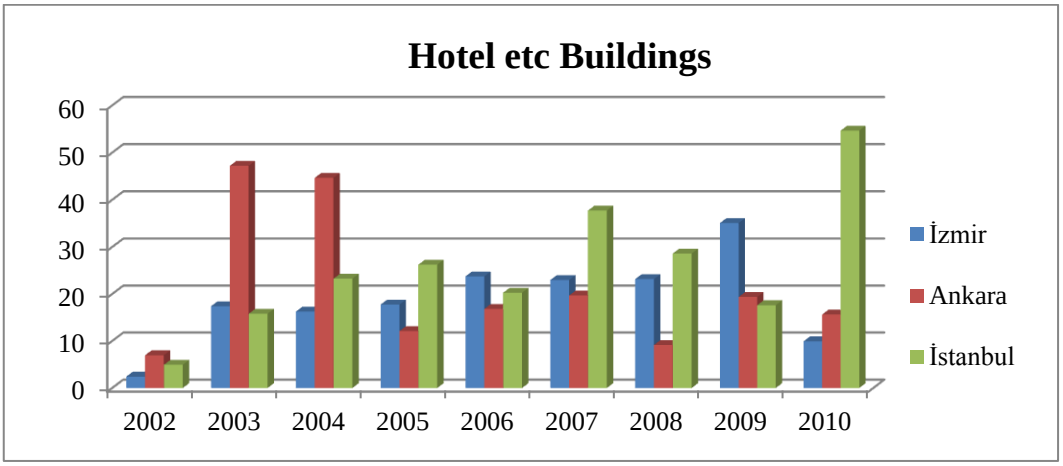
13 Figure 3.9 Total Floor Area of Construction Permits by Standardized to 1000 Population in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

This standardization declares the basic service needs for each 1000 population in those cities. In this respect, by means of the population census of TUIK's Address based Population Registration System 2000 and 2010, each year's population has been calculated between 200-2006 by the formula;

$P_{(n)} = P_0 (1 + r)^n$

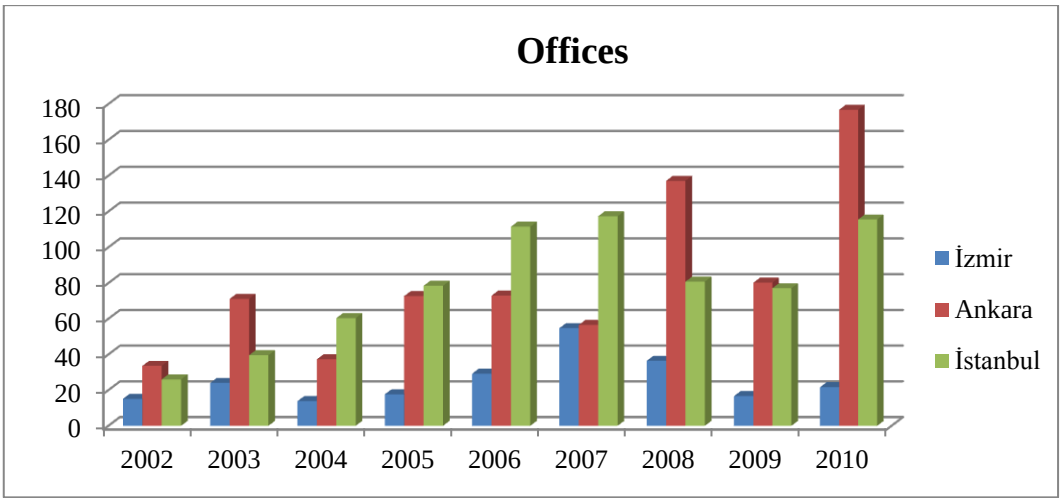
(P_n is the future population after n years, P_0 is the initial population and r is the growth rate)

After the calculations of each year between 2002 and 2010, the areas (m^2) per 1000 population are estimated.



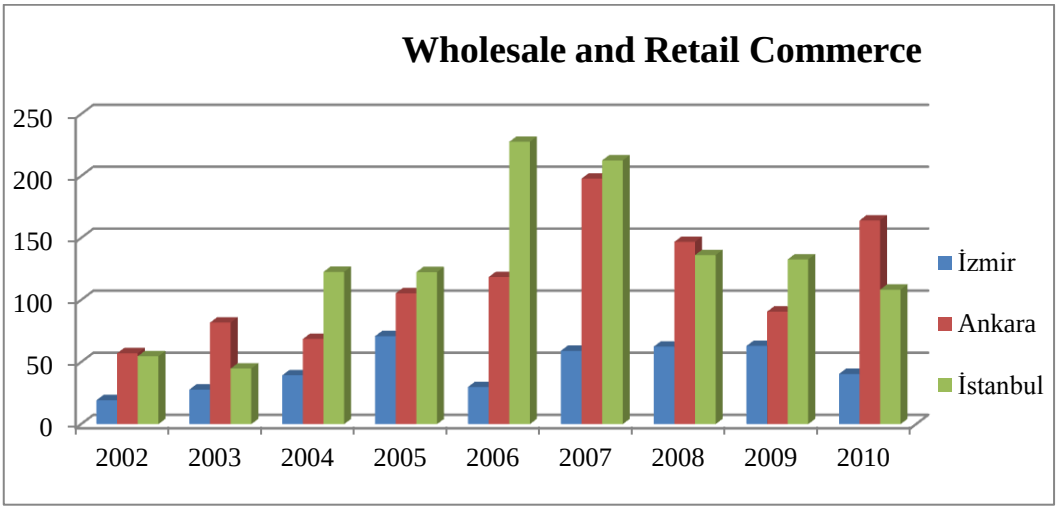
14 Figure 3.10 Total Floor Area of Construction Permits by Standardized to 1000 Population for Hotel etc Building Sector in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

Istanbul has attraction in Hotel etc Buildings Sector generally, and it increases in 2010 again which creates a big gap with Izmir and Ankara.



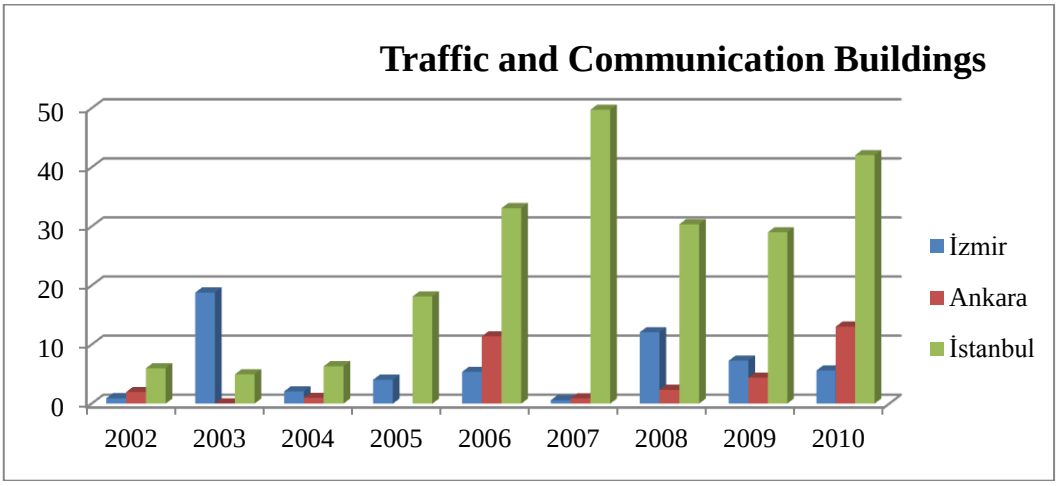
15 Figure 3.11 Total Floor Area of Construction Permits by Standardized to 1000 Population for Office Sector in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

In the office sector, Istanbul and Ankara are the dominant cities in the sector with respect to 1000 population.



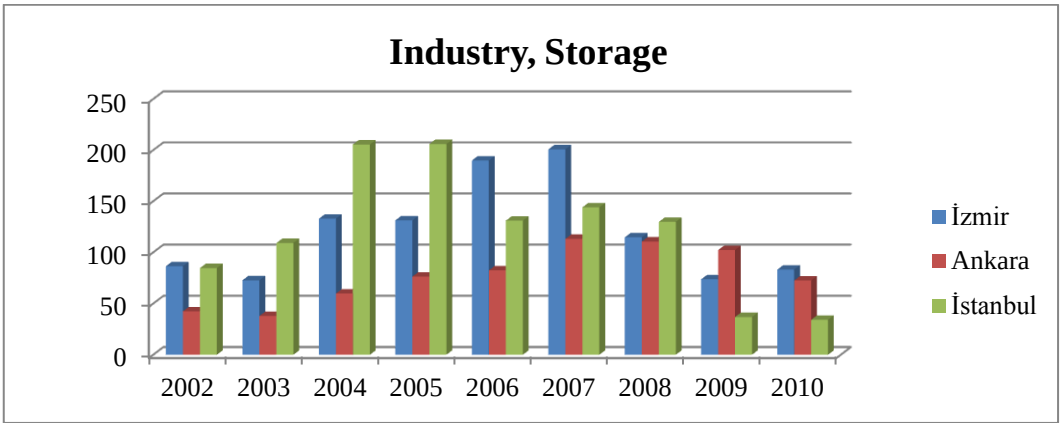
16 Figure 3.12 Total Floor Area of Construction Permits by Standardized to 1000 Population for Wholesale and Retail Commerce Sector in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

In the Wholesale and Retail Commerce sector, again Istanbul and Ankara are the dominant cities as regards the standardized population.



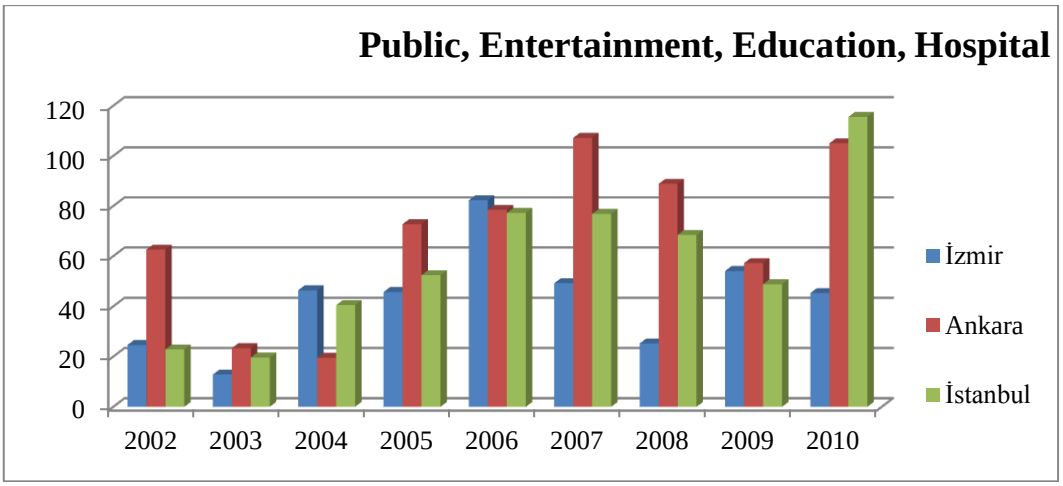
17 Figure 3.13 Total Floor Area of Construction Permits by Standardized to 1000 Population for Traffic and Communication Sector in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

In Traffic and Communication Buildings' Sector, Istanbul has the only high demand between the years 2002 and 2010.



18 Figure 3.14 Total Floor Area of Construction Permits by Standardized to 1000 Population for Industry, Storage Sector in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

Considering the total population, it can be seen that Istanbul has been far ahead from the other cities. However, when the amount is standardized to 1000 population, organized industrial zones appear and the competition increases. Therefore, industry sector does not relatively depend on the population. There are organized industry zones in Ankara and Izmir which have big pie in the sector. There are 13 Organized Industrial Zones in Izmir, whereas industry is discouraged in Istanbul. The share of industry in total employment in Istanbul is tried industrial establishments are decreased from %30 to %20, and to be transferred to the outside of the municipal boundaries, which are Gebze, Çorlu, Çerkezköy.



19 Figure 3.15 Total Floor Area of Construction Permits by Standardized to 1000 Population for Public, Entertainment, Education, Hospital Building Sector in Istanbul, Ankara and Izmir between the years 2002-2010 (Source: TUIK)

In accordane with 1000 population standardization of Public, Entertainment, Education, Hospital sector, they compete each other. Furthermore, Istanbul and

Ankara have significant increase in 2010, and Izmir has a lower share. There are not high differentiation between the cities in respect of the standardized sectors' areas. Furthermore, Istanbul is the city where the investments are mostly done in such as in wholesale and retail commerce sector.
It can be clarified that, Istanbul has importance in offices, hotels and the wholesale and retail commerce sector, however, it can also have global specialty in the industry and storage sector in consolidation with Friedmann's hypothesis.
Moreover, Istanbul is the most preferred city for the firms to invest due to labor intensive industry, cheap labor force, and global characteristics. Istanbul's global function in the industry sector beside the service sectors also supports its relation to Friedmann's thesis.

3.2 EVALUATION

Floor area is not related to population in Istanbul, since those supplies do not only serve to its population. This reflects in two dimensions. First, investments made already comprehend the needed services. Second, there are investments exceeding the population's need in Istanbul that shows the high demand not related to the overall population. For instance, office production does not reflect the need of the population only. Whereas, in Ankara there is a new development corridor for offices and the city is government center that also supports office production.

Due to the lacking of land, Istanbul cannot supply as large office floor area as Ankara and Izmir in service sector per employee that causes city constructed more intensive which deviates the analyze of the data for standardized to 1000 population.

Thus, the best results that give the globalization process of Istanbul can be identified by the total numbers.

As per employee floor areas are likely different between those three cities and floor areas cannot possibly be translated to employed population.

4. CONCLUSION

These analyzes indicate Istanbul's position in the globalization process that there is a rapid increase of industry sector until 2007-2008 as the manufacturing and command sectors continue to grow in lines with Friedmann's hypothesis. Even though the decentralization policy for industry in Istanbul is in effect, it still develops in the city and as well as within its region. Since, Istanbul is a big market that feeds these industrial regions; it keeps Istanbul's importance as an attraction center that consolidates the city's global articulation.

In 2008, as to the globalization process of Istanbul continues, serve of the new investors are coming to the city to exploit local, product marketing. A portion of the international capital is attracted by the shopping centers that develop trade centers in Istanbul. After decreases in the 2008-2009 crises, demand for each sector keeps on decreasing in 2010. However, foreign capital and the local investments still have

attraction on this sector that shows Istanbul's competitiveness and attraction potential in the globalization process.

In the service sector, there is a general increase in Istanbul especially in 2006-2007. After the 2008-2009 crises finished, market again bounces back itself and develops in 2010, yet cannot reach to the highest level. In the globalization process of Istanbul, service sector has been more important than manufacturing industry. Among the studies and world-city rankings before financial services in, Istanbul has already taken place in the rankings. After the crises, demand for new commercial real estates in service sector started to increase again. This can be interpreted Istanbul as a world city in relatively early stage of the globalization process, and with respect to Friedmann's theory; the city shows the world-city concept's features comprising importance of manufacturing industry and service sectors together.

Regarding Friedmann, Istanbul articulates to its regional, national and international economies by means of flows of money, workers, information, commodities, etc that integrates the city to the complex spatial hierarchy by articulating to the global economy and the space of accumulation of national and regional capital. Istanbul's presence as finance center, including corporate headquarters, international institutions, business services, manufacturing, industry, transportation and it high population size also embody its hierarchical integration.

In order to be a global city, Istanbul has the characteristics of world city in terms of finance, manufacturing, firms, administration, and proficiency services. Moreover, developed industry-storage, hotels, offices, wholesale and retail commerce sectors in Istanbul indicate its global activities in support of the world city concept of Friedmann.

To sum up, the commercial real estate production in Istanbul is relatively in the earlier stage of globalization as a world city as defined in line with the Friedmann's theory. Therefore, the global city functions develop as world city functions in Istanbul and with respect to the analyzes, studies and literature review have done, the developments in Istanbul are more in line with the growth of the world city functions compare to global cities.

The Expansion of Renewable Energies - powered by Regional Energy Concepts?

Prof. Dr.-Ing. Sabine Baumgart (sabine.baumgart@tu-dortmund.de)

TU Dortmund University, Faculty of Spatial Planning

August-Schmidt-Straße 10, 44227 Dortmund, Germany

Key words: renewable energies, regional energy concept, regional planning, regional development strategies

Abstract

The climate change has raised the political debates on climate protection all over the world. In Germany the "Integrated Energy and Climate Concept of the Federal Government" (2007) stated the goal to significantly increase the use of renewable energy sources by 2020 and is in general pursuing the goal of decentralising the provision of energy in order to reduce import dependency. In a number of German regions planning institutions have already drafted initiatives towards a strategic energy portfolio and energy management as a contribution to the provision and security of technical infrastructure.

Renewable energy systems have strong spatial impacts and often depend on specific local and consumer related conditions which differ greatly throughout regions. Furthermore they require regional and supra-regional grids and coordination mainly because of the limitations of storing electricity. Thus the integration of renewable energies in concepts for energy-policy requires coordination with spatial planning. The principle objective of spatial planning is to cater for a balanced spatial development and to avoid undesirable spatial impacts, but in Germany it has no constitutional responsibilities for energy-policy.

The focus of the presentation is on the so-called Regional Energy Concepts and the identified regional actors who could support the increasing utilisation of renewable energies. Regional Energy Concepts may provide guiding principles to determine and agree upon the reduction of energy consumption and the use of local sources for energy generation. A scientific study "Strategic integration of Renewable Energies into Regional Energy Concepts – Implications and Recommendations from the Perspective of Spatial Planning" in order of the Federal Ministry of Transport, Building and Urban Development has been conducted during the period between October 2008 – September 2011 by the Faculty of Spatial Planning namely Prof. Dr. Hans-Peter Tietz, Dr. Jörg Fromme and the author. Based on selected case study regions there have been assessed measures and instruments of region-

al planning as well as examples of administrative structures and processes needed for the development and implementation of Regional Energy Concepts. Recommendations have identified promising strategic elements of Regional Energy Concepts with regard to the expansion of renewable energy systems and demonstrate starting points for the further development of regional planning instruments.

The target groups of strategies to integrate renewable energies in Regional Energy Concepts are regional planning bodies in collaboration with municipalities, the private business sector and civil society. Strategic approaches for the advancement of renewable energies at regional level try to mobilize stakeholders through networks or financial incentives. Other measures are e.g. systematic compilations of information such as wind and solar cadasters, regional planning directives identifying preference areas for renewable energy production and non-statutory development concepts. Although the strategic importance of regional planning and its statutory and non-statutory instruments has been acknowledged effective strategies at regional level are lacking to expand the implementation of goals set in the energy policy.

Safeguarding of Energy Supply as Part of the State's Responsibility and the Role of the Region – the Framework

In Germany the safeguarding of energy supply is in the responsibility of the state, however with regard to the usage of renewable energy resources and grid expansion private industry has taken over the demand planning for infrastructure. On the basis of the constitutional allocation of powers the government assures the safeguarding by highly efficient interventions that at the same time control the energy market. This assignment is conform to the competitive market and make economy and consumer responsible for specific objectives oriented towards the public welfare like social and environment compatibility, value for money and security of supply. For this purpose the government has put in place a vast number of legal provisions that are intended to help with the expansion of renewable energies.

As a result of legally compulsory norms the EU is obliged to increase the proportion of renewable energy resources in gross domestic energy consumption to 18% by 2020. To this end a National Renewable Energy Action Plan (NAP EE) has been in existence since the middle of 2010. Its energy policy agenda was complemented and extended by the ratifying of the energy concept of the government in September 2010. By 2050 renewable energy resources should cover 60% of the gross end energy consumption and 80% of the gross electricity consumption. The expansion concept of the

government provides for a considerable increase of plans and measures relevant to regional planning for wind energy use, energy plant cultivation and photo-voltaic.

The role of the regions consists above all of in fulfilling multiplier functions and taking over a pioneering role in the expansion of the usage of renewable energy resources by overachieving governmental minimum targets within their sphere of influence by, inter alia, raising the acceptance for expanding the use of renewable energy resources locally.

Although in specific cases these projects face considerable conflicts with competing demands to use and protect, there are clear opportunities for seeing what the usage of renewable energy resources offer for regional development. In carrying out their spatial planning functions the regions can as a result influence the expansion of the usage of renewable energy resources both in a supportive or restrictive way. The coordination between the energy-specific objectives and regional planning management requirements should be improved accordingly.

Definitions: The Regional Energy Concept

Regional energy concepts express a strategy oriented towards the public welfare to influence the energy future of the region. Currently, goals and models of the so-called energy turnaround are in the foreground that refers on the one hand to the reduction of energy consumption and on the other hand to the expansion of the use of renewable energy resources.

Thus the energy concept has become a planning task that focuses on the system of the energy supply addressed by the comprehensive spatial planning. By contrast, the comprehensive spatial planning with its interdisciplinary orientation refers to conflict minimization in a specified demand of space into consideration all the competing claims. By its spatial impacts the expansion of the use of renewable energy resources moves more and more into the central focus of spatial planning.

Possibilities and Limits of Regional Planning Control of the Expansion of Renewable Energy Resources

On principle, regional planning can solely control regionally significant projects. Additionally, requirement and admissibility of spatial planning and regulation must be given. Thus a considerable part of projects on the use of renewable energies that are normally considered in the drawing up of (regional) energy concepts are not included by regional planning. They include solar energy usage on building surfaces as well as in most cases also the privileged energetic bioenergy usage, the near-

surface geothermics and in general every activity to increase (building and plant-specific) energy efficiency. Independently of the regionally significance regional planning control only restrictively includes repowering of old systems of wind energy, locations of which are outside planning regulated areas.

Furthermore, the energy plant cultivation defies regulation by an efficient regional planning control. At the core the spatial planning regulations and control still concentrate on the use of wind energy with its implementation depending particularly on regional planning.

As the up to now available formal regional planning instruments for controlling the renewable energy resources have come up against their limits, many regional planning authorities draw increasingly on **informal concepts** of location control which, also, if not integrated into a formal spatial development plan do not have any legally binding regulatory effect.

Status of Regional Energy Political Initiatives and Concepts

In total 110 regions are known at present that pursue their own energy political goals and strategies. This concerns either territorial corporations with or without regional planning competence, planning regions as statutory associations or inter-municipal cooperation. It must be stated that the approaches, targets, motivation and intensity of dealing with this topic are rather different in these regions. Up to now the regional territorial structures of the “energy regions” have scarcely corresponded to the formal regional planning; the participation of the regional planning authorities in the development and realization of strategies and concepts is rather an exception. However, the federal states increasingly support and demand the performing of these functions by regional planning.

Explorative Case Studies in the Planning Regions

The case studies refer to the planning regions Hannover, Nordschwarzwald and Trier. Besides the region Hannover is a territorial corporation and in the meantime looks back on decades of experience in regional strategy development and process control in terms of energy policy.

Also Trier can boast of a more than ten-year old experience in this field. Both regions have in common that they have set up a wide network of actors and have energy and climate protection agencies at their side that work as multipliers for information and consulting campaigns that also (can) take over strategic functions.

The region Nordschwarzwald has dealt systematically with the expansion of renewable energy resources only since the association decided to draw up a formal partial regional plan of renewable energy resources. At first the regional expansion of renewable energy resources was intended to be comprehensively as possible controlled with this instrument, a regional energy concept has not been produced yet. Due to objections to the laws relating to regional planning from the supreme land planning authority the formal regional plan should only control the expansion of wind energy use and contain reserve areas where special importance is attached to certain regionally significant functions or uses when balanced with competing regionally significant uses for the location of open space solar power systems. In addition, the regional association intends to draw up an informal regional development concept with the focus on renewable energy resources for the expansion of its use.

Guideline for Regional Energy Concepts

The guideline comprises recommendations for action with regard to the development, realization and monitoring of regional energy concepts. This overall process can be divided into the preparatory phase, concept phase, realization and monitoring phase although the phases do not have to follow this order strictly.

Preparatory Phase

In the preparation of the concept development **network building** is of fundamental importance. Territorial corporations, chambers, associations and the regional energy industry, forestry, agricultural and waste management should be included. For larger regions the establishing of accompanying working groups can be recommended to be made up of the actors of the regional energy network. As the conception and realization of a regional energy strategy is an ongoing task it stands to reason that a suitable office within the regional administration takes over the lead for the development and realization of the concept.

Additionally the costs for the overall process must be calculated and the funding possibilities must be checked. The availability of human resources in the region must be checked as well as the subsidies from the state and the investment opportunities from the private sector.

The decision to draw up is a further important milestone in a regional energy concept and should be made in writing to document the necessary binding character and should be considered accordingly in the communication concept.

Concept Phase

A central element in the preparatory phase is the **analysis and goal definition**. Here the formal regional planning should be included.

For all the usage options of renewable energy resources the expansion potentials or rather the expectation values for the state of expansion in the target year (or years) will be assessed by technical experts. Therefore scenarios are set up that also include usage options of renewable energy resources that do not belong to spatial significant projects in order to generate a consistent and complete picture of “desirable” and “feasible” energy futures for the region and to compare them with the other goals and models for regional development.

The varied scenarios should show a clear spatial relation in the form of maps with descriptions of spaces that are kept clear for the extensive large scale projects of renewable energy resources. They form an illustrative basis for the definition of goals both in the area of the energy concept and regional planning. Each different scenario is based on a framework of data that contains quantitative data of energy supply and capacity for transformation plants. These are contrasted with the projections for energy consumption in the target year in order to ascertain the probably resulting regional cover percentage of the renewable energy resources of the scenario in question.

If need be, the results are fed in the current procedure of redrawing up or rather establishing the regional plan to bring about a coordination between the goals of spatial planning and those of the energy concept. If necessary, statements of aims can be taken over as text definitions in the regional plan. After the definition of goals has been politically coordinated the planning of the concept realization of the individual activities and their organizations follows.

Beside the safeguarding resp. provision of location and land requirements through formal regional planning there are further measures for instrumenting a targeted support of the expansion of a regional usage of renewable energy resources, such as:

- Project support programmes for investive measures incl. flagship projects
- Use of renewable energy resources on regional and local properties serving as a model
- Organising information campaigns (eg in form of a solar roofage catastre)
- Providing consulting for the local government and small and medium sized enterprises for promoting the use of renewable energy resources, and
- Founding a regional energy agency for the operative planning and realization.

These measures show the financial requirements for the development of the concept and its realization. Funding by citizens and energy cooperatives offer transferable funding models for projects.

Crucial milestones such as the decision to draw up, the founding of an energy agency, the call for tender of a concept expertise, assigning the expert and the official agreement on the goals should be supported by media along within a communication concept. For this purpose a professional PR agency should be assigned.

Monitoring Phase

Monitoring is of a high strategic importance since only the implementing of a regular success control guarantees that the planning of goals and measures can be followed up consistently and subsequently adapted to the actual development. Thus it is provided that either the right point of time for an updating of the concept can be found or that the planning of goals and measures can be specified continuously and can be further developed.

Recommendations for the Further Development of Regional Planning Instruments

Recommendations for the further development of regional planning instruments especially refer to the specification of new principles of regional planning to produce the spatial requirements for an expansion of renewable energy resources.

Overall Model of Regional Planning in the Context of Expanding the Use of Renewable Energy Resources

It must be determined whether the three-phrased concepts of spatial development should be complemented by a further concept “Spatial Requirements for Climate Protection and Energy Supply” and which specific concept should spatially be communicated. Instead concept 2 “Maintaining Essential Services” could be added with regard to aspects of renewable energy resources.

Spatial Planning on Federal State Level

It is suggested to elaborate a plan of spatial planning on federal state level regarding renewable energy resources acc. to § 17 Federal Spatial Planning Act (ROG) that contains spatially differentiated regional expansion goals of renewable energy resources in the form of quantity goals that in sum

correspond to the overall goal on national level. These goals could serve for regional planning as an orientation regarding the areas reserved for the expansion of the renewable energy resources in the region. This would require a discussion on the principles as defined by the spatial planning on federal state level at the different planning levels.

Strategic Environmental Impact Assessment

In connection with the quantitative goals for the regional level questions come up especially on the background of the strategic environment impact assessment about the conflict of land use from landscaping. In consequence, tangible criteria come up against a background of a restrictive control on the one hand. On the other hand the visualization for sensitive landscape areas to be considered as an element resulting from landscaping is requested. Additionally, a systematic review of the expansion of renewable energy resources along the federal highways/roads should be done that could have bundling and synergy effects also for a grid extension.

Space-oriented Reporting and Spatial Monitoring

Space-oriented reporting must be systematic and application-oriented. The explorative study and the findings in the case studies have shown that uniform standards are required for data collection on the different types of renewable energies such as:

- structure of land use, availability of land and quantitative land requirements for energy facilities
- structure of areas used for renewable energy facilities and cultivation of energy plants and their storage
- potential land use conflicts, including conflicts regarding the economic valuation of land
- spatial impacts (on ecology, natural resources, visual landscape, heritage, protection against flooding)
- emissions (especially of wind turbines and bio-mass facilities)
- infrastructure (generation of traffic, grid integration, transport chains and distances)

Information and Communication Methods

Region-related overall models and goals developed in dialogue potentially form a contribution to the specification of the “spatial requirements” as demanded by the ROG. This dialogue is possible with the available regional planning instruments. (s.§ 10 ROG, participation in drawing up spatial structure

plans). A variety of experience in facilitated discussions and mediation (eg airport expansion, settlement procedures of large-scale retail) can be used as well as the dialogue-oriented elaboration of regional development concepts in rural areas. For the role and shaping of communication processes on regional level procedures for the drawing up of regional plans should be accompanied by pilot studies. These should refer to both the use and coupling of available instruments such as goal definitions and monitoring (product level), and design of procedure with innovative communication elements (process level) and shape them systematically involving an accompanying evaluation.

Strengthening the Region as an Action Level in the Context of National Strategies for the Expansion of Renewable Energy Resources

The role of the region as an action level depends on the multi-level vertical coordination of the expansion of renewable energy resources and the inter-departmental horizontal coordination between the spatial-overall planning control of the expansion of renewable energy resources and the energy environmentally motivated quantity control of the expansion of renewable energy resources. The following models are possible:

- The federal states (territorial states) prepare their own energy concepts, coordinated with the EU requirements for the expansion of renewable energy resources and coordinate these with the regional energy concepts in the institutions of regional planning. This requires an additional horizontal coordination at federal states level between the energy and planning departments.

- The federal states (territorial states) prepare their own energy concepts in close coordination with regional planning via affiliated energy agencies which are in charge of the regional energy concepts. For a further strengthening of the regional energy competence energy councils are established at the planning offices involving important energy actors. The regional energy agencies take over the task of the vertical coordination of the energy political goals and strategies with the land energy policy. However the horizontal coordination between energy policy and spatial planning takes place at regional level.

- The horizontal coordination between energy policy and spatial planning is made to a large extent at federal state level in line with the “Focused Regional Plans for the Development of the Federal Territory”. The vertical coordination is largely taken over by spatial planning considering the feedback principle and the countervailing influence. They contain spatially differentiated expansion targets for renewable energy resources that, in sum, are consistent with the national overall goals. The national funding strategies and supports are adjusted to the regionalized expansion targets.

Finally it is to state that a regional database for the energy sector is crucial for the regionalization of the energy policies with their cross sectional character. With the establishment of Regional Energy Concepts an appropriate instrument is provided. Science based energy data for analysis, prognoses and monitoring as well as the development of the Regional Energy Concepts prepare the standards for methods, goals and strategies with the participation of the regional planning bodies. This matches with the "National Renewable Energy Action Plan" on national level of Germany as well as with the European context (Art. 4, EU Directive 2009/28/EG). Thus the framework of the regions can be strengthened when delivering and realizing custom expansion strategies of renewable energy resources within the multilevel system of energy policy: government, federal state and local communities.

SHARED INFORMATION SPACE BETWEEN CROSS-BODER CAPITAL REGIONS

Kristi Grišakov [1]

Abstract

This paper is concentrating on the role of digital tools and open data in the planning processes of border-crossing regions in Europe. The research is concentrating on the case study of two capital cities Tallinn and Helsinki in the Baltic Sea Region. Although not an official border-crossing region, these two cities share a multitude a common projects and initiatives, among them an infrastructure project of a connecting tunnel.

This paper is concerned with both sides – the role of ICT in urban planning in general and the formation of a digitally enhanced cross-border space in particular – and is concentrating on the methodological challenges of such research.

This paper argues that for the emergence of a functional cross-border region, the discussion should steer from hard infrastructure and international logistics towards addressing urban values and citizenship ((Paasi and Newman, 1998), with an emphasis on creating common services and projects for a shared urban space. Secondly, the use of digital tools for the planning of border-crossing regions is a matter of understanding the intricate relationship between physical and virtual spaces as well as the dynamics of the relating communities (Augiri, 2008). It is not a matter of choosing applicable tools to use, but rather to outline the needs and goals of a border-crossing space towards a more ubiquitous, augmented version of itself. Such kind of augmentation would take into account the specific characteristics of a border-crossing space in moving towards an interactive use of urban space and more efficient communication. Thirdly, the actors included should encompass knowledge from the fields of cross-border cooperation, urban planning issues and urban informatics. It is relevant that viewpoints from different spatial scales and sectors (Hall, 2008) ranging from private to public are exchanged.

However, the key methodological question in tackling such a topic is how to encompass this complexity of cross-border actors and scales and not to disregard the activities taking place both in the virtual and physical realm. Especially regarding the case study mapping and analysis of an existing digital layer of such a cross-border space in a constant change of flux, also due to the quick change of technology and relation to digital tools, platforms and applications.

To create opportunities for the border-crossing region to develop further through shared knowledge and active use of ICT, would be a benchmark example in planning

[1] Doctoral Student. Aalto University, School of Engineering, Centre for Urban and Regional Studies. - kristi.grisakov@aalto.fi

border-crossing regions on an international scale. The use of digital tools in urban planning is a rapidly developing research topic, this research would enrich the discussion with introducing the specifics of a cross-border urban area in creating place-based interaction and communicating shared urban values.

1. Introduction

The influence of information and communication technologies (ICTs) has transformed the ways we communicate and interact with one another. Technological networks have become more accessible, more ubiquitous and more mobile, changing our concept of place by transforming our sense of proximity and distance. Consequently, urban and regional planning and the methods for mapping, data visualization and citizen participation are changing as well. The physical and virtual are no longer perceived as separate dimensions but have come to influence and define each other. Concepts such as augmented spaces, locative media and mediated localities all suggest an increased attention given again to the physical place and the local. However, extensive understanding of the digital tools and methodology in urban planning has not yet emerged. Different disciplines (geography, computing sciences, social sciences and architecture) researching the topic are developing software programs and applications of their own, targeted knowledge and tools are produced only in a certain field of interest. Furthermore, there is a need to move beyond deterministic discourses about the impacts of technological networks on society to understand in rich empirical detail at the complex ways in which ICT technologies are being used in real ways in real places (Graham, 2005). There is a need to develop more integrated urban and ICT strategies that concentrate on digital agendas instead of specific tools and look at larger urban planning processes instead of a single neighbourhood or urban setting. Thus this research is looking at the field of ICTs in urban planning through the framework of regional planning processes, namely the border-crossing city.

Planning border-crossing regions/cities should be about creating transnational social spaces and crossing cognitive barriers not merely transnational exchange and regional politics. A more flexible approach towards planning and visioning border crossing regions/cities has to be developed that would include not only the planning elites (city officials, local cooperation and governance networks), but also the knowledge of the citizens. Cross-border territory needs to be conceptualized as cohesive in the sense of being well-appointed all the way round, so that people will want to attach themselves to them, work in them and develop them (Faludi, 2007). Paasi (2002) has suggested a checklist of forces to evaluate to what degree a border-crossing region does exist and how it might develop in the future. He emphasizes that territories emerge, develop and exist through an “institutionalization” process resulting from the simultaneous and interconnected working of four different forces (“shapes”) that all have to be included in the process of planning a border-crossing region/city.

Thus the case of the border-crossing city forms a rich framework for the research of integrated urban and ICT strategies because of the variety of actors and interests involved as well as the representation of different spatial contexts, ranging from the

international to local. The research in concentrating on the case study of two capital cities Tallinn and Helsinki in the Baltic Sea Region. Although not an official border-crossing region, these two cities share a multitude a common projects and initiatives, among them an infrastructure project of a connecting tunnel. Helsinki-Tallinn case is characterized by the physical distance (80km) between the two cities, slow progress of official cross-border initiatives but a range of informal activities and flows linking the two metropolitan regions. Additionally, both cities take pride in the active development of public ICT services, good access to the Internet throughout the city as well as a high number of Internet users. However, the visioning and planning processes of the border-crossing region are not concentrated on active ICT strategies such as common mobile applications, open data initiatives or even Internet platforms.

Therefore, the aim of this research is to concentrate on the role of ICT in urban planning in general and the formation of a digitally enhanced cross-border space in particular. This digitally enhanced or augmented cross-border space would be a 'shared information space' between two capital regions, thus emphasising not only the shared data and information in cloud format but concentrating also on the importance of creating shared and mediated spaces. This paper is looking into the preliminary findings from he Helsinki-Tallinn case study paving the way towards the development of a cross-border digital strategy supporting the planning process of the border-crossing region. A framework for further research is proposed that would address both the complexity as well as future development opportunities of the case study through the use of the scenario planning method.

The main contribution of this research lies in enriching the discussion of digital tools in urban planning with introducing the specifics of a cross-border urban area in creating place-based interaction and communicating shared urban values. To create opportunities for the border-crossing region to develop further through shared knowledge and active use of ICT would be a benchmark example in planning border-crossing regions on an international scale.

This research proposal is structured as follows. First, Chapter 2 will provide the theoretical framework discussion the relationship between the city and ICT as well as the latest turn towards the locative media and open city concepts. Chapter 3 is concentrating on the thematic of the border-crossing cities of Europe and relating planning processes. The primary case study of Helsinki-Tallinn with its characteristics and problems is presented in Chapter 4 along with the preliminary findings. Chapter 5 will describe the framework for future research operationalizing the scenario planning method. Chapter 6 will provide the conclusions of the paper.

2. ICT City

The "network city" has been presented as a "new" old way of thinking about cities in the ICT (Information and Communication Technologies) age (Drewe, 2005). Cities have always been recombined through new technological networks (Thrift, 1996). Such new technologies (such as the telegraph, telephone or nowadays Internet and mobile devices) are subtly recombined with the spatial and social practices of the workers and managers, operating within the complex material and social spaces of

the City (Thrift, 1996). Thus there is no big picture of the modern City to be had but a set of constantly evolving sketches (Thrift, 1996). Graham (1998) has critically explored the different conceptualizations of the relationship between information technologies and space and place. He identifies three dominant discourses as 'substitution and transcendence', 'co-evolution perspective' and recombination perspective'. The first one is the idea that human territoriality can somehow be replaced by using new technologies. The second perspective argues that both electronic 'spaces' and territorial spaces are necessarily produced together. Most importantly, the final 'recombination perspective' draws on recent work in actor-network theory, emphasizing the fully relational view of the links between technology, time, space and social life. Indeed, cyberspace is not anymore discussed as possibility to replace physical space (Mitchell, 1995; McLuhan, 1964), nor are they considered to be two separate entities, where electronic space helps to deliver us from the current frustrations with the world (Castells,1996; Boyer, 1996). Opposite to the Internet replacing space or causing erosion of a "sense of place" (Massey, 1993) the ICTs are increasingly more discussed as re-enacting the importance of place and home as both geo-imaginary and socio-cultural precept (Thielman, 2010).

2.1 Augmented City

As most lifestyles are digitally enhanced in many different as well as subtle ways, the 'virtual' and 'physical' spaces are no longer argued to be two separate dimensions (Mitchell, 2005). The physical and the digital environments are defining each other and concepts such as public space and "third place", identity and knowledge, citizenship and public participation are all inevitably affected by this reconfigured urban space, the augmented city and augmented urban spaces (Aurigi, 2008; Manovich, 2006). Furthermore, the sense of continuity and belonging derives from being electronically networked to widely scattered people and places we care about (Mitchell, 2003). While geography tries to characterize the mixing of code, data and physical place as "DigiPlace" (Zook and Graham, 2007), cultural and media studies refer to location based media" or "locative media" (Tuters and Varnelis, 2006). Regardless of the terminology it refers to the spatial turn in media studies and the media turn in geographical studies, also known as "geomedia"(Manovich and Thielman, 2009).

The two emerging technologies – the geospatial web and ubiquitous computing – suggest an intertwining of the network and the local (Varnelis, 2008). The two conceptual formations diverging from this development are locative media and mediated localities. Locative media turn implies that digital media is applied more and more to real places, thus triggering real social interactions (Varnelis and Friedberg 2008). Mediated localities attempt to re-animate the place of thought – mapping as means of expressing self through tagged objects and thus creating places that form a network of relations and connections.

Through the options of tagging and tracking with GPS, Wi-Fi and RFID tags we have seen a mass spread of mapping and geocoding in all areas. We are dealing with places in the form of a network of relations and connections between control space and ludic space (McQuire, 2010). In a nutshell, we can leave our mark on the world

or read the marks others left behind, re-creating place in a Borgesian digital map (Varnelis and Friedberg, 2008). Furthermore, November, Camacho-Hübner and Latour (2010) point out that digital technologies have reconfigured the whole experience of mapping into something else we wish to call navigational platform. The contemporary flâneurs could well be the young digital natives exploring the city through their mobile devices and being copresent with others at a distance through the aid of networking technology (Varnelis and Friedberg, 2008).
It may very well be, that 'augmented spaces' and 'geomedia' are only new concepts for old discussions about the relationship with consciousness to place and other people? We can also question the necessity of such extensive data production through posting, tagging and visualizing our surrounding space. There are also concerns over privacy matters and most importantly the ownership of the data produced. Finally, there is the question about the further use of the all the continuously produced and reproduced data – how can it support urban planning processes?

2.2 Open City

The merging of digital media technologies and urban life is leading to the creation of new resources in the form of huge volumes of data on all manner of urban processes. The evolution of networked technologies has always come in waves – databases, e-mail, the world wide, web, the social web – all offering new ways for doing things differently and each have posed financial and organizational opportunities and risks to those having to decide on whether to adopt or ignore them, or how adoption should take place (Powell, Davies and Taylor, 2012). The term Web 3.0 is now increasingly more used to describe the increasing emphasis on data and its description. Web 3.0 technologies facilitate new forms of linkage between data (as opposed to links between web pages) and support new forms of manipulation and presentation of data (Powell, Davies and Taylor, 2012). In relation to the Web 3.0 new buzzwords have emerged such as 'data commons', 'open city' and 'open data'. 'Open data' advocates call on owners to make it available so that it can be easily accessed and discovered, easily manipulated and licensed for re-use. 'Data commons' refers to combined data collections accumulated by the citizens either consciously or unconsciously on the use of all manner of products and services (De Lange and De Waal, 2012). 'Open city' is used more as a buzzword than a coined term and could be partly linked also to the 'Smart Cities' concept. However, in this context the open city rather refers to the city as a platform for data commons. 'City as a platform' can thus be viewed as a playground for emergent models of social organization that do not acknowledge any distinction between bottom-up and top-down approaches (De Lange and De Waal, 2012). Like the early Internet, which relied on public funding and open standards to foster innovation (Zittrain, 2008), the open city movement hopes to demonstrate that the sum of individual actions can give rise to more or less coherent forms of knowledge, understanding and behavior.
Examples include Open Data Eindhoven[2], that attempts to open up government data

[2] http://www.openeindhoven.nl/

for meaningful reuse in collaboration with citizens to foster new content and application development. Open Cities Project[3] is co-funded with European Union and aims to validate how to approach Open&User Driven Innovation methodologies to develop future Internet services for Smart Cities. The focus here is also on exploring crowdsourcing tools, enabling the use of public data for innovative mobile services and most importantly, the validation of pan-European Platforms for Crowdsourcing and Open Data.

While the process of applying open data is still in its infancy, the underlying principles of collaboration between multiple stakeholder parties and raising citizens awareness as well as the ownership of this data, propose a new way of creating transparency, simplification and exchange. It is not so much about choosing the specific tools to use, but rather about the goals behind utilizing these data resources – for urban planning, for citizen services, for commercial use or all of the above? More specifically, is the emergence of an open border-crossing city possible?

3. Border-Crossing Cities of Europe

While the last chapter discussed the relationship between the networked technologies and the city, concentrating on the latest development of concepts such as 'geomedia' and 'open city', this chapter will explore further the cross-border city thematic. The aim is to provide a better understanding of the background for the emergence of border-crossing cities as well as the core problems of the planning process.

Over the last decades, regional cross-border cooperation in Europe has led to the emergence of various forms of interregional and intermunicipal institutional frameworks and operational bodies (e.g. Euregios, Eurodistricts), as the European Union has simultaneously been actively cultivating and encouraging the disappearance of state borders as well as the emergence of border-crossing regions/cites. Cross-border studies have focused on the liberalization of borders and the increasing interaction due to globalization; the changing character of borders has been intensively described (Metroborder, 2010). Political geography as well as political science analyses have almost exclusively focused on organizational and governance issues including barriers to cooperation by mostly actor-centered perspectives (Newman, 2006, Paasi, 2005). As the institutional borders of Europe are not finalized and open to political struggles (Eder, 2006)□, the emerging border-crossing cites of Europe could be considered both the 'guinea pigs' and the catalysts in this process.

Although border-crossing cities by definition should foster border-crossing contacts, irrespective of mutual differences, but inspired by common interests and attractive opportunities (Buurisink, 2001), the everyday reality of this cooperation faces a number of difficulties. The territorial dimension of cross-border co-operations often has an almost arbitrary background and unclear political mandates (Metroborder, 2010). Forming border-crossing regions/cities is not only complicated because its rather seen as a pooled territory of the respective domestic institutions, but this lack of territoriality reveals itself also when imagining a common public for the future

[3] http://opencities.net/

cross-border regions/cities. Furthermore, current research about border-crossing cities (Ehlers, Buursink, and Boekema, 2001) indicates, that linking up and integrating paired border cities is not merely to be deduced from spatial adjacency, it is far more a matter of social relations and mental proximity. The (ir)relevance of spatial adjacency is put to test by a new type of paired border cities, namely '*connected cities*' (Buursink, 2001), that have been paired by new infrastructure, as in the *Sund* between Denmark and Sweden and in the *Channel* between France and Great Britain. It could be argued at least from the spatial adjacency perspective that in the case of Helsinki-Tallinn we are also dealing with connected cities, the relating tunnel project for the future supporting this argument.

Future cross-border planning efforts have also been ensured by the 1999 European Spatial Development Perspective (ESDP) but also with the Territorial Agenda (2007) and Europe 2020 strategy. There are significant differences in the administrative bodies that have been set up to initiate, plan and implement cross-border cooperation among the varied *euregios* of the European Union (Kramsch, 2001; Pikner, 2008; Metroborder 2010). The critics of "EU-phoric" cross-border cooperation argue that hardly any transfer exists between functional cross-border cooperation and processes of social integration (Strüver, 2005). For the emergence of a functional cross-border region, the discussion should steer from hard infrastructure and international logistics towards addressing urban values and citizenship (Paasi and Newman, 1998).

This can be seen as a critical response to the largely uncritical belief, held particularly in the European Union, that border cities and border regions should be seen as micro- scale laboratories for the larger European Union that dominated the debate on cross-border governance. '*People may associate themselves globally with images, brands, destinations but still live their daily lives in political communities. The human imagination is unlimited, but willingly restricted, as it is focused on voluntary associations of comfort, pleasure and adventure that fits its specific identity*' (van Houtum and Ernste, 2001). As a result the border-crossing cities have boost themselves even more inside, to their respective communities. The established of a cross-border region should directly improve inhabitants' opportunities to live, work and leisure. In practice citizens start to cross the border when it is also economically beneficial (work/housing opportunities) and convenient (combined services).

4. Towards Connected Cities

This research started as an exploration of digital tools contributing to the urban planning and governance of border-crossing regions. After working with the theoretical background of planning practices of border-crossing regions as well as the use of ICT in urban planning and public participation, it was determined that the underlying issue is in the quality and availability of data and information to utilize into digital tools ranging from service platforms to social media based applications. While the concepts of 'data commons' and 'open data' address the problem from the stakeholders' perspective – opening up public databases, inclusion of citizens and their participation as well as the cooperation with the private sector and NGO's – geomedia addresses the importance of inclusion of different spatial scales as well as

the mapping and visualization of various layers. As mentioned, the cross-border territory is not flat and should be regarded as an interactive environment. The latter can be described as an open environment that connects a number of closed systems to one another. The concept of interactivity is thus always in relation to an environment. In addition, interactivity is not a neutral or value-free entity but rather an entrance point to different spatiality, sphere or neighborhood (Jong and Schuilenburg, 2006).
In the case of Helsinki-Tallinn the contextual conditions are of high relevance and case study is a comprehensive research strategy covering the logic of design, data collection techniques, and specific approaches to data analysis. The suitability of the case study method was supported by the fact that multiple sources of data had to used to collect the evidence needed to solve the research problem. A preliminary data gathering was conducted regarding the case of Helsinki-Tallinn to identify first of all the core planning issues regarding future border-crossing region of Helsinki-Tallinn, the actors involved and the current use of digital tools for planning processes in both core cities. Preliminary research consisted of extensive desk research as well as focus group meetings held as part of cross-border events, both official and unofficial. The desk research consisted of official policy documents about the cross-border project and relating studies. Equally important were newspaper articles, conference presentations and statistical data regarding both metropolitan areas. Additionally to searching materials related to the border-crossing project, the digital initiatives from both cities also had to be mapped. In this aspect, the web presence of any form of cross-border activities or discussion was of relevance, as well as local open data and geomedia initiatives.
In this chapter the Helsinki-Tallinn case study with its key characteristics as well as the preliminary findings will be further discussed.

4.1 Helsinki and Tallinn

The Tallinn-Helsinki case is not what you would consider traditional border-crossing cities. Tallinn and Helsinki are both capital cities and as the primate cities of their countries, they are embedded in the national economies but also in national culture of their respective countries. The friendly relationship between Finns and Estonians has developed on the basis of spoken language and culture, by which Finns and Estonian belong to the same group, but this alone would not cause identity shifts and cultural homogenization (Zetterberg, 2004; Alenius, 1998).
Since Estonia escaped from Soviet-imposed isolation, the connections between the two countries and capital cities have intensified. The physical distance between Tallinn and Helsinki has almost disappeared due to the intensive traffic and communication flows. As Tallinn has become a Nordic gateway and transit destination for Eastern riches and Helsinki locates close to a technology hub, in the land of Nokia, then one could easily envision these national capital cities forming a single functional entity (Berg, 2002; Kurik and Terk, 2000).
The future of Helsinki-Tallinn, city pairs reaching towards each other, has been a topic of lively yet somewhat episodic discussion since the early 1990s, with persistent talks about a twin-city as well of viewpoints emphasizing strong

interaction without twinning (Ruoppila et al.,2007; Raagmaa, 2000). One persistent topic that has evolved in connection with the plans of cross-border cooperation has been the undersea tunnel meant to be uniting and further integrating the two cities.
The current overlaying discussion of Tallinn-Helsinki border-crossing region is primarily about infrastructure connecting the cities and the future common region with the rest of Europe. In a situation with two separate capitals with their respective city regions, the physical infrastructure in a form of a tunnel seems to be the common reference point and a shared project to imagine common futures. However, infrastructure is not only about concrete and logistics, it is also about accessibility to information.

4.2 Preliminary Results

The cross-border territory of Tallinn-Helsinki and their respective regions is already a rather abstract space, relating communities can be transient and dispersed. Information turbulence between the two regions and well as the discussion about a common border-crossing region is very much enclosed in national and municipal information systems. The information space of Tallinn and Helsinki seem to be as separated as the cities by the Finnish Gulf.
International sites bring together information from both cities and citizens, but it is often segregated on a national and language basis. The accessibility to information for the layperson but also for an urban planner or a developer of digital tools is made difficult by the scattered information between various institutions and the small amount of cohesive open data. At the same time Tallinn and Helsinki have the geographical closeness necessary to operationalize information to be used in everyday activities. The access to the neighboring city is fairly good due to geographical proximity (2h by ferry); however, the information about further activities in that urban space is limited. There is a change of a mindset needed in regarding frequent visitors from both sides of the gulf as something more than regular tourists and rather as temporary urban citizens. Secondly, the accessibility of information about various events and activities has to be closely connected to common services and the continuous development of new cross-border applications, thus utilizing data from both cities and using collected data for the further planning of the cross-border region.
Although there is a lot of effort towards developing and popularizing ICT and the use of digital tools in both capital regions, key differences need to be communicated regarding a common information space targeting the cross-border space. These differences include public-private collaboration activities, mentalities towards public participation and privacy as well as the actual use of digital tools in tackling urban issues. Although the creation of a common information space has been referred to as a relevant topic in the projects of networking organization Euregio, it has not been clarified, what is meant by information space, what kind of information is targeted, what would be the goals of a shared information space for the development of a border-crossing region ect.? From the official documents of Euregio, the Euregio 2010 Forum and Demos publication, it appears that information space is broadly understood as media space. While it covers different types of media, it is rather old

media centered, focusing on television and print media. The goals for the development of a common information space are unclear; the focus is rather on media as such and not about its relevance for the border-crossing region.
The publication by Demos, Helsinki situated think tank, is more innovative in proposing possible digital tools for the further development of this „urban union". They make a division between activities of the administration of a border-crossing region and possible grassroots initiatives. The emphasis is put on a cooperation portal providing service for citizens from both sides. The goal of the portal is to share both everyday information (such as tourism information) or find partners for cooperation projects. Thus, the portal is combining two functions without acknowledging different interest groups. A question emerges if something meant for everyone, from tourists to entrepreneurs, will be actively used by anyone?
The most recent initiative is the Talsinki.net knowledge platform, developed as part of the ongoing Helsinki-Tallinn transport and planning scenarios project[4]. The platforms' target is to "*collect and make accessible material that is relevant for the urban and traffic planning professionals, politicians and other project partners, concerned with the development of Helsinki Region, Tallinn Region and the common issues between the two*", listing actors, media coverage, policies, infrastructure projects, planning documents and other research. So far it's the only public cross-border collection of such materials.

4.3 Towards Common Information Space

In a situation, where technology is rapidly developing and popular applications change on a yearly basis, the challenge for urban planning is not so much about developing its own digital tools to compete with this constant change, but to collect existing information catered by different actors and applications as well as supporting local private and grassroots initiatives in developing their tools in a more systematic ways. Often these initiatives are scattered, lack funding or clear focus. Having an overview of the existing field of digital tools in an urban region supports in finding uncovered areas for development and strategic ways of operationalize existing ones. When discussing a common information space between two capital regions, the focus has to shift from the cross-border networking organizations and entrepreneurs focusing on urban informatics to NGOs and other urban communities focusing on urban issues and working in different spatial scales with the supporting aid of digital tools.
It appears that also the role of the expert planners has started to remind rather the task of an interaction designer concentrated on knowledge management. This means that information and ideas produced by various parties have to be analyzed and the interests of various stakeholders have to be communicated. Information is data that has been given meaning by a way of relational connection. This "meaning" can be useful, but not necessarily. Knowledge is then the appropriate collection of information, such that it's intent is to be useful - it is a deterministic process (Ackoff, 1989). Knowledge management refers to processes that are employed to manage the creation, dissemination and utilization of knowledge and that the organization's

[4] http://www.euregio-heltal.org/httransplan/

structures are developed to support knowledge processes (Gupta et al, 2003). However, this means that various data systems and tools supporting it have to be in place. In addition to data collected by the public registries and databases, many other parties produce knowledge in addition to the municipal organizations. Only after having an understanding of knowledge produced by the active urban agents in the region, can further goals be set about the knowledge that is lacking and the digital means to produce it. The competence and willingness of various actors to work interactively is one of the key issues here. Furthermore, the point of view of the inhabitants also has to be stressed as data is often given out on a very functional basis and public participation requires that data is also given back to the citizens and put to further development of common good.

4.4 Future research

For the future development of a shared information space a digital strategy is needed outlining the specific needs and goals for the development of the border-crossing region with an adequate timeframe.
Next stage of this research will concentrate on the variety of cross-border actors from the public and private sector as well as urban NGO's and activist groups to collect opinions of experts working on different spatial scales and sectors, while maintaining a focus on urban planning and 'open city' concept. The expert opinions along with other data gathered will be operationalized through scenario planning method.
The scenario planning method is not about predicting the future, rather about perceiving possible futures in the present (Schwartz, 1996). Any strategy involves a selective focus to identify one of more concepts, images and/or principles that are 'meaningful' and orienting (Healey, 2007). Scenario planning method is about finding new opportunities, storytelling, questioning assumptions and pinning down the critical uncertainties (Verwijnen). The construction of future scenarios helps to determine alternative futures and play out different decisions (Healey, 2007). A set of scenarios can be viewed at least from 3 inseparable viewpoints: the set of relationships, alliances and conflicts; the spatial aspects of these same relationships; the concrete nature of all the materials these relationships utilize and construct (Secchi, 2002). Thus, the scenario planning method is used in the last stage of the research to determine a flexible strategy for shared information space development between Helsinki and Tallinn. While the scenarios themselves are created to depict the range of development paths, the end strategy for a shared information space is the optimal route that is built on the core knowledge gathered from scenario planning method.

5. Conclusions

This paper discussed the preliminary results of the research about the cross-border region of Helsinki-Tallinn for the development of a shared information space between the two metropolitan regions. That shared information space has to stretch further than the occasional turbulence of information between old and new media channels crisscrossing the capital regions, but has to strive to create further

knowledge – intent for the border-crossing region. Furthermore, although there is willingness and initial project ideas from the networking organizations and other stakeholders, they lack a cohesive vision about the impact or the outcome that a cross-border digital agenda should have in the framework of the future border-crossing region. From a more practical side, the confusion stems from the overall definition of digital terminology, knowledge about the use of various digital tools in relation to physical space and experiences with public participation.

For the emergence of a functional cross-border region, the discussion should steer from hard infrastructure and international logistics towards addressing urban values and citizenship), with an emphasis on creating common services and projects for a shared urban space. The concept of 'open city' was discussed as a potential strategy component for the future development of the border-crossing region. Establishment of cross-border data commons would support the emergence of wider variety of common services and applications. Re-use of the data could be actively encouraged. The role of geomedia in the data production calls for a renewed consciousness towards place and other people – visualization of previously invisible flows and nodes as well as creating entrance points to different partialities.

The development of the shared information space for a border-crossing region is a matter of understanding the intricate relationship between physical and virtual spaces as well as the dynamics of the relating communities. It is not a matter of choosing applicable tools to use, but rather to outline the needs and goals of a border-crossing space towards a more ubiquitous, augmented version of itself. Such kind of augmentation would take into account the specific characteristics of a border-crossing space in moving towards an interactive use of urban space and more efficient communication. The actors included should encompass knowledge from the fields of cross-border cooperation, urban planning issues and/or urban informatics. It is relevant that viewpoints from different spatial scales and sectors (Hall, 2008) ranging from private to public are exchanged. The scenario planning method is used in the last stage of the research to determine a flexible strategy for shared information space development between Helsinki and Tallinn to prepare a wide range of possible decisions based on an entire range of possible futures.

TERRITORIAL RISK AND VULNERABILITY: PLANNING TOOLS AT MUNICIPAL SCALE

Marcella Samakovlija[1], Angela Colucci [2]

Abstract

The paper focuses on the link between territorial planning and risk management. Starting from the results of an interdisciplinary and international research called Quater-Interreg IIIB, we will underline the importance of territorial knowledge and the role that planning can play to mitigate risks such as floods, landslide and other natural and anthropical hazards. The aim of the research was a kind of certification than can help the municipality to learn and operate on their territory. We worked to elaborate a method that can measure the short term and long term decision that public administration should take to switch a risky land in a secure territory. We worked to understand how the territorial planning can mitigate the effect of hazard especially on the vulnerability components. Toscolano Maderno (Bs) and Seriate (Bg) are the two case studies that we will present here. Furthermore, we will introduce the Emergency Plans that we provided for this municipality and the link that we made with the ordinary tools of planning. In fact we don't think that it is necessary to introduce a new kind of tool, but we believe that the importance of the knowledge of a territory can be integrated in ordinary planning tools, in accordance with the 12/2005 Act of the Lombardy Region, and be helpful in the phases of mitigation, prevention and response. An important role that planner can have is in the recovery phase, especially if we introduce the concept of building a resilience city.

1. Introduction

Every year national and local communities face increasing costs due to the environmental and technological catastrophic events. The impact of these events on the environmental and territorial system is really complex. Due to the increase and the overlapping of the environmental costs, all institutions (public and private) feel the need to change the government system from emergency to prevention and mitigation actions.

Either in ordinary planning or in sectoral planning like the one of emergency, the role that occupies the knowledge of the territory is fundamental. In fact, this analytic phase can become the common base for a planning that takes into

[1] Politecnico di Milano, Milano, Italy - samakov@polimi.it
[2] Politecnico di Milano, Milano, Dipartimento di Architettura e Pianificazione, Italy - angela.colucci@polimi.it

consideration the intrinsic characteristics of the territory (represented also from the presence of risks), towards a development and a sustainable and harmonious management of the territory.

The goal of the research QUATER – INTERREG IIIB, that will synthetically be illustrated in the first paragraphs of this paper, is the development of a "procedure handbook for the territorial risk management". The different workgroups involved in the research have analysed: territorial vulnerability, flood, landslide, chemical and seismic risk, vulnerability of public buildings. The final goal of the research was to integrate the territorial risk prevention into the ordinary planning system of the public institutions.

The research was applied on a local scale. In the Italian context, the municipal authorities are competent in urban planning and they have a deeper knowledge of the context. The research has been tested on three municipalities with different risks: Seriate (BG), Toscolano Maderno (BS) and Lainate (MI).

On the Municipality of Toscolano Maderno and Seriate the research has not been concluded with the application of the QUATER method, but it has been continued with the predisposition of the Municipality Emergency Plan (PEC). The General objective of the restricted instrument of planning like the PEC, is the predisposition of adequate models of intervention and procedures of emergency to place in action in case of a calamitous event, in order to support the population affected. A description of the innovative elements that characterize these PEC is reported in the 6th paragraphs and followings. The application of the methodologies used for the integration of the prevention of the territorial, anthropic and technological risks, in the ordinary planning and in the daily operating of the Local Agencies is slowly starting to pay off, but there is still lot of work to do because these applications do not result as isolate cases, but enter instead in the daily practise of the planner.

2. The research methodological framework

The methodology framework (analysis and assessment) is based on the evaluation of the potential damages due to the territorial risks that characterise the municipal context. Two aspects can be identified in the general methodology: the risk analysis/assessment and the response system. The risk analysis depends on four interrelated factors:

1. Sensitivity – intrinsic characteristics and resources of the municipal territory/context (natural or human);

2. Exposure – number of goods, people and activities potentially involved during the event;

3. Vulnerability – the tendency of goods, people and activities to get damaged;

4. Hazard – the characteristics (intensity, frequency, areas involved) of the hazardous events.

Risk is the result of all these aspects. The analysis of the hazard and vulnerability can be extended beyond the municipality boundary (local level and territorial level). The aim is to verify the presence of a potential hazard near the municipality boundary that can have some indirect effects on it.

The response system, based on the risk analysis, is characterised by two intervention levels on the territory: the first consider the emergency management measures and risk mitigation interventions (these actions must be implemented in a short period); and the second level regards the territorial risks prevention measures, that must be implemented in a long period (and that must be integrated in the planning and land uses plan instruments). (fig. 1)

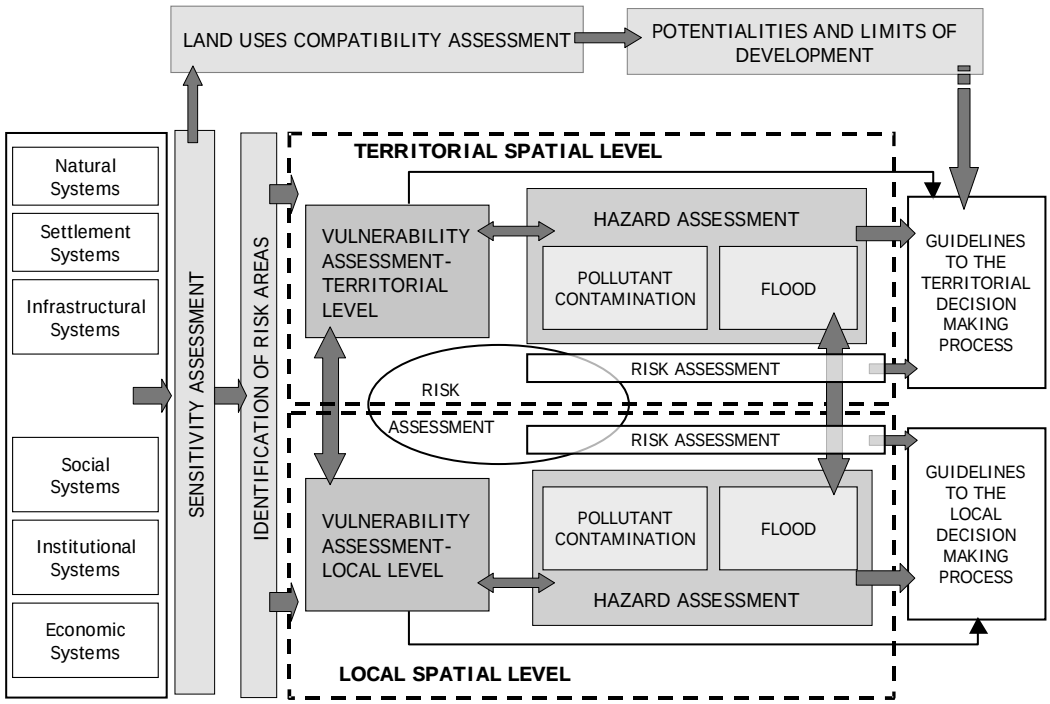

Fig. 1: The research methodological framework

3. The territorial vulnerability analysis and assessment: methodological framework

The method for the territorial vulnerability analysis consists of three steps: a preliminary analysis step (level 1), a detailed analysis step (level 2), and a further detailed analysis step (level 3).

The outcome of the preliminary analysis step (level 1) is the determination of the Basic Knowledge (territorial information/data) concerning the municipality. In particular, this level pinpoints the distribution of the population and the localisation of strategic buildings.

The second step (level 2) outcome is an investigation into the sensitivity by means of specific indicators, varying according to the characteristics of each municipality, and a preliminary exposure and vulnerability assessment of the territorial system for each risk.

The detailed analysis step (level 3) enhances the results of the previous step by means of a specific analysis (of the different hazards and the area of the territory involved).

The outcomes of these three analysis steps help municipal authorities to select an action and intervention system aimed to decrease/reduce territorial vulnerability. Every step uses parameters and indicators that can be used to assess vulnerability and carry out a periodic audit of the certification procedure. (fig. 2)

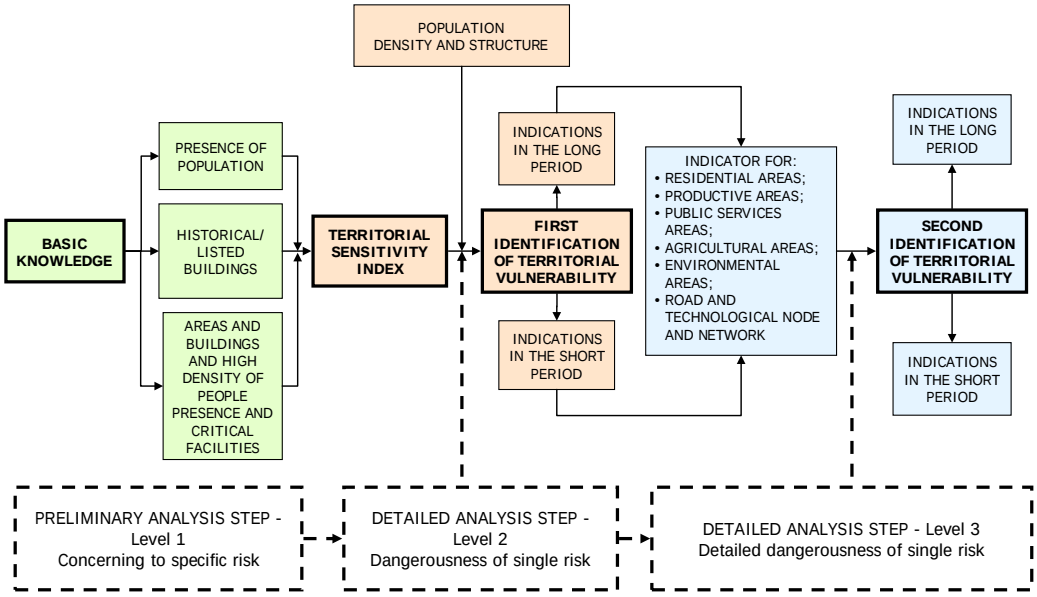

Fig. 2: Steps of territorial vulnerability analysis and assessment method

4. Indications

Like we have already mentioned, after the detailed analysis, the method allows the recognition of some indications in the short period and in the long period. The short period indications are related to emergency management measures and risk mitigation interventions (Municipality Emergency Plan, information campaign for the inhabitants, risk mitigation interventions on strategic buildings). The long period indications are related to territorial risk prevention measures, which have

to be integrated in the planning and land use plans instruments (for example a program for new location of strategic buildings and a land use code).

Table I shows an example of short term and long term indications in the case studies of Toscolano Maderno; the indications are divided in mitigation interventions, Civil Protection actions and planning measures (the red line divides short term indications from long term indications). All the indications are related to the analysis that we have made on the Municipal territory.

In the case studies analyzed, the town/city plan was in use from various years and little or nothing it has been done in order to introduce measures of mitigation which not only refer to the dangerousness, but also to the vulnerability of the territory. The long term indications, in the future phases of updating the plan, would have to be integrated or to be held in consideration in order to create the connection between ordinary and sectoral planning which was foretold, with the support of the procedures of maintenance of the certification.

Table I: Example of short term and long term indications

Indications framework						
	A	Mitigation interventions	B	Civil Protection actions	C	Planning
SHORT TERM	A1	Programming and design of hazard mitigation interventions.	B1	Updating of Municipal Emergency Plan with all risks present on the territory.	C1	Development of internal Municipal office collaboration: development of Territorial Information System.
LONG TERM	A2	Municipal programs finalised to hazard analysis.	B2	Design and development of information campaign for inhabitants.	C2	Verification and comparison with future land use plan and territorial risk.
	A3	Realization of hazard mitigation interventions.	B3	Development of a program to stimulate the intervention to keep the safety of the buildings.	C3	Development of municipality program for new location of strategic buildings.
	A4	Reduction of exposure level for inhabitants and strategic building.	B4	Realization of inhabitants information.	C4	Identification of alternative roads in dangerous areas.
		... ...	B5	Development of municipal Emergency Plan.	C5	Development of new location for public services buildings.
			B6	Arrangement of information about territorial and network vulnerability.	C6	Development of programs and systems for territorial and network monitoring; improvement of Territorial Information System.
				... ...		... ...

An important aspect of the proposed method is the verification of goals and actions. The actions efficacy and the targets gained can be checked in two ways: a continuous enrichment of the Basic Knowledge (which improves the efficacy of the indications) and the monitoring of actions over time.

5. The methodology realized for the redaction of the Municipality Emergency Plans

Like it was suggested in the indication of short term from QUATER methodology, for the Municipality of Toscolano Maderno and of Seriate, we have elaborated the Municipality Emergency Plans (PEC). If we go back to the three parts that compose a PEC, we can then disclose the methodology set in action in the specific cases present in the introduction and highlight some innovative elements and the relations with the planning and the management of the territory.

Firstly, in both cases we have elaborated a multi-risks plans that also takes into consideration those hazards not explicitly cited in the reference norms. The choice that we carried out is the result of the consideration that the hazards are intrinsically part of the territory and all hazards, in the first analysis, must be considered and analyzed with the exact same relevance. Only after a careful assessment it is possible to decide which ones are negligible in the plan.

Regarding the general structure of a PEC, it is composed of three fundamental parts: the Basic Knowledge, the Operative Part and the Part of Verification and Updating.

The Basic Knowledge contains:

- a territorial organization that must be elaborated independently of the presence of risks;

- the analysis of the direct or induced dangerousness, also from a close Municipality;

- the individuation of the vulnerable elements exposed to the risks (es. hospitals, schools, zones at elevated population density, technological infrastructures, etc);

- the individuation of the available resources (es. rapid-reaction force at local and regional levels, areas of reception and/or shelter, vehicles and materials);

- the drawing up of the risk scenes.

The Operative Part identifies the systems of monitoring and premonitoring an event for the expectable risks (es. the alluvial risk) and the drawing up of the aid models (individuation of members of the Local Unit of Crisis, that comprises the rapid-reaction force of the Municipal territory; the localization of over-local useful forces of intervention in the case of particularly serious events or for a particular typology of risks; for every force involved the "who - does - what" of the tasks).

The Part of Verification and Updating comprises:

- the verification of the PEC by drill and, in the case of incidental events, through the former post-analysis of the procedures of emergency action;

- the updating of the PEC through the individuation of protocols of updating of short and long period.

For the realization of the PEC we have used GIS, which allows to share and to update the information arranged systematically in a fast and effective way.

6. The Basic Knowledge of the Municipality Emergency Plans

In the Basic Knowledge, after a general organization of the territory object of planning which comprises of thematics like: climate, geomorphology, hydrography, we have analyzed the urban settlement and the infrastructural system, the distribution and the characteristics of the population, the economic activities, agriculture and public services, the emergency infrastructures and the resources available.

The first phase comprises of the analysis of the population census and the mapping of the strategic and vulnerable buildings; of the emergency areas available (subdivided in waiting areas, reception areas and recovery areas); of the public infrastructures service and of the available resources of Municipal property that we have at disposition in the case of a necessity. Every information obtained in this first part of the Basic Knowledge of a PEC becomes mapped by GIS and in such a way we provide a cartography which is always updated and available for the PEC, but also for the ordinary planning.

The ideal successive step, today still not completed in these two cases, sees this basic information of the territory, at the moment independent from the typology of present risk, contained into a Municipal SIT (Territorial Information System) where all the councillorships can reach and contribute in the given terms of updating. The structuring of the PEC for this purpose has concurred to supply a common working base in which, once the financial resources have been obtained, a Municipality will be able to construct the SIT.

Another important and innovative element in this type of sectoral plan, regards the drawing up and the continuous updating of the file dedicated to the emergency areas; they contain important information on the accessibility, the extension, the equipment of independent infrastructure service, etc. Often neglected inside the norm of writing of the PEC, usually the planner localizes the areas without entering in their specific characteristics.

The second phase of the Basic Knowledge of a Municipality Emergency Plan, regards the analysis of the dangerousness and the risks present in the territory. For the Municipality object of the research, the analyses have already been carried out from the work groups of the project QUATER.

The heart of this phase of surveying the PEC are the risk scenarios, meant from the Regional Directive like verbal and synthetic descriptions, accompanied with an explicative cartography of the possible effects on the population and on the infrastructures, by adverse meteorological events (flooding, also gave away dams), of geologic or natural phenomena (earthquakes, landslides and avalanches), by forest fires, or industrial accidents or of dangerous substances in freight accidents. From the point of view of the risk analysis, it is important to emphasize the presence and the involvement of various disciplines and expertise in this phase. These experts have not only supplied a risk assessment on the present territory, but also a reflection on the relation between these risks and the development of the actual urban area, on the effect of the future forecast urban growth.

The abilities of the planner to represent the territory through a reasoned and synthetic cartography are fundamental in order to give back a general picture of the risks and the complex systems that compose the territory, that a specific scientific sector does not succeed in condensing. In fact, in the phase of knowledge and planning of the territory, we would have to already be notified of the presence of a risk in our area of surveying.

Once again the relation between sector planning, the one of emergency and the ordinary planning emerge. In fact, the new Regional Law of Lombardy 12/2005, considers it obligatory that there is a risk analysis for the plans at different territorial levels, the problem is that all the risks are not taken into consideration and there isn't a directed connection between the ordinary territorial plans with the emergency plans that instead consider, as we have previously said, all the types of risk. Localization of a public structure, for example a school, would have to take into consideration not only the economic reasons, but the planner would have to also take into consideration the degree of dangerousness in the different territorial risks that characterize the area to settle. This information is contained in a PEC.

It is obvious that not always, in our territory, we can refer to new constructions, but we always have to take into consideration public buildings already constructed: in this case, given the impossibility to eliminate the risk, the intervention of mitigation would be opportune and useful in order to diminish the possibility of damage caused on the buildings. In both cases, a deeper knowledge of the territory is necessary, whether in punctual terms (es. localization of the building), or in the analysis of various systems that compose it.

The localization inside the Plan of Government of the Territory of particular services involved in the emergency phase and in accessible areas, is not subordinate to eventual risks (e.g. municipal civil protection, Red Cross, fire brigade, etc.), it allows to supply a ready answer to the emergency and therefore a more effective and efficient management of the event. If we placed side by side these two instruments and a Plan of the Urban Traffic, we could then be sure that

the time of reacting to the event and the dispersion of the forces involved will be limited.

Also regarding the second phase of the Basic Knowledge of a PEC, we have written up a series of explicative cartographies of the dangerousness, the present risks and of the risk scenarios that we have decided to adopts for the drawing up of the intervention models.

Another innovative aspect that deserves further discussion, regards the cartography of the risk scenarios. This cartography has been planned in such a way as to have in an only picture all the reference for the portion of territory interested in the calamitous event, with the indication of the strategic and vulnerable buildings, service infrastructures, that have been involved in the event. Where possible, we specified the civic number of the building involved and consequently we gave a brief description of the characteristic of the single inhabitants. In fact, in the PEC, we have also attempted to distinguish the sensitive population, that is the young people, old people or disabled ones who need particular assistance in the cases of evacuation of the areas at risk.

7. The Operative Part of the Municipality Emergency Plans

As anticipated, the Operative Part of a PEC also characterizes the systems of monitoring an event in the premonitory phase and it drawing up the intervention models. The first aids to the populations are directed and coordinated by the Mayor of the Municipality involved in the event. The Major, in accord to the Italian legislation, is local authority in matter of Civil Protection. In the case of events which cannot cope with local resources, the Mayor could ask for assistance at the Prefect who activates and manages the over-local forces of intervention. Therefore, the first step in the drawing up of the intervention model is the localization of the local forces of intervention, they will then be involved in the Local Crisis Unit (UCL) and the over-local forces will support it.

For every risk scenario contemplated in the Plans, we have identified specific procedures of intervention that, in this methodology are made up of:

- one matrix time/components of UCL; where we identified, subdivided for temporarily and succeeded passages, the activities to place in action part of every member of the UCL (for clarity, the main forces of over-local participation are also comprised in the matrix);

- one matrix activity/responsibility; where, for every identified activity we specify the responsibilities of every member of the UCL (if he is responsible for an action, if he is simply informed or just supporting);

- a job description for every member of the UCL; where the activities placed in the head of every Agency are explained. The job description contains all useful and indispensable elements to know in an emergency

phase (es. telephone numbers of the managers of technological networks, etc.);

- a cartography that summarises all the main information of the intervention procedures.

Where possible, as an example for the alluvial risk, all these procedures of intervention are multiplied for the pre-alarm phase, alarm or emergency phase. For the not expectable risks the procedures are formulated only for the emergency phase.

Particularly innovative and interesting in the contents is the job description and the cartography of the intervention models. Like we had observed for the cartography of the risk scenarios, also in this case we can find in a single cartography the necessary information for the activation of the intervention procedures: one clear map of the area interested in the event with the indication of the interested vulnerable elements, the indication of the ways to escape and the usable emergency areas. This cartography, beyond the graphical part, is physically structured with a series of "pockets" where the main intervention procedures have been collected (matrix time/components UCL, matrix activity/responsibility UCL, job description for every member of the UCL and a list of the population have been involved for typology)

8. The part of Verification and Updating of the Municipality Emergency Plans

All the "architecture of emergency" adjusted with this methodology, introduces to the third fundamental part of a PEC, that Verification and Updating of the data and information are contained in it.

The verification of a PEC generally occurs by drill, in the case of incidental events, through former-post analysis of the procedures of emergency. Closely correlated at the verification of the plan there is the periodic updating, necessary in order to be able to manage the emergency better, because the PEC must be used as a dynamic and modifiable instrument in consequence of the changes of the territorial system to which it belongs. For the review of the PEC we have identified a protocol of updating a short and a long period. The updating of the short period regards the population exposed (with particular regard to the sensitive population) the members of the UCL, the over-local forces of intervention and all the information that changes or could change in a minimal temporal arc. The updating of a long period regards the territory (which changes independently from the presence of risks) and the present dangerousness (that could modify in the light of new studies).

Also in this phase there is a strong relation between the emergency planning and the ordinary planning that can, with its decisions, aggravate or mitigate a present risk.

From the operational point of view the updating of a PEC is therefore also conceived inside a Municipality which adopts a system of certification like that one proposed from the QUATER method , it is useful to emphasize the necessity of a strong collaboration between several operative sectors of the Municipality, from the office of Civil Protection to the Technical Office up to the Registry Office.

9. Conclusion

The QUATER method develops a procedure handbook of the territorial risk management not only with short period actions, but also with some indications for risk mitigation and prevention in a long term vision. The method aims at integrating the risk mitigation aspects in ordinary planning.

The procedure allows the arrangement of information about the territory (Territorial Information System) and develops a public and private collaboration.

The system is managed by the Municipality, in a flexible and incremental way, through a constant process of goals update and verification. Moreover, the support of planning instruments such as a sectorial Emergency Plan, directly connected to the ordinary planning and to the certification process, allows to achieve those goals which were initially set for the mitigation of the risk through the planning instruments.

Table II: The innovative elements inserted Municipality Emergency Plans

	Innovative elements	Relation between ordinary planning
Basic Knowledge	Analysis of dangerousness also outside the municipal boundaries Organization of the information by GIS Interactive cartography	Use of the same information about the territory inside the Municipality SIT Use of the same information about the dangerousness and risk inside the Municipality SIT
Operative	Design of the intervention procedure with matrix, job description and interactive cartography	Coordination of the choice take in the ordinary planning and sectorial planning, in order to avoid a worsening of the situation at risk and to mitigate the effects.
Verification and Updating	Protocol of updating of the information organized by GIS	Continuous updating of the information regarding the territory and the Municipality goods

The task of making the connection between these two typology of plans more effective is still a lot. We do not think that the introduction of new instruments of planning is necessary, but that the correct and sustainable use of the existing instruments is enough. As planners, we think that we can’t stop to think of the single destination of land use, the instruments of mitigation in our "hands" are various (eg. the adoption of particular building regulations, the maintenance and the promotion of the use of particular natural buffer areas, etc.) and it is necessary to enter in the perspective that in order to plan a secure territory, we must think of

different levels of action in space and time and that a synergy between various sectorial expert is necessary.

When we think about "resilience", we often think only for the recovery of a city in the phase post-event, almost as if this stage was a sort of "closure" quantifiable. Instead, for resilience we mean the ability to get out of a stalemate, so do not necessarily equal to the initial pre-event. The ability of a territory to be resilient consists largely from the organization and from the relationships existing prior to the event, more the system will be flexible and more rapid will be the recovery to normal activities with a view to improvement and awareness.

Often, the concept of sustainability is partnered by resilience. Sustainability, in fact, does not necessarily mean that all risks are eliminated, but that a degree of balance between the issues related to risk, the social and economic ones are reached. Certain levels of risk may be necessary and acceptable. Where a community chooses to continue living in a territory, despite the risk, the development should go towards the creation of cities resilient, able to react to the effects of a disaster. This type of approach, namely to know and to work on the nature and not against it, can simultaneously achieve the goals of conservation and enhancement of natural resources without diminishing the chances of developing [Burby, 1998].

The integrated use of appropriate tools for management and planning, as we've tried using in the territories of Seriate and Toscolano, it is necessary for try to plan a resilient city, reducing the intensity of development in hazardous areas, reducing the need to alter and hinder the natural processes, we could reduce the economical and social costs, of vulnerable city.

National Security Threat and Its Measurement: Protecting Society's Vital Infrastructures in Finland

Antti Silvast[1]

Abstract

Recently, the protection of societal 'critical' infrastructures has become a topical security issue in most Western governments and the EU. The manners in which experts generate responses to infrastructure risk and cope with risky infrastructures has been studied in the US. The paper tests this theory on another region by asking: how has risk been manifested in the management of energy supply in Finland, and how did the techniques of risk management emerge? The material of the study is organizational histories and expert interviews. The methodology centers in the different kinds of risk governance and their shifts in these materials. I pay particular attention to the manners in which the risk management of Finnish national energy provisions has been problematized at different times, often motivated by the experiences of pivotal national disasters such as wars, shortages and energy crises. A key tension in Finnish debates on national security stems from the energy crises and worries over technological dependency in the 1970s. This is between the storing of national raw resources and the securing of continuous and uninterrupted provision of energy, food, communication and other systems. The same tension I claim is still prominent in the more recent Finnish debates about infrastructures and security, emergency preparedness, and civil and military contingencies. Furthermore, the paper proposes that the tension also poses a useful analogue for thinking about the risks of other organizational fields, such as information technology, finance and logistics.

Keywords: infrastructures, risk, risk management, technological disasters

1 Introduction

In their historical study of the security of US infrastructures, anthropologists Stephen Collier and Andrew Lakoff (2006, 2008) identify three elements in the worries over

[1]University of Helsinki, Finland - antti.silvast@helsinki.fi

societal vital infrastructures: i) "a concern with critical systems upon which modern society, economy and polity depend"; ii) "the identification of vulnerabilities of these systems and of threats that might exploit these vulnerabilities as matters of national security"; and iii) "the effort to develop techniques to mitigate system vulnerabilities" (Collier & Lakoff 2008, p. 24). Importantly, none of these three aspirations requires a late 20th century or early 21st century societal, economic or technological situation to be justified. Indeed, national security experts have often raised similar worries before: for example, in the strategic bombing theories of the early 20th century (Collier & Lakoff 2008); and in concerns over the impacts of a Soviet nuclear strike on the US's critical systems (Collier 2008). The protection of such critical systems – or *critical infrastructures* – is a marked concern for most Western governments today (Brunner & Suter 2009). Yet, Collier and Lakoff (2008) argue that the current thinking about critical infrastructures is a relatively minor redeployment of much older ideas about national security, emergency preparedness and civil and military contingencies.

This previous research pertains to the case of the US. This paper on the other hand tests the model by Collier and Lakoff on the history of electricity infrastructure protection in Finland. The key objective is to acknowledge the intellectual origins of ideas, techniques and concepts regarding Finnish infrastructure protection. Thereby the aim is to underscore parallels between recent debates and more historic discussions on emergency preparedness. The research question is: *What kind of security problem is the functioning of electricity supply in Finland and how did this security problem emerge? What have the main concerns, concepts and techniques regarding infrastructure security been during the last 100 years?*

The structure of this paper is as follows. I first present the emegence of infrastructure security practice by looking at three pivotal periods: the origins of Finnish crisis management in the 1920s; the late 1960s, 1970s and early 1980s when one particular rational approach to Finnish national security, namely the storing of raw resources, became a target of criticism; and the diffusion of these security concerns over the last few decades. The last section concludes and discusses possibilities for further research.

2 Infrastructural crisis preparedness in Finland

2.1 From defence economic planning to total national defence and storage security

Historical studies of Finnish emergency supplies (Seppinen 1996; Voimatalouspooli 50 vuotta, 2006) concur on the origin of infrastructure protection in Finland. This origin is not the 1973 energy crisis and not the 1910s paraffin crisis (Myllyntaus 1991, p. 78;

pp. 132-134), but the food shortage of 1917. Often attributed as an acute cause for the Finnish Civil War in 1918 (Myllyntaus 1991, p. 78), experience from the 1917 food shortage and depression from 1917 to 1919 raised discussions about the need for planning for national emergencies in Finland. In 1929, the Finnish government proposed the founding of an Economic Defence Board. Although having 'defence' in its name, the concerns of the board were actually more extensive. According to the government proposal for founding the board, the board's underlying aim was ambitious: to "mitigate and reduce the effects that an emergency period has on the society's machinery". The aim comprised broad responsibilities for the state as well as for industry. In particular, the anticipation of emergencies was a matter of

> the defence preparedness of the whole industry, the maintaining of agricultural activities and food production, the rationing of the consumption of food, fuel, clothes etc, the organization of many kinds of relief efforts etc. social actions and the arrangement of monetary and credit conditions. (Government proposal, 1 February 1929; quoted in Seppinen 1996, p. 21.)

The board was founded in 1929, but its tasks were soon narrowed down and the board was later terminated. The reason for this was political defence: with the Second World War looming, the Finnish government was much more concerned with war preparations than with crisis preparedness in the civil life (Seppinen 1996, p. 22). The situation changed after the war, as Finland had lost the war to the Soviet Union and the private sector could not mobilize any war efforts for about a decade. After the global détente of 1955 and once Finland joined the United Nations and the Nordic Council, however, the concerns for preparedness found new support especially within the security environment of the Cold War. Economic Defence Planning Authority, established 1955-56 in place of the Economic Defence Board, was concerned with "total national defence". This meant defence which involved both political and economic aspects (hence the term 'total') (ibid, p. 37). However, experts still tended to always equate crisis with war, as we shall see later.

The security concerns that figured in this period stemmed from experiences of foreign trade crises, shortages, rationing, poverty, and depression (Voimatalouspooli 50 vuotta, 2006, p. 11). There was therefore an overaching concern about the exhaustion of raw resources. And as national security experts widely believed then, the dangers of future shortages could be mitigated by stockpiling nationally important resources. Figure 1 is a rather rudimentary example of a Finnish stockpile. Dating back to the Second World War, it shows wood for burning being stored in a market place. Here a stockpile is a concrete *storage* where materials are kept and managed.

A couple of decades later, the approach to national risks in storage security had become markedly more analytical. Figure 2, from 1972, displays the consumption (thousand

Figure 1: Woods are stockpiled in a market place during the war in Helsinki, 1943 (from Seppinen 1996, p. 28).

Code	Type of crisis
A1	State of war
A2	Threat of war
B1	Worldwide disorder
B2	Nationwide disorder
C	Regulator conditions

Table 1: A Finnish crisis typology in economic defence planning, proposed in 1956 but never implemented. Each crisis has a code (Seppinen 1996, p. 32).

tonne) and stockpile (duration in months) of various Finnish goods. The goods include crops, sugar, coffee, cigarettes, cattle feed, vegetable oil, butter, fertilizers, chemicals, different kinds of coal, oil and gasoline, textiles, rubber and tires, and various types of metal and steel. You can see that the storage of coal, for example, lasts for a little over seven months, while coffee runs out in three months. There are two kinds of bars in the figure, one for "commercial centre storages" (diagonal filling) and other for "state security storages" (cross filling). While most goods are stored by private entrepreneurs for the most part, particularly lead and tin are actually stockpiled by the state.

The visuals of the image are basic especially by today's standards. Yet, this storing conveys already a rather sophisticaced *technique of risk governance*. This is: once you knew the duration of raw resources by calculating it, you could then assign responsibilites of stockpiling both to the state, and private companies. But in spite of its systemicity, and continued relevance in societies that depend on goods, this style of reasoning also has some limitations. Most particularly, as already briefly mentioned, storage security only dealt with the threat of war. In 1956, the Chair of Economic Defence Board, General K. A. Tapola, had proposed a "crisis typology", which consisted of five kinds of crises (see Table 1) ranging from regular conditions to various kinds of disturbances. Such considerations of crises were not altogether unusual in the 1950s: early American studies of disasters had also proposed that *disasters* are not merely military attacks but all those incidents that prevent the maintenance of essential societal functions, and disrupt social order (Perry 2007, p. 6). In Finland, it would nonetheless actually take several decades before Tapola's typology was implemented. For almost 20 years, the concerns for natural security remained preoccupied with military threats, and with a notion of crisis that is rather straightforward: a crisis was equated with military pressure, and most particularly with the rapid onset of the actual state of war.

2.2 New security problems and 'security of provision'

By the late 1960s and early 1970s, a number of events had challenged Finnish national security. Perhaps the most dramatic was the 1973 energy crisis, which happened to

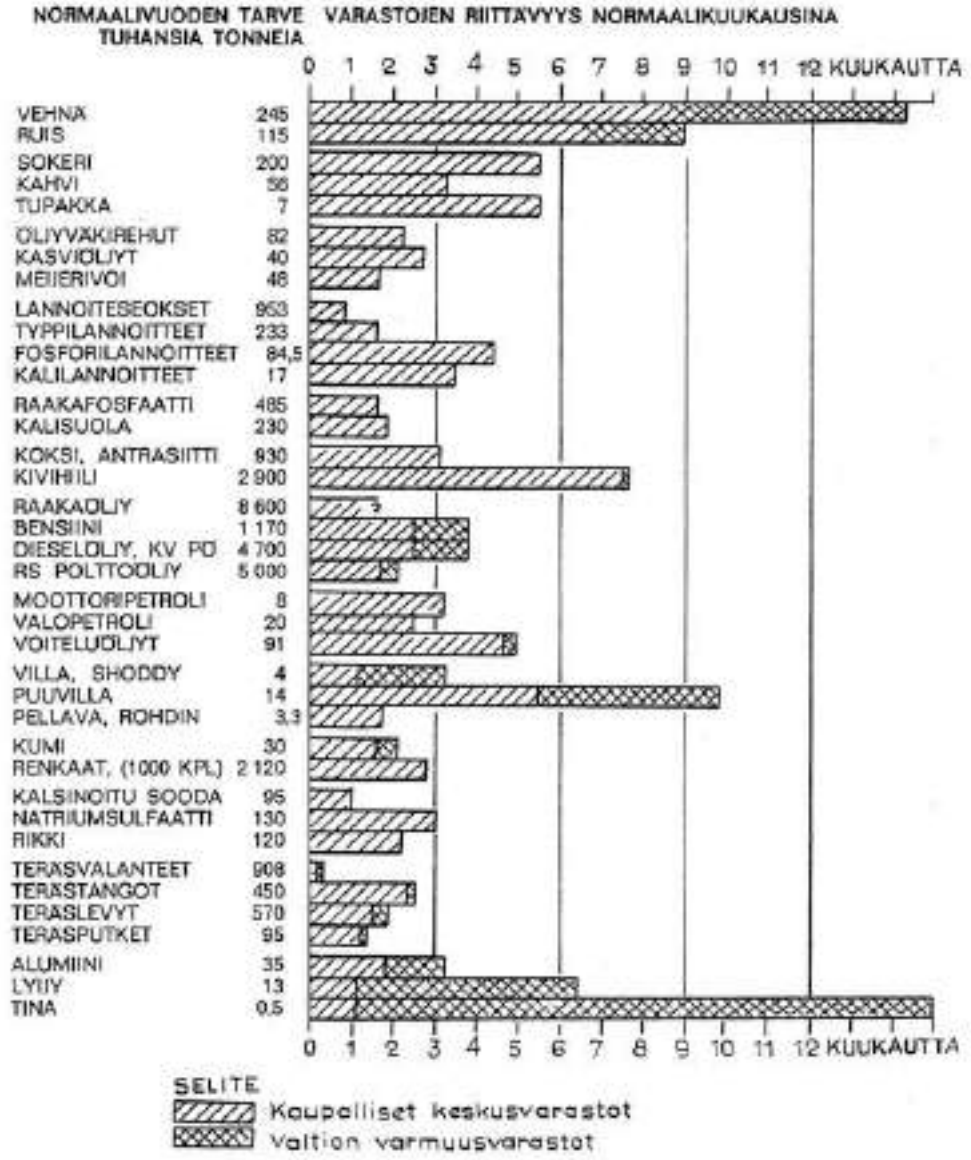

Figure 2: The duration (in months) of various Finnish goods in 1972, including wheat, coffee, cigarettes, crude oil, rubber, and other goods. Both commercial central storages (diagonal filling) and State security storages (cross filling) are displayed. The figure concerns the need of a "normal year" and in "normal months" (from Seppinen 1996, p. 75).

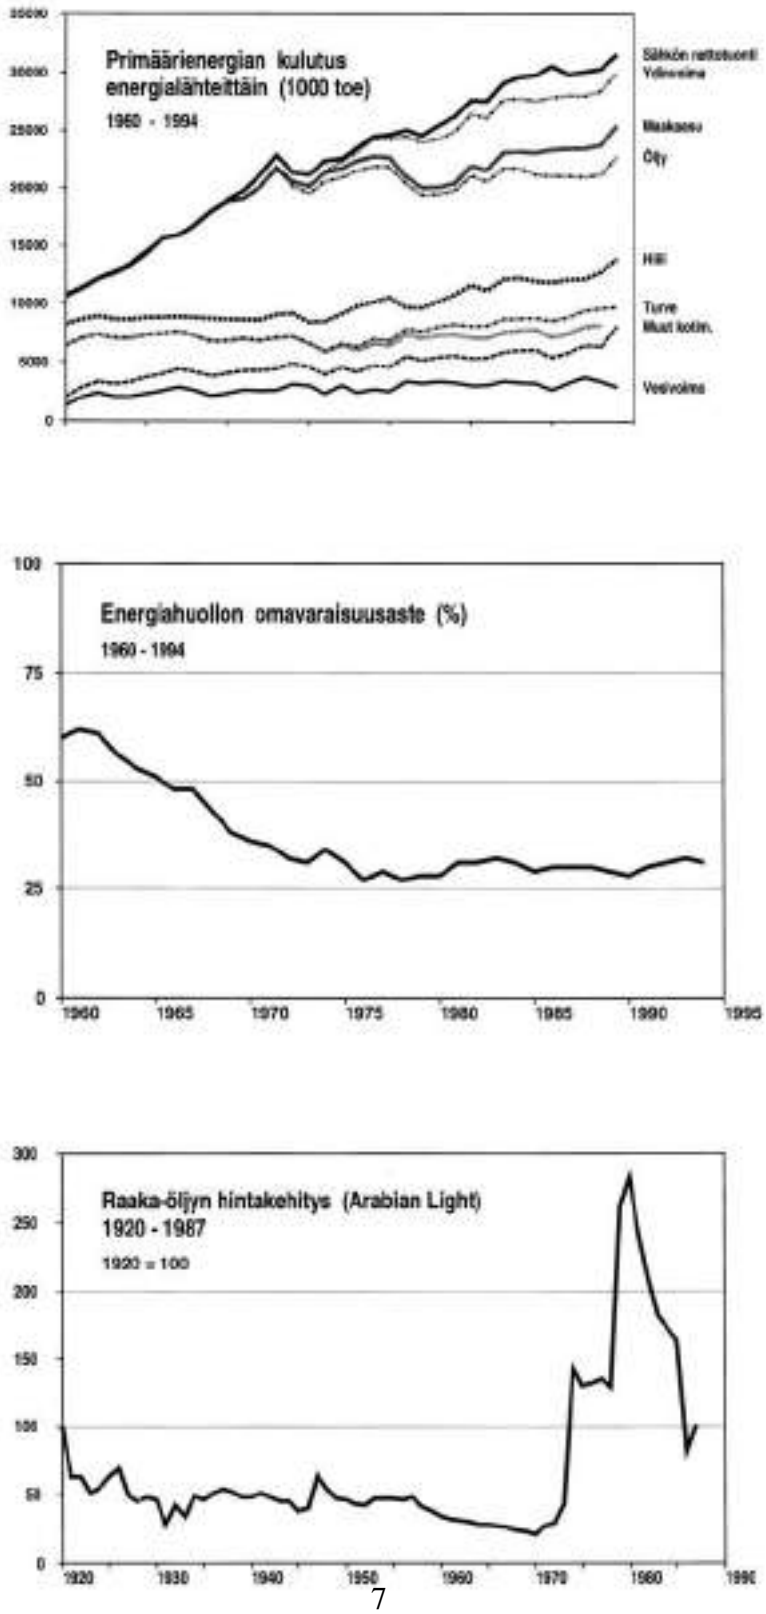

Figure 3: Finnish energy consumption levels, energy self-sufficiency, and the price of crude oil. As the consumption of exported energy grows, the society becomes vulnerable to energy price shocks (from Seppinen 1996, p. 81).

concur with a marked decrease in Finland's energy self-reliance. An illustration of the crisis is in Figure 3, which shows three graphs. The lowest is the price of crude oil, displaying in 1973 a sudden shock. Less dramatic, however, are the two upper graphs. They show that Finnish society has slowly become a larger consumer of energy, and is less self-sufficient energy-wise. These two trends can be see as a gradual development that caused vulnerability to the oil price shock.

Secondly, it was also becoming more apparent that perhaps not all 'indispensable' economic activities had been identified within the mainstream national security practice, and thinking. As discussed in the previous section, it was a tradition to prepare for crises by stockpiling goods such as oil, fuel, and food (Seppinen 1996, p. 88-89). By the late 1960s, technologies had arrived however which required more than just a storage place to function reliably. Indeed, these technologies needed to work all the time. This was true for the computer systems that were already used extensively in the 1970s finance, and industrial processes, while it was also apparent that 1970s convenience stores with their lighting and cooling systems were entirely dependent on electric energy supplies (ibid, p. 89).

The Economic Defence Planning Authority, and its Economic Power Pool were in what is reported to have been strong internal arguments. The central disagreement was about whether these organizations had comprehended up-to-date hazards, and threats like the above (Voimatalouspooli 50 vuotta, 2006, p. 25). While disparate events, the oil crisis, computerization, and dependence on electricity all showed that a crisis develops over many weeks, not through rapid onset like a military attack. A catastrophe may arise or almost lurk in the midst of 'normal' civil conditions; not merely in the context of a state of war. (Seppinen 1996, pp. 81-83.)

With this in mind, security thinking, and practice was problematized by critical national security experts. In 1977, K. H. Pentti, the then vice CEO of the state petrol company Neste, and the soon to become planning director of the Economic Defence Planning Authority, intervened in security debates by coining the term *security of provision* (huoltovarmuus). It was meant to replace the established term *storage security* (varastovarmuus).

These terms cannot carry all of their connotations to an English translation. The official translation of *huoltovarmuus* has either been *security of supply* or *emergency supply*. In English, *supply* means a provision or a resource, which might actually also be a storage. The word *huolto* has these meanings as well, nonetheless its most literal translation might be *maintenance*: the process of keeping something in good condition. While nowadays having quite a specialized technical, and military meaning in the Finnish language, *huolto* is an old word that stems from the late 18th century, and is derived from the word *huoli*. *Huoli* literally means a *concern* and acquired the form *huolehtia*, meaning *to take care of*, in the mid 19th century. All of this indicates not just a supply

of resources, but that *huoltovarmuus* is a broader process of taking care of people's living conditions.

For Pentti, the new term was characteristic of the security situation in many ways:

> The old question had been: "How long do raw resources last with normal consumption?" Now the question has become: "Which level of provision is satisfactory with regards to the need of raw material and fuel in different kinds of crises?" (Quoted in Seppinen 1996, p. 91.)

The security thinking did not change altogether. The above definition by Pentti is still calculative similarly to the older security practice. The problem is about calculating, and hence mitigating national security threats. But the objective of the calculation has changed: from determining the duration of raw resources to finding a level of provision. And even more significant changes are visible when we look at the definition in detail. It ends by noting that there are "different kinds of crises". Hence, in other words, there is more than just *military* crises to national security.

New kinds of social crises and emergencies were indeed soon raised on the agenda: disasters that had effect in everyday life, and took on a life of their own rather than being merely short-lived military events. Such crises also required a new typology, which was deployed in 1978 (Table 2). This was actually very close to to K. A. Tapola's proposal from 1956 (Table 1 on page 5). The classifications are similar to Tapola's – from a major accident to economic crisis, threat of war, and military attack. In addition, the crises were also given durations. Excluding major accidents, each crisis had three phases: first, a preliminary stage, second, the actual crisis and finally, recovery. Military attack also included a six-month blockage of foreign trade. Crises were hence diversified on many parameters: not only by their type, but also by the time they typically took to escalate, develop and eventually finish. Summing up, crises act like processes: there is a period of stability, followed by disruption and adjustment, and subsequently, new disruptions, which follow a similar cycle. This Finnish multi-scale typology of disasters was sophisticated for its time: similar considerations figured in the American academic literature on disaster studies in the 1960s (Perry 2007, p. 8).

But the change was not only academic according to the experts themselves. According to the official history of the organization that is responsible for security supply, national security had now opened up to the needs of civil society (Seppinen 1996, p. 94). Preparedness practice used to be highly secretive: according to one expert, it was encouraged that preparedness plans by electricity utilities be kept in a safe because crisis was an event that might always escalate to a war. The new security practice proposed in this section, however, concerned more than such a military preparedness. As another expert explained, it might be best characterized as continuity planning: "this simply means that different situations have been thought about, regarding how we act if this

Type of crisis	Preliminary stage	Crisis	Recovery
Major accident	-	-	-
Economic crisis	0.5 - 1 months	12 months	3 months
Threat of war	0.5 - 1 months	12 months	3 months
Military attack (including 6 months of total blockage of foreign trade)	0.5 - 1 months	3 months	3 months

Table 2: A Finnish crisis typology in security of supply, first implemented in 1978 (Seppinen 1996, pp. 90-92).

or that happens, if influenza sickens the majority of your personnel, then how will you act, and how do you keep the wheel turning."

Continuity is a grave concern of businesses in all conditions. Influenzas, and other incidents can happen all the time, not merely when a military power strikes. These are civil and not military *problems*. But it is important to add that the crisis management *techniques* themselves were not 'demilitarized'. Rather, the critical security experts took risk techniques from military security, and redeployed them in the civil crisis management context. Closely parallel events may also be seen in the US: techniques like evacuation planning, and training emergency responders stem from the military, although they may be applied to natural disasters, energy shortages, infrastructure failures, and humanitarian emergencies (Collier & Lakoff 2008). We will see how such redeployments have diffused in Finland in the following section.

2.3 Towards critical infrastructure protection and vital functions security

As a practical matter, the systems, and provisions which are part of society's security of provision cannot be safeguarded before they are defined. In 1984, Finland's first outline of basic provision systems was produced (Table 3 on page 11). The Finnish National Emergency Supply Agency was established in 1992 and became responsible for securing 'indispensable' economic activities like the above. Storage security also became one part of emergency supply: the first Security of Supply Act (1992) incorporated the previous Legislation on State Security Storages (1958). Today, both terms *security of supply*, and *storage security* are rather eclectic and rarely used in everyday language. But I would claim that their underlying ideas and tensions have stayed markedly influential when we start to consider more recent developments in infrastructure security.

Provision, *huolto*, figured in the ways that energy experts of my study talked about what they supply. Electricity appeared more than a technology or even a technical

infrastructure. One expert said:

> I have taken electricity as a natural trait of a modern society. Electricity is very much a factor in that the society even stays together. It's a little like the education system or health care, energy belongs structurally to the society.

The likening of energy to education, and health care may sound somewhat dubious. But in one sense it is understandable: in the style of reasoning of society's basic provisions, outlined above. Indeed a number of experts implied to me that energy is a provision, and not merely any market commodity.

Today it is more common to talk about the security and protection of infrastructures than about a provision, supply or a storage (e.g. Dunn Cavelty 2008; European Council

2008; Brunner & Suter 2009; US Department of Homeland Security 2009). In 2002, also the Finnish government produced its first list of 'critical infrastructure sectors'. Viewed alongside the list of basic supply systems (Table 3), it is clear that the lists have similarities. More than half of the sectors in the 2002 list have counterparts in the 1984 list. The only notable change is that the newer list is that it was more technical. It drew on the words *networks* and *systems*: for example, the list included energy networks (rather than just energy supply); telecommunication networks (rather than just communications); and payment systems (rather than just finance). The critical infrastructures in this were less a 'supply', more a networked technological system. It may even be that the notion of a technological infrastructure is finding more support and expanding. This would correspond with the analyses of the US infrastructure protection policy (Dunn Cavelty 2008). Yet, it is also clear that the expansion has a different character in Finland. It is not a matter of first being concerned with information and communication technologies and then extending the worry to other infrastructures. Rather, the list of provisions is extensive to begin with and is only subsequently added to with networked technical systems.

There is also a second style of reasoning that figures in the Finnish efforts to protect systems such as electricity: the protection of society's vital systems. It is more recent than security of supply, and the first official document that concerned it was released in 2003. As the name implies, vital functions security thinking is about various functions that are deemed *vital,* and according to institutional security documents, its origins are in the Finnish security and defence policy concerns for internationalization and 'new security risks' in the early 2000s.

The first official document that considered the provisions that are needed for the 'functioning of society' was released in Finland in 2003. The document was called The Strategy for Securing Functions Vital to Society (henceforth YETTS from the established Finnish acronym) and these functions were defined as those measures "whose protection is necessary for helping to maintain national sovereignty and the citizen's livelihood and security" (YETTS 2003, p. 22). Curiously, although in line with the idea that security practice is redeployed rather than reinvented, the definition is not very far from the definition of security of provision in legislation: "the economic functions and related technical systems which are indispensable for securing the livelihood of the population, the country's economy and national defence in case of serious emergencies" (Security of Supply Act 2005, 1 §). The YETTS (2003, p. 22) definition does not mention emergencies, but otherwise both texts contain almost the same elements. A look at these 'vital functions' shows again marked similarities to the 1984 list of basic provision systems: only one of the 1984 'systems', clothing, was dropped from the 2003 list of 'vital functions'.

- Management of government affairs

- International activity
- National military defence
- Internal security
- The functioning of the economy and society
- The population's income security and capability to function
- Psychological crisis tolerance

This strategy was first revised in 2006 and then in 2010. Most of the vital functions remained unaltered in 2006, however one of the 2003 vital functions "functioning of the economy and society" was changed to "functioning of the economy and infrastructure". Furthermore, infrastructures received a formal definition which they lacked in the 2003 strategy; this was "the technical structures and organizations which are necessary to provide a livelihood for the population and for the functioning of society" (YETTS 2006, p. 16). In 2010, the name of the strategy was changed to the *Security Strategy for Society*, but the list of the vital functions remained the same as in 2006, although some terms were changed, in particular "national military defence" became "Finland's defence capability" while "psychological crisis tolerance" is now "psychological resilience to crisis".

Summing up, the list of society's vital functions has expanded, yet the idea that there are basic provisions in society that can be identified is not new as such. The same also seems to apply to many of the points made by the new Finnish strategies on vital functions and societal security. For example, new Finnish national security strategies problematize complex infrastructural interdependencies, especially starting from the 2006 strategy. Particular attention is paid to the reliance on electricity, as in this passage from 2006: "A new focus area, exemplifying the growing dependency on technology, is the security of energy supply. It is a fundamental prerequisite for the systems to function in the information society." (YETTS 2006, p. 45) Yet, it is rather easy to see parallels to the 1970s considerations for computerization and electricity dependence here. 1970s banking, industrial processes and daily commerce already depended on automation, electric lighting and cooling to function reliably and as Table 3 showed, many of these more general systems were themselves considered society's basic 'supply'.

Each Finnish strategy on vital systems outlines different threat scenarios regarding society's vital functions – there are ten scenarios in 2003, nine in 2006, and thirteen scenarios in 2010 – ranging from disturbances in the electricity grid to natural disasters, terrorism, illegal immigration, and the use of military force. The strategy from 2006 also highlights the diversity with an image in Figure 4. The image displays the interrelationship between a risk, and threat analysis and the resources of the actors that

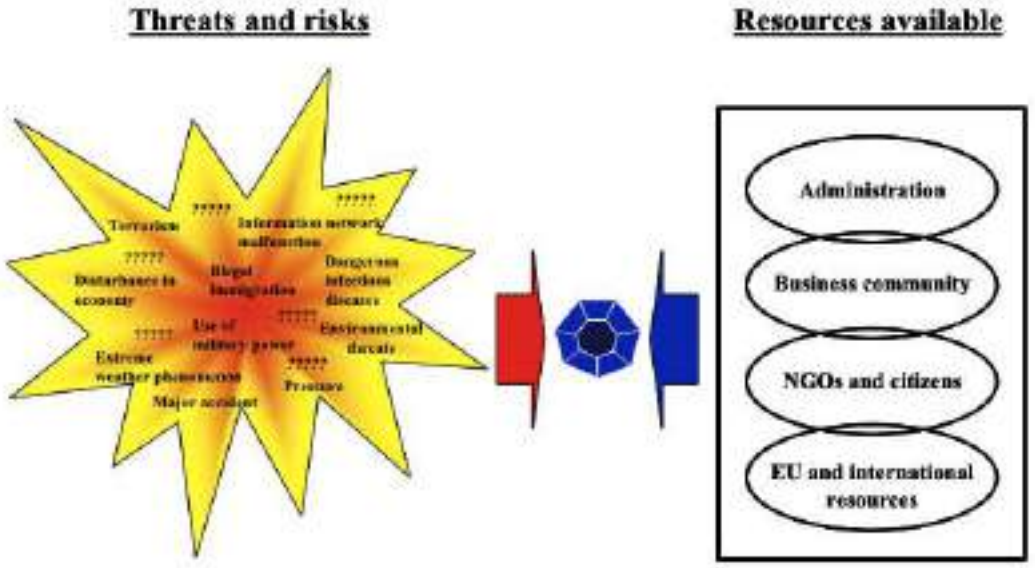

Figure 4: A Finnish analysis of threats and risks from a national security strategy (YETTS 2006, p. 22). Question marks represent still unknown threats and risks.

are concerned with the risks, and threats. Strategy is represented by the symbol in the middle, mediating between the resources, and what seems like a very diverse notion of threats and risks indeed. Inside the explosion on the left, there are various threats, such as illegal immigration, information network malfunction and pressure. Even more visible, however, are the multiple question marks. It is apparent here that the national security threats have become so diverse that even experts do not know what kind of events might pose a future harm.

Yet, these are not an entirely novel or original security concern. The notion of diverse Finnish crises can be traced back as far the 1950s, starting from K. A. Tapola's unconventional crisis typology and its deployment in 1978 in the context of security of provision. Even then, the idea was that national risks are different and comprise not merely states of war, but also civil contigencies such as economic crises and major accidents. The Finnish strategies from the 2000s add even more to the diversity especially by admitting that the national security threat might well be unknown (Furedi 2007), but they are still drawing on ideas and techniques which are old and already established.

On the other hand, similar charting of national risks is more widespread than just Finnish security strategies. For example, the UK government has published two *National Risk Registers* since 2008 and outlined those high-consequence risks that face the UK ranging from coastal flooding to animal disease, cyber attacks, and attacks on transport infrastructures (Figure 5). There are just two main differences between the UK picture and the Finnish picture; namely, the UK figure talks about likelihoods and

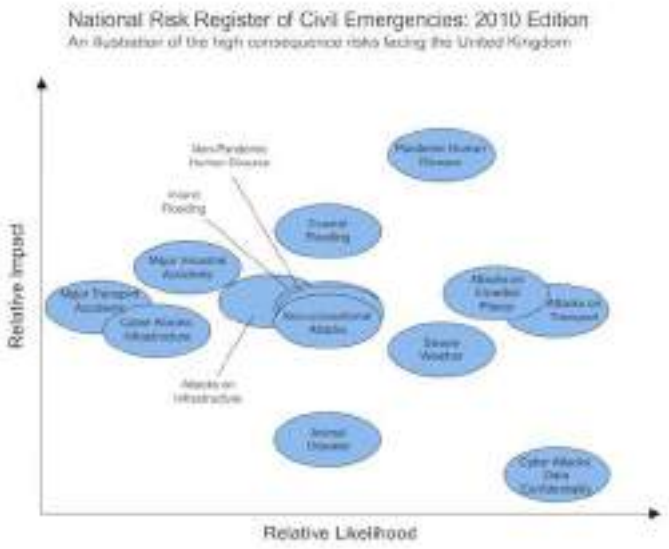

Figure 5: The UK National Risk Register (2010) from the web, or a "Risk Matrix". Estimates the relative impact and relative likelihoods of various national risks.

impacts, while the Finnish figure has no magnitudes at all, not even schematic ones, and the Finnish strategy also has question marks which are missing from the UK figure.

The energy company managers I interviewed were clearly influenced by such ways of thinking about uncertain security problems – and probably they had also influenced this thinking back. Many emphasized that disturbances to electricity supply come as surprises to them, that electricity blackouts are inevitable, and that there are threats whose impacts are even unknown: "if many large energy plants disconnect from the network due to an error, no-one knows if we can manage it or not". When prompted about a major electricity transmission failure in Finland, the same manager told me "everything is possible. I'd rather use the term it is not very probable." Another's interest was not with financial effects of risks, but with something much more serious: "Major blackouts are rare, but still possible, and if they occur, lacking preparedness and anticipation could mean that we shall really see deaths." These risks are not altogether calculative but they still have grave consequences.

2.4 Results

A tentative summary of the history of infrastructure problematizations is presented in Figure 6. It displays how concerns for basic provisions were first made official in the government initiatives for economic defence planning in 1929. During the Second

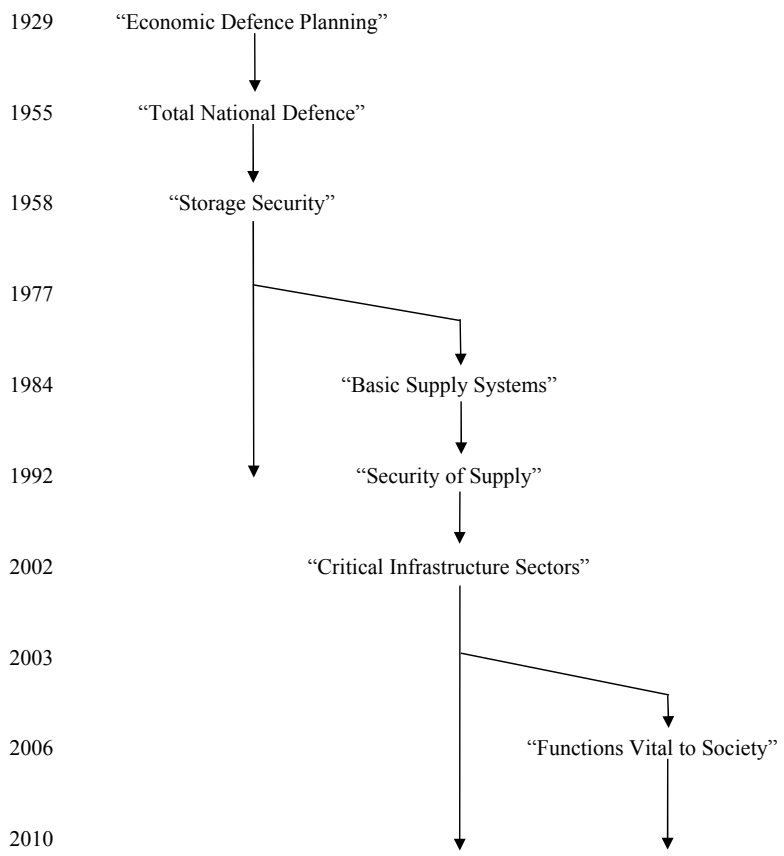

Figure 6: The emergence of infrastructural crisis preparedness in Finland.

World War, the concerns for security were narrowed down, and after the war, preparedness of the civil sector was impossible for political reasons. In 1955, a less tense security environment meant that infrastructure problems could be put back on the political agenda. Such problems included concerns with the total national defence, later exemplified by concrete efforts to secure a storage and self-reliance should foreign exports be blocked. In the 1970s, critical arguments were raised, however, on the types of threats that had been and could be imagined in the context of total national defence. Critical security experts wanted to address security of supply, which was not merely a matter of storage, but also of securing various 'provisions' (such as energy, transport, food, finance, government) continuously. In 1992, security of supply received its own legislation and organization, namely the National Emergency Supply Agency. This new legislation also incorporated the previous practices of storage security. The Finnish government produced its first list of critical infrastructures in 2002, and it published three strategies on the securing of the functions vital to society in 2003, 2006 and

2010. These new strategies show clear continuation to the older concerns for national emergencies, but especially the 2006 strategy started to develop the response to risk in a novel direction with respects to the role of calculations in risk management.

3 Conclusions

Three key conclusions emerge from the results. Firstly, although national security discourse often raises highly novel security problems of the last ten years – such as technological development and globalization (Puolustusministeriö 2008) – the styles of reasoning about security risks also clearly draw on old styles of reasoning. Security expertise gains shape from the already existing expertise, and has been reinvented little by little rather than facing a complete transition. Such connections and continuities are indeed highly contrary to the considerations of national security debates, and also to the popular social scientific discussions where risk is often an 'epochal' concept that signifies dramatic global shifts in all societies everywhere (Beck 1992; Furedi 2007; cf. Collier 2008).

Secondly, the tension between *storage* and *supply* might also be rather convenient in making sense of the security of provisions other than electricity. In the banking sector, for example, vulnerabilities are highly topical due to the financial crisis that started in 2007 (Langley 2011). In the 19th and early 20th centuries, the value of money was relative to the gold standard, and the amount of money that circulated was hence directly relative to the national storage of gold. Such a situation makes national storage security a highly topical concern. More recently, especially after the US dollar was detached from the gold standard in 1971, the problem has changed. The banking sector should be able to provide loans and credits continuously, somewhat regardless of the storage of gold or money by different countries. Maybe banking might now be increasingly considered an *infrastructural system*, and its security of provision is a central concern. The recent bank stress tests deployed after the financial crisis do not just calculate the magnitude of stored money, but try to identify vulnerabilities in the banking system and attempt to generate trust and hope into the continuous functioning of the markets (Langley 2011). Future research might pay even more attention to the figurations of these kinds of 'infrastructural' modes of security thinking on various domains like information technology, logistics and food supply.

As a third conclusion, such investigations might pay particular attention to the calculations that mitigate risk. Storage security was altogether a calculative logic: the national security threat was already known (it was always a military attack) and the vulnerability of society's basic provisions could be mitigated by calculating how long raw resources would last in case of an attack and blockage of foreign trade. Security of supply shifted towards greater uncertainty about the nature of potential crises, yet, it also emphasized

that the level of security of supply and the duration of infrastructural crises in Finland should be calculated. The newest security practice – *vital functions thinking* – is in fact the direct opposite. It draws on almost no calculations at all and tries instead to imagine worst-case scenarios and teach responsibilities to the actors that might face these scenarios.

Yet, at the same time, the vital functions strategies do also measure risk if one understands risk not as a numerical method per se, but as a technique that determines the impacts of future unwanted events. As new research on the precautionary principle (Ewald 2002) and governing of uncertainty (O'Malley 2004) has pointed out, future harms cannot always be calculated. They can also be imagined and governed through innovative techniques such as precaution, prudence, foresight and rules of thumb (O'Malley 2004). Rather than dismissing the Finnish security experts and claiming that they are exaggerating threats and 'inviting' catastrophes (Furedi 2007), it is in fact plausible that these experts are charting these "unknowns" and developing new ways of dealing with them.

A SUSTAINABLE RURAL URBANIZATION IN CHINA THROUGH THE ANALYSIS OF ITS ENVIRONMENTAL ISSUES AND ENERGY RESOURCES

Valentina Rocca [1]

Abstract

After a research experience in China, this paper offers a perspective on the potential of Chinese rural areas, exploring the main resources and their current management. Investigating the contemporary landscape transformations, the paper intends to introduce the concept of natural countryside as multifunctional system, as preferred way out from a tendency of degradations and abandonment of the rural lands.
What is happening in rural China and what perspectives and challenges will we face in the incoming years? What is the role of agriculture in the environmental dynamics for a better rural development? What does urbanization mean in these lands?
Starting from effectively facing out today's China problems, the analysis aims at catching what we can learn from qualitative changes through the exploration of the complex relationships among rural/peripheral territories and its main resources.
In this perspective, the goal to reach is twofold: on the one hand, to carry out an analysis of environmental issues, such as sustainable agriculture, focusing on new ecological agriculture systems; on the other hand, to deepen matters such are energy-valorisation of biomass production, as well as the effective development of renewable technologies.
The development of China's rural areas is severely linked with the new development perspectives that are focussed on the capacity of local territorial issues to be re-oriented towards the organisation of social and economic life and needs. Is it possible to realize new rural eco-villages and self-sufficient farms in China, able to survive only using renewable energies as primary sources?
Good practises and case studies have been proposed with the intention of communicate the real possibility to design from an ecological point of view, to help China to make the correct policy choices, preserving the identity of rural areas.
To this purpose, current status and future outlooks have been considered: the output of this research wants to establish a starting point for developing methodologies on rational management of local resources in China's rural areas through a sustainable planning process.

1. Introduction

[1] Ph.D Candidate, Department of Territorial Planning, University of Calabria, Rende (Cosenza), Italy
vrocca@unical.it

Currently, rural areas seem to be in trouble in every part of the world, especially in those countries where natural surroundings are not favourable for agricultural production and policy proceedings have not shaped protected economic settings. In Asia, the differences between the rural and urban world are creating a lot of social, ecological and economic difficulties, due to out-migration of young people, climate change, and increasing cultural and social isolation. China is the country with the highest percentage of worldwide urbanization, a process that is sharpening social and energy problems in rural areas.
What are the sustainable solutions for the rural population?
A strong action plan might be the only way to achieve a sustainable model and develop rational projects for rural areas.
China is striving hard to develop a sustainable urbanization, improve a modern and efficient agriculture and promote energy saving. As a matter of fact, a sustainable use of local resources should permit to protect the natural environment: ecological agriculture represents one of the potential alternatives to conventional agriculture and the biomass sector is identified as the main source of economic and social improvement.

2. What does *urbanization* mean in rural China?

Usually, the term urbanization indicates the expansion of urban areas as a result of the migration of the agricultural population. "Urbanizing" means to apply a method to reduce rural-urban disparities and permit the transition to a market economy by balancing productivity in both urban/rural agro-economical sectors.
The process of urbanisation in China is strictly linked to the typology of the territory, often transformed without any rule, especially in rural areas. It seems to be a very complicated phenomenon: new neighbourhoods and cities are emerging in every part of the country.

Fig. 1: An anonymous rural village in Pinghu, Zhejiang (Source: Ming Shang)

A very large number of farmers have lost their sustenance and the expansion of big cities has deprived peasants of their lands, leaving them without any jobs and with no compensation to cover their losses. According to the statistics of World Bank, from 2010 the number of rural residents in China is about 670 million: 50.32% of China's population lives in rural areas and most of them in the central and western parts. Today, the current structure of millions of small farms is not competitive; it is clear that there is the need of a consolidation into larger farms for a more efficient use of inputs.

Which direction will China's rural development follow?

The Chinese government has set a series of strategies regarding ecological development, with sustainable agricultural choices, to promote the economy and environment, but also to conceive new sustainable urbanizations in rural reality. Primarily, it has been currently implementing three types of different measures: promoting large-scale infrastructure projects, such as east-west railways, water reservoirs and electrification projects; introducing regulamentations that protect rural areas, favouring a handling of rural-urban migration of household registration; developing new sustainable projects to preserve nature and human life.

Fig. 2: The Chinese *kang* is a traditional combined brick platforms, used in rural areas: it consists of a stove, a *kang* body (similar to a bed) and a chimney. It allows at least four different home functions of cooking, bed, domestic heating and ventilation, integrated into one system. (Source: Ming Shang)

Regarding the latter, at the moment, there are more than 500 eco-agricultural counties in China, with eco-agriculture demonstration zones. From 2005, the Chinese government has dispensed over 700 million Yuan to build dry farming and to plan water-saving agriculture demonstrations in arid territories, with the aid of agronomic and biological measures.

Looking for new sustainable solutions for rural development, China intends to turn to all the abundant renewable energy sources and territories of unproductive lands; the attention would also emphasize the research of new promising technologies. First of all, it might be significant to distribute advanced energy-saving stoves, improve the *kang* system (Fig. 2) and heating systems for cooking/heating and then, will be crucial to improve energy efficiency.
The rural urbanization in China might be divided into different subsystems: the first one should regard all the rural production aspects and the quality of life; the second one should be addressed to an improvement of the biomass sector and the bio-energy factory. In other words, to build a social and ecological environment with the aim of promoting the development of renewable energy.

3. Current energy situation in China's rural areas

As the biggest agricultural countries, China's arable land is a precious resource for its development. All suitable to agriculture, mountains and dry grasslands give shape the country, but often they are covered by new cities and constructions.
Also, natural disasters, soil erosion and pollution problems are changing the identity of these lands. Many factors influence the rural structure, such as economy, society, climate, culture and local energy sources: they are different for each region, due to the complexity of its geography and social economy.
In particular, an evident dissimilarity subsists between northern and southern China: the northern regions have the longer cold season, a fragile environment and the poorest economic status, but the soils are fertile and the biomass resources are copious. Heating energy consumption depends mainly on straw, firewood and coal.

3.1 Agricultural system and its residues

Since 1978, rural development in China has been an unprecedented success. In two decades, the agricultural productivity has exploded and the number of rural poor decreased by millions. But China continues to have some serious problems due to urban expansion: most of the fertile lands are located around the population centers, used for expanding settlements, roads and railways, as well as industrial and business compounds.
Between 1988 and 1995, the croplands have been converted into fishponds, forest plantations and horticulture land. Looking for new skills and best practices to preserve agriculture seems necessary to pursue an efficient policy for the national food security. In thousands of years of traditional agricultural cultivation, Chinese farmers have developed various agricultural techniques, contributing to the maintenance of soil fertility.
The Taoism philosophy has indicated the importance to follow earth's basic needs to achieve the food supply and besides that keeping agro-ecosystem process intact. According with principles of balance between humans and nature, traditional agricultural practices were ecologically sustainable and adapted to high population densities in every part of the country. From 1949 to 1979, the Chinese government carried out a series of agricultural reforms, replacing traditional practices with new

technologies measures; influenced by the Soviet model, the Western practices of industrialised agriculture demonstrated their limitations.
In the last decades, China has increased crop production for food directed to 1.338 billion of people, with only 6.5% of the world's arable land. In this scenario, new goals have to be reached, such are: protecting natural resources and the environment, coordinating needs of the agro and socio-economic systems, minimizing the environmental impact, facilitating the recycling of agricultural resources into biomass, and promoting the exploration of alternative practices. This vision has been promoted by a new agricultural production system, the Chinese ecological agriculture. The system is described as a unique body and a result of different factors such as natural environment, agricultural practises and technologies, ecological integrity, and biodiversity. In this perspective, making a good use of agricultural residues may be important in relieving energy pressure.

Fig. 3: Agricultural by-products, such as the corncob, are easy to collect and they are good raw materials to use as a new energy. (Source: Ming Shang)

The Chinese ecological movement in agriculture started with the review of the environmental impacts of conventional agricultural practices and the limitations of traditional agriculture in providing enough food to a growing population.
It offers a good opportunity to help alleviate poverty and solve the needs of many people, to establish ecological balance.
Since a universal plan for sustainability does not exist, the development of ecological agriculture requires a farmer participation strategy and a high sensitivity to local socio-cultural values. In this sense, the economic feasibility, social effects and institutional capacity of ecological agriculture in relation to the environment and rural development need to be further explored.

In most parts of China, agricultural technologies and management practices are still far from the concept of "precision" agriculture, so popular in Europe also as an indispensible strategy to control the territory.

3.2 Biomass vs. coal

Closely related to the urban sprawl, the unsustainable consumption of energy is causing the increase of environmental pollution. Indeed, fossil resources, especially coal but also natural gas and oil, guarantee most of the energy produced in China. For these not-contained uses, this big country has today a distinctive responsibility towards the entire world, mainly considering the global climate change and huge CO_2 emissions.

Fig. 4: Store of agricultural residues for cooking and heating (Source: Ming Shang)

In this very moment, China has the richest biomass sources, including primary biomass from agriculture, forestry and aquatic resources. The proportion of traditional biomass energy consumption to total energy consumption decreased from 56% in 1996 to 47% in 2005.
In the last years, renewable energy has rapidly developed in China: energy-saving measures, such as energy-saving stoves and *kang* have achieved great advancements too. Both played an important role in ameliorating the rural household energy supply and improving energy efficiency in rural areas.
What to do in rural/urban China to reduce the environmental pollution?
Coal, dung, firewood or charcoal are the main sources of energy for rural areas' inhabitants. Sufficient attention must be paid on the biomass sector because of its carbon neutral character: in fact, the bio-energy represents a renewable energy produced from all kinds of biomass with energy value as raw materials. Biomass energy is considered to be a clean energy resource because of the amount of contaminant materials. As soon as rural life improves, the demand for clean and

convenient energy increases.
The utilization of bio-energy can substitute the current fossil energy with the agricultural residues as an important component, successful for energy-saving and emission reduction in China. Biomass energy should become the major component in the future energy system; reminding us of the importance and respect for Mother Earth, the urbanism practices have to result from real sustainable principles.
As the largest country in coal production (and utilisation), the Chinese government has thought about ecological projects that should consist in the utilization of renewable energy sources: hydropower, solar, wind power, biomass and geothermal energy. From last decades, many nationwide programs have been carried out on renewable energy sources, but the use of biomass seems to be the best solution for rural problems.

Fig. 5: Circle coal bricks for domestic uses (source: Ming Shang)

Currently, 900 million of rural residents are still reliant on biomass, due to the limited supply of commercial energy: in fact, a large amount of crop straw and firewood are used as residential fuel. Some important researches on "Energy conservation and environment in Chinese rural housing" by the Department of Building Science of Tsinghua University (Beijing, R.P.C.) show that the energy consumption of the Northern China represents 56% of the total energy used in rural houses, and the 80% of energy is used for heating in winter time.
High energy consumptions are due to poor thermal performances of rural housing envelops. To improve such thermal performances, a sustainable action can be to substitute coal by carbon neutral biomass pellets, as well as to apply passive energy methods on building constructions.
Coal, dung, firewood or charcoal are the main sources of energy for rural areas' inhabitants. Sufficient attention must be paid on the biomass sector because of its

carbon neutral character: in fact, the bio-energy represents a renewable energy produced from all kinds of biomass with energy value as raw materials.
Biomass energy is considered to be a clean energy resource because of the amount of contaminant materials. As soon as rural life improves, the demand for clean and convenient energy increases. The utilization of bio-energy can substitute the current fossil energy with the agricultural residues as an important component, successful for energy-saving and emission reduction in China.
Biomass energy should become the major component in the future energy system, reminding us of the importance and respect for Mother Earth, the urbanism practices have to result from real sustainable principles.

4. Demonstration projects for a sustainable urbanization

From 2000, a collaboration between the Italian Ministry for the Environment, Land and Sea and the Ministry of the Environmental Protection of the People's Republic of China have launched a series of ambitious projects on international cooperation for the environmental protection.
About 80 projects were implemented within this framework in the field of sustainable urban planning, environmental protection in China's poorest areas, sustainable agriculture, water resources management, waste-to-energy, energy efficiency and renewable energies development. To give a reference, in Inner Mongolia a total of 100 KWp of photovoltaic energy was installed to supply power to 191 households in three different villages.

Fig. 6: "Huai Rou New Town", a project for a new eco-city in a rural area near Beijing, designed by Moa Architetture (Source: www.occhiuto.it)

This "Solar Village" was a pilot project for rural electrification through renewable sources instead of coal, concluded in 2005.
As regard bio-energy, a project in Ningxia Province was conducted with the aim of exploiting herbaceous materials, shrubs and woody plants.
Moreover, some projects of "green agriculture" were implemented in some rural

areas near Shanghai, together with other two different projects in Xinjang and Inner Mongolia (China's most depressed rural areas for desertification problem), with the final goal to test and spread the best techniques and practices for the development of sustainable agriculture.
Also, a set of environmental guidelines for a sustainable planning of suburban district was developed. "Huai Rou New Town" (Fig. 6) is one of the best examples of a master plan, addressed to 70 thousand inhabitants and located in a huge rural area closed to Beijing. This project took in consideration the importance of rural areas, as the driver for the economy of the future city. This new urbanization will maintain the identity of the historical town, following bioclimatic principles and sustainable technologies.

Fig. 7: " Wanzhuang eco-city ", a project that promotes the Chinase rural landscape, designed by Arup (source: www.arup.com)

With a focus on agriculture as a starting point, the " Wanzhuang eco-city" is a project of conservation of productive land and agricultural heritage by Arup, located halfway between Beijing and Tianjin. The rural landscape encourages the contact with nature, as a source of well-being.
The main goal of this proposal is a cluster of villages around a shared town centre, linked to the Beijing-Tianjin corridor.
The compact, mixed-use development proposed around the existing villages allows for the conservation of important productive land and agricultural heritage, the existing urban fabrics of the villages and other elements of the existing natural landscape.
The successful development of ecological and sustainable demonstration projects could help to explore new and different ways of solving China’s urban-rural gap and

to achieve harmonious urbanisation.

5. Conclusions

It could be naïve to believe that the transformation of China's rural areas, from an agricultural society into an industrial empire, would have been possible without any environmental damage. Instead of condemning China's reckless development and its consequences, we should also remember that the European natural environment was tampered by modernization, creating highly artificial landscape forms, a trend that has fortunately stopped.

In rural China, urbanization is still in progress and this action is not yet fully sustainable. We hope that China will be able to use its financial resources to remedy the ecological destructions and to conceive new eco-towns, inspiring bioclimatic principles and respecting the natural environment and human health.

It should be said that China can not use the large amount of bio-energy storage, because of limited techniques for selection and cultivation of energy plants, low bio-energy use efficiency, difficulties in collection of bio-energy materials and so on.

At the moment, China has been planning its bio-energy development strategy (2006–2015), emphasizing the desire to activate an advanced bio-energy facilities for a better use of local resources.

According to the Chinese strategy adopted for the biomass sector, a first solution could be the collection of all the wastes from agriculture, forestry and people’s life.

The requirements for a better rural development could be characterized by the following actions: improving energy efficiency using fossil energy, strengthening international cooperation and expanding energy supply sources, protecting the environment using ecological best practices.

In addition, a good setting of polices, regulations and finances should be created to grant the development of alternative energy usage in China's rural areas.

Finally, a real sustainable urbanization in China should be in line with the definition of sustainable development expressed by the UN Food and Agricultural Organization, which states that "a sustainable development is to be referred to the management and conservation of the natural resources; all the technological and institutional choices have to ensure the satisfaction of human needs, for present and future generations."

Such sustainable development has to be applied in agriculture, forestry and fisheries sectors, to preserve lands, water, plant and animal resources.

Following this significance, China is seeking to move towards a sustainable urban future, in harmony with the natural environment.

Maybe marked by futuristic buildings, these new eco-villages will be able to preserve and maintain the function of the agricultural soils and the value of surrounding areas. In this way, a sustainable urbanization in rural areas will not forget human and nature needs.

6 Acknowledgment

I am most grateful to Professor Xudong Yang for his guidance and comments

throughout a semester of research as a visiting PhD candidate at the Department of Building Science, School of Architecture, Tsinghua University (Beijing, R.P.C). However, any errors are entirely my responsibility. I also would like to thank Ming Shan for giving me his kindly permission to publish his photos in this paper.

URBAN FORM AND TRAVEL BEHAVIOUR: A MULTIPLE-FACETED ANALYSIS

Aida Pontes de Aquino [1], Aloys Borgers[2], Harry Timmermans[3]

Abstract

This paper proposes a methodology to analyse urban form characteristics in the context of research on the relationship between urban form and activity-travel behaviour. In particular, this methodology will be used to categorize neighbourhoods in the Netherlands in the context of a long-term project about the dynamic changes on activity-travel behaviour. The methodology proposes the use of four main features of the urban form: density, mixed-land use, street network, and accessibility. As a case study, we use data from different sources to apply the methodology in the Rotterdam area, in the Netherlands. Data about 15 cities is analysed in the neighbourhood level using cluster analysis. The results suggest that ten types of neighbourhoods can be used to illustrate the differences among the neighbourhoods in the study area, and that the methodology leads to sound results on such characterization.

1. Introduction

Designing cities for a more sustainable mobility relies on our understanding about if and how we can really shape the city to develop a more sustainable travel behaviour in its inhabitants. There is a common belief that the urban form affects people's travel behaviour. Because of that, the amount of research done on the relationship between the built environment and travel behaviour is vast. Notably, however, there is no common outcome about if and how the built environment is affecting the way people travel in a city.

Nevertheless, most of the research didn't consider in its analysis the complexity of cities: a great amount of the papers published on this subject limited their analysis to a single aspect of the urban form, usually density or mixed land-use, or a combination of both. Fewer studies took into account more characteristics of the city, such as the 3D's concept (density, diversity and design), and whether the street network was a grid or a cul-de-sac.

We argue that these approaches are too narrow for the subject at hand. They leave out fundamental aspects that can influence people's travel behaviour, such as features that affect the accessibility (for example, distance to public

[3] Eindhoven University of Technology, Eindhoven, the Netherlands – h.j.p.timmermans@tue.nl

transportation) and characteristics of buildings and neighbourhoods that influence how people decide where to live, which in turn influences their travel behaviour.

In this paper we propose a methodology to analyse the urban form in a broader way. Four main features of the built environment are considered: density, land use, street network, accessibility, and housing/building characteristics. This methodology is based on a detailed definition of all these features, considering, among other facets of the urban form, two types of density, a variety of land use characteristics and different measurements of the accessibility. The definition of these features at different scales of measurement (neighbourhood, postcode, and city levels) is also addressed.

For the analysis we used data from the Rotterdam region, which includes 15 cities and 565 neighbourhoods. GIS data at the neighbourhood level from the 15 different cities were combined from different sources. The data contains information about the different aspects of urban form used in the analysis. Using cluster analysis we categorized the neighbourhoods in 10 types.

This methodology will be used in the context of our research project, where we have retrospective data about 350 respondents that are living now in the Rotterdam area. This data consists of details about different residential places and activity-travel behaviour for the last 20 years of people's lives.

2. The study on urban forms

During the last decades, a large amount of research was done in the relationship between urban form and travel behaviour. In the literature there is no common definition about types of urban forms. Each study defines its own urban forms, what can complicate the job of policies makers trying to leverage their results collectively. We don't aim here to make new definitions of urban forms and or to prescribe how it should be considered in future work, we rather intend to provide a discussion about how the different aspects of urban forms have been studied and how they could be considered in future studies.

Among the existent studies in the literature, often there is no detailed information on how the urban form characteristics were analysed or acquired. Some studies consider the most commonly used definition while others create new specific definitions for their studies. Usually the studies concentrate on the following characteristics: density, mixed land-use (being these two the most common), street network and accessibility.

2.1 Density

Alongside with land use, density is one of the features of urban form most studied in the literature about the relationship between urban form and travel behaviour (Cervero, 1995; Naess, 1995; Naess and Sandberg, 1996; Krizek, 2003; Cervero and Kockelman, 1997; Boarnet and Crane, 2001; Miranda-Morena et al., 2011).

This is perhaps because density is one attribute that implicitly relates to many other characteristics of a city or region. Higher density means not only more people living in a certain area but it usually also means more diversity of urban functions, more transport infrastructure and more complex urban systems. However, there are different types of density that can be explored in an urban area, and often the literature refers only to the most common type of density: the residential gross density, which is defined by the population living in an area divided by the surface of the that area.

Besides the most used type of density, different categories of density can be calculated, notably the employment density. A main distinction that can also be made is between gross and net densities, being the first one the population divided by the whole area concerned, while the second one being the population divided by the area concerned with its use, for example residential use or employment places. Moreover, there are other measurements that can be calculated and are related to density, such as the floor area ratio and the site coverage. The floor area ratio refers to the ratio of a total floor area of development to its area, while the site coverage is a measure of the proportion of the site area covered by buildings. (see more about types of density in Jenks and Dempsey, 2005; Churchman, 1999; Alexander, 1993; Berghauser and Haupt, 2004; and Vicky Cheng, 2010).

The reflection about the different types of density is important in terms of analysis. The residential gross density, for example, gives an idea about the amount of people living in an area. However, as it considers the whole surface of the area, a low residential gross density can mean that there are few people living in the area or that there is only a small part of the area that is used as residential area. A park or shops in the area concerned might decrease the density even if the residential portion of the area is dense. In this sense, the gross density also gives a clue of the use in the area. On the other side, the net residential area can give the exact number of people living in the area concerned for its use. The floor ratio and site coverage can provide an idea of the proportion between space occupied by land and by streets.

Despite the extensive literature on the definition and types of density, the literature about the relationship between urban form and travel behaviour is mainly concentrated on the residential gross population (Maat and Timmermans, 2009; Cervero and Kockelman, 1997). Some studies combined the residential density with employment density (Maat and Timmermans, 2009; Cervero and Kockelman, 1997; and Frank and Pivo, 1994). Others calculated the household density, which means the amount of household divided by the area concerned (Krizek, 2003; Cervero and Kockelman, 1997).

2.2 Mixed Land Use

Another important feature that can indicate differences between urban areas is the mix of uses. Especially when it concerns its relationship with travel behaviour. The availability of different services and shops close to home, for example, can

influence directly how a person reaches the places needed. As a result, mixed land use is probably the most studied feature in the literature (Handy, 1996a; Handy et al., 2005; Kitamura et al., 1997; Cao et al., 2009; Cervero and Radish, 1996; Frank and Pivo, 1994; Maat et al., 2005; Mogridge, 1985; and Krizek, 2003).

The types of land use that were considered to calculate mixed land use vary widely in the literature. While some research focuses only on the difference between residential and non-residential, others take into account a variety of land uses. The common feature that is used in the literature is commercial and retail uses, with some studies detailing which types of shops are in the area. Handy (1996b), for example, took into consideration only commercial areas, examining the amount of commercial establishments per 10000 inhabitants, including laundromat, beauty salon, day-care, and others. Krizek (2003) also focused on retail use at the neighbourhood level to calculate the land use mix. Another way of calculating land use mix is the relation between residential and shopping areas (see for example Maat and Timmermans, 2009; and Cervero, 1995).

Other studies used a higher diversity of land uses to calculate mixed land use indices. Frank and Pivo (1994) calculated the level of land use mixe using an entropy value. The land uses they considered were: single family house, multifamily house, retail and services, office, entertainment, institutional, and industrial/manufacturing. Different aspects of mixed land use were examined by Cervero and Kockelman (1997): dissimilarity index, entropy, vertical mixture, intensities of land use, activity centre mixture, commercial intensities, and proximities to commercial-retail uses. These last studies are particularly interesting because they considered the proportions of different land uses in an area.

2.3 Accessibility

Measures of accessibility in the literature differ among grid cell, neighbourhood and respondent levels. The most common way of calculating accessibility in the existent literature is through the distance from different origins to different destinations, which can be residence, work, city centre and public transportation facilities.

The distance to the city centre, to the station and to the sub-centre was, for example, a measure in the study by Snellen, Borgers and Timmermans (2002). Krizek (2003) took into consideration the urban characteristics of the residential places and of the work place. To measure accessibility, he used a standard gravity model taking into consideration the total number of retail employment on a grid cell of 150m to 150m. The workplace was also the level of analysis of Naess (1995). He calculated the average commuting distance, average percentage of commuting by different transport modes, the distance between the workplace and downtown Oslo, parking facilities, and the distance from public transport stops to workplace.

Maat and Timmermans (2009) calculated accessibility according to the average distance to work, nearest train station and work railway station, using a grid cell level. Accessibility was defined by Handy (1996b) using the types of activities and where they were located in the neighbourhood. She calculated the average number of activities that could be reached in 5, 10, and 15 minutes, considering different types of stores.

et al (2005) used the access to shopping places, freeway and public transit service. The same group of researchers (Cao et al, 2010) used a higher diversity of land use types to measure the accessibility for each respondent. They calculated the distance along the street network from home to a variety of destinations. Snellen el al. (2001; 2002) analysed 19 neighbourhoods from nine different cities in the Netherlands. The following characteristics of accessibility were considered: location in relation to the city centre, location vis-à-vis the main train station, and location with respect to a services sub-centre at the district level (when present).

As much as accessibility is concerned, distance is always present in the literature. However there are some other aspects that should be a matter of concern. Distance to public transportation might be an important aspect, but also frequency of the public transportation can be decisive in choosing for the public transport. Also, the size of a shopping area can have a higher importance than its distance from home.

2.4 Street Network

Most of the studies that analysed the street network did it according to the difference between neighbourhoods based on visual inspection. Usually this difference was related to the question whether the neighbourhood had either a grid-like or a cul-de-sac street network. In a few cases, the research included networks that were a mix of these two characteristics (e.g. Crane and Crepeau, 1998; Schwanen and Mokhtarian, 2005; Boarnet and Crane, 2005; and Handy, 1996b; Krizek, 2003).

Snellen et al. (2001; 2002) analysed the street network at the city and at the neighbourhood level. Nine cities in the Netherlands were chosen according to two components of urban form: the shape of the cities, and the street network for motorized transportation. They considered the transportation network as radial, ring, (shifted) grid, or linear networks. Three dimensions of the street network were analysed by Cervero and Kockelman (1997): the street, the pedestrian and cycling provisions, and the site design. One interesting aspect of this methodology is that it considered the proportion between the blocks and different types of street. Moreover it took account of the facilities existent in the streets, such as trees, lights, and signalization.

The street network is a basic characteristic of a city that is totally related to travel behaviour. Its analyses related to the study about the relationship between urban form and travel behaviour is central. At the same time, it allows different levels of

study: varying from the shape to capacity, or from size to the urban mobility. It is once more important to bring the reflection about which characteristic of the street network influences most people's travel behaviour.

2. Proposed urban forms

The decision about the urban forms that should be considered in our project was also related to its context. We consider that during people's lives needs and constraints make people choose to live in a certain place. Not only the characteristics of their environment is taken into consideration but also the needs related to their lives, such as work or family. In this way the urban form in our project, besides having a direct effect on people's activity-travel behaviour, has the role of intermediating people's personal needs to their activity-travel behaviour.

The data collected for our project consists on retrospective data from people living in the Netherlands for the last 20 years. Although the respondents are living in the Rotterdam area during the data collection, they could have lived anywhere in the Netherlands before. Because of that we need to be able to categorize any neighbourhood in the country. Due to the big amount of neighbourhoods, we have to find a way of objectively qualifying any neighbourhood in the Netherlands.

The combination of different aspects of the urban form is especially important when the context is the Netherlands due to the similarity among the different areas within the country. Considering that, four main directions of the urban forms where identified in the literature review and combined in our project: density, land use, neighbourhood characteristics, street network and accessibility. The data needed for this analysis, as can be seen in Table 1, was collected from different sources and combined in a geographical information system.

Table 1 | Urban form characteristics

urban forms	definition	description	source
Density	Gross density	#inhabitants / surface of the neighbourhood (in km2)	Population and #dwellings: CBS Areas: CBS and BAG
	Net density	#inhabitants / residential area in the neighbourhood	
Land Use	Residential		BAG
	Shopping		
	Other functions		
	Office		
	Industry		
	Sport Center		
	Health Care		
	Gathering		
	Accommodation		
	Education		
	Mixed gathering	mixed use where its majority is gathering places	Cluster analysis
	Mixed industry	mixed use where its majority is industry buildings	
	Mixed offices	mixed use where its majority is office buildings	
	Mixed other functions	mixed use where its majority is other functions	
	Mixed residential	mixed land use where its majority is residential places	
	Mixed retail and lodging	mixed land use that is a mixe of retail and lodging	
Street network	distance to highway	distance to closest access of the highway considering the existent street network	Kadaster
Accessibility	train station	distance from centroid of the neighbourhood to closest train station	Open source
	bus stop	distance from centroid of the neighbourhood to closest bus stop	
		amount of bus stops in the neighbourhood (standardized values)	
	tram stops	distance from centroid of the neighbourhood to closest tram stop	
		amount of tram stops in the neighbourhood (standardized values)	
	subway entrance	distance from centroid of the neighbourhood to closest subway entrance	
		amount of subway entrances in the neighbourhood (standardized values)	
	distance to city center	centroid of the neighbourhood to closest area of non-daily shops	DANS
	distance to green areas	centroid of the neighbourhood to centroid closest green area	

After deciding which indices of urban form will be analysed, a region in the Netherlands was selected as a case study for our analysis. The region decided to study is the Rotterdam region, which is the second-largest urbanised area in the country. The Rotterdam area consists of 15 cities: Albrandswaard, Barendrecht, Bernisse, Brielle, Capelle aan den Ijssel, Hellevoetsluis, Krimpen aan den Ijssel, Lansingerland, Maasluis, Ridderkerk, Rotterdam, Schiedam, Spijkenisse, Vlaardingen, and Westvoorne (Figure 1). Together, these cities have 1199710 inhabitants (CBS, 2010) and it is one of the areas with the most diverse types of urban form in the Netherlands.

Figure 1 | Rotterdam area

2.1 Density

From the different types of density that were exposed in Section 1.1, we decided that the most useful ones for our project were residential gross and net densities, which would measure aspects of the distribution of the population as well as the dwellings in the studied area. The definition for these two types of density was based on Pont and Haupt (2002), and consists, for the gross density, the population of the area divided by the whole area concerned. For the net density, the population of the area is divided by the residential area.

Maps for the two densities were created. Each density was discretised in 5 levels and plotted in the maps shown in Figure 2 and Figure 3. The maps also include the agricultural, water, and green areas illustrate well the difference between urbanized and natural areas. It is also evident the concentration of higher dense areas around the city centre of Rotterdam, and other concentrations in the city center of the other cities.

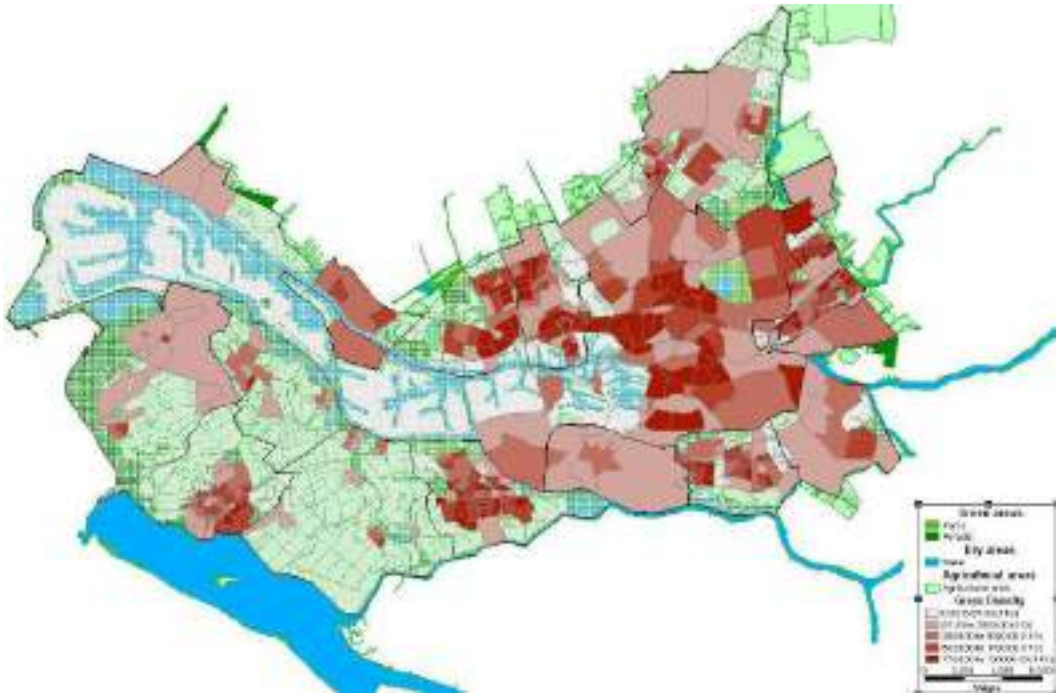

Figure 2 | Gross density in the Rotterdam area

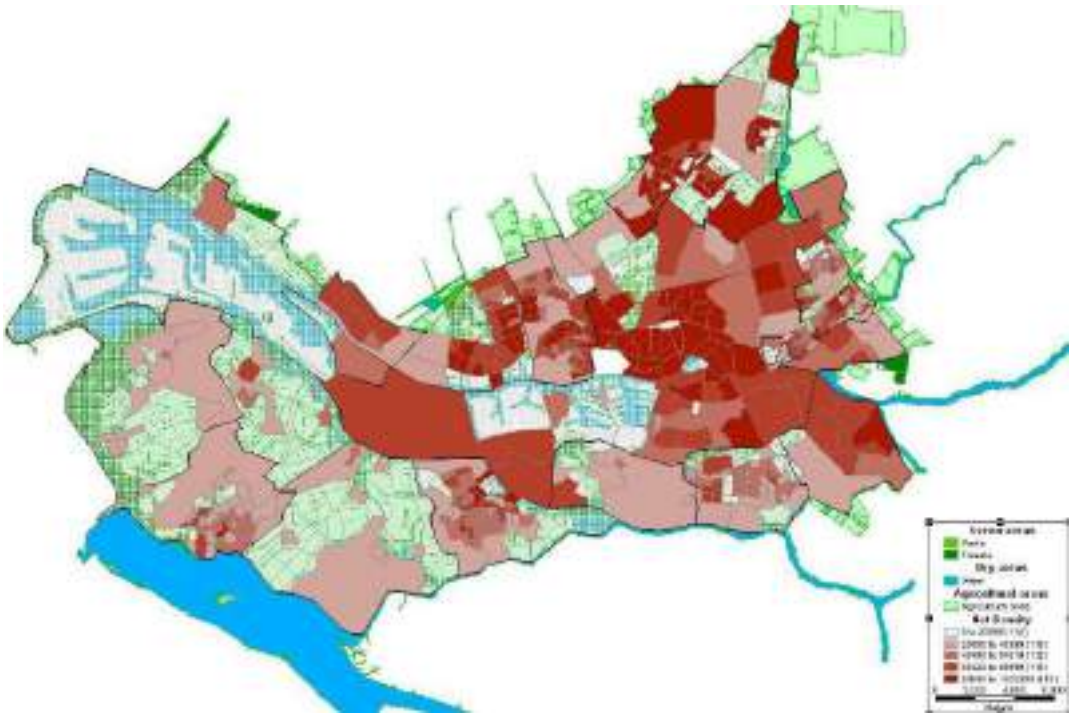

Figure 3 | Net density in the Rotterdam area

Comparing the two maps, it is apparent the influence of the size of the neighbourhood in the density: when only the residential area is considered, the

density values increase and the areas that are specific for residential purpose differ less among them when comparing to the gross density. Some neighbourhoods that appear as low density in the gross density might have more green spaces and other uses in their area, but they might still have a high density in its residential portion.

Considering the outcome distinction of the two densities. It was decided to consider in our project only the residential net density, which better demonstrates the distribution of the population in the residential areas. Green areas and other land uses are considered in the analysis of mixed land use and accessibility.

2.2 Mixed Land Use

Types of land use were taken from the BAG-database at the building level. The proportion of the different functions in the building (residential, offices, retailing, etc.) is known. However there is missing information for 39% of the buildings. Most of the buildings are solely residential (50,8%). Approximately 5% of the buildings have a mixed land use, which is the second most common land use type (see Table 3 for all functions).

The exact type of land use mixture for a building is not known from the data. This mixture must be categorized for each building so that we can later determine the mixture of land uses for the neighbourhoods, which is the level of analysis of our project. To define the categories of mixed land use that exist in our data, we used a cluster analysis to group the buildings there were identified as 'mixed land use' according to the proportion of each land use type in the buildings.

From the cluster analysis, six types of mixed land use buildings were identified: (1) mostly residential use, (2) mostly 'other functions', (3) mostly industries, mostly offices, mostly gathering, and mixture of retail and lodging. Table 2 displays the average proportion of each function in the clusters.

Table 2 | Cluster analysis at the building level

	Cluster					
	1	2	3	4	5	6
Residential	,99	,02	,04	,04	,06	,09
Retail	,00	,00	,02	,01	,01	,34
Other functions	,00	,97	,01	,02	,01	,01
Office	,00	,00	,02	,89	,01	,01
Industry	,00	,00	,91	,02	,01	,01
Sport	,00	,00	,00	,00	,01	,04
Health	,00	,00	,00	,00	,00	,05
Gathering	,00	,00	,00	,01	,89	,01
Lodging	,00	,00	,00	,00	,00	,33
Education	,00	,00	,00	,00	,01	,11

Considering the single land uses we have in total 16 types of land use. Table 3

displays the land use types at the building level in our data.

Table 3 | Land uses at the building level

Uses		Frequency	Percent
Missing		190972	39,0%
Gathering		1885	,4%
Health		358	,1%
Industry		5104	1,0%
Office		1789	,4%
Lodging		2459	,5%
Education		789	,2%
Other functions		14180	2,9%
Sport		313	,1%
Retail		1618	,3%
Residential		249198	50,8%
Mixed uses	Mostly gathering	1162	,2%
	Mostly industry	1776	,4%
	Mostly office	794	,2%
	Mostly other functions	1404	,3%
	Mostly residential	14391	2,9%
	Mixed retail and lodging	2064	,4%
Total		490256	100,0%

The different mixed uses at the building level were used as input to perform a cluster analysis at the neighbourhood level, so that we can visualize differences in neighbourhood land uses for the case study area. Neighbourhoods were clustered according to the proportion of each land use type, considering the 16 types of land use presented in Table 3. Figure 4 shows the results of this cluster analysis.

The cluster analysis at the neighbourhood level identified three main neighbourhood types: mostly residential, mostly industrial, and mixed with a large amount of residential areas. This looks a rather broad classification but it supports the idea that only one characteristic of the urban form is not ample enough to display subtle differences in urban forms. This is a rather interesting outcome for the analysis of the urban forms in the Netherlands. It demonstrates that the land use mixture doesn't gather enough difference between neighbourhoods.

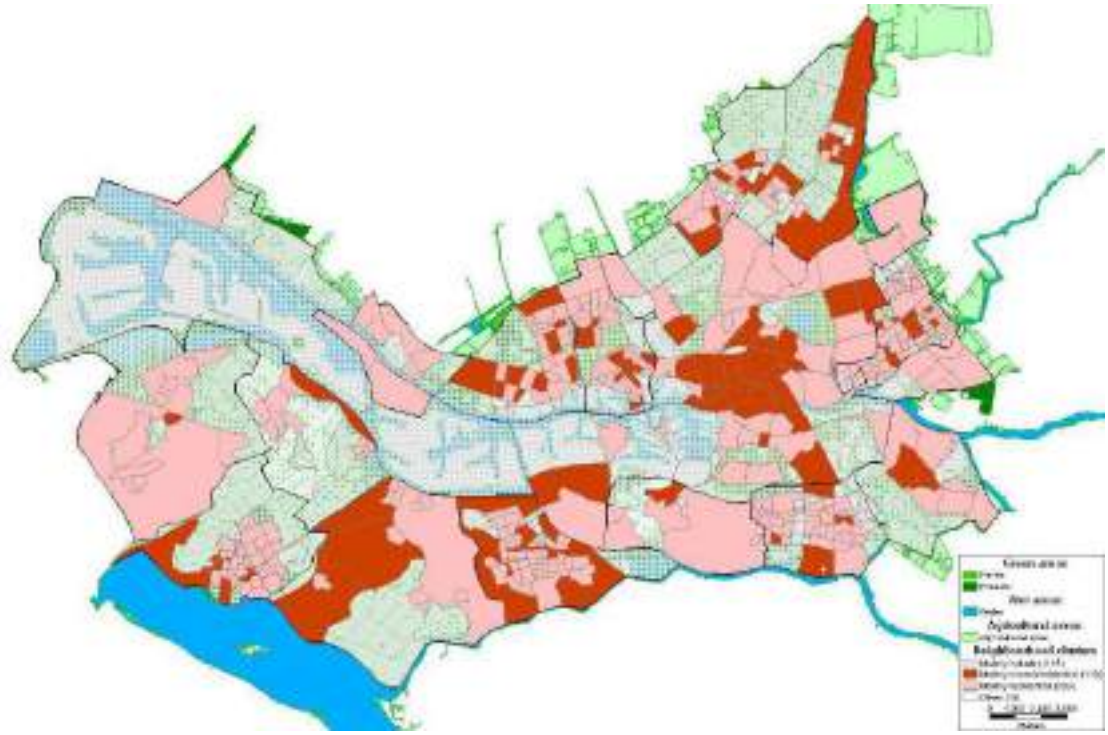

Figure 4 | Clusters at the neighbourhood level

One other interesting outcome of the neighbourhood clustering is that, comparing it with the density maps, we can see that mix of uses it not strictly related to higher density areas. This information reinforces the need of combining different features in the urban form analysis.

2.3 Street Network

Street Network is a very complex system to analyse, which might be the reason that it is analysed in diverse ways in the literature. Often the analyses are strict to visual verification, which is would not be a solution for our project because of the amount of neighbourhoods in our dataset.

For this study we decided to take into consideration the street network to calculate the distance from the neighbourhoods to the highway. We had access to the kadaster database of the motorized street network in the Netherlands. To determine the centre of the neighbourhoods we used the street node the most central. The nodes that represent the access to the highway were identified and used to calculate the distance.

2.4 Accessibility

Accessibility was calculated in terms of distance to public transportation, number of public transportation stops/stations, distance to city centre, and distance to green areas. All distances were calculating using the centroid of the neighbourhoods. For public transportation types were considered: train station, metro entrance, bus stops,

and tram stops. The distances to the different public transportations were calculated from the centroid of the neighbourhood to the closest station or stop.

To complement the calculations of the public transportation, the amount of tram stops, bus stops, train station, and metro entrances were calculated per neighbourhood. Standardized z-score values of each of these amounts were used in the analysis.

To identify the city centres we used the non-daily shopping areas that are bigger than 10000 squared meters. The distance was calculated using the centroids of both neighbourhoods and retail areas.

Different types and scales of green areas exist in our land use database, varying from parks to forests. The decision about which urban form to examine was taken in relation to the context of our project, where the distance to green areas influence the decision to move to a new place. In this sense, we decided to consider the distance to closest green areas, independently of it classification. Here also the centroids were considered.

3. Neighbourhood cluster analysis

We performed a cluster analysis using the 28 parameters that represent density, accessibility, street network, and mixed land use. Solutions with 6 to 10 clusters were analysed in detail. Among these, particularly two solutions had attractive results, those with 6 and 10 clusters.

In the 6 clusters solution it is simpler to distinguish between different neighbourhood types: there are striking differences among them. However, the lower density area of the study area was represented in one single neighbourhood type.

As for the 10 clusters solution, it is possible to identify different neighbourhood types in the lower density area. This is particularly important to be able to distinguish between the urban and rural areas of the smaller cities around the city of Rotterdam. Based on this distinction we decided that the solution with 10 clusters better describes the data. Moreover, the variance of neighbourhood types can provide a richer variation of urban forms to the analysis that will be performed with this neighbourhood classification.

We now describe the solution with 10 clusters. There are 17 neighbourhoods that could not be clustered because of missing data in one of the parameters. This issue will be taken into consideration in future analysis. Some clusters are formed by a single neighbourhood, suggesting that these neighbourhoods may be outliers in the data. The 10 clusters are described below and in Table 4, and they are represented in the map at Figure 5.

1. Mixed industrial. Neighbourhoods with a majority of 'mixed industrial' land use, and a high density. They are distant to city centre, close to green spaces, and have an average distance to highways. They have an average distance to public transportation facilities and few public transport stations/stops. This is an unusual neighbourhood type with its cluster formed by a single neighbourhood.

2. Mixed-industry suburbs. Neighbourhoods with mostly 'mixed residential' combined with other land uses, especially 'mixed-industry'. The distances to highway and the city centre are high, but the distance to public transportation facilities is average. This type of neighbourhood has a high number of public transportation stops/stations and average net density.

3. Industrial suburbs with low PT accessibility. Neighbourhoods with predominately industrial or residential land uses and distant from the city centre. They have a high accessibility to the highway. They have low public transportation accessibility and low density.

4. Residential with high PT accessibility. Neighbourhoods with low-density mainly residential land use with some mixed land uses. The distance to highway is high, to the city centre is average, and to green areas is average. They have a good accessibility to public transportation.

5. Mixed-residential highly accessible. Neighbourhoods with mostly mixed-residential land use with some offices. They are close to the highway and to public transportation facilities, but with few public transportation stations/stops. This is another single-case neighbourhood cluster.

6. Residential and central with low accessibility. Neighbourhoods with mostly ‘single residential’ and ‘mixed residential’ uses. They are distant to public transportation facilities and to highways, but close to the city centre. They have few public transportation stations/stops, and average net density.

7. Residential-office area with low accessibility. Neighbourhoods with a majority residential area with some other uses, especially office. They have high distance to public transport, to the highway, and to the city centre. They also have few public transportation stations/stops and average net density.

8. Industrial area. Neighbourhoods with a majority of ‘single industrial’ and 'mixed-industrial' land uses. They have low accessibility and a high net density.

9. Typical suburb. This cluster has characteristics of the suburbs in the first outskirts out of city: it is partially residential areas with a large amount of other mixed-land uses, in a low net density area. It is close to city centre, to green areas, and to public transportation. It has a large amount of public transportation stations/stops.

10. Residential low density. Neighbourhoods with mostly residential uses with some other mixed-land uses in a low net density area. They have average distances to city centre, green areas, and to public transportation facilities, but are close to highways.

Table 4 | Neighbourhood cluster analysis

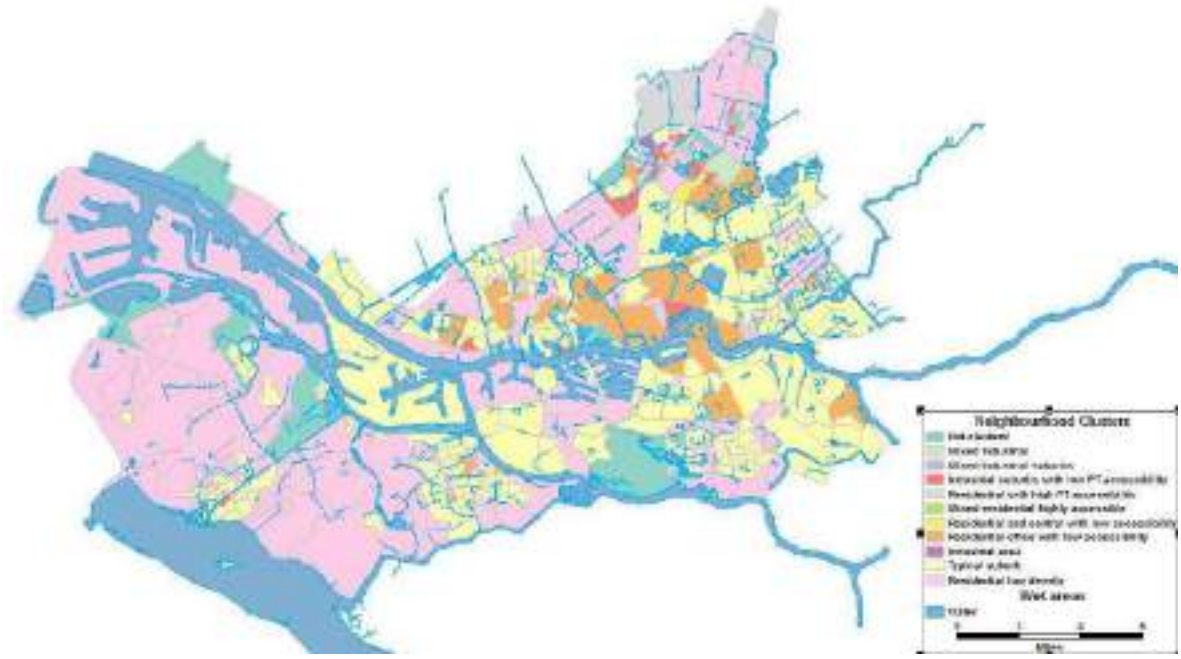

Figure 5 | Neighbourhood cluster analysis

Two regularities can be observed in the clusters. First, neighbourhoods with high density usually correspond to neighbourhoods that have a high diversity. This implies that residential areas in mixed-land use neighbourhoods are more compact and neighbourhoods with predominant residential land use are usually low net density areas. Second, we observed that there is a low variance of the distance to green areas among the neighbourhoods. This is perhaps a consequence of the attributes of green areas considered in the analysis, which does not differentiate between the type and sizes of the green areas. Such observation suggests that a more detailed distinction of green areas should be taken into consideration in the future.

4. Conclusions

This paper proposes a methodology to cluster different neighbourhoods according to their urban form characteristics. Combining data from different sources in the Netherlands, it used the Rotterdam area as a case study in the application of the methodology. Four themes of urban form were proposed together with methods to calculate them from generally available data: density, mixed-land use, street network, and accessibility.

Each feature of urban form revealed some importance in defining the final clusters. The analysis of the density displayed that, depending on the purpose of analysis, it is important to consider which density type has an impact on the results. In the context of our project, we could observe that residential net density is preferable than the residential gross density.

The mixed-land use study indicated that, in the case study of this research, there are little differences in neighbourhood types if only this characteristic is considered. Distance to highway was considered as street network parameters, and our analysis revealed it to be an important factor to capture the contrast among similar neighbourhoods. In addition, accessibility, not surprisingly, was an essential component in differentiating neighbourhoods.

The results from the cluster analysis suggest that neighbourhoods can be categorized in ten different types. This classification appears to reflect the nuances from the study area, considering at the same time density, mixed land use, street network and accessibility.

The methodology appeared to be satisfactory to categorize the neighbourhoods, particularly in the context of our project, where the neighbourhood types will be included into the analysis to each respondent. Most likely there are some refinement that must be done when incorporating it into the analysis. Nevertheless, the methodology presented here adds a new perspective on how to combine and analyse different aspect of the urban form.

THE URBAN PLANNING OF FRENCH CITIES AND THE CHALLENGE OF SUSTAINABLE TOWN PLANNING: IMPROVEMENTS AND LIMITS

Aurélie Prévost[1], Nathalie Molines[2] , Philippe Dehan[3] , Jean Bandet[4]

Abstract

This article challenges the efficiency of the French urban planning system in front of national and European legislative objectives regarding sustainable urban development. It is based on a historical analysis of the effectiveness of urban management tools. Thus, in a first part, one will show that the major problems of cities such as they exist today, namely urban sprawl and zoning by unique urban function (Williams *et al.*, 2000; Mangin, 2004) and the creation of districts in the 60 ‘s fostering social problems today, appeared in spite of the development of the urban planning system at the same time.

The awareness of these problems and the rise of the notion of sustainable development have made the practices in town planning evolve (Raffaud, 2003). "By making” the legislation “green", they have also strongly developed the rules which change the contents and forms of urban planning (Mathieu *et al.*, 2005).

Then, one needs to ask the question of the current efficiency of the documents dealing with the planning of French cities confronted to the challenges of sustainable development. After a quick presentation of the French planning system and the local plan, which is its tool at the scale of the city, the article will present, in the second part, the advantages and the difficulties encountered. It will hence to light the difficulties we have to translate in a statutory way the planning orientations. One will also highlight other problems, such as the necessity to make the local planning orientation consistent with other public policies of planning and the variety of temporalities, and the limitation of the effects of local plans … (Blanc *et al.*, 2008).

This article will also attempt to demonstrate that town planning documents, if accurately written, can be invaluable tools to improve the quality of town planning and that the limitation of its "impacts", made compulsory by the European legislation

in 2001, seems to be an extra security for the quality of the cities (Lerond *et al.*, 2003; Miller *et al.*, 2005; Alexander, 2006).
To conclude, after having presented the recent sustainable objectives of planning, by showing the improvements along with the numerous difficulties with which the planners are confronted, the article will focus on the fact that urban planning is not the only tool to be mobilized to make the sustainable city, but a necessary control lever, to be coordinated with other positive public actions, urban studies and responsible political choices.

1. Introduction

This article fits into an international context of urban development (Rogers, 2000) and studies on the quality of urban environments and resource conservation. In France, "sustainable planning" issues are increasingly present, owing to the Grenelle 1 and 2 laws (which aim to improve the awareness of the environment) and the legislative reinforcement in the assessment of plans and programmes (2001 EU directive, translated into French law in 2004).
In this context, the article questions the actual efficiency of urban planning with regard to sustainable development and the environment. To do so, it provides an analysis of the means and tools made available for the urban planning of French cities today, highlighting the improvements and limits encountered throughout the course of history.

The first section of the article shows that urban planning in France has existed for over a century, although this has not kept problems linked to social, demographic, economic and cultural factors, as well as to political decisions, from arising. Thus, history shows that planning and its developments aimed at improving urban quality have mainly been the translation of political choices, the latter being influenced by societal change.
In the meantime, global environmental issues, linked to the difficulties encountered by cities, have contributed to the emergence of global awareness, leading to the generalization of the "sustainable development" concept. Through legislation, sustainable development has also brought about changes in urban planning philosophy, as can be seen through the effects of the 2000 law on Urban Solidarity and Renewal, as well as the significant developments in urban planning practices.

The second section is focused on urban planning at the city level. Urban planning gathers all the institutional means that are implemented to try and control urban changes and city expansion. In France, such control is carried out through zoning and land use regulations at the city level. The second section shows precisely where these plans stand in the French urban planning system, the way they are linked to other planning documents and their actual impact. It also highlights the regulatory levers that the *Plan Local d'Urbanisme* (PLU) is provided with to act in favour of the environment, even though sectoral PLU efforts must be completed with other policies.

Finally, the last section deals with the assessment of these plans. This assessment, which was reinforced through EU laws in 2001, aims to curb their impact on the environment. Considering the State's level of environmental requirements, there are reasons to be optimistic about the impact of such procedures.

2. A century of urban planning hindered by uneven control of urban development

2.1 Evolution of urban planning in France

Originally, the urban planning of French cities boasted few legal instruments. It dealt with issues separately: traffic lanes and public area planning, public health, protection of heritage, management of hazardous institutions, etc.

The first significant law pertaining to town planning was the *Loi Cornudet* of 1919, in a post-war reconstruction context. This law, which stipulated "extension and improvement plans" in cities of over 10,000 inhabitants, was grounded in the values and goals of the time: health awareness and aesthetics. However, these first tools of urban planning did not produce the desired effect. After very long delays[5], only a quarter of the Cornudet plans were implemented, while a single regional project came into existence (that of the Paris region).[6]

Then, in 1958, "urban master plans" and "detailed plans"[7] were introduced. The master plan included land use zoning, dedicated spots for public facilities and protected woodland areas.
The detailed plan was a kind of "floor plan" that dealt with sectors defined in the master plan. In particular, this "floor plan" pattern was then blamed for being too rigid (the prescribed "floor plan" leaving no room during the building permit process).
Another major criticism was the lack of a global project, causing land speculation and excessive clustering. And yet, the aim of city planning, which was invented in the late 19th century according to Françoise Choay's analysis (Choay, 1965), is the management of urbanisation to help meet human needs. It was therefore essential to place regulatory town planning within a project context (Raffaud, 2003).

This was first attempted in the 1960s, when the notion of "territorial management" emerged, with the *Loi d'Orientation Foncière* (LOF) of 1967. This law (which remained in force until 2000), allowed for the creation of the *Schéma Directeur d'Aménagement et d'Urbanisme* (SDAU) and the *Plan d'Occupation des Sols* (POS), two town planning documents.

---

[5] The first plans only received final approval on the eve of World War II. See P. Merlin, L'urbanisme, Que sais-je, PUF p.65.
[6] Le coin du droit de l'urbanisme website: http://www.coin-urbanisme.org/urbanisme. J.-H. DRIARD
[7] Since urban master plans were not compulsory for all towns, additional plans also existed (for large towns or towns confronted with specific problems) and basic plans.

The SDAU is a supra local planning document that sets out development guidelines while the POS is the local document that must be compatible with SDAU guidelines. The POS includes a territorial diagnosis and statutory documents that are binding on third parties and aimed at conditioning future constructions. Two elements stand out from these documents: the desire to define a coherent territorial urban project, and the willingness to respond to previous criticism by separating the project from the regulation to improve building rights management.
These documents aim to instil a strategic vision into territorial management, both in the SDAU at the supra local level through development guidelines, and in the POS at the local level through compatibility with the SDAU. However, with the POS, the town does not have a true guidance tool. That flaw and the criticism it incurred led to a redrafting of town planning documents in 2000 with the *Schémas de Cohérence Territoriaux* (SCOT) and today's *Plans Locaux d'Urbanisme* (PLU). Thus, the *Solidarité et Renouvellement Urbains*[8] (SRU) law of 2000 deeply changed the approach to territorial planning and remains a milestone in the history of French law. If it brings a new dimension in town planning, it does so also in terms of sustainable development and environment[9].

Thus, the evolution of urban planning in France has seen the emergence of a global town project, as well as the willingness to base decisions on a more accurate and scientific analysis of the territory. Yet, the urbanisation of French cities was far from flawless in the early years of town planning, probably because changing lifestyles and economic context as well as current political decisions precede issues and planning tools, thus conditioning planning to a great extent. These changes, which recent laws have tried to mend, often caught the fledgling town planning process unprepared. Indeed, such laws as the SRU laws or the more recent Grenelle[10] laws, which have made urban planning more sustainable, seem to have been created as a response to the issues we are now going to discuss.

[8] Or "Urban Solidarity and Renewal Act »

[9] The goals of the PLU as defined by the laws pertain to urban renewal, protection of natural areas and heritage, urban quality and urban functions such as housing and environmental awareness. (According to article L121-1 of the French Town Planning Code)

[10] Since the last decree of the Grenelle 2 law was published in February 2012, we lack the required perspective to assess the actual effects of the law. Therefore, this article will mostly address the PLU in its "SRU law" version, by introducing a few major tools brought by the Grenelle 2 law.
Furthermore, it seems that this law has helped raise environmental awareness and introduced some new tools and concepts, though it has not changed significantly the form or substance of PLUs.

2.2 Urban forms facing influences

This section aims to present urban evolution in France throughout the years, in order to compare the problems that occurred with public policy decisions and the evolutions of urban planning.

As early as the 1950s, the "house" was highly acclaimed. Yet, in the beginning, the state was more inclined to favour the construction of large collective apartment blocks to try and solve the housing crisis, while structuring a building industry that was too fragmented. After an initial satisfactory reception, apartment blocks were soon blamed for their monotony, formal rigidity and defects, and lost their appeal within a very short time. This lack of intrinsic quality, combined with the fast-increasing purchasing power of working and middle classes during the post war *trente glorieuses* (thirty glorious years) led these populations to fulfil their dream by leaving these dwellings in favour of individual houses. The attractiveness of the latter has not decreased ever since (Djefal et al., 2004).

The complete transformation of French urban designs was favoured by policies (the State's in particular) that radically shifted in terms of housing strategies. After fifteen years or so of restrictive policies regarding individual houses, their attractiveness was then strengthened by the implemented policies. Thus, in 1969, Albin Chalandon, then Minister for Infrastructure and Housing, claimed he wanted to "be able to give people what they wanted" (M.Carmona quoting A.Chalendon in Paquot, 2010). To do so, he organized a contest on individual houses, with the aim of finding an inexpensive "product" for villages of 3,000 to 4,000 houses. However, the so-called "*Chalandonnettes*" brought about a number of problems. While low-value individual houses became more accessible, sub-urbanisation increased with the inherent problems of energy, commuting and space consumption. Furthermore, with urban sprawl came an additional problem that is particularly acute in France, which Éric Charmes (Füzesséry et al., 2010) calls "crumbling". The town or the village is sucked up by the city centre, which tends to sprawl, in particular through the building of housing estates. This "crumbling" is problematic in terms of coexistence between natural, agricultural and urban areas, since it increases contact between populated areas, natural areas and farms.

In industrialized countries, increased access to individual housing accelerated urban sprawl. Indeed, this phenomenon, correlated to increased access to cars from 1960 to 1985 and the appearance of numerous shopping centres and *zones d'activité* (activity areas), began in the 1960s (Mangin, 2004, Figure 1.).

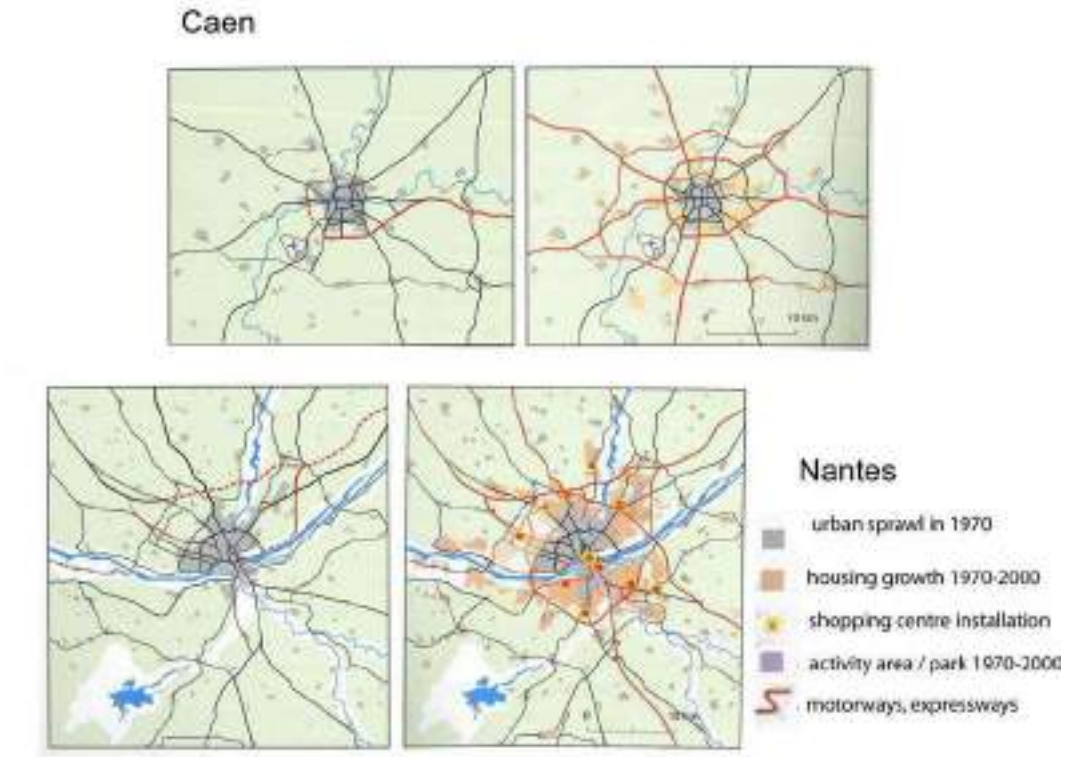

Figure 1. Concentric growth of Caen and Nantes from 1970 to 2000
Source: According to Mangin 2004 p.86, 87.

Increased access to cars, changing road networks and consumption modes are linked to evolving city structures and therefore to urban sprawl processes. Thus, we perceive that the reasons for the rapid growth of "houses" and "detached houses" in suburban areas are numerous. Such sprawl is linked to the home-owning dream, land prices, and mobility and consumption modes made easier by cars. In addition to - and as a response to - these societal levers, public policies have backed all these changes. Through this historic study of the urbanisation of French cities, we can see that public authorities and politicians have endorsed planning choices that perpetuated difficulties over 40 years, with the massive increase of detached houses and a political willingness to develop road and trade networks in favour of automobiles.

Finally, the *Loi de décentralisation* of March 2nd, 1982, was a turning point in urban planning since it entrusts competence to local authorities in planning matters – until then, it was the State's prerogative. To sum up, decentralization clearly proved beneficial for towns as it ensured localized action and strong involvement. However, it sometimes created pitfalls due to the complex planning system. Profits - whether financial or electoral - for the various actors, the quest for the collective interest and the definition of the common good that may vary from one individual to another do not always guarantee optimal planning choices.

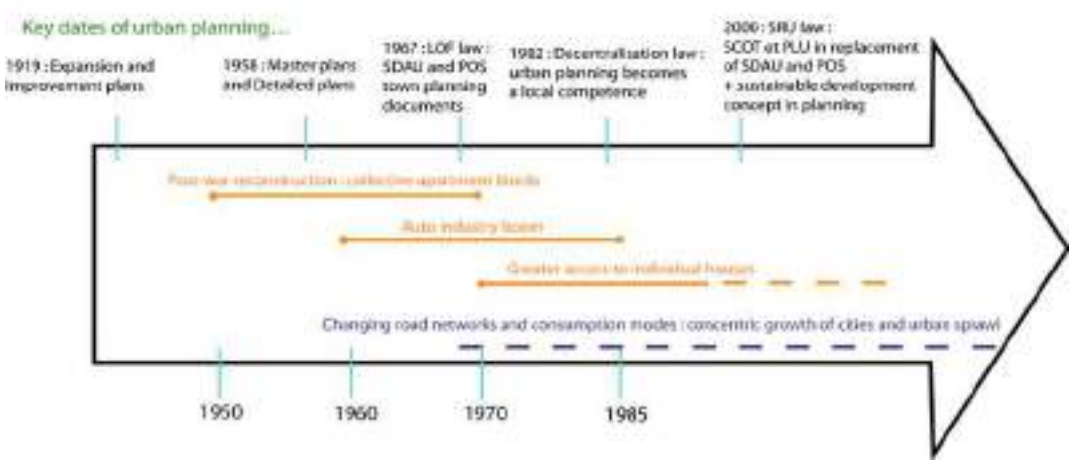

Figure 2. Evolution of urban planning and urban dynamics

Today, owing to these changes, the role of sustainable development in urban planning has become significant, as shown by the changes presented in 2.1. The next section deals more precisely with the functioning of the French planning system and the means of integrating the environmental component into city planning.

3. Local urban plans can be levers of sustainable development, provided they are coordinated with additional public policies

3.1 The role of local urban plans and their impact on the French urban planning system

From the late 1990s and the publication of the Labetoulle[11] report - a critical assessment of urban planning in the previous decade - the government has been trying to mend the errors pertaining to decentralization and the weaknesses of documents originating from the LOF law. To do so, it passed the SRU law in 2000, which changed the philosophy and structure of French urban planning.

As in the past, the current French planning system is built on two levels: the supra local and the local (of a town or of its agglomeration) levels.
The first tool at the supra local level is the *Schéma de cohérence territorial* (SCOT). This inter-municipality document allows towns or their groups of municipalities "to

[11] « L'urbanisme pour un droit plus efficace », French Council of State report, Labetoulle Commission. Documentation Francaise, May 1992.

provide coherence and coordinate policies in terms of urban planning, housing, economic development, commuting and commercial installations in a sustainable development perspective." (Goze, 2007)[12]
The broad guidelines for urban development at the supra local level contained in the SCOT were then enforced in the *Plans de Déplacements Urbains* (PDU) for cities with over 100,000 inhabitants and the *Programme Local de l'Habitat* (PLH).
PDUs aim to define the organizing principles of human and merchandise transportation, traffic and parking within urban transport perimeters in an attempt to achieve a balanced use of the different modes of transport and promote the cleanest and most energy-efficient modes.
PLHs aim to meet housing and accommodation needs while favouring urban renewal and social diversity.

At the local level, cities are provided with the *Plan Local d'Urbanisme* (PLU), which must be compatible with the SCOT and other PDUs and PLHs[13].
As for the actual content of the PLU, the SRU law of 2000 brought a new dimension to the former Plans d'Occupation des Sols (POS) by endowing them with a *Projet d'Aménagement et de Développement Durables* (PADD), which sets out territorial management priorities with a crosscutting approach (town planning, functions, commuting, environment, equipment, etc.). In order to be consistent with identified dynamics, strengths and weaknesses, the PADD is based on a territorial diagnosis. The development guidelines set out in the PADD are then translated into the PLU regulations, which condition future construction in terms of land occupation, volume and layout. Local territory zoning makes it possible to adapt the rules dictated by the general urban structure and space characteristics. Thus, the PLU regulations condition building rights (setting up, volume, outdoor areas) and space organisation (function, land reserves for equipment, etc.), while making sure that the PADD local objectives and PLU general objectives defined by the laws are respected. These general objectives apply to urban renewal, the preservation of natural areas and heritage, urban quality and urban functions such as housing and environmental awareness.

In their current form, these regulations are very often blamed for one aspect: they are regarded as extremely complex, either in expression (legal regulations that may be difficult for citizens to grasp), or in rule interaction that sometimes makes their consequences in terms of buildings and urban landscape difficult to anticipate. For each plan area, there are 16 articles available to restrict destination, aspect, installation, volume, surroundings and connection to future buildings, but only 2 are mandatory: those which condition installation in relation to the road and to

[12] GOZE, M. 2007. "Schéma de cohérence territoriale" Les outils de l'aménagement, http://www.outil2amenagement.certu.developpementdurable.gouv.fr/rubrique.php3?id_rubrique=41 website
[13] There are also "*cartes communales*", very simplified document adapted to municipalities with no land pressure or need for requalification of public spaces for instance. As soon as town planning becomes a true local issue, the low building impact of these "maps" (the National Master plan Regulation is applied) may encourage the drafting of a PLU.

boundaries. However, all PLUs use at least ten of them in order to control development as much as possible. That difficulty in reading regulations and grasping their impact is increased by the ever-changing city itself. The French government claimed it wished to simplify urban documents. If this reform becomes reality, one may wonder about the "right" form to give to these documents, the right balance between constraint and freedom, and the complexity of their future use.

The function of regulations is to translate the highly crosscutting guidelines of the PADD on a regulatory basis, the PADD being merely the political project for the city, while taking supra local prescriptions and legislative objectives into account. However, it is clear that the scope of regulations - building rights, urban functions, zoning and spatial organisation – does not systematically allow an extensive translation of all political challenges that may be set out in the PADD. The PADD either goes beyond the scope of the PLU (willingness to stand for political actions that exceed the scope of the PLU), or the complex PADD guidelines require regulatory decisions (see next section). Thus, some guidelines, like density growth in a particular zone or the conservation of heritage buildings, will be translated directly. Others will be addressed less directly through regulatory tools with less impact, and/or the PLU, with its regulations, will mostly make sure that it does not hinder its implementation through more adequate public policy tools. The example of how environmental issues are taken into consideration in regulations will be developed in the following paragraph.

Finally, we will see in the final section of the article that PLUs should comprise elements related to project assessment faced with sustainable development and the environment.
The following paragraph presents the means made available to PLU regulations to take environmental issues into account.

3.2 PLUs can be used as a tool in favour of sustainable development and environmental protection

Throughout history, laws have become more ambitious in terms of sustainable development. The SRU and Grenelle 2 laws have defined goals for PLUs that cover all urban components in terms of housing, functional and social diversity, equipment, but also the environment. However, it seems that all of these challenges should be dealt with adequately according to the territory and its characteristics. If local authorities are willing to be ambitious in terms of sustainable development, they must fix priorities and make decisions so as to best respond to the challenges of their territory.
Within this "green" legislative framework and the political and urban context of each city, the PLU translates the political development project, and also attempts to translate other supra local policies regarding housing, commuting, trades, etc.
To achieve these goals, its regulatory scope makes it possible for the PLU to have an impact on a number of urban and environmental aspects, with varying levels of prescription and prohibition. Besides systematically defining zoning and building

regulations, the PLU can be regarded as a “tool box”, from which each town may be free to pick the most interesting one to translate a development plan in coherence with territories and laws. Moreover, some PLUs also have to take into consideration the “plans and programmes” European directive regarding the effects of plans on the environment, and prove that the chosen regulations have no impact on the environment.

We will see that the first interesting “tool” is local plan zoning, which allocates specific functions (in particular agricultural and natural ones) to some areas, and defines town planning rules (morphological ones in particular) that are related to them. The second tool directly regards the rules, either written or graphical, that can be applied.

The “zoning” of urban functions, which is designed to reduce nuisance and incompatibility between industrial activities and housing for instance, is widespread in many countries. The use of “buffer zones”, which enable the separation of nuisance sources from housing areas through green areas, is common practice. (Pearce, 2005). In France, at the local level (that of PLUs), these buffer zones exist and are mainly defined in two ways.
First, there are regulatory buffer zones around the sectors presenting a technological or natural risk, or a high level of nuisance such as airport-related sound pollution. These buffer zones have an influence on the chosen types of activity, as well as on building rights, in order to curb the density of houses in the vicinity of nuisance sources in particular. Such zones are mostly the result of State prescriptions and are transcribed as such in the PLU. These prescriptions come on top of zoning and corresponding regulations. This is the case for the *Plans de Prévention des Risques* (Risk prevention plans).

Secondly, as for noise pollution from road infrastructures and industrial activities, the towns that elaborate plans can organize zoning to protect populated areas, without being legally obliged to do so. Thus, areas dedicated to industry and commercial activities can be primarily located in the vicinity of major road networks in order to reduce their impact on populated areas. Guidelines from the building code, which are not taken into account in PLUs, strengthen this scheme as they are directly applied to the building industry.
Finally, areas where construction is no longer allowed are also dedicated to the protection of natural, agricultural and forest spaces. Green areas can also be created through land restriction tools used in PLUs.

Furthermore, the Grenelle laws have made the implementation and protection of *Trames Vertes et Bleues* (which include “ecological corridors”) compulsory. These belts may be favoured through various PLU tools, including zoning. However, it seems quite difficult today to make these belts consistent at the local level (i.e. the town level) as they are defined on a larger scale. (Cormier et al., 2010). These guidelines are recent and it will be interesting to see how PLUs try to overcome these difficulties.

As far as regulations are concerned, local plans can operate in two very different ways. They can either fit into the general everyday town planning framework by "legally" conditioning the building permits filed in the different urban areas; or these regulations act as an expression of a global project (mostly at the neighbourhood level), conducted by local authorities or within the framework of negotiated projects (Rousseaux, 2009; Burkart, 1999). Therefore, it is logical that environmental and sustainable planning efforts should be easier in a "project" town planning approach. This is also the case for the new *Orientations d'Aménagements et de Programmation* (OAP), which were introduced by the Grenelle 2 law and make it possible to define "development guidelines" for a sector that are binding on third parties in terms of accountancy. They would contribute to make town planning more flexible and more controlled at the neighbourhood level.
The various examples we are now going to present mostly apply in the case of building permits that are filed on a daily basis rather than in the case of global projects, for which PLU rules are mainly a framework that were made compatible with these projects' development plans.

The issues of urban shapes and functional diversity are widely addressed in PLUs as they meet the first purpose of local plans. Zoning and regulations allow certain urban functions to be allocated to particular areas, while prohibiting others. The buildings that are expected in each zone are conditioned by rules of height, hold, size, etc. These tools may be used to achieve the quest for a "sustainable" city morphology, even if such a notion is the subject of debate and seems closely linked to the characteristics of each territory (Williams et al., 2000).
These morphological rules, provided they are drafted properly, can have an impact on the amount of sunshine, which helps improve energy performance ratings (Prévost et al., 2011).

As far as integrated devices of renewable energy production are concerned, the recent Grenelle 2 law provides that PLU rules will no longer be allowed to oppose the installation of such equipment. This new law also provides for the possibility to impose energy performance criteria, although we do not know exactly how. Until now, the PLU could not enforce any energy regulations. However, some incentive schemes already existed and are still valuable today since they provide the possibility of increasing constructability provided an effort in favour of energy is made.

Other themes, such as the protection of heritage buildings, social diversity, rainwater management and sanitation per plot, can be found in PLUs.
All these themes may be addressed within the rules of each area in various (more or less pro-active) manners, and by using incentive measures such as derogations under specified conditions. Moreover, they may be taken into consideration as a guideline within the framework of OAPs, for instance in view of a global project at the neighbourhood level.

In this section, we have seen that local town plans in France are provided with a number of tools to integrate the environment in the management of the changing city. Furthermore, although the PLU is sometimes limited in prescription by its regulatory scope (in terms of water or biodiversity for instance), one should bear in mind that territorial management and other actions in favour of the city are also addressed by other public policies. These general interest measures are sometimes more adequate and complement the effects of the PLU. For example, within the cross-industry *Agenda 21*, which takes all sustainable and environmental dimensions into account, the French PLU could act as a lever, on such aspects as the coherence between urban planning and transport (prioritising density along public transport corridors), or the development of new forms of housing such as intermediary housing (through morphological rules).

It is clear that PLUs are provided with sustainable development and environmental tools. Indeed, if there are limits in taking the environmental component into consideration, such limits may be found elsewhere. There may be difficulties in bringing together policies that are defined at different levels, and others in translating urban guidelines on complex territories into concrete terms. This is due to the choice of rules and tools, the impact of which is not always easy to anticipate.
Eventually, there may also be a lack of political ambition in terms of sustainable development, which may result in “minimum” PLUs.

The PLU regulation is the element that is applied to buildings and equipment in concrete terms. The next section will illustrate that this component is not the only one in the PLU from which the environment may benefit. In addition to the diagnosis, the PADD and regulations, the PLU comprises elements pertaining to the environmental assessment of the project. The coming chapter will present its content, contributions and limits.

4. Environmental assessment of urban planning documents: a global approach for less impactful planning, while facing urban complexity

Since the SRU law of 2000, urban planning documents have been required to develop a more transparent approach on the protection of natural areas and resources, as well as on the limitation of pollution and nuisance within guidelines and projects. Besides defining legally consistent urban principles, these documents must include an “environmental profile”, an analysis of the Plan’s main foreseeable effects, and a presentation of the various choices made to define the PADD. Since the 2001 “plans and programmes” European directive, which was translated into French law in 2004, urban documents, including some PLUs, have had to provide reinforced environmental assessment, which sets compensation, reduction and avoidance measures for identified effects, as well as an analysis of the Plan’s effects at the end of a ten-year period following its approval (now a six-year period with the Grenelle 2 law).
This assessment is part of the strategic environmental assessment of policies, plans and programmes that precede projects (Strategic environmental assessment), and

have become common throughout the world (Lichfield, 1997). This strategic assessment can be carried out at different stages: before the process, in order to guide decisions regarding environment, during the implementation, or after the process for ex-post assessment of the plan (Lerond et al., 2003).

Significant PLUs which are not covered by a SCOT (or whose SCOT is not provided with assessment) as well as PLUs which cover an area close to or inside a Natura 2000 area[14], are subject to strengthened environmental assessment, that is under the European directive.
The State has become very strict about the quality of this assessment, especially when the area is related to a Natura 2000 site. Indeed, the State demands that all doubts concerning possible impact of the PLU on such sites be dispelled. Eventually, once the Plan has been created, the State may cancel the plan if it deems the quality of research insufficient (as with the Bouguenais PLU, which was cancelled in February 2011).

The content of the environmental assessment includes the environmental diagnosis of the area, the justification of planning choices, and the impact study. The impact study has to deal with political guidelines, urban planning rules, zoning, as well as with Natura 2000 sites and environmental themes as a whole. This accounts for its complexity since the impact of regulations is difficult to anticipate. As a result, the "impact" is sometimes defined "hypothetically", with no possible quantification. If negative impact is anticipated, the PLU must provide ways of avoiding, reducing, or compensating them[15] (ex-ante assessment).
Finally, the PLU must review its impact at the end of a six-year period following its implementation (ex-post assessment). Feedback in terms of PLU results is currently inexistent as the legislation is very recent. However, PLUs with a monitoring framework are all provided with a system of sustainable development territorial indicators, often in the form of "sets of indicators" that we may call "dashboards". This system of indicators is intended to help actors make decisions, grasp the complexity of the real world and work together (Joerin *et al.*, 2005).

One may tend to think that indicators measuring impact on sites (like Natura sites) are more specific and enable assessment of the actual impact of the PLU since they are based on precise, localized inventories. As for some thematic environmental indicators (that of a dashboard for instance), which provide a record of environmental issues (like water or air quality), from which the impact of the PLU is to be deduced, the analysis seems less direct (i.e. "hypothetically"). However, despite these few drawbacks, all these existing indicators (also in the case of impact studies) are quite useful to assess the changes in the territory and, if need be, to use the PLU or any other public policy which may be more efficient to improve the environment.

[14] "The Natura 2000 network gathers various natural sites in Europe, on land and at sea, that have been identified for the scarcity or fragility of animal and vegetal wild species, and of their habitat." (http://www.gouv.fr)
[15] "Compensation measures", within an impact study on Natura 2000 sites, are the last stage of measures to be set. They prompt the decision of higher authorities.

We have seen that the PLU is strictly controlled by the State in terms of assessment and circumscribed by law. Assessment brings greater attention to environmental issues and, while making people more aware of the crosscutting plan effects, also mobilises other more targeted and even fully dedicated public policies.
However, some limits need mentioning. The complexity of the city seems to make it impossible to precisely and thoroughly assess the impact of urban policies (hence the impact that is sometimes defined "hypothetically"). Furthermore, while modelling methods of urban phenomena are developing, no French town is currently ready to use these complex methods for assessment. The detail level of the requested assessment is often in coherence with the magnitude of the projects and the means (mostly data) available.
Finally, these environmental studies remain the responsibility of local authorities, which steer all projects, particularly those related to planning. Still, local authorities have a duty to favour major urban projects that are supported by representatives. Therefore, we are faced with a potential conflict between the obligation not to harm the environment on the one hand and political requests in terms of development on the other. As a result, the whole issue in terms of assessment is to avoid such impact while making room for development projects. It is up to the State and its competent environmental authorities to be sufficiently demanding while acting as advisors to all projects, including the PLU.

5. Conclusion

The emergence of urban problems and international awareness have brought about changes in the laws that govern French urban planning, by allowing planners to be more pro-active in terms of sustainable planning.

At the city level, PLUs, which have a number of tools available to them to incorporate environmental matters, must implement the recommendations of the SCOT. However, although laws set ambitious general goals, the use of regulatory tools varies considerably according to towns. Furthermore, it is extremely difficult to coordinate regulations that have an impact on intertwined urban themes. These are the restrictive points for handling environmental matters in PLUs.
On the other hand, all plans must provide an analysis of the likely impact through simple (under the SRU law) or strengthened (under the "*Plans et Programmes*" directive) assessment. This appears to be a real improvement in terms of environmentally-friendly planning in France.

Thus, considering what has been discussed in this article, we understand that "cautious" planning involves sensible political decisions. These decisions should be made through anticipating the maximum impact that planning may have on the various components of the city. Political guidelines should also be shared by urban actors, including among citizens (for environmental assessment, we have seen the importance of communication with government services in section 4.). Governance

and consulting are essential, lest the process should not be achieved and public policies should not be coordinated properly.

As far as urban planning is concerned, the anticipation of public policy impact accounts for a closer relationship between representatives, local authorities and the field of urban studies and research. Today, “reports” and the use of developing tools such as modelling are increasingly present before the creation of public policies and within ex-post16 assessment. A model for the complexity of urban rules itself will soon be developed (Brasebin et al., 2011).

Finally, we may hope that the next legislative and regulatory changes will help improve environmental awareness. The Grenelle 1 and 2 laws, though they have not revolutionized urban planning, have provided a number of interesting tools for PLUs, such as the development and programming guidelines, new measures in favour of coherence between urban planning and transport, the setting up of *Trames Vertes et Bleues*, etc. Within a few years’ time, we may witness a reform aimed at simplifying French urban documents, with the hope that these simplifications will allow for more incentives and innovation.

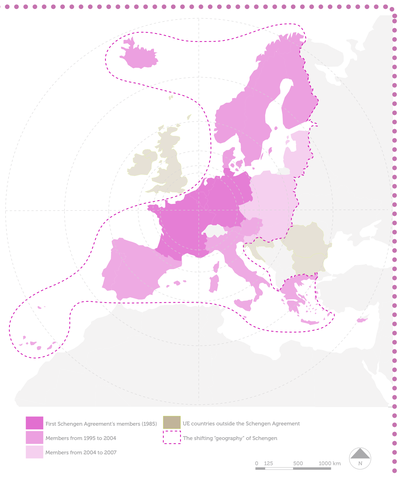
Cross-border areas in the Euro-Mediterranean context. The case of the Spanish-Moroccan region

Alice Buoli
DiAP, Politecnico di Milano, Milan (Italy)
alice.buoli@mail.polimi.it

The overlapping geographies of contemporary Europe

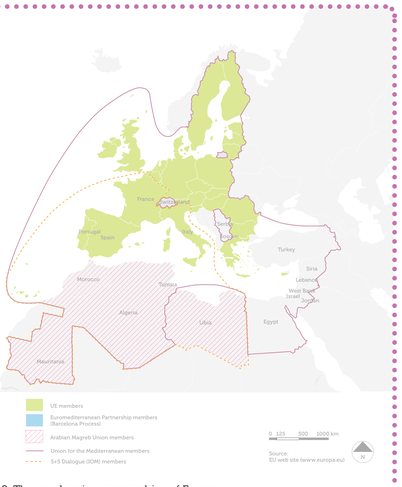
Political borders are places of conflict and encounter, counter-geographies where the main issues of our times are being performed: transnational production processes, global migration movements, gender inequities, security concerns, new colonialisms, capitalistic mechanisms.
In this context, Europe is assuming a more and more complex image, even richer than the Fortress metaphor: a **complex and multilayered geography** where different overlapping political entities, institutions and organizations operate simultaneously at different levels. An expanding nebula without defined boundaries, surrounded by **buffer zones** constantly changing.



1. The Schengen Space

The Mediterranean Border

This image is particularly relevant if we look at one of the most "sensitive" regions of the Schengen Space: the Euro-Mediterranean basin, where geographical elements, symbolical meanings, economical, social and cultural issues overlap creating a **complex fabric of relations and dynamics**.
To date, the Mediterranean can be seen as the land on which complex and contradictory relations are being played across regions and cultures overlooking its basin. In this context, Europe has taken, over the last fifteen years, a growing and crucial role, from the establishment of the Euro-mediterranean Association until the creation of the Union for the Mediterranean.



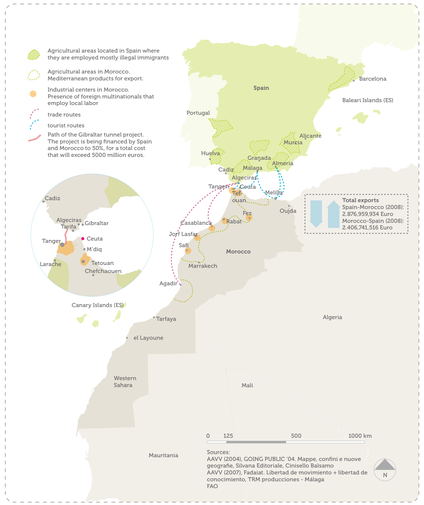
2. The overlapping geographies of Europe

Border regions as laboratories for transnational planning?

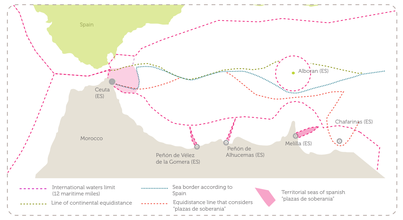
In the context of EU development programs, is it possible to consider border regions not only as sites of transnational capital production, but also as laboratories for new forms of cross-border planning cooperation in the Euro-Mediterranean region? Can we look at them as places of knowledge production and exchange for innovative tools and models of transnational governance and trans-border planning practices at different scales? What can be the role of cultural institutions, research centres and universities in this process of cooperation?

The Moroccan-Spanish border region

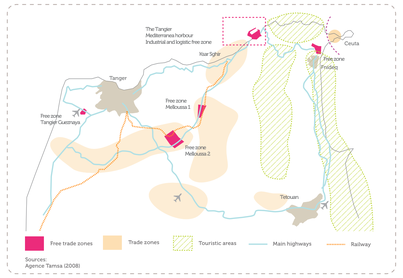
The Moroccan-Spanish region is becoming one of the most important areas in the Euro-Mediterranean Neighbourhood Policy context.
Like other cross-border areas, the northern region of Morocco has lived, in recent years, the increasing presence of multinational factories, the implantation of free trade zones, the implementation of the infrastructure networks and the construction of new production plants.
In this context, the Tanger-Med harbour will catalyse, in the next years, a huge amount of goods and financial fluxes. These are some of the direct and indirect consequences of transnational processes and of European border policies, as well, on local development programs and planning activities.
Moreover Spain and Morocco are involved in a complex relationship of cooperation and dispute on some political and economical crucial issues.



3. The economical relationships between Morocco and Spain: agricoltures areas, industrial plants and sea routes.



4. The sea-border between Spain and Morocco: disputes



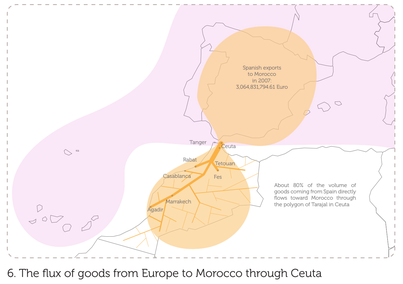
5. Develpment plans for North Morocco

For all these reasons the Spanish-Moroccan cross-border region seems to be a privileged point of observation of three main overlapping and interdependent systems:

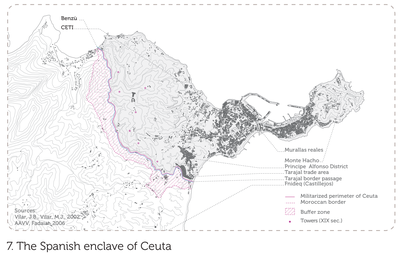
1. the international/transnational level of global market and financial dynamics;
2. the Euro-Mediterranean policies and development programs (UE/Morocco Action Plan);
3. the local spatial planning and administrative systems.

Case study: Ceuta, *the Island*

One of the most sensitive areas of the Spanish - Moroccan border is the iberian enclave of Ceuta. Being considered as part of Spain as "metropolitan territory", Ceuta is at the centre of the disputes between Morocco and Spain. Here the border materializes itself as an element of control and defense: a 8,3 kilometers militarized fence surrounds the city, in order to discourage the illegal entrance of migrants. The presence of the wall acts not only on a political level, but also symbolically as the sign of a function that the enclave had performed in the past: the defense from the "others" (the Arabs during the last four centuries, the migrants today). These spatial elements at different scales (the strait, the productive areas, the enclave and the fence) and the related fluxes (people, goods, information, money) constitute a complex spatial mechanism.



6. The flux of goods from Europe to Morocco through Ceuta



7. The Spanish enclave of Ceuta

Horizon 2020 and cross-border planning

Cross Border Cooperation (CBC) is a key priority in the EU's relations with the neighbourhood, aiming to reinforce cooperation between Member States and partner countries along the external borders of the European Union, around four key objectives: economic and social development; common challenges; efficient and secure borders; and people-to-people cooperation. The new EU Framework Programme (Horizon 2020) is going to have relevant effects on CBC and ENPI Program, particularly regarding the environmental regulation of the Mediterranean Basin. This could be the terrain on which border territories and countries can experiment forms of cooperation in environmental governance and planning.

Expected results

The research aims to set the starting "stock of knowledge" and the methodological background to answer to the research questions, looking for new approaches in the field of cross-border spatial governance and planning practices not only from an European point of view, but, above all, assuming a "south to north" knowledge transfer process.

Methodology

The research will be lead, according to the principles of empiric research, on a multidisciplinary basis: spatial planning, sociology, political studies. In this perspective the research will analyse in depth the actual Euro-Mediterranean Policies, looking at the strategic programs and plans involving the Spanish-Moroccan region. Moreover a particular attention will be addressed at the Moroccan Development programs and Planning strategies.

Acknowledgments

The starting point of the research is the MA thesis "Territori con_divisi: comunità in movimento attraverso la frontiera ispano-marocchina" discussed in 2009, Faculty of Architecture, Politecnico di Milano.
The research will be developed as PhD thesys inside the PhD Course in Territorial Design and Governance at DiAP, Politecnico di Milano.

Cosmopolitanism, Cotton and Curry in the Original Modern City

Yasminah Beebeejaun and Angela Connelly

Keywords: Cosmopolitanism, multiculturalism, community, Manchester

Abstract: This paper explores the relationship between the 'curry mile' in Manchester, England and the city's cosmopolitan narrative. It questions the relationship between the emergence of seemingly cosmopolitan city spaces and multicultural citizens. The British planning system has attempted to integrate values of multiculturalism in which social difference is recognised. This has enabled the rise of 'ethno-branding' of spaces for multicultural cities wanting to promote their diversity.

There are considerable limitations to this approach, particularly in the way that they hinder the development of ethical community relationships that recognise the deep power differences of ethnic minority groups. Current planning thought embraces diversity and difference, yet remains firmly entrenched in using ethnic lenses that essentialise difference and are myopic in the way that they give little attention to the historical connections between British cities and Empire. We want to draw upon sociological work which reminds us that 'contemporary social analysis must direct our attention to the actors and relationships that shape and respond to struggles against injustice and racism' (Glick-Schiller, 2010). We explored how has planning responded to 'difference' and to what extent does it fit with narratives of economic competitiveness?

We draw upon these insights to extend thinking about the tensions between Manchester's self-imagination as a global, entrepreneurial city with planning policies that seek to corral unruly citizens into manageable ethnic areas and subjects. The Manchester miracle is well rehearsed story on the entrepreneurialism of the Manchester men, focusing on urban planning and development (e.g. Peck & Ward, 2002; Williams, 2003). The paper argues that current planning approaches use a partial representation of ethnicity that, in this case, focused upon ethnic entrepreneurialism. The results of our research highlight a need for planning research and practice to engage with the inequalities caused by these approaches and to reassess their strategies for making local plans and engaging the local community.

Introduction

The Manchester miracle is a well-rehearsed story in the urban planning literature: one of the entrepreneurialism of the Manchester men, economic development (e.g. Peck & Ward, 2002). As the 'shock city' of the nineteenth century that drove forward the Industrial Revolution, the Manchester man became synonymous with cool, hard-headed, entrepreneurial drive and spirit (Tickell and Peck, 1996). From Victorian patriarchs down to the latter day urban elites, the city is promoted as dynamic, entrepreneurial and ready for business. The slogan to accompany the 1995 Unitary Development Framework sums it up in four words 'Manchester: Making it Happen'; an updated version of the well-known saying: 'what Manchester does today, the rest of the world does tomorrow'. Today, it has been restyled as the 'original modern' city, a concept that:

Figure 1: The Curry Mile Banner, Rusholme, Manchester, UK.

> explains Manchester's spirit, its indefatigable energy for progress and change, that 'do something' attitude, that desire to be different that always has and always will exist within the City. Original Modern is what runs through Manchester's blood and it's detectable in the best of what we do. (Marketing Manchester, 2009)

Less than 0.5 km from the University of Manchester, in a long-standing neighbourhood on the main southern gateway to the city, passengers who pause to look from the numerous buses that thunder towards the city centre can easily discern a shift in aesthetics. Moving from south to north, suburban and leafy Didsbury, the landscape gives way to the more densely packed red terracing of Rusholme with its neon street signs. This is Manchester's 'Curry Mile'. Even 20 years ago, Manchester City Council's used the area in order to attract potential new businesses to relocate to the city, describing it as:

> A slice of Asia approximately two miles from the city centre, close to the city's huge education precinct. You can take your pick from over 40 dining establishments, from cheerful and very cheap to grand, from Indian to Pakistani to Kashmiri and other speciality cuisines, your tastebuds may never recover! ... At least 40 restaurants generating £30 million of business in a growing visitor attraction for the region (Manchester City Council 1993).

Curry Mile is frequently cited as a representation of Manchester's diversity; an indication of the city's cosmopolitanism. Drawing upon a wide-range of literature from sociology, history, geography that consider various concepts of 'diaspora'; 'cosmopolitanism'; 'transnationalism', this paper examines the extent to which urban regeneration and planning practices in the city of Manchester market the consumption of difference through the ethno-branding of specific neighbourhoods. The vision of a cosmopolitan city is coterminous with globalisation and world cities. Manchester's rhetoric of entrepreneurialism sits within the concept of cosmopolitan cities as places of globalised and simplified difference. We will investigate the multiple forms of diasporic sociabilities and sensibilities (Glick Schiller et al, 2011) that contribute to a cosmopolitan city by connecting diverse diasporas both within the neighbourhood and across the city. We explore the role of businesses, community and social stakeholders, planners and regeneration professionals as they realise, subvert and negotiate place-making in one neighbourhood. How have representations of British Asian culture been referred to in planning and regeneration policies? Where is 'The Curry Mile' located within urban planning policy in the city of Manchester?

Dissatisfied with the essentialism implied in the celebration of culture and 'multi-cultural cities'; scholars have mined the concepts of 'diaspora'; 'transnationalism' and 'cosmopolitanism'. Yeoh et al (2005, p. 2432) highlights that cosmopolitanism differs from multiculturalism as it tries to 'avoid the pitfalls of essentialism or some kind of zero-sum, all-or-nothing understanding of identity issues within a nation-state framework.' (Vertovec and Cohen, 2002, p. 3). Yet for Devadason, looking at cosmopolitanism in a northern London suburb: 'The multi-ethnic city is often seen as emblematic-and constitutive-of vernacular and everyday forms of cosmopolitanism." (Devadason, 2010, p. 2). While cosmopolitanism may escape the narrow constraints of nation-states and nationalism, it remains bound to global elites and consumption. Moreover, cosmopolitanism is a particular and partial form of difference that becomes commodified for the global, middle-class elite: 'it is a reflexive process of engagement with difference, positioning oneself in relation to others, rather than relying on the established discourses of one community' (Devadason, 2010, p. 2946).

This requires looking beyond the forms of cosmopolitanism created in the city centre which becomes a sanitised space in the global city (Young et al, 2004). They are where we sleep, eat and shop activities also essential to the city's functioning. However, the British planning system operates under a regime of multiculturalism in which social difference is recognised. The rise of ethno-branding has become a key method of multicultural cities wanting to promote their diversity. In a study of Birmingham, McEwan et al (2006) argue that local and transnational diasporic links create unique and competitive products and services. They emphasise that city economies are relational and depend on transnational networks. Space is treated as networked and socially produced through the manufacture and flow of these hybrid goods rather than as a territory or a circumscribed locality. While McEwan et al (2006) are largely positive about the Birmingham experience they express concerns over the rigid and particular representations of ethnicity in policy, the extent to which BAME businesses access mainstream support and, importantly, that ethnic networks may harbour class and gender inequalities. In terms of regeneration, the rise of immigrant communities in decaying inner city areas gave rise to a vision of the ethnic minority entrepreneur as potential urban regenerator. Conversely, Oc and Tiesdell (1999) found in their assessment of Manchester's City Challenge that it suffered from being a top-down strategy that did not take local flexibility into account.

Nina Glick Schiller has recently reminded us that 'contemporary social analysis must direct our attention to the actors and relationships that shape and respond to struggles against injustice and racism' (Glick-Schiller, 2010). Yet, studies tend to focus on the present, neglecting how these networks emerge through time. Although Manchester has been spared some of the fractious relationships seen in other northern British cities that Ash Amin has examined, our case study of 'The

Curry Mile' draws upon his call for historically grounded explorations that 'highlights the powers of situated everyday life in neighbourhoods, workplaces and public spaces, through which historical, global, and local processes intersect to give meaning to living with diversity' (Amin 2002: 975 – 6). Here, the role of urban planners is reduced to tinkering with public spaces with little achieved in terms of ethnic relations.

There is limited work that teases out the power dynamics/ relative positions of ethnic groups within a planning process (Porter, 2010). The representation of ethnicity within planning policy uses ethnic difference to serve specific ends. Robinson (2011) writing about city strategies draws on the work of Tsing (2000) to discuss global 'flows' in which: "Distinctively, she sets herself against the alignment of the global and mobile with the included, connected world and the local or immobile with excluded and marginal groups". (Robinson 2011, p. 25) . Tsing (2000) rightly highlights that

> "Place making is always a cultural as well as political-economic activity. It involves assumptions about the nature of those subjects authorized to participate in the process and the kinds of claims they can reasonably put forth about their position in national, regional, and world classifications and hierarchies of places." (Tsing 2000, p. 338).

We bring together these visions and critiques of cosmopolitanism with pressing issues of ethnic difference and power asymmetries in the case of Manchester, specifically Rusholme. Urban planning helps to create a vision for communities with aspirations to improve the lives of citizens through providing broad frameworks to enact change – most commonly through the built environment and infrastructure but also through policy recommendations, community action plans and neighbourhood plans. Throughout the twentieth century in the UK, rational planners have assumed a largely cultural homogeneous population although one fractured by class differences. We draw upon these insights to extend thinking about the tensions between Manchester's self-imagination as a global, entrepreneurial city with planning policies that seek to corral unruly citizens into manageable ethnic areas and subjects. Our argument is that it is a representation of ethnicity that is partial and, in this case, focused upon ethnic entrepreneurialism.

Manchester: originally modern

The historical record focusses on the political and militaristic realities of managing an empire in which the imperial power (Britain) always assumes itself to be superior and to impose its democracy and social mores on indigenous populations. Drawing upon postmodern interpretations, historians increasingly demonstrate how 'Empire' intertwined with notions of 'Englishness' through commodities such as tea. These imperial connections are found in even the most everyday places including the home and in religious spaces (Hall and Rose 2006;

Driver and Gilbert 1999). The implication is that the relationships and actions of the colonies and colonisers should be rethought to consider that these relations were mutually constitutive.

This is particularly relevant in Manchester, the 'shock city' of the Victorian Age and 'cradle' of the Industrial Revolution. At the height of the Lancashire cotton famine in the late 1840s, the American civil war prevented the export of cotton from this source. Manufacturers turned their attention towards the colonies. One cotton manufacturer, Henry S. Gibbs, describes his experiences:

> …we naturally looked to our Indian possessions, where there was a great increase in the cotton cultivation. Notwithstanding the aversion felt by the workpeople towards "Surat," the poor despised article was eagerly bought by spinners at fabulous prices for want of better material. (Gibbs 1887, pp. 169 – 170)

Bengal was to become the richest market in India for Manchester cotton goods. Partially this was the result of Imperial policies as Britain sought to protect its own industries and Indians developed a taste for the new, mass-produced luxury items from the West (Bansal and Bansal 1984). With however much distaste the cotton spinners regarded 'surat', these 'colonies' played a large part in the making of Manchester both economically and culturally. It is a city built upon continual flows of internal and external migrants. Bill Williams' meticulous work on the Manchester Jewry highlights the immense contribution of this particular group to the continuing entrepreneurialism of late nineteenth century Manchester (Williams, 1996). Paul di Felice makes similar reference to the entrepreneurial character of immigrant Italians in Ancoats in the early twentieth century (Di Felice 2000). Mohammad Siddique Seddon (2007) looks at the contemporary relations between the Muslim and Jewish communities, particularly middle-eastern Muslims to Manchester, to find that 'their solitary appearances were usually temporary, these wandering vagrants and their miserable destitution provided lasting negative archetypes by which later settlers…would be stereotyped (Seddon 2007, p. 74).

Laura Tabili (2011) challenges conventional views that postcolonial migrants arriving after 1948 disrupted the harmony of a culturally and racially homogenous society. She examines the fluidity and flexibility of local and global migration shaped social relations in the north east of Britain and demonstrates that overseas migrants had close ties with existing inhabitants of Tyneside (Tabili 2006, 2011). For Tabili, the response to and acculturation of migrants is shaped inasmuch by local and global forces as they were by national and imperialistic ones. Tabili points out, that only by examining these multiple dimensions of inclusion and otherness, that 'may deepen our understanding that 'racial' conflict did not arrive in Britain with colonised subjects but inhered in Britain's 'imperial social formation' (Tabili 2006, p. 73).

While much of the original street pattern has been obliterated, enough exists to indicate how the Victorian city of Manchester was intertwined in the global reach of the British Empire. The great Manchester commodity of cotton is memorialised in an area to the north of the city. Restyled as 'Ancoats Urban Village', Loom Street, Cotton Street and Spinner Street are in close proximity to Prussia Street, Cornwall Street, Poland Street, Portugal Street, and Bengal Street laid out when the then suburban Ancoats was being planned in the late eighteenth century (figure 2).

Figure 2: Original street pattern in Ancoats, Manchester. 1851 ©Crown Copyright/database right 2011. An Ordnance Survey/EDINA supplied service

When planners came to reconstruct the City of Manchester following war time bombing in 1945, the city was not considered to be in flux and aimed to create homogenous neighbourhoods. The City of Manchester Plan (1945) disparaged a Victorian city whose entrepreneurialism had resulted in environmental degradation and congestion. Comprehensive redevelopment cleared slums to provide motorways, car parking and new modern developments. 'Neighbourhood' centres were created to cover a maximum of 10, 000 people drawn from a cross-section of the community. Several neighbourhoods were grouped into districts with adequate facilities to cultivate 'true citizens' (Nicholson, 1945, 134 – 5). A 1961 plan reaffirmed the 1945 proposals of zoning particular functions to certain areas of the city. Alongside this the city lost 23 per cent of its population between

1951 and 1971, mostly in the inner city areas such as Hulme, Rusholme and Ardwick (Lawless and Brown, 1986: 95).

It was a full 34 years before the 1995 Unitary Development Plan (Manchester: Making it Happen) was officially approved and adopted. This aimed to revitalize a now depressed 'post-industrial' local economy (Manchester City Council, 1995). Regeneration was driven forward by positioning the city on a global stage in order to attract inward flows of investment. Much of this was achieved through the formation of partnership working. Manchester City Council embraced a pragmatic model of working in partnership with the business sector particularly in regards to urban regeneration (Tickell and Peck 1996). Manchester City Council has shown precedent in having the skills, knowledge and motivations of particular individuals, for example under the charismatic leadership of Graham Stringer and Sir Howard Bernstein, for the capacity to act (Williams 2003). More recently active public consultation has tentatively embarked upon incorporating voluntary organisations in its partnership model (Blakeley 2010). So, the local council is developing a role as a coordinator rather than as a regulator or service provider.

The entrepreneurial and business ready vision of the Manchester elite sits uneasily within a formalised planning process. For a city of the size and status of Manchester it has been fragmentary and opaque. The Manchester Plan of 1945 is perhaps the most contemporary clear vision in a formal planning sense – and the quickest to make it to publication. The 1951 plan with its ten year strategy was not published until1961 (a ten year strategy).The Unitary Development Plan was published 34 years later 1995. Manchester City Council is still in the process of formulating their newest statutory document, the Local Development Framework in 2011 although the legislation enacting this process was adopted in 2004.

Meanwhile, the inner city demography altered considerably. In 1961, 3.6% of Manchester's population was born outside of the UK mainly from the 'New Commonwealth and Pakistan' (NCP). By 1991, this proportion was 12.6 % (see table 1). Policies often unintentionally limited the housing market to immigrants and therefore their settlement patterns tended to be in localised and run-down areas of the inner city (Rex, and Moore, 1967). They were predominantly younger and lived in old pre-1919 owner occupied housing stock that was cheap but decrepit. Both the NCP and Irish immigrants were typically associated with 'transience' and both groups correlated with areas of high unemployment, high fertility, large numbers of school children and overcrowding (Manchester City Council 1975).

In the 1970s, Manchester City Council addressed the social problems of Moss Side and Rusholme. The population would be reduced from 41, 000 to 31, 000 by building low density housing. Local elites came to believe Moss Side to be 'a relative success story in terms of race relations' with regulatory rehousing procedures where 'every coloured family has exactly the same rights as a white

family...there were no coloured tags on any applications for tenancies of corporation houses' (*The Guardian*, 2 Nov 1971: 7).

Equality in planning law was further bolstered after the RTPI/CRE report Planning for a Multi-Racial Britain in which the effect was to recognise and promote difference (RTPI/CRE, 1983). Planners, through local and district plans, were urged to formulate culturally sensitive policies and funds were subsequently provided that allowed communities to express their difference through cultural activities and events. In Manchester, recent years have seen a sea-change in specific cultural activities. Festivals, museum exhibitions and community outreach activities allow minority communities to express themselves and present difference as something to be celebrated in the public landscape. How has this played out in one particular neighbourhood?

Representations of the Curry Mile

Until 1959, Rusholme was home to the BBC with its main studios on Dickenson Road. The BBC intended to build its Manchester Headquarters on a site opposite Platt Fields. However, an increase in production required a larger building than could be accommodated and they moved to their present site on Oxford Road (The Manchester Guardian, 17 Dec 1959, p. 18).Barrett and McEvoy (2006) track the development of the Curry Mile from the 1960s. Immigrant communities required goods and services tailored to their cultural specificity. One of the catalysts was the opening of Rusholme cinemas on Sundays to show films from the Indian sub-continent which drew immigrant communities to the area (McEvoy and Hafeez, 2009, 58; The Guardian, 22 Jun, 1961, 21). From 6 in 1966, South Asian owned businesses had risen to 91 by 2006 with 43 of these being restaurants and takeaways. The number of business owned by 'whites and others' declined from 117 to 32 over the same period (Barrett and McEvoy, 2006: 196).

South Asian traders moved into vacant retail sites previously since these were amongst the cheapest. Rusholme's residential designation restricted the nature of that market for retail and consumer firms (Barret and McEvoy 2010). The majority now cater for the particular preferences of one or more minority ethnic groups (e.g. South Asian jewellers, African food suppliers), physically adapted their premises and developed distinctive fascias than those in the former (Figure 3).

Rusholme's population has increased and diversified. Between 1991 and 2001, the population of the Rusholme ward increased by 37.0 % (Manchester City Council, 2003). The 2001 census records the ethnic proportion as significantly higher than the city average. Almost two-thirds (61. 7%) described themselves as white along with significant groupings of Indians (4.7%), Bangladeshi (6.5%), Pakistani (11.5%). The ONS mid-year estimates indicate that this is growing. The number of mosques in Manchester has grown to over 50, many of located in and around

Rusholme [Figure 3]. It is the fastest growing ward in the city with predictions that it will grow even more. (The Manchester Partnership 2010, pp. 24 – 25).

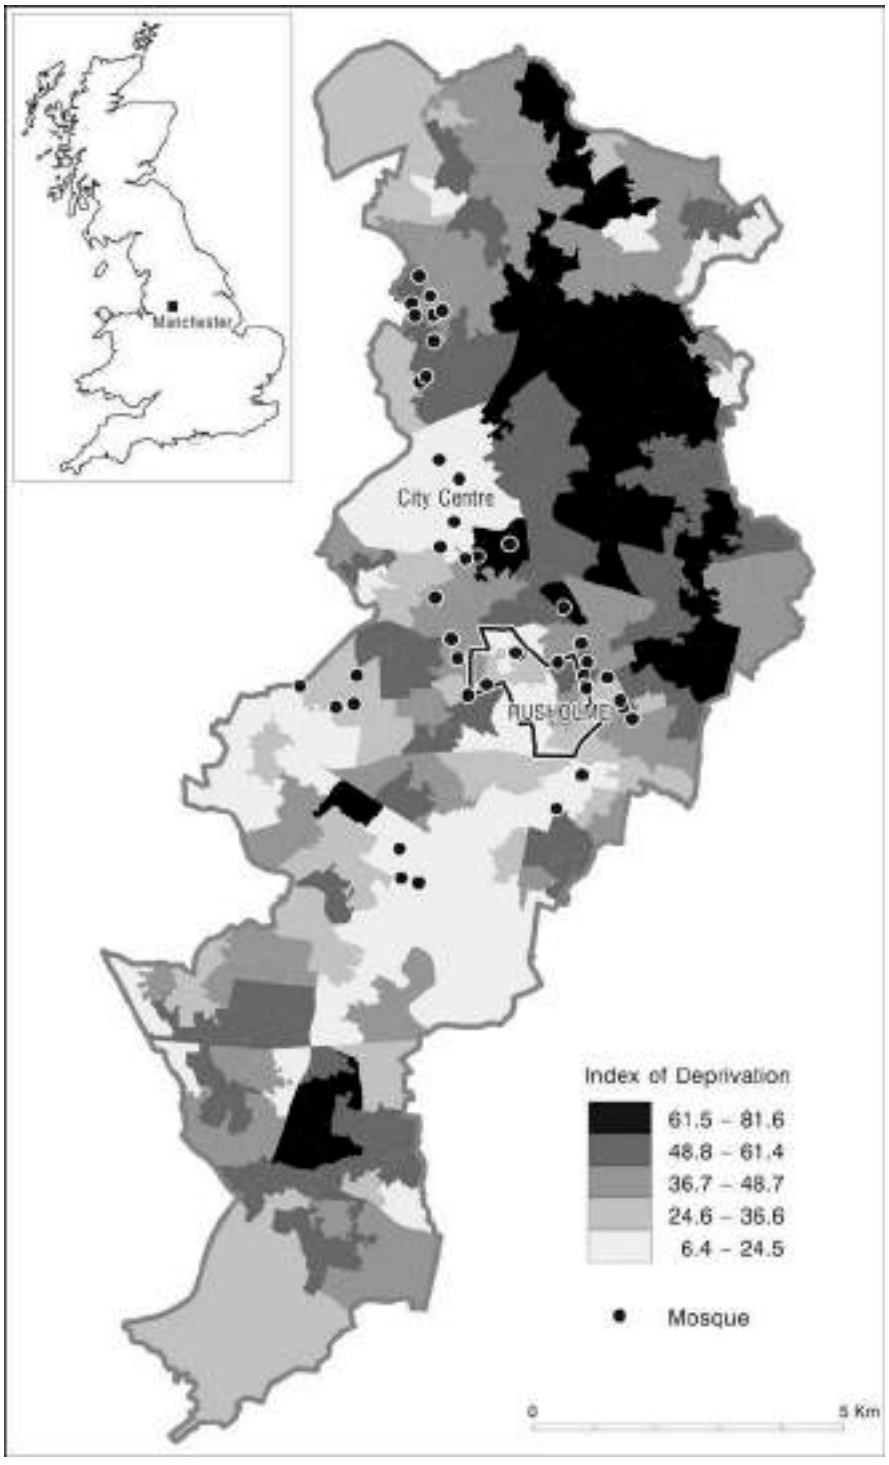

Figure 3: Mosques in Manchester with predominantly South Asian worshippers superimposed over the index of multiple deprivation in the UK.

Within the planning literature, Rusholme is part of a deliberate strategy that reveals a particular type of understanding of the role minorities can serve in the city narrative. Curry Mile is the exotic other; always 'vibrant' yet a deprived community that requires regeneration. We suggest that the planning process has responded in well-defined ways to the emergence of ethnic minorities. Issues of ethnic disadvantage have become the implicit focus of inner city urban programmes which historically tended to have larger BAME populations.

A 1994 City Council commissioned report looked into a potential marketing and economic strategy for Wilmslow Road with an aim of generating more jobs as well as tourism. The businesses were characterised as 'strong and dynamic' (AJA, 1994: 5) and that 'local traders were...independent and resourceful...They also come from a highly entrepreneurial culture.' (AJA, 1994: 72) The report drew contrasts with Chinatown. Firstly, Chinatown's location in the city centre limited potential disturbances to residents. Secondly, they were better placed to cater for business lunches. Thirdly, the organization of the Chinese community through the consulate limited the involvement of the city council to 'set the scene for investment through carrying out environmental improvements' (AJA, 1994, pp. 115). Therefore, it was felt that for Rusholme, specific strategic initiatives should be followed. These were thought to actively encouraging businesses to sign up to existing City Council marketing and tourism departments; to get them to participate in litter schemes; to provide advice to the City Council in producing information on the Asian shops and restaurants; to consult with businesses and to report their ideas on needs and marketing ideas. (AJA, 1994, pp. 106). Around this time, the Rusholme Traders Association decided to take forward the name 'The Curry Mile' and to erect banners to that end at either end of the strip (see figure 1).

These pronouncements sit uneasily when considered against Pnina Werbner's ethnographic studies of Manchester's Muslim diasporas. Her accounts show the shifting nature of so-called ethnic identities that continually interact and become reinterpreted and shaped by many other cross-cutting themes. Untangling the relationships between various factions, blocs and views, she describes a fractured sphere of debate with different discourses through both space (whether it was religious, Pakistani or South Asian) and time. In Werbner's anthropological accounts, the Manchester story is one of relative economic success and the co-operation and competition associated with community life, from the 'fun' spaces of popular culture to a transnational Sufi cult. However, whilst once again the largest minority ethnic grouping, Pakistanis in Manchester are much fewer in number than in Bradford and so have exerted far less power locally. Rather than any sharp boundary defining the ethnic group, it is the centre that imagines the boundary (Werbner 2002, p. 274).

Today, it is less of a homogenous 'Curry Mile'. Shish shops; sushi and Thai food can all be had – often in the same restaurant [Figure 4]. The strip is much more

than restaurants – world food markets, solicitors, newsagents and, particularly, jewellery shops ensure that it is a shopping mecca for the south Asian from across the city. In recent years, it has become a focal point for the Pakistani community's annual Eid celebrations. Curry Mile is not an unqualified success: the rate of business turnover is high. Nor even can it be considered as a truly convivial encounter since the restaurants mainly serve a white clientele who expect low prices. Restaurant staff are often poorly paid and landlords and other business actors remain within the community.

Figure 4: Restaurants on the curry mile now include noodle bars and shish kebabs. Source: Authors.

Our interviews with representatives of the City Council and its partners queried what the 'Curry Mile' offers to Manchester. For one local councillor, the Curry Mile 'generates incredible wealth for the city and the city region and it should continue to do so. There are great opportunities for emergent markets and we have through MIDAS, the inward investment agency, we've had a number of delegations to India in order to draw investment into the city and the city-region'.

Yet in terms of tourism, Curry Mile, and its focal point for celebrations such as Mela and Eid does not seemingly fit with the city's marketing machine::

> For us, we've got to differentiate Manchester from the rest of the UK so if we were promoting nationally or internationally are you going to get an international traveller coming to Manchester to take part in the Mela? No would be the answer… So the scale of events that we have got at the moment that are specifically focussed on ethnic minorities

> would not bring masses of people…It's about those events that might get people into a car or into a train or into a plane and come to Manchester and I think some of those events are too small-scale and not quite unique enough to bring a national or international traveller in.

The current Moss Side and Rusholme Local Plan (Manchester City Council, 2008) indicates the restaurant trade and evening economy 'drives its overall character and is an economic benefit [but] it is not serving the needs of the local community as there is a lack of other retail and service provision, especially large supermarket provision' (Manchester City Council 2008, p. 24 – 5). Diversifying away from the fast food and restaurant trade is backed up with public consultations. Although admirable attempts were made to reach the populations, only thirteen local traders filled in the questionnaire to accompany the consultation. Of these, 11 were White, 1 European and 1 Indian. 108 residents also responded to requests for consultation. The council's aspiration is to launch a long-term strategy 'to issues such as parking management, streetscape, cleanliness, unit frontages, marketing, branding and promotion' (Manchester City Council, 2008, p. 75). One precursor to supporting this approach was a special taskforce that that targeted shopkeepers who persistently violated street environment standards. In the past, the Rusholme Traders Association fulfilled this function. Manchester City Council organised the election of the chairman when the post became vacant around five years ago. Their spokesperson described his role:

> We just like to make sure that the Police are happy with us, the Environmental Health are happy with us we normally go with them and try and sort things out and help them out with the local community. Sometimes they don't get on with one another but I help and explain to them that we don't want to get bigger fines and whatever. Basically, if there is any problem we try to help. I am the community person.

For all its benefits to regional tourist strategies and for providing a central sense of community for Manchester's south Asian community, representations of ethnic entrepreneurialism sit uneasily with some sections of the community. The city council has established working links with certain community members:

> The problem is that when you ask about the question of how the council interfaces with the community, I think the truth is that communities don't know how, they don't have the means and the consultation just passes them by. And the fact is that the council likes to make its job easy. It wants one organisation in one place so that it can tick a box and go 'Woo hoo, I can go home and rest now.' It likes gatekeepers. It likes to keep things in place. It's like that age old thing,

> for me, of colonialism born again. It's in our backyard but its okay because Mr Patel is covering that.

Community groups bid for contracts to provide specialist services. While this gives an ethnically focused service, it equally means that dealing with ethnic difference is contracted out. Hard-to-reach communities thus become ever harder to reach. Ethnic difference has not become internalised into council services. South Asian women are at a particular disadvantage:

> Yes we [South Asian women] have some political organisation but not to the same extent as in places like Bradford or Blackburn. There aren't many female representatives from within our community. There are men but they are motivated by money or their own political interests. They cannot and do not represent a voice for South Asian women.

Tsing contrasts 'global newness' with 'imagined stagnant locals' (Tsing, 2000, p.346). This provides a useful dichotomy with which to consider the different levels of operation between the planning policies of global elites (Manchester man) with the local traders/ ethnic minorities of Rusholme and their inclusion (or not) within the planning strategies. Curry Mile means many different things to many different people at particular points and intersections in time. Yet in urban regeneration it retains an otherness that is not serving the city's ends. These ends reflect traditional stereotypes: dirty, unclean, hard to deal with. Consequently, the community who will most be affected by policies in this area are circumvented in the process.

Discussion and Conclusion

We have attempted to look at representations of diversity and visions of the cosmopolitan city through the lens of one area in Manchester, UK. It suggests that these representations treat Manchester's diversity as thoroughly recent: one in which some groups are the receivers and the others the received. The first argument that we will make is that cities are ephemeral places with a fluidity of people, goods and services. We celebrate it as 'otherness' but, in fact, it is very much 'intertwined' in the history of modern European Cities (whose urban planning story is typically told as the development of capitalism).

The creativity of entrepreneurial ethnic minorities is downplayed in regeneration strategies and, in this case, threatened by planners keen to promote tried and tested means of supermarket regeneration. In the past, the development of the Curry Mile has been left to the entrepreneurs. The Manchester brand is believed to implicitly encompass notions of Manchester's diversity without explicitly stating so even though there is acknowledgement that the Curry Mile has played an important role in strengthening Manchester's bid for investment from countries such as India. For Manchester's south Asian community, representations of ethnic

entrepreneurialism sit uneasily with some sections of the community. Although an extensive community consultation process was initiated for the Moss Side and Rusholme District plan, the response was low and did not reflect the diversity of the area. Community organisations therefore feel that the regeneration plans do not satisfactorily incorporate their views seem lost as to how best to influence it.

Cities such as Manchester have their own projects, compete globally and have their own narratives. Everyone who moves within it has to contribute to that project and all spaces and relationships are shaped by it but the planning narratives seem to ignore this. Our Curry Mile example shows that cities are on-going processes of transformation and plans seem unable to reflect this. It is in those spaces that capital is produced, reproduced, destroyed and accumulated on an unequal basis and that planners seem ill-equipped with the necessary tools to redress this balance or the power to effect a change in local institutional culture.

HISTORICAL DENSITY FOR CONTEMPORARY CITIES

Michela Barosio [1]

Abstract

During the 18th and 19th century, when the culture of the architectural preservation was born, only religious and political architectural objects were considered as heritage to preserve. In the following century, trough the Restoration Charts and the action World Heritage Centre of UNESCO, the concept of preservation has been extended to many others objects as civil buildings, industrial architectures, natural landscapes and historical cities or their monumental districts. From the Charter of Krakow (2000) the principles for the conservation and restoration of built heritage started to include the preservation of urban tissues instead of single monuments.

This paper considers Urban morphology as a form of heritage to preserve and to consider as a possible model for the developing of the contemporary city. Analyzing the formal relationships between the existing buildings, between the buildings and the public realm and between the different "open" spaces existing in the historical cities, we can identify spatial models to preserve. Those spatial models are very often strictly related to the way of life, to the aesthetical values and to the identity of the inhabitants of the city. That's why morphology and local identity seem to be strictly related: preserving urban shape means to strengthen community's sense of identity. The Turin's "industrial footprint" will be presented as a case study.

The paper will focus on the concept of density, which mainly characterizes the traditional urban tissues of the compact cities, trying to define more precisely the concept of density and its formal and social effects. Depending on the meaning of Density that we are considering (population density, residential density, floor area ratio, gross density, net density…) the fallout on urban design can be very different.

Beside, the paper will try to define new definition of the concept of density that can better describe and orientate our priorities in regenerating the compact city.

The expected outcomes are both on planning education and on planning analysis and practice. Defining new parameters for measuring the urban density means to better understand the urban morphology and, at the same time, to become able to

[1] Interuniversity Department of Urban and Regional Studies and Planning, Politecnico di Torino and Università di Torino - michela.barosio@polito.it

design and plan urban transformations being more aware of the physical and morphological fallout of planning.

1. Introduction

During the 18th and 19th century, when the culture of the architectural preservation was born, only religious and political architectural objects were considered as heritage to preserve. In the following century, trough the Restoration Charts and the action World Heritage Centre of UNESCO, the concept of preservation has been extended to many others objects as civil buildings, industrial architectures, natural landscapes and historical cities or their monumental districts. Trough the studies of Viollet-le-Duc and Camillo Sitte in the second half of the XIX century, European culture started to understand the importance of the preservation of some historical urban complexes or monumental districts. But only after the second world war, that seriously damaged the European cities, architects and planners stroke up a debate about the need of restoring and preserving historical city centres[2]. The urban shape began to be perceived as an heritage to preserve and the debate focused on the acknowledgement of the significant characteristics of the traditional urban tissue. The urban studies in Italy developed the typo - morphological analysis of the city whose works investigate the formal constants in urban morphology, in order to construct, or re-construct, the city on its archetypal figures and features[3].
At a world level we must wait the Charter of Krakow (2000) for the principles for the conservation and restoration of built heritage starting to include the preservation of urban tissues instead of single monuments, and the World Haritage Convention of l'UNESCO[4] in the 2005 to connect urban fabric and city's identity.
This paper considers Urban morphology as a form of heritage to preserve and to consider as a possible model for the developing of the contemporary city. Analyzing the formal relationships between the existing buildings, between the buildings and the public realm and between the different "open" spaces existing in the historical cities, we can identify spatial models to preserve. Those spatial models are very often strictly related to the way of life, to the aesthetical values and to the identity of the inhabitants of the city. That's why morphology and local identity seem to be strictly related: preserving urban shape means to strengthen community's sense of identity.

---

[4] *« L'inscription des centres historiques et des quartiers anciens est recommandée chaque fois que la densité et la qualité monumentales sont directement révélatrices des caractéristiques d'une ville d'intérêt exceptionnel. Il est déconseillé de faire des propositions ponctuelles portant sur plusieurs monuments isolés mais nullement complémentaires, censés évoquer à eux seuls une ville dont le tissu urbain a perdu toute cohérence. »*
Orientations devant guider la mise en oeuvre de la Convention du patrimoine mondial, Centre du Patrimoine mondial de l'UNESCO, 2005

If the city has always been perceived as more dense than "the rest", dense of commercial traffics, dense of population, dense of buildings, dense of culture and so on, from the late XIX century these "density" become a negative value. In that period the role of urban planners has been initially held by the sanitary engineers who considered the city has a sick body whose worst disease was the building and population density that forbad healthy life conditions[5]. The goal for the urban planners became to rarefy the city to provide air and light to heal the old city. Haussman in Paris, Ceppi in Turin, later on Piacentini in Rome simply tried to design a healthy and modern city. Following those ideals the Modern Movement born fighting against city density and for a completely new and healthy city. On these ideas Lecorbusier built his proposal for the modern city starting with the nearly complete demolition of the historical urban tissues that were, in his mind, to dense and compromised to be healed. Looking at his sketch comparing the historical tissues of Paris, New York and Buenos Aires with Le Corbusier's proposal for the Ville Radieuse his goal is clear: less density. But analysing carefully the drawing and the written theory, the goal becomes slightly different: Le Corbusier preaches for less built space at ground level (as less as possible) but for a densification of population distributed on very high buildings. For modern architects the city has to be crowded, but urban spaces should be free, open to air and light and characterized by nature with trees and lawn. In this vision of the city, life and car traffic should be isolated and separated, the street becomes only a leisure place: no commerce, no traffic, no business.
In this sense we have to distinguish among different meanings of the term density. As we will see on the next paragraph, density can refers to total building area or just to the area occupied on a specific plot or to population present on the plot or even to the functions present on the area. Two areas can have the same population density can, but different building density or different concentration on ground level which means completely different urban shapes. Beside, density doesn't refers only to quantity, but it can also describe quality when she expresses functional mix for an example.
In the period of post-world war II, in Europe, the massive reconstruction of the seriously damaged cities became a priority with two main goals: building many houses as far as possible, and reconstructing the identity of the nations. To reinforce national identity planners and architects started to rebuild the historical cities centres looking at their original shape, at their urban tradition. Sometimes those "new" building has been built "*à l'identique*" exactly how they were before the war, as in many German Cities like Frankfurt, to highlight the link with the tradition of the nations, other times new buildings were built with more contemporary architectural language to remark a distance towards the war and the national values that had led to it. In both cases the reconstruction is the opportunity to increase the density in historical cities keeping the urban characteristic as compact fronts, rhythm and proportions of the façades and of the streets, public spaces at a human scale and, last but not least, the mix of functions. At the same time, the development of the new suburbs didn't follow the same

[5] Guido Zucconi, La città contesa. Dagli ingegneri sanitari agli urbanisti (1885-1942), Jaca Book 1988.

criteria. The new neighbourhoods were designed looking at the garden city's model, with a low density, a lot of green areas, private and public, and over dimensioned public spaces. Hosting a very poor range of functions and nearly no commercial or leisure activities because of their low density, those districts became very often only dormitories. Speaking about low density of those new suburbs is not always correct in the sense that some of them were designed exactly on the garden city models, especially in the Anglo-Saxon area, others, especially in Mediterranean context, were conceived to be high density blocks lost in the middle of nowhere without connections with the traditional city (we can think about the very famous example of Corviale near Rome ore the ZEN in Palermo). This second case is characterized by an important density on the single plot, but by a very low density considering the entire area surrounding. The reconstruction of European cities ended with the petrol crisis together with the end of population exodus from the countryside towards the metropolis. Since then metropolitan areas had to face a new phenomenon: the urban sprawl. The progressive gentrification of the city's centres and the popular myth of the detached house as a personal paradise draw many people to move from the centre towards the suburban areas. Besides, many European countries present a much stronger regulation of the building activity in the city centre and a very softer regulation (o no regulation at all) for the new buildings in the suburban areas. This imbalance led to sprawled settlements not urban neither rural, simply unshaped, with no identity and, of course, with very low density.
In the 1980, la *Strada Nuovissima* fitted out at the *Biennale di Venezia* edited by Paolo Portoghesi, celebrated the importance of the historical concept of Street as urban fundamental element. Nearly sixty years before Le Corbusier exposed his theory of the *Rue Corridor* against historical streets – that in his mind hide sky and light -, arguing for their vanishing and preaching for new urban spaces, opens spaces without continuous façade, where sun and nature could come in, la "*Strada*" was back. But then Urban Design was missing urban shape of the traditional city and starting to understand that historical urban typologies can't aside from density. Moreover, the ecological movement has made the world aware of the waist of land that urban sprawling has ingenerated. That's why in the two last decades the urban debate is come back to the concept of density trying to define it more precisely and to conceive new urban and architectural typologies able to combine high density settlements and life quality, especially referring to residential typologies and public spaces.

2. Urban density: old concept, new challenge

Urban morphology expresses both qualitative and quantitative values. Urban density is a very large concept that has many different definitions and meanings. In the field of town planning it's used both to describe the city and to regulate its transformation, in this second case it's also called index.
Traditionally used to describe the physical proximity level between architectural objects or persons, nowadays digital networks allow us to consider urban density

not only as a physical matter, but also as a more immaterial parameter that shows the consistence of relationships and flows between the inhabitants (or it will be better to say "users") of a specific geographical area. That's why urban density can be considered as a combination of several specific densities (Malavolta 2007).

2.1 Building density

This indicator shows the quantity of square metres or cube meters built on a specific area or district. If the referring area includes streets and public spaces it's called gross density, otherwise if it's calculated only on the building area of the plot it's a net density. In both cases this parameter highlights the relation between solid spaces and open spaces but it doesn't reflects how much there is life in the area, how many people inhabit it.
It's also interesting to note how the unit of measurement affects the meaning of the building density. Considering the building density in square meters of floor means not to take in account the height of the single storey, so that urban settlements with the same storey area, but with very different total heights, and obviously different urban shapes, will be represented with the same building density. On the other side, to express building density in cube meters implies that having higher floors will increase the density value even if the number of inhabitants doesn't growths.
Some additional indicators can be used in order to describe in a more refined way urban shape and, particularly, the organization of space and mass in the city.
The Ground Space Index (GSI) indicates the relationship between the footprint of the building and the available site area. It doesn't take in account the total amount of floor surface but how much the available area is occupied by buildings and how much non-built space is available.
The Profile Density (PD) is the quotient of the surface area developed per horizontal metre of the cross section. It helps to understand how buildings are "deep".
The Façade Index (FI) stands for the ratio of the surface area to the gross floor area. It describes how buildings are compact or more articulated and, therefore, open toward the public space.
The Angle of Obstruction (AO) is determined by the pattern of built/unbuilt space as well as the profile of the ceiling height and the stacking factor. It shows the relationship interior/exterior.

2.2 Residential density

This parameter expresses how many people live in a specific area, it is expressed in people/sqm or in number of dwelling/sqm and it is obtained by multiplying the number of housing units in the area by the number of people who can inhabit in them. When referring strictly to the plot this is a net residential density. When referring to a district or a more large area, including streets and all sort of public space it's called population density and it's a gross density. Considering only people living in the area, this parameter doesn't take in account workers or general users of the area. Those people generate flows as traffic, noise, life that all together contribute

to generate a sense of density in the context. Those people populate some city areas only in specific time slots. We can think about business districts, which are very dense during the day but almost deserted in the evening or about residential suburban areas nearly empty during the day that start living in the late afternoon. To measure this phenomenon we need another parameter.

2.3 Use density

If the quantity of people living in a specific area still significant to describe it, many studies (Martinotti, 1993) demonstrate how the real amount of people in an area is often very different from the quantity of resident people. Many "temporary users" get advantage of services and spaces from areas where they are not "residential". Those city users can be divided on to four different categories: permanent, occasional, quick and touristic. The permanent city users are those who are present in a specific area (different from their residential area) regularly, almost at the same time as workers for an example. Occasional city users are attracted from a specific occasion, a special event as a sport meeting, an art exhibition. Quick city users are people who go to a place for a short time but with a certain regularity as people who move to commercial district but also to facilities as an airport or a maritime port. Touristic city users concentrate their presence in specific year's period. Obviously those four categories, that influence in different way the urban life, often mix.

It's also important to point out that historical European cities are strongly connoted by a mix of uses that guarantee life and urban quality nearly all day long. Those *mixité* has been lost as the zoning law has regulated most of the city's areas.

2.4 Flow density

Also the quantity and the typology of regular movement of people and goods can be considered as a factor of density. For instance we can observe as the sprawled city is characterized by long distance a high speed flows, whereas compact city is characterized by a lot of different short and almost lower flows. We can observe a strong interdependency between the speed, the frequency of the flows and the morphology of the public space. Related to the flows which cross the urban territory, the typology of the mobility infrastructures (roads, paths, railways, bridges, parking, and so on) engender different kind of perception of the space and consequently, a different feeling of density. Sometimes the mobility infrastructures can help reconnecting the urban tissue, and therefore contribute to improve urban density, other times infrastructures create a split inside the city that engenders discontinuity which can be considered as the opposite of the density.

Beside, we have to consider not only material flows and infrastructures, but also immaterial infrastructures such as digital networks. Digital flows contribute to make a city denser, denser of data, of information, of social connections, in a world more participated. In fact participation to city life and to city governance could be considered strictly related to the concept of urban density, a sort of metaphorical density. Nevertheless it's important to but their immaterial character can lead to new urban morphologies: dense of networks but rare of physical meeting places.

2.5 Results

Various combinations betweens those relative densities lead to different urban densities helpful in analyzing contemporary cities but also to plan their transformations and to manage their moving status.
Building density and residential density refer to very physical data. In this sense, interesting Dutch studies (Uytenhaak 2008) have try to define "The laws of density" in order to develop intelligent urban tissues in which density and primary spatial quality can be optimized. Those laws investigate the relationships between building density and different urban pattern (characterized by different higher, depth, or mutual disposition).
User density and flow density refer to more immaterial or non-physical dimensions but their influence on the urban morphology is not less important. First of all because they have a great impact in human perception of urban space and in second hand because power, as the fact of taking decision than can orient and transform city and landscape, and people concentration are traditionally considered as two strictly related phenomenon. A city which is user and flow dense is a city where is possible to reach a high quality of life.

3. Urban regeneration in Turin: the case study of Spina 3

Turin, one of the vertex of the Italian "industrial triangle", started to be massively concerned by the industrial dismantling at the beginning of the Eighty's. In the 1995 the city adopted a new and innovative Urban Planning Regulation[6] that still shaping the transformation of the city. This Plan considered the dismantled industrial areas as "transformation areas" strategic for the urban regeneration. Most of those dismantled areas were located in the centre of the city, along the railways, or along the rivers: that's why they were valuable and strategic areas. Furthermore thanks to their big dimensions those areas allowed important investments and were able to trigger regeneration processes. The innovative character of the PRGC conceived by Gregotti e Cagnardi consisted in designing the master plan of the transformation areas. The regulation plan doesn't limit itself giving functional and quantitative prescriptions, but it contains formal indications and prescriptions for the urban transformations.
In this sense the PRGC is structured by the "*Spina Centrale*", literally the "central backbone", which consists in the re-design of the dismantled areas along the railways and along the river Dora mixing residential, business and commercial buildings with a quite high density and a special attention to public spaces. To make up for the lack of services and public spaces of the city was one of the main goals in redesigning this strategic area. In fact PRGC planned to localized along the Spina several public buildings as the local authority's offices, the new public library, the most important railways station, the enlargement of the Politecnico among others. Moreover, the Plan provides public investments and facilitations for developing productive and manufacturing activities. All those measures contribute in realizing a functional density mixing different activities, planning the settlements of new residences and various activities avoiding zoning. Concerning the residential buildings, the PRGC sets aside 30% of the residential surface for social housing. This improves the social mixing and the use's density as it avoids the gentrification of the area.

[6] PRGC Piano Regolatore Generale Comunale by Gregotti A. and Cagnardi V..

The entire *Spina Centrale* covered an area of nearly 3 millions ha which represents almost 3% of the city's surface. Those dismantled areas were 70% private areas and 30% public areas. The idea of the planner was to give very high building index in exchange of the fulfilment of collective facilities and their following assignment to the City. This process aimed to achieve the proportion of 30% private areas and 70% public areas. The PRGC through various planning tool as PRIU[7] and *Varianti di Piano*[8] defines several formal aspects of the urban tissue as buildings alignment, buildings height, axes of urban development, roads axes, trying to develop the city in coherence with the existing urban fabric. The urban design of the *Spina centrale* conceived a high-density urbanisation with very high costs of infrastructuring borne by the private investors. Those costs could maybe have been afforded in the late Eighty's, during the real estate market boom, but has become non realistic since the real estate market and the industrial investments, together with demography, have started to slow down at the end of the Ninety's.

Comparing the building density of the historical consolidated city, of the city centre, and the building density of the transformation areas is not easy as in the consolidated city the building density is expressed referring to the building plot, so it doesn't include the public areas (net density), while in the transformation areas the building density is referred to the entire area concerned by the regeneration, including public realm (gross density). The average net density of the consolidated city is 1,35 sq m/sq m, while the gross density in the transformation area was established in 0,7 sq m/sq m by the PRGC but has been revised in 0,6 sq m/sq m. That's because planners, together with city administrators, realized that higher building index means higher quantity of public facilities and services to provide. The cost of those services together with the cost of the reclaim of the industrial soil would have made the investments unaffordable. It's interesting to highlight that density is here expressed in square metre instead of cubic metre. This allows architects to experiment less common typological solutions for residential units. As the height of the storey doesn't have any effect on the count of density, duplex and double level flat as well as lofts and open spaces become more and more common. Assuming that transformation areas will be characterized by 70% of public realm and 30 % of private plot, we can say that for a gross density of 0,6 sq m/sq m the net density in those plot would by near to 2 sq m/sq m.

Looking at the density perception, the PRGC also tries to design urban landmarks, urban furniture and visual design to generate a sort of corporate identity trough the city and to characterize the important and representative urban spaces that structure the "backbone" to make them meaningful and visually dense.

The *Spina Centrale* in divided in four sub-areas: *Spina 1*, *Spina 2*, *Spina 3* and *Spina 4* according to their distance from the city centre. *Spina 3* is a very interesting case study related to the topic of the urban density and its different meanings. The sub-Area of *Spina 3* has been transformed through an urban planning for urban regeneration, PRIU, which was to do 28% of residential use, 10% public facilities, 9% tertiary sector (including proximity commerce), 40% *Eurotorino* (a special plan

[7] PRIU *Programmi di Riqualificazione* Urbana means Urban Regenaration Programms.
[8] Zoning Plan Modifications

for research, exhibition, accommodation facilities and tertiary sector) and the rest for shopping mall. Tertiary sector and public facilities could only be located at the ground floor and at the first and second floor of the buildings to avoid the risk of a business centre that will be full of life during the working hours but empty the rest of the time. Now that the development of the local plan is nearly accomplished, we can observe that those two regulations have engendered a remarkable functional density – or use density - on the area of *Spina 3* that is becoming a lively quarter and not a dormitory suburb even if the amount of residences built is enormous (nearly 2300 residential units).

Concerning the building density we have to consider that at the beginning of the XXI century Turin's inhabitants started to leave the city moving towards the first metropolitan belt. To reverse this process, the regeneration of industrial dismantled areas of *Spina 3* tried to redesign the urban fabric following the model of the historical city's centre, that has just been regenerated and gentrificated with a successful real estate operation. In this sense, the industrial settlements are almost totally demolished – loosing the "industrial footprint" as well as a part of identity of Turin – and replaced with an urban tissue with the same building density of the historical city center but differently allocated. Traditional blocks are usually composed by four or five-storied buildings and they are approximately eighty metres in width, while new residential buildings on the area so called Ex-Michelin are seven- to nine-storied and they are more than one hundred in width. As in the historical fabric, the buildings are located on the perimeter of the plot but the façades are not continuous and the inside court is much bigger and green. In another example – always on the area of *Spina* 3 – the high building density of the traditional city is obtained concentrating very tall buildings in the centre of the plot (more than twenty-storied). Those two examples show how we can have almost the same building density with very different urban shapes. However the traditional urban elements are still the reference for the regeneration of this area as we can see in the design of the most important shopping mall conceived as a traditional *Piazza*: commercial and services buildings are located on the perimeter of the plot, their façades are various but harmonized and the inner space is designed as public square with bridges, fountains and mineral surface. The only difference with the classical *Piazza* is that this contemporary square is completely isolated from the rest of the public realm on a lower level separated from the surrounding streets.

4. Conclusions

Two fundamental fallout of the parameter of urban density have been highlighted in this paper: the leading part of the density in defining urban morphology and it's role in making cities alive. In this sense if importance of density indexes in the control of the urban morphology is clear, the role of the different kind of density has to be tested more precisely not only to better analyse existing urban operation, but also to made up more efficient planning indexes.

The use of Density not as an analysing tool but as a planning tool is very clear in the so called "critic reconstruction", a wide operation of urban regeneration with the aim of preserving and renewing the still existing typical European urban fabric that the city of Berlin started in the Ninety's he. This meant to improve and develop the

infrastructure of squares, boulevards and blocks with internal courtyard that characterized the traditional city. To preserve the city's morphology the maximum height has been limited to twenty-one metres. The plan of "critic reconstruction" avoided functional zoning and improved public transportation instead of private traffic. All this measure lead to a tradition urban shape designed trough contemporary architectural language. The regeneration of PariserPlatz and Luisenstadt has been the first step of a general plan for the city that recognized the importance of the different kind of densities at the scale of the entire city.

Abstract

National Parks are reserves of natural, semi-natural, or developed land owned or declared by a sovereign state, restricted from most development, and is set aside for human recreation and environmental protection. There are around 39 gazetted National Parks in Malaysia; 8 in Peninsular Malaysia, 7 in Sabah and 24 in Sarawak. Kubah National Park was gazetted as National Park in 11th May 1989 and opened to the public in 1995. Kubah National Park is one of the smallest National Park in Sarawak, covering only 2230 hectare yet the implication of its establishment and progresses is rather significant to be studied. Among the neighbors of the park are Matang Wildlife Centre, local villages, high schools and a college. This report reviews positive and negative impacts of Kubah National Park to its surrounding residents. An ethnography study and surveys have been carried out recently inquiring the surrounding residents of Kubah National Park of the benefits and implications of the National Park's establishment and progresses towards their lives. This includes changes occurred at their villages domestically and shared communally. The benefits and implications are categorized under five contributing factors which are economic influences, infrastructure influences, congestion influences, social influences and local attitude. The initial inventory of the case study distinguishes 6 traditional villages with an addition of 13 new villages found to be potentially affected by the progresses of Kubah National Park. A minimum number of 400 samples of survey questionnaires have been randomly collected from the residents of these villages and the analysis of the survey will be further discussed in this report in relation to the management of Kubah National Park. The analysis begins with assessment of the population distribution and density of the residents and later highlights the distribution of age, gender, ethnicity and socio-economy of the residents. The critical part of the analysis is evaluating the five contributing factors influencing the residents' opinions of the National Park. In response, the assessments and evaluations result to channels of improvements for National Park's management

of Kubah or any National Park which may encounter similar context and circumstances.

Keywords: National Park Management, Benefits and Implications, Residents' Opinions

1.0 INTRODUCTION

National Parks are areas protected primarily for their natural and cultural heritage. The parks are home to a surfeit of species that reside within their boundaries, many of which are endangered or threatened. National Parks also protect places important to aboriginal people and historical places that exhibit how people lived in the past (Hanke, 2004). The National Management Services outlined that National Parks are protected areas and it is clear defined geographical space, recognized, dedicated and managed, through legal or other effective methods, to realize a lasting conservation of nature with associated ecosystem services and cultural values.

According to population data established by Department of Statistics Malaysia (2010), Sarawak has 2506, 500 people at the area of 124, 450^2 km with population density of 20 people per 1^2 km. It has eight ethnics and Ibans are the biggest ethnic group, followed by Chinese and Malays. Malays are identified to be the main contributor for the growth of Sarawak's economy, tagged along by Chinese and Ibans. Kubah National Park is located at the small district of Padawan, and close to the district of Lundu. At the area of 526.19^2 km, Padawan has 12, 922 people which vary from multiracial communities such as Bidayuhs, Malays, Chinese, Javanese, Ibans and 'Orang Ulu' settlers. On the other hand, Lundu has 34, 576 people and a population density of 17.6 persons per 1^2 km, at the total district area of 1.962^2 km. Kubah National Park has 18 villages surrounding it.

The basis of the survey methodology is built on the objective of the research which is to explore significant contributions or consequences of Kubah National Park to its surrounding residents. In order to achieve this objective, the initial attempt is distinguishing residential areas and their distribution around Kubah National Park.

2.0 METHOD OF QUESTIONNAIRE SURVEY ACTIVITIES

Within 18 villages in the surrounding of Kubah National Park, five are traditional villages and the remaining 13 are new villages. A total of 376 survey samples are gathered from the villages. In order to be inclusive the research extends its location context by collecting survey samples from other areas which are expected to be influenced by development of Kubah National Park. These extra areas have contributed 57 survey samples which totals up to 433 survey samples. Table 2.1 lists residential areas where the survey samples are gathered from.

Table 2.1 Location of Survey Questionnaire Activities

VILLAGES SURROUNDING KNP		OTHER AREAS
TRADITIONAL VILLAGES	**NEW VILLAGES**	
1. Kampung Loba 2. Kambung Loba Rambungan 3. Kampung Sungai Agas Lama 4. Kampung Trombol 5. Unknown Village	1. Kampung Sri Kandong 2. Kampung Temenggong 3. Kampung Rayu 4. Kampung Rayu Iban 5. Kampung Jaya Bakti 6. Kampung Telaga Air 7. Kampung Selang 8. Kampung Selang Laut	1. Bandar Baru Semariang 2. Batu Kawah 3. Kuching 4. Lintang 5. Lok Simpoh 6. Lundu 7. Matang Jaya 8. Semarahan
	9. Kampung Temadak 10. Kampung Sungai Agas Baru 11. Kampung Matang 12. Kampung Matang Batu 10 13. Taman Palma Indah	9. Sentubong 10. Serikin 11. Sungai Aur 12. Sungai Belian 13. Sibu Laut 14. Taman Jublee Mas 15. Taman Palma Indah

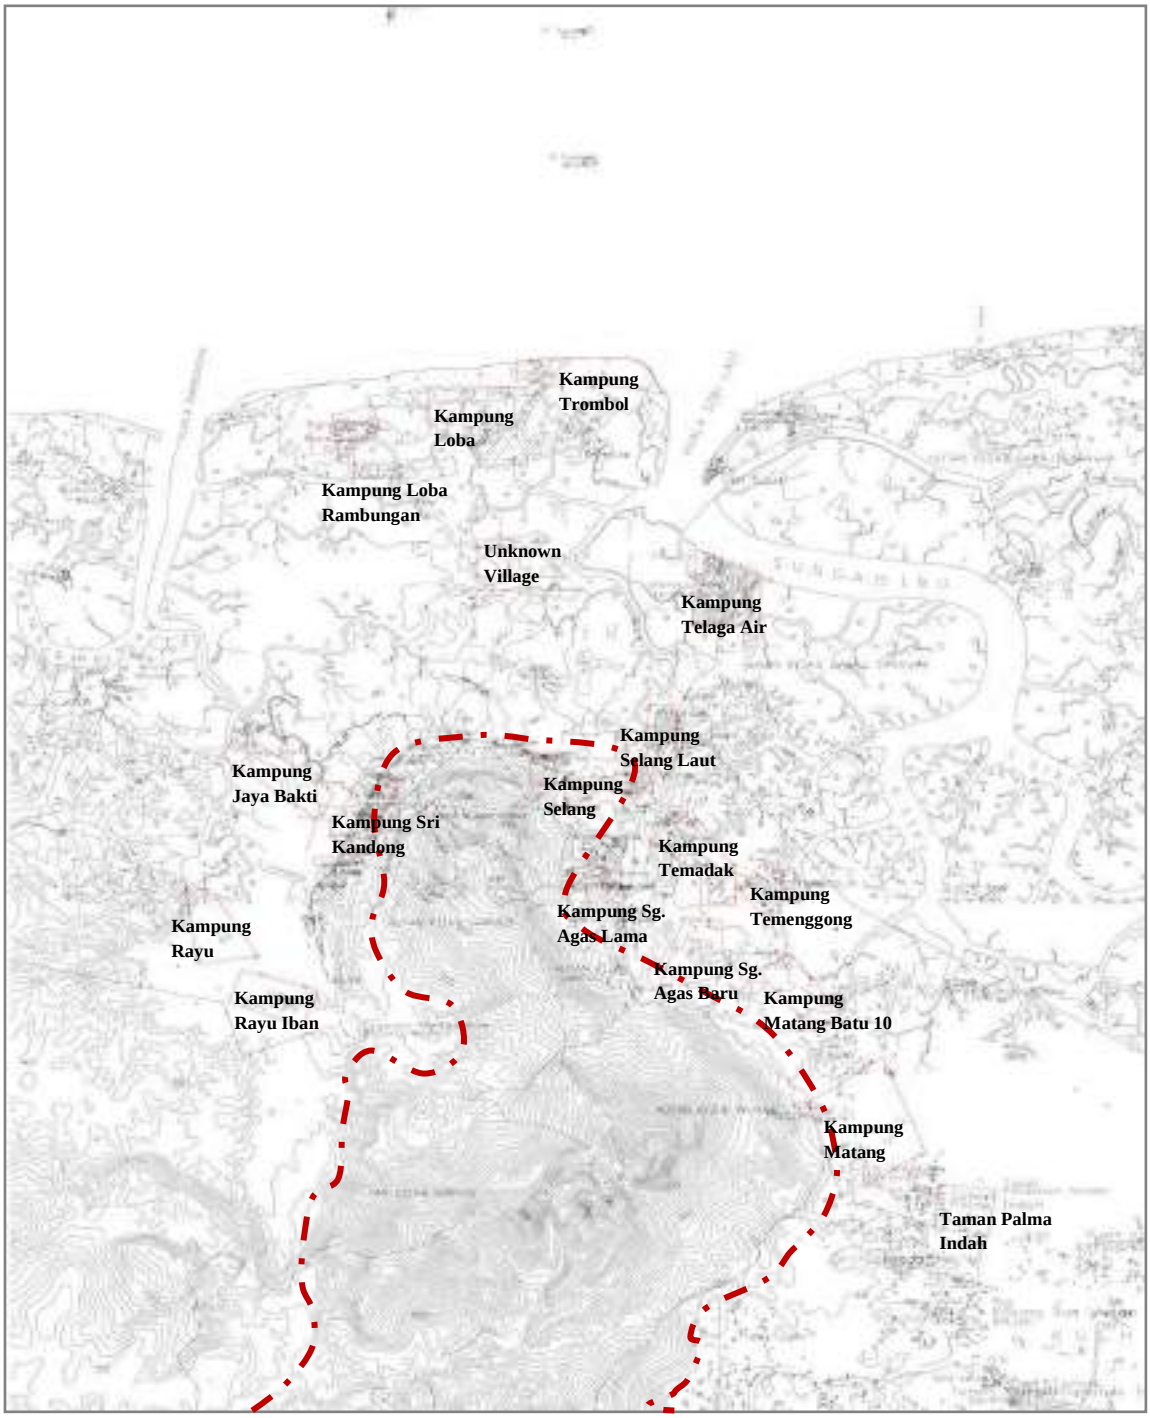

Figure 2.1 Map of Kubah National Park and Its Vicinity

The approaching strategy of the questionnaire survey activities are valued based two characters as the followings:

1. The Amount of Structure: All survey respondents are asked the same questions in an identical approach.
2. The Degree of Directedness: The extent to which direct questions are asked on the issues or topics of interest in the research

Thus, the more structured and direct the approaching strategy, the more generalizable are the answers (Peterson, 2000; Hammersey, 2008).

The questionnaire survey is divided under four general sections:

Section 1	: Respondent's Personal Information
Section 2	: Relationship of Respondents to Kubah National Park
Section 3	: Respondent's Opinions on the Influence of Kubah National Park
Section 4	: Respondent's Opinions on the Management of Kubah National Park

In Section 3, the research indicates five factors of National Park influences to its surrounding residents. The survey addresses scenarios based on these factors to which the respondents would reply according to their knowledge and opinions. These factors are:

1. Economic influences,
2. Infrastructure influences,
3. Congestion influences,
4. Social influences, and
5. Local attitude.

The scenario questions in the five critical factors assess the implications of Kubah National Park. The respondents determine whether the implications are positive or negative based on their opinions and experiences. Most of the questions are structured and direct thus ease the respondents to understand the inquiries. The sampling method of the survey activities is Simple Random Sampling. This means that everyone in the study area has an equal chance to be selected.

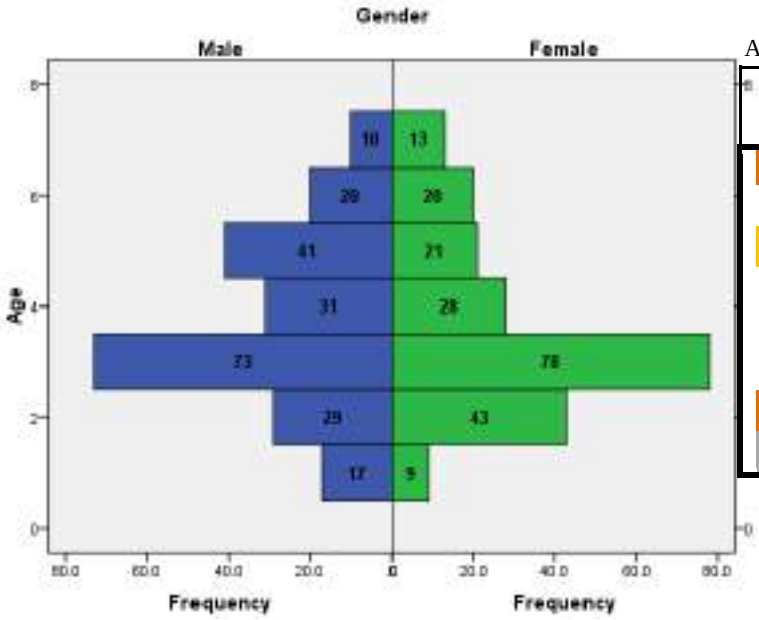
3.0 POPULATION DISTRIBUTION

In total, the respondents are residents of 33 residential areas surrounding Kubah National Park. Table 3.1 classifies the amount of samples collected from each residential area.

Table 3.1: Frequency of Respondents

		Frequency	Percent	Valid Percent
Valid	Traditional Villages	16	3.0	3.7
	New Villages	366	67.5	84.5
	Others	51	9.4	11.8
	Total	433	79.9	100.0

Table 3.1 highlights new villages as the most populated area which in total has contributed over 22% to the whole survey samples. Among the villages of high population density are Kampung Jaya Bakti, Kampung Matang, Kampung Rayu Iban, Kampung Selang, Kampung Selang Laut and Kampung Temenggong. The traditional villages only contribute 3.6% samples. The highest amount of survey samples are gathered from Kampung Telaga Air in new villages which contributes 15.7% to the total survey samples. It is reported that Kampung Telaga Air is the most populated village in comparison to other villages. Additionally it is also the result of villagers migrating from the traditional villages to new villages due to much reliable public facilities such as schools and commercial areas.

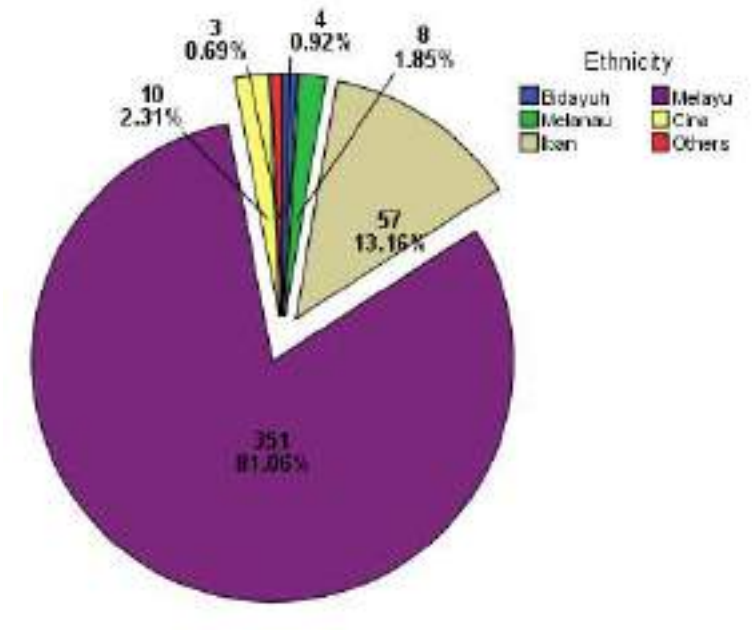


Age * Gender Crosstabulation

Age	Gender		
	Male	Female	Total
10 - 19 yrs old	17	9	26
20 - 29 yrs old	29	43	72
30 - 39 yrs old	73	78	151
40 - 49 yrs old	31	28	59
50 - 59 yrs old	41	21	62
60 - 69 yrs old	20	20	40
>70 yrs old	10	13	23
Total	221	212	433

Figure 3.1: Population Pyramid

The population pyramid as demonstrated in Figure 3.1 shows that the highest density of respondents is from the age of 30 to 39 years old. The smallest amount of respondents is from above the 70s, just shy of a few from the density of the teenage group. Additionally, the population pyramid also indicates that the first three younger age groups have higher density than the last three older age groups. From the age distribution of the total population, it shows that the residents surrounding Kubah National Park has a low death rate and relatively high birthrate. This suggests that the local residents are a rapidly growing population. Since National Parks are known for their strictly protected natural environment, thus promotes health and ecological values; location could be one of the strong contributing factors to the growing population density. Based on the total figures of Male (221) and Female (212), it can be implied that male and female is equally distributed in the population sample.



Ethnicity is an important study as it indicates the behavioral and cultural attributes of the population. According to Figure 3.2, the majority of the respondents are Malays while Iban is 13% of the whole population. The figure shows that the Malays are a significant population of the residents surrounding Kubah National Park, followed by Iban. Just over two percent of the population is the Chinese. Melanau and Bidayuh take up 1.85% and 0.92% of the population respectively.

Figure 3.2: Ethnicity Distribution

A Chi-Square test has been conducted to observe if the ethnicity in the sample represent the population ethnicity in Lundu District. The null hypothesis is the frequency of every ethnicity of the sample (observed frequency) reflects the expected frequency based on the population. The expected frequency is calculated based on the percentage of ethnicities in 2010 provided by Lundu District Office.

Table 3.2: Chi-Square for Goodness of Fit on Ethnicity

Test Statistics

	Ethnicity
Chi-Square	2.690E2
df	5
Asymp. Sig.	.000

a. 1 cells (16.7%) have expected frequencies less than 5. The minimum expected cell frequency is 4.0.

Frequencies

	Ethnicity			
	Category	Observed N	Expected N	Residual

1	Bidayuh	4	121.0	-117.0
2	Melanau	8	4.0	4.0
3	Iban	57	65.0	-8.0
4	Melayu	351	195.0	156.0
5	Cina	10	43.0	-33.0
6	Others	3	5.0	-2.0
Total		433		

Based on Frequencies in Table 3.2, the residual column displays the differences of observed and expected frequencies. All the ethnicities have relatively significant values of residuals. This output indicates differing values of observed and expected frequencies (X^2 (5) = 2.690E2, p = 0.000 < 0.05). Since the value of Chi-Square is not significant, the null hypothesis that observed frequency reflects the expected frequency is rejected. This means that there is lack of accuracy of the sample representing the population. This implies that the population in location chosen for survey does not reflect the overall ethnicity distribution of Lundu population.

Historically, the settlement at the traditional villages has begun over 100 years ago. Lands are owned by individual owners and have been inherited from one generation to another generation. Despite over a century of existence, the traditional villages are considered rather orthodox compared to the new villages. The traditional villages significantly lack infrastructure and facilities improvement which result to absence of electricity and water utilities in majority of the houses. It is reported by the villagers that for daily needs, the villagers have to make use of generators to light their houses at night and either pump the underground water or channel the water from nearby hills for some water supplies. The traditional villages also have little access to their surrounding settlements due to lack of road connections.

Alternatively, the new villages which have been instituted after World War 2 in 1945 experiences decent development of communal necessities such as schools, bus stops and mosques. As reported by the heads of the villages, the development processes significantly upsurge around 20 years ago. Coincidently Kubah National Park was gazetted in 1989 which is a relative year when the villages experience an increase of development. This suggests that the development of Kubah National Park may perhaps be the reason of the development of its surrounding villages. Nevertheless, some villagers believe differently. It is reported by some of the neighboring villagers that the strict protection policies of the National Park has result to slow urbanization progresses of the National Park's neighboring areas.

The following sections discuss five factors of possible influences of Kubah National Park to the surrounding areas from the angle of villagers' lives, experiences and perspectives. These influences are addressed in five categories, Economic influences; Infrastructure influences, Congestion influences, Social influences and Local attitude.

4.0 INFLUENCES OF KUBAH NATIONAL PARK

There are varieties of positive outcomes of National Parks to their surrounding human residents. Apart from the ecological values which are highly promoted, development of the Parks offer opportunities of employments, increase of infrastructure to allow access for outsiders and insiders as well as development of recreational facilities for public use.

In the attempt to distinguish significant impacts of Kubah National Park (KNP) to its surrounding local residents, the survey begins with inquiring the respondents to address positive contributions of Kubah National Park to their lives.

Although there are seven contributions addressed by the respondents, over half of the respondents claim that Kubah National Park has no significant contribution towards their lives. 12.7 % and 10.9% of the respondents claim that progresses of Kubah National Park shows positive outcome to economy and infrastructure aspects respectively. Figure 4.1 and Table 4.1 display the output.

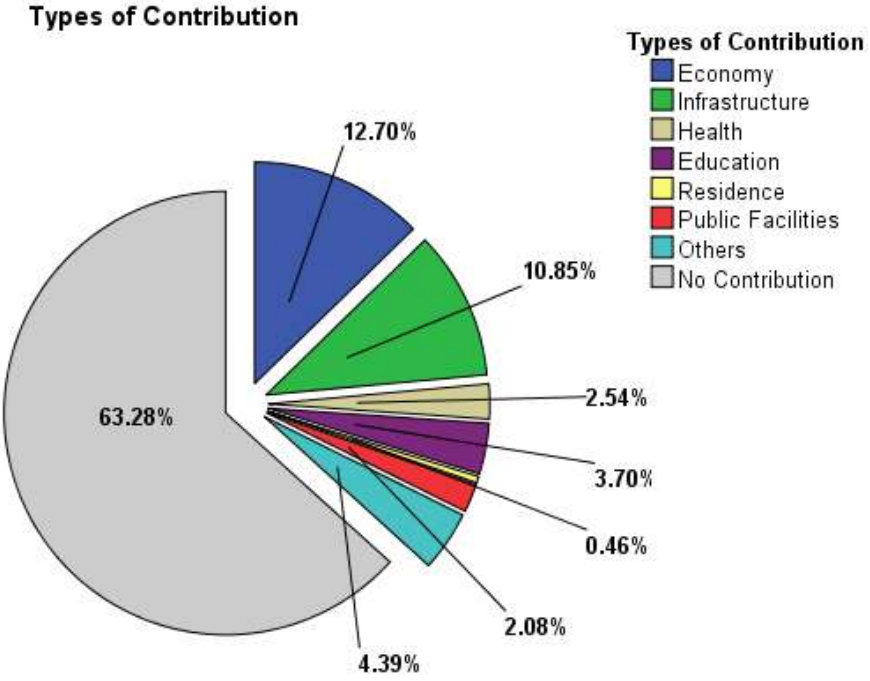


Figure 4.1: Contribution of Kubah National Park

Table 4.1Frequency of KNP Employees

Types of Contribution	Work at KNP?				
	Yes	No	Total	Percent	Cumulative Percent

Economy	23	32	55	12.7	12.7
Infrastructure	5	42	47	10.9	23.6
Health	1	10	11	2.5	26.1
Education	0	16	16	3.7	29.8
Residence	1	1	2	.5	30.3
Public Facilities	0	9	9	2.1	32.3
Others	3	16	19	4.4	36.7
NA	20	254	274	63.3	100.0
Total	53	380	433	100.0	

From the total number of respondents who claim of the economic contribution, 23 of them work for Kubah National Park. Additionally, out of 47 respondents who address the infrastructure contribution, 5 of them are employed by the National Park. This suggests that development of Kubah National Park offers employment opportunities to the villagers. This may perhaps be the factor which affects the perspective of the respondents.

5.0 ECONOMIC INFLUENCE

Socioeconomic is a vital study in understanding the economic growth of an area. Based on income, education and occupation, socioeconomic status can be determined. Socioeconomic status indicates work experiences, individual or family social position in relation to others and education background. Occupational status reflects both income and education background in attaining the job requirement. In the attempt to determine the economic influences of Kubah National Park, the research begins with distinguishing the socioeconomic and occupational status of the residents. The following table shows the occupational status of the respondents.

Table 5.1: Cross tabulation Household Income by Occupation

Family Income	Occupation								
	Government	Private Sector	Public Sector	Student	Pensioner	Unemployed	others	housewife	Total
< RM500	2	0	34	10	5	11	28	10	100
RM500 - RM1000	11	10	74	9	7	6	30	29	176
RM1000 - RM1500	4	5	32	4	4	6	14	0	69
RM1500 - RM2000	8	3	7	3	2	0	5	6	34
RM2000 - RM2500	4	2	6	3	0	0	1	0	16
RM2500 - RM3000	5	3	5	1	0	0	0	0	14
RM3000 - RM3500	2	1	2	0	1	1	0	1	8
> RM3500	8	3	3	0	1	0	0	1	16
Total	44	27	163	30	20	24	78	47	433

Table 5.1 shows that the majority of the respondents work in the Public Sector. 78 of the respondents in the 'others' column are self-employed and work as farmers, fishermen and traders while 21 of the respondents are unemployed. Based on the occupation and household income displayed in the table, it implies that there is a probability that education levels of the respondents are mostly medium or rather low.

Table 5.2: Cross tabulation Household Income by Household Members

Family Income	No. Family Members					
	1 - 3	4 - 6	7 - 9	10 - 12	> 12	Total
< RM500	17	59	17	7	0	100
RM500 - RM1000	23	82	50	17	4	176
RM1000 - RM1500	8	29	23	6	3	69
RM1500 - RM2000	2	16	11	2	3	34
RM2000 - RM2500	1	13	1	1	0	16
RM2500 - RM3000	0	12	2	0	0	14
RM3000 - RM3500	0	5	1	1	1	8
> RM3500	8	6	1	1	0	16
Total	59	222	106	35	11	433

The cross tabulation of table 5.2 shows that majority of the respondents have 4 to 6 household members. 106 of the total respondents have 7 to 9 household members yet only 1 of the respondents receives more than RM 3,500 monthly. Majority of the respondents gain below than RM 1,000 per month. Out of that number, 100 of them gain below RM 500. This suggests socioeconomic status of the respondents is very low. This also implies that majority of the respondents have low education level to attain some high income professions.

Table 5.3: KNP Increase Job Opportunity

KNP Increase Job Opportunity	Work at KNP?		
	Yes	No	Total
Strongly Agree	13	44	57
Agree	18	106	124
Disagree	13	179	192
Strongly Disagree	9	51	60
Total	53	380	433

In the scenario-based inquiry of the questionnaire, majority of the respondents claim that Kubah National Park does not increase job opportunity. Although 31 of the National Park employees agree that Kubah National Park does increase job opportunities, 22 of the employees claim that the National Park does not increase job opportunities.

Table 5.4: KNP Influence Unemployment

Residents		Work at KNP?		
		Yes	No	Total
Traditional Villages	Agree	0	2	2
	Disagree	0	7	7
	Strongly Disagree	2	5	7
	Total	2	14	16
New Villages	Strongly Agree	1	5	6
	Agree	9	41	50
	Disagree	22	193	215
	Strongly Disagree	14	81	95
	Total	46	320	366
Others	Strongly Agree	1	0	1
	Agree	1	8	9
	Disagree	1	28	29
	Strongly Disagree	2	10	12
	Total	5	46	51

As National Parks are also tourists destination, Kubah National Park and its surroundings experiences seasonal tourists' arrival. For residents who make use of the opportunity, tourism-based activity could contribute to their income. Still the tourists arrival is seasonal thus may result to unemployment for these residents as season goes. Based on Table 5.4, 17.3% of the respondents agree that Kubah National Park results to unemployment. Out of the figure, 12 of them are employees of Kubah National Park. Nevertheless, majority of the respondents disagree that the park influences unemployment. Both Table 5.3 and Table 5.4 significantly suggest that Kubah National Park has a low impact on job opportunities or employment in general.

The research attempts to observe the differences of means on perception of Job Opportunities being affected by Kubah National Park of respondents who are employees and are not employees of the National Park based on their level of household income. In order to determine the interactions of the three variables, 'KNP Increase Job Opportunity', Categories of Household Income and Employees of KNP, Factorial Anova is implemented. For this test, three null hypotheses are addressed.

1. Respondents who are Employees of KNP and respondents who are otherwise have the same perception on 'KNP Increase Job Opportunity'.
2. Perception on 'KNP Increase Job Opportunity' is not influenced by Categories of Household Income.
3. There is no interaction between being employees of KNP and Categories of Income. That is the effect of being Employees of KNP or otherwise from different Categories of Household Income is equal.

However, since Factorial Anova is best used for ratio data, it unlikely to obtain a good result if the variable 'KNP Increase Job Opportunity' is an ordinal variable.

Thus, the Likert 4 point agree or disagree scale of 'KNP Increase Job Opportunity' is recoded into Anchored 4 point scale. The rationale for this transformation is to give score for the variable for better understanding on the output of means. The following table shows how the variable is transformed.

'KNP Increase Job Opportunity'

Likert 4 Point		*Strongly Agree*	*Agree*	*Disagree*	*Strongly Disagree*	
Anchored 4 Point	Most Likely	4	3	2	1	Most Unlikely

Table 5.5: Factorial Anova on Employees of KNP, Categories of Household Income and Perception on 'KNP Increase Job Opportunity'

Between-Subjects Factors

		Value Label	N
KNP Employees	1	No	380
	2	Yes	53
HouseholdIncome	1	< RM500	100
	2	RM500 - RM1,999	279
	3	RM2000 - RM3500	38
	4	> RM3500	16

Descriptive Statistics

KNPEmp	HouseholdIncome	Mean	Std. Deviation	N
No	< RM500	1.8293	.69929	82
	RM500 - RM1,999	1.9040	.63908	250
	RM2000 - RM3500	1.9429	.53922	35
	> RM3500	2.3846	.86972	13
	Total	1.9079	.65736	380
Yes	< RM500	1.9444	.63914	18
	RM500 - RM1,999	1.7586	.83045	29
	RM2000 - RM3500	3.0000	1.00000	3
	> RM3500	2.3333	1.15470	3
	Total	1.9245	.82855	53
Total	< RM500	1.8500	.68718	100
	RM500 - RM1,999	1.8889	.66125	279
	RM2000 - RM3500	2.0263	.63616	38
	> RM3500	2.3750	.88506	16
	Total	1.9099	.67954	433

The Descriptive Table displays the means of 'KNP Increase Job Opportunity' scores. Based on the HouseholdIncome and Mean Columns, Income which is more than RM 2000 have mean figure above 2.0 (approaching 'Most Likely'). This suggests there is a possibility that most respondents whose household income are above RM 2000 perceive that most likely KNP Increase Job Opportunity. However, based on KNPEmp column; the row indicating not employees of KNP, only respondents whose household income is above RM 3500 perceive that most likely KNP Increase Job Opportunity. Thus there is a possibility that being employees of KNP or otherwise does not influence perception on 'KNP Increase Job Opportunity'. The following Tests of Between Subject Effects table reveals the significance of the interaction between these three variables.

Tests of Between-Subjects Effects

Dependent Variable:InfluenceUnemp

Source	Type III Sum of Squares	df	Mean Square	F	Sig.
Corrected Model	8.297[a]	7	1.185	2.635	.011
Intercept	332.780	1	332.780	739.744	.000
KNPEmp	1.084	1	1.084	2.409	**A** .121
HouseholdIncome	6.119	3	2.040	4.534	**B** .004
KNPEmp * HouseholdIncome	3.828	3	1.276	2.837	**C** .038
Error	191.190	425	.450		
Total	1779.000	433			
Corrected Total	199.487	432			

a. R Squared = .042 (Adjusted R Squared = .026)

The test of Between Subject Effects table displays the significant value for the three conditions of interactions between variables. The first is condition A where the effect of being employees of KNP or otherwise towards perception on 'KNP Increase Job Opportunity'. The p-value for condition A is 0.121 > 0.05, therefore fails to reject the first hypothesis that the effect of being employees of KNP or otherwise is not significant. On average, the perception of 'KNP Increase Job Opportunity' is the same for respondents who are employees of KNP or not employees of KNP. The p-value for condition B indicating the effect of Household Income towards 'KNP Increase Job Opportunity' is 0.04 < 0.05, thus it is significant. Therefore rejects the second null hypothesis that perception on 'KNP Increase Job Opportunity' is not influenced by Categories of Household Income. This means that on average, perception of 'KNP Increase Job Opportunity' is influenced by different categories of household income. Lastly for condition C where all three variables are being interrelated, the p-value is 0.038 < 0.05. Since the p value is significant, the third null hypothesis is also rejected. This shows that there is an interaction between being employees of KNP and Categories of Houshold Income. That is the effect of being Employees of KNP or otherwise from different Categories of Household Income is different. There are two important points which can be concluded from the output.

1. Most respondents whose income are above RM 3500 either they are employees of KNP or otherwise believe that most likely KNP Increase Job Opportunity. Additionally, if the respondents are employees of KNP, the household income level is slightly lower (above RM 2500) for them to believe that most likely KNP Increase Job Opportunity.
2. Despite there are respondents who believe that KNP Increase Job Opportunity, these respondents are considered high income respondents from the rest of the respondents. Respondents whose household income is lower than RM 2000 are 379 in total which takes up more than half of the total respondents. This suggest that vast majority of the respondents especially those whose household income are lower than RM 2000 do not believe that KNP Increase Job Opportunity.

There are two assumptions which can be implied from this result. The first is to suggest that even though Kubah National Park offers employment opportunities, they are not sufficient to cater the whole population or the residents. The second is to imply that the residents may not be entirely accessible or competent to the employment opportunities due to access of information, power distribution in the community or requirement of the job scope.

Table 5.5: KNP Increase Living Cost and Land Value Cross Tabulation

TNK Increase Living Cost	TNK Increase Land Value				
	Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Strongly Agree	42	2	6	0	50
Agree	1	105	14	1	121
Disagree	5	20	153	7	185
Strongly Disagree	1	6	4	66	77
Total	49	133	177	74	433

As the surrounding residents of the strictly protected land and tourism destination, the living cost and land value of the area ought to increase in reflecting the significance of the National Park. Approximately 30% of the respondents agree or strongly agree that both land values and living cost have increased. In spite of this, majority of the respondents disagree that the land value or the living cost has increase significantly. This suggests that Kubah National Park has rather low land value or receives slow reaction from tourism industry. This may be due to nearby tourism locations such as Bako National Park or Kuching which have better tourism attractions, thus dominate most of the tourism responds.

Table 5.7: KNP Increase Economic Standard

	Work at KNP?		
Residents	Yes	No	Total

Traditional Villages	Strongly Agree	0	3	3
	Agree	0	3	3
	Disagree	0	6	6
	Strongly Disagree	2	2	4
	Total	2	14	16
New Villages	Strongly Agree	13	50	63
	Agree	16	103	119
	Disagree	12	127	139
	Strongly Disagree	5	40	45
	Total	46	320	366
Others	Strongly Agree	2	6	8
	Agree	2	18	20
	Disagree	0	16	16
	Strongly Disagree	1	6	7
	Total	5	46	51

Table 5.7 concludes the overall scenario inquiries of Economic Influence of Kubah National Park. Most of the residents disagree that the National Park has increase the surrounding economic standard. Again, this may perhaps due to slow tourism reaction. Kubah National Park is lacking significant tourism attraction in comparison to nearby tourism destinations. Additionally, this may due to the slow development of the surrounding areas. The following sections discuss the infrastructure influences of Kubah National Park.

6.0 INFRASTRUCTURE INFLUENCE

The influence of infrastructure is measured according to the maintenance of the road systems and facilities in the residential areas. At the same time, increase in infrastructure should also contribute to positive outcome to the service quality of shops, restaurants and other businesses.

Table 6.1: KNP Increase Maintenance and Infrastructure Cross Tabulation

TNK Increase Infrastructure	TNK Increase Maintenance of Road System & Facilities				
	Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Strongly Agree	78	10	0	1	89
Agree	23	167	12	2	204
Disagree	9	33	56	3	101
Strongly Disagree	0	5	10	24	39
Total	110	215	78	30	433

Based on Table 6.1 over 60% of the respondents agree or strongly disagree that Kubah National Park has shown positive outcome to surrounding maintenance and

infrastructure development. This implies that the development of Kubah National Park has influenced the development of the surrounding local settlements.

Table 6.2: KNP Increase Service Quality

		KNP Increase Service Quality				
		Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Residents	Traditional Villages	2	8	4	2	16
	New Villages	63	117	142	44	366
	Others	6	21	19	5	51
	Total	71	146	165	51	433

Table 6.2 shows equal number of respondents either agrees or disagrees that Kubah National Park has influenced the service quality of shops, restaurants and other businesses. This suggests that the local residents are still dependent on themselves in the terms of local improvements within the residential areas.

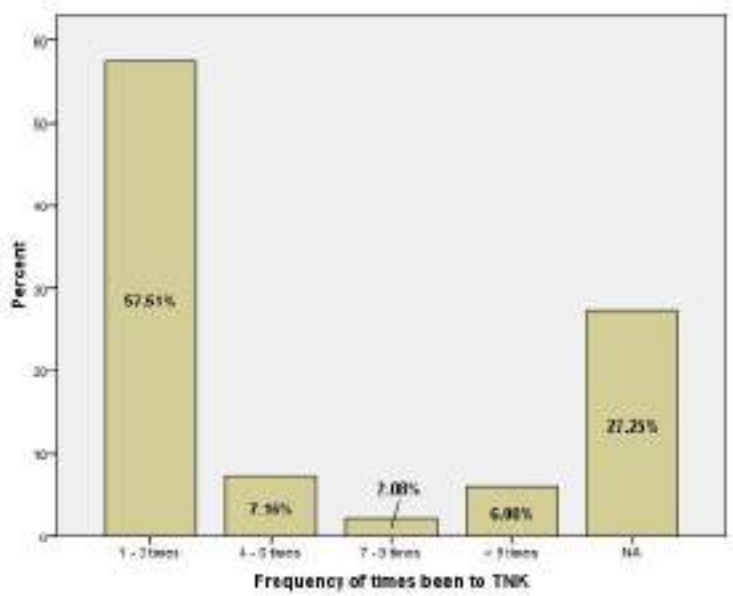

Figure 6.1: Frequency of times have been to KNP

Figure 6.1 indicates that the frequency of times of which the respondents have been to Kubah National Park. The figure shows that just over a quarter of the respondents have not been to Kubah National Park while more than half of the respondents have only been to the Park 1 to 3 time. Nevertheless, as observed during field study, the neighbor of Kubah National Park, Matang Family Center has many visitors. It is reported by some of the respondents that most of them prefer the alternative recreational area as it is more convenient to access. In addition, the attraction of Kubah National Park especially the waterfalls require them to hike and force a way through the forest to reach there when Matang Family Center has a similar attraction and much convenient to reach.

The research attempts to observe if the variable of 'KNP Increase Land Value', affects variable 'KNP Increase Development'. Both of these variables have the same quantity of ordinal levels based on the 4 point Likert Scale Agree or Disagree Questions in the Survey. However, for better understanding on comparison of mean values, the Likert 4 Point Agree or Disagree Scale of both variables is recoded into

Anchored 4 point scale. The rationale for this transformation is to give score for the variable for better understanding on the output of means. The following table shows how the variable is transformed. For this test, Paired Sample T-Test is implemented. The null hypothesis is there is no significant difference between means of 'KNP Increase Land Value' and 'KNP Increase Development'.

'KNP Increase Land Value' and 'KNP Increase Development'

Likert 4 Point		*Strongly Agree*	*Agree*	*Disagree*	*Strongly Disagree*	
Anchored 4 Point	Most Likely	4	3	2	1	Most Unlikely

Table 6.7: Paired Sample T-Test on Land Value and Development

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	KNPLandValue	2.3626	433	.89504	.04301
	KNPDevelopment	2.8014	433	.86725	.04168

Paired Samples Correlations

		N	Correlation	Sig.
Pair 1	KNPLandValue & KNPDevelopment	433	.141	.003

Paired Samples Test

		Paired Differences					t	df	Sig. (2-tailed)
		Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference				
					Lower	Upper			
Pair 1	KNPLandValue - KNPDevelopment	-.43880	1.15533	.05552	-.54793	-.32967	-7.903	432	.000

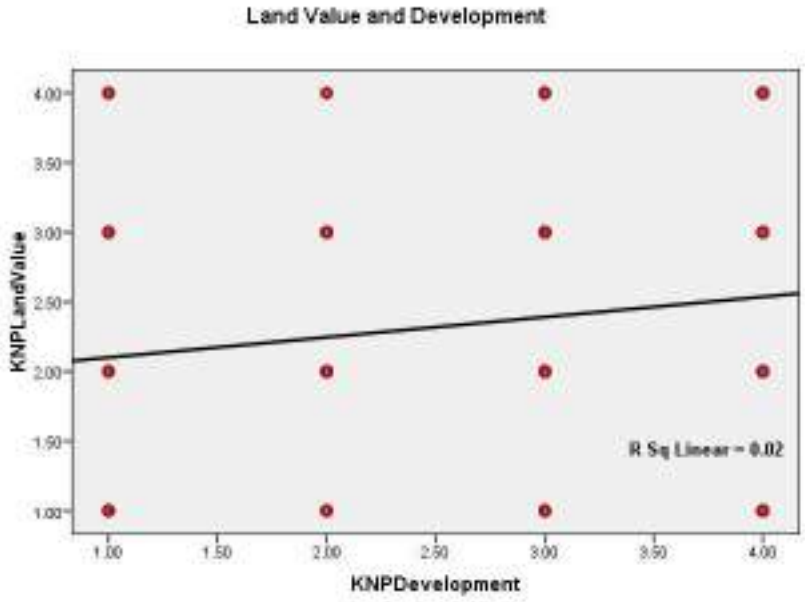

Figure 6.3: Scatter Plot of Land Value and Development

Based on the Paired Samples Statistics Table, the mean of 'KNP Increase Development' is higher than the mean of 'KNP Increase Land Value' with a difference of 0.4388 which implies that more respondents believe that the National Park has increased development than the land value. The Paired Samples Correlation Table shows positive correlation of 0.141 which suggests that as the land value increases, the development also increases. The output of the Paired Samples T-Test indicates that there is a significant difference between the means of 'KNP Increase Development' and 'KNP Increase Land Value' $t(432) = -7.903$, $p = 0.000 < 0.05$. Thus rejects the null hypothesis that there is no significant difference between means of 'KNP Increase Land Value' and 'KNP Increase Development'. The scatter plot also displays a weak yet positive correlation of 0.238 between the two variables which indicates that the increases on land value are correlated with increases in Development. This suggests that Increase in land due to expansion of Kubah National Park affect the surrounding development of the local residents.

Since respondents have been asked a few question based on the two themes Surrounding Development and the score of Living Economic Standard, all the responds have been totaled up into scores in order to observe whether these two themes influence each other. Such inquiries in Living Economic Standard include question on increase in living cost, land value and service charges. On the other hand, inquiries in Surrounding Development include increase in infrastructure, maintenance and surrounding improvements. Another similar scatter plot has been conducted based on the score of the two themes.

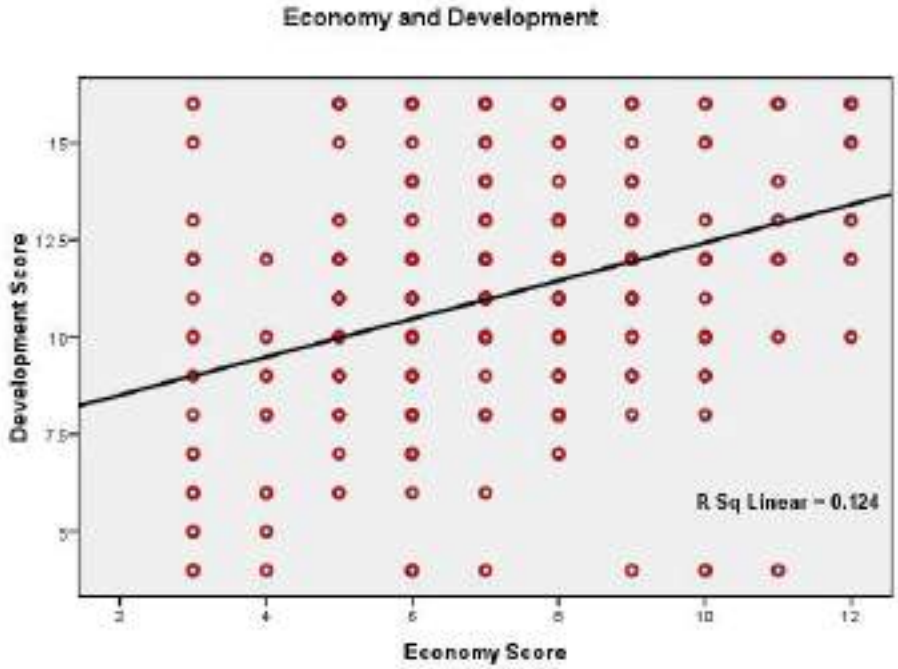

Figure 6.3: Scatter Plot of Living Economic Standard and Surrounding Development

The scatter plot displays positive but correlation of 0.124 for the two variables. This implies that the increases on the score of Living Economic Standard are correlated with increases on the score of Surrounding Development. Thus also suggests that increase in Living Economic Standard due to Kubah National Park has influenced the surrounding development of the local residents.

7.0 CONGESTION INFLUENCE

Factor of congestion refers to density of tourists crowding during seasonal tourists arrival. It has been reported by some of the residents of Kampung Telaga Air that tourists from the National Park stop by in their village to admire the rural environment. At the same time the tourists enjoy witnessing some of their cultural displays especially the wedding ceremonies of the Malays. The research inquires the respondents to address if the tourists have caused crowding in their settlement during peak tourists' season. Vast majority of the respondents disagree that Kubah National Park has result to serious crowding in the area of the National Park itself or the local settlements.

8.0 SOCIAL INFLUENCE AND LOCAL ATTITUDE

Social influence refers to the consequence of tourism activities towards social aspects of the residents. On the other hand local attitude is the responses of the residents regarding the changes occurring in their surroundings.

Table 8.1: KNP offers Opportunities to Interact with Tourists

		Opp. to interact with tourists				
		Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Residents	Traditional Villages	7	4	4	1	16
	New Villages	102	135	112	17	366
	Others	19	21	8	3	51
	Total	128	160	124	21	433

Table 8.2: KNP Tourism Influence Local Culture Changes

		KNP Tourism influence local culture changes				
		Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Residents	Traditional Villages	1	2	5	8	16
	New Villages	47	57	195	67	366
	Others	7	11	24	9	51
	Total	55	70	224	84	433

According to Table 8.1, 33% of the respondents disagree that Kubah National Park creates opportunities for the residents to interact with the tourists. 112 of them are from the New Villages which was reported to receive most tourists' attention. However, vast majority of the respondents agrees or strongly agrees that the National Park has allowed the residents to interact with the tourists. Table 8.2 shows significant amount of respondents disagree that tourism has influenced the culture changes of the local settlement.

Table 8.3: KNP Tourism Increase Cultural Display

		KNP Tourism increase cultural display				
		Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Residents	Traditional Villages	2	3	3	8	16
	New Villages	72	88	158	48	366
	Others	8	11	24	8	51
	Total	82	102	185	64	433

As reported by the villagers, cultural display specifically wedding ceremony is one of the main factors which encourage the tourists to visit their villages. According to table 8.3, 42% of the respondents agree that cultural display has increased due to tourists visits. However cultural display such as weddings in the villages depends on communal cultural events which are not fixed. Thus depending on chance tourists can only witness the cultural display if only there is an event.

Table 8.4: KNP Increase Environmental Appreciation

		KNP increase env. appreciation				
		Strongly Agree	Agree	Disagree	Strongly Disagree	Total
Residents	Traditional Villages	9	6	1	0	16

	Others	25	18	6	2	51
	Total	208	177	35	13	433

Table 8.4 shows significant number of respondents agrees or strongly agrees that progresses of Kubah National Park have increased the locals' environmental appreciation. This suggests that the locals are aware of their lands' worth and responsive to their surrounding occurrences.

Table 8.5: Locals can Voice out Opinions at KNP

		Locals can voice out opinions on TNK				
		Strongly Agree	Agree	Disagree	Strongly Disagree	Total
TNK dev. cares abt locals	Yes	30	28	13	4	75
	No	55	67	177	59	358
	Total	85	95	190	63	433

Even though the locals have attempted to make a positive use of the National Park, based on table 8.5, the locals have little power to voice their opinions to the Kubah National Park management. Table 8.8 shows significant number of the respondents claims that the management of Kubah National Park has not taken into account their perspective or wellbeing.

9.0 RECOMMENDATION AND CONCLUSION

Kubah National Park is a well acknowledged protected and recreational area for the local residents and the outsiders. The Park has provided the neighboring residents some rare experiences from dealing with escaped endangered animals to common encounters of interaction with tourists from many parts of the world. Apart from the indirect physical effects of economy and infrastructure, Kubah National Park affects the local residents' awareness and appreciation towards natural surroundings. Thus, while the development of Kubah National Park may not be intended to affect the local residents, the influences of the Park have in many ways delivers to the residents some indirect benefits and negative outcomes.

The analysis shows that the local residents are indirectly involved in the progresses of Kubah National Park. However based on the results from the aspect of economic influences, majority of the residents have yet to receive some consideration. Vast majority of the residents are in the group of very low income earners. Provided with the fact that majority of the residents have 4 to 6 and 7 to 9 household members, as

well as considering they are a growing population, some attention towards their economic earnings must be reflected by the management of the Park. Apart from job opportunities, the Park can offer some business or agricultural resources for the residents to make some earnings from. Since it is a National Park protecting rare and endangered species of flora and fauna, the surrounding should also reflect the unique characteristics of Kubah National Park.

It also must be noted than even though the economic aspect has not significantly affecting the local residents, the land value and cost of living as claimed by majority of the respondents are stagnant or could be increasing but very slowly. This suggests that the National Park is lacking tourism responses. Looking from another angle, the residents have responded positively to the development of the National Park. Appreciation of natural environment and willingness to accommodate the tourists are among the positive effort which the residents can contribute to the Park. Community participation methods can be operated allowing the residents to voice their opinions and ideas on how they could assist the National Park attractions. This can also result to a strong and better relationship between the management of the Park and the surrounding local residents.

It is recommended that the resource planning of the surrounding of Kubah National Park to be reviewed. The management should treat the local residents and the surrounding areas as a part of the resource for the progressions of the Park. The rural and cultural characteristics of the villages can be a good attraction for homestays and sightseeing. The villagers who are self-employed and working as fishermen and farmers can play significant roles in promoting the natural characteristics of the Park. More involvement of the local residents is highly urged. Apart from giving back to the community, local involvement would be a good prospect to increase skills and awareness level of the villagers.

Further study should be carried out on the natural and cultural resources of the local residents in determining local participation methods to enhance the surrounding of the park as well as aiding the residents to make more earnings as the land value increases.

THE CONCEPT OF EUROPEAN METROPOLITAN REGIONS IN GERMANY AND ITS IMPACT ON REGIONAL DEVELOPMENT – THE EXAMPLES OF NUREMBERG AND HAMBURG

Swantje Grotheer[1]

Abstract

The Standing Conference of Federal and State Ministers Responsible for Spatial Planning (MKRO) in Germany decided on the "concepts and approaches for the spatial development of Germany" in April 2006. The three concepts are "growth and innovation", "securing services of public interest" and "conservation of resources, shaping of cultural landscapes". They have equal priority and were developed to cope with the main tasks for spatial planning in Germany over the next years. The concept of "growth and innovation" includes the spatial planning concept of the "European Metropolitan Regions in Germany". It names eleven Metropolitan Regions that are recognized as (structurally) "strong" regions that perform as "engines" of growth and development – a role that should be strengthened and enhanced for the positioning of Germany in the global and European economy. At the same time Metropolitan Regions should develop partnerships with peripheral and structurally weak regions for sharing responsibilities and fostering equivalent living conditions. Through the foundation on the federal level of planning in Germany, the concept of European Metropolitan Regions is not an administrative construct or legally binding objective in planning. Each of the eleven Metropolitan Regions defines its "boundaries" and means of regional cooperation and governance in an implementation process.

These processes of implementation in the eleven regions are proceeding with varying speeds. In most of the regions cooperation and forms of governance are based on different types of regional networks. These try to address current and future conditions and challenges of spatial development. The paper will analyze the implementation of the concept of Metropolitan Regions in Nuremberg and Hamburg and the resulting impacts on their regional development through the development of new and the consolidation of existing regional networks.

The value of networking as a means of exchanging information, knowledge and experience for mutual benefit is crucial in terms of the implementation of the concept of European Metropolitan Regions in Germany. Networks and different ways of inter-municipal and regional co-operation play an important and nevertheless differentiated role for the regional development of these regions. Key actors play

[1] University of Kaiserslautern, Kaiserslautern, Germany – swantje.grotheer@ru.uni-kl.de

another important role for effective and valuable co-operation and networking. One important challenge of European Metropolitan Regions in Germany, especially in the two analyzed regions, is the co-operation of structurally different sub-regions – economically weak and peripheral regions vs. prosperous and innovative regions – in the frame of one big network. The participation in the metropolitan cooperation is voluntary and mainly serves a harmonization of common objectives, in which the latter may be difficult because of the heterogeneity of these regions.

Nevertheless a range of thematic networks came to existence in the Metropolitan Regions of Hamburg and Nuremberg. They emerged from different existing structures and are relatively new in Nuremberg (constitution of the metropolitan co-operation in 2005). In Hamburg there is a constant advancement of existing co-operation structures. The paper is based on findings of studies in a dissertation that was finished in March 2011.

1. Introduction: The concept of European Metropolitan Regions in Germany

The economic key role of big cities, metropolises and their interlinked regions has become more and more obvious in the processes of European integration and globalization. This led to an increasing relevance of big cities and metropolitan regions within the German spatial development policy, and to the formulation of the spatial planning concept of the European Metropolitan Regions as a strategic concept for the spatial development of Germany.

The term "Metropolitan Region" – that is not always used with the add-on "European" – is used in the scientific community in two ways: Firstly in an analytical understanding and secondly in the political and spatial planning-related practice. To clarify the meaning of this term, it is important to differentiate between these two conceptual understandings of Metropolitan Regions (ARL, 2007, p. 3; Blotevogel, Danielzyk, 2009, p. 24). The analytical understanding functionally assumes metropolitan regions as regional clusters of locations with metropolitan functions or institutions (Blotevogel, Danielzyk, 2009, p. 24). The normative understanding of Metropolitan Regions follows the definition of the Standing Conference of Federal and State Ministers Responsible for Spatial Planning in Germany (MKRO) and leads to an understanding of metropolitan regions as regional cooperation areas with different forms of governance and participation of local and regional actors (Blotevogel, Danielzyk, 2009, p. 24). These regional cooperation areas are predominantly informally organized and based on ***regional networks*** of various regional actors. Their aim is to perform as "engines of growth and development" and to strengthen their metropolitan functions: foster innovation, a good standing in the regional competition, pool political and economic decision-making and to be a gateway to people and other regions.

This paper is based on the second, the normative, political and spatial planning-related, understanding of metropolitan regions and analyses how the concept is implemented in the two Metropolitan Regions Hamburg and Nuremberg.

The federal spatial planning policy document HARA ("Raumordnungspolitischer Handlungsrahmen") was the first document that formulated the normative concept and defined European Metropolitan Regions in Germany as spatial and functional locations with excellent functions in the international competition between regions. In this document they are classified as engines of social, economic and cultural development and shall contribute to the international and European competitiveness of Germany and Europe (BMBS, 1995, p. 27). This document labeled six German regions as Metropolitan regions: Berlin/Brandenburg, Hamburg, Munich, Rhine-Main, Rhine-Ruhr and Stuttgart.

This normative concept was again highlighted and further developed in the "concepts and approaches for the spatial development of Germany" that were adopted by the MKRO in Germany in April 2006. Another five Metropolitan Regions were labeled and finally eleven Metropolitan Regions are recognized as structurally strong regions that perform as "engines" of growth and development in this document. The approval of the new five Metropolitan Regions was a policy decision with two main backgrounds: Firstly, most of the new and potential Metropolitan Regions, especially Rhine-Neckar and Nuremberg, ran for an approval. Secondly, the concept has been further developed with the policy that Metropolitan Regions should develop partnerships with peripheral and structurally weak regions for sharing responsibilities and fostering equivalent living conditions in Germany. A spatially more balanced distribution of Metropolitan Regions in Germany was a necessary basis to achieve this. The concept of Metropolitan Regions was discussed intensively and also very critical in spatial planning practice and in the German scientific planning community between the spatial planning priorities of growth (competitiveness) and equivalence (cohesion) (e.g. Aring; Sinz, 2006, pp. 43).

1.1 The implementation of the concept of European Metropolitan Regions in Germany

Through the foundation on the federal level of planning in Germany, the concept of European Metropolitan Regions is not an administrative construct or legally binding objective in planning. Nevertheless, most regions implemented this concept. Each of the eleven Metropolitan Regions defines its regional "boundaries" and means of regional cooperation and governance. The Metropolitan Regions in Germany established their regional cooperation based on different existing structures and structural preconditions. Their all developed – and some still develop – different forms of regional governance with the influence of a great amount of regional actors. They vary in financing, objectives and structures. The form of regional governance and cooperation are predominantly based on different forms of regional networks.

The European Metropolitan Regions in Germany build up a national platform for an exchange of knowledge and for a further development of the concept of European Metropolitan Regions in Germany, the so called "Initiativkreis Europäische Metropolregionen in Deutschland". In the latest regional monitoring of the German Metropolitan Regions a map is showing the administrative and "self-defined" boundaries of the eleven regions in Germany. The following map shows, that these regions vary very much in their extent.

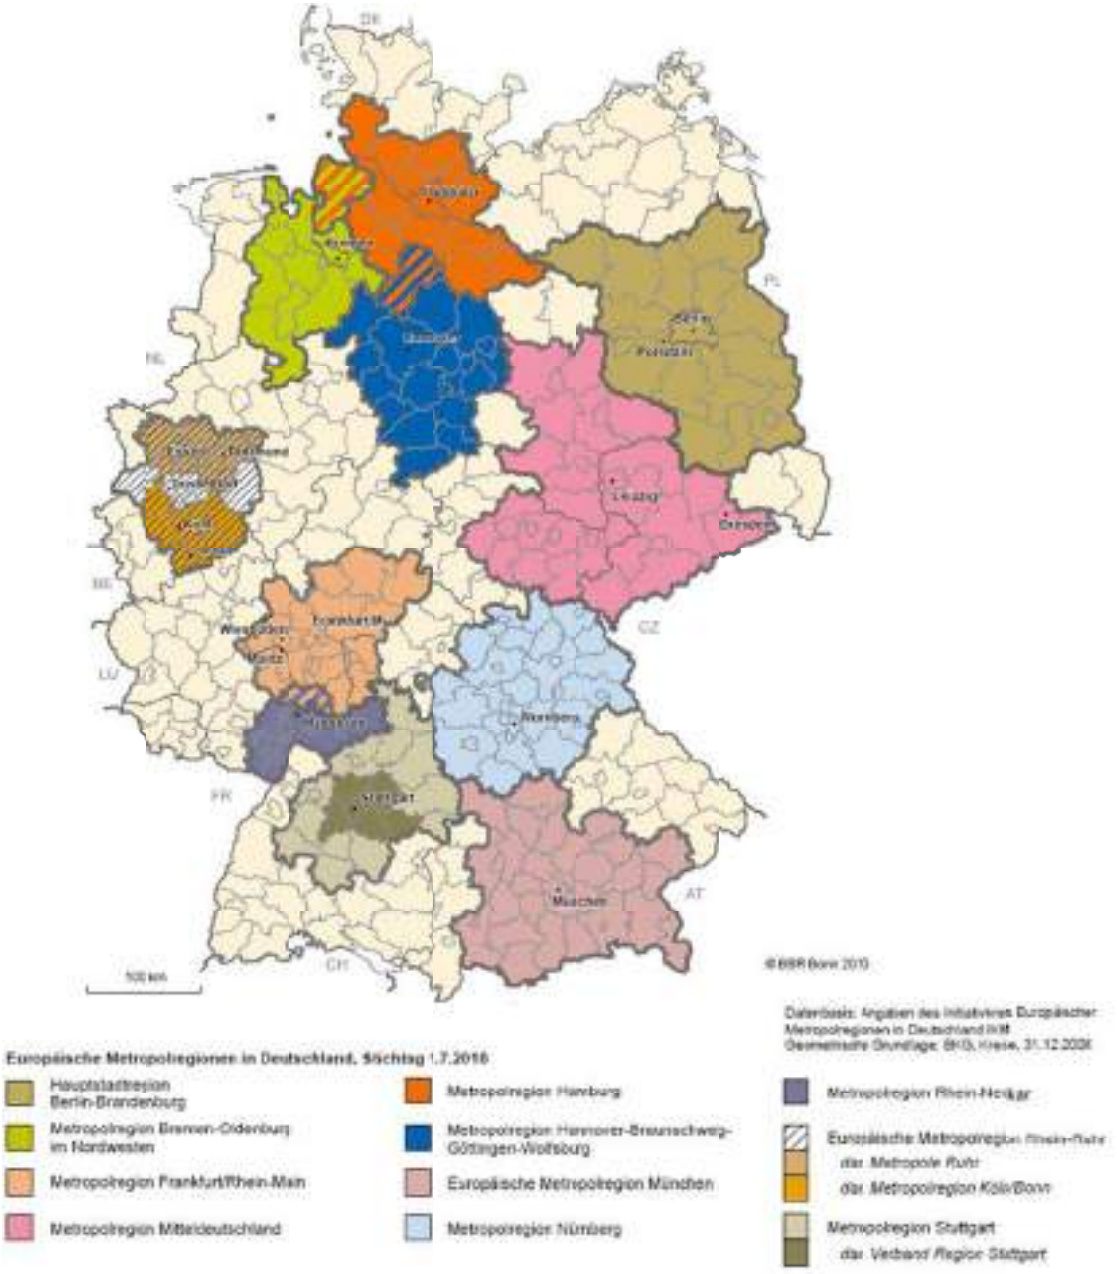

Figure 1. Metropolitan Regions in Germany, 2010 (IKM, BBSR, 2010, p.7)

1.2 Regional networks and regional cooperation and their role in regional development

Regional networks are topics in regional sciences in the light of socio-economic structural changes since the mid-1980s and with their role for in regional development processes. Emerging trends such as knowledge-based society, globalization and regionalization, pluralizing and individualizing, and the upcoming public debt were important triggers for this discussion. The innovation capacity of regions and economies became one of the main factors of success for development that can be positively influenced in a regional milieu with good and high quality communication processes between regional actors (Schubert et al., 2001, p.11).

A regional network is a voluntary, mainly permanent and equal cooperation between at least three regional – private and public – actors of different organizations with interdependent interests. They are based on written or oral agreements. Regional networks are target-oriented, reciprocal and serve for their members as a platform to gain medium to long-term social and economic synergy effects (Adrian, 2003, p.11). The central functions of regional networks are building trust, to reduce uncertainty, consensus-building and to form a framework for negotiations.

Although there are a number of problems that may lead to failure of regional networks, e.g. long time periods to make decisions, problems in coordinating actors with different interests, or differences in power of actors that ideal-typical should be equal (Messner, 1995, pp.214-239), regional networks can affect regional development in different ways:

- Regional networks can replace missing or inadequate institutional decision-making structures on the regional level and thus organize necessary regional processes of coordination;
- Regional networks can contribute to overcoming of sectorial and local perspectives of regional actors.
- Regional networks can serve as forums to identify common problems and innovative forms of action (Schubert, 2001, p. 12).

Finally, regional networks and regional cooperation cause outcomes in three dimensions: Firstly, they have “soft” effects especially in the field of building up trust between actors (developing social capital) with positive effects on regional coordination and the execution of projects. Secondly, substantial outcomes such as plans, programs, projects and agreements can be outcomes of regional networks. Thirdly, regional networks can promote regional development by different means, whereas this is difficult to verify (Diller, 2002, pp.136). It is important for successful regional networks to consist of different actors: political and administrative as well as economic and different interest groups.

2. The Implementation of the concept of European Metropolitan Regions in Hamburg and Nuremberg

The concept of Metropolitan Regions was implemented in different patterns in Nuremberg and Hamburg. In Hamburg an existing administrative cooperation of the three Länder Hamburg, Lower Saxony and Schleswig-Holstein was advanced to a strategic cooperation, which pursues an internationalization strategy for the whole region. The application for the approval as Metropolitan Region in Nuremberg was followed by the development of a new, own, flexible structure characterized by networks with the central objective of increasing the international visibility of the whole region. The development paths of both regions are important for the current Metropolitan cooperation, their structure, actor constellation and impacts of cooperation.

2.1 The Metropolitan Region Hamburg (MRH)

The regional cooperation of the Metropolitan Region Hamburg (MRH) involves administrative districts[2] of the three Länder Hamburg, Lower Saxony and Schleswig Holstein, thus its regional boundary, financing and cooperation is defined in a treaty between these three Länder.[3] The region comprises structurally very different regions and has its economic and population-based focus in Hamburg and its closer surrounding regions. Analyses of the distribution of metropolitan functions in Germany distinctly show that these are concentrated in the city of Hamburg. Nevertheless there is a high interconnectedness between Hamburg and its surrounding area especially in the fields of recreation and living in the surrounding area. These structural preconditions have different influences on the regional cooperation structures.

[2] Administrative districts are “Landkreise” in Lower Saxony and “Kreise” in Schleswig-Holstein. In America it can be compared to the level of “counties”.

[3] The Metropolitan Region Hamburg extended in April 2012 and is now including further administrative districts in Schleswig Holstein and of a now fourth partner-Land Mecklenburg-Vorpommern. This extension is not considered in this paper.

Figure 2. The Metropolitan Region Hamburg, 2011 (map basis: Freie und Hansestadt Hamburg, Landesbetrieb Geoinformation und Vermessung)

Regional cooperation structures and regional networks

The Metropolitan Region Hamburg was developed out of the cooperation of governments between the three Länder Lower Saxony, Hamburg and Schleswig-Holstein. Since the mid-1950s, these Länder worked together with changing intensity on the challenges of the spatial and settlement development in the interlacing area of the city Hamburg. The political actors on the Länder level, here especially the ones from Hamburg, had an important influence on the strengths of the cooperation, the function and mutual suspicion or difficulties.

In the early years, the cooperation was limited to Spatial Planning and the topics infrastructure and settlement development had priority until the 1990s (Bose, 1995, pp.140). The Länder build up funding funds (bilaterally Lower-Saxony and Hamburg as well as Schleswig-Holstein and Hamburg) in the 1960s, which were meant to co-finance infrastructural projects in the municipalities – in the beginning only in the surrounding region and later on also in Hamburg itself as an important instrument in the cooperation. In the midst of the 1990s happened a change in the cooperation which was signalized by the regional development concept decided in the year 1996 and the official use of the title "Metropolitan Region". With regard to the content of this concept, the next regional development concept in the year 2000 was the first one that contained structural policy topics and thus represents the strategic further

development of the regional cooperation. The national discussion about the strategic meaning and the concept of Metropolitan Regions also had an influence on the expansion of themes. Since 1995, the Metropolitan Region Hamburg was already established in the decided scope of action in spatial planning policy and had a stressed meaning in the North German area. There were more strategic re-orientations after the regional development concept 2000 which are related to a stronger consideration of structural policy themes and the international positioning. Thereby the concept of Metropolitan Regions for the region was further developed and formulated. Appropriate structures for the accomplishment of upcoming challenges were discussed – regularly, detailed and comprehensive – and finally decided on a stronger involvement of communal members through the administrative agreement in the year 2005.

The administrative agreement between the three Länder and the participating administrative districts was signed on 1.12.2005 and defines the cooperation in the Metropolitan Region as a voluntary union that is based on voluntary involvement and consensus decisions. Furthermore the agreement defines the bodies and their competences. Key elements are the deciding body (a regional council) where all administrative districts and the three Länder are represented, a strategic body (Lenkungsausschuss) that is deciding on projects and priorities of regional cooperation where a small number of representatives work together and decide in general about the distribution of funding and (thematic) working groups (Facharbeitsgruppen) which are set up of different regional actors.

With the definition of regional networks as it was described above, the working groups can be characterized as regional networks as the only element of the official organizational structure of the Metropolitan Region Hamburg. The other bodies are predominantly regional *political* networks with a limited access and thus cannot be characterized as regional networks. A detailed analysis of the composition of the working groups shows, that these are also dominated by administrative actors of the Länder whereas only relatively few actors of the municipal and administrative districts level or other regional actors participate. Nevertheless, these have the possibility to participate and do this in especially during specific projects.

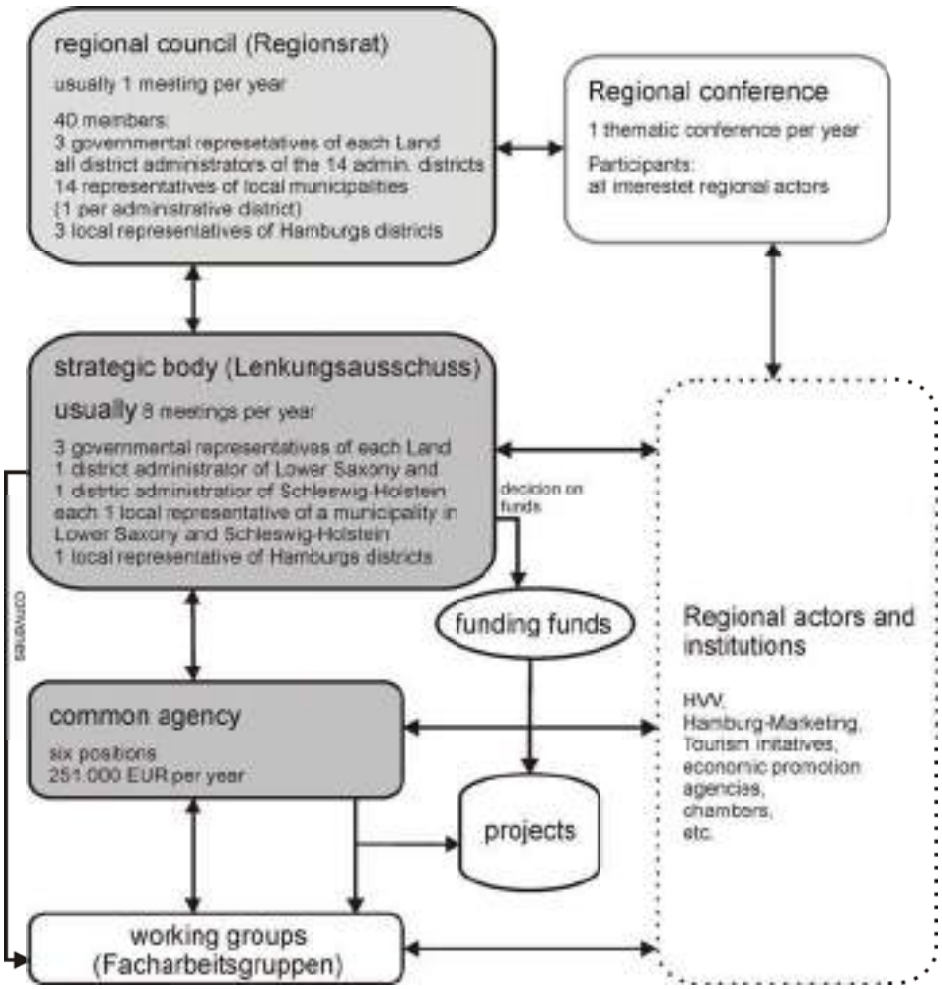

Figure 3. Metropolitan Regions Hamburg – organizational structure based on the administrative agreement 2005

2.2 The Metropolitan Region Nuremberg (EMN)

The Metropolitan Region Nuremberg (EMN) is a voluntary union of northern Bavarian administrative districts and independent cities. It was founded directly after the official approval of the region to be a "Metropolitan Region" by the MKRO in the year 2005. All participating administrative districts and independent cities signed a so called "Charta of the Metropolitan Region Nuremberg" that defined the general principles of the cooperation. These principles are

- voluntariness,
- subsidiarity,
- openness and spatially and thematically dynamic,
- decisions should be made consensually,
- establish a democratic core to decide on the main points of cooperation (council of the Metropolitan Region),
- cooperation at eye level (especially of all different political actors), and

- intensive networking of economic, academic, cultural and administrative actors.

The principle of openness offers all administrative districts and independent cities to decide on the question of they want to become a member of the Metropolitan Region Nuremberg. This has led to some changes in the regional boundary of the cooperation (at the edge of the region) and is now as shown in the following figure.

Figure 4. The Metropolitan Region Nuremberg 2011

The socio-economic structure of this relatively big region is rather heterogeneous. Although much of the economic activity and of the population is concentrated in the core area with the cities Nuremberg-Fuerth-Erlangen-Schwabach and their directly adjoining administrative districts, the regions doesn't have a functionally dominant center. The northern and north-eastern administrative districts tend to be the structurally weakest, especially in terms of ageing and shrinking population.

Regional cooperation structures and regional networks

The regional cooperation structure of the Metropolitan Region Nuremberg was developed with the idea to have a flexible and non-bureaucratic structure based on the principle of "regional governance without government". This guiding principle emphasizes that cooperation and consensus are dominating; all partners are balanced in power. The figure shows the organizational structure of the Metropolitan Region Nuremberg. The principles of the cooperation reflect in this structure: all decisions of

the council are made in consensus and every member – administrative district, independent city and one municipality per administrative district (the municipality with the most inhabitants) has one vote (no matter how many inhabitants the municipality has).

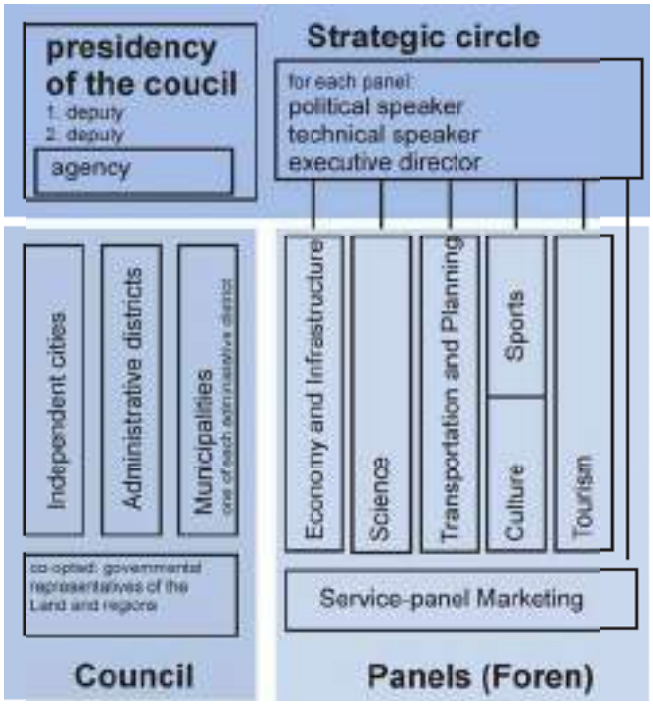

Figure 5. Metropolitan Region Nuremberg – organizational structure

The different panels work on the main topics of the metropolitan cooperation. They are open for interested regional actors and function as regional networks. Each panel has a political speaker, a technical speaker and an executive director which form together with the presidency of the council the strategic circle of the whole cooperation. With this three-person leading managerial task force a balanced consideration of different interests is guaranteed. Furthermore, the three speakers represent the ideas of the Metropolitan Region in different target groups and thus contribute to the dissemination of their ideas and projects.

3. Assessment of the impacts of the Implementation of the concept of European Metropolitan Regions in Hamburg and Nuremberg on regional development

The following results are based on partly structured interviews with political and administrative representatives of members of the Metropolitan Regions Hamburg and Nuremberg (Grotheer, 2011, pp.190).[4]

[4] The results are based on 9 interviews and one written answer of the questions in the Metropolitan Region Hamburg (September 2008) and 38 interviews in the Metropolitan Region Nuremberg (July – September 2008).

3.1 The Metropolitan Region Hamburg

For a conclusive evaluation the political and administrative representatives were asked for an assessment what the Metropolitan Region Hamburg can actually achieve (or not achieve) for the regional and municipal development (expectations and limits of the Metropolitan Region Hamburg). To give a review, the answers were not homogenous. Merely the aspect that the level of the administrative districts and communities can keep their municipal autonomy and that this can't be questioned by the work of the Metropolitan Region or that its influence becomes too high was named as an obvious limit of the work. Following aspects should be achieved:

- Strengthening of the regional awareness, especially by the positive use of important personalities who promote the regional thought,
- To be an initiator for regional projects and contents,
- Strengthening of the international awareness and the publicity of the whole region,
- Development of joint strategies for the regional development, especially in the topics marketing and economy and their realization through projects (sponsorship of funding fonds)
- Handling of topics which can be processed rational on a regional level, especially public transport and industry land-use as well as
- Provision of regional networking structures as an offer for actors to collaborate in projects or themes which match with the own interests.

Two administrative districts that are further away from Hamburg formulated the expectation that economic activities have an increased impact in the further region, which originates into a stronger economic cooperation. This expectation may cause difficulties in the cooperation, because it is necessary to find a balance between the unavoidable competition among municipalities and regional cooperation. There are only some possibilities for a Metropolitan Region to arrange the economic activities in an actual balance but rather represent a platform on which the (administrative) districts can position themselves. Besides the positive expectations, limits of what **should not be achieved** were also formulated. The observance of the municipal autonomy is highlighted as a main priority in this context. In particular the following aspects were named:

- Formal planning cannot be replaced by informal coordination on regional level so that the Metropolitan Region can't take over decisions in own jurisdiction (e.g. regional planning),
- It is not possible to initiate projects which can be realized automatically on-site (Top-down) and
- The cooperation can't lead to an increased centralization or to a rearrangement of the administration (e.g. elimination of administrative districts).

The development of the regional cooperation structures plays an important role in the current work. The concept of the Metropolitan Regions was integrated into existing

structures of cooperation and extended these by strategic and structural policy contents. Based on the development of the cooperation in Metropolitan Regions the official committees are mainly characterized by political and especially administrative actors of the three Länder and more and more also of the administrative districts. The municipal actors were integrated steadier with the administrative agreement in the year 2005. This is still clearly visible in the low participation at the working groups. Besides the originally assigned structures in the Metropolitan Region, further networks originated of different organizational structures for the strategic tasks of international awareness, the linking of companies in the region among themselves with research institutions and economic promotions. To these belongs for example the growth initiative Süderelbe AG, the logistic-initiative Hamburg e.V. or the Hamburg Marketing GmbH. These networks concerning the integration of (administrative) districts are not congruent with the official distinction of the Metropolitan Region, but rather smaller like the Süderelbe AG and the logistic-initiative Hamburg e.V. or bigger like in the case of the Hamburg Marketing GmbH where the partner district Ludwigslust is involved.

However, the possibility to participate in the funding funds or the funding of projects with the cooperation has the highest impact on regional development. Most of the impacts on regional and local level as well as on the level of (administrative) districts and municipalities are generated by this. Projects on local level were realized with direct impacts and improvements due to the funding of infrastructure projects (e.g. Park and Ride facilities, cycle paths, etc.) and touristic facilities (e.g. visitor guidance concepts, etc.). According to the principle of variable geometry in the Metropolitan Region Hamburg it is clear, that not all administrative districts are involved in each project that is funded by the funding funds. This is rated as a central principle by the involved administrative districts based on the precondition that the three Länder provide financing for the funds.

The City of Hamburg is not only the key element of the functioning cooperation but rather an essential influence on the international awareness, the economic power and the potential for innovation in a monocentric Metropolitan Region. This can be classified as an advantage but also as a disadvantage. In each case it is the most urgent precondition for the cooperation and the created impacts on the whole region.

Even though the Metropolitan Region Hamburg works as a voluntary fusion there is still the expectation in the municipal members to integrate themselves partly stronger with their own strengths into the cooperation and the outward marketing as well as to launch regional topics. Occasionally it is pointed out that the capacities of the (administrative) districts and municipalities are not always available in the strength as this is for example the case in the city Hamburg so that with the realization of projects there are partly “different rates”.

3.2 The Metropolitan Region Nuremberg

Expectations on the impact of the Metropolitan Region cooperation for the regional and municipal development are not pitched too high because it is an alliance of municipalities on a voluntary basis. It is mainly designed to offer a platform for mutual exchange and to generate synergy effects. Due to the fact that it is a voluntary alliance, the Metropolitan Region Nuremberg can and will only achieve what each member contributes to it. By means of cooperation another quality can be attained or subjects can be transported. Nonetheless municipal members of the Metropolitan Region expect various aspects that the cooperation shall afford:

They expect an **increase of international awareness** in the competition between regions and the related expectation of a rise of public and private investments in (projects) of the region. A focused marketing of the "Highlights" in the branches tourism, culture, economy and science will be possible via the Metropolitan Region (especially on European Level in Brussels and on fairs). Thus the "title" can be filled in with specific contents and unique features in the international awareness. Closely linked to this is the opportunity to improve the representation of regional interests on the national and international level.

The **strengthening of regional thinking and acting** results into positive links for the development of the participating administrative districts and independent cities. Through the personal communication and the meetings in the committees of the Metropolitan Region, joint problems and challenges can be discussed and most notably joint and better solutions such as the realization of innovative projects can be worked out. Regional cooperation forms a platform for mutual exchange of experiences and beyond that the possibility to manage municipal services in a regional cluster. The facts that they succeeded to define a joint aim in the Metropolitan Region and to work together are important preconditions for this.

The Metropolitan Region can contribute to the regional and local development with the **initiation and realization of projects**. Important examples are the expansion of the regional linked transport system (Verkehrsverbund Grossraum Nuremberg, VGN), which implies an improvement in the transport connection of the region, as well as the MORO-Project (Pilot Projects of Spatial Planning that are funded by the federal spatial planning ministry) that aims at strengthening regional economic cycles and value chains. The new qualities (increase of inner-regional transport connecting qualities and the associated accessibility to cultural facilities and offers) in the location marketing can be used in the administrative districts which are not located central to achieve an increase of attraction for companies.

The array in which the Metropolitan Region Nuremberg can contribute to the development is based on its structure and basic understanding to bring together municipal actors on regional level with other actors voluntarily and issue-specific. The cooperation allows all participating actors to succeed in an early detection of

joint problems and to develop innovative strategies and approaches without complicated or bureaucratic structures.

Although the Metropolitan Region can achieve different aspects for regional and local development there are also limits that are named by the participating administrative districts and independent cities. The focus is set on subsidiarity and the statement that the Metropolitan Region is not in charge of the development on local level of the administrative districts and independent cities, because the challenges there need to be solved by the actors themselves. According to that the adherence of subsidiarity is both: not "being able" to afford it and not "supposed" to. This means that the Metropolitan Regions shall concentrate on such topics and projects that are important on a regional or international level. Furthermore the preservation of peculiarities of partial subspaces shall to be guaranteed, despite of the cooperation under the joint label Metropolitan Region. Rural areas need to be preserved on the one side with their characteristics, diversity and strengths and not to be characterized as "residue" in the area of a Metropolitan Region and on the other side not to overlay their problems and challenges but rather support them specifically although they are a part of a Metropolitan Region.

Conclusion

The Metropolitan Region was founded at the start of the new millennium in the course of the discussion about the development of the "Concepts and Strategies for Spatial Development in Germany". There was no other comparable voluntary cooperation in the Area of Northern Bavaria before. The much smaller region Nuremberg was the only one who disbanded its existing structures of regional cooperation or transferred it into the Metropolitan Region Nuremberg. Along with that the marketing association opened up for further members and transported its messages no longer with the term "Region Nuremberg" but "Metropolitan Region Nuremberg". The cooperation structures in the Metropolitan Region are especially characterized by the principles of voluntariness and same eye level of all partners. This is reflected in the distribution of votes in the democratic core committee, the council of the Metropolitan Region. The structures are featured transparent and flexible to achieve an actual involvement of the administrative districts and independent cities. A very important driving force in the organization and development of the Metropolitan Region was the city Nuremberg with its mayor. This is also displayed in the support of the created structures, especially by the comprehensive personal and financial support of the office in the starting phase.

The official approval as Metropolitan Region, with which different expectations were connected, was a possibility for the city of Nuremberg to improve the outline in the international competition, whereas the integration of the region with further independent cities and administrative districts was a necessary precondition. The other independent cities and administrative districts which jointed the Metropolitan Region are also integrated in a variety of further regional cooperation structures, both on-topic and cross-sectorial initiatives of different spatial extent. Their aims are not

opposed but rather complementary because these cooperation structures primarily address other audiences. Nonetheless a variety of the created committees, working groups, events and conferences are linked to an increased involvement of personal capacities, which are not unlimited. The Bottom-up development and decisions are rated positive for the cooperation in the Metropolitan Region and the created networking in the forums but also in the political committees. A regional spirit of optimism could be generated by the actual approval as Metropolitan Region by the MKRO. Not all municipal actors were integrated equally into the phase of initiation. Some key actors contributed considerably more. To encounter the provisions of a metropolis, the affirmation of participating in the Metropolitan Region of elected rural administrative districts as well as the mayor were of elementary importance in order to underline the characteristics of an urban-rural relationship. Besides the successful formulation of basic aims in the Bad Windsheimer declaration, the Metropolitan Region Nuremberg represents a strategic alliance that succeeded in developing a strategic aim for the economic development under the aegis of the Chamber of Industry and Commerce. Following this strategic aim the further fostering of clusters in the region should be realized. In the forums regional actors of policy, administration, economy, science and society work together, whereas the created platforms in the region serve for generating innovative ideas and realization of projects as well as the transfer of knowledge. The transfer of knowledge between the different rural areas of the Metropolitan Region, which are confronted with similar challenges e.g. West Middle Franconia and Upper Franconia but had so far barely points of contact, can contribute to a sped-up solution approach or the avoidance of faults.

On long-term it is important that projects are successfully realized and that this is also communicated appropriate in the region. An important challenge is the financial sustainability. The membership subscription raised by the region is not very high – especially to avoid entrance barriers at the beginning – but they need to be adequate to sustain the basic structures, e.g. the personal equipment of the office in a necessary extent. The formulated projects created in the forums shall be realized through extern funds. The meaning of the summarized represented central aspects of the implementation of the concept of the Metropolitan Region Nuremberg for local and regional development can be estimated only with difficulties because the cooperation and networking is relatively young. Nonetheless some projects could already be realized and their long-term impacts still need to be evaluated. To these projects belong for example the further strengthening of the in the development outline represented cluster, the strengthening of regional economic cycles by “Original Regional” or effects of the international awareness e.g. by international fair participation. Within Bavaria and Germany the Metropolitan Region succeeded in generating awareness and to position itself as a confident region, even with the created structure.

4. Meaning of the concept of Metropolitan Regions for the regional development in Nuremberg and Hamburg

The difficulty for an analysis of the meaning of the implementation of the concept of Metropolitan Regions for regional and municipal development of the Metropolitan Regions Hamburg and Nuremberg is to trace the development and changes back to the actual work of a Metropolitan Region. In addition to that, the case of the Metropolitan Region Nuremberg is more difficult because it was initiated as recently as the year 2005. The key elements for regional development in the Metropolitan Region Hamburg are the specific funding funds, which are provided with financial means by the three Länder. With these funds communal as well as regional measures and projects are co-financed, which have immediate and mediate impacts. Because a number of infrastructural measurements on municipal level could be financed by these funds, the meaning of Metropolitan Regions on this level is rapidly understandable. The assessment of municipal actors of the Metropolitan Region Hamburg shows very plainly, that the implementation of projects has the highest importance and accordingly also contributes to an involvement of these actors in the cooperation. The Metropolitan Region has developed from a pure administrative cooperation to a strategic oriented, involving the structure of the municipal level in the past years. Nonetheless private and economic regional actors as well as other regional institutions play a marginal role in the official committees and structures of the Metropolitan Region Hamburg, whereby the existing regional networks on that level can be characterized as unbalanced. On the political level an improvement of neighborly agreement and the rise of a common thinking can be noticed – although each side of the Elbe is separate. Based on this improved information exchange, advantages and a speedup of projects and processes of coordination can be achieved. The dominating center Hamburg is adjudicated a changed attitude towards urban hinterlands, wherewith for example potential areas can be used better in the (further and narrower) hinterlands for logistic settlements and the thereby connected effects. The step by step expansion of the HVV is due to the changed regional perspective which boosts especially the surrounding region of Hamburg. The cooperation on the level of Metropolitan Region plays an essential role. However the challenge is to succeed in the step by step development, away from a pure administrative cooperation, to actually achieve its objectives and to realize long-term effects on municipal and regional level.

The networks which originate from a wide and comprehensive integration of economy, science, politics and further social actors in thematic forums, have a significant additional value for the Metropolitan Region Nuremberg. They also have a huge potential for the initiation and implementation of projects for regional and municipal development. At the same time they are connected with well-known risks of networks, such as the problem of the large number of actors and possible slowdown of decision processes or the problem of coordination due to various interests of horizontal actors. For the regional and municipal development – together with the relatively short existing cooperation – the improved possibility for joint

lobbying on Bavarian, national and European level e.g. for the implementation of transportation projects, the possibility of participation in international specialized fairs, the positive regional cooperation as well as good and innovative joint public relations are rated positive due to the Metropolitan Region cooperation. For a number of administrative districts the possibility for integration in the VGN is still an important incentive for the assistance in the Metropolitan Region Nuremberg, which can be supported or impelled by the existing networks there.

Altogether, the implementation of the concept of European Metropolitan Regions distinguished itself by resulting into a number of regional networks, which are a platform for the formulation and implementation of innovative projects for regional development and regional learning processes (learning of good and bad practices of other members in the network). In the case of the Metropolitan Region Hamburg there are mainly political and administrative networks while other regional actors are marginally integrated. The cooperation in the Metropolitan Region Nuremberg essentially relies on the intensive participation of the actors (especially municipal) of the region. On long-term, this can be achieved only when the use and chances of the cooperation are visible. In the Metropolitan Region Hamburg the structures are due to the specific situation of the cooperation of the three Länder basically more stable, although it is formal voluntarily. This is on the one hand an advantage because for instance the financing and the equipment of the agency are being secured comprehensive and on long-term. On the other hand actor structures in the working groups are relatively stable due to the development of the administrative cooperation.

The analysis of both case studies has clearly shown that initial conditions and development paths of regional cooperation play an essential role for the implementation and final organization of the concept of Metropolitan Regions. For other Metropolitan Regions especially projects such as funding of regional economic cycles, setup of a joint regional marketing or cooperation's of research and scientific institutions can be exemplary.

THE VANNISHING WATERSCAPE OF THE 19th CENTURY BELGRADE: LESSONS FOR ADAPTATION TO THE CLIMATE CHANGE

Dragana Ćorović[1], Ljiljana Blagojević[2]

Abstract

This paper examines urban history of Belgrade in the 19th century by focusing on transformation of the waterscape in the context of specific social relations and processes of emancipation of Belgrade as the capital of the Princedom, respectively the Kingdom of Serbia, and its transformation from the Ottoman into the European city. Our study of water, thus, explores its role in the socio-political and cultural environment during decisive historical events, in the physical, geographical, and symbolic sense. The historical waterscape consisted of a complex web of small rivers and streams which played a significant role in the urban life and functioning of the city, but have since disappeared in the process of urbanization. In this paper we will try to reconstruct the socio-spatial water network with an insight into its physical, geomorphologic, climatic, medical-hygienic, artistic and symbolic aspects. We will also outline the first modern public water supply system originating from the foundations of the Roman and the Ottoman waterworks, establishment of public baths on the river banks and public fountains in the parks, as well as water features and devices in the city. We will highlight, from a viewpoint of architectural and town planning, the changes in the urban landscape of Belgrade, by looking into artistic and photographic evidence, travel writing, maps and plans which show spontaneous and controlled transformations of its waterscape.

The text is an analysis of the spatiality of the changing relation of society to water, antagonisms and conflicts emerging from it, with the aim to underline the importance of water as a resource, with the view to contemporary environmental concerns. Specifically, we will focus on the Topčider River, which flows into the Sava upstream from the confluence with the Danube. While in the 19th century this river and the area around it held central political, social, cultural and natural significance, today it is one of the most polluted watercourses in Belgrade. Are there lessons to be learned from the urban history which can point to the methods of contemporary water management, as one of the principal aspects of urban sustainability? In this sense, we aim to open a discussion on contemporary waterscape as key to sustainable town planning of Belgrade

today.

1. Introduction

Synonyms of the phrase *urban landscape* include *townscape*, *cityscape*, *city scene*, *city view*, all of which imply looking or gazing onto a city. Similarly, the term *waterscape*, the topic of this paper, contains the meaning of looking onto water, or within the context of the discipline of urban history, looking into the relationship of the city and water through history. Surveying the scene, including a waterscape, can lead to its better or more profound understanding. Indicative of this is a piece of travel writing from the 19th century, in which the author describes the view gleamed from the Danube's slope in Belgrade:

"I pushed open the door, and there, completely secluded from the bustle of the town, and the view of the stranger, grew the vegetation as luxuriant as ever, relieving with its dark green frame the clear white of the numerous domes and minarets of the Turkish quarter, and the broad-bosomed Danube which filled up the centre of the picture; but the house and stable [...] were tenantless, ruinous, and silent." (Paton, 1845, p. 51)

The central piece of this image is the Danube, viewed from an abandoned house in a Turkish suburb of Belgrade. It is a good metaphor for the dual nature of the character of scenery around Belgrade: an ensemble of landscape elements of an Oriental city against the backdrop of the massive waterway, with the interplay of the two yielding a new quality, despite the ruinous surroundings.

Figure 1. Geologic map of Serbia, detail (Viquesnel, 1842, Pl. XIX)

The first geologic map of Serbia, published in 1842, includes information about the geologic history of the terrain, as well as of the geopolitical situation of the day. The map shows the Belgrade waterscape as an intertwinement of waterways framed by the river border between the great empires of the time. The Belgrade waterscape was shaped

by the interaction of the broader state, politically strategic and economic picture, and the narrower, city context of various cultures and communities.

2. The Belgrade Waterscape

Viewed from Zemun, Belgrade was a city without much life on its rivers, despite its skyline of myriad minarets and domes nestled in the green of gardens and arboreta. Fuelled by fear of the plague, strict quarantine regulations from the first half of the 19th century forced ships to pass by Belgrade, holding as much as possible to the Hungarian side. As opposed to the view from the river, for the sojourner arriving by way of land Belgrade was "unusually colourful, prettier and more European-like of any other city" (Hervé, 1837, in: Momčilović, ed., 1993, p. 49) of the Ottoman Empire. The position of the large rivers, the presence of waterways within the city, as well as a general relationship to water, allowed for the existence of multiple meanings and perceptions of the landscape.

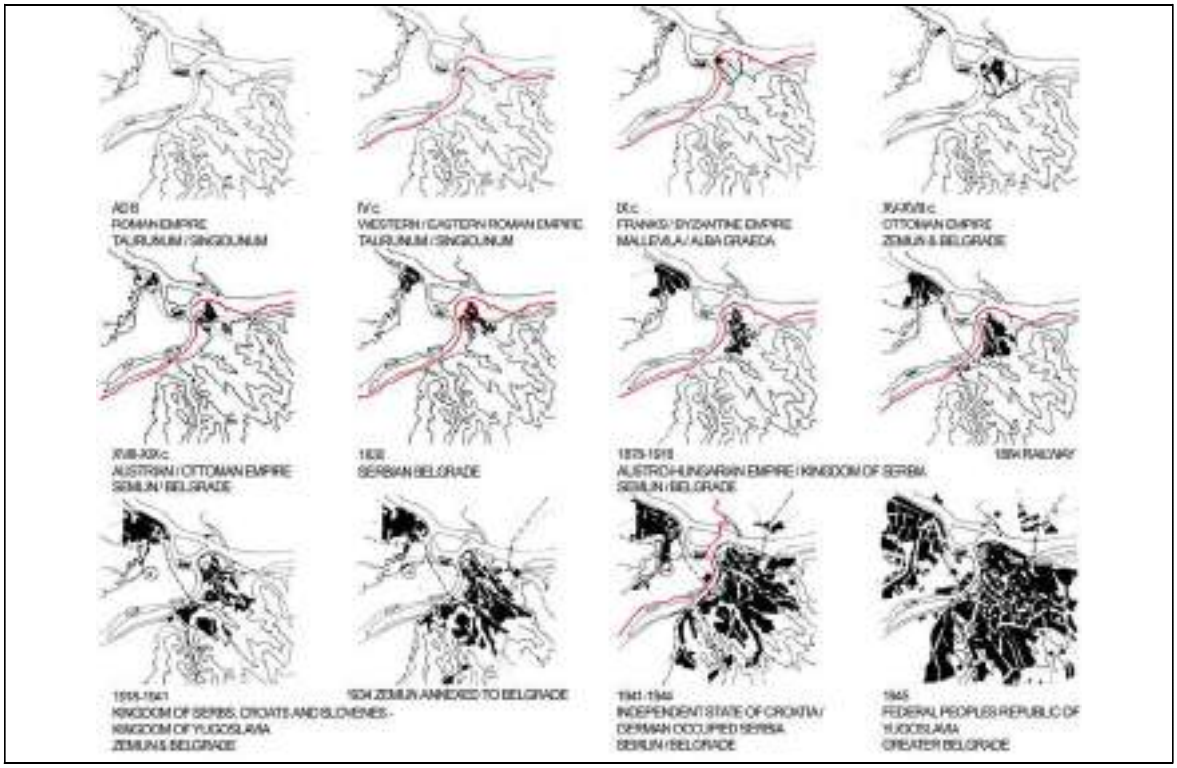

Figure 2. Belgrade's shifting borders, diagram by Ljiljana Blagojević

The very size of the waterways of the Danube and Sava and Belgrade's strategic position as a trading port for goods passing through the Balkans, Asia Minor, and Central Europe, were a decisive influence on the city's urban history, making the surrounding waterscape often a war landscape. As noted by Blagojević (2009, p. 28): "Belgrade's position at the

confluence of the river Sava into the Danube, is marked historically by the condition of constantly shifting borders of divided and conflicting empires. The river Sava marked a geographical and political borderline from the fourth century division of the Roman Empire into the Eastern and Western Empires, until the mid-twentieth century Third Reich's remapping of Europe."

The establishment of the Danube and Sava as the border between the Ottoman and Austrian Empires came in 1739 with the signing of the Treaty of Belgrade. The ratification of the agreement was carried out through the official exchange of letters, precisely on that border, the river Sava. Thanks to its position as a military and trade port, Belgrade was important to the Ottoman Empire for maintaining a political and army presence in the region throughout the 19th century. This affected the form that the urbanization of the city took at that time, and the speed with which it was executed.

2.1. Life on the water and the relationship with the water

Despite the awareness that the river represented a political, state and military border, Belgrade city life still took place on the river banks. A document from 1838, at the very beginning of the partial autonomy of the Principality of Serbia, dealt with the traffic and fishing on the rivers Sava and Danube. The document was addressed to boatmen and fishermen and sanctioned rules of conduct and acceptable ways of using the river, so as not to cause conflict with the Austrian authorities.

The German Karl (Dragutin) Karlovanski was the owner of the first bathing and swimming area on the Sava, opened on June 6th 1847, on the bank below Kalemegdan. Visitors, mostly children and youth, could learn to swim and use the river safely. The pool was approximately 26 meters by 7 meters, and there were 10 changing rooms. "Seeing the scarcity of baths on the river" (*Srbske*, 1856, p. 423), captain Miša Anastasijević built a bathing area in 1854, also on the Sava, near the spot where the Railway bridge stands today, and which was open to all citizens without charge. The demand was so great that during the summer people sometimes waited up to an hour in line to get in. In 1856 the Belgrade municipal government appealed to citizens for donations to help build a general bathing area on the Sava which would allow 50 people at a time to bathe. These bathing areas, "one of the centres of Belgrade life of the day," (Deroko in: *Beograd u*, 1977, p. 26) were made from wooden planks floating on barrels, marking off the area of the pool.

Towards the end of the 19th and beginning of the 20th century, life on the water only intensified compared to previous decades. There was more traffic, industry, entertainment and recreation, as well as an active interest in what could be found on the opposite bank. The public swimming areas were still present, as were now swimming, rowing and diving competitions. The latter were held from the only bridge on the two rivers, the Railway Bridge. The city was deeply engaged with the rivers, even though, or

possibly precisely because *over there* was a foreign land. On the place of today's Belgrade Fair, the Rowing, Fishing and Swimming society built a bathing area on the Sava in 1904, naming it *Six Poplars*. A club house accompanied the bathing area, and soon that whole stretch was livened by rowing practice and competitions. The sports activities, along with all other entertainment and recreation, took place parallel with the water's flow, up to the imaginary line in the middle of the river. Everyone who spent time on the riverbanks and on the water, all the travellers, merchants, fishermen, soldiers, bathers, rowers, or anyone otherwise connected to the river, formed part of the waterscape of Belgrade. All of this was effaced by the regulation of the riverbank, the design of cargo ports and a quay with metal planks, separating the city and its people from the rivers, discontinuing and forever changing an important part of the waterscape.

2.2. The Public Water Supply System

Aside from Sava and Danube, the waterscape of Belgrade was and is made up of other waterways, sources, streams and underground rivers. These had an important role in the past, as they were the backbone of the city's water supply system for a long time. Up until the last decade of the 19th century, Belgrade's water supply system was made up of three systems, all created in different periods, and came out of different traditions and civilizations. These were the Roman, Austrian and Ottoman waterworks. What they had in common was that they sourced the water in the south-eastern part of the Belgrade region, from whence it was channelled to the fortress, meaning old Belgrade within the confines of the Moat. On its way, the old system supplied water to a series of public fountains, usually erected at intersections.

Figure 3. Hydro-geology map of Belgrade. (Dukić, 1970, p. 12-13)

The Austrian system supplied the Sava slope, whereas the Ottoman followed the Bulbulder stream and brought water to fountains in the Turkish parts of town, on the

Danube slope. The Roman waterworks traced its way in between the other two along a canal where Knez Mihailova Street is today, and entered the Belgrade fortress. The Austrian one, otherwise known as the Town waterworks, was the longest of the three, and the Ottoman one, or Bulbulder, was the shortest. The hydro-geological map of Belgrade and the region shows the clearly divided river-basins of the Mokri Lug and Bulbulder streams, which were the major contributors to the old water supply systems.

In addition to these, the citizens of Belgrade used other methods of obtaining water, including wells in gardens and yards, as well as river and collected rain water for washing and cleaning. There were also professional water suppliers who sold water from barrels and skins, carried the city over by carts, on horseback, even by foot. The *sakadžije*, as they were known (from the word *saka* for animal skin used to transport the water), brought drinking water from fountains or streams into the city, the most prized of which was water poured from the Topčider fountain, and which was sometimes up to six times more expensive than river water. They could be seen in Belgrade as late as the beginning of the 20th century, meaning that until that time, there were two ways of obtaining water: the old one and the modern.

Emilijan Josimović, an engineer and mathematician, presented his first modern urban plan of Belgrade in his 1867 publication *Explanation of proposal for urban regularization of that part of Belgrade which lays within the Moat, by a lithographic plan scaled 1/3000*. Prior to publishing the plan, Josimović spent three years surveying the city and assessing the condition of the existing structures as well as the quality of the completed streets and urban sanitary conditions, thus creating the most complete survey of the period. Among Belgrade's shortcomings, ones he thought should be addressed through regulation, Josimović points to the lack of drinking and household water, as well as the lack of a proper sewer system for excess rain and waste water. As an alternative to the existing system that supplied the city from surrounding streams, he suggested supplying Belgrade with treated river water pumped up from the Danube into the upper part of the fortress, from where it would be distributed throughout the city. To solve this important question of city life, Josimović suggests using modern technological devices.

After 1867, a series of regulations were passed, with the goal of improving sanitary and hygienic conditions in Belgrade. Among these, it was forbidden for private individuals to dump household waste water into the existing system of drainage, "since the poorly built street pipes are thus overloaded, blocked, and spill into the street." (Stanojević, 1966, p. 143) Rather, citizens were told to dig septic tanks in their yards for that purpose. Following an epidemic of cholera in Belgrade in 1884, the president of the municipal government, Dr. Vladan Đorđević, declared the construction of a sewer system more important than that of the water supply system. In the end, however, it was the modern water supply system that won the day.

The clearing of forests in the area, as well as the growth in population after 1867

weakened the water sources in the city's surroundings, causing an ever poorer water supply. Even the renewal of the water supply system in 1890-91 which saw the connecting of the Roman and Austrian systems, and then the Austrian and Ottoman ones, the cleaning of sources, the partial replacement of pipes, and the building of several new reservoirs, did not solve the problem. The first step towards the installation of a modern water system was the suggestion of the municipal president Živko Karabiberović in 1880 to charge for the city customs in order to collect funds for a new water system, sewer, schools and roads. The adopted plan for the construction of utility systems in Belgrade finally got underway with the legalization of taxing and earmarking funds in 1884 and 1885. Along with the paving of streets, building street lighting, the water supply and sewer systems were planned for the first phase of construction. The second phase included the building of a quay and a depot, outlined in Josimović's plan. We can see from this that 50% of the projected utility designs were regarding water, that is, access to it and its use. In 1885, the Belgrade municipality founded a "Permanent Technical Committee," in charge of finding solutions to questions regarding water supplying. During the 1888 examination of the Makiška plain, between the villages Ostružnica, Železnik and Žarkovo, it was established that there is a far-reaching and strong network of underground waters, which sloped from Železnik and Žarkovo towards Čukarica and the Sava. It was determined that this water basin could cover the city's water needs, not only for the current population, but taking into account future city growth. The digging of the first wells began in 1889. At the same time, the existing waterworks systems were reconstructed, and the building of a new one was under way. The waterworks system began working on June 29th 1892. Citizens were invited to witness its turning over for public use. The switching on of the fountain at Terazije symbolically marked the event. The municipal president, Milovan Marković, gave the signal, and a jet of water shot several meters into the air, accompanied by the sounds of the military band playing the national anthem. The dignitaries present were served with cups of water. In addition to the dignitaries, the press noted the presence of "several thousand souls." The same evening, a celebration was organized in Kalemegdan, in honour of this "epic moment in the life of Belgrade." The celebration included the lighting of "a thousand lamps," a concert, and fireworks which "made known to all that Belgrade was in every way set upon the path of progress, development, and modern life!" (Lujanović, ed., 1992, p. 30-31)

The nineteenth century Belgrade had some 1,200 private yard and garden wells. Publicly accessible fountains were fed by three old waterworks systems. They numbered around 50 in the city and another 20 built at various water sources. From official and police documents of the first half of the 19th century we can see the importance of their use and maintenance. To that end, the municipality employed a person to "oversee and maintain in good condition all the fountains in the city, as well as in the army barracks, at municipal cost." (Prpa et al., eds., 2003, p. 366) Tensions and conflicts that arose in Belgrade were reflected in the question of water. The agreed-upon and sanctioned ways of water use were often broken, and there were illegal redirections of water flow both by

the Ottoman and Serbian government, as well as by the citizenry. One of the suggestions made in Emilijan Josimović's book was for the city plan to ensure better locations and more space around public fountains, so that the crowds would impede street traffic less.

All the city fountains are woven into the city's history. The "Trećepozivačka" fountain was built alongside the monument in Karađorđe's park in honour of Third Call soldiers killed in the battle of Varovnica, in late 1914. The fountain was probably erected in 1915, in place of the old Bulbulder fountain at the source of the Ottoman water system, on the site that had been used for annual celebrations of Belgrade's Turkish population in the 19th century. The fountain was renovated in 1927 under the patronage of the Society for the Beautifying of Bulbulder, and then again in 1982. The statue of the Serbian soldier, today part of the monument honouring veterans and Third Call soldiers in Karađorđe's park, was initially supposed to be placed on the fountain. Paša's fountain, known also as Šarena (colourful) fountain and Šareni source is at the starting point of the Roman water system, and the likely site of death of Vizier Suleyman Pasha and his entourage in 1807. It was renovated after World War I, in honour of the fighters from Mali Mokri Lug in battles from 1912 until 1918. The Ottoman water system contained along its length certain structures similar to water towers, which served as reservoirs and methods of distributing water among public fountains, in other words, a kind of scale for measuring out water. One of the three locations where these towers could be found got its name from the Turkish word for a scale – Terazije. This infrastructure object was replaced by the Terazije fountain, in the new centre of the city, erected as part of the Austrian water system in 1860, in honour of the second reign of Miloš Obrenović (reigned 1815-39, 1859-60). This fountain drew the largest crowds in the city, and with its location and the fact that water was supplied to that spot, was an important symbolic representation of power. The idea for a fountain at Terazije existed from the middle of the 19th century, during the reign of Prince Aleksandar Karđorđević (1841-58). Two blueprints for the project were created, in 1846 and again in 1855, but neither was executed. The Terazije fountain was moved to Topčider before World War I, when there were plans for the square to get a new road and traffic solution, as well as a new monumental fountain with the statue of the Victor, work of the sculptor Ivan Meštrović. Instead, Terazije saw a fountain 17 meters in diameter, with lion heads, bronze turtles, and a revolving water jet, built in 1927, most likely according to a blueprint by Edouard Lèger, the technical director of the city board at the time, and certain designs of the sculptor Ivan Meštrović. The fountain was taken apart after World War II, as part of the new traffic solution. The original fountain was moved back to Terazije from the yard of the Church of Saint Apostles Peter and Paul in 1976.

The establishment of a modern sewer system in Belgrade began at the dawn of the 20th century. After World War I, the Bulbulder, Mokri Lug, and Čubura streams were incorporated into the new system, their beds paved, and tunnels constructed intermittently. In addition to those three, there are entire rivers coursing through the Belgrade underground that have since been tamed. The strength and importance of

brooks of the past is reflected in the importance of individual streets to the overall traffic network built atop. The underground waters gush in full force when foundations for big structures are struck or trenches for infrastructure are dug. Not much is known about these water networks, since the only extant maps are old, arbitrary, and show old Belgrade sources. In the years prior to World War II, exploration of underground waters was performed, and an operation plan in case of war was developed for the waterworks system. Several wells were dug, mostly in parks, and some of the source fountains were redesigned with a view towards creating an alternative supply system should the need arise. The map of underground water networks was destroyed during the bombing of Belgrade in 1941.

2.3. The Topčider River

In 1831 in Topčider ("cannon valley" in Turkish and Persian) the suburb about five kilometres from the city centre, Prince Miloš built his residence, *Milošev Konak*. In the 18th century, the area was a field surrounding a stream that meandered through the marshy valley, and which was grounds to a few Austrian hunting lodges and summer houses, as well as home to several villages of German settlers. At the beginning of the 19th century, the Turkish artillery units used to perform training practice there, and it was also used for *čair* – a field for horse grazing. Turkish prelates used this area as a resort and hunting ground. For the purpose of the construction of his residence (court) and a supporting complex, Prince Miloš ordered the displacement of local villages and denied the right to the use of land for horse grazing. The formation of the park around the residence began in 1842, when Atanasije Nikolić, an engineer educated in Vienna, was appointed for its arrangement. Nikolić, who was both professor and engineer, also founded a seed-plot in Topčider, as well as the School of Agriculture, the first of its kind in the Balkans. The park in Topčider was the first Serbian park system based on European models of the palace complex located in the "natural, yet cultivated environment." (Milanović, 2008, p. 79) The park replicates the English garden style with its meandering paths, lush vegetation, and abundant presence of still water, as well as with several aquatic devices, and adds to these a few classical elements.

A distinct feature of the park is the Topčider River, which flows through the park. Its path was regulated in 1863, under the supervision of engineer Jakov Slivić. Swimming areas were designated along the sandy beach of the river. The park also contained a steam bath. In the 1880s, at the time of King Milan Obrenović (reigned 1872-89), a fountain was built between the park's obelisk and the glasshouse. The fountain had a decorative bowl in the centre of a basin, containing exotic aquatic plants and the sculpture of a boy with a heron, since demolished. Today, Topčider park with its area of 12.8 hectares is one of the favourite recreation areas in Belgrade. It has three parts: the part near the glasshouse and the drinking fountain that bears the name of Prince Miloš, with an area of 2.5 hectares; the park around Prince Miloš's Residence, with ornamental flower beds *parterre*, measuring 7.1 hectares; and last, the part with a surface of 3.2

hectares containing playgrounds for children and an artificial lake constructed in the second half of the 20th century. The park has more than a thousand trees. There are over one hundred different species of trees and shrubs, among them ten different kinds of flowers. The park in Topčider, along with the forest of Košutnjak, is a unique complex from a natural, ambient, cultural and historical point of view. Košutnjak was once the hunting ground of the Obrenović dynasty, and today, with an area of 267 hectares, it serves as the link between an urban and suburban green, and a reservoir of fresh air that reduces weather extremes and affects the climate of the city.

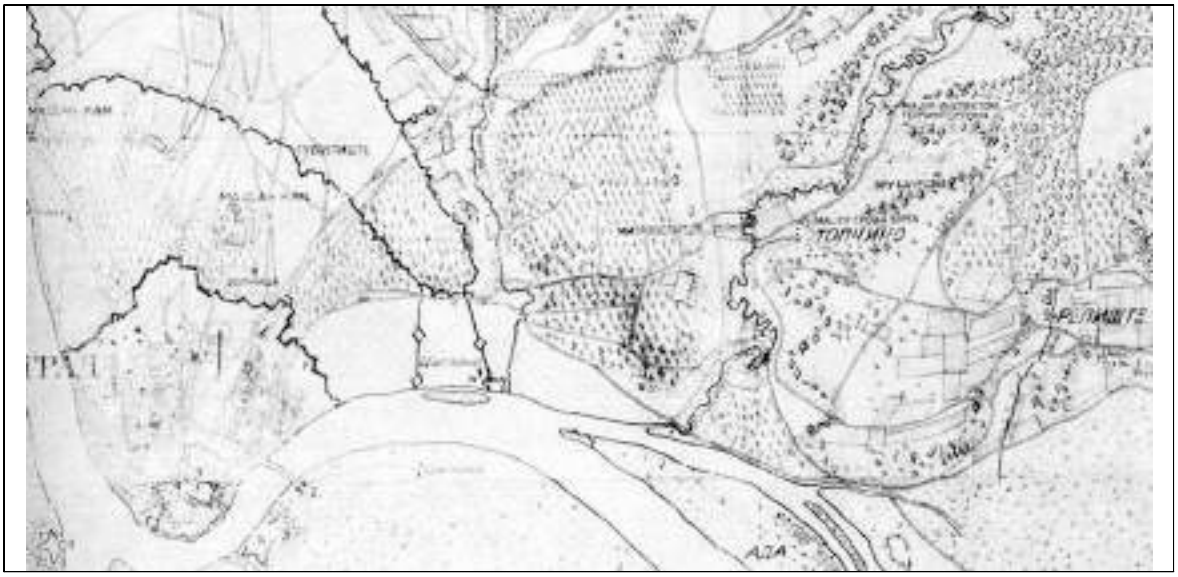

Figure 4. Belgrade and its environs in 1721, by Captain Aman (Miljanić, 1985, p. 48)

The Topčider River is a right bank tributary of the river Sava, and one of the streams that dominates the hilly southern terrain of Belgrade. It is about 30km long and has a basin of 148km^2. Its source is in the Lipovica forest on the mountain Kosmaj, and it flows through four current Belgrade municipalities, various zones and neighbourhoods. Archival records show unplanned expenditure in the budget of the princely grounds, caused by the overflow of the Topčider River in the 1850s. This same decade saw the first geodesic measurement of the Topčider River and park, executed by the cadets of the Gunnery school, that is, the Military Academy, in 1857-58. The oldest maps of the terrain come from the period when the river was first regulated, that is from 1863 when Topčider was officially incorporated into Belgrade. The area saw the Topčider river crossing ferry and a custom house, one of seventeen total on the Sava and Danube.

The current road from Belgrade to Mladenovac passes through the Topčider River valley, as well as the railway, first built in the 1880s, in the directions of Bor, Skopje, and Bar. The Topčider River is regulated in the part that flows through the city proper. It flows into the Sava near the narrow end of Ada Ciganlija, a popular recreation area in

Belgrade. With the newly built bridge passing over that section of Ada, the traffic passing through the Topčider valley has increased significantly. Several ecological incidents have been recorded in the last few years regarding the Topčider River, as it is polluted and characterized by high degree of environmental degradation. The river tends to flood during periods of sudden an abundant rainfall. The execution of the project for "the regulation of small water systems in the basin of the Topčider River" (The Jaroslav Černi Institute for the Development of Water Resources, 2007) should be one of the steps in the final regulation of this water network (which has been planned for over 30 years). This would protect populated areas and roads from flooding, improve the supply of water, increase the quality of the water in the lower portion of the river, and better use the accumulation for purposes of tourism. A project from the Faculty of Forestry for the regulation into a "blue" corridor of one of the streams in the basin of the Topčider River, namely, the Kaljavi stream, already exists. "Kaljavi Potok will be a kind of historical-naturalist reservation, since in addition to the Neolithic settlement nearby, the area is the habitat for some twenty species of endangered birds that do not normally live in the city core, three water sources, and surface lime-stone, a geologic phenomenon in itself." (Jokić-Stamenković, 2011)

3. Conclusion: Lessons To Be Learned

There are certain subtopics of the relations between architecture, urban design, and landscaping that come into consideration with regard to problems of revitalization of coastal areas and water networks in general. Those are:

- urbanism of infrastructure, or complex projects of landscape architecture that integrate infrastructure and city space;
- urban regeneration through the creation of public green areas, walkways, parks, blue and green networks of public city spaces;
- urban ecology and lessons for the fields of architecture and urbanism regarding spatial principles for the improvement of ecologically degraded areas of cities, as well as biodiversity through planning and projects;
- the comprehensive regulation of precipitation in urban environments, i.e., *Sustainable Urban Water Management* (SUWM)

Recent scholarship that gives a theoretical framework for achieving SUWM, or within that, for developing urban water transitions frameworks, defines the relationship of society towards water as a *hydro-social contract*, by which they mean the "pervading values and often implicit agreements between communities, governments and business on how water should be managed." (Brown et al., 2009, p. 848) In the examination of ideological and technological characteristics of this relationship in different historical periods, the authors differentiate six stages: *Water Supply City*, *Sewered City*, *Drained City*, *Waterways City*, *Water Cycle City*, *Water Sustainable City*. The first three stages belong to the 19th and first half of the 20th century. The next two represent a

recommendation for a comprehensive regulation of waters at this time. And the last one is the stage towards which the city aspires to in the future. *Waterways City* promotes, among other things, new normative values in the context of the protection of the natural environment, as well as an integration of urban waters in planning, as an important visual and recreational aspect. *Water Cycle City* includes the protection of water networks in this sense: “finding fit-for purpose diverse water supplies at a range of scales that are also sensitive to the energy and nutrient cycles and ultimately contingent on protecting waterway health.” (Brown et al., 2009, p. 853) Finally, *Water Sustainable City* implies a complete change and integration: “the normative values of environmental repair and protection, supply security, flood control, public health, amenity, liveability and economic sustainability.” (Brown et al., 2009, p. 854)

Based on these interpretations, this paper examines the waterscape of Belgrade of the last two centuries from a historical point of view, as well as forms of regulation of urban waters, in relation to considerations of the hydro-social contract in the present circumstances. With that in mind, first and foremost, we think that it is important to mark the stages already achieved, which are: *Water Supply City*, *Sewered City*, *Drained City*, and to an extent *Waterways City*. It is imperative that in the 21st century, Belgrade turn to a sustainable regulation of urban waters. Also, public green areas demand redefining in accordance with the idea the relation between urban landscape and waterscape. Awareness of climate change and the importance of water as a resource requires a radically new consideration of the relation of water and the city, one that moves the romantic image of the 19th century towards contemporary technical and technological solutions, and moves urban design strategy towards synergy of infrastructure, landscaping and ecological design, place-making, circulation and urban function, with the specific focus on flood risk and stormwater management, as components inherent in the design, rather than an addition to it.

We would argue that lessons to be learned concern the following:

- critical engagement and discussion of still widely open questions of urban landscape and waterscape, and internationalizing the issue in the context of debates worldwide
- recovery of nearly lost comparative advantages of the Belgrade area in reinterpretation of its waterscape in local, regional, as well as, in the European context
- a new generation of strategic schemes of truly sustainable development, open, transparent, and publicly verified offers to strategic partners, and subsequent planning and implementation processes that include regional partners.

SYSTEM DYNAMICS AS AN IMPORTANT TOOL FOR THE ESTIMATION OF URBAN PLANNING EFFECTIVENESS

Costas Portokalidis[1] / **Foteini Zygouri**[2]

Abstract

The idea of sustainability, as an entirely acceptable objective, attains a special dimension when it attempts to become a part of the philosophy of urban phenomenon and modern or (super) modern urbanism. Namely, it generates the framework of the goals of the urban planning, since it demonstrates a holistic, dynamic and cooperative approach which cannot at the same time be analyzed by Cartesian procedures, but to become a part of the theoretical of system analysis and especially system dynamics. It obviously accrues that the urban sustainability involves an 'in the egg' and 'by definition' systemic concept. The specific approach leads to the pursuit of appropriate (systemic) procedures in order to actively join the holistic content of the urban sustainability to that of urban planning, which is eventually demonstrated at the level of urban form or morphology. Thus, it accrues the need for clear delimitation and specification of the characteristics of the in question system of analysis, which joins the upper system of the city (urban area). The complexity of the specific system and the need for the emergence of the attributes of the different parameters which it includes, leads to the development of three basic sub-systems of approach with systemic procedures that involves the built space, the free space and the traffic network (infrastructure). Subsequent to the aforementioned the further development of the system is realized, that is the elements that are included in order to create the conditions for the examination of the connections, attachments, interactions etc, between the sub-systems of reference. In conclusion the urban morphology, as complex, open and dynamic system, needs its systemic characteristics to be approached in depth in order to acquire a specific status. Consequently, the general and special attributes which it includes as well as their connection (dependence - influence) with the outer surrounding (institutional-social-financial) environment, generate a specific balance point with specific pop up attributes each time. This fact makes the further approach of effectiveness of the urban dynamics, which is rising as a result of the objectives of the urban planning, which in order to be effective, it must always be a part of the urban sustainability.

Key-Words: Urban form, system dynamics, sustainable urban patterns

1. Introduction

Focus on design and planning of urban morphology, as a method and a technical process "objectively" and by "default" is a continuous and perpetual revision, by adopting the values, circumstances and general requirements or endorsements of time. It is, in short, the expression of "human affairs" in space, and includes philosophies, ideologies, production systems and perceptions of the times. But in any historical context than today, cities evolved in harmony and well supported by the local natural environment. This balance seems to disrupt the modern context. The traditional process of urban planning and the perception of urbanity, followed by industrial or postindustrial development, economic development, globalization, etc., and expressed mainly by the modern movement and various mechanistic theories.

An early problematic (critical) for this negative evolution, began to be expressed especially after the 60s when environmental skepticism started to grow and established a framework of principles (ecological movement, postmodern criticism, contemporary context, etc.) in response to constantly growing urban problems, such as the general deterioration of urban space, resource consumption, traffic, etc. Subsequently, more comprehensive and integrated concepts have been developed as today's total acceptance of the notion of "urban sustainability",[3] a key objective for planning and of broader perception of spatial phenomena.

The present approach, having as reference the specific search, which is part of an "ultramodern" urbanity, aims to adopt a systemic (holistic) process, to reproach to a fundamental level, the design and planning of the urban morphology. It analyzes individual spatial elements that ultimately include assessing the structural complexity of the status (self-organization). Ultimately, attempts a comprehensive, holistic, comparative and methodical problem with a view to assessing its systemic complexity and dynamic nature presents the design and planning of the urban morphology.

2. System Dynamics

Mainly, the current attempts are focused on understanding and developing the synergies between the different spatial aspects of the city, using analytical methods that lead mostly to one-dimensional studies of the issue through a Cartesian decomposition (UNEP, 1996:15).[4] This approach appears to not be able to provide

[3]There is a widespread concern and discussion about the concept and principles of urban sustainability. For more see Frumkin (2002), Frey (1999), Elkin et al (1991), Blowers (1993), Charter of Aalborg (2004), New Charter of Athens (ECTP, 2003) etc.

[4] Otherwise "Cartesian rationalism": Refers to the so-called analytical thought where every system can be examined in the individual components that it includes. By default, this logical (inclusive) process can not explain the behavior of complex phenomena, nor to analyze influences on different dimensions. Commonly, it is attempted a shift in thinking from the mechanistic (Cartesian) logic

appropriate solutions (answers), especially when is trying to relate with holistic approaches, such as “urban sustainability”. It becomes obvious that any attempt to analyze the dynamics of the urban morphology, it can not be successful enough when it focuses on the individual factors that affect the issue under examination. In contrast, the effort should first put on identifying factors that influence it, then examined in depth the properties and finally to study the interrelationships and interactions that arise between them and the wider environment.

In this problematic, the “system thinking” can contribute to a drafting target (ultimate objective) and identifying the means (process) (Dekleris, 2005). Overall, it is not just legitimate, but necessary, for multidimensional analysis systems, which have dynamic character and focus on conditions such as flexibility, interdisciplinarity and totality (Kousidonis, 2003; Hall, 1993). Thus, the transition from the analytical to the system process (vision), includes an approach that allows:

a) the recognition of the components of a system and the relations that make up the structure,
b) the examination and verification of the relevance,
c) the illustration of the conditions and the implementation through modeling.

From the above mentioned, it appears that the choice of the discrete parts of a system is one of the most important processes for the study. Of course, this process is not followed by strong nor specific physical laws. In contrast, an important question remains of who defines the system and why, since the elements are selected and controlled from a specific observer. Thus, the system is presented as an object, where different observers may give different interpretations. Because of that, in any case and despite of the use of common systemic rules, it remains a "mental construct" between the observer and the real world (Ashby, 1962). To overcome the above problem of relativity in structuring the system, is used a specific process based on system dynamics. This method focuses mainly on the structure and processes within the system, assuming that this can be explained better the dynamic behavior under conditions of "real world". In this sense, the structure and dynamic processes of "reality" can be (re)created in systemic diagrams and on mathematical models, capturing the relationships between cause and effect relationship (Flood & Jackson, 1996; Forrester, 1998).[5]

3. Urban Morphology in System Thinking

3.1 General

---

where "the whole equals the sum of its parts" in the belief that "the whole exceeding the sum of its parts".

[5] As it is clear from the above, system analyst construct (study) "sets" and not "parts". Priority is given to the whole (holism) rather than in parts (reductionism). For more see Miller et al (2004), Sterman (2000), Venix (1996) etc.

In system thinking, mainly it is needed a clear definition of the limits and the external environment of each system under study. Thus, the collaborative framework of the city, includes the physical, social, economic, ecological, environmental and institutional subsystems. In all these, there is a distinct subgroup that defines the physical space. With more appropriate way, it can be seen as a form and structure of the city (alternatively morphology), which has a direct and absolute link with the geometric, topological or ontological conception of urban space. More specific, the initial interpretations of urban morphology, described as a (physical) area of the city. Thus, it primarily associated with the geometry of space, through a largely formalistic and rigid approach (Lee & Moudon, 2006; Friedman, 1997).

Then, for the development of a broader and more specific theoretical problem for that matter, a portion of scientists, from very early on, tried to reach terms with systemic effect of morphology and specific constituent elements. Of particular importance are efforts and distinctive works of Lynch (1981) and Alexander et al (1977), who first reconcile the different interpretations and also they introduced a new, more collaborative and systemic approach.[6] In particular, Lynch defined it as "the spatial plan (ground) of large, inert, permanent physical objects" that can be nodes, corridors or areas, and create specific spatial identities such as density peaks, distribution of land uses and activities, access etc. Similarly, Alexander developed the content of the urban morphology more descriptive, mediated by specific spatial rules (patterns) which must meet certain conditions, purposes etc.

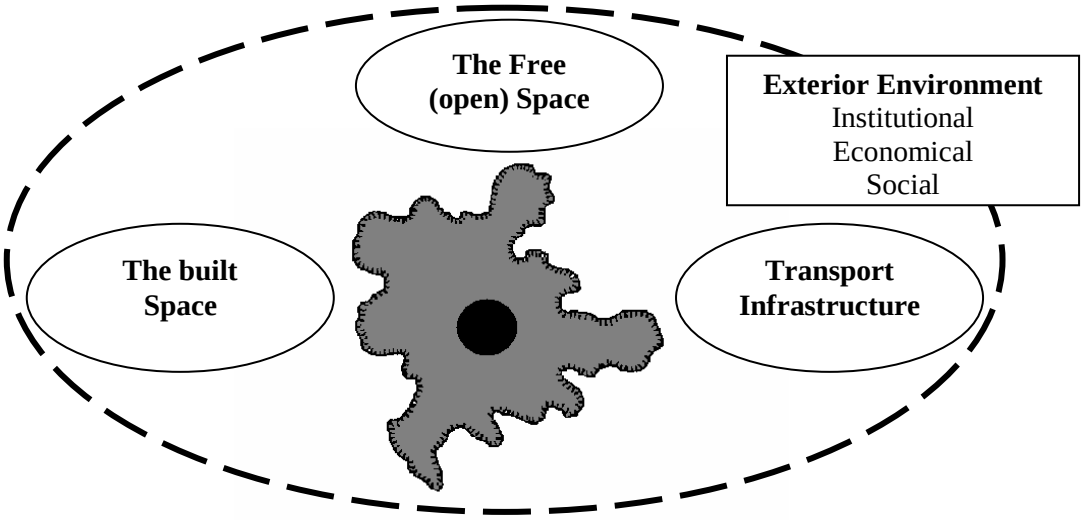
In this era where the concept of "ultramodern" urbanity is in constant change, there is a plethora of alternative approaches that attempt to describe the urban morphology, using new age or stochastic methods, qualitative or quantitative descriptions, etc., which may be based on network analysis, space syntax, fuzzy logic, neural networks etc. In any case, the plural search its contents, highlights the need for a systemic interpretation of how it really works and what dimensions it includes. Therefore, the use of system dynamic approach, as described above, attempts to overcome any weaknesses resulting from this subjective effort and moreover to deal with the limitations of this chaotic, dynamic and evolving system of reference, as the urban morphology (ie it is not static, linear, integrated etc).

In this sense Harvey (1996), supports that a dialectical approach between the theory of urbanization and spatial analysis, can lead to a better understanding of the urban morphology. In other words, she suggests a systemic process in synergy with classical spatial reading. Batty (2008a & b), has analyzed in detail this specific problem and he tried to give the clear content, based on three fundamental concepts for the interpretation of the urban morphology, such as "built (structured) space", “open (free) space“ and “road network” (alternative transport infrastructure). The main aim is the synthesis of natural (space) with the social and the economic environment. Then, the analysis focus on interactions and connections with the urban

[6] Apparently Lynch and Alexander, are not imprinted with a theory this way, but essentially similar holistic approaches used, included in this problematic. Thus, it can be argued that founded largely the spatial perception of the city that is timely and fully compatible with the attempted systemic view.

sustainability (in concordance with the approach of the urban phenomenon as a open, multi-layered and complex system).

Figure 1: The System and the Sub-Systems



Overall and in accordance with the above, Lynch (1981), Alexander et al (1977), Lee & Moudon (2006), Batty (2008a & b), Harvey (1996) and others, through their respective approaches, try to achieve a new global concept that includes all the features of the urban morphology. These efforts, might be enhanced with the (new) system dynamics processes and approaches, introduced by the specific problem. Thus, an attempt is made to introduce the general clarification of the "structural status" of the reference system. This method, involves the recognition and the understanding of the limits between the system and the exterior environment and also the hierarchies, interconnections and interdependencies within the system, as in Figure 1.

This particular system thinking and consideration of the urban morphology, has a twofold objective. Firstly, it is attempted a comprehensive description of a number of specific groups and spatial elements contained in the above three subsystems. Secondly, it is developed a comprehensive assessment of synergies, relationships, convergences and divergences, in order to become enable the emergence the fully knowledge of the urban morphology. This makes possible the "holistic" treatment of the reference system, in absolute identification with what is supported for system dynamic theory (Kropf, 2009; Whitehand, 2009 a & b; Williams et al, 2000).

3.2 The Sub-System of Built Space

According to the above, in the sense (vision) of built space, are included analysis elements (variables) which are critical for urban morphology planning. So, are recognized:

"Density." The spatial dynamic that density develops, is critical. Usually it includes upper and lower limits or thresholds. Generally, it is argued that density planning creates conditions to produce the interactions needed for making effective the urban functions and activities. Thus, its (quantitative) character can affect almost all other elements (parameters) of the spatial reference system. Also, t is considered as an important factor in relation with travel demand, consumption of land and energy, the character of neighborhoods etc. (Williams et al, 2000; TRB, 1996; McLaren, 1992, etc.).

"Compactness". It refers to urban link (connectivity) and intensity of built development. Commonly, compactness attempts to include a third dimension to quantify the density. Thus, it presents more accurate the built complexity and it is of great importance in assessing the overall status of the urban morphology. Also, it is strongly associated with approaches that attempt to examine the nature of expansions or enhancement of urban space (Wheeler, 2004; Scoffham & Vale, 1996; Rudlin & Falk, 1999).

"Land Use". The spatial distribution and in particular the composition of the land use, which varies both horizontally and vertically (ie in the building), it is generally accepted that largely affects the characteristics of the reference system. Thus, in any occasions, the specific land use planning is primarily a dynamic rather than a static phenomenon, and it is influenced by the conditions of market economy and the broader social and institutional environment (externalities) (DETR, 2000; Burton, 2002 etc).

The "quality" of space. It includes all those aspects of the urban morphology that create perceptual relationship with the environment at all spatial scales of reference, such as adaptability, diversity, choice, beauty, nature, etc. Overall, it expresses an important, complex and multifaceted element (Jacobs, 1961; Wheeler, 2004; Tesdeorpf et al, 1997:16; Thorns, 2002; CABE, 2002 & 2004).

As shown above, it becomes clear, that this particular structural configuration, leads to a hierarchy, which needs further study, since it reproduces the strong interrelations between the elements involved. Overall, the density is presented as a priority that is directly associated with the element of compactness and together produce a significant weight in the overall character of the built environment. Then, the land uses, seem to form part set up by the previous two items, causing a number of synergies that characterize the operation subsystem of the overall thinking. Finally, the quality of the space is presented as an independent element for the most point, which attempts to give the subsystem specific features. Overall, it can be said that is introduced a new concept for the interpretation of the creation of the built environment, based on more holistic treatment.

3.3 The Sub-System of Free (open) Space

The natural elements (attributes) of the environment of the city as open spaces (squares, unstructured regions, etc.), materials of urban furniture, greenery, trees, etc., are the free space of the reference system. More specifically, the elements should be made to describe the best qualities of the subsystem are:

The "provision (adequacy)." The quantitative expression between structured (similar subsystem) and unstructured (free) space which can alternatively be expressed as protection, emerges as a critical element for the urban morphology planning. Overall, it can be said that the provision of free space is necessary and sufficient condition for the operation of the subsystem analysis of free space. Below a certain limit, the lack of free space makes very difficult the controlling of whole systems functionality. Thus, such research are primarily designed to examine the appropriate (optimal) frame, in quantitative terms, which must determine the provision of free space (Carys et al, 2003; Heidt & Neef, 2005; Li et al, 2004 etc).

The "contribution." As an element, free space contribution is directly connected with the spatial arrangement of green networks (greenways) in terms of functional integration (distribution) in the urban fabric. Overall and in accordance with the nature of that item, it creates various types of open spaces, from point to very extensive city parks, green corridors etc (Moughtin & Shirley, 2005; Forman & Godron, 1986).

The "quality." This element gives significant properties related to aesthetics, diversity, convenience, land use, etc., in concordance with the element of quality built space, as analyzed above.[7]

Overall, the urban natural and open space interacts primarily with the residential areas (built environment) and it creates social and economic externalities, even in dense populated areas of city centers (Tjallingi, 1995). It is clear that internally in the subsystem approach, the element of provision is strongly linked with the other elements (qualitatively and quantitatively), in a context of system dynamic relations. Thus, the resulting synthetic image (general structural status) is multi-functional and it creates a set of synergies and influences to be considered.

3.4 The Sub-System of Transport Infrastructure

The relationship and interaction between urban space and transport, is crucial at every stage of the urban morphology (Barrett, 1996) and is perhaps the most important aspect of proper operation and efficient planning. Emerged especially after the rapid growth of car use causing a huge impact on the transformation of space-time parameter (Seller and Urry, 2000), where urban elements and spatial synergies accelerated and encouraged. Today, it is fully agreed that the urban morphology associated with, and influence each of the characteristics of the movements and the general transport system (infrastructure), making it as a critical reference subsystem, in this view (CEC, 2007 etc).

The search therefore of critical elements that make up the structural status of the

[7] There is an extensive literature that describes and analyzes this issue. For more see Moughtin et al (2005), Tjallingi (1995), Carys, et al (2003), Heidt - Neef (2005), Pauleit et al (2005), Li et al (2004) etc.

transport system can only focus on the appropriate system dynamic procedures, in order to allow the earliest possible full description. Thus, there is recognition of visa data as:

Provision of adequate infrastructure. As element, is strongly related with the achievements of access to buildings in various locations, operations, etc., because people move to participate in activities, according to parameters such as distance, cost, etc. (externalities). Overall, the systemic approach focuses on the synergies created and alters the accessibility balance of the transport system (e.g. the reduction of infrastructure for the vehicles).[8]

The management of the infrastructure (mobility). The modern approach, based on the urban (sustainable) mobility shifts the attention from the provision of new infrastructure to the appropriate management of existing ones. To achieve this, the transport planning process, includes dynamic approaches that attempt to create appropriate and efficient spatial synergies that ultimately emerged from the car dependence (minimizing manual). This approach is essentially based on the belief that an ideal situation would increase accessibility to the smaller footprint without necessarily creating new infrastructure (Lynch, 1981; Bertolini, 2005; Doust, 2009:14 etc.).

The quality (balance, reliability, equity). This subsystem in order to meet all of the urban planning goals, according to the above respective approaches, should have an extra element that is referred to the appropriate conditions for overall quality. It refers to justice achievement, equal access (equity) etc. for all and especially the application of reliability of the overall operation of the subsystem reference. In a spatial context, expresses the need to provide secure, diverse and integrated transport facilities in the urban environment (Coplák & Raksanyi, 2003; White, 1994, etc.).

The (synergy) of the transport subsystem with the entire urban morphology, includes some new (dynamic) elements, so it is attempted to put an alternative description of transportation, especially now which that urban areas are dominated by theories that focus on public and free space consumption for creating roads and support infrastructure such as parking lots, etc. Also, it can be said that the crucial element is the infrastructure provision, so it occurs in the first level of a hierarchical relationship with other elements. Mobility includes features of a more qualitative and focuses on efficiency and intensity, in order to be created the character of the transport subsystem. Finally, the new element of quality, try to enter some not obvious parameters which are very important and make the system to meet the urban sustainability issues.

4. Conclusions

From the above analysis, it became clear that the systems theory (systemic approach, thought) is able to visualize the relationships between a system, its components and

[8] For instance there are the designed and organic (traditional) urban road networks. The first are highly functional for a traffic operation and can be adapted to modern needs, while the latter have emerged historically without planning and poorer infrastructure (narrow roads, bad junctions etc).

the external environment. Also, system dynamics could help to create a new way of interpreting and studying the spatial effects (as meta-theory. This will fill the positions of Newtonian analytical thinking (analysis and reduction) putting the composition together with the analysis, the regulatory process with the narrative. Thus, the systemic approach focuses on functionalism as a fundamental process, which means that the characteristics of a system, are based on the operation and cooperation of its parts.

In this direction, converging the current general and specific targeting of the design and management of urban morphology, which focuses and integrates most dynamic (systemic) conditions such as flexibility, totality and interdisciplinarity. Therefore, the use of system thinking for a clear definition (interpretation) of the urban morphology, it becomes very important for the development of this problem. Also, the opportunity to focus on the character, the limits and the hierarchy of the elements, gives the opportunity to deal with the real behavior of the reference system.

In this context, once established, the structural interpretation of the urban morphology, the problem focus on the elements of subsystems included as separate entities. Clearly, it concluded that the urban morphologies should be examined as complex (organic) systems. This finding, in general it has very important implications in spatial recognition and urban planning. It also means that scientists, must use systemic versus Cartesian logic. Therefore, the system approach is introduced, may be offered the younger specific theoretical framework, which aims to identify the overall character of the urban morphology.

COASTAL TOWNS IN CHANGE: A NEW PARADIGMA

Graça Moreira [1],

Abstract

This paper presents the first conclusions of a research project concerning the relationships of the architecture and the sea. It studies in particular the coastal cities of the south of Portugal during the XX century.
The coastal cities developed due to the economy of harbors and fishing, very often with locations relatively guarded from the sea.
During the XX century, the traditional location lost importance, because on one hand the coastal areas became safer and on the other hand the charm of the sea landscape attracted the population to the coastal line. It is also important consider that the emerging economy connected to the tourism needed to sell the landscape as an added value.
This change in the attitude towards the sea, promoted great changes in the morphology of the cities, leaving traces that are interesting to study while the older areas don't disappear or are totally adulterated.
We also try to analyze the sustainability of these areas, once they relatively recent in the context of urban history and bare higher maintenance costs by being more exposed to the maritime influence and have very often a seasonal use.
This paper analysis the evolution of urban areas of part of the littoral of Portugal, in the southern coast, with remote occupation, with vestiges of roman occupation that were subject to great urban changes with the destruction
The role of the tourist becomes controversial because he aims more and more landscapes and traditional urban centers instead of areas of recent construction completely decharacterized that are built to welcome them.

1. Introduction

During the XX century the population of Portugal changed significantly, from a relatively stable distribution between rural and urban areas and between the interior and the littoral, to levels of urbanization quite different due to a move of the population towards the littoral.

This change is due to structural reasons common with the socio-economic changes in Europe and in the World, with the growing abandon of agricultural

[1] Technical University of Lisbon, Lisbon, Portugal - gmoreira@fa.utl.pt

activity and the implied increase of the process of urbanization of the population and the choice of milder areas from a climatic point of view; in the Portuguese process this was reinforced by the weight of the tourism sector in the national economy with the development of the tourism "sun and beach" since the 60s of the XX century.

This change of the patterns of urbanization can be evaluated among other aspects by the urban sustainability that has been analyzed in an ongoing research project.

The process of litoralisation associated with the development of tourism has created a kind of urbanization, that has been analyzed in a research project in development.

2. Cities, Sectors of activity and urban morphology

Urban development of cities located in the littoral, was very much connected to the development of harbor activity whether in what concerns merchandises, with some ports important to the national and Iberian economies, connected to cities of bigger dimensions whether in what concerns the fishing activity, with these ports spread along the coast and connected to population agglomerations of diversified dimension.

These urban agglomerations whose urban economy was at least partially related to the fishing harbor present from a morphological point of view a concentration around the harbor and the centre related to it.

From the moment when the tourism sector starts to emerge some agglomerations gain a new economic dynamic related to tourism and its morphology tends to change.

It's this process of change based on the relation between the increase of the resident population, due to the increase of employment, and the increase of dwellings, due to the demand of permanent and seasonal habitation, that we analyze in this paper.

The number of permanent habitants often show a growth that can be considered within average but the growth of urbanized areas that support secondary dwellings and seasonal services change completely the physiognomy of urban space.

3. The Case study of Algarve/Sotavento of Algarve

This theme has great relevance in the urban development of Algarve (region that enclose all the southern strip of Portugal) where a climate of

Mediterranean characteristics enhanced a sharp urbanization biased towards tourism, unlike what happened in other areas of the littoral f the country, where this specificity has a lesser importance.

This paper analyzes in particular the eastern part of Algarve (Sotavento Algarvio – Algarve leeward), an area characterized by having in its territory a group of sand islands, that allows the existence of several haven harbours to the fisherman.

Beyond the fishing villages we find a group of equipments and warehouses, that were used in the tuna fishing (Moreira, 1987).

These sand islands belong nowadays to the Natural Park of Ria Formosa as they constitute a valuable natural heritage.

In the Sotavento Algarvio are located several diversified urban centers, representing various typologies of agglomerations.

3.1 Evolution and distribution of the population of Algarve

Analyzing the distribution of the growth rate of the population between 1950 and 2001 in the Algarve (Fig.1), we note that the municipalities experience great changes with some parishes to submit a demographic dynamics rather than the media, including Se(Faro) and Quarteira.

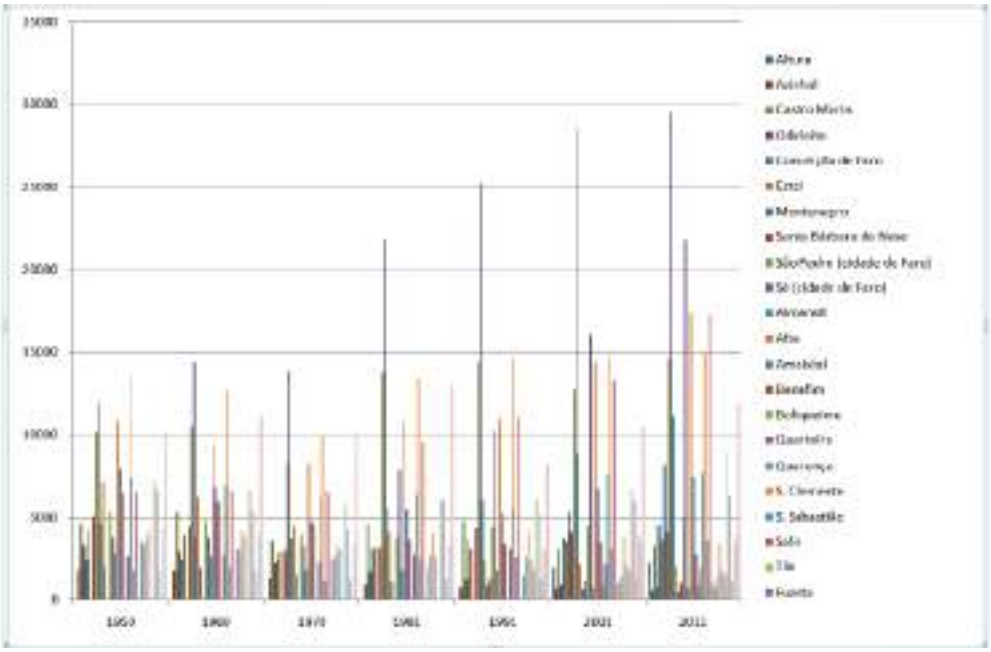

Figure 1. Evolution of the resident population by parish, between 1950 and 2011

Analyzing the distribution of the rate of population growth between 1991 and 2001 in the Algarve (Fig.2), it appears that the counties have very large variations.

Figure2. Population growth rate between 1991 and 2001 of the Algarve, by municipality

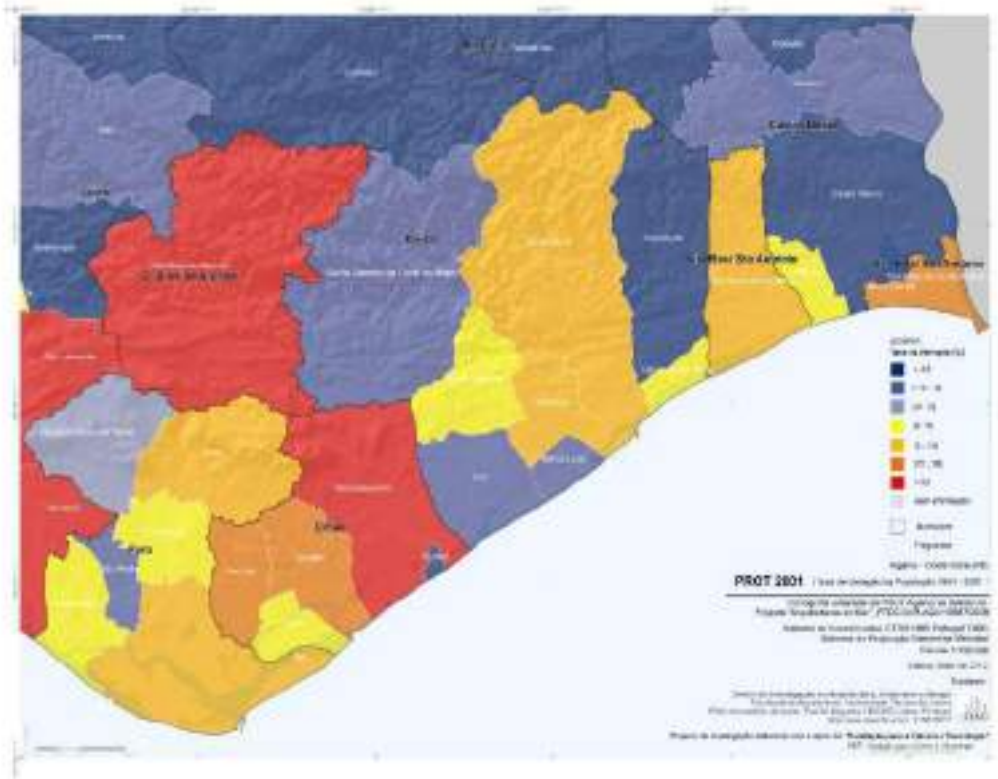

Figure 3. Population growth rate between 1991 and 2001 , by parish

This characteristic is explained by the configuration of the municipalities that include the littoral areas as well as the inner rural ones.
In this decade some areas further away from the coast line already show a growing pressure of construction.

When we analyze on a more detailed scale (Fig.3) we verify that inside the same municipality it's the littoral parishes that show a stronger growth.
Within the studied area, some littoral parishes don't show great demographic dynamic, keeping population densities relatively weak compared to the region average.

3.2 Evolution and distribution of the dwellings

The evolution of the dwellings show another geography.
One of the characteristics of the touristic activities is the need to dwell seasonally an elevated number of persons. This process can be achieved with the use of hotels, and the possibility of maximizing its utilization or, as in the case study, building apartments that are used in short periods of time during the year.

When we analyze the evolution of the data since 1960 we verify that the growth started on a slow note (Fig.4).
.

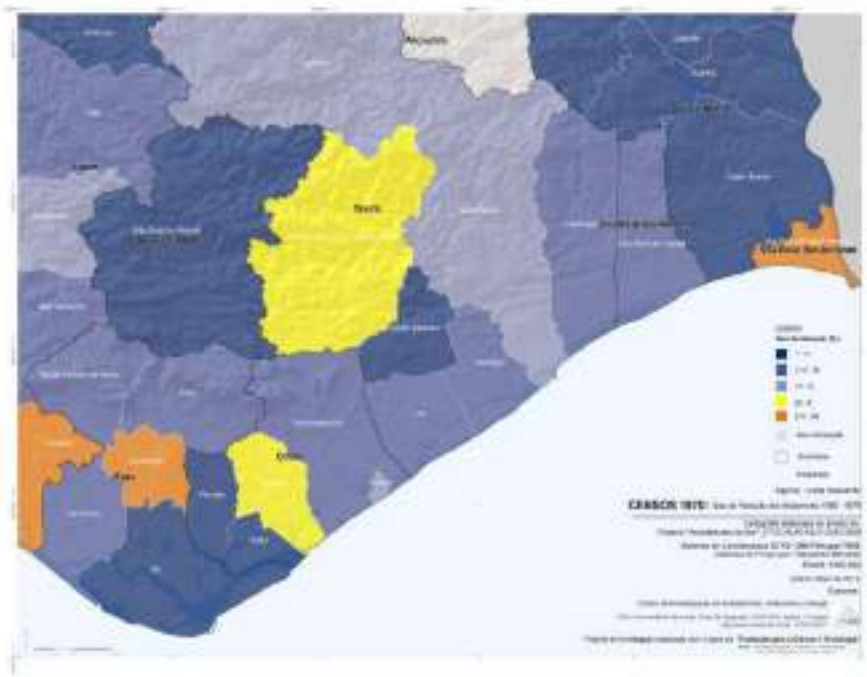

Figure 4. Growth rate of households between 1960 e1970, by parish

In the decade of 1960 the growth of dwellings was still quite weak, tourism was in its starting in this area of Algarve, only in some parishes belonging to cities like Olhão and V.R. Santo António.

But in the decade of 1980 the evolution of the resident population and the dwellings was quite different with a general increase of the population but a much greater increase of the dwellings.

In the map with the situation in 2001(Fig.5) the littoral parishes show densities of dwellings much greater when compared with the average of the region.

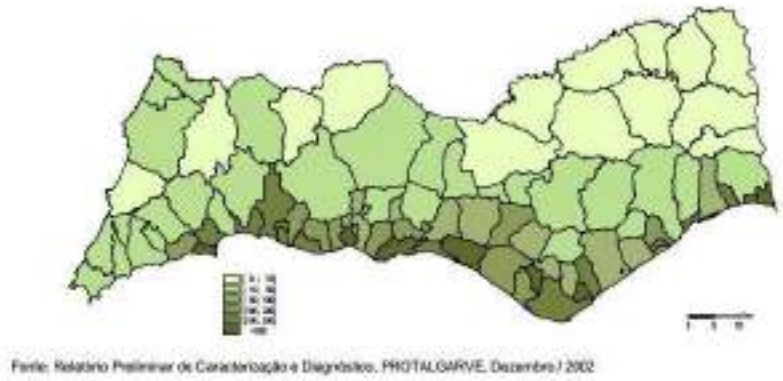

Figure 5 Number of dwellings per km2, by parish (2001)

When we analyze the relationship between the types of occupation of the dwellings (Fig.6) we note that the weight of the seasonal use is quite high in the peripheral areas, but less relevant in the area of study.

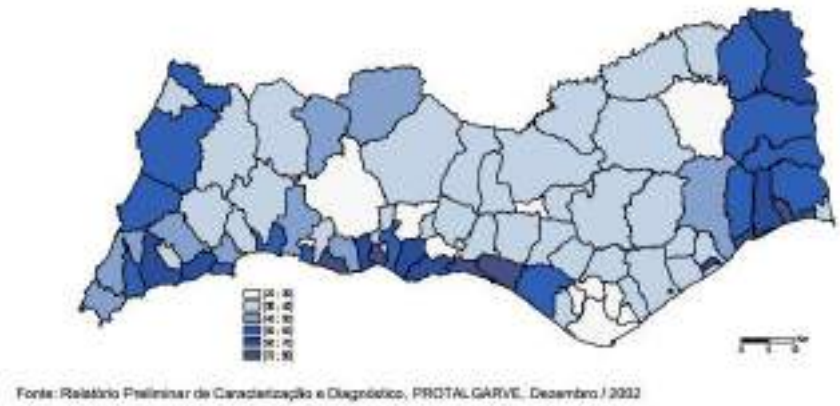

Figure 6. Percentage of housing occupancy seasonal / secondary and vague in total households, by parish (2001)

Comparing the rates of growth of the dwellings in the decades of 1981-1991(Table1) and 2001-2011(Fig7)., we verify the slowing of the construction

in some parishes and the increase in the coastal parishes, namely in those with smaller coastal fronts.

Table 1. Comparison between the rate of change of the population and the dwellings 1981 – 1991

		1981-1991	
Concelhos	Freguesias	Popul.	Aloj
Castro Marin	Castro Marin	3	34
	São Pedro (cidade de Faro)		19
Faro	Sé (cidade de Faro)	4	30
	Almansil	14	46
Loulé	Quarteira	8	68
	Fuzeta	23	40
Olhão	Moncarapacho	9	-1
	Olhão	-17	7
	Pechão	9	15
	Quelfes	2	36
	Luz de Tavira	14	20
Tavira	Santa Maria	0	25
	Santiago	-15	6
V. R. St. Antonio	Vila Nova de Cacela	-10	19
	Vila Real de Santo António	-59	-17

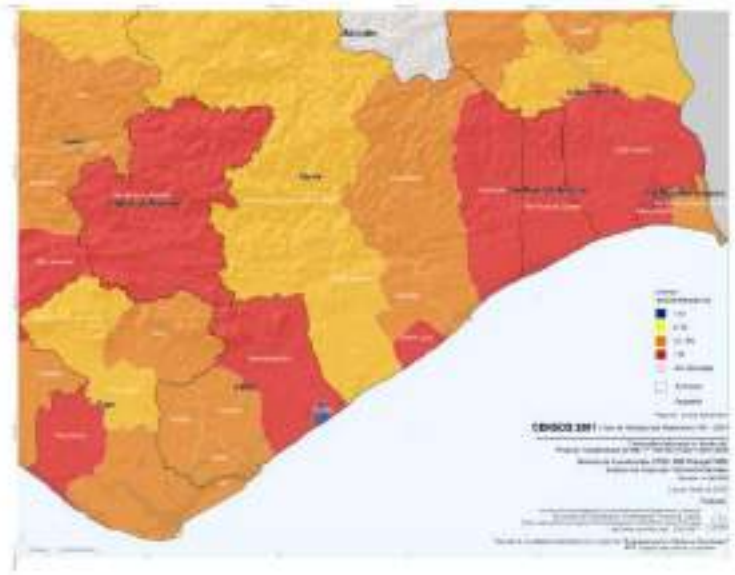

Figure 7. Growth rate of households between 1991 e 2001, by parish

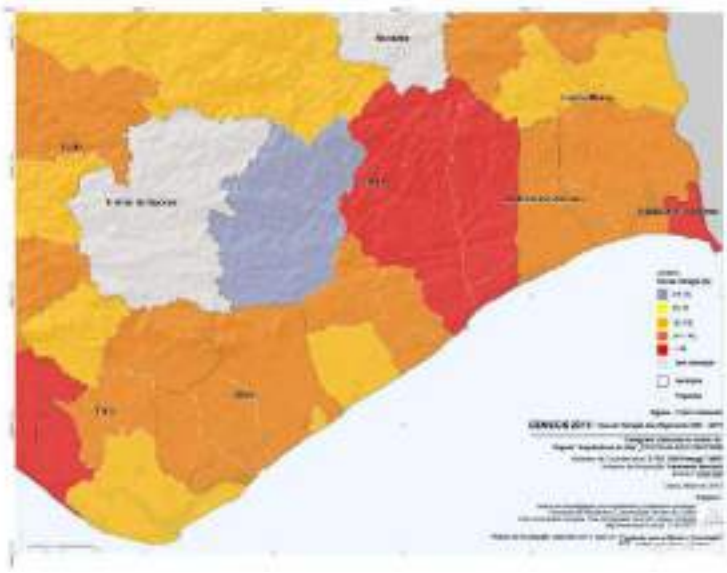

Figure 8. Growth rate of households between 2001 e2011, by parish

3.3 Morphologies

The morphology of the cities has suffered great changes with a significant growth towards north, with a significant seclusion from the coastal front that had been the economic engine, with the tourist
accommodation, occupying former agricultural areas now abandoned (Fig. 9 and 10)

Figure 9. Quarteira Area

Figure 10. Olhão Area

3.4 Results

From this presentation we note that the evolution of the population has not been uniform with the parishes of Fuzeta, Luz de Tavira, Santa Luzia and Monte Gordo a decrease of the resident population in the decade of 2001 corresponding to a significant increase of the dwellings (Fig 11).

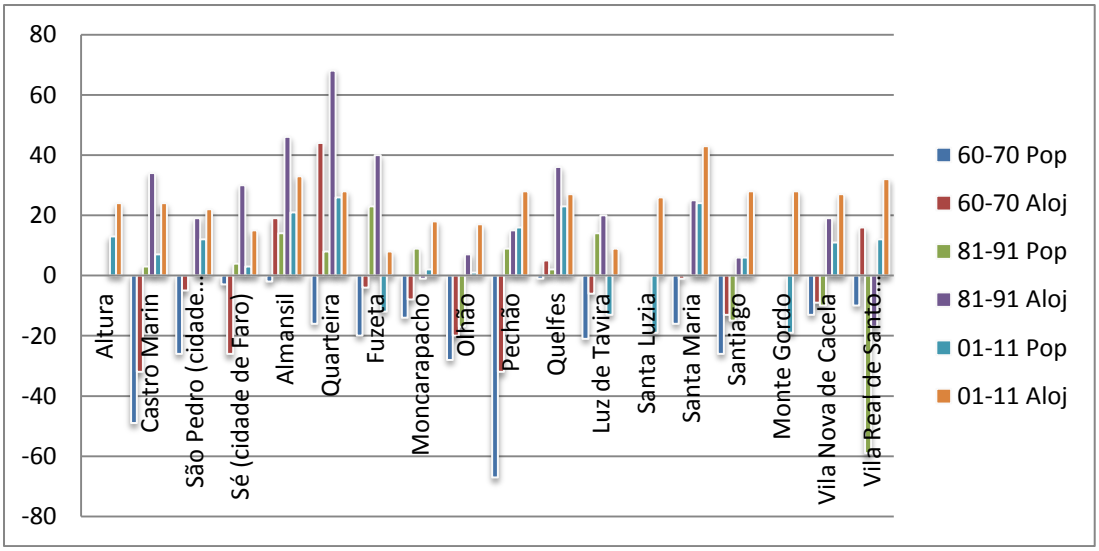

Figure 11. Comparison of rates of change of population and housing, by parish

4. Conclusions

The littoral cities went through an urban behavior, making them more and more unsustainable, when opting for a growth of the dwellings related to seasonal uses.

Littoral areas are being occupied through a process of filing from the coast line towards the interior, in a mostly continuous way.

Its lack of sustainability is also shown by the occupation of inner areas that, considering the population that seeks them because of the existence of beaches, promote the use of individual transportation with the underlying parking problems close to the beaches.

In the Sotavento Algarvio we can consider a new paradigm of urban growth, where the actors are the sea and the beaches and the growth occurs towards the interior in a process of diffusion, quite uninteresting under a perspective of urban sustainability.

THE EVOLUTION OF THE CONCEPT OF PUBLIC PARTICIPATION IN HERITAGE PLANNING
WITH PARTICULAR FOCOUS ON ICOMOS CHARTERS AND UNESCO OPERATIONAL GUIDELINES

Mojgan Rasouli[1], Dr.Luna Khirfan[2]

Abstract

This paper traces the evolution of public participation in the debates on heritage planning in international charters especially, those that pertain to World Heritage such as ICOMOS charters, the UNESCO Convention on World Heritage, and the various iterations of the Convention's Operational Guidelines.
Public participation has been debated in the planning literature and practice since Paul Davidoff's 1965 landmark article "Advocacy and Pluralism in Planning". Nevertheless, it took over twenty years for the concept of public participation to appear in any of the ICOMOS International charters, and specifically, until 1987 when the Charter of the Conservation of Historic Towns and Urban Areas, also known as the Washington Charter 1987, was first made public. Likewise, the documents issued by UNESCO regarding World Heritage did not, that is, until the late 1980s, address local communities, their representation, or their engagement.
Adopting a longitudinal study this article traces the unfolding of the concept of public participation and its development throughout the decades in the ICOMOS International Charters and the UNESCO Convention and Operational Guidelines on World Heritage. By framing how public participation first developed in the theory and practice of urban and regional planning, this article investigates the public participation introduction and then application in the field of international heritage.
Through this longitudinal historic analysis, this article reveals that the international heritage planning has lagged behind other aspects of urban and regional planning in terms of community engagement and public participation.

Keywords: Public participation, Collaboration, ICOMOS Charters, UNESCO Convention, Operational Guidelines, World heritage.

1. Introduction

Public participation has been debated in the planning literature and practice since Paul Davidoff's (1965) landmark article "Advocacy and Pluralism in Planning" (Davidoff, 1965; Checkoway, 1994). This article seemed to have opened a Pandora's

[1] University of Waterloo, Waterloo, Canada – mojgan.rasouli@uwaterloo.ca
[2] University of Waterloo, Waterloo, Canada – lkhirfan@uwaterloo.ca

Box on the debates of community involvement in the decision-making process {Checkoway, 1994 #529}. Nevertheless, it took over twenty years for the concept of public participation to appear in any of the ICOMOS International Charters, and specifically, until 1987 when the Charter of the Conservation of Historic Towns and Urban Areas, also known as the Washington Charter 1987, was first made public. During that period, there were indeed intermittent mentions of local engagement in some of the national and supra-national documents such as a brief mention in the European Charter of Architectural Heritage, which in 1975 stated that "The public should be properly informed because citizens are entitled to participate in decisions affecting their environment" (The Council of Europe, 1975 , Article 9). A long gap exists until in 1983 ICOMOS Canada introduced the need for "consensus" that involves "public participation" (Canada, 1983, B-Framework).

Likewise, the documents issued by UNESCO regarding World Heritage did not, that is, until the late 1980s, address local communities, their representation, or their engagement in the international heritage planning process.

Through a longitudinal comparative analysis of the urban planning literature, the Operational Guidelines issued by UNESCO's World Heritage Centre and the Charters issued by ICOMOS International, this paper investigates the evolution of the concept of public participation in World Heritage Planning. Spatially, reveals that the participatory planning process lags behind the urban planning theory and practice in general and heritage planning in particular.

2. Research Methodology

This paper adopts a longitudinal study that compares the theories and practices of public participation in urban and regional planning on the one hand, and the 1972 UNESCO Convention Concerning the Protection of the World Cultural and Natural Heritage (herewith referred to as the Convention), its Operational Guidelines, and the ICOMOS International Charters on the other hand. In order to facilitate this comparison, we conduct a review of the urban planning literature that traces the unfolding of the concept of public participation in this field and its development throughout the decades. Likewise, we analyze the content of the UNESCO Convention and all the subsequent Operational Guidelines as well as all the internationally and nationally ICOMOS Charters and documents.

3. Engagement and public participation in planning literature

The notion of public participation emerged in the urban planning dialogue in the mid 1960s when Paul Davidoff (1965) first introduced the advocacy planning theory. While this theory did not call for active participation per se, it nonetheless drew on the legal profession and called for the planner to assume an advocate's role – one who represents, akin to a lawyer, his constituencies. Davidoff's therefore, was a theory that focused on the representation of the interests of those constituencies who are affected by the planning decisions.

Notwithstanding his view on advocacy, Davidoff emphasizes transparency and participation 'The right course of action is always a matter of choice, never of fact […] great care must be taken that choices remain in the area of public view and participation' (Davidoff, 1965, p.332). David Godschalk and William Mills (Godschalk, 1966) introduced what they dubbed "collaborative planning", which similar to Davidoff's drew on another discipline, albeit marketing in this case.

According to Godschalk and Mills, marketing experts are "skilled counsellors" who help consumers in defining their desires and hence, these experts work "with rather than for" the subcommunities (Godschalk, 1966, p.86). Accordingly, representation occurs either by electing representatives from the different pools of subcommunities or by directly involving all the subcommunities to represent themselves (for example by holding a public meeting in a city hall). In that, collaborative planning differs from advocacy planning in its definition of representation, whereas it shifts this definition from "who is representing" to "what is being represented". In collaborative planning thus, the representation becomes less about identifying a representative who may advocate for stakeholders' needs, and more about representing all the interests and the needs of all stakeholders. Accordingly, representation in collaborative planning includes, in addition to the identities, the needs, interests and choices of all subcommunities (Godschalk, 1966). In contrast to this approach that emphasized those influenced by planning decisions, Burke addressed citizen participation through the lens of the planning organization's needs and objectives (Burke, 1968). For Bruke (1968), in a democratic society, public participation becomes a matter of right, and accordingly, he identifies five roles/strategies: review and comment, consultation, advisory, shared decision-making and controlled decision-making.

Building on these notions, Sherry Arnstein (1969) reverts back to the constituencies instead of the institutions in her classic article "A Ladder of Citizen Participation". She identifies three primary levels of participation: non-participation, tokenism, and citizen power whereas non-participation occurs when the planners employ manipulation and therapy in order to appease to their constituencies. In tokenism, planners resolve merely to informing, consultation, or to placation. Lastly, when planners create genuine partnerships with their constituencies, delegate power to them, or allow them to assume complete control over the planning process, then the participatory process reaches a level of citizen empowerment (Figure 1) (Arnstein, 1969).

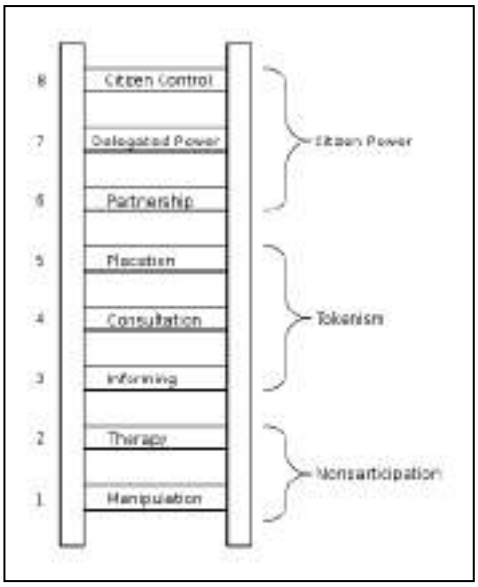

Figure1. Ladder of Public Participation, Arnstein (1969)

Although thorough, none of these debates discussed the timing per se. In other words, missing in these debates were the exact stages of public participation and their relationship to the planning and implementation processes. The notion of timing was first introduced by Nabeel Hamdi and Reinhard Goethert (Hamdi, 1997, p. 72) in their discussion of "the stages of projects and programmes". They propose five stages that commence with initiation during which the problems and needs are identified, and the basic goals, objectives, and scope are defined. Next, comes the planning stage where specific activities are identified including the budget and resources. This is followed by the design stage during which more technical details are developed and then the implementation stage, which witnesses the execution of the various aspects of the plan. Lastly, the maintenance stage incorporates the long-term, on-going repair and upkeep of what was implemented (Hamdi, 1997, p.72).

The next section investigates the transfer of these notions into the debates on World Heritage and pays particular attention to how and when are these notions introduced.

4. Public participation in World Heritage conservation principles

One of the significant achievements for the heritage planning process is the development of conservation principles or guidelines at the international level. The International organizations such as the United Nations Educational, Scientific and Cultural Organization (UNESCO) and the International Council on Monuments and Sites (ICOMOS) initiated these principles or guidelines.

Specify that the ICOMOS Venice charter led to the establishment of the World Heritage principle and eventually, to the UNESCO Convention. Then define the relationship between ICOMOS and UNESCO –the former is an advisory body to the latter, and the latter oversees all matters related to World Heritage Sites. Also, in order to interpret the Convention on World Heritage, UNESCO employs the expertise of ICOMOS, among others to develop what came to be known as the Operational Guidelines, and which have been continuously updated since 1977. Also, ICOMOS continues to design charters to establish international standards with regards to the management of heritage resources around the world. Some of these are adopted by the general assembly of ICOMOS, while are charters adopted by the national committees of ICOMOS, ICOMOS also endorses resolutions and declarations, and lastly other international standards (refer to ICOMOS website: http://www.icomos.org/index.php/en/charters-and-texts).

Given its leadership role in World Heritage, we begin the following review with the UNESCO documents, particularly, the UNESCO Convention and the subsequent operational guidelines that interpret it. The review then continues with the ICOMOS charters, both international and national, and all the documents that it endorses.

4.1 Public participation in UNESCO Convention and Operational Guidelines

To begin with, the 1972 Convention places the emphasis on the international community to unite in the protection and management of world heritage. Naturally, this macro perspective at the international level overlooked the micro perspective of the local communities at World Heritage Sites. A detailed review of the Convention reveals that to this day, the text lacks any mention of the local communities at the micro level with the exception of a brief mention of how World Heritage Sites relate to the daily lives of the local communities: “to adopt a general policy which aims to give the cultural and natural heritage a function in the life of the community and to integrate the protection of that heritage into comprehensive planning programmes” (UNESCO, 1972, Article 5, a).

Likewise, it was not until 1987 that the Operational Guidelines mention anything about the micro level for the first time. This mention highlights ‘informing’ the local inhabitants about the decisions regarding the conservation and protection measures for nearby World Heritage Sites as essential: “…. Informed awareness on the part of the population concerned, without whose active participation any conservation scheme would be impractical, is also essential” (UNESCO, 1987, C, Article 31).

Immediately the following year, the Operational Guidelines maintained this article. However, simultaneously the 1988 revision included an additional article, that instead of increasing the public engagement in the inscription process actually called for secrecy and withholding information about the inscription: “In all cases so as to maintain the objectivity of the evaluation process and to avoid possible embarrassment to those concerned, States Parties should refrain from giving undue

publicity to the fact that a property has been nominated for inscription pending the final decision of the Committee on the nomination in question" (UNESCO, 1988, B, Article 14).

Although the 1988 Operational Guidelines were revised four years later, the 1992 revision maintained the same stipulation regarding 'informing' the 'concerned populations' and also 'refraining from undue publicity' (UNESCO, 1992, B, Article 14).

It was not until the Operational Guidelines of 1994 that a significant development with regards to local engagement was incorporated. In addition to their 'informed awareness' (UNESCO, 1994 , C, Article 34), the 'active participation' of 'concerned populations' is mentioned for the first time and especially, with regards to the conservation schemes: "In all cases, so as to maintain the objectivity of the evaluation process and to avoid possible embarrassment to those concerned, states Parties should refrain from giving undue publicity to the fact that a property has been nominated for inscription pending the final decision of the committee on the nomination in question. Participation of local people in the nomination process is essential to make them feel a shared responsibility with the State Party in the maintenance of the site, but should not prejudice future decision-making by the committee" (UNESCO, 1994, B, Article 14).

Another significant amendment in the 1994 Operational Guidelines is that of introducing the concepts of "collaboration" with and "local communities" instead of "concerned populations" for the very first time in any of the UNESCO documents on World Heritage: "... It is important that due attention be paid to the full range of values represented in the landscape, both cultural and natural. The nominations should be prepared in **collaboration** with and the **full approval** of local communities" (UNESCO, 1994, C, Article 41, emphasis ours).

Once embraced, the concept of local involvement began to appear more conspicuously in the subsequent iterations of the Operational Guidelines. During 1995, a revision was proposed for the Operational Guidelines in which the role of the local people in the nomination process was revised to state that the "Participation of local people in the nomination process is essential". The rationale however, is not to include them in the decision-making process per se, but in order "to make them feel a shared responsibility with the State Party in the maintenance of the site". The same articles goes on to confirm that such participation "should not prejudice future decision-making by the Committee" and thus places limitations on the participatory component suggested earlier (UNESCO, 1995, Article A.2.1).

These amendments remained in effect for the following decade without any changes until 2005 when the revised Operational Guidelines finally requested from State Parties to ensure the participation of all stakeholders at the micro level: "States Parties to the Convention are encouraged to ensure the participation of a wide variety of stakeholders, including site managers, local and regional governments, local

communities, non-governmental organizations (NGOs) and other interested parties and partners in the identification, nomination and protection of World Heritage properties" (UNESCO, 2005, I.C. Article 12).

For the first time, the Operational Guidelines stipulate the need for micro level participation from the outset, that is, at the nomination phase: "Participation of local people in the nomination process is essential to enable them to have a shared responsibility with the State Party in the maintenance of the property. States Parties are encouraged to prepare nominations with the participation of a wide variety of stakeholders, including site managers, local and regional governments, local communities, NGOs and other interested parties." (UNESCO, 2005, II.F. Article 123).

The 2005 Operational Guidelines did not stop at this, but also underscored the participation of local communities at the micro level in the protection and conservation of World Heritage: "Partners in the protection and conservation of World Heritage can be those individuals and other stakeholders, especially local communities, governmental, nongovernmental and private organizations and owners who have an interest and involvement in the conservation and management of a World Heritage property" (UNESCO, 2005, I.I. Article 40).

For the first time, the Operational Guidelines elaborate on the micro level public participation of local communities in more than one article, and within several tasks related to World Heritage. For example, there are article dedicated to the participation of local communities in the preparation of the Tentative Lists, which stands in stark contrast to the 1988 Operational Guidelines that advocated secrecy and withholding information at the earlier stages. Furthermore, the 2005 Operational Guidelines emphasize the micro level participation of local communities in the protection and the management of inscribed World Heritage Sites (UNESCO, 2005, II.F. Articles 111, 117).

The subsequent revisions in 2008 and 2011 maintained the same changes from 2005 regarding the participation of local communities at the micro level.

4.2 Public participation in ICOMOS Documents

The International Council on Monuments and Sites (ICOMOS) documents exist both at the international and the national levels. As mentioned earlier, the ICOMOS documents may be classified into three major categories namely, the ICOMOS international charters as well as the national charters and the various international resolutions and standards that are endorsed by ICOMOS (Table 1).

Table 1. ICOMOS Documents

International ICOMOS Charters	ICOMOS Resolutions / Standards	National ICOMOS Charters
Charter for the Conservation of Historic Towns and Urban Areas, (The Washington Charter) ICOMOS, 1987.	European Charter of the Architectural Heritage, Council of Europe, 1975.	Appleton Charter for the Protection and Enhancement of the Built Environment ICOMOS Canada, 1983.
Charter for the Protection and Management of the Archeological Heritage Sites, ICOMOS 1990.	Resolution of the International Symposium on the conservation of smaller Historic Towns, at the 4th ICOMOS General Assembly, 1975.	The Australia ICOMOS Charter of the Conservation of Places of Cultural Significance, (The Burra Charter), 1999.
International Cultural Tourism Charter, Managing Tourism at Places of Heritage Significance, ICOMOS 1999.	Guidelines for Education and Training in the Conservation of Monuments, Ensembles and Sites, ICOMOS, 1993.	-
Charter on the Built Vernacular Heritage, ICOMOS, 1999.	Nara Document on Authenticity, Japan and UNESCO, 1994.	-
Charter on Cultural Routes ICOMOS, 2008	The Declaration of San Antonio, 1996.	-
Charters on the Principles for the Conservation of Industrial Heritage Sites, ICOMOS, 2011	Principles for the Recording of Monuments, Groups of Buildings and Sites, ICOMOS, 1996.	-
Valetta Principles for the Safeguarding and Management of Historic Cities, Towns and Urban Areas, ICOMOS, 2011	-	-

Beginning with the ICOMOS International Charters, it is not surprising to observe that the Venice Charter, which was adopted in 1964, lacks any mention of micro level participation with the local communities. In fact, the first time that such a notion is mentioned in these international documents appears in the Charter for the Conservation of Historic Towns and Urban Areas, known as the Washington Charter 1987. This charter considered the participation of the residents of historic towns important for the success of “heritage conservation programs”. The Washington Charter even proposed the need for “a general information program” that ensures micro level public involvement, and went to the extent of encouraging school children to participate in these programs (ICOMOS, 1987, Articles 3, 15).

By 1990, the Charter for the Protection and Management of the Archaeological Heritage Sites introduced the notion of public participation as part of the conservation and management policies for heritage sites: “Active participation by the general public must form part of policies for the protection of the archaeological heritage” (ICOMOS, 1990, Article 2).

Interestingly, as early as 1990, this charter firmly advocates local engagement in all aspects related to cultural heritage “Local commitment and participation should be actively sought and encouraged”. It elaborates the significance of such participation for the continuous care of heritage sites “as a means of promoting the maintenance of the archaeological heritage.” Most importantly, this charter acknowledges the micro level links between local communities and their heritage “This principle is especially important when dealing with the heritage of indigenous peoples or local cultural groups” and even empowers local communities to assume ownership of their cultural heritage “In some cases it may be appropriate to entrust responsibility for the protection and management of sites and monuments to indigenous peoples” (ICOMOS, 1990, Article 6).

Even the ICOMOS International Cultural Tourism Charter of 1999 acknowledges the need for “The involvement and co-operation of local and/or indigenous community representatives” among the wide array of other stakeholders in the preparation of plans to “achieve a sustainable tourism industry and enhance the protection of heritage resources for future generations” (ICOMOS, 1999b). This charter therefore encourages the involvement of “host communities and indigenous people” in the management of tourism especially, in the cases when “conflicting interests, responsibilities, and obligations” exist at cultural heritage sites (ICOMOS, 1999b).

Subsequent charters over the next few years address technical aspects of cultural heritage such as structures, timbers, and wall paintings but nevertheless some of them like the 1999 ICOMOS Charter on the Built Vernacular Heritage; briefly mentions the importance of community involvement for the protection and conservation of vernacular heritage (ICOMOS, 1999c).

Local engagement only appears more conspicuously and forcefully in the subsequent charters albeit using different terminology. The 2008 ICOMOS Charter on Cultural Routes or the more recent 2011 ICOMOS Charters on the Principles for the Conservation of Industrial Heritage Sites and the Valetta Principles for the Safeguarding and Management of Historic Cities, Towns and Urban Areas all refer to public participation (ICOMOS, 2008a; ICOMOS, 2011a; ICOMOS, 2011b). However, the 2008 ICOMOS Charter on the Interpretation and Presentation of Cultural Heritage Sites refers to ‘inclusiveness’ (ICOMOS, 2008b, Article 6).

Notably, some of the national ICOMOS charters preceded the international ICOMOS charters in addressing micro level participation. In fact, as early as 1983, the term “public participation” appeared in ICOMOS Canada’s Appleton Charter for the Protection and Enhancement of the Built Environment. This charter refers to

"Legitimate consensus" that "will involve public participation" (ICOMOS Canada, 1983, B). No other national ICOMOS charters matched ICOMOS Canada's approach toward local engagement until the latest 1999 version of Australia ICOMOS' Charter for Places of Cultural Significance, also known as the Burra Charter. The first version of this charter, which dates to 1979, as well as the 1981 and 1988 iterations lack any hint at participatory processes. The 1999 revision however, does recognize "the need to involve people in the decision-making process, particularly those [decisions] that have strong associations with a place" (ICOMOS Australia, 1999a, Background). Moreover, this charter clarifies further that: "Conservation, interpretation and management of a place should provide for the participation of people for whom the place has special associations and meanings, or who have social, spiritual or other cultural responsibilities for the place." (ICOMOS Australia, 1999a, Article 12).

A review of the other resolutions and standards endorsed by ICOMOS reveals that some of them introduced the micro level participatory component relatively early in the cultural heritage debate. More specifically, as early as 1975, the Council of Europe in its European Charter of the Architectural Heritage went beyond 'informing' local communities about decisions regarding cultural heritage, to actually engaging them in the decision-making process: "The public should be properly informed because citizens are entitled to participate in decisions affecting their environment…" (The Council of Europe, 1975, Article 9).

Simultaneously, the General Assembly of ICOMOS reached a set of resolutions at its 1975 International Symposium on the Conservation of Smaller Historic Towns, which was held in Bruges among which a mere mention for the need to encourage local preservation initiatives appears (ICOMOS, 1975, Article 6). By 1993, the Guidelines for Education and Training in the Conservation of Monuments, Ensembles and Sites recommend an understanding of the local community's needs and encourages working with locals as an appropriate strategy for resolving any conflicts that may ensue from conservation practices (ICOMOS, 1993).

Although the 1994 Nara Document on Authenticity requires community consensus in attributing heritage values in one of its appendixes, the 1996 Declaration of San Antonio however, states that the Nara Document excludes the local community from the heritage identification process (ICOMOS, 1994; ICOMOS, 1996). Adopting a North American perspective, the participants in the San Antonio Symposium called for a stronger involvement of the local communities in all the processes of heritage management and especially, at the outset during the definition of cultural heritage and the identification of its significance (ICOMOS, 1996). Likewise, the Principles for the Recording of Monuments, Groups of Buildings and Sites from 1996 also recommend the consideration of local interests and their involvement in the early stages of the documentation of cultural heritage, which eventually leads to decisions about its conservation (ICOMOS, 1996b).

5. Results: A longitudinal comparison of the evolution of public participation in ICOMOS and UNESCO documents

Adopting a longitudinal study this article traces the unfolding concept of public participation and its development throughout the decades in the UNESCO Convention and Operational Guidelines on World Heritage and the ICOMOS International, National Charters and documents.

While the UNESCO Convention was written in 1972, a few years before that (1960's), the debate on public engagement in urban planning had emerged forcefully. Between 1965 and 1970 several theories on public engagement emerged from advocacy, to collaborative to strategic to Arnstein's levels. However, the UNESCO and the ICOMOS documents lag behind in these debates on local engagement (Figure 2).

In other words, for example, while the advocacy planning and following it the collaborative planning, level of participation theories introduced in late 1960s the Washington Charter in 1987 as an International Charter, more than twenty years later, mentions public participation and emphasizes it, and also the UNESCO Operational Guidelines that were contemporary to it, do not follow up on the participation theories, so a gap or even a recession at the international heritage planning documents is obvious in this period (between 1965 and 1987) (Figure 2).

6. Conclusion

The heritage planning debates needs to adapt and incorporate the established principles of participatory and inclusive planning. The analysis reveals that the international heritage debate addresses the timing of participation, especially in the ICOMOS documents and resolutions that discuss the early stages of recording and documenting. However, this analysis also reveals that the international heritage debate still lags behind other planning practices in terms of addressing the levels of participation and the representation of stakeholders. Therefore, this study reveals the need for further studies that lead to models and frameworks that account for the various levels of participation and the different forms of stakeholder representation at all the stages of the heritage management process.

THE COMMUNITY-BASED STUDIO: PARTICIPATORY PLANNING AND URBAN DESIGN WITH STUDENTS AND COMMUNITIES IN CALIFORNIA

ABSTRACT

Originating in the 1960's as a new pedagogical approach, the community-based studio (CBS) offers students the distinct advantage of providing a stage for real-world planning and urban design. While the advantages and challenges of CBS have been discussed in existing literature, the operational steps to maximize the advantages and avoid challenges are useful for faculty interested in CBS. In this paper, three CBS models based on three recent cases are developed. Their advantages and disadvantages in relation to studio learning outcomes are discussed. Building on this discussion, the paper presents a conceptual framework and operational steps for future CBS experiences.

INTRODUCTION

The growing role of planners in interactive, multi-organizational decision-making has led in the past two decades to an ever-increasing need for teaching practices that emphasize interactive and experiential learning. City planning and urban design programs responded to this need by developing in-class simulations of real decision-making situations or "settings" (Christensen, 1993). As an extension, beyond simulations, the Community Based Studio (CBS) has fast gained prominence in planning and design fields (Dorgan, 2008). In 2000, Forsyth, Lu and McGirr's survey found seventeen university-based outreach centers[1] practicing urban design.

Originated in the 1960's as a new pedagogical approach (Sanoff, 2007), the community-based studio provides a distinct advantage by forming the stage for real-world situations. According to Schweitzer et.al.'s classification (2008), CBS covers "problem-based learning" (Shepherd and Cosgrif, 1998), and "service learning" (Roakes and Norris-Tirrell, 2000). A wide body of literature has discussed the advantages of community-based studios, while more recently the number of pieces pointing at potential disadvantages and challenges associated with CBS have increased. Literature in this area, however, could be more explicit in providing methods to avoid potential challenges for faculty interested in pursuing CBS. As Forsyth et al (2000) suggest, the schools pursuing CBS tend to be independent of each other, and efforts tend to be scattered among faculty interested in the model. A larger scale effort to identify methods to avoid challenges in the community based studio is needed, if it is to be further refined so as to be more clearly operationalized.

[1] University-based outreach in planning and design, particularly CBS, differs from Community Design Centers (CDCs), which are often staffed by professionals - since students do the work, for the purpose of learning.

Dorgan's paper (2008) provides an excellent conceptual framework for conducting community based studios. The framework offers four main principles: transparency, capacity, flexibility, and accountability. *Transparency* refers to every participant in the process understanding the definition of the work to be done, and who is doing the work. Participants must have a *capacity* to fulfill their tasks. *Flexibility* is needed to coordinate the studio schedule, project schedule and the academic schedule. Finally, every effort should be made to make sure that the studio work is as close as possible to professional standards, and the class achieves its learning objectives to insure *accountability*.

To date, Dorgan's (2008) framework provides the most comprehensive look into the CBS from an operational point of view. However, this framework stays at the conceptual level; the author does not provide concrete techniques to follow this framework. The objective of this paper is to take this discussion one step further, and operationalize Dorgan's (2008) framework by developing recommendations to avoid potential disadvantages and challenges in the community-based studio process while making the most out of its potential advantages.

This paper presents three CBS models, their implications and a CBS conceptual framework. The intent is to provide a reference set for faculty interested in pursuing CBS, and to fuel further discussion with faculty currently conducting community based studios[2].

1. Advantages, Disadvantages and Challenges of the Community-based Studio

1.1. Advantages

There is a large body of literature discussing the advantages of the community-based studio, substantiating the increasing rate by which the model has been gaining prominence. These advantages can be summarized under five main groups:

1. cognitive skill building in students,
2. the learning process and learning efficiency of students,
3. the professional development of students,
4. the empowerment of students in the educational institution,
5. providing benefits to the community.

1.1.1. Cognitive development

The CBS presents a learning process in which planning and design concepts can be applied in practical means. Shepherd and Cosgrif (1998), for example, argue that problem-based learning helps students learn to practice. Roakes and Norris-Tirrell

[2] The cases introduced in this paper occur in a small, medium and a large city. These scales do not affect the basic learning experiences, but demonstrate that the three models can be applied in any urban setting.

(2000) underline that this process can help students develop skills and competence in a particular area by converting what they have learned within a theoretical framework into application. According to Sanoff (2007), the community based learning process helps the student link all relevant information related to the problem, people and place. The CBS therefore helps develop cognitive skills by allowing the students to identify and respond to problems by integrating the knowledge they have gathered at the conceptual level.

A good example is the very notion of public participation in planning and design. Planning students receive information about community participation in many contemporary curricula. Developing and practicing skills in the area is a different story (Friedmann, 1996). As Arnstein's (1969), Wulz's (1984), Carp's (2004), and Toker's (2012) work indicates in the history of community design, participatory planning and design can be practiced in very different ways, ranging from manipulation to collaborative decision-making. Through CBS, students experience the multiple levels of community participation first-hand, an experience that cannot be provided by assignments or readings.

1.1.2. Knowledge retention

CBS supports students' retention of knowledge. According to Sanoff, "what is learned is likely to be available for use if it is learned in a situation much like that in which it is to be used and immediately preceding the time when it is needed (Sanoff 2007, pp.3)." Knowledge retention in CBS is supported by CBS's capability of making knowledge more memorable and providing motivation for learning actively in a real-world setting (Shepherd and Cosgrif, 1998). Another factor that contributes to knowledge retention in CBS is its capability of bringing the complexity and uncertainty encountered in practical situations into the studio (Roakes and Norris-Tirrell, 2000). This promotes reflective observation and active experimentation, therefore learning by actively responding to a problem.

1.1.3. Professional development

Dalton (2008) identifies a continuum of professional planning roles in the field. This study, which is based on the largest sample selection to date, indicates that professional planners focus on a wide array of activities, and are employed in general purpose governments, special purpose governments, private firms, nonprofit organizations, or universities. Their work activities range from policymaking to administrative, interactive, analytical and political tasks. CBS provides an environment where the students can work on and interrelate these multiple facets of the profession.

A particularly critical skill in the planning profession is communication (Friedmann, 1996). Lusk and Kantrowitz (1990) point at this, and underline that many students, after extensive periods of classroom and studio education, are still challenged by the communication skills required by the profession. This still appears to be the case.

CBS creates an environment where complex communication skills (i.e. verbal, written, visual) can be developed simultaneously. Shepherd and Cosgrif (1998) underline the similarity between CBS and professional practice, in which individuals have to work on their own or in a group setting, therefore thinking about the implications of one's actions. This also helps the student to self-evaluate actions and outcomes, rather than being evaluated by a series of abstract external measurements (Sanoff, 2007). CBS also contributes to the professional development of students through promoting the feeling of responsibility to peers, professionals and the community. Working with a community promotes the feeling of responsibility to the community and the profession (Roakes and Norris-Tirrell, 2000).

1.1.4. Student empowerment

CBS empowers the student by disintegrating the conventional hierarchy in which the teacher is the evaluator and the student is the learner. The teacher assumes a coaching role, helping the students in identifying problems and resources necessary to move towards solutions (Sanoff, 2007). Sanoff emphasizes that in this process "the learner becomes involved in all decision-making processes related to education (2007, pp.3)", and thus is empowered.

1.1.5. Community benefits

Finally, CBS has proven advantageous to all stakeholders in the process, - students, educators and the communities involved. The teaching and learning processes are enhanced by the experience, and the communities eventually receive direct and indirect benefit (Roakes and Norris-Tirrell, 2000). For example, Harris (2004) has recently provided an in-depth account of how rural communities can benefit from service learning activities, in the context of rural northern New York.

1.2. Disadvantages and Challenges

While the advantages of CBS have been acknowledged in the existing literature, an increasing number of authors warn about potential problems the model can create for students, faculty and the community if precautions are not taken.

1.2.1. Potential problems for students

Due to the outreach-based, community oriented nature of CBS, communities that are selected for such projects are more likely to be economically disadvantaged, hence offering more limitations. Forsyth, Lu and McGirr (2000) warn that students may not favor these limitations, and may even question the benefits of working with such communities. Another potential problem may be the students' being intimidated by the range of problems and issues presented by the community. This may put unnecessary pressure on the basic learning objectives, such as learning time management and organization skills.

1.2.2. Potential problems for faculty

The biggest potential problem for faculty undertaking CBS projects is the high likelihood of the project creating additional tasks and hence an increased workload (Forsyth, Lu and McGirr, 2000). Contacting the community, doing preliminary outreach work, organization, and efforts on creating a correspondence between the class timeline and the project development timeline are examples of additional tasks that will appear in many CBS experiences.

1.2.3. Potential problems for the community

Dorgan (2008) warns that CBS may have a larger emphasis on communities' deficiencies rather than their assets. This may indeed be an issue since student involvement may create the perception that the community is incapable of recruiting, or affording, professional help. Related to this, Forsyth, Lu and McGirr (2000) warn that the pre-professional quality of student work may translate into lower quality products, eventually becoming a problem for the community. Perhaps the biggest issue, however, may be that the CBS may raise false hopes about solving significant problems (Forsyth, Lu and McGirr, 2000) in instances of poor execution (Dorgan, 2008). This is particularly risky if key individuals in the community recruit the academic institution but fail to display any examples of implementation.

2. Where does a CBS fit in a Community's Process? Three Models

Due to the variety of projects that CBS can address, it is very hard to develop specific guidelines to avoid the problems mentioned in the previous section. While Dorgan's 2008 framework (discussed in the introduction) is helpful in identifying specific action points to mitigate problems, the literature in the area predominantly provides case-specific actions, not intermediate steps in operationalizing the conceptual framework. The following sections provide specific steps to operationalize Dorgan's framework, by introducing CBS examples from California.

A typical studio planning process includes the following phases: existing conditions analysis (physical and social conditions in and around the project area), conceptual development (i.e. conceptual diagramming, early idea generation), land use decisions (i.e. residential, commercial and public), circulation (i.e. transportation, public transport, streetscaping), development of design guidelines or codes, development of illustrations about physical implications of the plan (i.e. 3D modeling, illustrative site plans, etc.). Depending on the learning objectives of the studio, infrastructure implications, implementation and phasing recommendations may be included (Figure 1). Working with a community adds a new layer of variables on top of the typical work process: outreach before community involvement, community involvement, analysis of collected information from the community, and feedback cycles between the studio and the community.

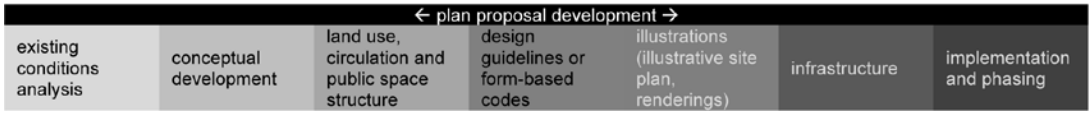

Figure 1. A typical planning process in the studio. Tasks beyond land use, circulation and public space structure depend on learning objectives and studio level.

The main question on the interaction between the studio and the community is about where the studio fits in the community's process. Faculty may consider three different models in which the CBS can fit in the process. Model 1 incorporates community involvement and planning within the studio's timeframe. Model 2 is based on providing findings from a recent community participation process conducted by faculty to the studio. Model 3 involves the teaming up of the studio with a local institution to develop an alternative proposal. Figure 2 identifies the models' components and allocates them into three time frames: pre-studio, during the studio and post-studio. In the three following subsections the advantages and disadvantages of each model will be discussed along with an examination of three cases.

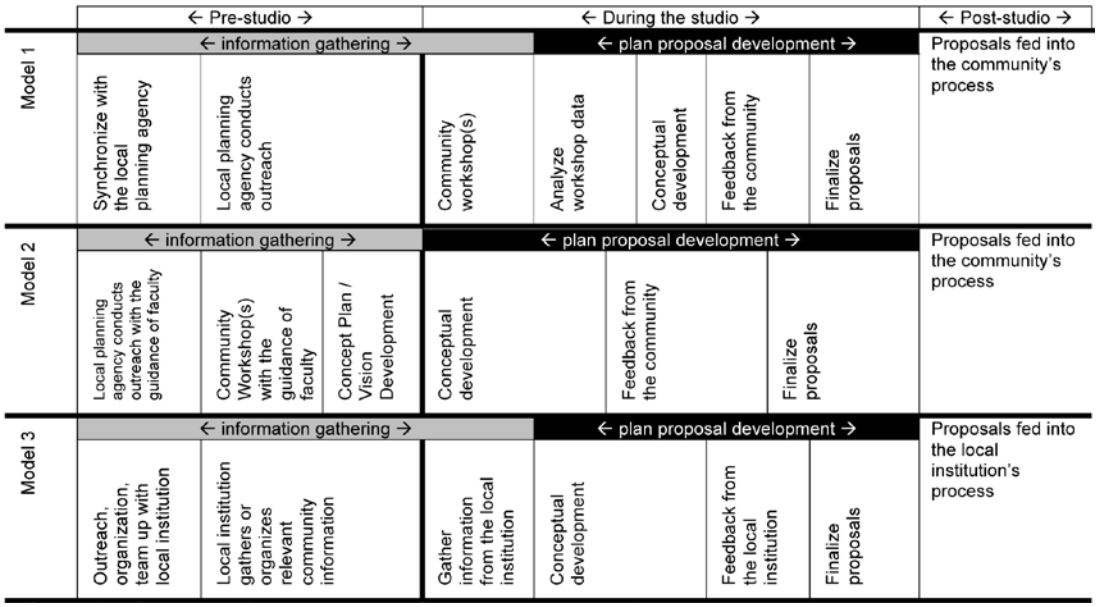

Figure 2. A visual summary of the three CBS models and their timelines with pre-studio and post-studio stages.

2.1. CBS Model 1: Community Involvement and Planning within the Studio's Timeframe

The first way in which the CBS can fit in the community's process is introducing community involvement and the planning process within the studio's timeframe, that is, having the studio and the community's process occur simultaneously. Following this model, in Spring 2009, the author taught a 10-week urban design studio working with the Salinas Redevelopment Agency and community members to develop urban

design plan proposals for Salinas Chinatown[3]. The learning objectives of the second-year intermediate urban design studio that undertook this process were to:

- Develop an intermediate understanding of urban design principles, the urban design process, and urban design plans,
- Develop basic methods and techniques to understand users' needs,
- Develop basic skills in addressing and evaluating design solutions for medium sized urban projects,
- Develop an understanding of the integration of an urban design plan to its context (local and regional), to urban systems, and to larger plans,
- Develop an understanding of the role of the planner in the urban design process, including the development of design guidelines, form-based codes, and other tools during the interaction with architects and landscape architects,
- Develop advanced skills in design representation and graphic, written, verbal communication.

The students were organized into five teams and conducted a site inventory and analysis the beginning of the quarter. Following this, the class attended a community workshop to identify community members' wishes about the future of Chinatown. Two to three students facilitated discussion and a "design your ideal Chinatown" exercise with community members organized as groups around ten tables. Each table was provided with a blank base map of the project area, color markers, and pens. Students worked with the community members and facilitated the discussion as community members made drawings of their "ideal" future on the base maps provided. Following this, each community group presented their findings to the rest of the community, with the help of students. As a result of this process, the students developed a clear understanding of the community's wishes and needs.

Building on this, student teams developed lists of issues that need to be addressed, and started working on five alternative urban design plan proposals. The objective was to present the community with urban design solutions and their implications based on their wishes. Each team developed a land use plan, circulation plan, and form-based codes for the area. These proposals were also illustrated in detail by means of 3D modeling and developing an illustrative site plan for each proposal. Throughout the plan development process, the studio was visited a number of times by the representatives and consultants of Salinas Redevelopment agency to review the work and provide feedback. The final plan documents from each team was presented to the city. Salinas Redevelopment Agency is currently moving forward with their efforts with the help of a group of consultants.

The advantages of this model of community engagement in an urban design studio were several. First, the students gained experience in setting up and facilitated a community workshop at an early stage in their careers. The exercise of converting

[3] Salinas has a population of approximately 150,000. Its economy is based on agricultural production and processing. It serves as the regional hub of Salinas Valley in California.

what they learned from the community into tangible urban design plans increased a sense of ownership of the process. The visits by the representatives and consultants of Salinas Redevelopment agency brought professional feedback into the classroom, adding an increased sense of responsibility to professional planners and designers.

Model 1 had some constraints as well. The main one is the limited amount of time. The particular case described in this section was limited to only ten weeks, and this constraint will be less of an issue in semester-based schools. Nevertheless, working towards the achievement of learning objectives and development of quality project proposals in either time frame requires extensive pre-studio planning as well as constant in-studio attention by faculty. The natural extension of this constraint is the limited amount of time available for community participation. This may be particularly risky if there is not an ongoing pre-studio and post-studio process in place. In the Salinas example, community participation will be continuing using the studio's work, and eventually the community will receive a final plan from the consultants hired. If the community relied on the outreach provided by the studio only, some stakeholders could be left out of the process, endangering the entire project.

2.2. CBS Model 2: Providing findings from a recent community participation process conducted by faculty to the studio

The second model in which a CBS can fit in a community's process is by completing the community outreach and participation component prior to the actual studio dates, and then developing the plan in the studio based on the findings from the community. Following this strategy, in Spring 2008, the author taught a 10-week urban design studio that worked with the City of Delano Community Development Department to produce three urban design plan proposals for Downtown Delano[4]. The project was undertaken in two phases. First, through Winter 2008, a Downtown Concept Plan was developed based on a community participation process with Delano residents. Second, in Spring 2008 quarter, the studio developed three Urban Design Plan Proposals based on the Concept Plan.

Four community workshops were held in the development of the Concept Plan for Downtown Delano. These workshops were held by a project team, which consisted the author and four student assistants that were not going to take the upcoming studio, but were previously trained in a community design methods class.

The first community workshop was held with two planned activities: an awareness walk and focus group interviews. During the awareness walk, participants took photos of what they liked and disliked about downtown using disposable cameras provided by the project team. This activity was followed by focus group interviews,

[4] Delano has a population of approximately 50,000. It is an agricultural town with an enterprise zone, located about 75 miles from Fresno, California. It is one of the many small towns in California's "Central Valley".

during which participants elaborated on their ideas in groups and discussed these with the project team.

Analysis of this information led the project team in the development of an idea generation instrument, to help participants of future workshops identify goals and strategies for the future of downtown. During the second community workshop a discussion of goals, and accompanying strategies to achieve these goals was conducted. The information gathered in the second community workshop was used to develop an action-planning instrument to be used in the third community workshop. This instrument was designed to help the participants identify potential first steps to take, potential project facilitators, and potential funding resources.

During the third workshop participants identified action steps to implement the strategies identified in the previous workshop. The last community workshop was designed to become a capstone event, which focused specifically on space related issues. The project team developed a board game-style “downtown planning game” for this event, which consisted of a plan of the existing downtown, space use icons on stickers, as well as markers. In four groups participants planned their “ideal downtown” through this process. Using the information gathered in these four workshops, the project team developed a concept plan, which included a series of recommendations and implementation strategies for Downtown Delano. The recommendations focused on four areas: (i) land use and economics, (ii) urban form and visual quality, (iii) circulation and transportation, and (iv) public amenities and recreation. The Concept Plan was presented to the City Council, received positive feedback, and then guided the following studio’s urban design proposals.

In the following quarter, the author’s undergraduate urban design studio undertook the task of developing urban design plans based on the concept plan. Three urban design teams were formed, each of which picked one “ideal downtown” scheme developed by Delano residents in workshop four. In-depth study of the concept plan as well as visits from the Community Development Department deepened the studio’ understanding of local issues. Site analysis was conducted with the presence of the Community Development Director. The students were able to visually document the site, and connect their findings to the concept plan developed prior to the studio.

In the conceptual development phase, each urban design team developed one conceptual diagram, each of which responded to Delano residents’ wishes with different solutions. Following this, a group of students representing each team visited the Downtown Delano Street Fair under faculty supervision. Posters displaying the three conceptual diagrams and accompanying urban design concepts were set up at the department stand. Throughout the fair, numerous residents visited the students’ stand. Students explained their conceptual diagrams and the rationale behind them. Residents were asked to provide verbal feedback as well as to leave their comments on note cards provided at the stand. The feedback attained at the street fair further helped the student teams in developing land use ideas.

In the remaining weeks of the studio, the studio received frequent visits from the Community Development Director. Student teams developed land use, circulation and public realm plans. Teams then studied the concept of form-based codes (Parolek, Parolek and Crawford 2008), and developed design guidelines that focused on five main areas: (i) land use and economic development, (ii) circulation, transportation and street networks, (iii) community amenities and recreation, (iv) urban form, visual quality and massing, (v) standards for street furniture, lighting and signs, and (vi) sustainability and natural resources. In the last phase of the project, student teams developed illustrative site plans that represented a variety of solutions for different areas of downtown. Following a presentation to the community, three urban design plan proposals were submitted to the City of Delano Community Development Department.

The main advantage of CBS Model 2, compared to CBS Model 1 was that, it placed less time constraints on the technical development of urban design plan proposals, helping the students to develop their physical and urban design skills. Second, since faculty developed the concept plan, the students were exposed to professional level work conducted on the site prior to the studio. This also reflected on the depth of community participation and development of conceptual diagrams positively. Model 2, however, is limited in providing the students with an actual community participation experience. While the students interacted with the community at a street fair, and received periodical feedback from the Community Development Director, they did not get a chance to experience directly the development and conduct of a community workshop.

2.3. CBS Model 3: Teaming up with a local institution to develop an alternative proposal

The third model that can bring community-level information into the studio involves teaming up with a local institution, one that possesses the information the studio would need to meet its learning objectives. Such an institutional role might be taken on by the local planning agency, a local non-profit organization, or in some cases even a local consultant firm who has worked with the community.

The author's specific plan (also known as area plan or sector plan) oriented graduate studio undertook such a process in Spring 2009. With a focus on the specific plan, this studio shared the learning objectives identified for the two Urban Design Plan studios discussed above, with the addition of the following objectives:

- To foster an understanding of the specific plan in response to the stakeholders' needs;
- To foster an understanding of the role of the contemporary planner in the specific planning process, in relation to other professionals in built environment related disciplines, such as architects, landscape architects, engineers and project managers,

- To provide a collective learning environment for students to engage in planning and designing for urban places that meet human needs within a context of sustainable development.

The studio undertook the Broadway Auto Row Corridor area in Oakland, CA[5] as the site. Originally a stretch that accommodated many of the city's auto dealerships, the site was the subject of a new specific plan study initiated by the City of Oakland. The main issue was how to reuse the lots that had been left by auto dealerships who were relocating and leaving vacancies on the site. In doing so, one of the main concerns was to provide more residential units in the area along with destination retail uses. In this process, the studio approached the problem as an academic exercise, and teamed up with a local non-profit housing organization that had an advocacy role for providing affordable housing in the area.

The studio started with two visits to the site for site inventory and analysis. In these visits, the local non-profit organization and its affiliated organizations were present, giving the students background information about the community, its opportunities, constraints, and the built environment in the project area. Students developed a detailed site inventory and analysis based on these visits.

Following site analysis, the studio studied the information provided by the local non-profit organization, and proceeded with conceptual diagramming and developing land use ideas. Within the first three weeks of the studio, students attended a stakeholders meeting organized by the City and its consultants. This experience gave the students a good understanding of the stakeholders and their positions. Approximately halfway through the studio process, student representatives attended a community workshop organized by the City of Oakland, its consultants and local non-profit organizations. Since the workshop was organized as a larger scale vision identification exercise, student representatives' attendance proved to be a high-quality input opportunity. Students got to learn about many day-to-day issues from the residents, but did not have to spend valuable class time on outreach or workshop design.

Having heard from the community members the studio proceeded with the development of land use, circulation and public space structure decisions, form-based codes, sustainable development strategies, affordable housing strategies and implementation strategies. This process was undertaken with the understanding that the work would be presented to the local non-profit organization. Therefore as the work progressed students had to keep in mind that it would be presented to a group very knowledgeable about the community, but did not necessarily have planning or design expertise.

[5] Oakland has a population of approximately 400,000. It is the second largest city in the San Francisco Bay area, and is located east of San Francisco.

The main advantage of Model 3 was that, while the studio was exposed to community issues and concerns, it did not have to spend time on outreach, event planning and related activities. Attending a stakeholders meeting and a community workshop organized by the city and its consultants also provided the students with the experience of a community workshop, but did not require them to spend time on workshop-oriented activities. With more faculty and student time devoted to the product, the local non-profit organization received higher quality alternatives that would give them leverage in their arguments, and students received more time to work on their plan development skills.

Model 3 also has its obvious disadvantages. Despite the above-mentioned benefits, students did not get the experience of developing, running and analyzing community workshops in this CBS; leaving the students with a need for further training in the area of community design, which may or may not be available in the program they are enrolled. Model 3 can also easily be vulnerable since it is possible that students get exposed to a single set of interests or issues, rather than work with multiple sections of a community. In the case presented here, the focus on affordable housing did provide a good mixture of diverse interests and issues; however this could easily be different depending on the community studied, and the local institution the studio partners with.

2.4. Advantages and Disadvantages of the Three Models

Based on the above discussion, the three models of conducting community-based studios each come with a series of advantages and challenges. These lead to a group of recommendations for faculty to consider while designing a community-based studio (Table 1).

Table 1. Three models for community-based studios: advantages, disadvantages and recommendations.

MODEL	ADVANTAGES	CHALLENGES	RECOMMENDATIONS
CBS MODEL 1: Community Involvement and Planning within the Studio's Timeframe	☐ Students gain experience in setting up and facilitating community workshops at an early stage in their careers. ☐ The exercise of converting what students learn from the community into tangible urban design plans increases a sense of ownership of the process. ☐ The visits by the representatives and consultants of the "client" bring professional feedback into the classroom, adding an increased sense of responsibility.	☐ Limited amount of time. The particular case described in this section was limited to only ten weeks, and this constraint will be less of an issue in semester-based schools. ☐ Limited amount of time available for community participation.	☐ Ensure that there is excellent pre-studio and pre community involvement. There will be minimum time available for in-studio instant modifications. ☐ Ensure that the community understands that the studio has a support function
CBS MODEL 2: Providing findings from a recent community participation process conducted by faculty to the studio	☐ This model places less time constraints on the technical development of urban design plan proposals, helping the students to develop their urban design skills. ☐ The students are exposed to professional level work conducted on the site prior to the studio. ☐ This reflects on the development of conceptual ideas positively.	☐ Limited in providing the students with an actual community participation experience. ☐ While visits by the representatives and consultants of the "client" bring professional feedback, face-to-face community involvement may be limited.	☐ Ensure a feedback mechanism from the community, since the students are indirectly exposed to community participation. ☐ Ensure that the students are presented with an in-depth explanation of the community involvement and concept planning process.
CBS MODEL 3: Teaming up with a local institution to develop an alternative proposal	☐ Attending community workshops organized by the "client" and its consultants provides the students with the experience of a community workshop, but does not require them to spend time on workshop-oriented activities. ☐ With more faculty and student time devoted to the product, the "client" receives higher quality alternatives that would give them leverage in their arguments. ☐ Students received more time to work on their plan development skills.	☐ Students do not get the experience of developing, running and analyzing community workshops. ☐ Students may be exposed to a single set of interests or issues, rather than working with multiple sections of a community.	☐ Ensure a feedback mechanism from the local institution, since the students are indirectly exposed to community participation ☐ Ensure that the students are exposed to a multitude of community interests.

3. A Conceptual Framework for the Community-based Studio

The discussion on the three models of conducting CBS is useful in building a conceptual framework to serve as a reference for faculty interested in CBS. This section builds such a framework by developing recommendations under five main headings, based on the existing literature and this paper.

3.1. The role of the studio in the community's process

It is very important to clearly identify the role of the studio in the community's process. Most often students will be developing technical and community outreach skills along with the studio process. Therefore they will not be able to efficiently perform tasks such as recruiting community participants or identifying strategies in their first attempt. As discussed in the existing literature, this may increase the pressure on students and faculty, while undermining the community's trust in the process.

To mitigate such potential risks, faculty must study the community's process in depth prior to making any commitments and clearly specify the studio's role. A pre-

studio and a post-studio process must be established, and the input to the studio as well as the studio products must be very clearly identified at this stage. For example, a pre-studio conceptual development process has proven very useful and effective for Downtown Delano urban design studio. Also, the fact that community outreach was handled by the Salinas Redevelopment Agency prior to the 2009 studio's involvement helped the studio to focus on learning objectives.

These experiences indicate that taking the following steps may help avoid potential problems. First, the community's expectations need to be specified, and how the community participation will be conducted need to be clarified. On the part of the faculty, this means (i) letting the community or its representatives know what products they will and will not receive, and (ii) specifying the number of community meetings or events that will be held, their intents and outcomes prior to the studio.

Second, considering the time constraints of the studio, the community or its representatives need to understand that the studio may not conduct the entire outreach and organization. In such cases the tasks for outreach and organization need to be identified and allocated to responsible parties within a timeline. On the part of the faculty, this means (i) specifying who will conduct outreach and by which methods (i.e. TV ads, flyers, phone calls…), and (ii) specifying who will organize the community meetings and logistics prior to the studio.

Third, it must be ensured that a post-studio process is in place, so that community members and students can observe further development after the studio. On the part of the faculty, this means specifying how the studio outcomes will be instrumental for the community prior to the studio. For example, the outcomes from the Salinas Chinatown studio were used by the Redevelopment Agency in a follow-up community meeting after the studio, to help sustain the momentum. Student work was displayed, and community members were able to identify ideas that would best accommodate the area's needs from the five alternative plans. This helped the community move forward with the project, and helped the students see the outcomes of their work.

3.2. The process champion

While the faculty needs to make an informed decision about how the studio will fit into the community's process, ultimately neither the students nor the faculty will have a long-term presence in the community. This means the project needs a champion in the community; one who will see that the studio receives the support and the help it needs, and "glues" the process together. The role of this person or entity would also include pushing towards implementation of the studio's products. In these terms, this person or entity would be a key to mitigating the problems discussed in the existing literature. The champion would visit the studio frequently, answer students' questions, and make the process more transparent to the students and the community. The champion would reduce the additional amount of work that would have to be done by the faculty, by helping with outreach, contacting key

people in the community, and providing guidance in scheduling. A very important task for the faculty, therefore, is to identify and encourage such a champion early in the process, and work with this person or entity very closely throughout the process.

3.3. The studio process, developing alternatives and learning objectives

Once the role of the studio is clarified and the process champion is identified, the studio needs to start developing the work. At this point the question is how the studio will respond to the community's request as a whole. At the level of urban design plans and specific plans, while it is possible to develop one plan proposal as an entire class, this strategy also presents a number of problems. First of all, organizing the entire studio to respond to one project problem will create a substantial number of organizational tasks for the faculty, as they need to make an effort to ensure that all students meet the class learning objectives to an equal degree[6]. Second, the faculty will need to make sure that all students undertake an equal share of the workload affiliated with the project. In a quarter or semester long process with more than 15 students achieving such equity in division of labor can become a big challenge, and requires careful screening and assignment of studio members. Third, the faculty need to ensure that this equality in division of labor is paralleled with an effort to make sure that all students get enough experience in all aspects of the project. In a ten to fifteen week process where one proposal is developed by at least fifteen students, students can easily be confined to working in a particular area of the project. For example, a student focusing on writing can end up missing the experience of graphic development, or a student with good graphic skills may miss learning opportunities in strategy development and expressing ideas in a written document. In such cases students may end up achieving only parts of the complete set of intended learning objectives. Working to avoid this while trying to achieve systematic project development will put a significant amount of stress on the faculty member.

One strategy to overcome such problems is to divide the studio into small teams of equal sizes (i.e. three to five students per team), who develop multiple alternatives to the problem posed. This strategy remedies the problems mentioned above, along with some additional advantages. First of all, students are exposed to a moderate amount of stress while engaging in teamwork through the small group process. This is particularly advantageous in reaching a balanced and healthy interaction among team members. Second, faculty can efficiently monitor each team's and team member's progress, since comparing team products regularly in the process easily reveals milestones or objectives that have not been met by individual students or teams. Third, the small group process makes it possible for faculty to efficiently identify and remedy inequalities in labor division, both in terms of workload and in terms of exposure to all aspects of the project. Students can exchange roles and tasks easily, since through the small group process they can closely follow the development of all aspects of work. By taking advantage of this, faculty can make

[6] It is critical for faculty to establish clear learning objectives that can be operationalized through the required assignments and sub-tasks.

sure that students exchange roles and tasks regularly and are exposed to various aspects of the project. Fourth, by monitoring fellow teams' work, students can develop a healthy peer review process, and this contributes to the overall quality of work. Finally, this strategy results in the development of multiple alternative solutions to the same problem, helping the community consider and visualize multiple options.

4. The Community Based Studio: Future Implications

A framework for structuring a CBS is illustrated in Figure 3. As the CBS evolves in contemporary planning education, certain out-of studio factors can contribute to the successful implementation of this framework. The discussion indicates that community-based studios are already under pressure in terms of time, be it under quarter or semester calendars. Starting the community involvement process parallel with training about community participation methods will in many cases only increase this pressure. In addition to timing issues, this may also hinder the quality of community participation that is at the heart of the studio process. Therefore it is crucial to have a course on community participation methods that can be taken prior to, or simultaneously with, the community-based studio.

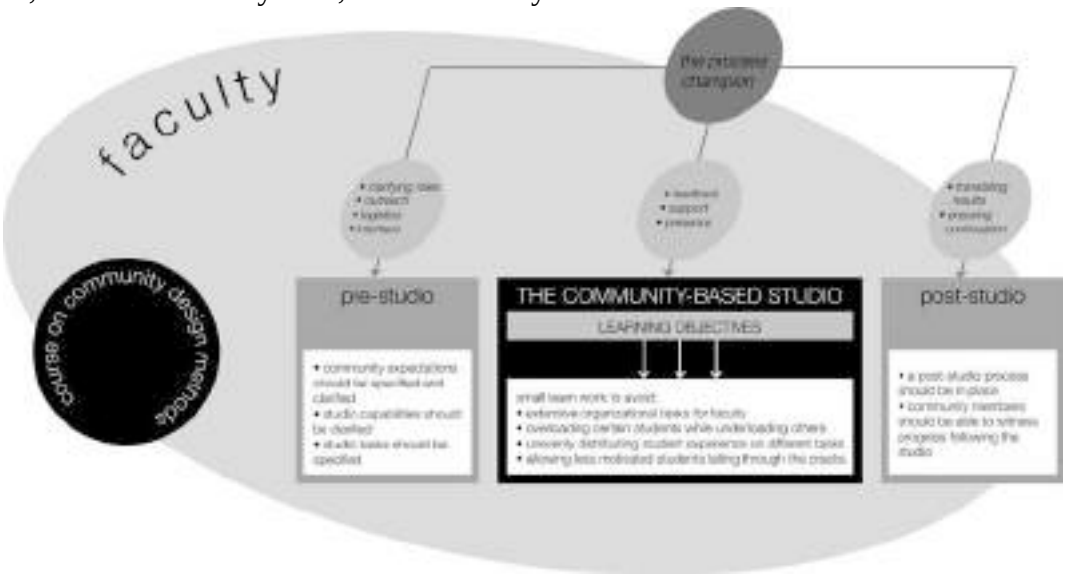

Figure 3. A conceptual model for organizing an effective community-based studio.

This paper has presented three models for conducting community based studios and a conceptual framework for conducting such studios. It has introduced the project champion concept, and pointed out the need for faculty pre-studio involvement as well as continuous studio management. It will be an important task for faculty and researchers interested in the area to build a wider body of literature by analyzing new experiences in CBS, enabling it to evolve and become increasingly effective.

EMPIRICAL EVIDENCE ON AGRICULTURAL LAND-USE CHANGE IN SARDINIA (ITALY) FROM GIS-BASED ANALYSIS AND A TOBIT MODEL

Corrado Zoppi [1], Sabrina Lai [2]

Abstract

This paper analyzes the quantitative change in agricultural land uses in the Sardinian region in the time period the 2000-2006 EAGGF-based part of the Regional Operational Program (2000-2006 ROP-EAGGF) was implemented, in order to assess if, and to what extent, it was effective in maintaining agricultural land use compared to other signals concerning local development, such as income and urbanization.
The assessment is based on a geographic information system and a Tobit model. The results are a source of important information to address the on-going policies of the 2007-2013 Rural Development Programme, and the question of geographic concentration of investments.

1. Introduction

In this essay we study agricultural land-use change in the Region of Sardinia (Italy) in the time period 2003-2008, which is the period in which the European Agricultural Guidance and Guarantee Fund (EAGGF)-based part of the 2000-2006 Regional Operational Program of Sardinia (2000-2006 ROP-EAGGF) on regional agricultural land use was implemented.
The general objective is to assess whether, and to what extent, the 2000-2006 ROP-EAGGF was effective in maintaining agricultural land use compared to other physical, economic and social characteristics concerning local development.
What we deem of particular interest in this context, in terms of policy assessment, is that the 2000-2006 ROP-EAGGF is the most important program concerning agricultural land use implemented in Sardinia during the first decade of the new century, and quite similar in both strategy and structure to the other 2000-2006 ROP-EAGGF's of several Regions of the European Union (EU) under the 2000-2006 Structural Funds. In Sardinia as elsewhere, investments were spread over almost all of the regional municipalities (only three Sardinian municipalities out of 377 did not receive funds under the 2000-2006 ROP-EAGGF), and represented an important effort to support local development based on the vitality of the traditional primary sector of production. Therefore, the methodological approach proposed and applied

[1] Dipartimento di Ingegneria Civile, Ambientale e Architettura, University of Cagliari, Cagliari, Italy - zoppi@unica.it
[2] Dipartimento di Ingegneria Civile, Ambientale e Architettura, University of Cagliari, Cagliari, Italy - sabrinalai@unica.it

in this essay could be easily exported to other regional contexts in order to study agricultural land-use change.

The 2000-2006 ROP was a plurifund program based on the EAGGF, the European Regional Development Fund (ERDF), the European Social Fund (ESF) and the Financial Instrument for Fisheries Guidance (FIFG), and it was a fundamental pillar of the 2000-2006 cohesion policy of the European Union concerning Sardinia. The part of the program funded by the EAGGF amounted to around 770 million Euros, that is, approximately a 20 percent of the total investment expenditure of the program. More than 90 percent of the expenditure of the 2000-2006 ROP-EAGGF occurred in the period 2003-2008 (Regione Autonoma della Sardegna, 2009, pp. 18, 53, 56-57). The final executive report of the 2000-2006 ROP-EAGGF (ibid., p. 232) indicates that drastic measures aimed at simplifying payment procedures were adopted only starting from the year 2003, due to dramatic delays in the program implementation, and that only from that year did the program really start. Moreover, the European Commission stated that the expenditure of the 2000-2006 ROP had to be entirely realized and the official statements of account had to be made available to the European Commission by June 30, 2009, due to the impossibility of meeting the original deadline of December 31, 2006.

For this reason, we consider the period 2003-2008 as the most suitable to assess if and to what extent the 2000-2006 ROP-EAGGF succeeded in maintaining agricultural land use. Objectives and operations of the 2000-2006 ROP-EAGGF are discussed in the following section, with reference to the Sardinian agricultural economy.

It has to be put in evidence that what we feel really innovative in the comprehensive discussion of this paper is the intermixed use of Geographic information system (GIS) and econometric models in order to assess agricultural land-use processes related to the implementation of the cohesion policy of the European Union. More precisely, the results of a fairly standard censored regression (Tobit) model are spatially represented and implemented through GIS. The model is founded on, and motivated through, a GIS-based representation of its variables referred to Sardinian municipalities, and in particular of Sardinian agricultural land use, which is the focus of the assessment. The Tobit model results make it clear that there is a strong relationship between agricultural land-use change and the other variables. These results entail some interesting insights concerning investment policies to maintain, reinforce and possibly expand agricultural land use, whose relevance can be clarified only through a spatial representation.

The third section defines a territorial taxonomy of Sardinian municipalities, by analyzing the spatial distribution of 2000-2006 ROP-EAGGF investment and of other characteristics which we believe are effective in describing the physical, economic and social environment of the Sardinian economy. The definition of this taxonomy is carried out by means of a GIS because it requires data integration from a number of sources, as it happens with many problems in geographical analysis (Chrisman, 2002, p. 119). The ability both to integrate a wide variety of geographic data types and to develop new information building on available spatial and non-spatial data makes GIS a powerful support tool for modeling operations (Longley et al., 2001; p. 30); furthermore, GIS readily lends itself to combination with other

technologies and techniques. In the fourth section we implement a censored (Tobit) regression model in order to discuss relations between the variables represented by means of the GIS. In this section, we explain why we choose the Tobit approach to implement our estimates in the context of the on-going literature on regression models. In the concluding section we discuss the implications of the results for the regional investment policy though a GIS-based representation and the exportability of the proposed methodological approach to other regional contexts.

2. The 2000-2006 ROP-EAGGF of Sardinia

The 2000-2006 ROP-EAGGF[3] is based on a set of measures that address several problems pertaining agriculture and rural development in Sardinia. Each measure contains several actions to be implemented through projects financed by the EAGGF.
A first concern of the program is to improve the use of water resources for agriculture in terms of efficiency, effectiveness and productivity, which implies investment in irrigation infrastructure and water resource management (measure 1.2, integrated cycle of water resource management: irrigation systems of agricultural zones; axis 1, natural resources). This is complementary to infrastructural and technological improvements, and capacity building, referred to other aspects of agricultural land use. These concern: i. reduction in production costs; ii. product quality; iii. a better environment for livestock; better living and working conditions for agricultural workforce; iv. conversion of current agricultural production into more profitable crops; v. rural aqueducts, electrical lines and roads. These issues are addressed by measures 4.9 (investment in agricultural firms; axis 4, local development systems), 4.19 (rural reparcelling), and 4.20 (development and improvement of rural infrastructure for agriculture).
Another important question is capacity building and quality of rural life. This is addressed by measure 1.2, in terms of capacity building concerning water resource management, and by measure 4.9, with reference to farm management. Moreover, measure 4.13 (essential services for the economy and the rural population) is concerned with actions aimed at making services available for the rural population, such as ICT-based network services (e.g., online request for documents from the public register's office), centralized laboratories for chemical and micro-biological analyses of agricultural products, etc.
A third important issue is the marketing of the products of Sardinian agriculture. The lack of expertise in dealing with Italian, European and world markets is identified by the 2000-2006 ROP-EAGGF as a difficult obstacle for the future of Sardinian agriculture, and addressed through the tenth and eleventh measures of axis 4 (improvement of transformation and marketing of agricultural products; marketing of agricultural products characterized by a high qualitative level).
Moreover, the program invests (measure 1.9, prevention and control concerning forest fires, and reforestation; measure 4.12, diversification of agricultural activities

[3] The last version of the 2000-2006 ROP-EAGGF was established by Decision C 2007/1991 of the European Commission. This version is available on the Internet, in Italian only, at http://www.sardegnaprogrammazione.it/documenti/1_84_20080409115630.zip (accessed January 2, 2012).

and the like; measure 4.14, promotion of adaptation and development of rural areas; measure 4.17, restoration of the rural environment damaged by fire and natural disasters, and prevention; measure 4.18, professional education referred to all of the 2000-2006 ROP-EAGGF measures; 4.21, young farmers' start-up support) in: i. renovation and conservation of buildings and settlements identified as historical heritage of the rural environment; ii. construction of new rural buildings for exhibitions and conferences concerning rural civilization, recreation and educational activities; iii. conservation of traditional rural productive processes in order to prevent their loss (with particular reference to craftsmanship), even though they are not profitable any longer; iv. (recovered or new) rural paths for bikers, skaters, joggers, and hikers; v. professional education as stated by measure 4.18 above.

Table 1. Measures of the 2000-2006 ROP-EAGG (Regione Autonoma della Sardegna, 2009a, pp. 300, 313, 367-391).

Measure	*Expenditure (million Euros)*	*Type of operations*
1.2 - Integrated cycle of water resource management: irrigation systems of agricultural zones	43.494	Public infrastructure and services
1.9 - Prevention and control concerning forest fires, and reforestation	11.000	Public infrastructure and services
4.9 - Investment in agricultural firms	183.092	Funds granted under the aid regime rules
4.10 - Improvement of transformation and marketing of agricultural products	137.848	Funds granted under the aid regime rules
4.11 - Marketing of agricultural products characterized by a high qualitative level	27.796	Funds granted under the aid regime rules
4.12 - Diversification of agricultural activities and the like	10.000	Funds granted under the aid regime rules
4.13 - Essential services for the economy and the rural population	15.659	Public infrastructure and services
4.14 - Promotion of adaptation and development of rural areas	31.740	Public infrastructure and services
4.17 - Restoration of the rural environment damaged by fire and natural disasters, and prevention	16.000	Public infrastructure and services
4.18 - Professional education referred to all of the 2000-2006 ROP-EAGGF measures	6.000	Education
4.19 - Rural reparcelling	59.957	Feasibility studies; funds granted under the aid regime rules
4.20 – Development and improvement of rural infrastructure for agriculture	143.626	Public infrastructure and services
4.21 - Young farmers' start-up support	84.325	Funds granted under the aid regime rules

It is evident that the thirteen measures of the 2000-2006 ROP-EAGGF show a comprehensive approach which entails addressing several aspects of rural development: conservation of natural resources and of rural cultural heritage, protection from fire and natural disasters, restoration and renovation of rural buildings and settlements, capacity building and professional education, tourism and tourism-related activities, reforestation, and support to agriculture, in terms of infrastructure and services.

Our objective here is not to evaluate the comprehensive impact and effectiveness of the program, but only to assess its impact on agricultural land use. We therefore consider only the subset of measures which finance public infrastructure and services for agricultural land use, that is measures 1.2, 1.9, 4.13, 4.14, 4.17, 4.20. We assume that the other measures, which are essentially funds granted to agricultural firms under the aid regime rules[4], and to promote professional education, do not influence agricultural land use, at least in the short run, even though they could possibly have an impact on rural economy. The investment expenditure referred to the six measures is about one third of the total investment of the 2000-2006 ROP-EAGGF (see Table 1).

Financial support referred to the aid-regime rules is granted to rural entrepreneurs on a small scale in order to accomplish several goals. For instance, these funds were used to increase the firms' physical capital (machinery, plants, buildings) and professional education, to help young farmers' start-ups, to develop rural tourism, to implement land improvement operations, and so on and so forth. In general, funds are granted to rural firms in order to deal with questions related to their present condition, whose improvement should not have generated a quantitative change in agricultural land use, during the period 2003-2008. However, a quantitative impact could have possibly come from an income effect on agricultural land use (expansion) which we try to detect in the model discussed in the fourth section through an income-related explanatory variable. The reason is that an income increase could possibly drive an agricultural firm to buy or rent land suitable for agricultural production if it is available.

3. A GIS-based taxonomy of Sardinian agricultural land use and related variables

Sections should be used to make it easier to follow the paper. Section and sub- In order to analyze agricultural land use in the time frame 2003-2008 and other physical, economic and social characteristics concerning local development, a descriptive table was needed. Since this analysis was to be carried out at the municipal level, by assuming cities as basic spatial units, such table had to have as many rows as Sardinian municipalities are, and as many fields as relevant attributes are. Data from various sources and in various digital formats were therefore collected; some data (e.g. those pertaining to demography, income, and levels of expenditure) were calculated by building on available spreadsheets; some others (e.g. spatial distribution of land uses, or delimitation of coastal landscape units) were derived from available spatial datasets. In other words, integration of available (both spatial and non-spatial) information was required to develop new knowledge and obtain new layers of either spatial or non-spatial information, which called for a GIS-based analysis.

As far as the geographic description of municipalities is concerned, only one shapefile ("Municipal Administrative Boundaries", MAB) was used to implement the GIS. Produced by the Regional Administration of Sardinia and freely

[4] Regulation n. 1999/1257 EC of the European Council, artt. 51 and 52.

downloadable from the Internet[5], this shapefile contains 377 polygons and multi-part polygons, each corresponding to the area included within the administrative boundary of a given municipality. This section aims at explaining how variables relevant to the analysis were identified, and their values calculated for each municipality, by means of GIS.

Data concerning land cover and land-cover changes in the time frame 1990-2006 are provided, at the European level, by the European Environmental Agency[6]. Of particular interest for a study of land-cover changes are two datasets, showing changes between 1990 and 2000 and between 2000 and 2006 (Figure 1), since authors claim to have been able to draw a distinction between real evolution processes and different interpretations of the same subject, and therefore to expunge the latter from the datasets. However, the above data were not used here because their level of detail (e.g. scale of the maps produced and minimum mapping units) did not appear to be appropriate for this study; moreover, the date of production of the datasets would have not allowed for the best possible study of the effects of the ROP-EAGGF in maintaining agricultural land uses, since, as explained earlier in the introduction, the most part of the 2000-2006 program was actually implemented between 2003 and 2008.

We therefore chose to study variables related to land uses on the basis of the 2003[7] and the 2008[8] regional land-use maps, in which land uses are organized according to a four-level hierarchical[9] nomenclature, in compliance with the European project "CORINE Land Cover".

---

[5] The shapefile is available at: http://webgis.regione.sardegna.it/scaricocartografiaETL/limitiAmministrativi/limitiAmministrComunali/limitiAmministrComunali.zip (accessed January 10, 2012).

[6] http://www.eea.europa.eu/data-and-maps/data#c11=landuse (accessed January 10, 2012).

[7] Completed in 2003, the "Land Use Map of the Region of Sardinia - 2003 Edition" is a spatial dataset that covers the whole island. Data were mainly obtained from photo interpretation of aerial photographs dating 1997-1998, satellite images and orthoimages, but other vector datasets (e.g. regional digital cartography) were also used; on-site surveys were carried out between 2002 and 2003. The map has a scale of 1:25,000, and it can be freely downloaded from: http://www.sardegnageoportale.it/index.php?xsl=1598&s=141401&v= 2&c=8831&t=1 (accessed January 10, 2012).

[8] The so-called "New Land Use Map of the Region of Sardinia" was completed in 2008 building upon the 2003 land-use map and photo interpretation of satellite images, orthoimages, and ancillary vector datasets. On-site surveys were carried out between 2005 and 2007. Minimum mapping unit (Longley et al., 2001; p.151) of the map equals 0.5 hectares in urban areas and 0.75 hectares in the countryside. The dataset can be freely downloaded from: http://www.sardegnageoportale.it/index.php?xsl=1598&s=141401&v= 2&c=8831&t=1 (accessed January 10, 2012).

[9] This means that the first letter of the code corresponds to a general land use, which is described in greater detail by means of a second letter, and further by means of a third letter, and so on. General class 1 corresponds to "artificial surfaces", class 2 to "agricultural areas", class 3 to "forest and semi-natural areas", class 4 to "wetlands", and class 5 to "water bodies".

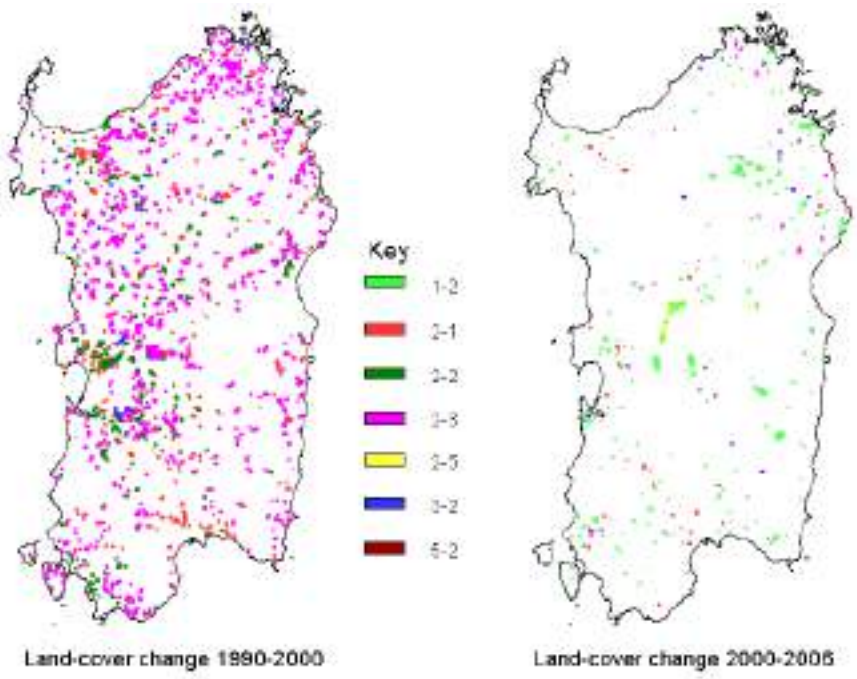

Figure 1. The land-cover changes involving areas classed as agricultural between 1990 and 2000 and between 2000 and 2006 (data from www.eea.europa.eu)

Strictly speaking, the so-called "regional land-use map" is therefore actually a land-cover map, although, thanks to its level of detail, it does also provide reliable information on how land is used by humans, especially as far as agricultural areas and forests are concerned. In the remainder of this paper, the expression "land use" will therefore be used.

According to the two datasets, in Sardinia the amount of land occupied by agriculture has globally increased: Table 2 shows both the nomenclature of agricultural land uses according to the 2003 and the 2008 regional land-use maps and their corresponding area.

In the MAB shapefile, a number of descriptive attribute fields characterizing each Sardinian municipality and related to land uses or land-use changes were at first introduced, and their values were calculated for each municipality. We will however present here only two of these attributes, that is the dependent variable (percentage change in a municipality's agricultural land use between 2003 and 2008) and another land-use related variable that was discovered to have an impact on the dependent variable by running the model presented in the next section.

The attribute "Percentage change in a municipality's agricultural land use between 2003 and 2008" (label: PLUAA3_8) accounts for the increase or decrease in size of a municipality's total agricultural area, which consists of polygons whose codes start with "2", according to the Corine nomenclature. To fill in the values in this field, a series of basic operations (filtering, intersecting, area calculations, dissolving,

summarizing) were performed in gvSIG[10] by using three datasets: the 2003 land-use map, the 2008 land-use map and the MAB layer. In Figure 3.a, Sardinian municipalities are classed according to the values of PLUAA3_8.
The attribute "Percentage change in a municipality's urbanized land between 2003 and 2008" (label: VARUU3_8) accounts for the increase or decrease in size of a municipality's artificial surfaces, which, according to the Corine nomenclature, are characterized by codes starting with "1". A series of basic operations (filtering, intersecting, area calculations, dissolving, summarizing) were performed separately on the 2003 and the 2008 land-use maps so as to obtain the value of the attribute "urbanized land area" for each municipality in the two datasets; next, land-use maps attribute tables were joined to the MAB layer's attribute table and the percentage change was finally calculated for each municipality. In Figure 3.c, Sardinian municipalities are classed according to the values of VARUU3_8.

Table 2. Agricultural land uses in Sardinia according to the 2003 and 2008 land-use maps

2nd level	*3rd level*	*4th level*	*Total area in 2003 [hectares]*	*Total area in 2008 [hectares]*
21 Arable land	211 Non-irrigated arable land	2111 Non-irrigated arable land	144,537.8	251,181.45
		2112 Artificial meadows	142,587.2	164,575.47
	212 Permanently irrigated land	2121 Arable land and horticultural crops in open fields	346,524.70	205,735.63
		2122 Rice fields	4,584.17	4,660.69
		2123 Nurseries	240.08	341.00
		2124 Crops in greenhouses	1,184.98	1,769.04

	244 Agro-forestry areas		50,493.25	57,429.67
		TOTAL	***903,002.15***	***922,947.21***

[10] gvSIG is an open source desktop application, freely available at http://www.gvsig.org (accessed January 10, 2012).

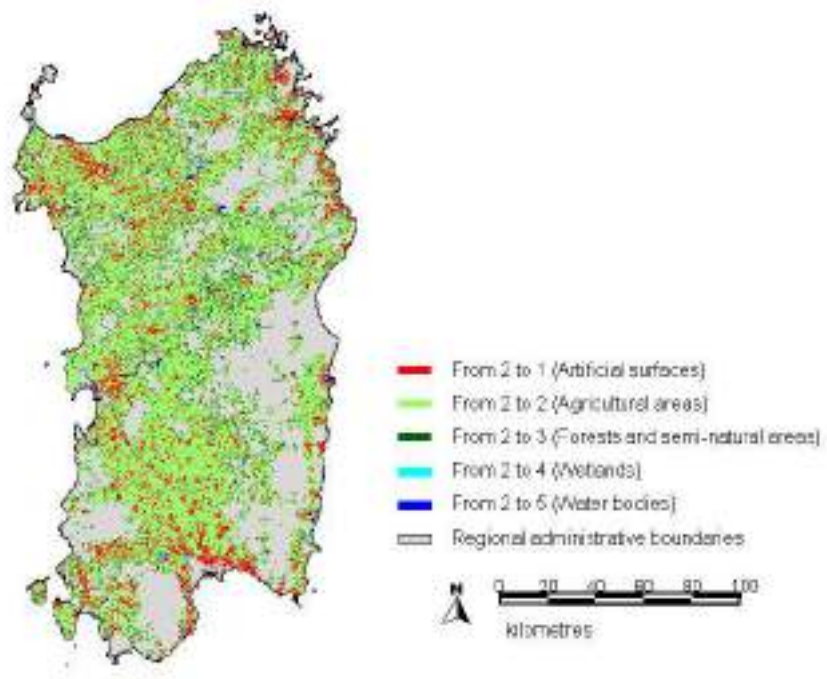

Figure 2. Land-use changes in the 2003-2008 time frame, taking into account only areas that in 2003 were classed as agricultural (Corine land cover first-level code = 2) according to the regional land-use maps (data from http://www.sardegnageoportale.it/)

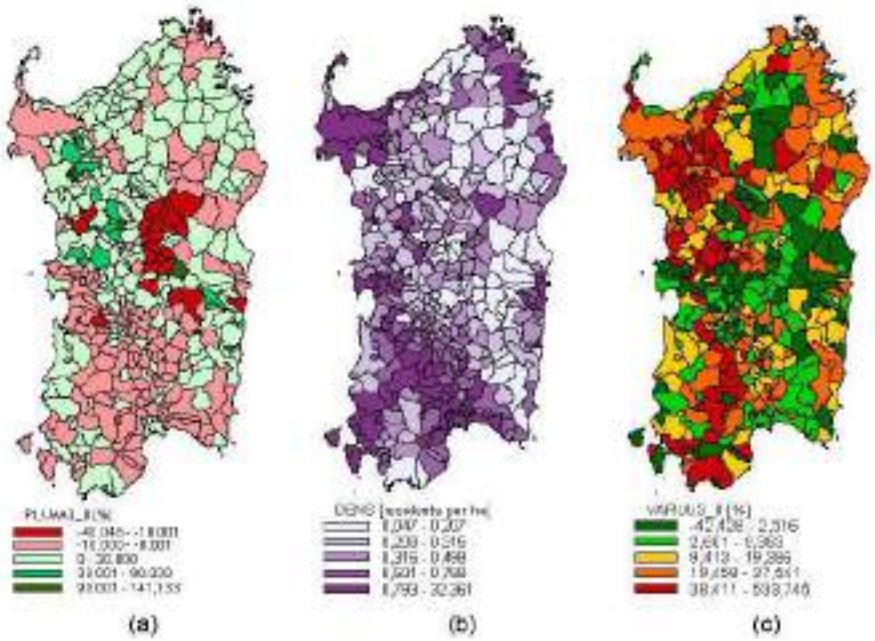

Figure 3. A classification of Sardinian municipalities based on: percentage change in a municipality's agricultural land use between 2003 and 2008 (a); residential density in 2008 (b); percentage change in artificial surfaces between 2003 and 2008 (c)

The four remaining attributes do not deal with land uses, but, respectively, with demography, regional planning, income and implementation of agricultural policy.
The first of these descriptive attributes is the residential density (label: DENS) measured, for each municipality, in residents (as of 2008[11]) per hectare. A choropleth map in which municipalities are categorized into according to their values of residential density in 2008 is provided in Figure 3.b.

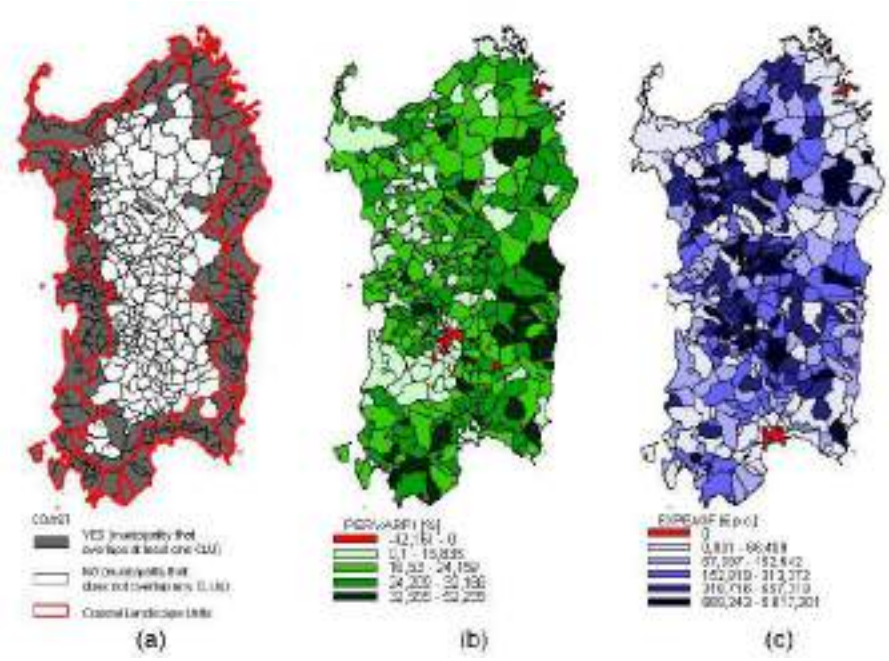

Figure 4. A classification of Sardinian municipalities based on: whether a municipality overlaps at least one coastal landscape unit (a); percentage change in per-capita income in the time frame 2003-2008 (b); 2000-2006 ROP-EAGGF per-capita investment on public infrastructure and services for agriculture (c)

The second attribute (label: COAST) is a dichotomous one (taking only "yes" and "no" values), and it accounts for whether a municipality overlaps at least one coastal landscape unit (CLU), as defined in the Regional Landscape Plan (RLP). Approved in 2006 and currently under revision, the RLP is the first statutory landscape plan with regional dimensions produced in Italy under the National Code of Cultural Heritage and Landscape. The Regional Administration of Sardinian initially focused on coastal areas only, in order to protect a part of the island considered both economically strategic and environmentally fragile, and therefore identified 27 coastal landscape units (Figure 4.a). General rules and restrictions on building activities and transformation of land are in force in those municipalities whose land area overlaps, or is completely contained in, the CLUs.

[11] Data available at http://www.sardegnastatistiche.it (accessed January 10, 2012).

For the remaining municipalities only specific rules concerning preservation of specific and precisely identified landscape features or assets are in force. Whether or not a municipality overlaps a CLU thus directly affects the possibility of producing changes in land uses. In Figure 4.a, Sardinian municipalities are classed according to the value of COAST.
The third attribute is the percentage change in a municipality's per-capita income in the period 2003-2008 (label: PERVARPI). Raw data on per-capita income in 2003 and 2008 were collected from two websites[12] and reorganized into a spreadsheet, later joined to the attribute table of the MAB shapefile. In Figure 4.b, Sardinian municipalities are classed according to the values of PERVARPI.
Finally, the fourth attribute is the 2000-2006 ROP-EAGGF per-capita investment for each municipality on public infrastructure and services for agriculture (label: EXPEAGF). Implementation of projects co-financed through European funds in Italy was monitored, at the national level, by means of a web database called MONIT, from which we selected only those records for which all of the following conditions held true: (i) projects were carried out in Sardinia, (ii) they were funded through the EAGGF, and (iii) funds were granted for public services and infrastructure. Only projects funded through measures 1.2, 1.9, 4.13, 4.14, 4.17, 4.20 of the ROP were therefore selected for the reasons explained in the previous section. A total of Euros 220,793,919.07 had been spent, on these projects, by June 30th 2009. The resulting table had 374 rows, meaning that three of the 377 Sardinian municipalities were not granted any funds for public services and infrastructures through the EAGGF. In Figure 4.c, Sardinian municipalities are categorized into according to the values of EXPEAGF.

4. Agricultural land use change in the context of the 2000-2006 ROP-EAGGF

This section is organized as follows. In the first paragraph, the censored regression (Tobit model) methodology is presented in the context of the case study discussed in this paper. In this paragraph, we explain why we choose the Tobit approach to implement our estimates and which part of the methodology is already used in other papers. Secondly, the results concerning the analysis of the impact of the 2000-2006 ROP-EAGGF on agricultural land use are discussed, in a context characterized by other physical, economic and social variables concerning local development.

4.1 Methodology

We use a censored regression model since the dependent variable of our analysis, that is the percentage change in Sardinian municipalities' agricultural land use in the period 2003-2008, is continuous in the interval between about -40% percent and about 140 percent, while it is not observable below -40 percent. This is the standard technique to deal with phenomena represented by inherently continuous

[12] http://www.sardegnastatistiche.it and http://www.comuni-italiani.it.

variables that for some reasons are not observable (censored) in a region of their variation range.

Censored regression models are also named "Tobit models" with reference to Tobin (1958), who discussed this type of models in the first place. Tobit models have a widespread use in empirical analysis concerning land use and land-use choice. A very interesting application is proposed by Gebremedhin and Swinton (2003), who assess the impact of public intervention and security of tenure rights on the attitude of farmers toward soil conservation in the Tigray region (Northern Ethiopia). Another important essay concerning Ethiopian agriculture (West Shoa Zone, Central Highlands) is discussed by Alene et al. (2000), who apply a Tobit model to estimate the relationship between adoption and intensity of utilization of improved maize varieties, and education, household labour, farm size, extension services, farm income, and timely availability of improved maize seeds. Coomes et al. (2000) apply a Tobit regression to analyze the relationships between non-market mediated access to land and labor, and forest fallow management and duration in the Peruvian Amazon. Pfaffermayr et al. (1991) assess the labor-supply decisions of farm workers between part-time off-farm and full-time in-farm options through probit and Tobit models as possibly dependent on farm size, household characteristics and education. Baidu Forson (1999) applies a Tobit model to analyze the determinants of level and intensity of adoption of innovative technologies for soil conservation and water resource management in Niger, and finds that a very important role is played by degraded farmland, education, risk aversion, and availability of short-term profits. Rajasekharan and Veeraputhran (2002) use Tobit regressions to study the relationship between intercropping decisions and availability of family labor and the type of intercrops during the initial gestation periods of natural rubber cultivation in the Kerala region (India); they find that very important determinants are banana, cassava and pineapple crops.

The aforementioned studies are a very small share of hundreds of published papers that constitute the vast literature related to questions concerning physical, economic and social determinants of agricultural land use analyzed through censored regression models. Common features of these case studies are the continuous and censored nature of the variables representative of the issues, the intermix of physical, economic, social, and agricultural land use phenomena, the identification of spatial units as points of reference for the representation and the assessment of the variables and of their relationships.

In this paper we use a Tobit model to analyze the relation between a censored variable, the percentage change in Sardinian municipalities' agricultural land use in the period 2003-2008, and a set of variables representing physical, economic and social characteristics concerning Sardinian local development. We use a standard Tobit model, based on Greene's (1993, pp. 694-700). For this reason, we think worth proposing just a synthetic description on its implementation, as described below.

We consider a censored or latent dependent variable, y*, which is related to an observable variable, y, as follows:

$y = L$ if $y^* \leq L$;
$y = y^*$ if $y^* > L$. (1)

The model operationalizes by assuming that y* is linearly dependent on a vector of explanatory variables, $x = (x_1,\ldots, x_m)$, through the following relation:

$$y^* = \boldsymbol{\beta}'\mathbf{x} + \varepsilon, \quad (2)$$

where $\beta = (\beta_1,\ldots, \beta_m)$ is a vector of coefficients.

If we substitute (2) in (1) we obtain the following model, which, under the usual hypotheses of ordinary least-squares models concerning the mean, variance and covariance of the ε term[13], can be estimated by the maximum likelihood estimator (MLE), which is unbiased and efficient, even though non-linear (Greene, ibid.):

$y = L$ if $y^* \leq L$;
$y = \boldsymbol{\beta}'\mathbf{x} + \varepsilon$ if $y^* > L$. (3)

The MLE for β is the vector $b = (b_1,\ldots, b_m)$ that maximizes the following maximum likelihood function:

$$\ln L = \sum_{y>L} \frac{1}{2}\left[\ln(2\pi) + \ln(s^2) + \frac{(y-b'x)^2}{s^2}\right] + \sum_{y=L} ln\left[1 - \phi\left[\frac{(y-b'x)}{s}\right]\right] \quad (4)$$

where s^2 is the MLE estimator for the variance of the error term[14] and ϕ is the cumulative normal distribution operator (Greene, *ibid.*).
The values of the vectors of coefficients b_j's which maximize (4) are the solution of the system which comes from equalizing to zero the derivatives of ln L with respect to the m components of vector b.
The values of the estimates b_j's of the vector of coefficients β_j's make it possible to estimate the marginal effects of a change of the vector of explanatory variables x on the censored variable y as follows (Greene, *ibid.*):

. (5)

4.2 The impact of the 2000-2006 ROP-EAGGF on agriculture land use

The analysis of the change in Sardinian municipalities' agricultural land use in the period 2003-2008 is based on the model described in the second part of the first paragraph of this section. The characteristics of vector $x = (x_1,\ldots, x_m)$ and their

[13] The model assumes that the error term ε is normally distributed and: i. $E(\varepsilon|x) = 0$ (i.e., the error terms in the regression have a 0 conditional mean), ii. $Var(\varepsilon) = \sigma^2$ (i.e.: the error term has the same variance at each observation), and iii. $E[\varepsilon_i\ \varepsilon_j|X] = 0$ (i.e.: the error terms are uncorrelated between observations).

[14] $s^2 = \frac{(y-xb)'(y-xb)}{n}$, where y is the vector of observations of the censored variable y and x is the matrix (n,m) of the n observations of the m explanatory variables.

measures are defined, and the results of the model application are reported with reference to: i. the estimates $b = (b_1,\ldots, b_m)$ of the components of vector β, and ii. the marginal effects from (5).

Dependent and explanatory variables, referred to spatial units identified with the 377 municipalities of Sardinia, which correspond to variables y and $x = (x_1,\ldots, x_m)$ of model 1-5, are reported in Table 3. The spatial taxonomy of these variables is described in the preceding section.

The dependent variable is the percentage change of agricultural land use in 2008 with respect to agricultural land use in 2003 and labeled PLUAA3_8. This is a precise quantitative measure concerning the impact of the 2000-2006 ROP-EAGGF on agricultural land use, which is referred, as we put in evidence above, only to the subset of measures which finance public infrastructure and services for agricultural land use, that is measures 1.2, 1.9, 4.13, 4.14, 4.17, 4.20 of the 2000-2006 ROP-EAGGF.

The choice of the explanatory variables that characterize the 377 Sardinian municipalities is motivated as follows. Residential density, which is almost constant between 2003 and 2008, is considered as an important characteristic, since it makes it possible to control for an agglomeration effect which could possibly entail evidence of investment attraction to municipalities where people are more concentrated.

The change in the area of urbanized land after the program's implementation (VARUU3_8) could impact agricultural land-use change. Increasing urbanization could possibly make a municipality comparatively more attractive for investment, and for investment in agriculture, even though new urbanized land could be a detriment to agricultural land use. Therefore, the change in urbanized land should be considered a significant aspect, although the expected impact is fuzzy.

Table 3. Definition of variables and descriptive statistics

Variable	Definition	Mean	St.dev.
PLUAA3_8	Percentage change in a municipality's agricultural land use between 2003 and 2008	4.6660	17.2699
DENS	Residential density of a municipality in 2008 (residents per hectare)	0.7744	2.0981
VARUU3_8	Percentage change in a municipality's urbanized land between 2003 and 2008	22.8301	41.1650
COAST	Dummy - A municipality overlaps a coastal landscape unit as defined by the Regional Landscape Plan	0.4430	0.4974
PERVARPI	Percentage change in a municipality's per-capita income in the period 2003-2008	21.8675	9.5568
EXPEAGF	2000-2006 ROP-EAGGF per-capita expenditure for measures 1.2, 1.9, 4.13, 4.14, 4.17, 4.20 concerning a municipality (Euros per resident)	456.1207	669.9753

The variable that indicates if a municipality is coastal or non-coastal, labeled COAST, aims at assessing if agricultural land-use change is influenced by this characteristic, which is relevant because, since November 2004, when Regional Law no. 8 was approved, Sardinian coastal municipalities have had to make their planning policies consistent with very strict planning rules, especially for areas

included in the coastal zone (Zoppi, 2008)[15]. In particular, new urbanization was almost totally prevented in coastal municipalities, which could eventually have become more attractive for investment in agriculture. We assume that a municipality is coastal if it overlaps a coastal landscape unit as defined by the zoning cartography and implementation rules of the Regional Landscape Plan (*ibid.*).

We use the change in per-capita income from 2003 to 2008 (PERVARPI) as the variable that controls for a possible income effect. As with VARUU3_8, change in per-capita income should be considered a significant aspect, although we do not have a definite expectation on the sign of the coefficient, since increasing per-capita income could possibly make a municipality more willing to invest in agriculture, or displace agriculture if the available investment, coming from increased income, is diverted elsewhere.

The variable that represents the per-capita investment concerning a municipality from the 2000-2006 ROP-EAGGF (EXPEAGF) characterizes the relative importance that the ROP recognizes to a particular municipality's territory, and the level of trust of the regional administration in the capability of generating a positive impact on agricultural land use. This variable's impact on the dependent variable is expected to be positive, since we expect that investment in public infrastructure and services for agricultural land use would help maintaining and possibly increasing a municipality's agricultural land use.

The estimates of the components of vector β, that is the vector $b = (b_1,\ldots, b_m)$ of (4), and the marginal effects of explanatory variables x's on the dependent variable y of (5) are reported in Table 4 and Table 5. The decomposition-based fit measure, which indicates the share of the total variance of the censored variable explained by the model, is about 50%.

The results are significant at 2.5 percent with the exception of VARUU3_8, which is slightly less significant (7.5 percent) and show the expected sign when there is one.

Table 4. Estimates of coefficients of the components of vector β, $b = (b_1,\ldots, b_m)$, calculated by solving the maximization problem expressed by (4)

Variable	Coefficient b_i	Standard error	z-statistic	Hypothesis test: $\beta_i=0$
DENS	0.3479	0.0680	5.116	0.0000
VARUU3_8	0.0394	0.0220	1.791	0.0732
COAST	4.1603	1.8525	2.246	0.0247
PERVARPI	0.2073	0.0737	2.812	0.0049
EXPEAGF	0.0070	0.0007	10.434	0.0000
Decomposition-based fit measure = 0.466				

The marginal effect of residential density (DENS) indicates that an increase of about 3.5 percent of the agricultural land use extension would occur if DENS increased by 10 residents

[15] This law (named "The saving-coast law") identifies the coastal areas as those included in a 2-km belt from the coastal line. The definition of the coastal zone changed after the Regional Landscape Plan (RLP) approval (through Deliberation of the Sardinian Regional Government no. 36/7 of September 5, 2006), which established a new and generally wider limit for the coastal zone.

per hectare, which puts in evidence a significant agglomeration effect.

Table 5. Estimates of the marginal effects of the explanatory variables on the censored variable from (5)

Variable	Marginal effect	Standard error	z-statistic	Hypothesis test: $\beta_i=0$
DENS	0.3470	0.0678	5.119	0.0000
VARUU3_8	0.0393	0.0219	1.791	0.0732
COAST	4.1498	1.8466	2.247	0.0246
PERVARPI	0.2067	0.0736	2.809	0.0050
EXPEAGF	0.0070	0.0007	10.429	0.0000

The dichotomous variable COAST indicates if a municipality belongs to a coastal landscape unit. This variable has a positive and significant marginal effect, which puts in evidence that investment in infrastructure and services to improve agricultural land use is more effective in coastal areas than in inner ones. The results imply, *ceteris paribus*, a 4 percent positive differential in agricultural land use.

The change in a municipality's urbanization also reveals a positive marginal effect, even though not quantitatively strong: approximately only a 3.9 percent of a percentage point for a one percent increase. However, this is important since it shows that increasing urbanization does not seem to prevent conservation or expansion of agricultural land use. From this point of view, the results of the estimates suggest that municipalities characterized by urban expansion should be targeted for agricultural land-use investment.

A positive marginal effect is put in evidence by the variable concerning the percentage increase in real per-capita income as well (a 0.2 percent increase in agricultural land use per a one-percent increase of per-capita income). This observation indicates that, everything else being equal, a positive income effect is supported by the estimates of the model. This implies not only that there is an income effect that does not displace at all agricultural activities, but also that, in principle, whichever policy aiming at increasing local people's income can be considered an indirect support to maintaining and possibly increasing agricultural land use. In other words, we can state that our results suggest that all of the measures of the 2000-2006 ROP-EAGGF have positive impacts on agricultural land use: i. direct measures, that is those here taken into account to define the variable EXPEAGF (measures 1.2, 1.9, 4.13, 4.14, 4.17, 4.20), as we see below; ii. all the other measures, which grant funds to farmers and rural entrepreneurs under the regime of state aids, and, by doing so, increase their income.

Finally, the marginal impact of the investment concerning a municipality from the 2000-2006 ROP-EAGGF is positive, as expected, and highly significant. However, this impact is quantitatively weak, since it indicates that a hundred-Euro increase of per-capita investment implies approximately a 0.7 percent increase in agricultural land use. In other words, this means that an investment of nearly 165 million Euros, that is more than one fifth of the total 2000-2006 ROP-EAGGF expenditure, would have been required to increase the agricultural land use extension in 2008 with respect to 2003 by approximately 63 km^2.

5. Concluding remarks: a spatial representation of policy implications from the model results

This paper proposes a discussion on quantitative change in agricultural land use at the municipal level as a phenomenon influenced by physical, economic, social and investment policy variables. The methodological approach is based on the intermixed use of GIS techniques and econometric models. We feel that the use of a Tobit model based on a GIS-based taxonomy of dependent and explanatory variables could be easily and effectively exported to other European Union regional contexts, since the 2000-2006 ROP's of the European regions at the NUTS 2 level were fairly standard. The reproducibility of the proposed approach makes it possible to assess the results concerning the impact of ROP-EAGGF's on agricultural land-use change and to compare such impacts across regions, at the intra-national and inter-national levels. Moreover, the results are useful not only in terms of ex-post assessment, but also with reference to the definition and implementation of regional policies concerning investment aimed at maintaining and increasing agricultural land use, that is in terms of ex-ante and on-going assessment.

In the rest of this concluding remarks we use GIS to comment and discuss policy implications of our results through a spatial representation. The GIS-based representation is easily reproducible with reference to other contexts of the EU NUTS 2 regions, and it allows for a pretty straightforward spatial interpretation of the results. As we put in evidence above, the impacts of the policy (explanatory) variables on agricultural land-use change do not always have an *a priori* expectation on the sign of the impact; therefore, a comparative analysis of spatial interpretation of results across regions may eventually indicate different policy approaches at the regional level.

Background policy implication for the GIS-based discussion on policy variables that follows is that, as we discussed at the end of previous session, it should be more effective to invest in agriculture in those municipalities characterized by significant values of residential density and in those municipalities whose territory overlaps a coastal landscape unit.

We started by simulating a "what-if" scenario by building upon the results of the Tobit model, and more precisely upon marginal effects presented in Table 5: for each municipality, we estimated the magnitude of the impact on the percentage change in a municipality's agricultural land use between 2003 and 2008 that would be produced if a single explanatory variable increased by a given quantity (that is, ten percentiles in the distribution of that variable). Next, since the values of one explanatory variable (namely, COAST) is fixed, we estimated the magnitude of the impact that would be produced by implementing simultaneously policies that increase the four remaining variables (DENS, VARUU3_8, PERVARPI, EXPEAGF).

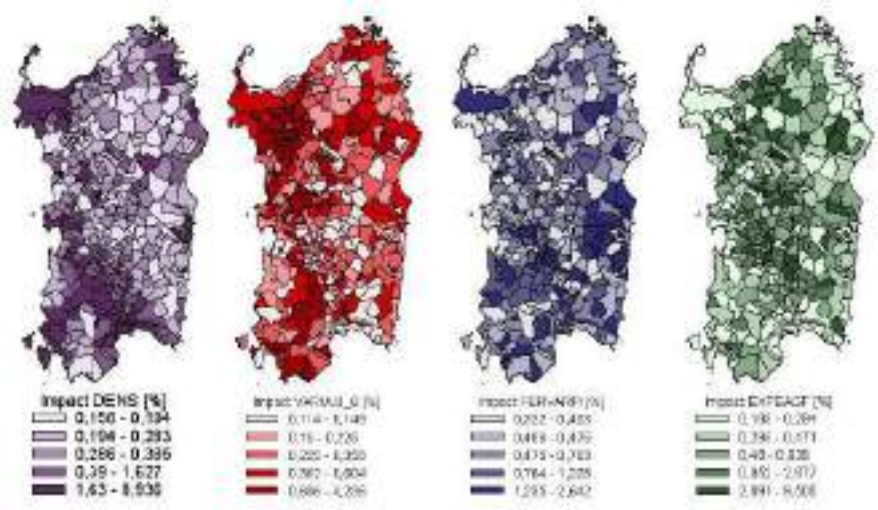

Figure 5. Spatial representation of policy implications: impacts on agricultural land use stemming from policies that increase: a municipality's residential density (a); percentage change in a municipality's urbanized land between 2003 and 2008 (b) per-capita income at the municipal level (c); per-capita investment on public infrastructure and services for agriculture (d)

Figure 5 presents some of the results of the first process: by implementing policies that increase per-capita income, a positive change in agriculture land use between 0.322 percent and 2.642 percent is produced (Figure 5.c); this percentage rises to 0.114 to 4.236 percent when policies that augment the amount of a municipality's urbanized land are put in place (Figure 5.b), and takes the highest values (0.158 to 8.936 percent and 0.193 to 9.506 percent) if policies that intensify residential density or per-capita investment funded through the ROP-EAGGF are implemented (Figures 5.a and 5.d respectively). Some clusters of municipalities taking either the highest or the lowest values are clearly identifiable in these maps, which could provide regional decision-makers with useful insights on the spatial dimension of regional policies aimed at strengthening the above policy variables, if agricultural land uses are to be preserved and increased.

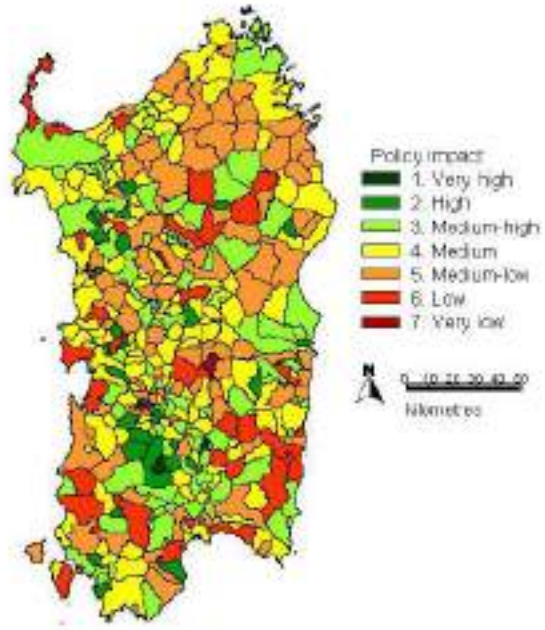

Figure 6. Spatial representation of policy implications: impacts on agricultural land use stemming from policies that increase simultaneously, at the municipal level: residential density, urbanized land, per-capita income, per-capita investment on public infrastructure and services for agriculture

An ever more powerful suggestion for policy makers is provided in Figure 6, which spatially represents, in qualitative terms, impacts on preservation of agricultural land uses produced by implementing policies that increase residential density, urbanized land, per-capita income, per-capita investment on public services and infrastructure for agricultural areas.
Such spatial representations provide decision-makers with clear indications on which are the "best" possible areas that policies should target in order to preserve, and where possible and appropriate to reinforce, agricultural land uses.

Abstract

Early this century, urban population in the world as a whole has reached an unprecedented number in human history with over 7 billion individuals and today more than half these live in cities. In the life of human societies, milestones such as these encourage a critical assessment of the past to project what the future holds. After all "how well we learn from the lessons our cities teach us will determine whether our urban species will flourish in what can be a new golden age of the city".

This paper attempts to assess how numerous noted scholars since the middle of the last half of the 20th Century predicted the future of urbanism in the 21st Century and beyond. How the rapid acceleration of the use and the phenomenal advancements in the capabilities of digital technologies, particularly information processing and communications would determine the urban future had influenced many of these predictions. However, very few of the predictions, if any, had considered the influence of the unprecedented intensification of urbanism in their forecasts of the urban future. This is the main contention this paper has in its critique of them as it posits that a reciprocal causality exists between digital technologies and urbanization. The critique is cognizant of the fact that cities are increasingly becoming mediated by flows of electronic information and symbols, as evidenced by the progressive digitization of money, services, media, information, education, and logistics while at the same time the demands of the contemporary urban life, work, and play; initiate, sustain, and nurture innovations in digital technologies.

Centrally, the paper explores what the impact of digital technologies will be in the near future on the contemporary spatial, social, economic, geographical, political, and cultural processes that urbanites are engaged in, in mostly in urban areas of the globe. Or more succinctly, it inquires and dares to discover if there is a reciprocal cause-and-effect relationship between digital technologies and urban life as many futurists in the past ignored. Thus the paper focuses the ever-ubiquitous digital technologies and urbanization and inquires how these technologies affect –and are

affected by the broader processes of modernization, internationalization, globalization, industrialization, restructuring, and cultural change.

The four dimensions of urbanism, people, place, process, and time constitute how the futurist scholarship on urbanism is critiqued. This results in the identifications of four **"Romantic Visions" of Post-urban Fantasy,** which then are critiqued in terms of their strengths and weaknesses as well as the commonalities and differences in their assumptions and predictions. The paper's conclusion is that the "end-of-urbanism" forecast by the Romantic Visions unanimously–at least as we have come to understand it, is not valid given the state of urbanism today.

While the paper concludes that cities are here to stay, it recognizes that urbanity will gradually and increasingly function in a different way than only half a century ago as digital technologies continue to alter urban life while the demands of urban living continue to influence how digital technologies may enhance its quality.

1. Introduction – Questions and Axioms

Today, the information age is an increasingly urban age, because, since 2008, more than half of the world's population can be called urbanite. In this second decade of the 21st Century, urban population in the world as a whole has reached 7 billion and still continues to grow at a fast rate. The digital society on the other hand is a society, which is mostly domiciled in cities and metropolitan regions.

Given this state of matters, a prudent question one may be prompted to ask is what the current nexus is (and in the future would be) of the rapid acceleration of the use and the phenomenal advancements in the capabilities of digital technologies, particularly information processing and communications on the one hand, and the intensifying urbanization of the planet on the other. That is, one may wonder, what the impact of these technologies is on the contemporary spatial, social, economic, geographical, political, and cultural processes urbanites are engaged in, in mostly the urban areas of the globe. Or more succinctly posed: is there a cause-and-effect relationship between digital technologies and contemporary urban life? If there is, which is the cause and which is the effect? Are (or aren't) the ever-ubiquitous digital technologies and urbanization constitutive elements of broader processes of modernization, internationalization, globalization, industrialization, restructuring, and cultural change? These constitute the main questions this paper attempts to answer.

Cities continue to be, as they have always been, where financial and human capital is concentrated as more and more of the regionally or nationally focused, if not internationally oriented firms and institutions, flock. At the global scale, these cities attract people with higher disposable incomes who initiate, demand, and nurture cosmopolitan and multicultural social environments. Further, cities are increasingly becoming mediated by flows of electronic information and symbols, as evidenced by the progressive digitization of money, services, media, information, education, and

logistics. In light of these, at the very basic level and isn't it prudent to explore the ways digital technologies help facilitate, nurture, and intensify the urbanization processes at the global scale? Conversely, how do the demands of the contemporary urban life, work, and play; initiate, sustain, and nurture innovations in digital technologies?

A priori, three main axioms can be cited on the nexus between digital technologies and urbanism:

First, digital technologies encourage urbanized entities, mainly service and manufacturing as well as cultural centers, to mostly locate in cities and facilitate them to extend their markets, powers, and control to over ever more distant regional, national, international, and even global hinterlands. Cities after all have the infrastructure to facilitate this influence and consequently affect urbanity. Urban infrastructure in turn helps binds, integrates, and adds economic dynamism to the vast, extended, and multi-centered urban settlements, corridors and regions of our age.

Second, in an intensely complex, multivalent, and currently volatile global economy, and the growing speed, complexity, and riskiness of innovation in all sectors, cities seem to attract a parallel concentration of creative assets and nurture an 'innovative milieu' to sustain the ongoing competitiveness. Creators and innovators of the digital technologies still need to be in the proximity of one another, i.e., in the thick of the innovation process, even though their products can the often be instantaneously sent online to distant markets and users, as well as to local urbanites.

Finally, demand for digital technologies, be it mobile and land-based telephones, satellite and cable TVs, computer networks, electronic commerce, Internet services, etc., is overwhelmingly driven by the growth of metropolitan markets. Global cities, which rely on digital technologies, drive most aspects of innovation and investment necessary for developing and sustaining digital technologies. After all, urban social and economic processes that take place in cities require speed and mobility and in turn result in complexity and dynamism.

2. Previous Futurist Scholarship on the Nexus between Digital Technologies and Urbanism

From the mid 20th century and until the early 1990s, the complex links between cities and the digital information processing and communication technologies had generated a curiously meager body of scholarship in urban studies, mainly because of the relative invisibility of these technologies compared to physical communications systems. Information and communications studies, on the other hand had traditionally tended to neglect the dominant role of modern cities, again until the last decade of the 20th century. There were few, but significant exceptions to these in literature and film, particularly in late 19th and early 20th centuries but most of these had a science fiction slant.

Since the mid 1990s however, notable theoretical, empirical, and policy research on the links between the ever developing digital technologies and the changing nature of cities and urban life have rapidly emerged in urban studies, anthropology, geography, planning, art, sociology, architecture, cultural studies, and transport studies, as well as in information, communication, and media studies. So much so that a sub-discipline seems to be emerging as scholars are positing the reciprocal impact of Internet, mobile phones, Geographical Information Systems (GIS), and Virtual Reality (VR) on urbanism. Currently, urban scholars are particularly interested in the mutual influence of the forms, processes, experiences, and ideas of urban life and the digital technologies in a wide variety of contexts across the world. Nevertheless, debates about both the implications of digital technologies for cities and urban life, and the effects of the cities and urban life on digital technologies, have yet to move to center stage on urban research agenda.

Against the widespread assumption from the 1960s to late 1990s that electronic communications would necessarily work to *undermine* if not outright *threaten* the very existence of cities, notable empirical evidence suggests that the two realms are actually supporting each other. So much so that nowadays coming across counter claims such as the ones that posit that the current and potential use and application of digital technologies within and between cities constitutes a critical, strategic, and positive nexus that underpins the development of human societies, settlements, and, indeed, civilizations is no longer an isolated occurrence in the relevant literature but is more commonplace than the contrarian view.

However, it was only a few decades ago, mostly during the second half of the 20th century, that “dis-urbanists” dominated the urban discourse that was taking place mostly in the western world. Many commentators, business writers, futurists, novelists, utopians, media theorists, architects, planners, and social scientists portrayed digital technologies as being effectively at war with any urban-based activity, which generated the need, or desire, for geographical concentration of people and economic and social processes in cities and urban regions. Their critical justification was that conventional, i.e., face-to-face human interactions would be gradually replaced by growing flows and capabilities of electronic communications. This, it was alleged, might even lead to the gradual dematerialization of advanced societies resulting in a post-urban fantasy. For example:

In 1964, media theorist, the late Marshall McLuhan, known for his aphorisms such as “if it works, it is obsolete” and “turn on, tune in, drop out” (by way of Timothy Leary who wrote a book that had this as its title), suggested that the coming of the “global village” would inevitably mean that “the city as a form of major dimensions must inevitably dissolve like the fading shot in a movie”. (Understanding Media, McLuhan, 1964.)

Urban theorist and professor emeritus at the University of California, Berkeley, the late Melvin Webber argued, around the same time, that in the near future, 'for the

first time in history, it might be possible to locate on a mountain top and to maintain intimate, real-time, and realistic contact with business and other societies. All persons tapped into the global communications network would have ties approximating those used in a given metropolitan region'. Reflecting on the complexity of urban development in an age of rapidly growing communications and mobility, he challenged the conceptual foundations of urban studies, postulating that urban planners and transportation analysts should focus less on the notion of place and more on the linkages and connections, both physical and informational, that bound together what he called “non-place realms.” Seeing the city as, in effect, a giant switchboard, he anticipated the ‘networked society’. In the light of new forms of communication and the prevalence of the automobile, he argued that concentrated, denser urban forms were not necessarily more desirable than more dispersed settlements. (The post-city age in Daedalus, Webber, 1968.)

French philosopher, cultural theorist, and urbanist Paul Virilio, best known for his writings about technology and credited for the often-referenced quote “The speed of light does not merely transform the world; it becomes the world; globalization is the speed of light” also speculated about the urban future shaped by digital technology. In 1993 he observed that the diffusion of digital technologies into cities would mean that 'the city of the past would slowly become a paradoxical agglomeration in which relations of immediate proximity give way to interrelationships over distance’. (Open Sky, Virilio, 1997.)

And at around the same time, i.e., in 1995, Nicholas Negroponte, then the Director of MIT's Media Lab, asserted that 'digital living’ would include less and less dependence upon being in a specific place at a specific time, and the *transmission of place* itself would start to become possible. Soon, he believed, homes would be equipped with 'electronic windows' allowing him, from Boston, to 'see the Alps, hear the cowbells, and smell the (digital) manure in summer'. Thus, while being in Boston, he would, in a way, be 'very much in Switzerland'. (Being Digital, Negroponte, 1995.)

Martin Pawley, an influential British architecture critic, pronounced in 1997 that, 'in urban terms, once time has become instantaneous, space becomes unnecessary. In a space-less city, the whole population might require no more than the 30-atom diameter light beam of an optical computer system'. He foresaw a society with ever-greater technical means of communication becoming paradoxically more insular and dysfunctional. (Terminal Architecture, Pawley,1997.)

Finally, British writer Charles Leadbeater pronounced that 'at the moment (in 2000) it is as if we occupied two worlds at once, especially in our congested cities: the physical world of clogged roads, which is inefficient, slow moving, and rigid; and the immaterial world of computers and communications, in which we can work at the touch of a button. The ease of use and responsiveness of the new, immaterial economy will make us increasingly frustrated with our experience of the cumbersome old economy of physical machines and roads'. (Living on Thin Air: The

New Economy, Leadbetter, 2000.)

Building on these and many other suggestions broadcast by writers that new technologies would overcome the need for spatial proximity, many more authors implied that the spread of digital exchanges at the speed-of-light pace, and the explosion of digital domains, would necessarily imply some catastrophic collapse for cities.

The implications of these predictions seemed depressing for those who cherished and valued vibrant cities in all their physical juxtaposition, conflict, unpredictability, and their social and cultural diversity. If such scenarios were to be believed, human reliance on urban places, urban infrastructures, transport flows, and even the corporeal presence of human bodies could, and would, ultimately be transcended. After 8,000 years, urban life, with all its messy and material ambivalence, its clashing territorialities, and its associated congestion, poverty, conflict, violence, pollution, and social problems, was on the way out. Crudely put, the pure, clean, and limitless realm of (post postmodern) 'cyberspace' would rescue us all urbanites from the dirty, polluted, contested, finite, (modern) city. To believe such authors was to believe that a new post-urban age was being ushered in, which would finally allow the rural utopias of the twentieth-century architects like Frank Lloyd Wright to be realized.

3. Four “Romantic Visions” of Post-urban Fantasy

a. Place - Breakdown of Materiality - Cyberspace:

The romantic vision of the demise of cities, in favor of place-less (non) urbanism stressed the technological basis of a post-urban societal revolution. Rather than seeing the digital technologies as means to be seized upon, shaped, and readily adopted within the fine-grained practices of everyday urban life, such technologies that enabled cyber-spatiality, were cast as a 'dazzling light,' ‘holy grail,’ and 'shining’ above everyday concerns of urbanism.

Replacing physical movement in and around the city would be the limitless domains of dematerialized cyberspace -the digital domain that results from the convergence of computers with digital telecommunications and new media technologies. First coined by science fiction writer William Gibson, the term cyberspace has been defined as 'a parallel universe' or 'a new kind of space, invisible to our direct senses, a space which might become more important than physical space itself’.

The period these romantic visions became the most common was the last two decades of the 20th century when the “information age” reached its pinnacle with the rapid growth of the Internet and world-wide-web, as computing power was doubling every two years and microchips were starting to saturate every domain of life. It seemed very possible that soon every equipment, instrument, appliance -even human

bodies, would be fitted with digital technologies and turned into globally connected digital appliances or terminals linked by broadband telecommunications services over fiber optics and global satellite links.

The “master narrative” or the 'teleology of cyberspace' suggested that digital technologies would transform 'information from something separate and contained within computers to a space we can inhabit'. The world of cyberspace, invariably, was pictured in this romantic discourse as 'a world that exists in the future ... a hope, an expectation, for future fulfillment'.

Architecture scholars who espoused this romantic vision, like Michael Benedikt, a professor at University of Texas-Austin yearned for a future when ‘materiality’ was ‘cast away' because humans could 'inhabit' a virtual world of pure information (Cyberspace: First Steps, Benedikt (ed.), 1992*)*, while software engineer David Gelerntner predicted that ‘reality’ such as cities, would be replaced gradually and piece by piece by its 'software imitation' i.e., the ‘virtual reality’ (Mirror Worlds, Gelerntner, 1991).

Because the software produced reality was immaterial, infinitely extendable, and an absolute substitution for all forms of physical mobility and corporeal presence, 'cyberspace' was thus seen as a force for decontaminating the natural and urban landscapes, redeeming them, saving them from the chain dragging bulldozers of the paper industry, from the diesel smoke of courier and post-office trucks, from jet fuel flames and clogged airports, from billboards, trashy, and pretentious architecture, hour long freeway commutes, ticket lines, choked subways - from all the inefficiencies, chemical and informational pollution, and corruptions associated with moving information attached to things, across, over, and under the vast and bumpy surface of the earth rather than letting it fly free in the soft hail of electrons that was cyberspace, declared - yet again- Michael Benedikt.

By late 1990s, the explosion of wireless infrastructure promised and began to deliver the unhitched computing and communications from fixed locations, as cyberspace advocates predicted. In its wake, a non-spatial world beckoned where digital streams of information, data, images, and video - manipulated and processed through an infinitely complex global skein of computer networks, pervaded every domain of contemporary society.

b. Process - Dawn of the more Egalitarian, Capitalistic, and Ecologically Sensitive Societies – Digital/Electronic “everything””

The second romantic vision of the post-urban discourse involved utopian assumptions that the shifts away from place- and city-based lives made possible by digital technologies could meld communities and mediate democratic processes in ways that would completely replace the political, social, and anthropological roles individuals and communities have played and continue to play in urban places. It was

often uncritically assumed that such a development would automatically lead to shifts towards more democratic, egalitarian, decentralized, and ecologically sensitive societies. As a matter of fact, the digital “revolution” would yield a cultural revolution because information could be transmitted and transmuted in fundamentally limitless ways, enabling the successes already being witnessed in digitally processed economic transactions. A global neoliberal marketplace where individuals engaged seamlessly as consumers with the entire planet based on globally stretched digital technologies was no longer a utopia.

Beyond the tangible, digital technologies would offer the priceless intangibles of friendship, community, and understanding leading to a new democracy dominated neither by vested interests of political parties nor of the crime syndicates or oligarchs. It could narrow the gap that separate capital from labor and it could deepen the bonds between people and planet.

Advocates declared that with reduced (or altogether eliminated) need for face-to-face encounters and interactions; tools to (re)-install some form of idealized Athenian or Jeffersonian democracy were now available in the national and global digital infrastructures. With the capabilities of the digital technologies that would support bi-directional and decentralized communications, communities, and democratic links could be forged irrespective of geography, resuscitating democracy itself.

c. People - End of the Actual Being and the complete substitution of corporeal (i.e. bodily) presence - Cyborg:

The third romantic vision of the post-urban discourse was the most bizarre of all: the progressive blending of digital technologies with human bodies! Society would effectively be dematerialized, as urban activities would effectively migrate into the ever-extending domains of virtual interaction. Thus, cities would become increasingly and conspicuously “old-fashioned” and unfit as political, social, and cultural expression of the time. As a matter of fact, it was claimed, cities would gradually be complemented, and eventually be replaced, by a fast-expanding universe of virtual realities, virtual communities, and digital economies, as well as unlimited and electronically constructed and maintained domains accessible from anywhere and at any time.

In a direct challenge to the human experience of “actual” place, “virtual” domains would increasingly evolve to be experienced immersively through Virtual Reality (VR) technologies. These “places” and the digital media would fuse with the human bodies and nervous systems of their cyborg (cyberneticorganism) hosts ever more seamlessly. Such 'terminal citizens' could, in a sense, 'leave' their physical bodies ('meatspace'), and their local geographies, 'behind' the arrays of technology they used to create, to inhabit the new simulated, replaceable, and infinitely extensible, virtual worlds. Richard Coyne, who is a Professor of Architectural Computing at the University of Edinburg, put it this way: “in a virtual world you can have instant

access to any coordinates in data space. You can be here, there, or any/everywhere, unlike the limited spatially constrained world we usually experience". Expressions such as this summarized the critical seam of the discourse prevalent in this romantic vision, often called Technoromanticism. More and more in this context, the concept of a person or of human beings appears to depend on the attenuated possibilities of cyberspace (Technoromanticism: Digital Narrative, Holism, and the Romance of the Real, Coyne, 1999).

For better -and certainly not worse, the crude and in most cases, bleak fantasies of a complete substitution of corporeal (i.e. bodily) presence and movement within and between urban places to habitation of a virtual domain are now less ubiquitous than during their heyday from 1960s to1990s. Nevertheless, 'at the turn of the twenty-first century', anthropologist Caren Kaplan, currently Professor of Gender and Women's Studies at University of California at Davis, has argued that it is still 'the rhetoric of cyberspace and information technologies that we hear and read, and the discourse is heavily reliant 'on a hyperbole of unlimited power through disembodied mobility'. Whether we encounter theorizations of new cityscapes published by university presses or are exposed to advertisements in magazines, references to boundless space, unfettered mobility, and speedy transfers abound.

d. Time - Collapse of Geographical and Temporal Constraints – Instant Massaging:

The last romantic vision emerging out of the post-urban revolution that is relevant here, involved the assumption that digital technologies would entail a generalized collapse of temporal constraints –mostly manifested by distance- on urbanites' interactions, which urban life is about. After all, people always chose to establish themselves in cities to overcome the "separation in time and space", i.e., distance, with other people whom they engage with in urban processes (service, trade, cultural partake, etc). The city had evolved for 8,000 years of urban history by concentrating human life in geographical territory. Through minimizing space constraints, cities had allowed the time constraints on physical human interaction to be reduced. Even in major metropolitan regions physical, face-to-face contact could be achieved within a reasonable time. The prediction was to continue witnessing the exponential growth of the communication technology in capability, scale, and sophistication to such an extent that they would directly displace, and substitute for the city. It followed that, in the future, the key relationships in the 'digital age' or the 'information society' would not link a person or a group and his/her or their home, their neighborhood, their city, or their nation, by rather, the urban relationships would continuously telescope between the individual and the integrated and planet-wide, digital civilization as a whole. Thus, parallel to the death of cities, the death of distance, by way of cyber space, was presented as both logical and obvious. Inevitably, the digital technologies would be detrimental to the future of urbanism. Since the digital technologies of communication would facilitate 'real time' interactions to occur: time -as a significant inhibitor of human interaction- would thus be no longer relevant in urban life. The underlying logic of this romantic vision was founded on the equating

of distance with time.

4. Critique of the Post-urban Fantasy

In the dialectic discourses that have been taking place in the last half of the 20th century, as posited by the romantic visions delineated here, the digital technologies and urbanism would diverge into polar opposites. However, these visions of the post-urban fantasy were far from being a single or even a unified discourse. They varied significantly in their assumptions, bases, arguments, and even in conclusions, save for the common belief in the death of cities –as we had come to know and experience them. A complex range of philosophical and theoretical antecedents served as bases on which each were put forth. Many had futurism, cyberpunk science fiction, media, and critical theory as their source, though architecture, planning, and urban studies were significant fields of study from which many of the discourses drew their genesis. A significant number of discourses, particularly the ones coming from science fiction, had bleak, cynical, and a pessimistic view and critique of the direction global political, economic, and technological change predicted to take place.

Nevertheless, all the depictions of the future, predicated on the speculated advances in digital technologies, had one commonality: they were based on a general, and thus uncritical, use of the metaphor that cities would simply be 'impacted' by new technologies, particularly those that pertained to communication, and this impact would be in the same way planets are impacted by asteroids. In all the above accounts, digital technologies were portrayed as arriving from 'out there', as a transformative 'force' or 'shock' hitting the fabric of urban society.

To regard new technologies as 'largely unproblematic and even autonomous in shaping the life and form of urbanity reflected the long-standing tendencies within the contemporary culture, and this may be held as the foundation for -and fountain out of which sprang the four “Romantic Visions” of post-urban fantasy outlined previously. In all, digital technologies were generally portrayed as some disembodied, external 'wave' of change which, quite literally, transformed cities and urban life single-handedly. Alvin Toffler, the author of Future Shock, even used the metaphor 'Third Wave' to capture the latest digitally based societal revolution, following on from the First (agricultural) and Second (industrial) revolutions.

This view reflects the classic, deterministic view of the role of new communications and transport innovations in which 'changes in technology lead inexorably to changes in urban form' and urban life, and not the other way round. In this view, the fledgling networked infrastructures like the Internet become little more than 'progenitor[s] of new urban geometries'. Such rhetoric assumes a simple, linear, cause-and-effect chain where the technology itself is as the direct and single causal agent of urban change. Commonly, this intellectual perspective is quickly translated into the broader use of technological and infrastructural depictions of historical urban 'ages': from the 'hydraulic civilizations' of the first urban centers in Mesopotamia, through to the

'steam', 'electric', 'auto', the 'nuclear', and 'information age' metropolises of the past three centuries.

Thus, the critical problem with the romantic fantasies is that they tend to portray technologies as having overwhelming power in ushering in simple and discrete societal shifts, which seem to amount to some naturalistic process of urban and societal evolution. In the process, the parallels and congruencies between historical periods tend to be underplayed or completely disregarded. Further, in the fantastic scenarios of place, processes, people, and time, each romantic vision also implies that all cities would somehow be 'impacted' by digital technologies in similar ways, irrespective of their starkly contrasting geographical positions, sociologies, economies, cultures, political structures, and histories, because technology it is assumed to operate in the same way in the general and at speculative levels. The tendencies of newer technologies to overlay, and subtly combine with, rather than replace, earlier ones are often ignored. And the forms and processes of city life tend to be simply read off as the deterministic result of the intrinsic nature of the new generation of technology.

Such ‘technological determinism' - the reading off of the universal effects of technologies from their intrinsic properties- is nevertheless attractive. It helps to create powerful scenarios, clear stories, and tangible predictions however simplistic they all are. It makes good copy for the media and creates glamorous notions of a new electronic 'frontier' awaiting colonization by those hardy pioneers that are up to the task. Such rhetoric seems to tally well with the early periods of the diffusion of a new set of technologies and practices. This is because, at this stage, people literally see the social world, and the urban landscape around them, gradually filling up over time with new equipment, new artifacts, new practices, and new ways of organizing human experiences -as if coming from nowhere. Above all, technological determinism and the metaphors of their impact accord well with the dominant experience in the Wild West in the U.S. several centuries ago.

What is unfortunate however is that the pervasive reliance on ‘technological determinism' leading to end of city visions actually obscures the complex relationships between new communications and information technologies and cities and urban life that have emerged as these have diffused to be embedded in real everyday lives and practices.

Many urban scholars find the digital technology-related shifts in everyday urban life occurring now to be more intriguing than could possibly have been predicted solely by the generalized scenarios pumped out between the 1960s and 1990s. The architecture critic and Yale University professor Keller Easterling for example, argues that 'the explosion of changes to the world's markets, cities, and means of shipping and communication [are] far more strange and unpredictable than any of the swaggering futurology scenarios'. Thus, there is a desperate need, as many sociologists suggest, to move beyond the deterministic discourses about the 'impacts' of 'cyberspace' on society to look in rich empirical detail at the complex ways in

which digital technologies are being used in real ways, in real urban regions, and in the real world. This is imperative.

Far from being a complete and revolutionary break with the past, most advances in digital technologies retain many intrinsic qualities of and maintain intimate connections with old media, old technologies, old practices, and mostly electromechanical old infrastructures and spaces e.g., telephone systems, broadcasting systems, electricity systems, highway systems, streets, airline systems, logistics systems. The so-called 'information age', then, is best considered not as a revolution but as a complex and subtle amalgam of new technologies and media fused onto, and 'remediating' the old ones. They are allowing for the subtle 'remediation' of TV, newspapers, magazines, radio, telephones, publishing, books, art, video, photography, face-to-face communication, and the social and anthropological experiences, and construction of place. This is happening as established practices subtly combine with, rather than disappear all together, in socially constructed technological patterns. There are a great many more continuities and synergies than many romantic visionaries of the post-urban fantasies would have us believe. We are not experiencing some wholesale and discrete break with the urban past ushered in by the 'impacts' of new technology. Rather, we are experiencing a complex and infinitely diverse range of transformations where new and old practices and media technologies become mutually linked and fused in an ongoing blizzard of change. 'Cyberspace' is very much a part of our contemporary world and it is constituted through a series of remediations. As a digital network, cyberspace remediates the electric communications networks of the past 150 years, the telegraph and the telephone; as virtual reality. It remediates the visual space of painting, film, and television; and as social space while it also remediates such historical places as cities and parks as well as 'non places' such as theme parks and shopping malls. Like other contemporary tele-mediated spaces, cyberspace refashions and extends earlier media, which are in and of themselves embedded in material and social environments.

5. Conclusion

The first problem is obvious: deterministic end of city accounts are simply, empirically wrong.

End of city discourses studiously ignore the fact that fast pace urbanization and growing digital technology use are actually going hand in hand.

The beginning of the 21st Century marked the milestone of the world population being more urbanite than not.

End of city perspectives also ignore the rapid rise in all forms of physical mobility at all geographical scales. These have actually grown in *parallel* with the application of digital technologies; they have not been replaced them.

The growing gridlock of city streets; the staggering rise of global automobile ownership; the exponential growth of airline travel; intensifying levels of consumer and business tourism; growing energy consumption; and a general acceleration of flows of goods, commodities and raw materials at all scales across the world.

Cities of all types across the world continue to be not only the powerhouses for all aspects innovation, research, application of digital technologies, but their demand and installation.

However, current processes of economic, political, social change mostly facilitated by digital technologies, are radically affecting cities. There could be no denying that cities are becoming more diffuse just as the condition of all spaces within societies becomes more generally urban.

The second problem with digital technology-based end of city visions is that they ignore the very material realities that make the supposedly 'virtual' realms of cyberspace' possible. 'Cyberspaces' do not exist on their own; the many supposedly 'virtual' domains and worlds are brought into existence, and constantly facilitated by massive and globally extended sets of material systems and infrastructures.

Because the material bases for cyberspace are usually invisible they tend only to be noticed when they collapse or fail through wars, terrorist attack, natural disasters, or technical failure. Thus, in contrast to the vast and land-hungry infrastructural edifices that sustain transport, electricity and water flows, the myth that cyberspace is an ethereal, unearthly and even immaterial realm continues to retain power.

The third problem with the utopian and anti-urban predictions of end of city visionaries is that they massively over-generalize. They imply that all experiences are the same anywhere and that digital technologies relate to all cities in the same way at all times.

Tough the digital technologies are helping to facilitate significant reconfigurations in the geography, mobility patterns and social economic and cultural dynamics of cities, and in the ways in which urban life is represented, lived and managed, these changes are subtle. They are often counterintuitive and they tend to involve many other processes of change.

The fourth problem with deterministic end of city predictions is that they tend to dramatically overestimate the capabilities of digital technologies to mediate human relationships. At the same time, they dramatically underestimate the complexity, richness, and the continuing anthropological and cultural power generated by co-present human bodies in places, which are predominantly urban.

The penultimate problem with end of the city scenarios is that they -at least in their utopian incarnations- tend to promote simplistic, biased and glossy ideologies of the so-called 'information age'. Many of these have been relentlessly used to improve the

public relations profiles of governments and digital media and telecommunications firms.

The final problem with end of city visions is that, in their depoliticized depictions of cities being 'impacted' by waves of autonomous, future technology, which seem to arrive from elsewhere, they imply that there is little or no space for policy innovation in cities, urban regions, or nations and supranational blocs.

It is the irrefutable reality that the twenty-first century will be a century marked by *both* the deepening urbanization of all parts of our planet *and* a growing reliance on fast-advancing information and communications technologies.

PUBLIC PARTICIPATION IN LOCAL POLICY DECISION USING GIS-BASED APPLICATION

Mihai Sercaianu [1], Oana Luca [2]

Abstract

This paper describes the development of a GIS-based application that provides for the public, local government organizations, public companies and agencies, the ability to communicate in order to propose solutions for a better local policy. A study case was conducted for an urban area in Buzau City, Romania. The key for these new applications of providing public access, and particularly in a more flexible and efficient way, is the use of spatial data in a user friendly structure. One of the main goals is to reduce the costs in the public governance sector while improving citizen feedback, related to information exchange. Public participation using GIS tools is achieved using online requests for problems related to their local neighborhoods. This solution raised some issues in relation to how many of citizens have knowledge about urban politics; governance rules or what is their professional background. On the other hand the Web-based services are popular among different type of users, from regular students to land consultants. This type of applications are meant as a service for all the citizens from urban area, as long as they are not too complex or too technically demanding, quantified in time spent by a person in seeking for help or proposing a solution.

1. Introduction

In Romania public participation in local government agencies and companies is very low due to historic bureaucratization and cloudy organizational structure. Because of two reasons citizen interaction has become sometimes counterproductive and for this, in most cases, the chosen solutions came from specialists. Participation proposal in decision making process, usually attract well-seen community actors who likely in the future will hold local political positions. These actors collect the information from the citizens and filter this type of proposals for future specific agenda, in most cases a political agenda. On the other hand, urban residents are invited to discuss finished local policy plans, instead of being involved in entire development process. The review that came from citizens is considered only an observation because the decisions have been already taken.

According to Romanian's frameworks for public sector, local administration is represented by mayors, local and county councils. Besides these institutions, there

[1] Technical University of Civil Engineering, Bucharest, Romania - sercaianumihai@yahoo.com
[2] Technical University of Civil Engineering, Bucharest, Romania - oana@utcb.ro

are a number of commercial companies whose work is closely related to public administration, main activities related with urban networks: water supply and sewerage, central heating systems, electricity, telephones, gas distribution and waste management (Petrescu, 2007). Taking into considerations these aspects we consider that public participation must apply not only for the institutions like mayor or Council County but for all types of public companies mentioned above.

2. Urban Policies and GIS technologies

The increase of urbanization, population density, life quality and public access to information leads to new economic, environmental and decision approach for towns and their inhabitants, as a result of the excessive use of traditional tools related to policy decision and citizen involvement. The opportunity offered to the citizens of the new member states of the European Union to benefit of ITC tools, as well as the acceleration of this trend as a consequence of foreign investment in these countries should be compensated by offering alternative measures, such as of Geographic Informatics Systems (GIS) application's management. Promoting such measures is highly important in these countries, especially if we consider that their citizens do not have satisfactory alternatives to the use of traditional methods, such as telephone or mail interaction with public authorities (Anderson, 2003). Also, it's important to ensure dissemination of best practices in addition to encouraging knowledge sharing by means of the current initiatives. For policy makers and local authority in terms of management key, GIS availability, as a tool in decision making processes has major implication in: public administration and policy; public information and community involvement; and services provision.

Initially, public policies were proposed by architects and engineers, due to the fact that technical-urban aspect was considered the most important key in local development. Starting the 6^{th} decade of the 20^{th} century, urban policies led to a complete abandonment of technical principles, in exchange of urban management's approach. For example, the social component, services, environment, education, culture, research represents the main elements that must be take into consideration in the entire city complex. The main results of the urban development aim to control and improve the community welfare by incorporating all areas of interest and components in local development.

The concept of urban policy must be analyzed from at least three points of view (Teodorof, 2004): (1) in terms of area of interest, urban policy emphasizes functional aspect of habitation, urban area, economic development, economic development, public services improvement and environmental protection; (2) in terms of content, an urban policy represents any principle or government plan on urban issues; approach should be on specific areas of analysis, that reflects the existing situation, based on identification and prioritization of urban issues that arise from data, information and indicators analysis; (3) in terms of process, an urban policy is a cyclical approach, which includes the formulation and evaluation of urban

development goals, planning development, design and implementation, incorporating public investment and consumption.

Public administration also refers to a form of community government or self government from a well-defined area. For this reason a successfully public policy depends on information and technology quality. In addition to this feature, should be considered also how citizens are affected by public choices (right or wrong ones). This requires accurate information, delivered to decision makers in a clearly and easily understandable form, reflected in the most appropriate strategy. In public companies or administrations, large amount of information is often not used due to apparent unrelated connection with financial activity. The public policy making process is an integrated one, however the elaboration stages depends on generated information and future evaluation (Danielson and White, 1998). This correlation is presented in Figure 1. At each stage of the entire development process of a public policy we can integrate the GIS technology for an more logical structure and easily evaluation.

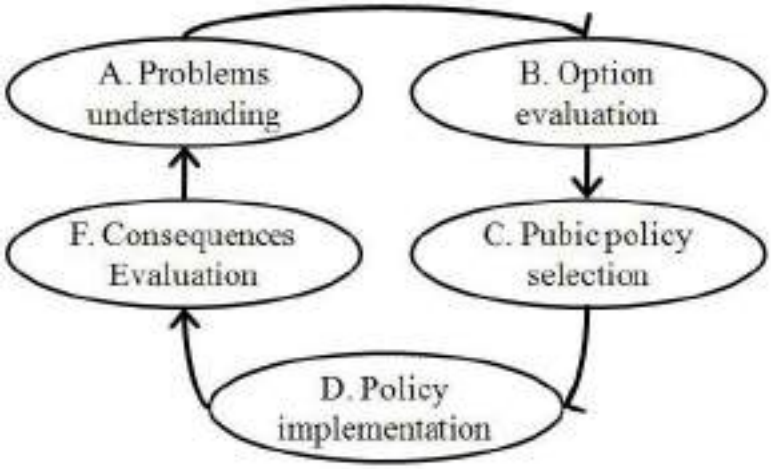

Figure 1. Public policy design steps using cyclical approach (Adaptation after Danielson and White, 1998).

The first step in policy life cycle requires understanding the basic and simpler principle of a problem. When information is presented only as a question or is displayed in charts or graphs form, it's difficult to understand the entire context. For example, if we want to identify and represent industrial area influence related to residential space in a medium dimension city like Buzau. Analysis on diagrams and graphs that are populated with data, like ownership and environment certificates, traffic routes, statistical sales problems, population employment, etc. could not provide similar ensemble analyses compared to maps that correlate all this information in an effective and comprehensive way. Therefore is recommended an increased attention in designing and developing the entire life cycle. For this, at local administration level, public policies aims to be geospatial related, referring in particular at the relationship between citizens an urban space.

This design trough all five steps is a cyclical and reprieve one as the input data is entered and/or processed. At each stage there is an evaluation and feedback component based on the new information developed during the entire process. These loops show that the underlying policy solutions could generate new challenges. Using GIS technology can be extremely useful in promoting the information dissemination to the local community, in a way that citizens can understand all the implication of an public policy troughs the entire process.

An important feature of a solution GIS in developing public policy is to establish a system for collecting, organizing and representing the information in a way that is easy to understand. A good example is the narrative description of a damaged drinking water network, in parallel with the representation of the same networks as a map that contains all specific attributes. GIS provides information visibility trough maps, and allow decision markers to identify problems more quickly and accurately.

3. Project Description

The scope of this application was to provide for citizens and policy maker situated in Buzau City Study area (Figure 2) a new tool to collaborate and interact. This tool will help people to propose better policy decision by improving communication.

Figure 2. Imagery Location of the study area, Buzau City

At the European level we can identify five types of public involvement in local government (Kingston, 2007) and public company decision making:
1. Information: the public authority informs the community (unidirectional process
2. Consultation: the public authority consults the citizens based on a field questionnaire with predefined and closed questions and answers (we used a questionnaire for the Buzau Study Case - Table 1.)

3. Deliberate involvement: the public authority engage local community in consultation process before general policy proposal
4. Government-led active participation – the public authority instigates the local community in proposal with control of the final policy decision
5. Citizen-led active participation – the public authority and local community are actively engaged in the entire process and share the ownership and responsibility related to final decisions

Table 1. Field questionnaire for Buzau Study Case

1. Public services quality	
*Generally, you are satisfied about the quality of public services?	1...10
1.1. You are satisfied about the quality of public services at neighborhood level?	1...10
1.2. You are satisfied about the quality of public services at the city level?	1...10
1.3. You are satisfied related to services modernization at the Mayor and Council level staring 2010?	1...10
2. Communication quality with the public authority	
* Generally, you are satisfied about the communication quality with the public authority?	1...10
2.1. Are you satisfied with the easy contact with the public authority?	1...10
2.2. Are you satisfied related to waiting answering time from the public authority?	1...10
2.3. Are you satisfied related to public announces that came from the public authority?	1...10
3. Tax collection services	
* Generally, you are satisfied about the local tax collection amount?	1...10
3.1. Are you satisfied related to distance to the nearest point of collecting taxes?	1...10
3.2. Are you satisfied related to waiting time for paying local taxes?	1...10
3.3. Are you satisfied related to charge taxes amount?	1...10
…….	
12. How do you want to get involved in the future decision process?	
12. 1. Using classical tools phone/fax/printed mail	Yes/No
12. 2. Directly at the public authority headquarter thought a printed form.	Yes/No
12. 3. Using web application with online forms.	Yes/No
12. 4. Using web application, online maps and graphical tools that contain street, zip and cadastral number reference .	Yes/No
5. Using web-mobile application.	Yes/No
Socio-demographic characteristics	
Street	……..
Cadastral no.	……..
Housing type	.....

Observations	.....

3.1. Buzau City – geodatabase structure

The largest amount of information that Buzau local administration operates has a geographic component, which specify the exact location of an object. Information related to assignation, area, properties, roads, schools, parks contains the geographical component as a mandatory requirement. Although computer use has become common in Romania, the GIS technology penetration in the public administration is performed in a slow rate. The main problems consist in high costs of creating spatial database. As the same time, as important are organizational costs, inevitably involved in introduction of new operational technologies (Anderson, 2003). GIS application related urban policy management are naturally implemented in the municipalities, county councils or public companies, and are not limited to simple informatics cadastral applications. This information could includes a variety of other application related to: private and public property, construction and restrictions licenses, planning areas, traffic analysis, emergency and disaster management, design and record of utility networks, territorial organization and systematization

Because we needed an urban area, with sufficient information provided by different institutions were we could perform various analyses we chose a surface of 3.4sq km located in District 4, Buzau City. As a general concept the geographic database contain both high density data, located strictly in Buzau urban area, as well as buffer information like county roads (figure 3 and 4).

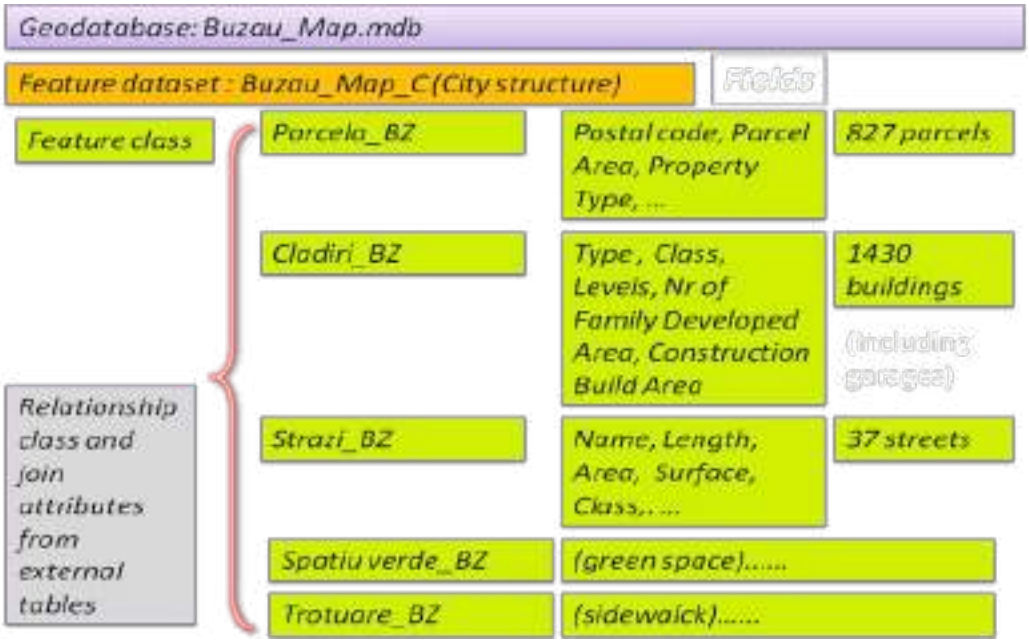

Figure 3. Geodatabase structure, Buzau City

It took about 6 months to construct the geodatabase that included exact location of parcels and buildings, total surface of streets, sidewalks and green space and an estimated condition of the land. We used ArcGIS Desktop to manage, analyze and visualize this type of data. The Buzau City Geodatabase consists in about 1430 building objects, 827 parcels distributed on 37 streets. For the study to be more concluding the property form is reprehended by public and private property according to local construction authorization.

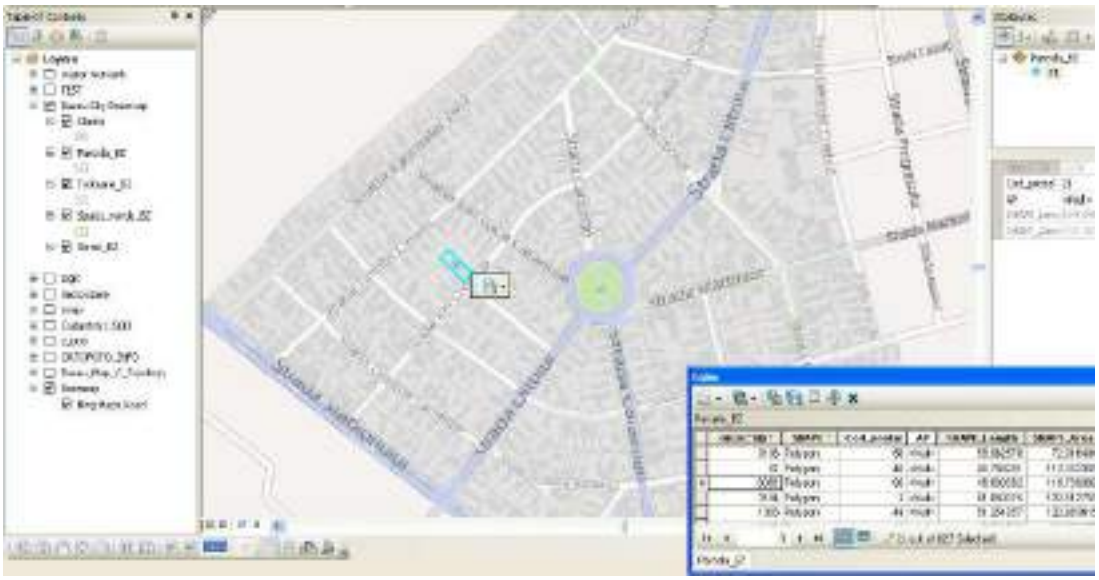

Figure 4. Study case map and attribute table for parcels, Buzau City

In terms of data management information approach, the system includes tools for inclusion, visualization and understands the relationship between different types of data to produce new information (figure 5).

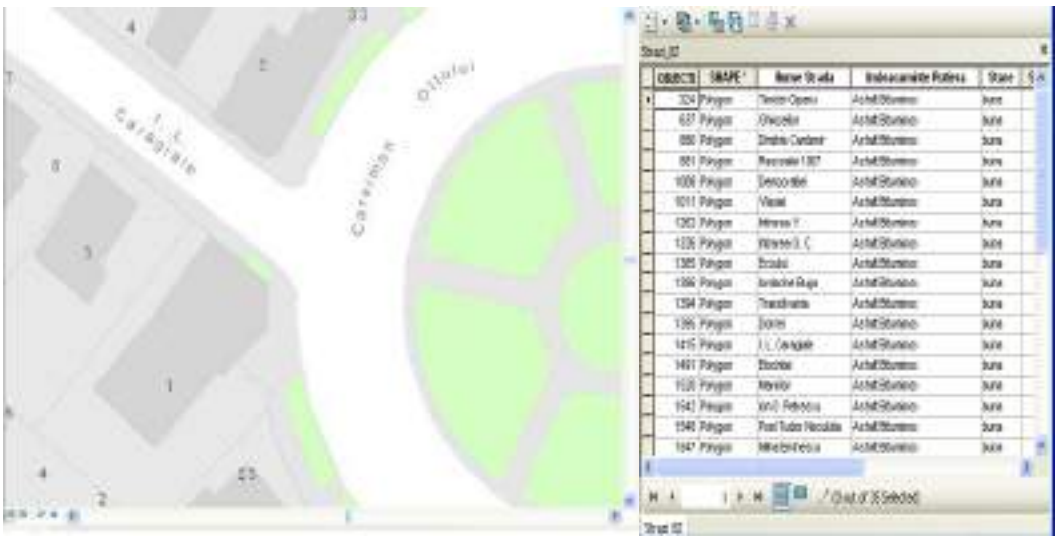

Figure 5. Study case map and attribute table for streets, Buzau City

The geodatabase allows decision makers to evaluate dependencies and interdependencies of these relationships based on this information. Also the stakeholders are able to assist and present this information on a consistent manner trough the citizens. This new approach also affects local authorities and public companies, which tend to be organized in regionalized structure.

3.2. Buzau City - web-GIS application

The internet offers new opportunities for distributing both geo-processing tools and geographic data to a wider range of potential users (Zhao, 2002). The web application system will allow, beyond a simple geographical storage, creation and management of new indicators resulting from intersection of available and relevant technical data with non technical information, enabling the simulation of the entire urban area evolution.

The web application provides the general public and other interested parties the ability to communicate service requests to their public company (the water company was used in this example). This interactive web application includes a base map constructed for the study case from Buzau City, and a simple tool to submit new service requests and comments, visualize past requests related to water distribution network. This base map provides a consumer representation of parcel information and can be used to locate the network, structures, etc. by geographic coordination (Figure 6.).

Figure 6. Web application for the study case

After submitting a request the user will be able to see past and future intervention from the company operator:
- Assigned – the request is assigned at the operator level for future solution (the user can complete with comments related to his problem);
- Unassigned – the request is unassigned at the operator level (the user will not be able to post new comments until the request is assigned);
- Closed – the request was solved by the network operator.
We must mention that due large amount of data included in the GIS application some tests were conducted only on specific type of services like water distribution network.

Example of the programming code from Buzau_Public_Request application used:

```
var manageTemplateParts = [];
manageTemplateParts.push(dojo.string.substitute("Change service request STATUS to <a href='javascript:assignRequest(${OBJECTID});'>Assigned</a>", requestFeature.attributes));
manageTemplateParts.push(dojo.string.substitute("Change service request STATUS to <a href='javascript:closeRequest(${OBJECTID});'>Closed</a>", requestFeature.attributes));
manageTemplateParts.push(dojo.string.substitute("<a href='javascript:deleteRequest(${OBJECTID});hideAttributeInfo();'>Delete</a> service request.", requestFeature.attributes));
……
if (requestStatus === 'Unassigned') {
     if (commentsTable.loaded) {
       esri.show(addCommentsContentsPane.domNode);
       if (comments.length === 0) {
         addCommentsTitleNode.innerHTML = "Be the first to add a comment";
       }
     } else {
       esri.hide(addCommentsContentsPane.domNode);
       addCommentsWarningPane.containerNode.innerHTML = "Adding new comments is currently unavailable...";
     }
   } else {
     esri.hide(addCommentsContentsPane.domNode);
     addCommentsWarningPane.containerNode.innerHTML = "New comments can only be added to unassigned service requests.";
   }
```

In the process of collecting request, we introduced the concept of citizen-sensors, because some information provided by the citizen will not have a technical character but will be solved in by the operator. The application provides the following main functions: reporting a problem, and visualize past requests from other citizens and exploring the digital map. The Previous example use design elements and includes parcels, buildings, roads and water distribution network features. We used ArcGIS

Server to publish and visualize Buzau geodatabase. Now any citizens, from District 4, can easily view imagery or cadastral plans of their neighborhood and get involved in reporting problems, or propose new solution related to local policy (Figure 7). The location and the comments are sent to the university department, which return a confirmation form, streamlining the procedure for citizens and public authority. In the future when the application will be developed all comments from the application will be send directly to the public authority server.

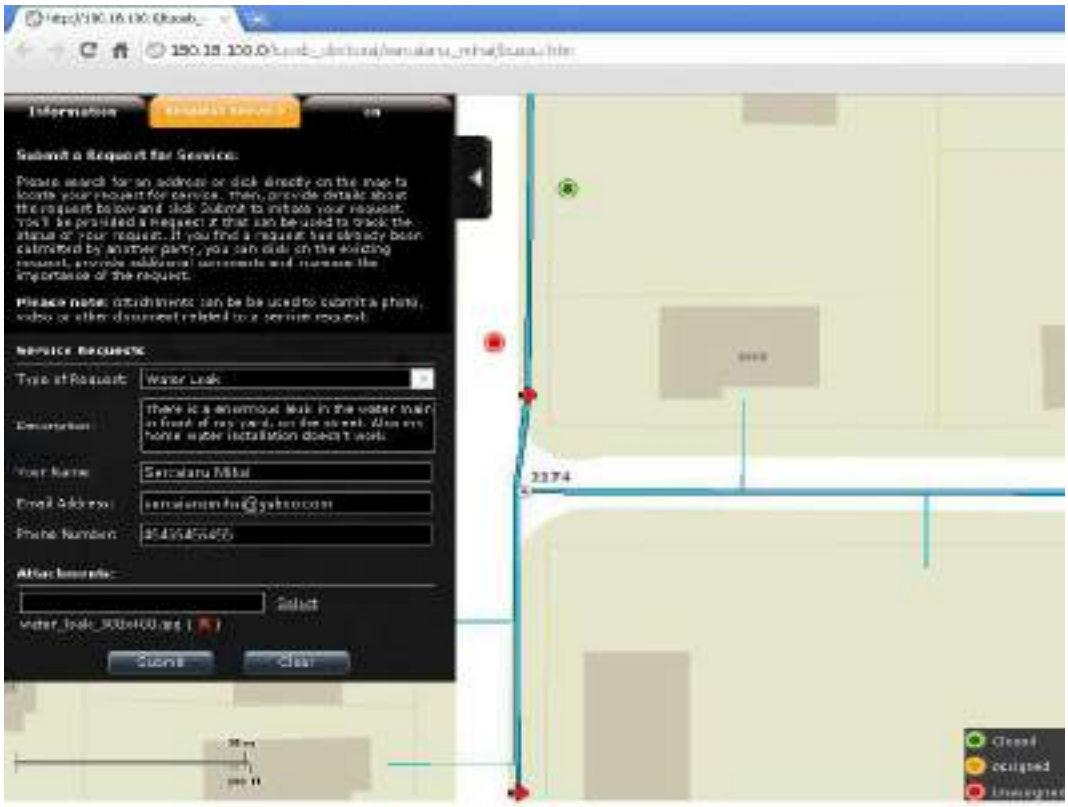

Figure 7. Citizen request solution for Buzau web-application

Based on, classification and quantification of water losses, recorded, the water company will be able to take decisions in accordance with the needs from the field. Technological solutions used to solve problems are justified not just by a simple analysis, but also future insertion in the progress reports the new indicators obtained.
The contributions are directly related to the development and use of information technologies. Digital technologies reinvigorated an already engaged community by creating proactive (rather than reactive) participatory field requests. In addition, some of the techniques that were used to revitalize the participatory process were made due to use of computer-mediated communication and visualization technologies. For instance, the use of a safe/neutral electronic space (the web site application), which allowed citizens to post request and comments, made it possible for citizens to share their real problems, placed in a specific geographic point.

Here are some examples of services that can be offered to citizens through a single

portal and the possibility of extending municipal coverage to other companies or public administration: (1) urban equipment, for example request installation or equipment maintenance; (2) request information related to local budget; (3) providing information about particular maps, for example cadastral plans info; (4) abandoned car lifting; (5) submitting street visibility problems , abundant vegetation, public land construction; (6) animals controls, rendering requests for abandoned pets; (7) report for clogged drains and missing sewer caps; (8) providing information about low pressure on water distribution systems; (9) unmarked constructions sites; (10) social services or police request; (11) road signs and street lighting proposal

3.3. Partial results and future application development

For real time solution the project we need the pilot test, based on requests collected from the field. For that, a more detailed impression of the users and the usage of the GIS-based web applications would be a valuable tool for evaluation and the strategy of further development. At this point, most of the GIS-based applications are targeted toward relatively specific user groups whose general abilities to comprehend and use GIS in specific tasks might not be known but can be estimated quite well. Still, there is a need to get a clearer impression of the understanding of the concepts of GIS among nonprofessional users. This paper presented a solution that can be combined with the water company software. Results of the research project may prove to be valuable at a much broader range than just develop the GIS-based applications at the regional and municipal web sites, as knowledge of users' understanding is crucial for the success of the transition toward digital management.

Although for the pilot phase of the study we considered as sufficient the 200 questionnaires for the field survey, their number cannot be relevant in the evaluation stage at the entire city level (Figure 8).

Figure 8. Field survey questionnaire area

For a relevant and complete conclusion related to perception related to public participation field data must be combined with information collected from the web application. To involve citizens in the scheme of reducing water losses several conditions must be met. According to William Huxhold, good decisions require good information (Huxhold, 1991). The first requirement was to complete the GIS database and the web portal, through which citizens can submit a applications request for reporting problems occurred in their neighborhood and may acquire assistance to remedy the problem. By generating a „claim number", issued in real time, the beneficiary can observe the progress report of the application and identify those responsible for his request. The online communities is be able to seek for help, may need different intervention requests, and provide multiple lines of communication and dissemination trough a single portal. Responsibility for solving the problem is in charge of public authority. If the public authority is not in charge or the proposal is to complex information will be transited to other urban networks companies, such as district heating networks.

In a possible application development and a diversification of services offered to citizens all public authorities companies who manage other urban area or network utilities can benefit from this experience. In the near future, it will identify possible development opportunities for citizen involvement in the system to evaluate environment impact or reduce losses from all municipal companies from Romania. Data quality and analysis in future applications will be made depending on input, type and quality of data, and analytical methods.

After implementing the system, traditional channels such as telephone or written requests are recorded in a second phase, but not eliminated entirely. At the institutional level this solutions will be used simultaneously spatial databases,

satellite imagery, internet services, new technologies and specialists' knowledge. Also, problems can arise in the implementation phase such as: citizen access to a poor developed infrastructure (computers, web); poor security and classification in acquisition phase; in case of extreme failures other networks could be affected; real time informatics system performance; reticence of some citizens to use modern technologies.

4. Conclusions

Implementing an informatics system and a database by digitizing all physical maps, developing the virtual infrastructure for disseminate relevant information will lead to renewal of underground urban infrastructure. Using GIS for information analysis relating to urban elements from urban areas is becoming increasingly common. Among other facilities, a GIS allows data to be structured by different information levels. Each information layer stores in a geodatabase a number of objects and related attributes of these objects. The GIS solution will allow, beyond simple geographical information storage, creation and implementing new indicators, resulting from the processing of existing information. Digital maps can be used as such (query, visualization, print) in the external portal by exploiting the spatial information and attributes included by each geodatabase feature class or by combining the information included in several themes. With this interactive digital maps citizen can request the solution of various problems

GIS data dissemination means making information available to several departments or beneficiaries, which opens broad prospects in cooperation between citizens, professionals, municipal companies and local government. In parallel with application bootstrapping is absolutely necessary to observe the database operation from the beginning of data acquisition through external web portal. It will follow if: data is stored in a predefined logical form; the entire functionality is unaffected by wrong access from the users; data is secured and national frameworks are respected; the information can be summarized in parallel to multiple users; the geographic data base can be exported to other potential user; the index mechanism is fully operational and reports can be searched; application with identical properties can be grouped.

The novelty rate that the project presents is the implementation trough GIS technology in a modern form the integrated network management, applied to urban area environment, and also the involving of citizens in decisional support for proposing new and modern public policy. The greatest risk is that the project will not be able to recover quite pronounced gap between dynamics and necessary need of information from the field.

From this analysis we identify in the future: (1) cooperation possibilities between citizen – public company – local authority, in terms of policy decision management; (2) future analysis of current capacity at national level in implementing Geographical Informatics Systems (GIS) technologies; (2) future possibilities and involvement degree of citizens in the systems of reducing water losses using spatial databases; (3)

analyzing the necessary changes to ensure minimum operation criteria of the new system.

For Buzau City administration this GIS-based application will inspire other departments to create or develop similar application for environmental protection, cultural heritage or touristic development.

SOCIO-SPATIAL DIMENSIONS IN SUSTAINABLE RESOURCE AND ENERGY MANAGEMENT IN BULGARIA

Elena Dimitrova[1]

Abstract

Resource and energy efficiency are issues of growing attention in European policy. The role of urban planning and design in achieving practical results is explicitly stressed upon in numerous European documents (Leipzig Charter, 2007; Toledo Declaration, 2010; Energy Roadmap 2050, 2011). This raises questions about how spatial planning could effectively contribute, and whose expertise and what procedures it could rely upon in defining and evaluating efficiency. Urban structure has been discussed as an important factor in planning literature (Naess, 2006) and broader considerations than the economic ones have been recommended in the evaluation of planning concepts (Miller & Patassini, 2007). Current situation in Bulgaria is still characterized by high energy consumption and admittedly low energy and resource efficiency (EC/COM, 2011). The efforts undertaken at the national level during the recent decade have resulted in raising public awareness in the field of energy efficiency and in increasing practical experience in resource and energy management at the municipal level. Current action is however mainly focused on technical measures to diminish resource and energy consumption through building insulation and energy saving heating/ lighting systems. Despite the already considerable experience in municipal energy planning in the country (Eneffect, 2004; Ecoenergy, 2012) and the published national guidelines insist upon the energy efficiency assessment of spatial strategies and plans at all levels (WRDPW, 2009), no practical steps have been undertaken yet in Bulgaria to explicitly address spatial planning implications of energy and resource efficiency. Recent attempts to promote imported assessment tools (BREEAM, LEED, DGBG, etc.), are rather fragmentary and technocratic. The market mechanisms applied lack sensitivity to the peculiarities of the national planning and sociocultural context and are broadly neglecting social injustice (Babourkova, 2010). Based on the teaching experience in the Programme in Urbanism and on current studies at UACEG, Sofia, the paper discusses the need for re-defining tasks and priorities of spatial planning education in order to more effectively include considerations about energy and resource efficiency. The comparative analysis of two case studies from the recent educational practice in the programme outlines a number of aspects – the applied methodological approach, related and influencing international events, the contact established with stakeholders throughout the project elaboration, and the further development potential of the

[1] University of Architecture, Civil Engineering and Geodesy, Sofia, Bulgaria - e-mail: eldim_far@uacg.bg

projects - contributions to planning practice, research and education. The results provide evidence that if issues of energy and resource efficiency are effectively addressed at all educational levels in direct dialogue with the local level in Bulgaria, this would have a manifold contribution in building the needed professional capacity for implementing integrated planning approaches and in encouraging experts' sensitivity to issues of social and environmental justice.

1. Introduction

Resource and energy efficiency are major issues in the process to a sustainable future and are recently ones of growing urgency in the European policy field. Since the Rio Summit in 1992 an increasing number of policy documents and research reports pose and discuss issues of efficiency with regard to spatial planning. This raises numerous questions about how spatial planning could practically contribute in the process, whose responsibility and expertise it could rely upon in defining and applying criteria in evaluating plan efficiency with regard to energy and resource use, at what stages of the planning process and through what procedures it should be done. All these have direct implications to the way planning education tasks and priorities are defined and implemented. The paper traces currently existing policy framework at the EU and Bulgarian national level and outlines the main efficiency aspects concerned in the planning field. It then analyses the interpretation of two topics with major importance to energy and resource efficiency (mobility and the spatial pattern of the settlement network) in two educational projects at UACEG. The efficiency of the educational approaches and results is estimated with regard to their further development potential and complex contributions to planning practice, research and education.

2. Resource and energy efficiency aspects in the planning field

The set of documents express societal expectations for spatial planning and design to contribute to achieving higher resource and energy efficiency in the process to sustainable development. This raises questions for research to answer about how spatial planning could effectively contribute, and whose expertise and what procedures it could rely upon in defining and evaluating efficiency.

2.1. EU policy documents

There was a clear message at Rio Summit to architects and planners about their responsibilities in the process towards a more sustainable future - Agenda 21 stated that there should be 'shelter for all' provided in a world of one billion homeless people, spatial planning and management should be improved and integrated approaches to building the urban infrastructure (electricity, water supply and sewage, waste collection, etc.) should be developed. Two aspects were actually addressed in the document – the importance of the planning and design results (from the urban system to the single building) but also of the planning process itself – the actors

involved and their interactions. The message was further detailed through European policy documents – Aalborg Charter, 1994; Goteborg Action Plan, 2001/2006; etc.

The Leipzig Charter on European Sustainable Cities (Informal Ministerial Meeting on Urban Development and Territorial Cohesion, 2007) was the one to explicitly stresses on the need for improving the energy efficiency of cities and towns. It outlined four priority issues in the SD process - political debate on implementing the principles at all levels, the introduction of integrated planning and a balanced territorial organization; the need for holistic strategies and coordinated action at all levels, the modernization of infrastructure networks and the improvement of the energy efficiency of cities. It also recommended particular attention to four measures to increase energy efficiency at the urban level – improvement of public transport, refurbishment of residential buildings, efficient resource use; reasonable use of the territory resulting in compact urban structures. Toledo Declaration (Informal Ministerial Meeting on Urban Development, 2010) confirmed that 'the core battle for urban sustainability lies in achieving the maximum possible eco-efficiency in the existing urban fabrics of cities'. The outlined key issues there comprise: (a) reducing transport needs by the promotion of proximity and mixed-uses schemes, while at the same time stimulating a more sustainable mobility; (b) improving the management of energy and material resources and flows in the city; (c) recycling land (by means of urban regeneration, the redevelopment or reuse of abandoned, derelict or unused areas, etc.). It is also stressed upon there that *'strategies and actions should be unitary, and address the whole complexity of urban development, taking into account the role of each part of the city in the whole structure'*. Stating that the role of local organizations and cities will be much greater in the energy systems of the future, the Energy Roadmap 2050 (EC/COM, 2011) foresees the need to answer *'questions on to what extent urban and spatial planning can contribute to saving energy in the medium and long term'*.

2.2. Key research questions on energy and resource use, and efficiency in planning

Recent European studies on energy and resource efficiency (EEA, 2011) outline that, generally, most countries in Europe nowadays interpret resource efficiency quite broadly (including raw materials, energy sources, biomass, waste, land and soil, water and biodiversity), which is *'largely in line with the European Commission's interpretation in documents published to date'*. According to the EEA report findings spatial planning issues have not been explicitly related to resource efficiency - in the national policy documents in Europe the term has appeared mainly in national sustainable development and environmental strategies and action plans, strategies and plans related to climate change; and economic reform programmes. According to the survey in 31 European countries, the top three priority resources are energy sources, biomass and raw materials, while half of the countries have also listed

waste, land and soil, and water as priority resources. Formulated strategic objectives for resource efficiency tend to be fairly general in nature, most often referring to ensuring more efficient use of natural resources, materials and energy; increasing recycling of waste; improving the share of renewables in the overall energy mix; and preventing waste or decoupling waste generation from economic growth (all reported by more than half of the countries). Concerning consumption areas with significant environmental impacts, several countries have reported having objectives and/or targets in the fields of housing (typically for energy efficiency in buildings and sometimes for appliances and electricity use); mobility (typically for increased use of biofuels in transport and fuel-efficiency standards for cars); and food (typically on the amount of land under organic farming). Indicators related to water, land use and forestry are relatively widespread. Only a few countries have established mechanisms to coordinate work on resource efficiency nationally. Some countries have set up 'specialised agencies' or research consortia to support policy development. The involvement of regional and local level administrations in policy making seems to be limited. Factors frequently reported to drive resource efficiency policy have been roughly grouped into those related to the environment and those related to the economy. From the responses on knowledge gaps and information needs, it has appeared that countries are most interested in information on how best to integrate resource efficiency into other policies and in sharing information and experience on good practice in policy implementation. EU policy initiatives have proved to be a strong driver of national policies, indicating both an opportunity and a need for EU resource efficiency policies to provide guidance and strategic direction. Conclusions have been drawn about efforts needed to ensure that resource efficiency policies are coherent with other key policies and about initiatives on institutional development and capacity-building, stimulating inter-institutional collaboration and strengthening coordination mechanisms to improve policy coherence and consistency. Social and cultural aspects related to resource and energy efficiency have not been explicitly mentioned in the report except indirectly in the conclusion that *'one possible approach could be for EU resource-related policies to use broad interpretations of 'resource efficiency' but leave it to the countries to decide which policies and resources are most relevant in their national context'*.

Urban structure has been already discussed as an important factor in planning literature (Naess, 2006) and research reports have focused on urban sprawl (EEA, 2010). European studies have already focused on mobility and transport issues and their linkages to urban development (EC, 2009; EEA, 2009). All these have outlined the importance of the urbanization mode and transport to the efficient use of land and energy resources and focused attention to the need for long term visions and strategies to impact behavioural modes but have not touched explicitly issues of social and environmental justice. Claiming the importance of place-based policy interventions, Davoudi argues in 2009 that on the ground of efficiency, place matters

because market failures and the unintended consequences of government policy impact on different places in different ways.

Efficiency is also a research issue still to more carefully focus upon as broader considerations than the economic ones have been recommended in the evaluation of planning concepts (Miller & Patassini, 2007). Development aspects in peripheral areas in SEE would also require innovative approaches and higher sensitivity to social equity and territorial cohesion (Dimitrova & Burov, 2011).

2.3. Energy efficiency in the planning field at the national level in Bulgaria

In Bulgaria energy efficiency issues are among the targets of the practical implementation of the National Strategic Reference Framework (NSRF) for the period 2007-2013 (Priority 4: Support for balanced territorial development) (MRDPW, 2007). NSRF is based on the national Regional Development Plan and the Operational programme on Regional Development (2007-2013), Part 3.8: Infrastructure development – energy infrastructure, including renewable energy sources and energy efficiency. The important accent is there put on the development of various types of urban centres and the improvement of their linkages with the adjacent rural regions. Transport infrastructure development is outlined as an important factor for the future spatial organization of the regions.

A major focus in the recommended updating on the implementation of the Regional Development Plans at level 2 for the period 2009-2013 (MRDPW, 2009) is the need for synchronization between regional and spatial plans and the cohesion aspects of development. The implementation of visualizations and maps is therefore strongly recommended in order to fully identify intraregional disparities and peculiarities of the regions. It is also recommended to explicitly outline the role of the Regional Development Plan for increasing energy efficiency, renewable energy resources (RES) implementation, and for green-house gas emissions reduction. Yet, there are no indicators mentioned on energy consumption and energy efficiency within the recommended indicator set. A similar approach is recommended to updating the mid-term documents – Integrated Development Strategies, at level 3 (district level) for the period 2009-2013. It is expected that the access to services and the service quality provided by the transport and energy infrastructure should be analyzed to estimate changes since the beginning of the strategy implementation and to identify current priority needs. Municipal development plans should, according the Guidelines, aim at identifying the common needs of neighbouring municipalities, defining common priorities and coordinating joint action. The rationale staying behind is the effort to concentrate existing capacity and resources, to improve EU funding accessibility and to support territorial cohesion and local partnership. The role of the Municipal Development Plan should be also estimated with regard to its role for increasing energy efficiency. Yet, in the recommendations on updating of the SWOT analysis there are no explicit energy accents. Neither is there such an accent traceable in the six strategic indicators chosen - concerning territories, emissions, expenditures and erosion.

On-going procurement procedures for the elaboration of integrated urban plans could have been a good chance for integrating more holistic considerations about resource and energy efficiency in the spatial planning process (MRDPW, 2011).

3. The response of planning education to the energy and resource efficiency challenge in Bulgaria: case study analysis

The review of current policy documents provides clear indications about needed proactive professional position is support of formulating integral qualitative requirements to both planning processes and products so that issues of resource and energy efficiency could be related to issues of social equity and environmental justice. Two educational projects addressing different aspects of efficiency and interested in integrated planning that guarantees *'equal opportunities for access to resources closely linked to European cultural roots'* (Girard et al, 2007) have been analyzed and results compared. The main research question addressed is how could planning education integrate aspects of energy and resource efficiency in a socio-culturally sensitive manner in order to more efficiently contribute to enhancing the professional capacity of the current planning system in Bulgaria for facing the challenge of energy and resource efficiency.

3.2. Project description

The two projects were developed in the winter semester of 2010/2011 at different levels of the Programme in Urbanism at UACEG, Sofia – a programme established 10 years ago and designed to be sensitive to EU processes and to the local context of Bulgaria – socio-cultural, spatial and institutional. Team working has been required in project A and encouraged in Project B. A general principle has been also followed in both – the topic of each projects was chosen (and detailed argumentation provided for the choice) by its authors.

Project A: BSc Programme in Urbanism programme, Course project, Teaching module in Sustainable development (optional), 3rd semester, 2010/2011;

Project title: Flexible (demand responsive) group and night transport in Razlog municipality; Students' team: Tsvetelina Kalinova and Aneta Stoycheva; Tutors: E. Dimitrova, A. Burov. H. Nikolov

The module introduces applied issues of sustainable development policy at the local level in Bulgaria. Case-study based approach is implemented as a way to encourage context sensitive and creative thinking and is responsive to priority issues and ongoing activities in Bulgarian municipalities (Dimitrova, 2011). The particular project has chosen to address mobility challenges and traffic conflicts in an internationally attractive skiing area (with considerable tourist flows causing high pressure on the environment) within a sparsely populated mountain region where market based transport services have become highly inefficient and are currently

strongly reduced and replaced by increased private car traffic (thus causing traffic conflicts but also additional economic, social and cultural marginalization of certain groups among the local population). The undertaken SWOT analysis of the existing situation regarding the natural conditions, inhabitants' and tourists' peculiarities, needs and mobility patterns, transport infrastructure and services (accessibility and reliability) has outlined the strengths and weaknesses of the area. The user groups identified and contacted were working people, pupils, youths, tourists, retired people, and people with disabilities. Contacted stakeholders belonged to municipal authorities, private transport companies, tourist agencies, local hotel owners. Material needs and infrastructure shortcomings but also behavioural patterns and attitudes were identified through field observations, a survey and a number of semi-structured interviews. The message of the project - addressed to all the actors and presented to the local community - contained a comprehensive list of tourist sites and possible routes of the DRPT, an analysis of the 24-hour transport demand (Figure 1) and recommendations about the distribution of responsibilities and possible benefits in order to achieve a 'win-win' situation in the municipality.

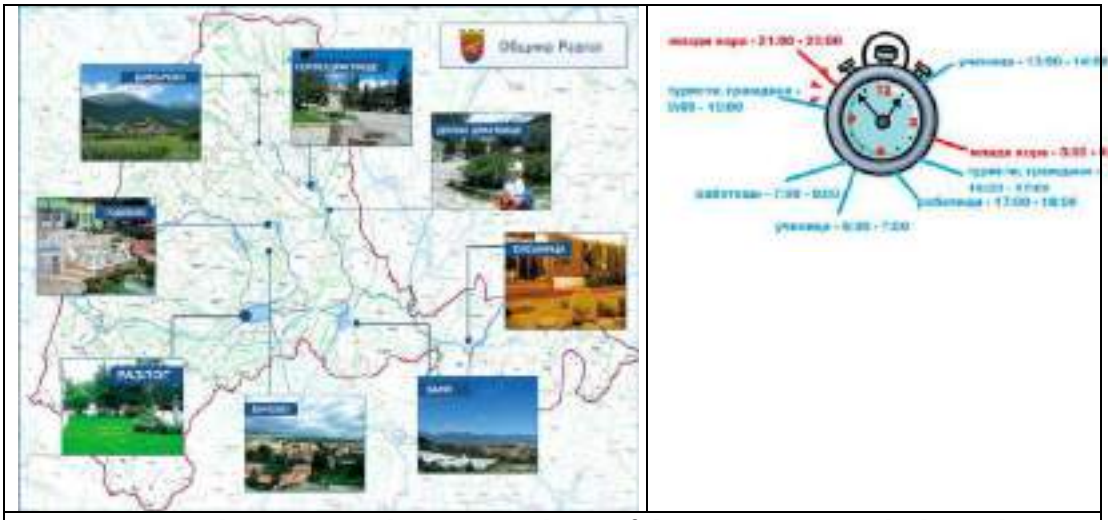

Figure 1. Razlog municipality: (a) Analysis of the tourist potential; (b) 24-hour distribution of the transport demand

Project B: MSc in Urbanism Programme, Diploma project;

Project title: Spatial concept for the development of Gabrovo municipality with a time horizon till 2035; Authors: Dimitrina Pironkova, Mila Yolova; Supervisors: E. Dimitrova, A. Burov.

The declared objective of the diploma project is the elaboration of a spatial concept for the long-term development of Gabrovo municipality (time horizon 2035), based on the estimation of available resource potential and the sustainable development concept priorities. The challenge addressed is the difficulty in sustaining high quality and attractive living environment in an inner periphery of the country - a rural area of abundant natural resources and cultural heritage yet with aging and shrinking

population and high unemployment rate, which makes efficiency issues particularly important to approach and re-formulate. The development of the project goes through several stages: analysis of the existing situation, formulation of sustainable development principles and identification of the development potential of the territory, elaboration of a spatial concept, strategy and action plan. The methodological approach applied by the project team integrates a set of integrative planning tools – (a) landscape ecological analysis, outlining the results of the interaction between local natural, social and cultural processes (Figures 1 and 2) and the identification of areas and settlements with development potential (Figure 3); and (b) back-casting, identifying development and planning priorities at consecutive time horizons with regard to the future state aimed at.

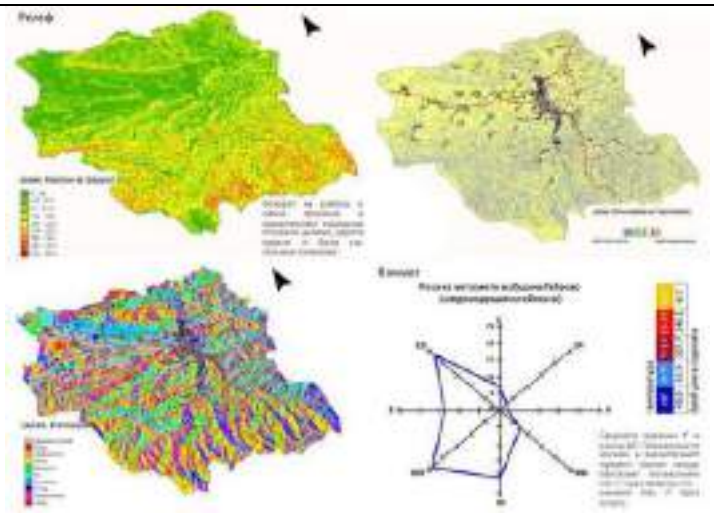

Figure 1. Analysis of the natural characteristics of Gabrovo municipality

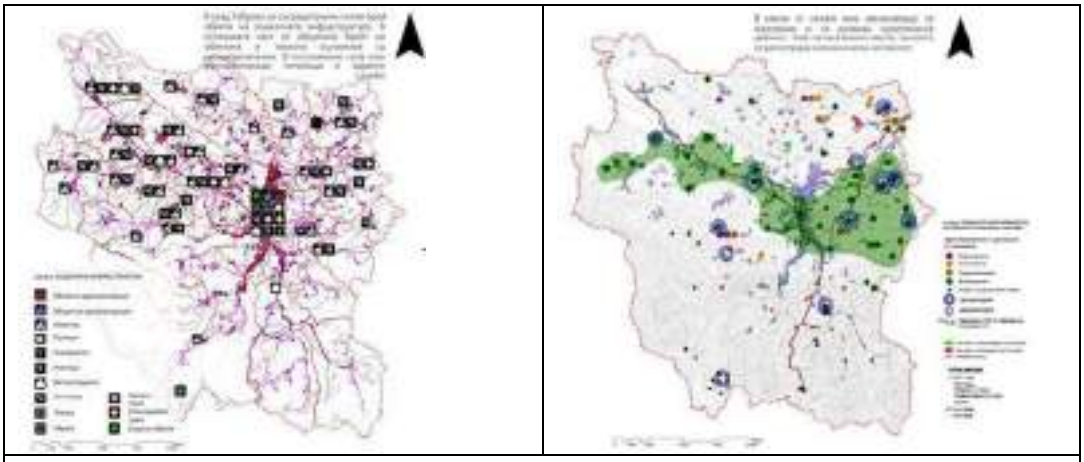

Figure 2. (a) Analysis of existing social infrastructure; and (b) Identification of settlements with development potential (economic activity, tourism development, stable/increasing population

Vision – horizon 2035:
- Competitiveness
- High quality of life
- Favourable age structure

Stages in achieving:
- Innovative technologies
- Educated population and favourable business climate
- Improved quality of the environment

Action to undertake in 2010-15:
- Information campaign
- Broad public debate

Figure 3. The 'backcasting' method applied

The project proposes a spatial concept for the development of the settlement network in the municipality with time horizon 2035 and a more detailed proposal for a fragment area with a time horizon 2015 (Figure 4). It also envisages four activity packages: (i) regeneration of the physical environment; (ii) improvement of transport accessibility; (iii) agriculture development; and (iv) landscape preservation. Each of the packages is structured with regard to priority actions recommended, funding opportunities, actors' benefits and responsibilities.

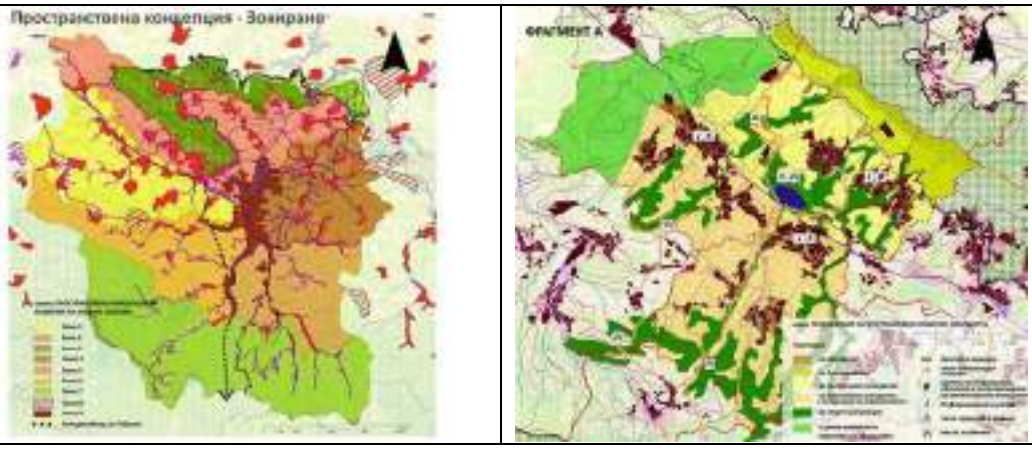

Figure 4. Spatial concept: (a) zoning proposal; (b) spatial development – a fragment

3.2. Comparative analysis of the two projects

The comparison is focused upon several characteristics of the projects: issues addressed, methodological approaches applied, factors influencing the choice of the

topic and development of the project, contacts with potential end-users and stakeholders during the project development and after the end of the project work, and the identified project potential to further contribute to planning practice, research and education (Table 1).

Table 1. Comparison of case studies

	Methodology applied	*Influencing factors/events*	*Project development potential*		
			Practice	*Research*	*Education*
A	SWOT analysis; Field observations; Survey; Interviews; Brain storming. 4. Results

Although the two projects are developed at different stages of the programme, the results of the comparison confirm a number of common factors and similarities in the development process. Neither of the projects was initially designed to explicitly focus on resource and energy efficiency issues. They were both however motivated to search for sustainable development options based on existing resources, development potential and cultural identity of the areas. As a result of the undertaken analyses the teams of both projects came to realize that providing for resource and energy efficiency is crucial to solving the identified social and environmental development problems.

The methodologies applied in the two projects were influenced by the issues addressed but they were also adequate to the professional experience of their authors. The methodological approaches of Project A are based on the initial and comparatively modest professional knowledge and skills acquired during the first year of study. The project has strongly focused upon the observation and interpretation of the real life situation (problems, needs, available resources) in the particular municipality and on the direct dialogue with stakeholders and end users. Positive and creative conceptual thinking and searching for adequate analysis and evaluation criteria and instruments are strongly encouraged. The methodological

approaches at the end of the programme (the diploma semester) build upon previous experience but also comprise much more sophisticated instruments.

Both projects have developed within the context of intensive international professional communication - in the University and in the municipalities. Students participated and were strongly influenced by the contacts – both in choosing the topics of their projects and methodological approaches to apply. Project A was developed after a series of joint Bulgarian-Flemish events organized in the UACEG, discussing issues of mobility and illustrating the implementation of. Although 2nd year students were naturally not capable of mastering and implementing the specialized software for traffic modeling in one semester, they were motivated to search for efficient solutions of the identified transport problems in Razlog municipality. The INTERREG IVC MMOVE project going on at the municipality in parallel with the course project was a chance for getting acquainted with advanced EU practice in achieving higher energy efficiency of mobility but also, by being involved in technical support to the surveys, to become aware of important social and cultural issues in the municipality. The diploma project (Project B) was developed by two graduates who had just attended the summer workshop of the Atoms & Bits project (Intensive Erasmus programme) at IUAV, Italy, where climate change and resource efficiency issues were discussed in parallel with current challenges of globalization and digital technologies; backcasting was also introduced there as an effective planning method. Joining in the international *Planning Days* event in the city of Gabrovo at the beginning of the diploma semester and getting acquainted with the landscape-ecological planning approach promoted by the Italian partners from Nichelino municipality in the EU project (MRDPW, 2008) in the municipal project, motivated the two diploma students to interpret the situation in the municipality from the broader perspective of efficiently using the territory but also the social and cultural resource in the municipality and by implementing innovative and integrated planning tools.

Although developed within different levels of the programme, both projects proved to have considerable further development potential. They were both able and motivated to provide useful feedback to planning practice – in Razlog municipality students' results were reported back to the municipality and were considered a useful source of ideas for the Action Plan currently developed. After the successful diploma defense the two graduates were invited to present their results at the regional *Location Centre* 2011 event in Gabrovo, and later on – to join in the team contracted to develop the new Integrated Plan of Gabrovo municipality. The educational process within project A also inspired a small university research project on the perspectives for implementing demand responsive transport in Bulgaria. Project B is hopefully the basis for a future PhD study on landscape-ecological planning (still to be confirmed). Both projects provided important experience in conceptualizing resource and energy efficiency while regarding broader spatial and social issues in the planning field. They confirmed that issues of resource and energy efficiency have multiple dimensions and should be much better integrated in the educational process at all levels. That was the reason for considering the possibilities for developing two new

teaching modules to be hopefully integrated into the curriculum – one addressing REE at the master level of the programme in Urbanism and the other – at the interdisciplinary post-graduate level at UACEG.

5. Conclusions

Despite the progress made there are important challenges still to face in increasing the professional sensitivity to energy and resource efficiency implications in spatial planning and in developing holistic and innovative approaches at different levels. In order to be able to cope with these challenges, spatial planning needs to re-consider traditionally applied technocratic and growth-oriented concepts and carefully re-define its objectives so that social and cultural dimensions could be effectively considered and evaluated in the planning process. The early introduction of the energy and resource efficiency topic in the planning education process is of key importance for raising professional awareness about it and for encouraging students' commitment to and motivation for developing context sensitive REE planning concepts. It seems to be of key importance all educational levels to be involved and continuity in addressing the REE issues throughout the educational process - persistently encouraged. Closer interdisciplinary communication and collaboration developed in the process would be of particular importance for applying integrated approaches to planning and evaluation and thus contribute to adequate capacity building for promoting REE in the spatial planning field.

Developing Integrated knowledge management framework for policy-making in Tehran

Vahideh Ebrahimnia[1], Asrin Mahmoudpour[2]

Abstract

Calling for enhanced integration of varying policy areas are driven from the assertions that regarding the varied and multiple agencies involved in metropolitan planning and policy-making, there are problems of communication and transfer of information. This makes these agencies to be unaware of others' aims, intentions, policies and programmes. Accordingly they may be contradictory instead of coordinated and competing instead of participating. In this context the most general purpose of policy integration, including sectoral integration, territorial integration, and organizational integration, is to improve efficiency and effectiveness by considering the consequences of policy implementation beyond the specific policy domains. More specifically, policy integration has been considered as an important mechanism for contributing to sustainable development. One vital source for setting up any mechanism towards achieving integration is knowledge. One major challenge in policy-making processes in metropolitan systems worldwide is the lack of relevant, accurate, available and integrated information which altogether makes up a knowledge base. Thus organising a knowledge base framework for policy-making, especially in the metropolitan areas that planning and policy-making is more complicated - mainly due to the multiplicity of stakeholders - can make arrangements for an integrated and probably more efficient policy-making environment which reduces duplication and lack of coordination while promotes consistency between policies. This requires knowledge management initiative that has been envisaged as a tool to integrate, store, retrieve, disseminate and manage information and knowledge plus aiming at facilitating the processes of collecting, maintaining, sharing and utilising information and knowledge. Providing a framework that integrates multiple information and knowledge in metropolitan planning will support any initiation towards integrated policy- making. Tehran is a metropolis with many decision-making agents and stakeholders with varying aims, aspirations and policies responding to their institutional agendas. This has caused incompatibility and competition among decision-makers, politicians and also decisions, per se. While there is no requirement concerning integration of the policies or the knowledge base of the policies. It is in this context that there is a need to propose a knowledge management and a knowledge base framework. The proposed framework is intended to facilitate integration, sharing and reusing knowledge to, first, ensure that all

Decision-making agencies involved in metropolitan planning use consistent information and knowledge and second, to support detecting inconsistencies among different decisions which is made at different levels of decision-making by different agencies involved in metropolitan planning and management in Tehran. Accordingly, this paper has adopted a dual aim of first analysing the existing situation of Tehran in terms of its using consistent information and knowledge in policy-making by different agents and second to envisage the ways and means of promoting knowledge and information integration Tehran metropolitan planning.

1. Introduction: Issue under study, aim and purpose

Metropolitan policy- making is a domain of intense involvement of an ever increasing variety of agendas and actors, possessing a range of interests, which make decisions at a number of different levels (Breda-Vázquez, et al, 2010). As a result, metropolitan policy- making is composed of multiple, linked decisions (Han & Lai, 2011) and the essential element of planning system in order to achieve the overall desired goals rather than the achievement of sector-orientated goals is integration of varying policy areas. In an integrated policy framework, considering the consequences of policy implementation beyond the specific policy domains, may improve efficiency and effectiveness of planning system.

In this context, the idea of integrated knowledge management framework is one dimension of policy integration (Kidd, 2007: p. 165; Stead and Meijers, 2009) which is needed to support making contradictory instead of coordinated and competing instead of participating decisions.

In this article, in one hand, the concept of Integrated knowledge management framework would be discussed and in the other hand, how planning system in Tehran could be developed on this basis of setting up and applying such a framework would be proposed to achieve the dual aim of this paper, which are (a) providing a knowledge management framework to support coordination and cooperation among all decision-making agencies involved in metropolitan planning, and (b) supporting detection of inconsistencies different decisions which is made at different levels of decision-making in Tehran.

In order to achieve these aims a method comprising a four staged process has been devised as follows and as is shown in Figure (1):

- First stage involves studying the conceptual framework produced by reviewing and summing-up the findings of the parallel experiences worldwide.
- Second stage involves analysing the current state of information and knowledge frameworks in Tehran in terms of their integration so as to find the strengths and weaknesses of such frameworks.
- Third stage, based on the conceptual framework produced by reviewing and summing-up the findings of the parallel worldwide experiences as well as the analysis done in the second stage, involves proposing a framework for an integrated knowledge management framework in Tehran.

- Fourth stage involves the application of the proposed framework in the third stage in Tehran to promote knowledge and information integration in Tehran metropolitan planning.

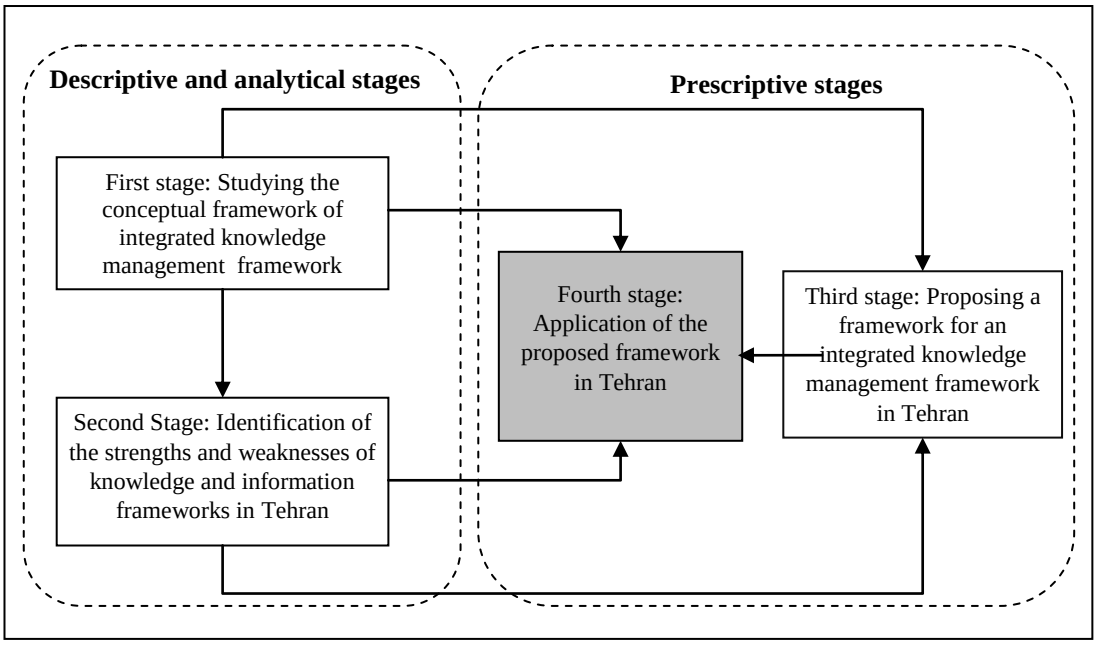

Figure 1. Flowchart depicting the method adopted in achieving the aims of this paper

2. Conceptual framework

Urban spatial planning involves making decisions and taking actions which has wide-ranging and diverse spatial information requirements. Information plays a central role in urban spatial planning.Information requirements of urban spatial planning include the collection, manipulation and analysis of spatial structure. One major challenge in existing urban spatial planning - on both fields of knowledge and practice - is the lack of relevant, accurate and available information or in other words an appropriate decision support system (DSS) along with a knowledge management framework (KMF) which not only establishes a DSS but also converts information to knowledge.

1-2. Knowledge management

For holistic understanding of knowledge management, it is necessary to intruduce knowledge. There are wide-ranging definitions of knowledge. A comprehensive definition has defined knowledge as “a fluid mix of framed experience, contextual information, values and expert insight that provides a framework for evaluating and incorporating new experiences and information” (Otim, 2006). Also, knowledge is defind from a dual perspective of practical and general, as follows (Dongsong, et al, 2002):

- Specific and practical definition of knowledge defines knowledge as applied information that actively guides task execution, problem-solving, and decision making.
- General definition of knowledge, defines knowledge as any fact, event, rule, hypothesis, or model that increases understanding or performance in a domain or discipline.

In the applied perspective "knowledge is to know when, why and which information is needed, how information could be obtained and processed, and where information can be found to achieve a desired objective" (Dongsong, et al, 2002).

Knowledge management is a concept which there is no general agreement on its definition, though some of its relevant definitions are listed below:

- knowledge management is "a discipline that promotes an integrated approach to identifying, managing, sharing, and reusing all of information assets by using advanced technology" (Dongsong, et al, 2002).
- Knowledge management is the creation and subsequent management of an environment which encourages knowledge to be created, shared, learnt, enhanced, organised and utilised (Sujit, et al, 2011).
- Knowledge management is "the practice of selectively applying knowledge from previous experiences of decision making to current and future decision making activities with the express purpose of improving the organisation's effectiveness"(Otim, 2006).
- Knowledge management is "the creation, organisation, sharing and use of knowledge for development results"(UNDP, 2007).
- Knowledge management is "about facilitating the process by which knowledge is created, shared and utilised"(Seneviratne, et al, 2010).

The process of Knowledge Management or what is known as the Knowledge Management Cycle (KMC) has three main essentials as follows (Sujit, et al, 2011):

Management: This focuses on capturing, organising and facilitating knowledge.
Application: This focuses on effective retrieval of relevant content through advanced searches and mining headed for conducting knowledge-related work and tasks.
Organizations: This focus on learning, sharing and collaborating.

Main processes of knowledge management are (Otim, 2006):
The process of knowledge creation: This can be done by (a) acquiring external knowledge, or (b) by means of creating knowledge in the process of learning.
The process of retention of knowledge: To keep knowledge available, some kind of memory is needed. Retention of knowledge refers to the process of storing knowledge and making its retrieval possible.
The process of knowledge sharing: Its aim is to make sure that (existing) knowledge is obtained and shared - or in other words knowledge disseminates or transferred - at the right place.

The process of application or use of knowledge: The other three knowledge processes (mentioned above) are supplementary to this process, i.e., the application of knowledge.

2-2. Policy- making and information and knowledge management in metropolitan planning

Knowledge management that aims at facilitating the processes of collecting, maintaining, sharing and utilising information and knowledge in policy- making can provide a framework that integrates multiple information in order to subsequently analyse and manage information.

1-2-2. The importance of information and knowledge management in policy-making in metropolitan planning

The major point about the adoption of any planning approaches, in any country or urban/metropolitan area, is that of their process, the different stages of the adopted process and the alteration of the process to the local circumstances as well as the information requirements of each of the stages. Almost all of these stages not only require spatial information but also require considerable information processing and analysis. Information requirements of the planning process, especially problem formulation and evaluation of the existing conditions, require the collection, manipulation and analysis of spatial features with the aim of being able to input in the subsequent stages of the planning process to produce plans, whether with strategic or operational nature. Not only problem definition but also problem formulation and the evaluation of circumstances require the collection; manipulation and analysis of spatial/aspatial information (Daneshpour, 2007).

The act of management requires agencies to use more detailed information for routine operations. These different requirements concerning information can "explain the existence of various specialised ad hoc systems in urban planning, such as management information system (MIS), land information system (LIS), and urban GIS".

Considering the above mentioned importance of information and knowledge, policy - making could be seen as a process of analysing information and using knowledge to resolve problems. During the policy-making process, the problems should be detected, relevant information should be gathered and the right judgment should be made so as to make appropriate decisions. In this context, policy-making is by and large faced with a variety of challenge such as (Daneshpour, et al, 2012):

- Gathering relevant information in a timely and accurate manner;
- Synchronized acquisition and analysis of distributed information;
- Reusing knowledge (or consider past experiences) to facilitate current decision making;
- Organising, sharing and managing the information efficiently; and
- Dynamically changing the situation under study.

Accordingly, using integrated, accurate, reliable and timely information has an important role in achieving the aims and objectives of any attempt related to policy-making.

2-2-2. Challenges related to information and knowledge in policy-making in metropolitan planning

One main barrier of effective planning in urban/metropolitan areas worldwide is related to their information system and knowledge base. These barriers can be listed as the following:

- Information and knowledge on disaster management are fragmented (Seneviratne, et al, 2010), widely distributed and owned by a great number of organizations/agents (Dongsong, et al, 2002).
- Information, experiences, approaches, adopted modalities and generated/created knowledge of previous planning documents remain in individual or institutional domains and are not usually translated to and transformed into applied knowledge for future policy-making for the communities (Seneviratne, et al, 2010; Sujit, et al, 2011).
- Information and knowledge coordination, sharing and creation on any stages of policy-making and planning is usually inadequate and ineffective (Seneviratne et al, 2010).
- The linkages among all agencies involved in metropolitan policy-making is usually weak and inefficient and this fact inhibits an efficient management approach and an integrated and an appropriate coping mechanism (Sujit et al, 2011).

3-3-2. The functions of knowledge management Frameworks in metropolitan policy-making

Though there is no way of integrating all aspects of metropolitan policy- making, efforts can be made to integrate and manage their information and knowledge requirements. knowledge management can undoubtedly maintain a decision-support system for planning in urban/metropolitan areas. This will have possible consequences for all levels, forms and aspects of decision-making, including urban/metropolitan planning. In this respect, some functions of knowledge management frameworks can be listed as below:

- Knowledge management frameworks can act as a tool to store, retrieve, disseminate and manage information related to urban/metropolitan planning (Sujit, et al, 2011).
- Knowledge management frameworks can facilitate the entire process of acquisition, sharing, management, and utilisation of information and knowledge for the support of urban/metropolitan planning processes (Dongsong, et al. 2002; Otim, 2006).
- Knowledge management frameworks can avoid repeating past errors of practice, highlight good practice to be replicated and make lesson-learning (UNDP, 2007).

- Knowledge management frameworks make it possible to learn from and leverage past experience in the management of current problems (Otim, 2006) and to build a culture of learning from previous lessons and the adoption of best practices in urban/metropolitan planning processes (Seneviratne, et al, 2010).

3. Analyzing the current state of metropolitan policy-making related information and knowledge in Tehran

Tehran, as the case study of this paper, is a metropolitan with many agencies which are involved in policy- making. The content, quality and especially integration of policies which is made in different agencies play / have important role in the life of its residents. This has been one of the most important challenges of the country generally as well as in planning, decision-making and managing this city. This requires not only an integrated method of planning and management but also an appropriate information system and knowledge base for the two areas of knowledge and practice. Information required for policy-making in Tehran is fragmented and is in the possession of diverse agencies/organisations. This is while this information system and knowledge base is not capable to be converted to an appropriate DSS and KMF.

The lack of reliability, consistency and coordination of urban/metropolitan planning related information and knowledge in Tehran has stemmed from factors such as (a) administrative inefficiencies, (b) resource limitations, (c) the shortage of skilled personnel and technical expertise and (d) the lack of funding or political will to support the construction of an appropriate and integrated DSS and KMF system. These factors, in addition, reflect a disapproval of the policy makers; urban planners and managers for the different aspects of application and importance of information systems and knowledge basis in any urban/metropolitan planning activity especially when continuance and sustainability reveal themselves as important agendas, locally and internationally (Daneshpour, 2007).

The main challenges of urban/metropolitan planning processes related information and knowledge in the case of Tehran can be listed as below:

- There is a large gap between the goals and priorities of different agencies/organisations which are involved in Tehran's policy-making. In other words, policy- making - as a vital part of planning activity - has been done without due consideration to integration between main actors.
- While there are many formal and informal sources of information in any urban/metropolitan area of Tehran, the official procedures are usually incapable of sharing and integrating necessary information to support policy-making, planning and managing in Tehran.
- Besides information deficiency in cities, there are many concealed and unused information potentialities that not included in or part of an established and effective DSS and KMF system.
- There is varied and multiple agencies/organisations involved in different stages of policy-making which perform the tasks such as research and action.

Accordingly it can be deduced that the information and knowledge required for operating policy- making within the broad context of urban planning in Tehran is fragmented.

- There is the lack of information and knowledge coordination at the different stages of urban/metropolitan planning in Tehran.
- Agencies involved in urban/metropolitan planning in Tehran have their own information sources, while others are not aware of the available information of the other agencies that might aid them and provide a support system for their task of policy-making.
- There is not relevant, accurate and available information system and knowledge base concerning urban planning in general and policy-making in particular in Tehran.

These challenges could be discussed in terms of the main processes of knowledge management (Table 1).

Table 1. Tehran metropolitan policy – making status in terms of Main processes of knowledge management

Main processes of knowledge management	Tehran metropolitan policy – making status
The process of knowledge creation	• Lack of relevant, accurate and available information system and knowledge base concerning urban planning in general and policy-making in particular.
The process of retention of knowledge	• Lack of mechanisms of knowledge upgrading, including agreed upon periods of knowledge upgrading. • existence of concealed and unused information potentialities that not included in or part of an established and effective DSS and KMF system.
The process of knowledge sharing	• Incapability of the official procedures in sharing and integrating necessary information, produced in many formal and informal sources of information • Lack of information and knowledge coordination at the different stages of metropolitan planning in Tehran. • Unawareness of agencies involved in metropolitan planning in Tehran the available information of the other agencies that might aid them and provide a support system for their task of policy-making.
The process of application or use of knowledge	• Lack of consideration to integration between main actors involved in Tehran metropolitan policy-making. • Incapability of varied and multiple agencies involved in Tehran metropolitan planning in using fragmented information required for operating policy-making.

4. Proposing a framework for an integrated knowledge management Framework for policy-making in Tehran

Knowledge management Framework in this paper has been envisaged as a tool to share, integrate, store, retrieve, disseminate and manage information and knowledge related to urban/metropolitan planning in Tehran. The main functions of knowledge management Framework in urban plannig process of Tehran are to enhance and develop the integrated policy-making and to support decision making within the urban/metropolitan planning context. Using comprehensive, integrated, accurate and reliable information and knowledge in this city may enhance the process of urban planning, and the quality of policies which is made in Tehran.

Two essential principles for establishing an appropriate information and knowledge management framework for integrating policy-making and supporting decisions making in urban planning context of Tehran are first defining the purpose of the framework, and second investigating the existing information system in Tehran in order to integrate the two (UNDP, 2007). In Tehran the main proposes of the proposed knowledge management Frameworks are:

- Integrating multiple information and knowledge related to metropolitan policy-making in order to subsequently analyse, manage information and create knowledge.
- Integrating sector-orientated policies of different agencies involved in urban planning activity.

Establishment of a knowledge base can facilitate the processes of knowledge creation, knowledge sharing, knowledge integrating and use of knowledge among the different stages of urban/metropolitan planning process and all agencies involved in the process. Such a knowledge base insures / support achievement of managing information and knowledge and knowledge management framework proposes in Tehran.

5. Application of knowledge management framework for policy-making in Tehran

A comprehensive knowledge management Framework is presented here in support of integrated policy-making in metropolitan area of Tehran. The core of the proposed framework is the knowledge base with a set of involved knowledge management processes for knowledge acquisition, organisation, creation, sharing and integrating. This knowledge base must evolve incrementally over the time (Figure 2).

The proposed framework is intended to facilitate integrating, sharing and reusing knowledge in order to support integrated policy-making in metropolitan planning in Tehran. The proposed framework - as a comprehensive, consistent and dependable knowledge base which will facilitate managing knowledge - can help achieving an efficient and effective urban/metropolitan process which can be integrated in order to

reduce making the contradictory, inconsistent and conflicting polices and to improve efficiency and effectiveness of planning system in Tehran.

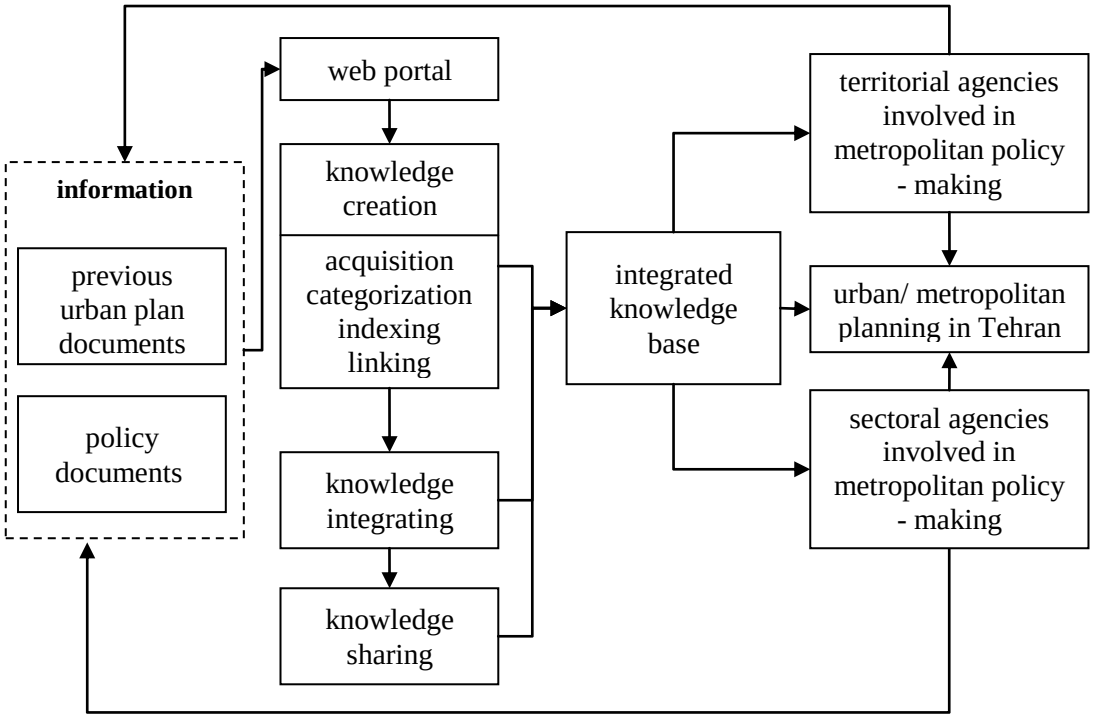

Figure 2. The proposed knowledge management framework of integrated policy-making in metropolitan planning process of Tehran

6. Conclusions

One important point about using the methods devised in the more developed countries of the world is that general principles and analytical tools that have been developed there is not feasible in the less developed countries of the world without considerable modifications and adaptations. So there is a need to develop new approaches to launch an appropriate decision support system (DSS) along with a knowledge management framework (KMF), appropriate to the varying conditions.

Knowledge management framework, in this paper, is envisaged as a tool to integrate, store, retrieve, disseminate and manage information and knowledge related to policy-making in urban/metropolitan area. Policy-making activity involves merging a variety of information in order to analyse the different elements of the applicable spatial structure and their interaction. Integration of incoherent, incomplete and dispersed information that have diverse information sources can reduce information gaps and strengthen the decisions to solve problems in an urban/metropolitan area.

This paper made an attempt to present a comprehensive knowledge management framework in support of policy-making process within a broader context of urban/

metropolitan planning. It advocates multiple knowledge management processes that create, maintain and share the knowledge, provide consistent support to decision-makers and recommend possible solutions based on the knowledge base which includes the past experiences and other agencies' decisions. In addition, being aware of other sectoral / territorial agencies decisions, may provide them with the necessary requirements of avoiding from making incompatible, contradictory, and conflicting policies. Summing up, such framework provide an important element of an integrated policy making in Tehran metropolitan planning.

The proposed knowledge management framework is intended to evolve incrementally while the framework must allow the urban/metropolitan agencies/organisations to transcend the existing limitations and redundancies created by fragmented information and knowledge.

RESPONDING TO NEOLIBERAL RAILWAY POLICIES IN SUB-SAHARAN AFRICA

Douglas Kolozsvari
Ph.D. Candidate, Urban & Regional Planning
University of Michigan

Abstract

Colonial railways play key roles in many less developed countries (LDCs), particularly in sub-Saharan Africa (SSA) where transportation infrastructure—of any mode—is relatively sparse. Colonial powers built scores of railways in SSA, but these lines have generally fallen into disrepair since independence despite the important and mostly unmeasured contributions they make to the urban and rural areas they serve. In fact, researchers and practitioners often portray colonial railways in a negative light because they require subsidies for operations or to rehabilitate infrastructure. Typically, the only time these railways receive praise is for their ability to transport bulk goods, which raises critiques of neocolonial resource extraction. Very few researchers call attention to railways' potential benefits including their contribution to food security, education, public health and safety, household wellbeing, affordable public transportation, and the environment. Using a review of the literature, official reports, newspaper articles and interviews with key actors who have participated in railway rehabilitation, this paper calls attention to colonial railways' benefits that have been mostly disregarded.

This paper also scrutinizes why railways continue to diminish despite their benefits. It argues that ideological framings within the development and transportation fields have unduly influenced railway service in LDCs. Namely, SSA lines have not fared well under these fields' positivist framings. Positivism, particularly in transportation planning, has promoted the view that decisions can be made objectively and that efficiency (e.g., economic) is the ultimate guiding principle. The overwhelming core of transportation planning research is positivist in nature and mostly concerned with empirical observation, predictive models and data analysis (Simon 1996; Willson 2001). Flyvbjerg notes that although "many planning researchers consider positivism a long-dead phenomenon of the 1960s and 1970s," others have argued that positivism has decreased "only on the surface of things" (Flyvbjerg 2004).

International development institutions (IDIs) have largely grounded their evaluations and policies in positivist terms. Their adherence to positivism manifests itself in what many experts, particularly critics, have termed neoliberal theory. Neoliberal adherents believe in free market resource allocation and the removal of "state 'distortions' of markets" (including transportation subsidies) so as to create the conditions for macro-scale economic growth and prosperity (Ferguson 2006; Murray and Overton 2011). Notwithstanding this goal's appeal, this paper demonstrates how neoliberal perspectives systematically disregard or undervalue important dimensions of railway service simply because they so often require governmental support.

This paper concludes by discussing the application of Friedmann's conception of *alternative development* to the transportation sector (Friedmann 1992). Whereas neoliberal evaluations feign objectivity despite their underlying normative motivations, alternative development openly embraces a substantive rationality. This paper considers how this more humanist model built on a "moral justification" and its espousal of "inclusive democracy" can change transportation decision-making processes in LDCs as well as the perception of colonial railways. This examination also facilitates the discussion of the compatibility or incompatibility of the neoliberal perspective with democratic participation in transportation decision-making.

1. Introduction

Colonial railways play key roles in many less developed countries (LDCs), particularly in sub-Saharan Africa (SSA) where transportation infrastructure—of any mode—is relatively sparse. Colonial powers built scores of railways in SSA, but these lines have generally fallen into disrepair since independence despite the important and mostly unmeasured contributions they make to the urban and rural areas they serve. Very few researchers call attention to railways' contributions to household wellbeing, food security, education, public health and safety, social stability, cultural heritage, and environmental protection. In fact, researchers and practitioners often portray colonial railways in a negative light because they require subsidies to operate or maintain. Typically, the only time these railways receive praise is for their ability to transport bulk goods, which may make them "profitable" but also raises critiques of neocolonial resource extraction. It is unsurprising, therefore, that so many railways in SSA which provide tangible benefits yet run a deficit are in poor shape or have already closed.

Articulating the many benefits provided by colonial railways raises the question about why these factors are rarely considered in transportation investment decisions affecting them. Many benefits outlined here are not easily measured or have complex causal connections to railways. Transportation planning is highly positivist and mostly concerned with empirical observation, predictive models and data analysis (Simon, 1996, pp. 2, 35; Willson, 2001, p.22). The social sciences largely view transportation planning as "unimaginative" or "technical" due in large part to the transportation field's strong disciplinary "ethos of 'rational science'" that focuses on technical design issues, empirical measurement or analyses using an uncritical lens of neoclassical economics (Simon, 1996, p.1). This prevailing positivist emphasis, particularly with an emphasis on financial performance, has been readily apparent under what many experts, particularly critics, have termed neoliberal theory.

Neoliberal theory also adopts an ideological stance whereby the state and public are largely removed from decisions about transportation services, and this has unduly harmed colonial railways. Although the same actors pushing neoliberal policies have increasingly made an effort to involve the public in transportation service decisions in LDCs, it is not certain that these efforts are effective or even intended to serve the public interest. Powerful actors who influence transportation decision-making

processes in LDCs, particularly international development institutions (IDIs), have largely set the goals and determined the measures that will be used to determine whether a colonial railway merits support.

This paper draws upon a review of the primary and secondary sources as well as interviews with focus groups and key actors who have participated in the rehabilitation of the Fianarantsoa-Côte Est railway (FCE) in Madagascar to better understand the worth of colonial railways and how their value has so often been minimized. The next section discusses the general trajectory of colonial railways in SSA and is followed by a section highlighting the underappreciated benefits that many of these railways provide. The subsequent section provides a discussion on neoliberal theory and how it impacts railways. This paper concludes by looking at how alternative development perspectives could help correct the neoliberal ideology that biases evaluations.

2. Railways in SSA: From Robust to Rust

Railways played a large role in colonial powers' development vision for SSA. At the time, colonial railways received extensive and often uncritical support that enabled their realization. Governments helped secure loans and laborers for railway construction while contending that these lines would enable indigenous populations to live in civilized, developed territories. Colonial administrators sometimes claimed that their greatest contribution to material welfare in Africa was the development of new markets through their investment in transportation technology (Austen and Headrick, 1983, p.177; Moore and Vaughan, 1994, p.135). Colonial supporters and critics alike also saw railways as key to ending the backbreaking practice of porterage that caused the abuse and suffering of many indigenous people (ILO, 1927, p.61; cf. Pourtier, 2007, p.192).

In reality, colonial railways were not the humanitarian endeavor their proponents sought to portray them as. Indigenous people suffered and died in great numbers while working as forced laborers to construct these railways. Colonial profiteers and administrators strongly lobbied their governments to recruit these workers and to provide financing because these transportation infrastructures facilitated the exploitation of new territory and the transport of their merchandise. Governments surely found it desirable to support their national railway manufacturers and the contractors who built these lines. Local administrations strove to make their territories economically self-sufficient at a minimum and, ideally, generate a surplus production for export (Sharp, 2003, p.78). The footprints of these railroads, which almost invariably run from the countries' ports to strategic hinterlands, reveal the desire by colonial powers to assert political and military control, access natural resources and create new markets for their own economic advantage (Hilling, 1996, p.77; Simon, 1996, p.50; Gray, 1999, p.87; Pourtier, 2007, p.192).

The end of colonialism removed a major source of financing as well as some of the initial justifications for subsidizing their infrastructure and operations. These

railways had long depended upon colonial subsidies for operations and free indigenous labor for maintenance and renewal projects. Even "profitable" railway operations received government subsidies for infrastructure rehabilitation work and rolling stock replacement. Many railways had also benefited from colonial policies prohibiting roads from directly competing with these lines (Taaffe et al., 1963, p.513). Newly independent countries largely eliminated these policies, and some even built trunk roads that duplicated railway routes and cut into their revenue (Griffiths, 1995, p.186). This made railway maintenance work even more challenging, which led to a "downward spiral" where lines' decreased reliability further increased the appeal of road-based travel and a further decline in revenue (Hilling, 1996, p.110).

Keeping the trains running in SSA has been anything but simple without their former resources and due to their declining ridership. Harsh climatic conditions present a pervasive challenge to maintaining railway service – particularly in the tropical counties where intense tropical storms frequently cut lines by causing landslides and washouts. Armed conflicts have led to the destruction of railway infrastructure. Even standard use has taken its toll on infrastructure and rolling stock, because the lack of functional transport options has meant overloading – resulting in broken axles, cracked rails and failed traction motors. The lack of domestically produced equipment and spare parts, particularly in SSA, has increased the expense of maintaining these lines because everything must be imported (Moriarty and Beed, 1989, p.128). Those railways that remained open following independence had to defer essential maintenance and cut back on service.

While all countries have limited budgetary resources for transportation provision, the gaps between LDCs' resources and their transportation needs are indeed greater than in developed countries. This is particularly true in SSA where governments have had to make tough decisions on how to allocate scarce resources. The relatively high costs necessary to maintain even basic railway operations and their geographically concentrated benefits may explain LDCs investing more on roadways. Railways not only vie for their share of renewal funding against other transportation investments, but also compete against other publicly funded services such as healthcare, education and security. In many cases, governments have had to borrow money from international development institutions (IDIs) to keep railways running. Yet these funds would only be provided if the railways (and governments) met the stipulations of these IDIs. This has shaped the outcome for many railways, including leading to many of them being closed.

These financial and external pressures have not benefited SSA railways. Railways extend roughly 90,000 kilometers across the African continent (Pourtier, 2007, p.190) and serve tens of millions of people.[1] When one looks at the broader statistics

[1] Just three colonial-era railways, the Republic of Congo's Congo Ocean Railway, the Democratic Republic of Congo's Matadi-Kinshasa Railway and Angola's Benguela Railway, serve populated areas totaling more than 11 million people.

of roadway and railway provision in LDCs, though, each country added thousands of kilometers of paved roadways in the first three decades after independence whereas at least half of their trackage figures actually declined (Simon, 1996, p.18-19). Even the conditions on some of the largest railways can be extremely poor (Hilling, 1996, pp.104-105). Railways in SSA have suffered steadily declining ridership, which is sometimes attributed to a lack of demand or a lack of available rolling stock (Bullock and Gwilliam, 2010, p.233). Regardless of the reasons, it is clear that fewer railways still provide passenger transport service.

3. The Benefits of SSA Railways

Even as railways have disappeared, their importance has not necessarily diminished. Gakenheimer notes that existing transportation systems in LDCs are woefully inadequate to serve existing demand (Gakenheimer, 1999, p.673). Many colonial-era railways continue to serve as the backbone of national or regional transportation systems and they support the livelihoods of millions of people. The lines that still do offer passenger service act as lifeline transportation service for vulnerable populations. Simon notes, “rail transport, both intraurban and interurban, forms an integral part of many poor countries’ transport systems and is utilised particularly by the poorer segments of the population, for example, long-distance migrants and commuting workers” (Simon, 1996, p.23).

Railways are often measured by their national economic impact (i.e., GDP), but they clearly stimulate local economies and preserve livelihood in rural areas. Examining the benefits these railways provide at the household and individual level makes this especially clear. Individuals make their living by working for these lines, by transporting their wares on them or even by selling goods to their passengers. This injects valuable cash into the local economy and allows households to pay for education, medicine, clothing or other products of primary necessity (PPN) such as lighting fuel, salt or staple foods. In the case of the FCE railway in Madagascar, nearly 100,000 people depend on railway for their livelihood – mostly because if there were no train, many villagers would not be able to get their goods to market (Freudenberger, 2003, p.140). In Mozambique, the railway increases the revenue of local farmers and merchants more than if they relied solely on the local market (Béranger, 2006, p.350). This has proved essential for reducing malnutrition by providing revenues to the population selling their agricultural products (ibid., p.355).

Evaluating the financial benefits of shipping goods on a railway versus other modes is a complicated task. Railways are recognized for their ability to ship goods at a lower cost than competing transportation modes, particularly for line-haul traffic on mineral lines (Bullock and Gwilliam, 2010, p.235). Their usefulness and value are shown in the number of colonial-era railways still serving a large private interest such as a mine or logging concession (Simon, 1996, p.17). Bullock and Gwilliam rightly point out, though, that the savings are not necessarily as clear for general freight that must still be transferred from the railway to their ultimate destination by other means (ibid.). Yet decreasing railway service would raise the price of

transporting all goods on the roadways (Béranger, 2006, pp.349-350), which would have a particularly significant impact on smallholders' profits. Evaluating these shipments must happen at an individual level and considerable variation will occur based on such variables as the weight of the good, the quantity being shipped, how it is stored (e.g., crates, containers, sacks, etc.) how perishable the good is, the distance traveled, etc.

When these lines run well, they often reduce the cost of goods imported to villages. Conversely, a reduction of train service can increase the price of consumer goods either from a lack of alternatives or a lack of competition. In villages not served by a paved roadway, the railway serves as the "regulator of exchange and the prices of foodstuffs" (Béranger, 2006, p.350). When the FCE railway service is cut due to a derailment or landslide, the price of PPN increases dramatically. After a series of cyclones halted train service on the FCE, the price of rice in village shops increased by 30 to 50 percent overnight (Freudenberger and Freudenberger, 2002, p.189).

Railways also increase household security by maintaining connections between families across great distances. In countries with little to no social safety net, personal relationships provide a lifeline to families in both rural and urban areas. Railways help structure urban-rural relations by acting as an economic regulator, an integrator and a means of repatriation (Béranger, 2006, p.355). For example, many rural communities have no educational offerings for children beyond the primary school level. Households can afford to send their school-aged children to secondary schools and universities because the fares on a public service are affordable and because they can furnish them with food they have grown themselves. Rural households can also send food to relatives and friends in need of support. Urban migrants also maintain connections to their rural families, which they support through remittances (World Bank, 2010, p.126). This support can be reciprocated, if necessary, with medicines, money or consumer goods not available in the countryside. Moreover, railways can help maintain these connections for less money than by roads.

For decades, IDIs have assumed that roads could provide these same or superior benefits to household livelihood. In practice, though, road-based travel can actually have a regressive effect. While it is possible for trucks to meet all the needs of village households, road-based transportation may be more expensive. Many villagers living along the FCE prefer the railway to road-based travel because the former is cheaper (Men's focus group interview, Tolongoina, 23 September 2009). They can ship one box, basket, luggage or chicken at a time and the money saved in transportation costs benefits the entire household. With the exception of clients regularly transporting large amount of merchandise, train users pay the same fees and the price structure does not depend on market fluctuations dictated by profit maximization.

Road-based alternatives exist, but middlemen often maintain a monopoly in bringing goods to market. Sometimes the state of road infrastructure can create a monopoly situation. Villagers along the FCE have noted decrepit road bridges can block out

very large trucks (Men's focus group interview, Sahasinaka, 18 September 2009). Small road bridges have been sabotaged in Madagascar to create monopoly situations where large truck operators can continue to serve villages and block out smaller vans and cars that can no longer reach these areas. So although the train may be said to have a monopoly along its route, political pressure and the goal of public service usually keeps the fares low. Gwilliam et al. (2010) note that one of the biggest passenger transport challenges in urban settings is that minibus cartels "self-regulation" means that supply is often "inadequate and expensive" (Gwilliam et al., 2010, p.224).[2] They also allude to this monopoly power that road-transport service providers have in rural communities (ibid., 223). As Simon notes, "unbridled competition is often no more desirable or efficient than total regulation" (Simon, 1996, p.170).

Breaking these monopoly situations would seem like an option if the roads were well maintained, but the ability to purchase, operate and maintain a motor vehicle is also out of the question for the vast majority of rural households. Even a bicycle is a luxury only the most prosperous social strata can afford in Mozambique (Béranger, 2006, p.347). It is also important to ask whether it is responsible to encourage more automobile use in a climate of ever-increasing fuel prices? While fuel prices affect public transportation too, these increases are spread out among more users.

Railways may also offer geographical benefits such as leading to greater population densities than along roadways. In Mozambique, districts with a railway presence had a much higher average density than those areas served exclusively by roads (ibid., p.343). The denser development along railways enables the state to save money on public services while providing those people living in railway-adjacent communities with the opportunity to participate in regional markets (ibid., p.344). Dispersing the population more—moving them farther from health services—increases healthcare-related costs for everyone and likely adversely impacts people's health. The accessibility of services may in fact help stem urban migration to already overburdened cities (ibid., p.343).

When villagers must go to the city for such needs as medical attention, the railway provides a relatively dependable and cheap means of doing so. Many roads become impassable during certain times of the year, making this mode less predictable. Moreover, when someone needs medical attention, they don't have to rent out an entire taxi-bus (if this is even an option) to evacuate a person to more sophisticated healthcare facilities in the urban areas (Women's focus group interview, Tolongoina, 22 September 2009). Women in Tolongoina stated that about 20 pregnant women go to the major regional hospital each year to deliver. The ones who cannot wait for the train will have to rent a car for 100,000 Ariary, which is equivalent to 50 working-day's worth of pay and is roughly five times the standard railway fare (ibid.). This

[2] "Self-regulation" may be a more politically palatable way of saying colluding.

could be why in Mozambique, the regions served by rail rather than just roads have a higher life expectancy and lower infant mortality rate (Béranger, 2006, pp.340, 344).

Railways also play an important function in keeping accidents to a minimum. Roadway accidents are significant cause of death in Africa. If railways and roadways were compared for safety, roadways would lose almost every time no matter how the numbers are parsed (Simon, 1996, p.179). Chilson's book *Riding the Demon* describes the fear that grips many Africans when they use the roads (Chilson, 1999, p.15). Gakenheimer attributes the risk to "weak driver discipline" (Gakenheimer, 1999, p.675). Yet the state of the vehicles and roadways also surely contribute to the risk, which comes at such a high price. Simon notes, "apart from the overall cost in terms of lives, medical treatment, damage and repairs, among the dead are many religious, political and business leaders and other professionals for whom long-distance work-related travel is regular. Developing countries can ill afford to lose so many skilled people" (Simon, 1996, p.179). On a continent that suffers from extremely high accident fatality rates, railways provide a relatively safe alternative for users to carry out business and personal activities.

Railways also protect the infrastructure investments because their ability to carry heavy loads reduces damage to the existing roadway network. A railway closure would likely shift such traffic to roads, but this comes at a price for society at large since heavy trucks do the most damage to roads. When they are overloaded, particularly during bad weather, they accelerate roads' degradation. Roadwork costs are increasing due to a lack of competing contractors and rising inputs, which some researchers suggest are likely to remain on an upward trajectory (Gwilliam et al., 2010, p.225). Fossil fuel costs also play a large role in the costs of roadwork both for powering the equipment needed to construct roads, but also for the asphalt used to pave the road – and these costs will continue to rise along with oil prices.

Railways also provide key environmental benefits and are recognized as the "more environmentally-friendly mode" of transportation in a Western context (Caïd 2006). This can also apply to SSA depending on how the railways are used and the alternatives that exist. If a mine or a lumber operation is going to operate anyway, it is better to put these materials on a single train rather than many trucks. This is because a railway is highly fuel-efficient when its rolling stock is used efficiently. In addition, both motor vehicles and railways run on refined fossil fuels, much of which is actually imported. Reducing fuel consumption therefore reduces greenhouse gas emissions even from reducing fuel shipments.

Railways also produce secondary environmental benefits. A dispersed population potentially increases the footprint of agricultural or urban development (Béranger, 2006, p.344). Moreover, ensuring a reliable train service allows farmers producing cash crops to eschew expensive transportation alternatives or avoid turning to subsistence production. An analysis of the FCE railway in Madagascar shows its operation protected nearly 100,000 hectares of tropical forest that holds some of the most unique biodiversity in the world (Freudenberger, 2003, p.141). Freudenberger

notes that "the [FCE] railway actually facilitates control over natural resources exploitation by centralizing transport rather than dispersing it among a multitude of small carriers, as happens with road networks" (ibid.).

One of the most challenging benefits to evaluate railways' worth is their less tangible impact on culture and society. Indigenous populations paid a hefty price for these colonial railways. Building a railway demanded thousands of men over many years. Jones puts it succinctly when he states, "the main thing that the railroad consumed in Africa was labor" (Jones, 2002, p.xix). Railway projects involved physically demanding and dangerous work including blasting, trenching, grading and tunneling. Colonial powers frequently realized railway projects only by forcing the indigenous population to build the infrastructure on which future trains would operate. Colons used forced labor for many activities, but one observer found that "the evils associated with forced labour are generally found to be most intense" on large public works projects, including constructing and even maintaining railways (Goudal, 1929, p.634). Railway projects came to epitomize many of the abuses associated with colonialism: "their size and the number of workers employed on them, besides bringing them more to public notice, has special dangers which are less evident in other cases of compulsion, and the literature on this subject is particularly unhappy reading" (ILO, 1929, p.246).

Users of the FCE, though, actually used its lamentable past to unify people behind its protection, which benefited the entire country. During the 2002 political crisis when bridges across the country were being bombed, villagers actually camped out at bridges and tunnels along the line for up to four months to prevent saboteurs from attacking these vital infrastructure points. Many of these men attributed their actions to the sense of heritage and the sacrifice of their ancestors to The heritage value of the FCE actually led many villagers along the line to protect its vulnerable infrastructure points. One only need look at the conflicts and wars that have closed or interrupted railway links in Angola, Côte d'Ivoire, Eritrea, Ethiopia, Mozambique and the Republic of Congo to see the very real threat to the FCE (Bullock and Gwilliam, 2010, pp.229, 232).

If a railway can bring people together, can the lack of one lead to conflict? This is a difficult question to answer given how intertwined causality is with other factors at play in pushing a "fragile state" into an armed conflict.[3] Sometimes the benefits of a railway system are only noticed once a railway closes, such as the case of the Sierra Leone Government Railway (SLGR). The World Bank made the closure of the SLGR a loan condition for a highway infrastructure project (Abraham and Sesay, 1993). This requirement did not trouble the government; President Siaka Stevens

[3] The World Bank calls certain countries "fragile states" if they are "low-income countries that face particularly severe development challenges, such as weak governance, limited administrative capacity, violence, or the legacy of conflict" (Briceño-Garmendia, Smits and Foster, 2008 in Foster and Briceño-Garmendia, 2010, p.51).

purportedly wanted to uproot the railway because it provided an important economic link to the constituents of his political rivals (Richards, 2001, p.71). Richards suggests that cutting off railway service only served to alienate the area from the rest of the country and enable the Revolutionary United Front to build an alternative regime 'from below' (Richards, 1996, p.140). Shortly before his death, former-President Stevens stated that the only decision he regretted making during his presidency was closing down the railway (Abraham and Sesay, 1993, p.120). Although there is no evidence to confirm whether the World Bank also came to regret this decision, clearly the costs of the country's lengthy civil war and post-conflict reconstruction cost the government, its people and the international community many times the savings of closing the railway.

4. The Partiality Hiding Behind Rationality: Neoliberal Theory and Railways

If colonial-era railways in SSA provide so many benefits, why have they been closing down with ever-increasing frequency? A major reason for this can be attributed to prevailing ideologies guiding development and transportation decision-making as well as the power of those who adhere to them. Namely, the prevailing values and rationalities of modernization theory, and the more recent neoliberal theory, continue to drive transportation decision-making processes in LDCs. These two theories have strong roots in the ostensibly positivistic fields of engineering and economics. Flyvbjerg notes that while "many planning researchers consider positivism a long-dead phenomenon of the 1960s and 1970s," others have argued persuasively that positivism has decreased "only on the surface of things" (Flyvbjerg, 2004, p.286).

Unfortunately for those users who rely on them, colonial-era railway benefits are frequently overlooked or discounted in positivistic analyses. Especially prominent is the assumption that higher measures of economic growth on a national scale (e.g., GDP or GNP) translate into increased development (Friedman, 1992, p.38).[4] Easily calculated measures appeal to the transportation field's prevailing disciplinary culture that tends to elevate presumably neutral and objective forms of quantifiable information above all others. As such, transportation experts and professionals tend to focus on design issues, developing better performance measures and crafting ever-more sophisticated models for analyses aimed at explaining the transportation systems we have or ought to have when using "rational" criteria. Simon notes that positivism, rational science and modernization theory "form the conceptual foundation of the major international financial institutions and development agencies, like the IMF, World Bank and regional development banks, and most UN agencies" that impact transportation decisions (Simon, 1996, p.35).

[4] Such metrics can be instructive when used appropriately and critically. Many times, though, an average is used to mask serious inequity (Rodney, 1981, p.15).

The transportation field has fallen victim to what Flyvbjerg calls the "rational fallacy." The rational fallacy "consists of raising analysis and rationality into the most important mode of operation for human activity, and allowing these to dominate our view of human activity: so much so that other equally important modes of human understanding and behavior are made invisible" (Flyvbjerg, 2001, p. 23). Indeed, by focusing so heavily on measures, models and technical processes, the transportation field too often leaves concealed the true genesis of planning decisions. This does not mean that those attributes the transportation field has traditionally investigated do not matter. Flyvbjerg asserts, "we should not criticize rules, logic, signs and rationality in themselves. We should criticize only the dominance of these phenomena to the exclusion of others in modern society and in social science" (Flyvbjerg, 2001, p.49). Correcting the rational fallacy requires transportation experts to carefully scrutinize such factors as the actors involved, their interaction with each other, their explicit and implicit motivations, and the ways they impact transportation provision.

The temptation to continue to follow a "positivist" (and purportedly objective) approach instead of a normative one, though, is strong because it can provide the various actors involved in transportation decision-making with some political advantage or cover (Simon, 1996, pp.56-57). Although portraying their goals as consistent with positivist ideals of rationality and objectivity, neoliberal adherents are motivated by specific ideological positions that are far from neutral. They believe free market resource allocation and the removal of "state 'distortions' of markets" (including transportation subsidies) will create better opportunities for macro-scale economic growth and prosperity (Ferguson, 2006, p.11; Murray and Overton, 2011, p.308). Following the Washington Consensus in 1980, the predominant development agenda of neoliberalism called for this "disengagement of the state" (Diouf, 1997, p.309) and "structural adjustment" policies limited the types of transportation projects that LDCs could fund (Hilling, 1996, p.317). The prevailing neoliberal ideology that governments should participate as little as possible in transportation provision means that colonial-era railways, which usually require some form state support, has remained strong.

An influential World Bank publication called *The Railways Problem* provides an insightful look into how the language and ideas of neoliberalism specifically affected railways. In this report, the Bank took the position that governments needed to take action on railways because they had "become a bottleneck to development as well as a growing drain on Government financial resources" (World Bank, 1983, executive summary). The report continued by noting, "unfortunately, Government authorities, and the general public, often perceive railways as a public service, to be shielded from commercial pressure" (ibid., p.i). The Bank cautioned governments that they "should not only avoid arbitrary interventions and uneconomic investments but also take positive action to steadily strengthen the functioning of the transport market by: derestricting competing modes and taxing them more appropriately; demanding and supporting suppression of uneconomic railway services; [and] increasing railway management's own decision-making powers" (ibid.). This report also criticizes the

use of public subsidies for unprofitable lines and encourages strong measures to avoid them (ibid., pp.32-33, 39-40). Above all else, "economic efficiency, as demonstrated by railways' ability to attract traffic at prices related to costs, is what is sought" (ibid., p.39).

Neoliberal adherents advance two main solutions to the "railway problem." First, they suggest the replacement of railways by roadways. For example, Bullock and Gwilliam state that the "only solution" for isolated villages served exclusively by rail should in the long-term is "to create feeder roads for motorized access, enabling more cost-effective means of transporting goods and greatly improving accessibility to such locations" (Bullock and Gwilliam, 2010, p.235). The problem with replacing railways with roads is multifold, though, as discussed in the section above. The second proposal for which neoliberal supporters advocate is some degree of privatization of railways. This has most often taken the form of concessioning. In that arrangement, the state retains ownership of the right-of-way and infrastructure, while private operators takeover the rolling stock and operations. Since the neoliberal theory became so influential, "most national economies and national railways have been liberalized" (ibid., p.229).

Privatization and economic liberalization have produced mixed results and scholars are still debating the virtues and vices of the neoliberal approach. Researchers, politicians and activists have widely critiqued neoliberal policies, such as structural adjustment programs, for having the opposite of their stated development goal in that they caused great social and environmental harm (Friedmann, 1992, p.5; Ferguson, 2006, p.71). Although proponents of privatization decry the unresponsiveness of publicly run transportation, "private sector inefficiency and corruption are also well known" (Simon, 1996, p.166). Specifically, concessionaires can subjugate the public interest to private ones by creating a monopoly situation or through an asymmetric transfer of information (Pourcet, 2006, p.212). Simon argues "there is no evidence that private monopolies are necessarily more efficient than public monopolies or any reason why they should be" (Simon, 1996, pp.166-167). Even supporters of railway concessions state that this strategy has met with mixed results (Bullock and Gwilliam, 2010, p.229). Neoliberal policies have, nonetheless, hit unprofitable railways harshly. Simon notes that "since the 1980s, concern with liberalization and privatization of state owned and operated infrastructure under structural adjustment and economic recovery programmes…has seen underutilized branch lines and even some main lines closed in a few countries in the South" (Simon, 1996, p.17).

Despite pushback from critics that attempts to broaden the scope of transportation investment decisions, the neoliberal perspective and related policy recommendations remain dominant even today. In a recent book published by the World Bank, the authors note, "as long as the railways are government operated, bureaucratic constraints will prevent them from competing successfully" (Bullock and Gwilliam, 2010, p.229). They go on to say that "today, few railways outside South Africa, other than dedicated mineral lines, are essential to the functioning of the economy" (ibid.). IDIs' perspectives remain influential because they are the largest source of non-state

funding for transportation projects in LDCs (Hilling, 1996, p.102), and colonial railways must compete with other modes.

Support from IDIs clearly influences how decisions are made. Schroeder explains that because much of the road construction and maintenance in LDCs is externally financed by IDIs, this brings these institutions—and their experts staff and consultants—in as "stakeholders" (Schroeder, 1997, p.396). He notes that IDIs' "roles in the process are seldom entirely passive" (ibid.) In fact, IDIs have the power to provide or block financing that could help these distressed countries and their crumbling transportation systems. For example, the World Bank's railways report noted above asserts that if governments and railways departed from the "basic objectives of a structural change program," then the Bank "should be quite ready to cease approvals for new commitments out of the loan, or even suspend its disbursements or call the loan" (World Bank, 1983, p.40). The World Bank threatened both the Malagasy government and the Kenyan government with such actions related to their unprofitable railways (Galenson and Thompson, 1994, p.13; Freudenberger, 2003, p.140).

The key point that neoliberal theory simultaneously ignores and masks is the importance power plays in project evaluations – including what aspects are considered benefits or liabilities. Believing that the most rational argument will prevail is highly problematic when considering the fact that power can determine who participates in the process as well as what counts as "rational." Yet this power is also self-reinforcing because the process used excludes actors who could potentially impact these decisions by arguing in favor of certain railway benefits. As Foucault would contend, "power produces rationality and truth; rationality and truth produce power" (Flyvbjerg, 2001, p.124). Power is clearly intertwined with the rationalities at work in decisions about colonial railways. Paraphrasing Pascal, Flyvbjerg argues, "power has a rationality that rationality does not know. Rationality, on the other hand, does not have a power that power does not know" (Flyvbjerg, 1998, p.234).

Should we then eschew metrics and performances when evaluating transportation investments and services? Taking this position arguably takes decision-making to the other undesirable extreme. Foucault argues, "to respect rationalism as an ideal should never constitute a blackmail to prevent analysis of the rationalities really at work" (Foucault, 1980, p.317 in Flyvbjerg, 2001, p.98). It is entirely possible, therefore, to unmask the real motivations behind decisions while also using a process that considers quantitative information for many of the benefits railways provide but are not currently considered. In other words, making debates transparent and open to public participation does not mean we should abandon performance measures, but it means that we can better understand how certain actors and their underlying normative values influence the types of transportation services countries provide.

5. Conclusion

The preceding sections of this paper made the argument that colonial-era railways in SSA have significant value despite their crumbling infrastructure and increasingly unreliable service. Their benefits extend to millions of people living in the regions they serve, the natural environment and even to a more stable society. Yet the evaluations and measures that have traditionally been used to decide what transportation service in which to invest has adversely affected railways. Ideologies underlying neoliberal theory, the power of actors making evaluations and the rationalizations they have employed have had a particularly strong impact on these lines.

So how should decisions about these railways be made if the current neoliberal-influenced approach monopolizes power in such a way as to influence transportation decision-making? Understanding how power influences transportation information, values, and decisions, particularly about railways, means that constructive steps can be taken to ensure a transparent and fair process. Having a genuine public participation process that could identify the benefits of a particular railway would be a key remediating step. Nietzsche has argued, "objective research is not contemplation without interest" as positivist researchers presume; rather, it uses "a *variety* of perspectives and affective interpretations in the service of knowledge" (Nietzsche, 1969, p.119 in Flyvbjerg, 2001, p.139). The same should be true for decisions about colonial railways and the decision-making process should be broadened to allow more voices to meaningfully participate, which is consistent with Friedmann's conception of what one of the principle ends of *alternative development* should be: the political dimension of "inclusive democracy" (Friedmann, 1992, p.34).

Applying Friedmann's conception of alternative development and its embrace of substantive rationality in the transportation sector offers a counterpoint to prevailing neoliberal ideology. Abandoning the pretense of neutrality by using a more humanist model built on a "moral justification" and its espousal of "inclusive democracy" can change transportation decision-making processes to better incorporate long-ignored variables of colonial railways. Understanding and acting, therefore, should be based on a "context-dependent common world view and interests among a reference group, well aware that different groups typically have different world views and different interests" (Flyvbjerg, 2001, p.101). This can help develop better goals and measures for these lines.

Arriving at this point, though, requires active public participation in the transportation decision-making process and requires a shift in existing power relations. As Sen states, "in arriving at an 'agreed' range for social evaluation…there has to be some kind of a reasoned 'consensus' on weights, or at least on a range of weights. This is a 'social choice' exercise, and it requires public discussion and a democratic understanding and acceptance" (Sen, 1999, pp.78-79). He goes on to say, "public debates and discussions, permitted by political freedoms and civil rights, can

also play a major part in the formation of values. Indeed, even the identification of needs cannot but be influenced by the nature of public participation and dialogue" (ibid., p.158). In balancing current neoliberal ideology, it is essential to realize genuine inclusive democracy that no longer ignores the many benefits of railways in SSA.

STRATEGIES WITHOUT PLANS, PLANS WITHOUT STRATEGIES

(Draft version)

Paulo Silva[1]

Abstract

Key words: metropolitan areas, governance, urban and detailed plans, strategy

Most of Southern European metropolitan areas experienced a considerable growth on recent decades. Some works reported how differentiated was the growth on metropolitan areas in countries like Portugal, Spain, France or Italy. In the Portuguese case, it is evident the contrast in terms of urban characteristics between the two main metropolitan areas of Lisbon and Oporto.

Lisbon Metropolitan Area witnessed a deep change in the three last decades. During this period the planning system emerged from almost non - existent to a consolidated status, where national, regional and local levels take place. Important steps have been given in terms of designing a vision to the region. Although the hierarchy of plans is clear in legal terms, not always local planning has been able to implement the visions designed at a regional level.

At local level, land use plans are mandatory for the municipalities. Since the 90's of last century all the country turned to be completely covered by these kinds of plans. On the other hand, urban and detailed plans are not mandatory which creates a larger variety of situations, from municipality to municipality.

A multileveled planning system is an opportunity to discuss important governance related issues: local elected decision makers versus regional non elected decision makers; the need of deal with certain issues at a multi – municipality level versus the local autonomy that symbolizes many conquers related with the establishment of a democratic regime are some of the critical questions.

The data used to this presentation is based on the large number of urban and of detailed plans that were aproved in the last two decades in the 18 municipalities that compose Lisbon Metropolitan Area. These plans play an important role on urban regeneration but at the same time it is evident the unclear relation with other strategical (and less physical) planning tools. In this context remains the question: what is the role of plans in implementing strategies?

[1] University of Aveiro, Aveiro, Portugal, paulosilva@ua.pt

1. Introduction

This paper argues that spatial planning tools have not been able to integrate important strategic components, both from bottom as well as from top levels. Strategies are mainly designed at upper (national and regional) levels and less also at a local level. For that matter, we will focus on how spatial planning in a metropolitan context has been dealing with former urban territories, among of which, illegal sttlements play an important role. It is our aim to show that lack of strategy has an important role on urban design and on the design of urban structures.

The history of strategic planning is already very reach although recent, in Portugal. However, strategic plans tend to be seen as a paralel process to spatial planning practice. In adition to that, other strategic documents have been produced and implemented in contexts that hardly link to spatial policies. Altough sometimes both are focused on a local level (and even on the same territorial context), they have very superficial encounter on the ground.

The diversity of territories, of patterns of urbanization and of planning problems are just an evidence of the need of a better integration between strategies and plans. Strategic planning has been seen as a paradigm to solve unsuficiencies on way plans were design on the second post war.

On a first part of this paper, we will focus in the concepts that can build bridges between strategic and spatial planning. Considering that a certain level of uncertainty is part of the process of planning, we will focus into a more specific context: the lack of prediction related with dynamics of illegal settlements. Additionally, we will take in consideration how spatial planning deals with illegal settlements in a metropolitan context.

For this matter, we will take in account the Portuguese spatial planning experience on dealing with illegal urban settlements. This example is particularly relevant, having in consideration how important are the illegal settlements to explain urban sprawl that happened on the last three decades, mainly around the Portuguese capital, Lisbon. These peripheral areas of the Portuguese capital, which were marked during the 70´s and 80´s of last century by illegal settlements, turned to be strategically located on the metropolitan frame of accessibilities.

Changes on some of these territories are due to new infrastructures, mostly implemented without a proper evaluation of their impact on pre - existent urban structures, mainly due to new forms of occupation. To discuss these matters we deeply find necessary to create new models in terms of spatial planning, assuming the complexity of built territories, often composed by several layers of occupation, corresponding to patterns of urbanization. Most of the urban sprawl we know around the largest Portuguese cities was based on dichotomies such as rich areas versus poor areas or legal versus illegal areas.

One of the most important of these dichotomies lays on the fact that a significant part of today's urban territories were illegally urbanized. To deal with this reality we will discuss the integration between strategy and spatial planning. The two main questions to be approached with this paper are: How has strategic plan been used in relation with spatial planning (particularly in urban areas)? Which kind of questions are evolved on strategy's design? Therefore, will focus on the last two decades of urban planning in Lisbon Metropolitan Area

2. New questions on strategy posed by the regional scale

Lisbon Metropolitan Area was established in the early 90's of last century after a period of fast territorial and demographic growth. We find different patterns of occupation between intensive occupation along major transportation axis and extensive growth in less accessible areas,. In the last decade, a new wave of occupation associated with private transportation affected dispersed areas, but also in consolidated areas. The combination of patterns from the last thirty years is visible in several studies, which analysed recent trends (Instituto de Ciências Sociais, 2000, FONT, 2003; SILVA, 2010).

The first study, coordinated by the geographer João Ferrão (ICS, 2000), is a contribute to identify the dimension and the limits of built occupation in Lisbon Metropolitan Area, with in comparison with eight other metropolitan areas in the Iberian Peninsula – Porto, Barcelona, Bilbao, Madrid, Malaga, Seville, Valencia and Zaragoza. In this study the main criteria to analyse these nine metropolitan areas is the proximity of constructions, based on the pattern defined by UN – HABITAT to characterize built continuity – a maximum distance of 200 meters between constructions. After the classification of all the metropolitan areas based on the number of continuous built spaces, the pattern of occupation is also defined by the combination of number of continuous spaces with the number of municipalities, density and the amount of population. Density is a way to measure dispersion. This study shows that reduced dispersion in Iberian metropolitan areas is linked with a higher number of continuous spaces.

In the second study - *Explosiò de la Ciutat* edited by Antoni Font and published for the 2004 world forum in Barcelona - Lisbon Metropolitan Area is compared with twelve other metropolitan areas from southern Europe - Porto, Madrid, Barcelona, Valencia, Donostia/Bayonne, Marseille, Montpellier, Milan, Bologna, Genoa, Naples and Veneto–Central. This comparison is made in terms of patterns of occupation: with several or with a single nucleus, with or without a dominant nucleus, with dispersed or concentrated growth, with linear our reticular occupation. The study concludes that Lisbon Metropolitan Area combines in a unique way among the thirteen metropolitan areas two of these characteristics: it is a mono – nucleus territory with areas of dispersed occupation. In general terms, to the whole of metropolitan territories on analysis in this study, the patterns are used as a main

contribution to define eight contemporaneous morphologies of built areas in addition to pre existent occupations: compact settlements, reinterpretation of central urban areas (due to the change on cities' organization and economy), new settlements disconnected from pre - existences, residential "garden – city"type of occupations, isolated occupations and linear occupations. We see by this "catalogue" of forms a not very clear criteria to classify different types of occupation (contributing to clarify approaches of this kind is one contribution, by learning from the process): in one specific one, the (residential) function is identified and it is referred to the typology of buildings; in others the main focus to identify forms is the relation with the pre – existent built areas; and finally there are some definitions in which the density (compact, linear and dispersed) is the main reference. In comparison with other metropolitan areas, identifies patterns of occupation.

These approaches tend to focus on patterns, but in a physical, built way. We tried to characterize the recent settlements in Lisbon Metropolitan Area based on data related with relevant changes in Lisbon Metropolitan Area in the last decade (SILVA, 2010). The analysis of this data allowed us to identify four – plus - one trends in Lisbon Metropolitan Area. The criteria were centred on the relation that new occupations established with the build and non build territory and pre – existent urban structures. We identified as major trends: the emergence of singular elements, large settlements isolated from other constructions, re – use of pre – existent central areas and the renovation of suburbs. A common characteristic (as well as a conclusion of the research) was the lack of structure between emergent and pre – existent elements. Regarding the planning tools, we found a "thematic" approach, more concerned with problems, than with solutions. This general conclusion leaded us to the need of new approaches. The following examples will help to understand by where these new approaches can go.

3. Illegal settlements and spatial planning approach: looking for strategy among different agents' behaviours

Our interest on how strategic tools work within spatial planning is a consequence of the study of the urban developments of the last decades that had place in an important part of Lisbon Metropolitan Area. The process of illegal division of land with urban purposes started to take place in the early 60's of last century and lasted almost three decades. Rooted in a context of lack of public regulation, the selling of small plots of land allowed the creation of thousands of small land owners. Normally, they were "recruited" in specific geographic areas of the country or out of it. There are records of some of these illegal entrepreneurs having office in Paris during the 60's and 70's in order to sell plots of land to Portuguese immigrants residing there.

This business was very successful, since the acquisition of lots was seen as a way of investment of their incomes. In general in Portugal and particularly in the middle-class suburbs around Lisbon, these transactions were very common. Prices in the early 70's were around 150 € for a plot of 300 square meters. The rules established

by the seller allowed buyers to pay it in instalments of 2.5 € per month. Gradually, these land owners start to organize themselves. As buyers get their plots of land they started individual processes of construction. Soon and without any spatial planning tool a structure started to emerge from this sum of individual initiatives.

One can distinguish two main periods in this process. Official records report the starting of illegal settlements in the early 60's, related with the increasing value of land, due to the construction of the then called Salazar Bridge inaugurated few years later in 1966. In the late 60's an important water flood affects the outskirts of Lisbon and made visible the increasing expression of illegal settlements. The censorship at the time had difficulties on suppressing the facts from the media. So, the old regime internally knew what was happening, didn't interact with the process and tried to disguise it when it became a problem.

The following period was marked by double standards in the way of dealing with illegal settlements. The establishment of a democratic regime with the revolution of 25th of April of 1974 is obviously an important milestone mark to take in account. At the early days of the democratic regime, left wing parties won the first local elections on most of the suburban municipalities of Lisbon Metropolitan Area. On one hand, these forces leaded by the Portuguese Communist Party were very close to the growth of the ecological political movements in Portugal.

This fact made them have a position against settlements that would affect ecosystems and landscapes. On the other hand, one part of illegal occupations were the new living places for people that escaped from worse conditions in early suburbanized areas around the capital. So, local authorities dealt with this fact with ambiguity, repressing and supporting illegal settlements, depending on the fact of being created to be a permanent residence (considered as a social need) or a temporary one (in this case, less relevant and more punishable).

The sum of thousands of small land owners' actions contributed to design the urban structure of many territories in a very specific way. Uses appeared to be organized more based in the sum of individual interests which influenced the rules that later were created through urban and detailed plans. The reasons that enhanced changes were based on individual needs and aims – first of all legalizing their constructions (mainly their new "homes"), later getting potable water and after sewage systems and proper public spaces. Strategic needs, from the spatial planners'point of view seek structured spaces, hierarchically organized. Private land owners on illegal settlements deliver disorganized spaces, lacking structure. What is the missing link between one and the others? Some features probably were missing to spatial planners and probably land owners do not reach to see ahead of their private interests.

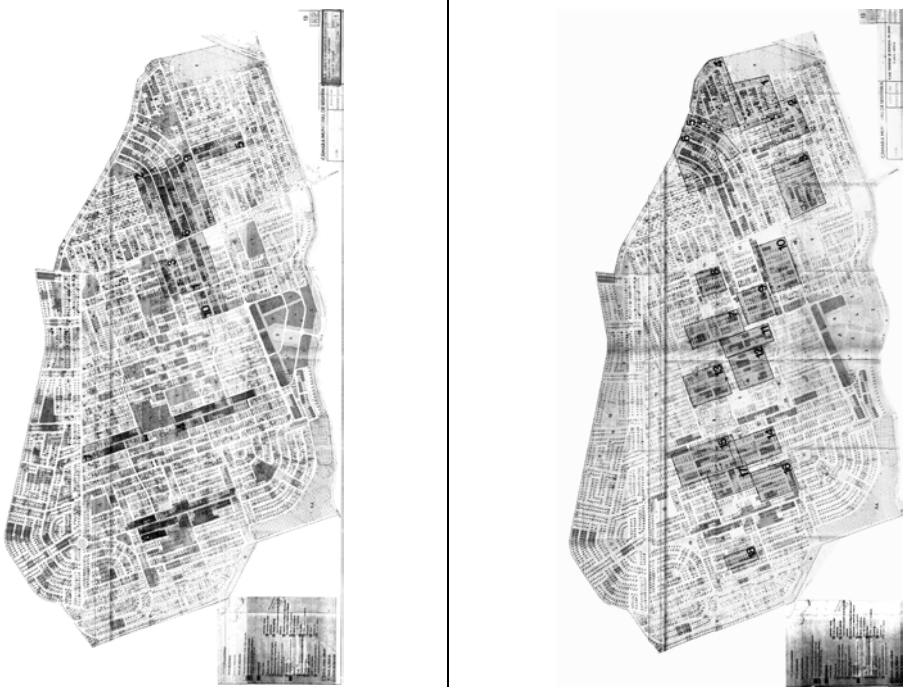

Figure 1. New typologies in one former illegal settlement in Lisbon Metropolitan Area (Quinta do Conde, in the municipality of Sesimbra)
(Credit: municipality of Sesimbra)

The reaction of spatial planning was to respond to individual behaviours superposing new features to pre existent ones. The following image (see Figure 1) shows how the first urban plan designed solutions based on new typologies. Since the first areas to be occupied were illegal, the new occupations previewed by the urban plan contradict the former occupations.

4. Description of the method of interaction between administration / planners and residents

The planning's methodology mostly used is based on Portuguese current law for spatial planning instruments (Regime Jurídico de Instrumentos de Gestão Territorial – Decree–Law 380/99) and simultaneously according to the Portuguese act for public administration procedures (Código de Procedimento Administrativo). These two legal instruments define in main lines: that any individual or institution has the right to know at any moment the status of a certain procedure taken by public administration (which includes the design of spatial plans), according to Código de Procedimento Administrativo; that any individual or institution is asked to participate in two different moments of the process – at the beginning, after being designed the "Opportunity" and the "Current situation" ("Oportunidade" and "Termos de Referência") and before the plan is approved by local authorities. In the first moment there is no proposal and at the second moment the proposal is technically concluded.

According to our experience, there are at least two different types of participatory processes which depend of the scale of people's evolvement with the planning process. Although the official discourse focuses on the virtues of participation, an exemplar process is when everything works in smooth way without many changes to the original ideas, despite of the fact that is important for the success of a plan to have a much participated process. In terms of acceptance contributions are always welcome.

How spatial planning does interacts with tactics and strategies

Sometimes spatial planning takes different directions from urban dynamics. Under the form of scenarios we present two of these situations in which spatial planning orients growth in one direction while tactics tends to create other types of dynamics. Figure 2 illustrates how spatial patterns are much more diverse, while spatial planning tends to be concentrated on hierarchical solutions.

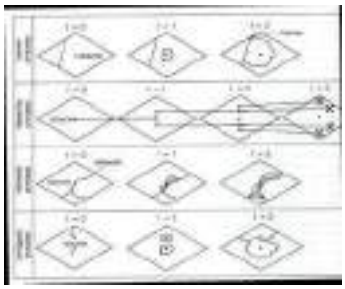

Figure 2. Spatial patterns produced through time, according to different processes: contiguity, network, hierarchy and barrier (BENNETT, 1978)
(Credit: AA. VV., 2000)

Functional organization

Functional organization can be seen as the result of the arrangement of different activities in a territory. Concentration and proximity to other activities are some of the criteria that help to organize and to plan a territory. The sum of multiple actions of several individuals creates a very different territory from the above described in functional terms. The sum of actions might not seem to make sense at a local scale, in the way that spatial planners look at urban territories, but often they make sense in terms of the daily life of residents, of connections between residence and work of employees, of stage of life – where the cycle "work abroad – accumulating savings – investing in a project for the end of active life – creating a small business close or together with the residence" has a crucial role.

Attractiveness

Shaping a territory in a broader scale is the result of metropolitan, when not national, trends. The change of patterns of occupation might give different interpretations to a same place. In the case of these illegally urbanized territories, periphery and

centrality have been two different concepts that spatial planning at a regional scale has seen in terms of "one **or** the other" and never "one **and** the other". Illegal territories were integrated on urban forms were part of more complex systems that in their way made sense. Designing centralities at a regional scale has implications to ancient peripheries.

On the experience of planning

Based on the experience of Lisbon Metropolitan Area research on how does spatial planning deals with illegal settlements, we identified two main behaviours. Unless we are talking about territories with attractiveness in metropolitan terms (which means centrality promoted by infra structures that benefit remote areas from qualities like tunnel – effect), spatial planning tends to deal with illegal settlements isolating it from the rest in terms of planning tools and in terms of urban structure. In 1995, an act was approved by the Portuguese govern usually known like *Lei das AUGI* (*AUGI* is the Portuguese acronym for urban areas generated in an illegal way). This act had as main goals to ease, using exceptional rules, the urban renewal of illegal settlements. The application of this law since then until 2007 was made by analysing the plans approved to these areas.

The result of this research shows that the appliance of this law promoted the production of much more planning tools. Some suburban municipalities that in previous periods had a very scarce production of plans are suddenly the largest producers of this kind of plans. Looking at those produced with the goal of renewal of illegal urban areas we can see that the achievements at the level of the urban structure and at the level of what can these areas mean in a new (metropolitan) context are almost null. Most of the plans produced "only" (only is a lot, having in consideration the fact that these plan represented de agreement designed to answer to the expectations of thousands of small land owners) a design closer to the original subdivision of rural land, with exception to the creation of public and collective spaces demanded by national law. Sometimes these spaces, in order to not to affect small land – owners' interests were reduced to the minimum or to below the minimum legal needs, even occupying space from protected areas included in agricultural and / or ecological national reserve.

On the opposite ground we found areas that were re – designed not because of the need of urban renewal but in order to adapt originally illegal urban areas to new challenges (in territorial terms). In this case planners were called to answer to external needs. The pressure of car – traffic, the preservation of important ecological corridors and the interest on reusing due to the plus value brought by new accessibilities were the key – ideas that remained from opportunities and the threats identified by these plans. In these scenario people's expectations were taken to second plan.

Vila Franca de Xira is a municipality in the north east sector of Lisbon Metropolitan Area, where over a rural structure emerged during last century one of the largest

industrial areas, benefiting by the proximity to main transportation infrastructures (which includes the port of Lisbon and some of the first railways – from the mid XIX century - and motorways ever built in Portugal). The industrial prosperity achieved since the Second World War until the oil crisis in 1973 and the Portuguese revolution only one year later in April, the 25th, was responsible by the localization of heavy industries in this municipality. Important migratory movements towards the capital started to occur since the early sixties. After the Portuguese revolution of 1974, the independence of former African colonies promoted a new migratory movement responsible by the arrival to the country of around one million people (more than one tenth of Portuguese population at the time). Most of these migrants / war refugees were settled in Lisbon and its suburbs. The demographic pressure around the capital provoked the emergence of a relevant amount of illegal districts in the municipality of Vila Franca de Xira. At the same time, this territory entered into industrial decay in the 80's and gradually was transformed in a suburb of Lisbon. After the approval of its first land use plan in the 90's and as a way to plan the renewal of those illegal settlements, Vila Franca de Xira turned to be one of the metropolitan municipalities with more approved detailed plans.

Sesimbra is a municipality in the south west tip of the south bank of Lisbon's Metropolitan Area. It remained like a rural forested area until 30 years ago. A relevant part of recent occupations emerged illegally, slowly but surely with the construction of the first bridge over the Tagus River close to Lisbon inaugurated in the mid – sixties of last century. The large – size estate that dominated the south bank's territory originated very few in number but very extensive in surface illegal occupations. The pressure in part motivated by its large scale made the municipality react earlier than others. In the mid 80's a significant part of the illegal areas had urban plans (this legal frame at the time was more flexible, than the one from detailed plans that were not so frequently used). The construction in the 90's of an important number of new infrastructures together with the fast raise of the number car - owners stimulated an intensive use of the area. While the first occupants were sometimes aiming for a secondary house in a pleasant environment the new comers hope to have a decent suburbia life; while the first land – owners saw the bought of land as an investment of a life time savings, the new buyers of dwellings correspond often to young families in transit from worse residential areas to better urban conditions that includes the need of sports and school facilities. In the case of Sesimbra, the solutions tend to neglect the first group while privileging the latest ones. In addition, they tend to impose solutions adapted to the large scale of these territories. Some of these places become the best connected territories in which the main concerns in terms of spatial planning are different from the first example: centrality, connectivity and poly nuclear net.

5. Conclusions

Both strategic and spatial planning tools play an important role in the consolidation of complex territories such as Lisbon Metropolitan Area. It can help planners to pay more attention to the processes related with consolidation of urban structures. The

inclusion of the concept of bottom – up tactics into spatial planning can help in particular the interpretation of emergent territorial dynamics.

Bottom – up methodologies have been included into spatial planning. Because of that, we started the interpretation by distinguishing this concept from our perception of self – organization. Self – organization does not only influence the way spatial planning is conceived. It can also influence the interpretation of the territory itself, connecting residential settlement with professional, leisure, or other activities. In that respect, self – organization is an important contribution to the interpretation of urban structures.

We had focus in a specific territorial dynamic that in our point of view would fit better into the concept of tactics versus strategy, the illegal urban processes and local planning versus regional planning. In the case of Lisbon Metropolitan Area, illegal settlements, despite of the differences presented between the north bank (represented here by Vila Franca de Xira) and the south bank (with the example of Sesimbra) had in common the fact that in both cases, a sum of thousands of actions would generate a whole not pre – perceived by those individuals / agents.

The intervention of municipalities and central administration on spatial planning was in many cases focused on the production of plans. We identified two typologies of "planning behaviours" taking in consideration, the integration with metropolitan networks, size of the areas affected by illegal occupation and its functional vocation. Firstly, the connection with metropolitan networks did n't prove to be by itself a factor that influences urban renewal. The fact that seems to make a difference between different cases is the moment in which these networks started to affect the territory.

In the case of Vila Franca de Xira, infrastructure networks were pre-existent when illegal settlements arise. Those infrastructures were the reason to the location of industries for almost one century. Illegal areas were located close to industries and then later when de - industrialization started they benefited from the proximity to the motor way and secondarily due to the rail way connections to Lisbon. The small size of spatial planning interventions, the availability of spaces for non – residential uses and the reinforcement of the municipality of Lisbon as a tertiary pole, influencing this area to turn into a suburb contributed, to the consolidation of the original occupations, recreating former systems. Therefore, planning processes revealed to be too focused on problems and not looking for solutions that could contribute to create new or to enhance old urban structures and to allow new uses.

In the case of Sesimbra, metropolitan networks are very recent and arrived after illegal occupation had already a considerable development. New rail ways, new motor ways linking to a more recent bridge over the river Tagus built only in late 90's of last century, attracted new inhabitants creating a new suburban pattern. Non – residential areas arrive after illegal settlements and, due to ecological constraints and measures to control urban sprawl, they have to compete with pre – existent illegal

residential occupations. The aim of urban renewal might tend to forget the importance of pre – existences. The concept of urban structure was super – imposed to a self – organized territory. Public discussions of plans proposals revealed a latent conflict between older residents wanting nothing to change, new residents that found a cheap place to leave while this area was not so close to metropolitan networks and those who see the opportunity of new vocations for these territories. Larger illegal settlements were approached like future big urban areas, which promoted the inclusion of new functions and of new built typologies.

While seeing non planned areas uniquely as illegal actions, the practice of spatial planners tend, on one hand to be just focused on legalizing these areas, providing them with all the facilities they need; on the other hand, they tend also to look to infrastructures as an opportunity to establish new uses. But if we add to these needs the fact that pre existent occupations have patterns at different scales then we are more able to discuss what should better plans bring to the territory.

Maybe it is too daring to declare that illegal settlements have to be accepted, which is not our point of view. Illegal settlements brought many impacts to the territory that had cost decades and enormous amounts of money to solve (and still going on). But we tend to not evaluate and forget the costs of inverting tendencies and starting processes letting others unfinished. Strategies tend to be designed on an up-to-bottom direction which, both at the regional and at a local level. But up to bottom decisions taken at a local level do not take necessarily in consideration decisions taken at a regional level.

As Oriol Bohigas (Bohigas, 1986) once wrote, “there is nothing worse than educated people when they get wrong” (“no hay nada peor que la gente de bien cuando se equivoca”)

Climate Change Mitigation and Adaptation: A Comparative Study of Local Governments Actions in NSW Australia and Nevada USA

Awais PIRACHA

Climate Change is perhaps the most pressing problem faced by humanity in the 21st century. Climate Change is occurring on global scale through the build-up of greenhouse gases in the atmosphere. However its impacts are often felt locally in vulnerable, low lying and densely populated regions. Climate change is predicted to affect climatic conditions by increasing the intensity and frequency of precipitation and heat waves. As a result regions and local areas will face more frequent and extreme flooding, droughts and heat-wave events. These conditions will threaten lives and properties of people in localities all over the world. Dry, hot and coastal communities like Nevada USA and NSW Australia

In Sydney, a significant proportion of the population resides in a coastal location, with impacts of climate change literally on their doorstep. Inland councils are also at risk with rising temperatures and increasing intensity and frequency of natural weather events. This research examines responses and the strategic directions of local councils in the Sydney Metropolitan region, Australia, in regards to climate change. Key documents, policies, and environmental planning instruments were analysed for their usefulness. Mitigation and Adaptation action are essential to combating the present and future impacts, and thus are the key to managing climate change. One such example of a mitigative response is through the Cities for Climate Protection (CCP) program. The case studies of two coastal and two non- coastal councils conducted as part of this research provide insight into the development of climate change responses.

Nevada, located in the southwest of the USA is a very hot and dry place. In the Southern end of Nevada, the Clark County and the Cities of Las Vegas and Henderson have a population of two million. Climate change is likely to threaten the water supply in the region as well as make an already very hot region hotter. Interviews were carried out with officials at the Southern Nevada Regional Transport Authority and planning and sustainability sections of the City of Las Vegas and the City of Henderson to learn about their mitigation and adaptation measures in relation

to climate change. I have organized meeting with a few more people at the City of Las Vegas and neighbouring City of Henderson.

Analysing responses of the local councils in Sydney Metro NSW and those of authorities in Southern Nevada helped in determining usefulness of various policies, instruments and programs in the two individual regions. Also the comparison of policy cultures and choice of instruments in the two regions led to several important and interesting findings.

1. Introduction

This study is an outcome of research in Sydney NSW Australia on local authorities actions on climate change mitigation and adaptation. Analysing key documents, policies, and environmental planning instruments, this research examines responses and the strategic directions of local councils in the Sydney Metropolitan region, in regards to climate change. Mitigation and Adaptation action are essential to combating the present and future impacts, and thus are the key to managing climate change. One such example of a mitigative response is through the Cities for Climate Protection (CCP) program. This research in particular looks at the action on climate change mitigation and adaptation at local level through the prism of CCP which seems to have wide traction with local councils in NSW.

In this research, case studies of two coastal and two non- coastal councils provide insights into the development of climate change responses. Analysing their responses helps determine the usefulness of various policies, instruments and programs. Analysis and comparison of the case studies has revealed a number of interesting findings along the themes of state government (of New South Wales) and local councils (in NSW) interactions and the understanding, desire, capabilities and action of (small) councils in addressing this huge challenge.

A somewhat similar study was latter conducted in Southern Nevada USA. This researcher spent two months in at the University of Nevada as a visiting scholar. During that time a number of interviews at the local agencies were conducted. The interviewees were asked about their agencies' actions on climate change mitigation and adaptation. Secondary material on that topic was also collected from those agencies. Field visits were also part of this exercise.

This paper presents findings from the two individual case studies as well as spells out commonalities, differences in approaches and lessons to be learnt from both sides.

2. Climate Change Mitigation and Adaptation at Local Governments in NSW

Climate Change is probably the most important and the most urgent issue faced at all levels of governance in the 21st century. Climate Change is occurring through the build up of greenhouse gases in the atmosphere on global scale; however its impacts are often felt locally in vulnerable, low lying and densely populated regions. In Sydney NSW, a significant proportion of the population resides in coastal locations, with impacts of climate change literally on their doorstep. Inland councils are also at risk due to rising temperatures and increasing intensity and frequency of natural weather events. Mitigation and adaptation are key to managing climate change. A comparative study of two coastal and two non-coastal local councils was conducted in the Sydney region of NSW with regard to their strategic responses to climate change reveals that some mitigation activity is in place, but that large-scale adaptation is limited.

2.2 Cities for Climate Protection (CCP)

One example of a mitigative response is the Cities for Climate Protection program. The International Council for Local Environmental Initiatives (ICLEI) set up Cities for Climate Protection (CCP) in 1993 (ICLEI, 1993; UN, 2006). ICLEI has become an internationally recognised organisation comprising local councils from over 900 cities, towns, counties and their associations (ICLEI, 2008c). Significant goals of the CCP program as stated in 'An International Campaign to Reduce Urban Emissions of Greenhouse Gases' (1993) include:

- Strengthening of local commitments to reduce urban emissions of greenhouse gases;
- Dissemination of planning and management tools to facilitate the development of cost effective CO2 reduction policies;
- Research and development of best practices and development of local model projects for reducing energy use in buildings and transport; and
- Enhancing national and international ties so that municipal level actions to reduce emissions are included in national action plans and future international deliberations.

ICLEI provides projects, program support, technical and policy support, workshops and training resources, opportunities for networking and information exchange, and recognition events. One of many tools it has created for local governments is a software package which can calculate, forecast, and monitor greenhouse gas emissions (Bulkeley & Betsill, 2003).

The CCP program is implemented through a strategic milestone framework, as follows (ICLEI, 2008a; ICLEI 2008b):

1. **Establish an inventory** of greenhouse emissions from all operations (corporate sector), and an analysis of sources of emissions from the community as a whole (community sector). Following this, a Business As Usual (BAC) forecast is undertaken to inform Council of its future projections.
2. **Set goals** to be achieved by a stated year in the future. Goals are usually expressed as a percentage of corporate and community emissions.
3. **Action plan**—a strategy toward achieving goals set in milestone 2 set out as a blueprint in the form of a Local Action Plan (LAP), containing:
4. **Implement and quantify** actions outlined in the LAP. Report reductions in greenhouse gas emissions as well as financial cost savings.
5. **Monitor and review** progress. Involves:

In Australia, CCP is a collaborative initiative between ICLEI, which delivers the framework to councils and works with them to develop and implement strategy, and the Department of the Environment, Water, Heritage and the Arts, which provides policy and funding support. There are currently over 230 councils participating in CCP in Australia, representing about 84% of the nation's population. New South Wales has (in 2008):

- 25 councils in the CCP Plus category;
- 12 councils completing milestone 5; and
- 22 councils completing milestones 1-4.
  (Department of Environment, Water, Heritage and the Arts, 2008)

CCP Plus is an extended arm of the CCP program for councils that have moved beyond milestone 5. CCP Plus aims to bolster greenhouse gas reduction goals by offering focused support in key areas of organisational review, planning, action projects, and corporate and community sectors. It requires yearly contributions to the annual CCP measures report (ICLEI, 2008b).

Following are case studies of two coastal and two non-coastal local councils in Sydney. Examination is made of each council's actions and priorities regarding climate change, their level of implementation of the CCP program, and their adoption of policies for mitigation and adaptation. A coastal council for the purposes of this article refers to a council with significant frontage to foreshore, estuarine and/or coastal waters, and also membership to a regional organisation (in this case SCCG).

2.3 Local Council Case Study 1: Ashfield Council

Inland Ashfield City Council is 12km south west of Sydney's central business district. The local government area (LGA) covers 8.3 square kilometres. It has a population of approximately 39,000 (ABS, 2006a).

Ashfield's vision is to be 'a community which protects and enhances its native and existing flora and native fauna and contributes to the wider responsibilities for the whole community to preserve the earth's environment.' In recent years the council has indicated ongoing commitment to environmental initiatives. It has adopted the Sustainable Streets program, established a staff sustainability committee and developed the GreenWay Coordination Strategy, the Cooks River Sustainability Initiative and Sustainable Ashfield. Ashfield has also adopted the Cities for Climate Protection program. A political declaration was completed in 2003, and they achieved milestone 2 in 2005. The Local Action Plan, part of milestone 3, is currently at draft stage.

Ashfield's LGA is growing at approximately 2% per year (ABS, 2006a). It is highly urbanised and dense. The area consists predominantly of residential buildings, with a moderate commercial element; industrial uses are minimal. The population makeup of this council suggests a very multicultural mix, and also contains an ageing population - 23.7% of the people are over 55 years of age. Department of Environment and Climate Change document 'Who Cares (DECC 2007) reveals that younger populations and people from English speaking households are more likely to be concerned and knowledgeable about climate change. Considering the makeup of Ashfield Council, it was important that the correct groups were targeted by educative campaigns.

Ashfiled Council's current management plan is for 2008-2012. The council also produces supplementary documents in the form of a Strategic Plan providing broad, long term action plans, and operational plans outlining management plan actions and key performance indicators on a yearly basis. The management plan is predominantly aimed at the community. While the council strives to achieve sustainable development, the plan doesn't necessarily indicate climate change specific action. It needs to be more specific to deliver clarity to the community and direction to the corporate sector. However, the Strategic Plan comprehensively outlines actions and reports on the progress of these tasks. The management plan does recognise commitment to ongoing implementation of the CCP program, and the achievement of milestone 3.

Ashfield's State of the Environment Report (SOE) is divided into 7 themes. Greenhouse gas emissions come under the heading of Atmosphere. The main pressures highlighted under this section are motor vehicle emissions and smoke from solid wood fire heaters. The regional pollution index indicates that increasing use of private automobiles is impacting significantly on local air quality.

Cities for Climate Protection (CCP) Milestones – ASHFIELD COUNCIL

1. **Establish an inventory**

   For the corporate sector, significant sources of emissions are from waste and street lighting. For the community sector, significant sources of emissions are from residential areas and transportation. Figures 1.1 and 1.2 indicate the emission distribution of Ashfield's corporate and community sectors.

2. **Set goals**

   Ashfield has committed to a reduction goal of 20% by 2010 from the baseline year of 1998 for the corporate sector, and 20% by 2010 from 1996 levels for the community sector. Selection of baseline and goal years has been influenced by goal setting by other Australian councils. 64% of Australian councils have endorsed a 20% or greater community reduction goal, while 90% of Australian councils have endorsed a 20% or greater corporate reduction goal (Ashfield Council, 2008). It is interesting to note the council 'following suit' rather than attempting to take initiative by leading reduction goals. However, 20% is a significant reduction goal, and it is recognised that considerable, innovative actions will be needed to reach it.

3. **Action plan**

   The draft LAP outlines actions to be taken, some of which include:

   Corporate actions

   - Staff energy awareness through education and campaigns, e.g. more efficient operating of appliances in the office;
   - Establishment of an internal sustainability committee;
   - Greater energy efficiency in office equipment through implementation of Energy Star Software on computers and installation of energy efficient flat screen monitors;
   - Retrofit of council buildings with light timers and sensors and, where possible, use of photovoltaic systems;
   - Audits on air conditioning systems and lighting in council buildings;
   - Participation in SSROC street lighting review; and

- Fleet vehicle policy review including introduction of 4-cylinder vehicles and diesel utes.

Community actions

- Promotion of reduction of greenhouse gases and energy efficiency including efficient heating and cooling through newsletters, websites and carnivals;
- Development of open space network that allows continuous pedestrian and bicycle access across the region;
- The Sustainability Street Program: providing education to residents regarding reducing energy, water and waste in their homes, and avenues for residents to become involved in local environmental projects; and
- Participation in regional projects such as the GreenWay project to provide walking and cycling linkages between the Cooks River and Iron Cove.

The majority of these actions have yet to be implemented and timeframes for their completion are absent from the plan.

Implementation

The Ecological Sustainable Development (ESD) policy adopted by Council in 2003 demonstrates Council's commitment to incorporating environmental policy development and state of the environment reporting into all aspects of operations, from management plans to development assessment. The public availability of this document signals intention to address environmental issues, and opens the council to scrutiny regarding its decisions on environmental issues.

Environmental Planning Instruments of Ashfield have been under revision. The new LEP is currently being prepared, consistent with the State Government standard instrument, including specific provisions to achieve Council's development outcomes. The DCP is also being updated to ensure consistency with the LEP. Appointment of an environmental officer has assisted in implementing environmental goals in these planning instruments.

Ashfield has a 'Building Design and Sustainability' DCP in Part D2 of the Act. This is an advisory document for ESD in residential and other development. However, state (BASIX) and national (Building Code of Australia) legislation already sets out requirements in accordance with sustainability. The purpose of Part D2 is to identify building designs that exhibit greater standards than set by existing legislation.

Adaptation

Whilst the council is aware of adaptative measures, there is little evidence of comprehensive action. The council states that adaptation is a capacity issue, but it would seem that it views adaptation as a large-scale, high-cost activity involving infrastructure development and ongoing high maintenance, rather than inclusive of education programs and modified urban design.

2.4 Local Council Case Study 2: Burwood Council

Inland Burwood Council is 14km south west of the Sydney CBD. The LGA covers 7.26 square kilometres. It has a population of approximately 31,000 (ABS, 2006b).

Burwood Council has not traditionally been environmentally aware. However, the council has indicated its concern about climate change through installation of energy efficient appliances and supply of rebates. Actions to date include production of the Green Action Plan, implementation of the Fridge Buyback Scheme, and participation in the regional group Inner West Regional Recycling Group (IWRRG). Burwood has also adopted the CCP program. A political declaration was completed in May 2006 and they achieved milestone 2 in 2007. The LAP, part of milestone 3, is currently at draft stage.

Burwood Council's current management plan covers 2008/09- 2010/11. Its vision is 'to make Burwood vibrant, prosperous, progressive and proud of its history and heritage'. Its statement of goals indicates that Council aims for 'environmental sustainability' to be achieved through objectives outlined in the Burwood Town Planning Scheme. The operational component of the management plan outlines key tasks relating to waste management, transportation networks, community support services, recreation services, health and environment.

Within the health and environment theme, a section on 'public health and pollution control' states Council's objectives 'to minimise the occurrence of pollution incidents in the council area' and 'to improve the environment through pollution control'.

The council indicates that, in order to reduce pollution, it is important to maintain regulatory and educative functions. How they will do this is unclear. The main service provision seems to be investigations into pollution complaints.

The management plan points to the Green Action Plan (GAP) as its primary document in environmental management. The GAP is a council-specific initiative with a particular focus on greenhouse gas emissions and climate change impacts in the local area. In some ways it is similar to an LAP, the milestone 3 requirement for the CCP program.

The council's SOE report is a 10 page document. Each of its 5 themes are identified in line with the LGA 1993. In 'Air,' objectives are to reduce greenhouse gas emissions and reduce instances of air pollution within the LGA. Assessments of corporate and community activities include:

- Council Chambers, Enfield Swimming Pool and the Library produce nearly half of all greenhouse gases in the corporate sector; and
- There is significant growth in the transport sector, in terms of the private car.

(Burwood Council, 2007b)

Involvement in the CCP program has been relatively recent. The management plan refers to the program under discussion of the GAP. In the annual report, current progress in the program is indicated.

Cities for Climate Protection (CCP) Milestones – BURWOOD COUNCIL

1. **Establish an inventory**
   For the corporate sector, significant sources of emissions are from buildings and street lighting. For the community sector, significant sources of emissions are from residential and commercial uses. Figures 2.1 and 2.2 indicate the respective distribution of emissions.

2. **Set goals**
   Burwood has committed to a reduction goal of 20% by 2012 from the baseline year 2005/06 for the corporate sector; and 20% by 2010 from 2001 levels for the community sector. Selection of baseline and goal years was due to the availability of data necessary for completion of the inventory. Lack of available data from other years indicates insufficiency and/or inadequacy in greenhouse gas emission recording instruments.

3. **Action plan**
   The LAP is in draft format, not yet available for public viewing.

Implementation

The council aims, through the GAP, to educate the community and outline operations being implemented. The GAP brings 'all of the council's "green" actions into one accessible document' (Burwood Council, 2008a). It contains the corporate GAP and the community GAP.

The corporate GAP addresses energy efficiency in council operations. Outlined below are some of the initiatives in the corporate GAP:

Reduction of energy usage

- Solar lighting has been trialled in Flockhart Park, Enfield. Further installations of solar lighting are planned; an expensive exercise. Vandalism of facilities has occurred and is costly to repair.

Council fleet management

- Council has encouraged downsizing of employee vehicles to fuel-efficient varieties. The council fleet has downsized to four-cylinder modes.
- A hybrid vehicle was purchased in 2006 for the council's car pooling system.
- The council's truck fleet now uses low sulphur content diesel, which reduces black smog and sulphur dioxide.

Office equipment

- Paper recycling systems have been introduced at the council offices, Library and the Woodstock Centre.
- Printer and toner cartridges are recycled.

The community GAP addresses environmental impacts of community activities.

- BASIX is mentioned as a community action, though it is a State requirement that new development be energy and water efficient to meet certain standards.
- Tree plantings have been an ongoing council initiative, with over 900 trees planted in the past 2 years.
- Examples of promotion of energy efficient practices include water tank rebates, recycling programs, and distribution of environmental fact sheets and an environmental events calendar.
- Second-Hand Saturday is a council-organised event that has been running for the past 6 years. It promotes reuse of items and reduces landfill.

The GAP is a good starter's document for the community and demonstrates some strategic direction. Whilst there is a comprehensive list of initiatives, it lacks statements of goals and plans for action. One might expect the production of the 'milestone 3' LAP to address environmental action with more detail.

The purpose of Burwood Council's ESD policy is to integrate sustainable development into the council's operations through economic, environmental and social considerations. Consequently, ESD principles have been incorporated into the new Burwood Town Centre LEP and DCP.

The LEP has been exhibited for public comment. It seeks to replace two former draft LEPs for 2 town centre precincts to maximise development opportunities. It aims for sustainable development features such as:

- Integrated approach to planning, management, development and economic use of land;
- Mixed balance of land uses;
- Development that encourages use of public transport and reduces reliance on, and the consequential environmental impacts of, private vehicles; and
- Development that promotes energy efficiency in relation to water conservation and aims to ensure waste and noise minimisation.

A particular DCP refers to 'Environmental Management', consisting of measures to maximise energy efficiency, minimise waste and conserve water. DCP No.8 refers to General Residential development. A specific clause, Part 5.4 'Energy Efficiency', requires that all development consider:

- Efficient building orientation toward north and east;
- Internal design that minimises heating and cooling; and
- Maximum natural ventilation.

Adaptation

There is a lack of available information regarding adaptive measures to be taken by this council. Sea level rise is an issue of State significance currently being addressed on a regional scale by SSROC; however, it does not appear to be of concern to Burwood council at present.

2.5 Local Council Case Study 3: Botany Bay Council

Coastal Botany Bay Council is 13 km south of Sydney's CBD. The LGA covers 10.3 square kilometres. It has a population of approximately 31,000 (ABS, 2006c).

Emission sources from Botany Bay are unique in that, both presently and historically, most pollution originates from the airport and from heavy industry. The area has traditionally been industrially used, the port being the major service for importing and exporting goods. Development of heavy industry depended on the water supplies off the Bay.

The planned airport expansion includes a development proposed by the State to facilitate required infrastructure. Sydney Airport's approved master plan will see a significant increase in flights, and increased activity from the airport will exacerbate pressure on development. Airport noise and flight paths mean that roughly 33% of the LGA is unsuitable for residential development. Restrictions on development are coupled by amenity impacts on existing residents and reductions in land value. The planned Botany Port expansion will impact not only this LGA, but also adjacent councils such as Rockdale Council. There is likely to be increased truck movement, and disturbances caused by freighting along the railway corridors.

Actions specifically addressing reduction of emissions have included trials of solar lighting at bus stops, adoption of hybrid vehicles for the council fleet, and implementation of an Energy Efficiency DCP. Botany Bay has also adopted the CCP program. A political declaration was completed in May 2001 and they achieved milestone 2 in 2002. The LAP is currently at draft stage.

The Botany Bay Council management plan is separated into principal activities undertaken, each detailing performance targets and measurements. There are no visions or goals in this document. The objective outlined in the Health and Environment section pledges 'to contribute to a safe living and working environment by providing a public health service which aims to meet community needs while satisfying statutory requirements' (Botany Bay Council, 2006). The plan doesn't point to any particular mechanism of managing greenhouse gases and climate change, but mentions review of the Energy Efficiency DCP as an ongoing activity.

Part 3 of the State of the Environment report is titled Air and Greenhouse. The main pressures outlined are climate change and air pollution. The report provides a brief summary of the principles of the greenhouse effect. Air pollution is identified as primarily derived from industry and automobile emissions. Two responses to climate change are recorded under Air and Greenhouse: extended trials of solar lighting at

bus stops, with investigation into possible future locations for solar lighting, and purchase of two hybrid vehicles for the council fleet, aiming to reduce corporate emissions and set an example for the community.

Botany Bay Council monitors air pollution through participation in ANSTO's (Australian Nuclear Science and Technology Organisation) fine particle Aerosol Sampling project. The project monitors and characterises particles at Mascot through the collection of filter samples taken twice a week (Botany Bay Council, 2007). The particles recorded are becoming smaller and affect human health and visible air quality.

Cities for Climate Protection (CCP) – BOTANY BAY COUNCIL

Botany Bay Council joined the CCP program in 2001. Currently they are completing milestone 3, and the LAP has been in draft for over 6 months. The other councils examined in this article have recorded superior CCP progress in a shorter timeframes.

There are many reasons for Botany Bay's slow progress with CCP. Firstly, the council is very small: the amount of office staff is limited. For instance, there is one environmental scientist who reports to the Director of Assets and Management. This person is responsible for many other tasks including review of development applications regarding environmental issues. This is a significant task, as the council has significant industrial areas and contaminated sites that require careful management. Secondly, and perhaps consequently, there has been a high staff changeover rate.

Resources at Botany Bay Council are very tight, and although the council is debt free, to undertake a significant project could result in an unmanageable debt. The Water Savings action plan has recently been completed in full, and Council states that this has taken priority over completion of the CCP milestone 3 report.

Milestones

1. **Establish an inventory**
   Council have committed to a reduction goal of 20% by 2012 from the baseline year of 1999/2000 for the corporate sector, and 20% by 2012 from 1996 levels for the community sector.

4. **Set goals**
   Some actions to be implemented from the LAP include development of an internal working group, retrofitting lights with fluorescents, installing light sensors, training internal staff, managing energy efficiency in the Aquatic Centre, trialling fuels and developing a bike plan.

5. **Action plan**
   Currently being drafted.

Implementation

Botany Bay is to also review its current environmental instruments in order to comply with the new standard instrument set by the State Government.

The Botany Bay Local Environmental Plan includes a specific section on the greenhouse effect and global warming—the first to be encountered in these case studies. Clause 22 of the LEP stipulates that applications for significant developments submit documents addressing global warming, water pollution, energy consumption and groundwater contamination wherever applicable. Developers are also to take into account any possible adverse effects on the development itself as a result of climate change due to the greenhouse effect (Botany Bay Council, 1995).

Botany Bay adopted an Energy Efficiency DCP in 2000. This plan was developed in the context of previous initiatives such as the SSROC Greenhouse Strategy 1992 and the Energy Efficient Development discussion paper 1993 (Botany Bay Council, 2000).

The objectives of the current DCP are to:

- Improve energy and water efficiency of all residential, commercial and industrial development;
- Reduce greenhouse gas emissions and conserve non-renewable energy sources;
- Promote residential, commercial and industrial developments that are more comfortable to live/work in and cost less to run; and
- Provide means by which the development community can uniformly and effectively implement and demonstrate compliance with the objectives of the LEP (1995), in particular clause 22.

Adaptation

The council seems to be waiting upon certainties before taking any significant action. There has not been any significant adaptation action to date. There have been discussions on risk of land, and on significant risks relating to sea level rise and flooding (any amount of sea level rise can potentially cover the whole LGA).

2.6 Local Council Case Study 4: Rockdale Council

Coastal Rockdale City Council is 12km south of Sydney's CBD. The LGA covers 30 square kilometres. Rockdale has a population of approximately 92,000 (ABS, 2006d).

The Rockdale LGA is growing at a rate of approximately 4% per year (ABS, 2006d). The majority of the area is residential, encompassing both low-density housing and higher density areas along the railway corridor. However, industry is also a significant emitter of greenhouse gases. In Rockdale, much of the LGA is very low

lying and vulnerable, comprising foreshore and bushland. A rise in the water table will have a significant effect; also a rise in sea level will immerse proportions of the LGA. Land is increasingly flood prone, decreasing house prices and creating issues around damage liability.

The council has been active with climate change policy development, including participation in the Greenfleet program, implementation of a Solid-Fuel-Heater-Buy-Back Program, creation of the Environmental Policy in 2003 and consequent adoption of the Environmental Plan. Rockdale has also adopted the CCP program. A political declaration was completed in 1999, just one year after the program's inception. As part of CCP Plus, Council embarked on the Greenhouse Purchasing program in 2006 and the Sustainable Transport program in 2007.

Rockdale Council's current management plan is for 2008/09- 2010/11. Rockdale's vision for the natural environment is for 'an ecologically sustainable city which protects and enhances its natural environment'. There is evidence that the council is committed to environmental sustainability. The strategic direction outlined in the city's succinct vision statement provides focus for managing environmental quality. The management plan points to the Environmental Policy (2003) as the backbone of environmental decision-making. It led to the production of the Environmental Plan: a key tool for reporting to the community on the progress and direction of environmental initiatives. The plan was produced in 2003 and underwent review in 2006.

Rockdale's State of the Environment Report contains seven themes. 'Atmosphere' is marked by an absence of objectives or goals. Pressures from community and corporate activities include:

- 70% of residents use cars for at least part of their journeys to work;
- Local air quality is affected by pollution from the M5 east motorway;
- Significant emissions come from the industry sector; and
- Adjacent land use by the Port Botany expansion and Sydney Airport Master Plan creates emissions and other stresses.

(Rockdale Council, 2007b)

Rockdale joined the CCP program in 1999 and has recorded significant progress. They achieved milestone 5 in 2005 and graduated from the program shortly after. The management plan identifies involvement in the CCP program as a demonstration of Rockdale's seriousness about environmental matters. It is clear that CCP provided leverage for action, and that through it various other environmental initiatives were made possible.

Cities for Climate Protection (CCP) Milestones – ROCKDALE COUNCIL

1. **Establish an inventory**
   Significant corporate sector emissions are from street lighting and buildings. Significant community sector emissions are from industrial and residential

activity. Figures 3.1 & 3.2 indicate the distribution of emissions for the corporate and community sectors.

2. **Set goals**
   Rockdale has committed to a reduction goal of 20% by 2010 from the baseline year of 1995 for the corporate sector, and 20% by 2010 from 1995 levels for the community sector.

3. **Action plan**
   A local action plan was produced. Completed projects therein include:

Corporate Actions

- Reduction of greenhouse gas emissions from office equipment including retrofitting the council administration building with fluorescent lamps, monitoring equipment and acquiring LG Flatron monitors with star ratings;
- Retrofitting council streetlights: replacement of 10,000 20 watt lights with 360 mercury vapour lights; and
- Updating Council's fleet to 4-cylinder vehicles and trialling alternate fuel vehicles.

Community Actions

- Energy conservation workshops to increase residents' awareness of energy efficient practices in the home;
- Newsletters, website and displays encouraging energy efficient appliances and water heating, and renewable green power;
- Information provided to local commercial and industrial businesses regarding energy audit guidelines and use of green power; and
- Facilitation of more bicycle storage areas in parks and shopping centres, encouraging cycling as a realistic transportation option.

A full list of completed projects is contained in the SOE report and Environmental Plan.

Rockdale have progressed to CCP Plus. Since 2005 they have participated in two further projects, Greenhouse Purchasing and Sustainable Transport.

<u>Greenhouse Purchasing</u>

Rockdale joined the Greenhouse Purchasing project in 2005. The plan requires review of existing council policies and practices by staff from the supply and environmental departments. A staff survey was also conducted.

Rockdale's Greenhouse Purchasing action plan identifies its key issues as:

- Updating the environmental policy and the environmental purchasing policy;
- Greenhouse purchasing criteria to be considered for tenders;
- Ensuring suppliers meet greenhouse purchasing criteria;

- Ensuring staff make informed decisions regarding sustainable purchasing through checklists, tracking systems and the like; and
- Educating staff through workshops and regular updates.

(Rockdale Council, 2006)

It is clear that Rockdale has a good platform for purchasing policies, and even though implementation has been minimal, staff have already been considering greenhouse issues in purchasing decisions.

Sustainable Transport

Rockdale's Sustainable Transport action plan states the following key goals:

- To integrate sustainable transport objectives and principles into all priority strategic planning projects;
- To encourage an integrated approach to sustainable transport issues across Council departments;
- To actively promote alternative transport modes to both staff and the community; and
- To reduce greenhouse gas emissions by the council vehicle fleet.

(Rockdale Council, 2007c)

In the past, Rockdale Council has had problems with lack of community awareness, lack of strategy/plan coordination, and limited influence on the State Government regarding sustainable transport. More recently, these issues have been partially addressed through their environmental policy, their management plan and their fleet policy, and through strategic planning via their Transport Traffic Plan.

Implementation

Environmental Policy

The Rockdale City Council Environmental Policy was developed and adopted in 2003 to achieve ESD through council decision-making processes. The policy specifies that council staff must:

- Comply with all applicable laws, regulations and standards, and apply additional standards that minimise environmental impacts resulting from operations or services;
- Communicate openly with the community about environmental issues;
- Ensure that environmental and social costs are considered when evaluating services provided by and to Council;
- Ensure that employees, local community and suppliers of goods and services are aware of their environmental responsibilities in relation to council business;
- Establish programs to protect the environment; and

- Provide employees and external parties with the necessary resources in order to comply with the requirements of Council's Environment Policy.

(Rockdale Council, 2003a)

The Environmental Plan is a key strategic document outlining the need for protection of the atmosphere globally, regionally and locally. Locally, carbon monoxide, sulphur dioxide, lead and other toxins are highlighted as key pollutants. The Environmental Plan outlines the need for ESD and cites an array of documents produced locally and regionally. Actions, listed in table format, span issues, action to be taken, departments responsible, performance indicators and completion timeframes. Categories in this table are designed to ensure uniformity with the 2006 SOE report.

The council is developing a new LEP, consistent with the NSW Government standard instrument. This plan aims to incorporate the targets of the Sydney Metropolitan Strategy. A new clause will deal with flood height and flood prone land. It is unclear how other environmental objectives will be incorporated.

Council has identified a high proportion of emissions from private automobiles. In 2004, Rockdale Council developed a draft Transport and Parking DCP setting controls for car parking provision in developments and encouraging alternative travel modes. Another DCP is currently being adopted to ensure that new development takes into account freight, car, cycling, walking and public transport. The plan aims to improve social inclusion, widen transport choices and reduce greenhouse emissions.

Adaptation

Preston (2008) state that Rockdale Council has a low adaptive capacity for climate change. There is a high degree of sensitivity due to its geographic position, topography and coastline. Given the circumstances, there is a great need to take stock of adaptation in this LGA.

Council seems to be aware of the concept of adaptation. There is regard for addressing risk management and liability issues involving the community. The management plan contains an objective for adaptation to climate change: 'to develop mechanisms to enable Council to adapt to climate change' (Rockdale Council, 2007a), and a deadline to achieve it: June 2009.

Climate Change modelling in Manly Council has revealed that a 1% sea level rise will result in the immersion of a significant amount of Manly's LGA. This flood model represents the higher end of realistic predicted emissions, and demonstrates the potential impacts sea level rise will have on a specific area. There is no such tool in use at Rockdale Council.

2.7 Comparative study of Climate Change Mitigation and Adaptation Strategies

There is a difference in environmental policy between the examined coastal councils and the non-coastal councils. Inland Burwood and Ashfield Councils have undertaken moderate climate change action.

In the non-coastal LGAs, a notable feature of the study is that councils appear to be motivated by issues involving their citizens' health, rather than the wider global fight to address climate change.

The two coastal councils are very low lying and vulnerable to sea level rise and storm activity. Awareness of this issue is expressed in both councils' documents, but actions have been limited. Rockdale has incorporated an adaptation objective into the management plan, and an adaptation plan is currently being produced. There is no evidence that Botany Bay is undertaking adaptive actions.

The most prominent difference between the actions of all these councils is their relative progress with CCP. Rockdale is very advanced, while Botany Bay has been very slow in progress, and Ashfield and Burwood have progressed at a moderate rate.

3 Climate Change Prevention and Adaptation in Southern Nevada

As mentioned before, this research is partly an outcome of two month long visit in 2011 of the University of Nevada Las Vegas (UNLV) as research scholar with the Water Resources and Environmental Engineering Department of the university. During that visit this scholar interviewed city and regional planners, transport planners and engineers, sustainability related staff and administrators at the Mountain Brooking Institute, UNLV, City of Las Vegas, City of Henderson, and RTC (Regional Transport Commission) of Southern Nevada. This author attended a number of sustainability seminars, workshops, presentations and exhibitions at UNLV and in Greater LV. A number of reports were also collected during the above mentioned interviews, and attendances. In addition this author extensively travelled on the RTC public transport for observations.

3.1 City of Las Vegas

At the City of Las Vegas, the Sustainability Officer Deputy Director Planning were interviewed. The two officials highlighted the liveability improvement initiatives of the city. They cited Downtown Centennial Plan, 10 feet sidewalks and 5 feet tree lined amenity zones buffering the pedestrians from traffic. As far as climate change is concerned, the city took a half-hearted measure which has been described below. However, not much progress could be made on this initiative. What the city of Las

Vegas does have on sustainability is the claim/motto that, “sustainability is more than just being green - it is a way to ensure that current and future generations will enjoy the quality of life we have all worked so hard to achieve”. The city has taken the following actions to back up its commitment to be “beyond green”:

Las Vegas City Council Adopted a Sustainable Community Strategy having three components: city operations; city codes and policies; and community involvement.

> City Operations: Goals included, working to reduce the city’s carbon footprint by 10 percent in 2011, 20 percent by 2020, and 30 percent by 2030. Also, to reduce the city’s electricity use by 5 percent per unit by 2011.
>
> City Codes, Regulations and Policies: Goals included, adopting an energy code that is 30 percent more efficient than the current code by 2011. Also, to work with the Green Building Council to revise the Green Building Program to include more mandates and incentives.
>
> Community Involvement: Goals included having a fully implemented residential solar rebate program by 2009. Also, to provide incentives for residents to take part in home energy audits by 2009.

Greenhouse Gas Emissions Reduction

The city of Las Vegas had a brief brush with action on climate change. In 2007, the city of Las Vegas had joined the International Council for Local Environmental Initiatives (ICLEI) Local Governments for Sustainability Campaign. The Local Governments for Sustainability Campaign incorporates a five-milestone structure that participating local governments work through: (1) establish a emission baseline; (2) setting a reduction target for emissions; (3) develop a local action plan to achieve the emission reduction target; (4) implement the local action plan; and (5) measuring our emission reduction results.

The city is still on phase 1 - establishing a baseline. The baseline is established by conducting an analysis of the city’s greenhouse gas emissions. The city began conducting these studies in August 2007, beginning with city facilities and buildings. The city of Las Vegas uses ICLEI’s Clean Air and Climate Protection (CACP) 2009 software to complete our greenhouse gas emissions analysis of city operations. CACP software serves as a one-stop emissions management tool for calculating and tracking the City’s greenhouse gas emissions and criteria air pollutants associated with electricity, fuel use, and waste disposal.

Climate Protection Resolution (US Conf. of Mayors): The city of Las Vegas works with businesses, organizations, government agencies and consumers to reduce emissions of the greenhouse gases that contribute to global climate change. On Aug. 2, 2006, the City Council signed the Climate Protection Resolution.

Alternative Fuels Program for city owned vehicles

The city of Las Vegas has been member of the U.S. Department of Energy's Clean Cities Program since October 1993. It entered the program with 50 fuel flexible vehicles. The city has gradually expanded its Alternative Fuels Program. The program has converted 90 percent of city's non-emergency fleet, approximately 1,350 vehicles. The alternative fuels used in the program are Compress Natural Gas (CNG), Biodiesel (B20) blend, Oxy gasoline and hydrogen. The city also uses Hybrid vehicles (http://www.lasvegasnevada.gov/sustainingglasvegas/16078.htm)

Urban Forestry Initiative i.e. planting

The city regularly participates in Arbor Day activities and is currently planting new trees under the Nevada Nursery Greening Project.

Trails

The city develops trails throughout the area that provide recreation opportunities, promote health and fitness, enhance economic opportunities, serve as a buffer and contribute to the conservation of natural resources.

Complete Streets

Complete streets are pedestrian friendly streets that allow for multiple modes of transportation, including cars, bicycles and transit. The city is upgrading streets in the community to make them more sustainable.

3.2 City of Henderson

In discussion with the City of Henderson it again came out that climate change is a dirty word. The officials of this wealthy city can only present their climate change related concerns and initiatives rapped in the efficiency and green sustainable feel good covers. The city houses the trendy parts of the city and has worked with the developers on providing new urbanist type residential development. The city has greened the bus stops by planting bushes around the stops, in actively replacing street light globe with more efficient varieties, and is promoting active living by maintaining a number of nature trails that can be used for walking or bicycling.

Increase energy efficiency

The City of Henderson received a large state rebate for facility retrofit program. The rebate helped to fund LED lighting fixtures in City Hall, Convention Centre and Civic Plaza parking lots. These highly efficient fixtures feature two-level motion sensors, one that brightens when a vehicle approaches and one that lowers to standby when the vehicle passes, reducing annual energy costs.

Weatherization and HOME Rehab Programs: Over 500 income-qualified home owners received $1.3 million in assistance to make energy-efficient improvements and reduce their energy costs. Common retrofits include insulation, reduce air leakage, repair or replace heating and air conditioning (HVAC) systems, replace refrigerators and perform general health and safety inspections.

Green Buildings and sustainable urban design

Henderson was one of the fastest-growing cities in the USA for two decades till the Global Financial Crisis. A vast majority of Henderson's housing stock was built after 1990. The City's first energy code, the 1989 Model Energy Code, was adopted in 1992. Henderson thus claims to largely have been built with energy efficiency in mind.

Public buildings in the city are being extended and built with higher energy efficiency criteria. The Detention Centre that recently completed expansion was remodel incorporating cost-saving upgrades for energy efficiency and water conservation, including energy efficient lighting, highly-efficient air conditioning and heating equipment and drought tolerant landscaping.

Also the Heritage Park Aquatics Facility and Senior Centre were designed and constructed to meet high standards of energy efficiency, water conservation, occupant safety and comfort. In 2011, the City had applied for Gold Leadership in Energy and Environmental Design (LEED) certification from the U.S. Green Building Council.

3.3 RTC Regional Transport Commission of Southern Nevada

The Regional Transportation Commission of Southern Nevada (RTC) is responsible for providing a safe, convenient and effective regional transportation system for its two million residents and 39 million visitors. The RTC is both a transit authority and the transportation planning agency for Southern Nevada. The RTC functions as the Metropolitan Planning Organization (MPO) for the region. It is responsible for overseeing the transportation planning process and for directing funding generated from various local, state and federal sources for transportation purposes.

This author interviewed transport planners at RTC as well as participated (as an observer) in one of the stakeholders meeting on sustainability initiatives for the future of transport in Southern Nevada.

In the interview with the transport planners at the RTC it came out that the Commission is not engaged in any direct climate change abatement or greenhouse gas reduction scheme even though "reduce greenhouse gas carbon footprint" is one of its long-range goals. It is concerned about the sustainability in general terms and has a number of initiatives in place for the same. In addition to the specific green programs it deems its bus service as a contribution to sustainability as well. Some of its initiatives are listed below:

Sustainability policy

The RTC has the following sustainability goals are listed below. Climate change abatement or is not one of its sustainability policy goals. Description of the sustainability programs that follows the goals list provides a flavour of the nature of the measures taken for sustainability in Southern Nevada region.

- Implement transportation systems that improve air quality in Southern Nevada;
- Develop fully-integrated transit mode options;
- Integrate the transit system geographically;
- Secure funding for expansion, operation and maintenance of the transit system and routes; and
- Enhance public awareness and support of the regional transportation system.
- Bus Rapid Transit(R T C)
- The RTC is currently working on building a rapid transit system that will connect downtown Las Vegas, the Las Vegas Convention Centre, the Strip, Henderson and North Las Vegas. (R T C).

The Electric Bike Share (E-Bike) (R T C)

The new Electric Bike Share Program is for the government staff who need to get around downtown. RTC promotes the E-Bikes as state of the art in sustainable transportation that can help the environment through reduced air pollution and traffic congestion.

RTC claims, sunny and dry climate makes Las Vegas a suitable place for cycling, particularly for short trips. The RTC tested the concept through a pilot program in summer 2010 with the cooperation of other government agencies. RTC hopes to make the program available to public soon
(http://www.rtcsnv.com/cycling/ebike.cfm)

Public transportation improvements

RTC has a network of bus service of which Bus Rapid Transit (BRT) line is light rail style limited stop fast service. RTC is planning to extend that service to several key corridors and by constructing stations and other amenities in mixed traffic operations where dedicated lanes cannot be created.

Bonneville Transfer Centre

RTC is built the BTC which houses Las Vegas Valley's transit services, including park and ride express routes. It has a commuter cycling station which has the capability of accommodating up to 120 bicycles. The bike station is a first for Las Vegas. It has other amenities such as restrooms with showers, 24-hour access and a bicycle repair shop and service area.

LEED Gold Certified Green Buildings

As a partner with the community, the RTC has designed and delivered a building that is also environmentally friendly. To achieve LEED Gold certified building water reclamation; use of recycled materials; energy-efficient cooling systems; and architectural practices such as the right building position and shade systems were adopted.

Bikes and Buses

All RTC transit vehicles are fitted with bicycle racks. RTC transit carries more than 55,000 bikes on buses per month. This author in his two months of heavy RTC bus use observed frequent use of the bicycle racks fitted in front of all busses.

Westcliffe transit centre park and ride

The Westcliffe Transit Centre is located near Summerlin Parkway. It has been provided with "sustainable features" include more than 140 parking and ride spaces, a climate-controlled transit centre and water efficient landscaping.

Facilities

RTC Facilities Department has made following sustainable improvements: Intelligent illumination systems have been installed in RTC buildings. These systems automatically switch off the lights when the rooms are not in use. The RTC facilities is also exploring use of LED exterior lighting on their premises again to save energy.

The RTC has implemented a no idle program with operating vendors, performing timely maintenance and repairs, including adjusting and maintaining proper tire pressure. These measures save fuel.

Conclusion and recommendations

As far as Sydney NSW is concerned it was found that transport emissions are by far the biggest contributors toward overall emissions in the community sector. This needs to be acknowledged and addressed. There has been little pressure on councils to act, from the State Government or from the community. There is a need to review urban design and environmental planning instruments to encourage alternate forms of transport. The situation in Southern Nevada is no different. Like Sydney most sustainability measures are in house applied to the buildings they hold and the staff they employ. While the local authorities in both regions have made efforts to reduce their environmental footprints, they have not been vocal/forceful when it comes to communities' impact on the environment in general and climate change in particular.

In Sydney NSW motivations for climate change action and joining CCP have largely been tied up with asset management and insurance premiums. Councils are taking economic precautions rather than addressing climate change. Councils are meanwhile becoming more vulnerable as a result of climate change impacts, and are likely to experience an increase in lawsuits.

Terms such as *sustainability* and *ecologically sustainable development* are over-used in policy documents and reporting, or used vaguely. It is recommended that councils research and employ more specific and accurate terminologies. That is true for both NSW and Southern Nevada. A lot advertisement of green credentials in S. Nevada pointed to sloganeering and marketing more than substance on sustainability/green credentials.

In NSW Coastal councils seem to be more aware of climate change impacts and adaptation than non-coastal councils, as they are under more immediate threat.

In interviews in Southern Nevada (Las Vegas) it came out that individuals and agencies and are dismissive of peak oil and climate change. One of the interviewees asserted that Las Vegas is already sustainable due to limitations on its expansion. The same person implied peak oil is myth and climate change a hoax.

In S. Nevada planning and sustainability officials at various agencies admitted climate change is not an easy topic to broach. They have to tackle it indirectly portraying it to be an efficiency measure or a green/quality of life issue in general.

It was observed in S. Nevada it was a unified opinion that the solution to any sustainability problems has to technological and has to be delivered by private

enterprise. This inclination can be seen in the sustainability measure outlined by various authorities such as Green Building initiatives.

In both regions there are talks about what how much GHG emission has been avoided and will be avoided. However no mention is made of how much it should be or what difference has the carbon savings and environmental measures have practically made.

Ian Riekes Trivers, University of Michigan

Casey Knoettgen, University of New Orleans

AESOP, Ankara, July 11 -15, 2012

Rental Housing Development in a Shrinking City: The Case of New Orleans after Hurricane Katrina

Abstract:
New Orleans was a shrinking city when it was devastated by hurricanes Katrina and Rita in 2005. New Orleans's rental housing sustained significant damage, and Louisiana received an additional allocation of LIHTCs to help rebuild the rental housing stock. New Orleans was also a city that had experienced decades-long population loss before the hurricanes that had resulted in excess developed land and housing units, a situation that the hurricanes exacerbated. This paper examines impacts that the different types of LIHTC projects—scattered site, multifamily, and detached singles and doubles—had on rebuilding the urban fabric in a way that would result in sustainable neighborhoods for a smaller population. We analyzed nine select projects to determine their infill, continuity, land use and density impacts. No single project provided enough infill to stabilize the neighborhood where it was built. The scattered site and detached unit projects used more land per unit, but the analysis demonstrated that infill and continuity were dimensions needed to ensure maximum impact from new development.

Introduction: New Rental Housing in Depopulating Cities, a Solution or a Problem?

New Orleans needed rental housing after the devastating flooding that followed the 2005 hurricanes Katrina and Rita. Wind, rain and flooding effected 70% or 134,000 of the city's occupied housing units (GNOCDC, 2009) and approximately 67% of the rental units (GNOCDC, 2006). Half the structures had major damage (GNOCDC, 2009). The rental housing damage impacted many New Orleanians since 54% of the population lived rented their housing.

Because New Orleans had lost population since 1960—at first losing residents but retaining households as household size decreased but, in later decades, losing both residents and households—the disaster occurred in a shrinking city context. The 2010 census count of 343,829 residents was over 70% of the 2005 estimate but closer to 55% of over 627,000 people who made the city home in 1960 (GNOCDC, 2011). In addition, suburban subdivisions within the city boundaries added housing units in the 1960s, 1970s and 1980s. These trends cumulatively resulted in a city that had widespread property abandonment before 2005 and increased blighted property and vacant land as a result of the 2005 disaster.

Although rental housing redevelopment was necessary, new development had the potential to exacerbate the pervasive problem with derelict buildings. Would new development shift people from one area to other, leading to new patterns of blight and settlement? Would new construction discourage repair of existing housing? Or could new development and strategic rehabilitation contribute to developing a sustainable urban form for a smaller population? To examine the impact of new development in a depopulated city, we evaluated the form and pattern of rental housing financed through Low Income Housing Tax Credit (LIHTC) program. We chose to examine LIHTC projects because LIHTCs are a significant source of public funding in U.S. shrinking cities. Lan Deng (2012) has estimated that if Detroit received LIHTC investment

proportionate to its share of the state's population in 2001, the total LIHTC investment would a third of the city's Community Development Block Grant allocation, a major source of public funding to urban areas. Between 1986 and 2006, the LIHTC program contributed to 1.6 million units, about one sixth of all multifamily units built (Schwartz, 2010, 103). Forty five projects with a total of over 5000 units were built in New Orleans during the period we examined.

The focus of this paper is to examine what contributes to patterns that would maximize land stewardship. We evaluated the LIHTC projects in relation to three urban form dimensions that contribute to increased sustainability—density, continuity and infill—to illustrate how characteristics of the new development, and not only the extent of new development, impact neighborhood rebuilding in a depopulating growth situation. In the case of shrinking cities, using more abandoned land is a net positive and this was an additional dimension that we examined. No project or projects as built stabilized the neighborhood with a smaller population. Infill and continuity contributed most to stabilizing depopulating cities.

New Orleans is an extreme case to consider redevelopment in a shrinking city. It received massive damage and a significant influx of redevelopment funds. New Orleans rate of redevelopment greatly exceeds that which shrinking cities experience. From excess public facilities to vacant land, New Orleans "recovery" nevertheless has been shaped by long term shrinkage and the recovery reflects an intensified process of depopulation and shifting resettlement patterns. In this paper, we first explain prior research that shaped this analysis. We then turn to the post-Katrina period in New Orleans, and explain the rental housing recovery programs. A comparison of the total development and operating costs of nine projects follows, along with our analysis of their neighborhood impacts. Finally, we include a discussion about the differences between within-neighborhood and among-neighborhood impacts.

Conceptual Underpinnings: Sustainable form without growth?

Scholars define urban form in various ways. We draw on Glen Bramley and Karren Kirk's (2005, p. 356) definition of urban form as "the size, shape, and intensity of urban settlements and the spatial organisation of different types of land use within them." Based on an analysis of the sustainability and environmental planning literature, Yosef Jabareen (2006) identified seven design concepts that contribute to sustainable urban forms: compactness, sustainable transport, density, mixed land uses, diversity, passive solar design, and greening. When synthesizing the characteristics of sprawl, an imprecise concept poised as the antithesis of sustainable form, George Galster *et al* (2001) define sprawl as scoring low values on one or more of eight land use dimensions: density, continuity, concentration, clustering, centrality, nuclearity, mixed uses and proximity.

This paper is based on the premise that distinct interventions will be required to increase sustainability in shrinking cities. Some considerations in shrinking cities parallel sustainability concerns in growing areas including efficient infrastructure and urban services (that in some contexts would come with compactness) and greening interventions from stormwater management to tree coverage and urban gardening. Other concerns diverge. Shrinking cities have underutilized disturbed land that impacts remaining residents and encourages movement in outlying areas. The question of land stewardship is critical to create vibrant smaller cities and ensure residents can thrive. How can excess land be managed and used? What settlement patterns will stabilize shrinking cities? For this paper, we include land use and shape of settlement within a city or smaller urban division, down to the design of specific projects. Although the units are smaller than many scholars who examine urban form, the connections

among site specific design, neighborhood infill and a sustainable region interrelate, as we discuss in our analysis.

Observers have heralded the possibilities of greening shrinking cities because urban land becomes increasingly available (Lawson and Harmon, 2012; Oswalt, 2006). Relaxed zoning ordinances also could facilitate mixed land uses when neighborhood populations decline (Hollander, 2011). Planning however is more influential in areas with high demand (Bramley and Kirk, 2006), and policies have different impacts in fast and slow growth areas although local governments do not always take this into account (Leo and Brown, 2000; Leo and Anderson, 2006). Although the general objectives are consistent with sustainability in growing areas, adapting shrinking cities must take into account sparser settlement in already developed areas and infrastructure designed for populations that exceed current residency. We propose that rebuilding a sustainable urban form in shrinking cities also requires performance outcomes that reflect decreasing densities in which settlement patterns result in good land stewardship and infrastructure and urban services that are maintainable long-term. In contrast with growing areas, shrinking cities require both infill and lowering densities (Ehrenfeucht and Nelson, 2011). Actions to retrofit cities to smaller populations can become contradictory. For example infrastructure efficiency has different density requirements than land stewardship, revitalization in one neighborhood can draw residents from other neighborhoods, and decreasing densities can make public services more expensive. In addition, slow growth regions with cities that are losing residents can still growing on the outskirts (Couch, Karecha, Nuissl, and Rink, 2004).

This paper focuses on the question of land stewardship because millions of people live in cities with a glut of property and no ready way to facilitate its use. How to facilitate effective land stewardship in areas with diminishing property demand remains a pervasive issue. In the

U.S., planning responses to population loss and property decline have focused on strategies to attract private investment. In many cities, central neighborhoods have higher levels of housing abandonment (Cohen, 2001; Accordino and Johnson, 2000; Keenan, Lowe and Spence, 1999), and evidence suggests that significant targeted investment such as in Richmond, Virginia's Neighborhoods in Bloom program can increase property values and spur localized improvements (Galster, Tatian and Accordino, 2006). Targeted efforts alone are inadequate to address the magnitude and types of problems generated by widespread depopulation, and they can lead to a zero sum game for the city or region with persistent and widespread depopulation by moving investment from one area to another rather than stimulating new development (Couch, Karecha, Nuissl and Rink, 2005).

Urban residents, public officials and planners or other urban professionals have disagreed about what types of interventions are acceptable. Proposals to close off neighborhoods have been consistently resisted (Shiffman, 2005-2006; Rybczynski and Linneman, 1999; Nelson, Ehrenfeucht and Laska, 2007). In post-Katrina planning processes, residents and public officials made an explicit decision to retain the city's neighborhoods (Ehrenfeucht and Nelson, 2011, 2012). "Shrinking the footprint" or decommissioning neighborhood or occupied areas became analogous with denying African American residents the right to return to the city after the flooding has subsided (Nelson, Ehrenfeucht and Laska, 2008). Even in Youngstown, Ohio, where residents agreed through an extensive planning process to reduce or eliminate services to depopulated areas, when specific households were offered relocation assistance, they opted against moving.

On a parcel and block level, individuals legally and informally absorb underused parcels into their properties, but neighborhoods with high rates of homeownership and residents with

higher incomes are better able to integrate unused properties into occupied parcels and create larger lot, less dense neighborhoods (Hollander, 2010). In neighborhoods with rental property, market rate rents do not support significant rehabilitation of aging buildings. Rental property owners have less incentive to integrate abutting properties and are not present to occupy or maintain them, and the occupants have less property control. Stronger neighborhoods can also thrive amongst struggling neighborhoods.

Even real estate development to facilitate growth is a common economic development strategy in U.S. shrinking cities, it has never changed a city's circumstances. National aid can help offset local market disadvantage by giving cities or regions more bargaining power (Savitch and Kantor, 2002). No federal policies help U.S. cities address population loss however. Instead New Orleans was in a "dependent private" bargaining context with few resources, but also little public aid. In the case of Detroit, this situation results in strategies oriented towards attracting new business (Savitch and Kantor, 2002: 223-266). U.S. cities with weak market positions nevertheless can have influence. Margaret Dewar (2006, 2007) has found that land management strategies can impact how effectively vacant land is reused even when demand is weak. Land banking, bundling and selective sales, and selling property to abutting property owners result in higher reuse rates and maintenance than tax sale auctions.

For this paper, we examine new development financed with tax credits allocated through Low Income Housing Tax Credit program. We chose the LIHTC projects for three reasons. First, as we stated in the introduction, LIHTC are a significant source of public subsidy and new development in shrinking US cities. Second, state agencies that allocate LIHTCs have significant leeway to incentivize different types of development. Through developing a Qualified Allocation Plan, each state develops criteria on which to evaluate proposed projects. In case of the LIHTC

program, states have the possibility of taking growth patterns seriously. Because shrinkage is common, twelve of the largest 50 U.S. cities lost population in consecutive decades from 1980 to 2000 and 9 of the 50 largest cities lost population steadily between 1950 and 2000 (Beauregard, 2009), rethinking how policies function in different growth scenarios is both necessary and possible.

Although housing development can be a mechanism to stimulate neighborhood revitalization (Schill and Wachter, 2001), and Alan Mallach (2006) has argued that housing policies in weak market areas *should* be neighborhood development policies, how to best build housing in areas with surplus land and housing structures remains unclear. When Lan Deng (2012) investigated the impact of LIHTC projects in Detroit, she found that the projects alone were insufficient to stimulate neighborhood change—based on demographic and property value change—and most were located in neighborhoods with stronger real estate markets and relatively more demand. The final reason to examine LIHTC projects is that even though housing investment can help revitalize neighborhoods, in areas with limited demand, new housing in one area can also negatively impact another. As the rental market loosens, rents fall and housing can be readily available. Low rents and neighborhood decline also discourage reinvestment in rental housing however and maintenance decreases. Housing quality and neighborhood decline, not affordability, become primary concerns. If housing quality is declining, many residents would prefer new housing units if available. In a city losing population, moves among neighborhoods will impact residents in other neighborhoods and patterns of property abandonment (Beauregard, 2012).Youngstown, a city often used as the forward thinking example of planning for a smaller population, declined LIHTCs (Beauregard, 2012).

LIHTC Development in Post-Katrina New Orleans

Despite the need for rental housing in the years following Katrina, much damaged property sat unrepaired. From 2004, before the hurricanes, to 2008, rents spiked 27% in the New Orleans metropolitan area and 41% in New Orleans (Plyer *et al*, 2009). The percentage of households that were cost burdened increased significantly to 66% in 2008 with almost all low income households in this category (Plyer *et al*, 2009). Prior to the hurricanes, much housing had been affordable because vacancy was high, but when the structures were damaged they were not profitable to rebuild.[1]

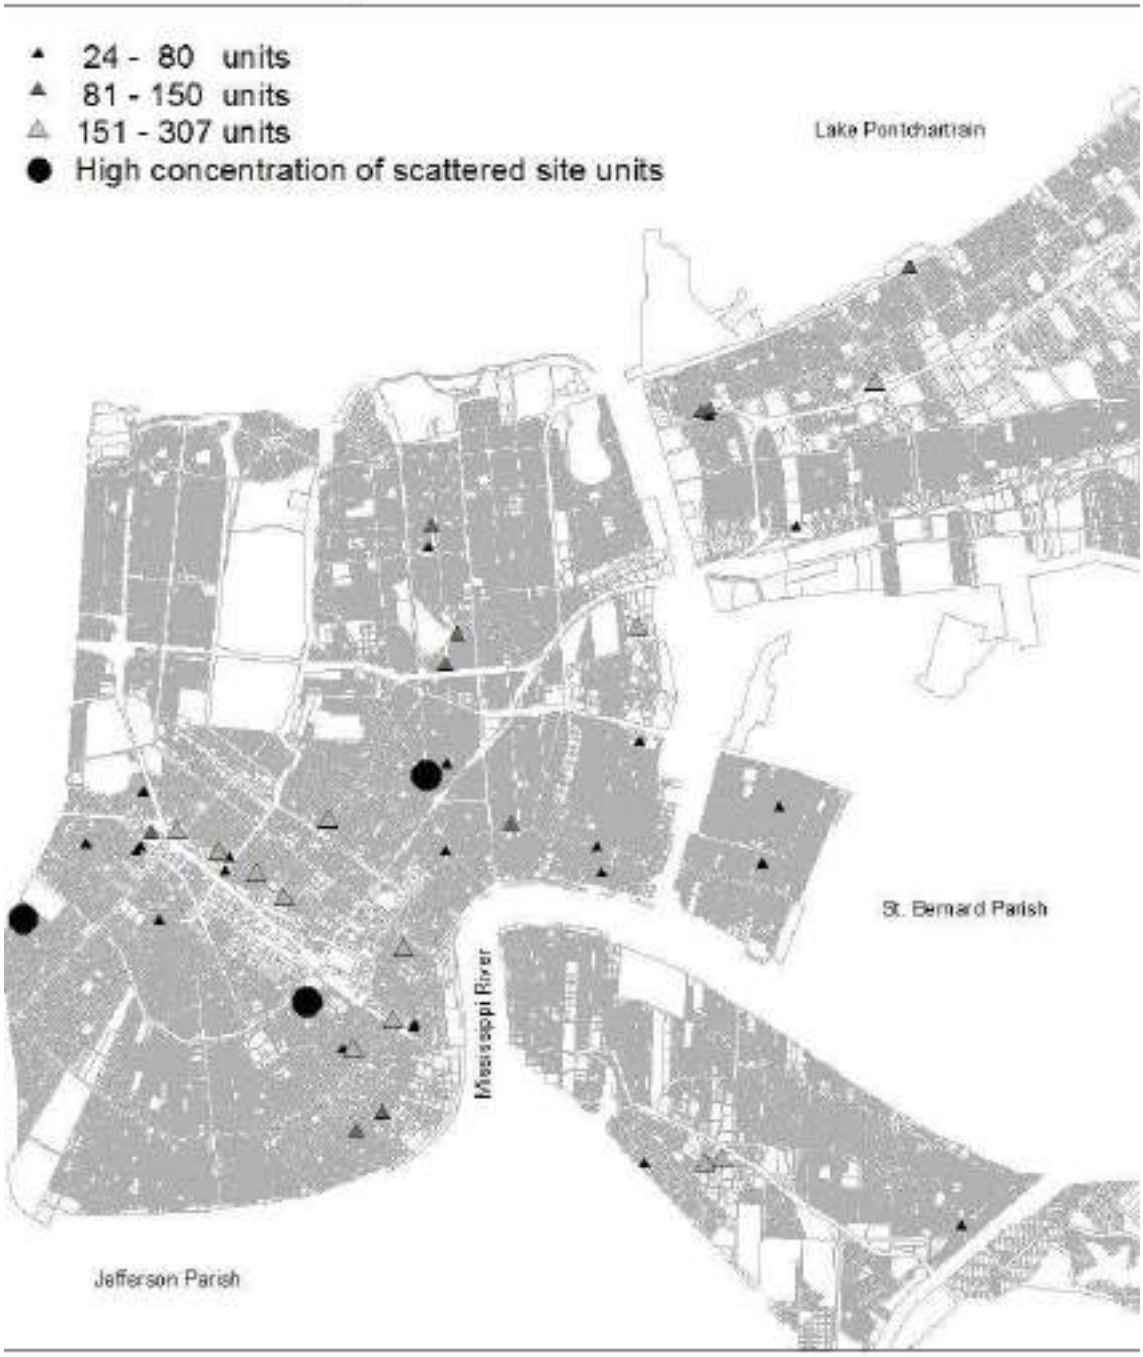
With high development costs, environmental risk that made conventional financing difficult, and uncertain rents, developers and existing property owners depended on public funds to repair or build housing. Two programs addressed rental housing redevelopment in Louisiana. In December 2005, the U.S. Congress adopted the Gulf Opportunity Zone (GO Zone) to encourage private development in the impacted region. The Louisiana Housing Finance Agency administered a multifamily program that, between 2006 and 2008, received a $170 million special allocation of Low Income Housing Tax Credits for rental housing recovery in the GO Zone. An additional $667 million of Community Development Block Grants was allocated for a "piggyback" program to incentivize new developments to serve populations with lower incomes and special needs (Clark and Rose, 2007). The state's Road Home housing recovery program also included a competitive small landlord program that reimbursed landlords of properties with four or fewer units for eligible repair costs.

[1] The rental rate remains high. In 2008, the rental rate had declined from 54% in 2000 to 47% (compared with 34% in the abutting Jefferson Parish and 33% nationally) (GNOCDC, 2009, Housing Production Needs). The 2010 census count however showed that the rental figure had again increased to 52%.

In New Orleans, 46 projects for a total of 5,157 housing units were built using LIHTCs.[2] The project ranged from 24 to 307 units with an average size of 113 units (figure 1) Most projects were constructed on a single site although three projects were on individual parcels scattered throughout the city. Figure one identifies the location of the highest concentration of the scattered site parcels by a circle. This paper addresses three interrelated questions about the LIHTC projects. How did the LIHTC projects impact the neighborhoods where they were built? How did the LIHTC projects respond to the conditions of population loss and property abandonment? And, given the location and patterns of development, what possible impacts will the LIHTC projects have on property stewardship across the city?

[2] The projects include those that received tax credit allocations after the hurricanes and were substantially put into service by 2011. One scattered site project considered in this analysis is still under construction but the buildings are mostly constructed, and rented as they are finished, and therefore adequate for this analysis. We excluded public housing redevelopment projects that utilized LIHTCs.

Figure 1: LIHTC projects built after the 2005 hurricanes in New Orleans.



A 2007 analysis of the LIHTC applications for the state of Louisiana indicated that the LIHTC allocations would contribute to rebuilding damaged housing (Clark and Rose, 2007).

Although some existing housing complexes in New Orleans were repaired, most projects were multifamily new construction. Other projects included new singles or doubles on single and scattered sites. During this period one adaptive reuse project was built with LIHTC tax credits.

To evaluate the impact of the projects, we selected a subsection of projects for closer analysis. To identify the scattered site projects, we requested all applications from the Louisiana Housing Finance Agency (LHFA) for projects that were described as scattered site. This designation included projects that were detached units on single sites and projects with singles or doubles on noncontiguous, individual parcels. Nine projects fit this criterion and we examined all nine projects. One project had two phases that were counted as a single project, and we excluded one project. This resulted in seven projects for comparison that ranged from 15 detached doubles on a single site to 166 properties. Three projects were built on individual parcels scattered throughout the city (two affordable doubles, one mixed income singles) and four projects were detached, single site projects (two doubles, two singles). Doubles are a common housing type in New Orleans. We also chose two award winning single site multifamily mixed income projects to include in the comparison.[3] These projects were located in two areas that typified the resettlement shifts that were facilitated by the hurricanes and responded to changing market dynamics where both were in up and coming areas. In the following subsections, we first briefly describe the projects. We then outline a cost comparison of the selected projects. Third, we

[3] In 2010, Domain Companies, the Crescent Club's developer, received an Affordable Housing Finance honor. The landscape design for The Muses Apartments in New Orleans received the President's Award of Excellence by the Louisiana Chapter of the American Society of Landscape Architects. In 2010, the Muses also won a Novogradac Journal of Tax Credits Development of Distinction award for Overcoming Significant Obstacles.

compare the neighborhood impacts based on urban from dimensions that impact land stewardship in shrinking cities.

The Projects Of the nine projects, four—Louisiana Freedmen Homes, Indiana Homes, Elmwood Homes, and Orleans Place—were single site projects with detached units. In this case, a single site means that the parcel or parcels were contiguous and uninterrupted (except by streets). All four of these projects were affordable. Louisiana Freedmen Homes was the smallest project and comprised of 15 detached doubles. The project was located in Gert Town, a disinvested centrally located neighborhood. Each two story building fronts a street. The 30 doubles of Orleans Place front three newly developed streets (figure 2). The shared common space behind the houses is enclosed similar to a condominium complex. Indiana and Elmwood Homes were single detached houses on adjacent undeveloped tracts resulting in a new single family development with 100 houses (figure 3).

Figure 2: Orleans Place

Figure 3: Indiana / Elmwood Homes

The three scattered site projects, Classic Construction, Crescent Garden Homes and Opportunity Homes, were comprised of singles and doubles on single infill parcels throughout the city (figures 4 and 5). Most but not all properties were in centrally located neighborhoods, and each concentrated units in particular (but not the same) neighborhoods. Many parcels were blighted or vacant prior to redevelopment. Crescent Garden Homes was the only project of the three that was a mix of new construction and renovation as well as being mixed income. The new construction was modular with different designs that included both one and two story structures. Fewer existing structures were renovated. When structures were renovated, Crescent Garden Homes would repair two adjacent houses. The restricted and unrestricted units were interspersed, and adjacent or nearby buildings would be alternatively designated affordable and market rate.

Figure 4: Scattered site project parcels

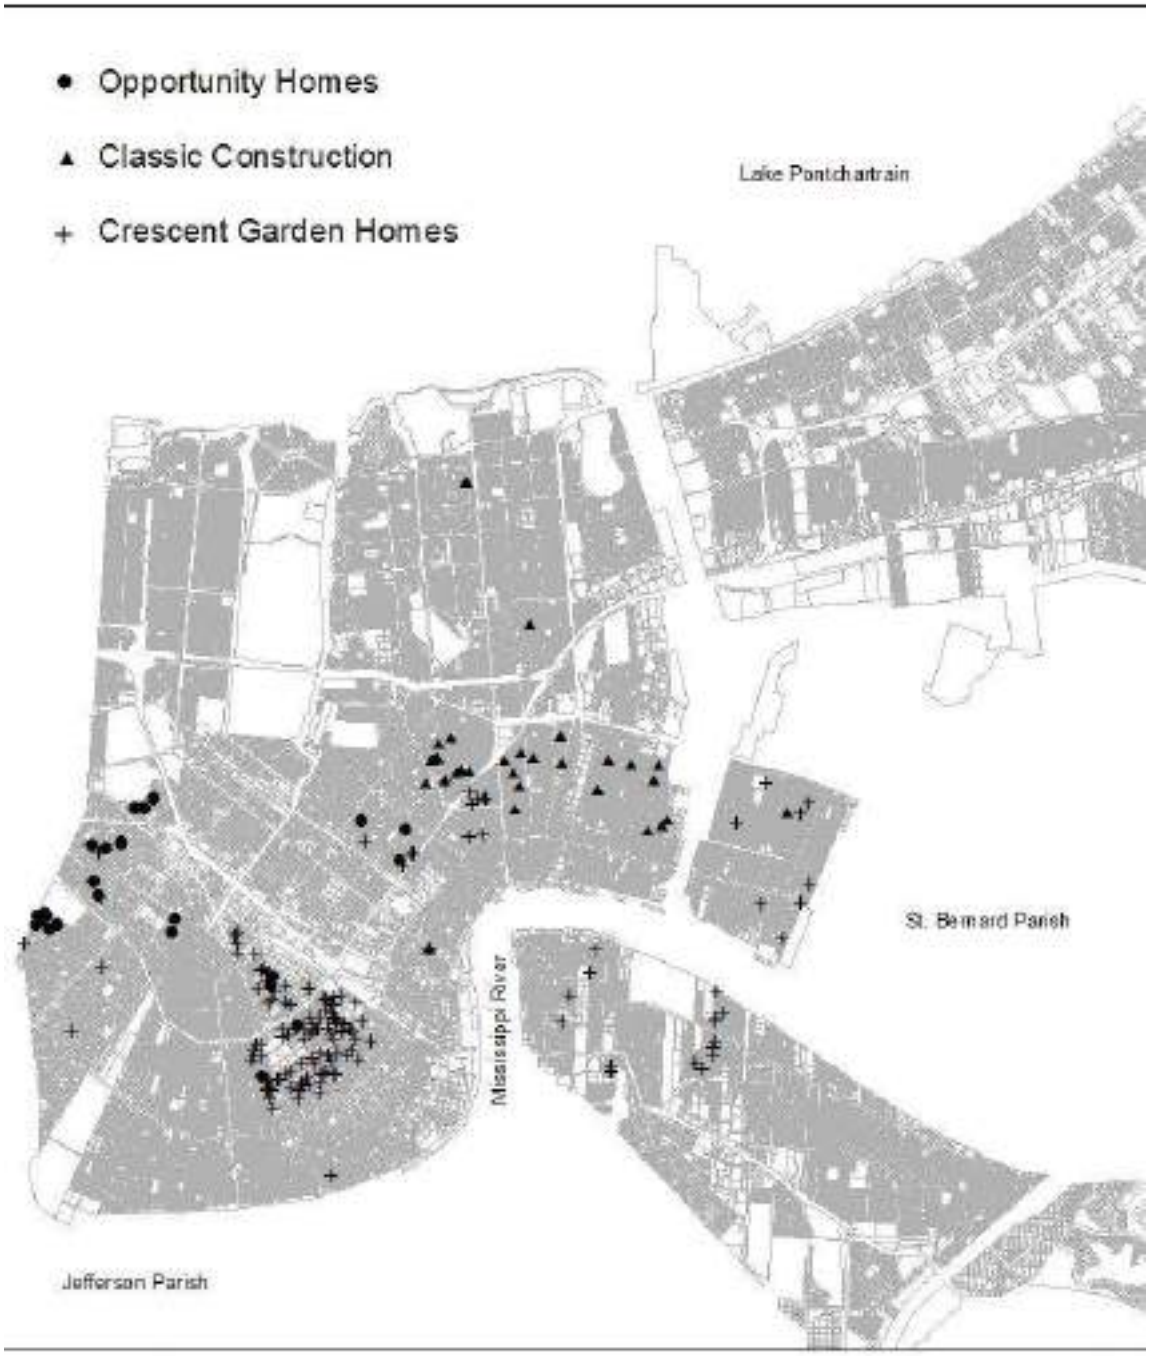


Figure 5: House built by Crescent Garden Homes

The two single site, multifamily mixed income new construction projects were gated structures built in areas with significant market potential. The Muses, a 263 unit project on a 4.8 acre site, was located in Central City, less than a mile from the Warehouse District, a gentrifying neighborhood adjacent to downtown, close to the gentrified Lower Garden District, and a block away a prominent thoroughfare that is lined with hotels, restaurants and other viable businesses. Central City had extensive pre-Katrina disinvestment, vacant land and blighted property, but that also retained historic housing stock. The Muses was the city's first LEED NC-Silver multifamily structure. The area near the Muses site also received significant public investment in the post-Katrina period. In 2010 the Mayor's Office authorized the New Orleans Redevelopment Authority (NORA) to invest over $10 million of Community Development Block Grant money in several commercial corridors, and NORA allocated $2 million to commercial projects on Oretha Castle (O.C.) Haley Boulevard, a historic corridor in Central City close to the Muses. Through a gap financing program, NORA provided financing for 14 commercial projects along

O.C. Haley Boulevard, including a 20,000 square foot building where NORA planned to relocate its offices. NORA also worked with other partners and sources of funding to develop over 50 single-family houses and 70 rentals units for seniors on currently blighted property in nearby residential areas (NORA, 2010). Numerous other residential and commercial projects have been constructed in the vicinity, and the city was to make $300,000 in street improvements (Elie, 2009). The site is only minutes from downtown, the historic French Quarter and the revitalizing Warehouse District.

The 226 unit multifamily Crescent Club was located along Tulane Avenue (figure 6). Tulane Avenue was an underdeveloped six lane arterial prior to the hurricanes. In the years after the hurricanes, it developed rapidly in response to plans for proposed medical district in the vicinity. In 2011, site preparation for two major hospitals had begun. The site was only minutes from downtown.

Figure 6: The Crescent Club corner elevation

Development and Operating Cost Comparison Table one compares development costs, land costs, subsidies and operating costs across the projects.[4] To compare total development costs among the projects, we drew on the project reviews available in the LHFA's

[4] Because some projects did not have finalized cost certifications, the final development costs may differ somewhat from the figures used. Given the multiple subsidies that LIHTC projects receive, total subsidies were difficult to analyze. The terms of the subsidy sources also varied. For the purposes of this paper, we only considered subsidies that were cash transfers or equivalent, which was primarily LIHTC, CDBG and HOME and TCAP funding. We did not consider FHA or GSE mortgage insurance or similar government backed programs. In addition, we did not consider PILOTS, nonprofit tax exemptions, accelerated depreciation, and other tax treatment nor the philanthropic funding that some projects received. To calculate the value of the LIHTCs, we conducted a simplified analysis of the credit award over ten years with a 7.78% present value credit (PVC) rate for the "9%" credits. The PVC rate is designed to adjust the present value of the LIHTC award to 70% of eligible basis for 9% credits at the time of closing the transaction.

LIHTC application files.[5] Costs for all projects regardless of physical arrangement (scattered single site, scattered multi-sites, large single site), income mix, and construction type (new or rehab) varied considerably.

Anticipating that scattered site development would be more expensive, initially the objective was to account for tradeoffs between development types and housing units. Since the purpose of the program is to construct rental housing, if multifamily development cost less per unit, for example, and therefore provided more housing for equal expenditures but had less neighborhood impact, this would be a tradeoff when considering total project impact. Although we anticipated substantially higher land costs and operating costs for the scattered site projects, the land costs varied greatly and the operating costs varied less than anticipated. Direct tradeoffs were not apparent.

Prior research about LIHTCs suggests that the financing tool incentivizes higher quality and therefore more expensive materials (Eriksen, 2008). We did not consider qualitative differences among the projects. The LIHTC projects had different styles, tenant mixes, locations, amenities and aesthetics, all of which influence costs, desirability to tenants and attractiveness to investors. The multifamily projects provided amenities for the households unavailable to the other projects.

[5] The affordable projects had a mix of income restricted units but all the units have rent restrictions. Mixed income projects had both income restricted affordable units and market rate or unrestricted units and the market rate and affordable units are indistinguishable.

Table 1: Comparison of development and operating costs[6]

	Total units	Bldgs	Per unit cost	Per unit subsidy	Per unit operations	Per unit land cost
Scattered Site Projects						
Crescent Garden Homes	166	166	174,095	135,621	5,136	7,303
Classic Construction	112	56	232,496	184,199	4,171	17,588
Opportunity Homes	54	30	147,668	119,658	4,161	9,603
Multifamily Single Site Projects						
Crescent Club	228	2	228,865	156,596	4,528	9,816
Muses Total	263	3	224,896	175,528	4,655	35,765
Single Site Detached Dwelling Projects						
Indiana Homes*	60	60	245,399	216,171	4,161	30,833
Louisiana Freedmen	30	15	149,965	128,845	4,173	16,033
Elmwood Homes*	40	40	214,286	150,814	4,469	11,624
Orleans Place	60	30	260,419	224,148	4,610	10,833

*Sites are adjacent with seamless boundaries between projects

The costs among the projects that we evaluated were more similar than a previous analysis of LIHTC applications. In 2007, the Bureau of Governmental Research (BGR) found little difference between the total development costs for the proposed mixed income and affordable only developments state wide ($177,000 mixed income per unit, $174,000 affordable per unit), but a greater difference in Orleans Parish ($210,000 per mixed income unit versus $184,000 per affordable only unit). Public housing redevelopments cost on average 40% more or

[6] *Sources:* LIHTC Applications, available from the Louisiana Housing Finance Agency

$273,000 per unit, and adaptive reuse projects also cost significantly more per unit (BGR, 2007, Public Investment, Private Developers, 5).

Neighborhood Impact Analysis To maximize the possibility of land stewardship, occupancy patterns and levels must facilitate regular maintenance. In other words, otherwise unoccupied or blighted properties need to be used. We evaluated the projects across the following dimensions: infill; continuity; total land used by project; and, increased density by project. In a shrinking city context, better outcomes would come from infilling vacant or blighted previously developed parcels, creating continuous development patterns within and among neighborhoods, using more rather than less previously developed land, and creating densities that would facilitate infill throughout the city given realistic population projections.

The Impact of Infill

We defined infill as occupying developed parcels at the neighborhood scale. Did the project use previously developed land? Although in growing areas, virtually all parcels are occupied, in shrinking areas, this stops being a realistic outcome. Infill therefore must create patterns of settlement where residents' reach extends to land that would be abandoned. When parcels are unused in areas where residents can lay permanent claim, residents are more likely maintain abandoned properties and often absorb unmaintained parcels, either formally or informally, into their property.

To ranking highly on an infill criterion, a project had to be developed on previously developed parcels, regardless whether parcels were a vacant lot or had a structure at the time of construction. All scattered site projects used parcels that had been previously occupied by

existing housing. The scattered site projects used blighted and abandoned parcels within neighborhoods acquired through various sources including properties unsold at tax sales. Many of the parcels were blighted at the time they were acquired by the developer. The Crescent Club was located on a site previously occupied by a commercial use that was no longer operating. The Muses was built on vacant property within a residential area with some commercial uses.

The single site detached projects varied. Louisiana Freedmen Homes was located on a vacant block within a neighborhood with significant occupancy as well as notable disinvestment (figure 7). Orleans Place (figure 8), Indiana Homes and Elmwood Homes however were new greenfield developments within the city boundaries. Like Louisiana Freedmen Homes and the Muses, the sites were sizable undeveloped tracts. Unlike the Louisiana Freedmen Homes and the Muses, these developments abut additional undeveloped land that was located against physical barriers (a canal in the case of Indiana and Elmwood Homes and the Intercoastal Waterway in the case of Orleans Place). Figures 7 and 8 compare the location of Louisiana Freedmen Homes and Orleans Place. Although the land is platted, the parcels to the east and west of Orleans Place have never been developed. Prior to the development of Orleans Place, the development ended at the road that runs along the development's northern boundary.

Figure 7: Louisiana Freedmen Homes

Figure 8: Orleans Place

Stewardship Requires Continuity

Did the project help create continuous development within the neighborhood? To contribute to the creation of continuous development, a project needed seamless boundaries with surrounding properties. The scattered site projects had less impact on given block than the single site project that occupied entire blocks and neighborhoods. Although each scattered site project had sites concentrated in a given neighborhood, in most cases, a block only has one or two new structures. Figures 9 and 10 compare similar areas for two scattered site projects. These areas were chosen for comparison because they show the maximum unit density for the projects. However, the houses were at similar scales and patterns, contributing to rebuilding the urban fabric. At times, the new houses contributed notable infill such as where Classic Construction built numerous units on contiguous parcels (figure 11 and the largest rectangle in figure 10).

Figures 9: Crescent Garden Homes

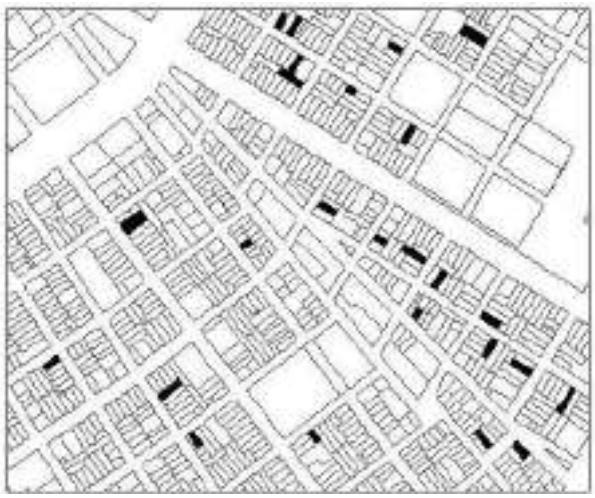

Figure 10: Classic Construction

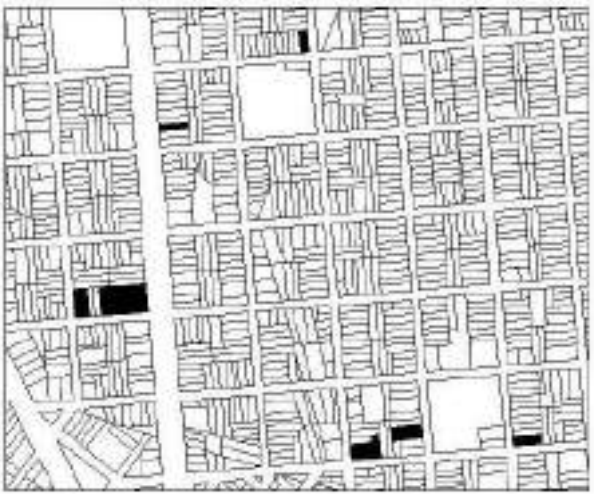

Figure 11: Classic Construction four adjacent doubles

In most locations, the blocks were occupied houses but had often one or more derelict structure or vacant land. In these cases, the incremental changes could lead to neighborhood stabilization. In some locations, however, single houses were built among many empty lots and derelict structures (figure 12) or, in few cases, the single units in areas that were very sparsely populated (figure 13). These units created no greater continuity.

Figure 12: New Crescent Garden Homes unit (3rd from left) between boarded structures

Figure 13: Crescent Garden Homes unit in a sparsely population part of the Lower Ninth Ward

The two multifamily projects—the Muses and the Crescent Club—were secured or gated buildings. The Muses has abruptly different character than the surrounding neighborhoods.

Therefore, it had a low continuity impact. Although similar in scale and massing, the Crescent Club is consistent with other blocky multistory buildings along the six lane thoroughfare where it is sited, and therefore has higher continuity impact. The four projects that were detached singles and doubles on single sites were extended development with form consistent with the surrounding neighborhoods although the three greenfield parcels (Orleans Place, Elmwood Homes and Indiana Homes) extended the developed area, thereby being continuous, but without being infill.

Using Land Is Good

In a shrinking city, land needs to be occupied and used. Which projects directly provided most stewardship? Table two shows the land used by each project. Overall, the Crescent Garden Homes scattered site project and the detached single site projects, Orleans Place, Elwood Homes and Indiana Homes, covered the most land. Louisiana Freedmen Homes developed a large vacant parcel that could otherwise have become blighted. The multifamily structures used less land per unit but were located on unused land in occupied neighborhoods.

Table 2: Lots occupied and total land area used

	Rehab	Total units	Bldgs	Parcels	Land area in square feet
Scattered Site Projects					
Crescent Garden Homes	Yes	166	166	166	550,000
Classic Construction Total	No	112	56	56	190,000
Opportunity Homes	NA	54	23	23	102,000
Multifamily Single Site Projects					
Crescent Club	No	228	2	36**	160,000
Muses Total	No	263	3	40**	180,000

Single Site Detached Dwelling Projects					
Indiana and Elmwood Homes*	No	100	100	210**	945,000
Louisiana Freedmen	No	29	15	16**	72,000
Orleans Place	No	60	30	65**	295,000

* Projects are have seamless boundaries on adjacent parcels

** Assuming an average parcel size of 4,500 sf

To show the contrast between the impact of the Muses as a single site project and available land if it were a scattered site project, we depict the Muses surrounded by vacant parcels (figure 14). The development's 263 units cover a 40 block equivalent (assuming a 4500 square foot lot size). Central City, where the Muses is located, had a moderate population recovery since the hurricanes. Approximately 60% of the neighborhood's 2000 population returned and the neighborhood had a 40% vacancy rate in 2010 according to the 2010 census counts. The vacancy rate had been 21 percent in 2000 and empty lots and derelict structures peppered the neighborhood. Since the hurricanes, additional buildings had been demolished, indicating that both vacant structures and parcels abound. Within five blocks to the north, east and west of the site, over 200 parcels were vacant. From the Muses site to the freeway between Central City and the Warehouse District, around 100 parcels lay vacant.

Figure 14: The Muses with surrounding vacant parcels

The Right Densities?

Determining what densities will make sense in shrinking cities requires a neighborhood scale analysis in conjunction with a citywide analysis. What densities make sense in a shrinking city? In May 2010 analysis, the Greater New Orleans Community Data found that 7,409

residential addresses were habitable but vacant (Plyer and Ortitz, 2010).[7] The 2010 census count of 47,738 vacant housing units, approximately 25% of the total, includes unrepaired but secured housing (US Census Bureau, 2010; Plyer and Ortitz, 2010). The 2010 census count also showed that 16% of all rental units were vacant.

In 2010, the LHFA estimated the rental vacancy rate at approximately ten percent with LIHTC projects reporting higher occupancy, and mixed income projects reporting waiting lists for the rental units (LHFA, 2010). The waiting lists could partially be explained by the fact that market rents remain high and the nonrestricted units were rented for less than attainable market rents. This also suggests that when new construction is available, it is preferable to some residents than other available rentals. However, given limited demand, this can lead to further deferred maintenance of older construction and abandonment of properties for which no demand emerges.

Return rates have varied significantly by neighborhood. Most flooded neighborhoods have significantly more vacant units than they had prior to the storm, despite the fact that many badly damaged structures were demolished. New Orleans has 13 planning districts and 73 officially designated neighborhoods. Table 3 compares vacancy rates by planning district, with some select neighborhoods included for comparison.

Table 3: 2010 population and vacancy by planning district with select neighborhood comparison

[7] Total unoccupied residences include blighted residences, empty residential lots and vacant but habitable residences.

Planning district/neighborhood	2010 population as percent of 2000 population[8]	Vacancy rate (2010)[9]

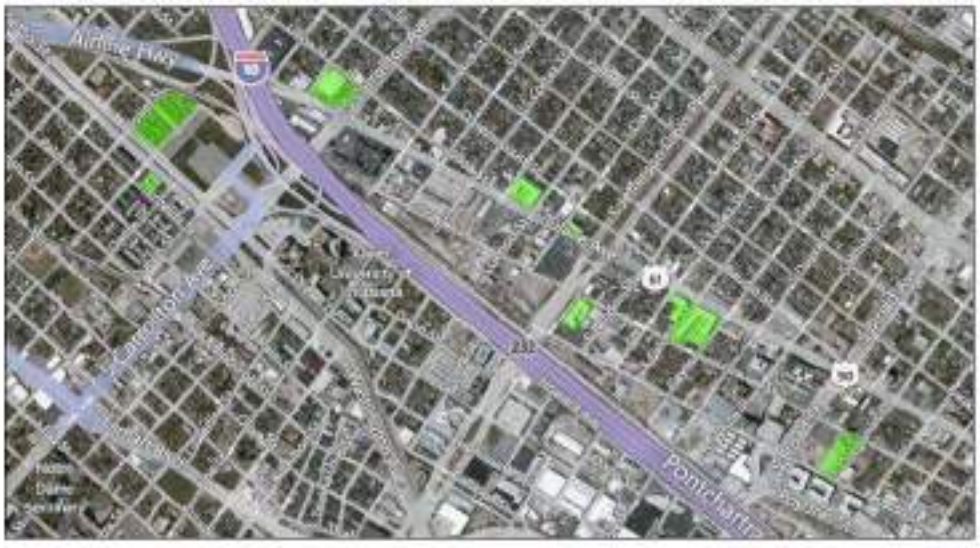
New construction was also disproportionately located in areas with stronger demand and less damage. New construction without additional population growth will further reduce demand for unrepaired property and vacant housing units. A number of major changes will impact patterns of redevelopment and settlement, including more multifamily projects built or proposed in centrally located neighborhoods.

The Crescent Club is a key example of a development trend that emerged post Katrina in response to an expanded medical district that will contain two new hospital and associated facilities. The Tulane Avenue corridor where the Crescent Club is located had suffered much disinvestment in the prior decades, resulting in available land and unoccupied structures. Close to nine hundred new tax credit units were built along or in close proximity to this corridor since 2005, and additional units using historic tax credits were also constructed. The apartments along Tulane Avenue have onsite amenities and are attracting residents to almost a 1000 units that did not exist prior to the hurricanes, decreasing demand for other units.

Figure 15: LIHTC properties along Tulane Avenue



It is important to also note that rental properties with fewer than ten units—small rental properties—house two out of three renter households and a fifth of U.S. households (Mallach, 2009). More than a third of US rentals are single family properties and another third have between 2 and 9 units, although this varies significantly by US region. Large apartment complexes tend to be at either end of the housing market—either upscale or affordable units—but over 70% of low income renters nonetheless live in one to four unit properties (Mallach, 2009). Singles and doubles were the most common rentals in New Orleans pre-Katrina. Because of the low rents and high risk, conventional financing for repairs was difficult. Many small landlords did not have resources to rebuild their properties, and the properties were not cost effective to repair. Although LIHTCs can be used for renovations, the costs associated with the program makes it only useful for developments greater than $1,000,000 and therefore not useful for small landlords, resulting in singles and doubles with a higher chance of abandonment.

Concluding Discussion

We made three primary determinations. First, singles and doubles whether on single sites or individual, non contiguous parcels used more land per unit. However, this alone did not create occupancy patterns that will reduce the burden on public agencies or create livable neighborhoods. The infill characteristics, the total land used considered in conjunction with it contribution to creating continuous development—including whether it seamlessly blends into the neighborhood and its relationship to hard boundaries—best captures how new development will contribute to rebuilding the urban fabric in a sustainable way. Second, sites—whether small or large—in outlying and undeveloped areas contribute less to reducing blight and facilitating viable, smaller cities. Unmaintained naturalistic property have less negative impact that blighted

and abandoned neighborhood parcels. Badly placed units could lead to "new blight," a phrase used to describe abandoned post-Katrina construction. Third, no single project was adequate to fill out a neighborhood. Louisiana Freemen Homes and Classic Construction properties that were built in adjoining lots made most impact per unit built. The Muses and Crescent Club provided the largest concentration of units—and therefore residents—but did not have an equivalent infill impact per unit. As a gated complex in a residential neighborhood, the Muses was separated from the adjoining blocks.

Making available property for effective infill would require a city wide strategy. Given the high levels of blight and abandonment and the New Orleans' 2011 efforts to establish a functional land bank, it could be possible for the city to acquire and make property available. If a city with excess land had a functioning land bank or other mechanisms with which to make residential parcels available for redevelopment, this would remove a barrier to creating dense multiple site scattered site projects and instead could facilitate clustered redevelopment.

Conclusions

In 2011, New Orleans was still growing slowly but it was unlikely to return to a size that available and proposed housing would be occupied. Before Katrina, the city had cheaper housing and lower income residents than the surrounding parishes, but the flood damaged more housing in New Orleans and rents increased significantly. When property values decline, some people are attracted to cheaper housing and a city and region could attract new residents with lower incomes but this would be limited. The opportunities in growing regions attract more newcomers than does affordable housing in depopulating areas. Population loss can increase rental stock, when moving owners cannot sell their house or sell low to an investor. When rents stagnate and

demand is limited, the incentives for property owners to maintain rental property decreases. People will move within the city and region for a better deal or better neighborhood. Nevertheless, because not everyone moves, efforts that result in local moves can depopulate some neighborhoods and stimulate additional blight that remaining residents live with.

In areas experiencing population loss, projects should be evaluated on their impact to the urban fabric. Does the project eliminate or reduce immediate blight? Will it create an urban fabric conducive to a safe and occupied neighborhood? New development that uses public money should also be evaluated based on its impact on blight reduction. In this analysis, the projects that occupied more lots and were lower density had a greater impact.

To the extent that new housing simply provides existing residents with better choices, LIHTC projects could provide better housing and result in additional abandonment when residents move to new housing. New LIHTC investments add to the housing stock, increasing the supply of housing overall. In 2011, New Orleans faced the potential of continued decline even when experiencing modest growth. All public investment in new development should take long term impacts into consideration so that one investment does not cause problems that require additional public investment in future years.

Risk communication in earthquake planning: the case of Kalamata city, Greece

Rigopoulou Dimitra [1]

Key words: earthquake planning; risk communication; mitigation; social vulnerability

Abstract

Cities are complex systems, vulnerable to threats from natural hazards. This paper describes the comprehensive strategy of hazard mitigation plans in Kalamata city in terms of risk communication. Historically, earthquakes in Greece have been seen as the major hazard. In recent times, there have been few large earthquakes that have affected people and infrastructure. The paper also considers the relationship between risk communication and earthquake planning and tries to discuss the following questions: how can risk communication reduce the disaster risk and increase the disaster risk awareness? In which ways can risk communication at local level contribute to maintain resilience in a city context, such as the context of the city of Kalamata or a larger scale urban complex? The case study this presentation refers to is the city of Kalamata, located in southern Greece. It is about a city that suffers often from earthquakes as it is located in one of the most seismic areas in Greece. The most effective seismic event has been one of 6.2 Richter that happened on September 13th 1986. It resulted in 26 people dead, 80 injured and severely damaged 2000 buildings (the 20% of the city's buildings). Although the earthquake destroyed a huge part of the city and its suburbs, the recovery was one of the most successful in Greece, creating various opportunities for the city. Today, the city of Kalamata with approximately 60,000 inhabitants is considered an earthquake-prone-city. As a result, pre- and post-event planning actions that observe preparedness and awareness in Kalamata are of great importance. In this context, the formulation of risk communication, including education and training, is examined in connection with social vulnerability of city's population groups, in order to enhance resilience and coping capacity of the city. Hence, risk communication and risk awareness monitoring has been considered important in all cases of potentially vulnerable groups and actors: decision makers, stakeholders, planners, vulnerable citizen groups.

1. Introduction

Risk communication has become an important issue in disaster risk management in the past decades. Several research studies introduced the concept of risk communication and its developing process. Its meaning in risk governance depends mostly on two parameters: the socio-cultural context of the society and the scale of the community (e.g. rural areas, small cities or megacities). Some attempts to adapt the risk communication process with the socio-cultural context in local scale were done by the municipality of Kalamata city, Greece. Thus, there should be some adjustments made before communicating the risks to the community. This study combines discussions on social vulnerability, risk communication and participatory approach for disaster preparedness in Kalamata city. Moreover, this study tries to address the problems and needs of disaster risk reduction for local communities. Nevertheless, they have been of importance to provide basic concepts in understanding the current threat.

2. The role of communication in risk management

Communication in risk management is of utmost importance, as it is the key-link between stakeholders and civil society to understand the risk itself and cope with it. It also allows them to recognize not only their role in risk governance, but also their own responsibilities. As a result, effective communication is the way to create trust and have the desired outcomes in risk management. According to the IRGC, the effective communication has to be at the core of any successful activity to assess and manage risks.

The field of risk communication was initially developed as a way to bridge the gap between the experts' assessments and how these assessments could be communicated to the society. At this concept, there were many discussions in the objective of educating the public concerning risks and finding the most appropriate practices to achieve the desired results in risk management.

Recent risk communication strategies stress a two-way communication process in which people that take part in are both members of the public and risk managers. According to Leiss, the objective of this communication effort is to build mutual trust between the public and the relevant stakeholders. The ultimate goal of risk communication is to assist stakeholders in understanding the rationale of risk assessment results and risk management decisions, and to help them arrive at a balanced judgement that reflects the factual evidence about the matter at hand in relation to their own interests and values. (IRGC, 2005)

Taking everything into account, risk communication is a necessary aspect at risk handling chain, from the framing of the risk to its monitoring. While communicating the risks it is important to reflect the nature of the risks under consideration, their context and the social involvement in them. For these reasons it is crucial to ensure that people involved in risk communication understand fully the risk governance strategies, for example how they are to be involved, and, where and

when appropriate, what their responsibilities are, and, the others outside the immediate risk management process are informed and engaged.

3. The main functions of risk communication

Recent approaches in risk governance list four major functions in risk communication process. (Morgan et al. 1992) The four functions that are basic in achieving effective communication are:

- *Education and enlightenment:* inform the public about risks and how to handle them, including risk assessment and management;
- *Risk training and inducement of behavioral changes:* help people cope with risks and potential disasters;
- *Creation of confidence in institutions responsible for the assessment and management of risk:* create trust by giving people the assurance that the existing risk governance policies can handle risks effectively.
- *Involvement in risk-related decisions and conflict resolution:* give stakeholders and representatives of the public the opportunity to participate in risk management efforts. Although, risk communication implies a stronger role for risk professionals. (IRGC, 2005)

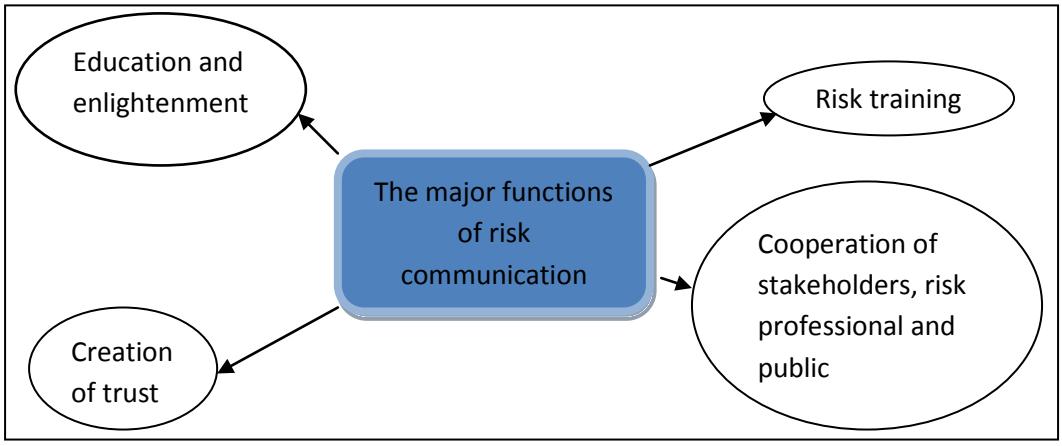

Figure 1. The major functions of risk communication

4. Earthquake risk communication

Earthquake threat is inherently less visible than other threats in the minds of most people. Rare or low-probability events of great severity and events that the public is not familiar with, such as earthquakes, are the most difficult to be mitigated. The

communication in seismic risk is influenced by features and factors that are connected to the actual seismic environment of each study area. For example, in areas with high seismicity the earthquake risk-related information are put forward and in areas with low seismicity the population is kept aware about the actual risk situation.

Other important factors influencing risk communication is the nature and the source of the information. The differences on the information are related to different approaches of the problem between the author and his client. For instance, we can get different approaches from a scientific article or a report for stakeholders that refer to the same problem.

Last but not least factor influencing communication is the receiver of the information. It is different to report to a professional user and different to an unprofessional. Professional users have the knowledge to understand the information correctly. In contrast, the unprofessional users have limited information on the subject of natural risks (J. M. Gaspar-Escribano and T. Iturrioz, 2011).

5. Case study: Kalamata city, Greece

Kalamata is the second-largest city of the Peloponnese in southern Greece. The capital and chief port of the Messenia prefecture, it lies along the Nedon River at the head of the Messenian Gulf. It lies 238 km SW of Athens. The 2001 census recorded 57,620 inhabitants, but it is a busy city and on a regular daily basis there are more than 90,000 people working and circulating in it.

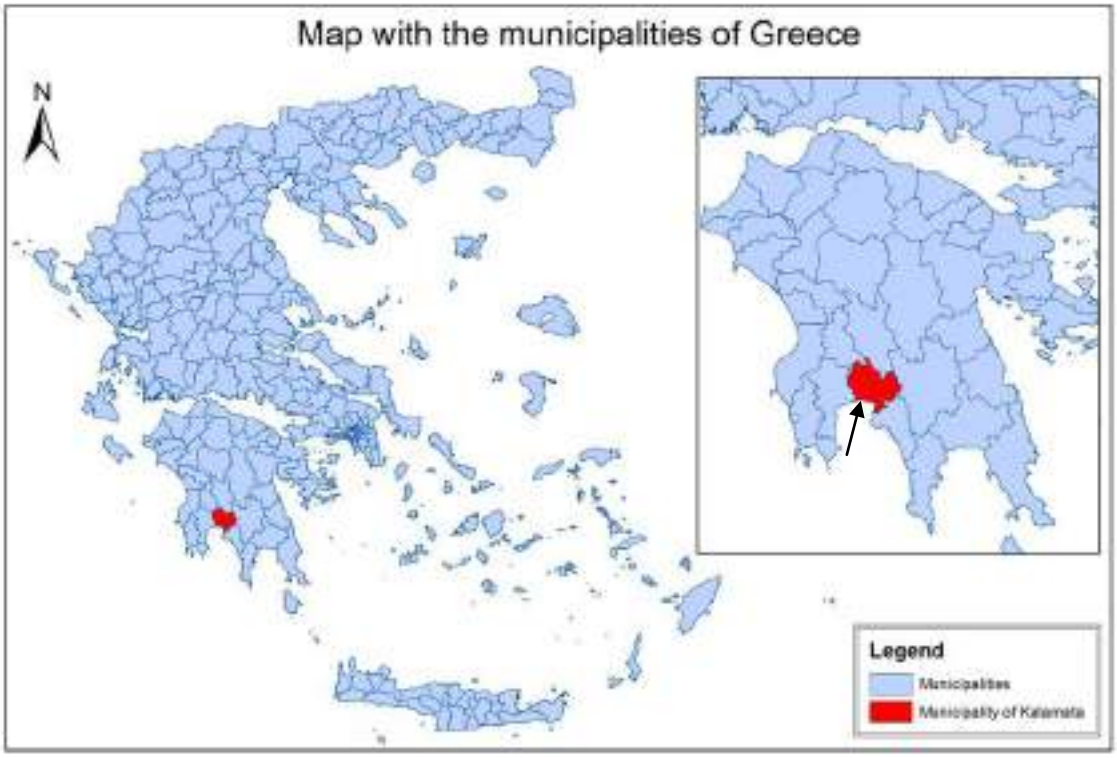

Figure 2. Map with the municipalities of Greece

Figure 3. The study area from Google Earth

6. The disaster in 1986

The September 13, 1986 Kalamata earthquake is one of the most destructive, but least studied earthquakes in Greece the last 30 years with magnitude *M*w 5.9 (USGS), following by only one aftershock two days later with magnitude Mw 4.8 (USGS). According to an analysis of pre-seismic and post-seismic leveling data, the 1986 earthquake caused because of the reactivation of a segmented, blind fault, part of a major fault zone associated with several earthquakes during the last 200 years in the area.

7. The geotectonic regime of the area

The area is affected by earthquake activity, because of its position in relation to the Hellenic Arc system. Kalamata is located very close (<70 km) to the Hellenic (Ionian) Trench region in which the subduction zone of the African plate below the European (Aegean) plate exists. (Fountoulis, 2004) The Messinia district located within the tectonic zone of the Hellenic Arc, is known to have suffered from several destructive earthquakes associated with this zone since historical times. (Elnashai et al., 1987) The area also is affected more frequently by small to medium size earthquakes not directly associated with the Hellenic Arc tectonic activity rather than by large shocks situated in the Arc.

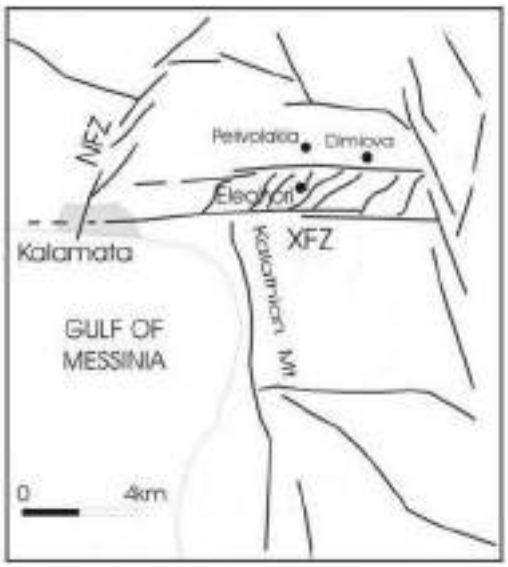

Figure 4: Sketch map of smaller order neotectonic macrostructures in the study area, XFZ:Xerilas Fault zone, NFZ:Nedon Fault Zone, Source: Mariolakos & Fountoulis, 2004. Modified by the author.

8. The need of earthquake planning in Kalamata Metropolitan Area

For the implementation of disaster preparedness to local community, in this study, the geotectonic and geological regime of the area described above are taken into account as prominent factors in selecting what planning strategies should be followed. Other factors considered in planning are connected with the social-economic vulnerability of the city and the lessons learnt from the event in 13th September 1986.

Before the main seismic event in Kalamata in 1986, few things had been done about earthquake planning. The emergency plan called "Xenokratis-Earthquakes" created by OASP (the Greek Organisation for Earthquake Planning and Protection) was under discussion and was not ready on how it could be followed by the city that period. Today, the emergency plan "Xenokratis-Earthquakes" is made by the local authorities following the legislation and taking into consideration the current conditions of the city (concerning the population, the town plan, the socio-economic vulnerabilities, etc). Although the current plan needs improvements and updating not only for the city of Kalamata but also for the districts of the municipality according to the new administrative reformation.

The scope of the study is restricted to local/urban scale risk analysis in the city of Kalamata, which is of moderate-to-high seismic activity. In the task of risk communication should be considered the direct ground-shaking and the physical damage of normal-importance buildings, the damage of infrastructures and lifelines and the social vulnerability related to the lack of preparedness and resilience of the society as a whole. In this work, the source of information is basically scientific and embraces contributions and interviews from the stakeholders of the city. Their roles are different and complement each other. Whereas a lot of discussion exists on how to bridge the communication gap between professionals with distinct backgrounds to external users. Finally, the receiver of the information considered in this work is varied.

9. Risk communication actions in the city of Kalamata

The main role of risk communication strategies is to increase disaster awareness as well as reduce the disaster risk. To fully assess this matter, we started the discussion from the theoretical concept of risk communication and we continue on how the theoretical concept is applied or not in our case.

With the imminent danger of earthquake, the role of risk communication is not put into priority. This implies that previous information and awareness of the earthquakes in Kalamata were low, despite the fact that there were recorded many earthquakes in the area before the event in 1986. Prior to the earthquake on September 13th 1986, it was obvious that there had not been any preparation done against earthquake disasters. Therefore, a key point of risk communication in spatial planning ahead of risks would be a form of warning the public and creating trust.

A type of warning about the seismic risk is provided through schools students' education. The actions taken at schools follow the instructions of OASP. According to the instructions, the students should get informed about the earthquakes and how to act in case of emergency. Each school has its own emergency plan and conduct earthquake drills once every three months. At this point, we have to mention that the municipality of Kalamata has gathered all the emergency plans from the schools.

Lots of discussions and conflicts about the ways of education in achieving a good level of risk communication are between the local authorities and the local rescue teams. From the one hand, the local rescue teams propose educational seminars for all the volunteers, the firemen, the policemen and generally the stakeholders involved in risk management of the area, especially on coordination issues. Apart from the educational seminars, they propose real time drills with the participation of the stakeholders and the public as well. On the other hand, the authorities support that such activities are too expensive and could cause panic at the public and fears of a big upcoming earthquake event. Therefore, there are no actions at all at this part.

The only exception is a seminar on the seismic risk in the area that was held in 2nd December 2011. It was organized by the local authorities and OASP with the participation of professionals such as planners, seismologists and geologists. The scope of the seminar was to inform the stakeholders about the local conditions for the seismic regime of the area and the risk management policies for the new administrative reformation of the municipality. However, these seminars are organized for the members of the Civil Protection. Of course they are open to the public, but they are not widely known. The local media, therefore, simply report such events without any further attention.

Nevertheless, the municipality has taken some actions in earthquake planning according to the 'Xenokratis-Earthquakes' plan for all the phases of risk management. The planning concerns the cooperation of the stakeholders (authorities, police, fire service, coastguard and volunteer teams), but it does not include the participation of the public. One of the actions that took place and was discussed a lot by the public and the local media, was the signing of the places of public gathering after earthquakes, that are planned for the city, during October and November 2011. The places of gathering in Kalamata are 27 and also have been tested for their suitability by a committee of engineerers and planners. This step could characterized as an effective way of communicating the earthquake risk to the public. However, it is an one-sided approach that provides information and it is not related with the actual meaning of risk communication in risk governance.

10. Suggestions on the current planning

Taking into account the current political and economic situation in Greece, issues of civil protection are not on the agenda. Although that's not an excuse of not taking actions that could inform and educate the public, especially at an earthquake-prone city such as Kalamata city.

Some suggestions in communicating the seismic risk in the city of Kalamata could be more seminars about earthquakes. Such seminars, except from their educational purposes, should create awareness and less fear to the public. The goals of the seminars will be to provide information about the actual risk in the area, as it is part of the citizens' lives and they have to adapt with it. Of course, the cooperation of professionals and stakeholders should play an important role at this stage, as the seminars could mislead the public, e.g. to thoughts of an upcoming destructive earthquake event.

Another suggestion has to do with the earthquake drills. It is basic while communicating the risk, to apply what you learn through this communication. The local authorities could organize open earthquake drills not only in schools, but also in the hospital of the city, in hotels and in other public buildings. Furthermore, these drills could be based on "Xenokratis – Earthquakes" plans and on different scenarios of effects with the participation of scientists, stakeholders, public and volunteers.

The actions described above should be supported by the local media (tv channels, radio, newspapers, websites). In this way the public could be informed about the citys' earthquake planning and how the citizens could be a part of this plan. The effective approach through the information from the social media will create trust and openness.

11. Discussion and Conclusions

This paper poses and tries to analyze the following questions: how can risk communication reduce the disaster risk and increase the disaster risk awareness? And in which ways can risk communication at local level contribute to maintain resilience in a city context, such as the context of the city of Kalamata or a larger scale urban complex?

Kalamata is the political, economic, social and cultural center of Messenia Prefecture. For years, this city has attracted people from the surrounding rural areas and is becoming more and more attractive as actions for development take place (the new National Road, the port, the airport). Hence, the vulnerability in seismic risk is obvious in the city of Kalamata. The general plan for earthquakes in the city could characterized as satisfactory in all phases of planning (prevention, emergency, rehabilitation). However, it needs improvements on the task of risk communication. Risk communication enables the concept of participatory at higher level. The way to achieve this can be done by introducing this concept at a meeting / workshop / seminar with many stakeholders who are involved with related

disasters (Sagala, 2007) and the public, in order to increase the disaster awareness in the society.

The issue of warning in risk communication is closely related with the social vulnerability and the worries of the public about the actual risk. This aspect requires specific attention, as it could lead to a failure in the implementation process of the warning. Consequently, this research contributes to the knowledge on whether risk communication is achieved or not in our case study. Furthermore, the main seismic event 26 years ago and the continuous events of smaller scale present different complexities of problems given the different natures of the disaster. Thus, this study offers distinct contributions by proposing options of risk communication implementation. Risk communication strategies aim to make the regulatory process more open and trustworthy, with the public participation more helpful to identify practical means and the role of scientists more accountable. In the Kalamata, however, the local authorities do not give the appropriate importance.

In relation with earthquake disaster preparedness, Kalamata should make best use of the opportunity of the direct disaster experience. This is true regarding earthquake issues because such events cannot be predicted accurately. Thus, risk communication aims to develop the participation of stakeholders and public as a means of creating common values in the process of risk management before, during and after a hazard event as a whole. However this research needs to be improved regarding data to be collected from the field through a quantitative research including the publics' concerns for the seismic risk.

SOUNDSCAPE APPROACH FOR A HOLISTIC URBAN DESIGN

Seckin Basturk[1], Luigi Maffei [2], Massimiliano Masullo [3]

Abstract

In the last decade we are witnessing a paradigm shift in our understanding of urban space; now it is defined with human experience rather than physical quantities. The full spectrum of human experience is usually summed up with the term 'atmosphere' and encompasses the influence of color, light, texture of materials, temperature, humidity, odor, and sound on individuals.

Within this trend soundscape research has developed its tools, like soundwalking and laboratory listening experiments coupled with sound recordings, in order to achieve a multidimensional holistic approach to understand soundscapes and necessities of local people.

However laboratory experimentation, usually focusing on audio characteristics of a place, underestimates the cooperation between sensory modalities which plays a complex role on overall satisfaction of end users. Therefore, an ecological assessment of environments should take into account the multisensory and interdependent nature of human perception.

In this preliminary study it is aimed to demonstrate the potentiality of a multisensory (audio-visual) evaluation technique, involving the end users during the design process and administration. The presented technique employs immersive virtual reality and auralization technology for a realistic presentation of environmental stimuli in laboratory conditions and captures various objective and subjective psychological responses of individuals to evaluate satisfaction due to presented environment. The multisensory evaluation technique has been applied to a case study in historic neighborhood Triana of Seville (Spain). This initial study is concluded with a demonstrative virtual reality application and with insights on possible future directions on multisensory evaluation supported soundscape and urban design.

1. Introduction

As space and spatial issues became the new paradigm of architectural theory at the end of the twentieth century, all disciplines are getting more involved with space,

[1] Seconda Università degli Studi di Napoli, Naples, Italy - seckin.basturk@gmail.com
[2] Seconda Università degli Studi di Napoli, Naples, Italy - luigi.maffei@unina2.it
[3] Seconda Università degli Studi di Napoli, Naples, Italy - massimiliano.masullo@unina2.it

architecture or engineering has no more right to it than any other. Space which is conceptual as well as physical, an embodiment of social relations and ideology, holds the person within. And spatial studies, within and in-between different disciplines, focus on relationships between people and their environments in order to promote spaces in line with the nature of these relationships.

The full spectrum of human experiences is being considered in a wide variety of fields; the design of consumer goods, marketing and the design of private and virtual spaces amongst others. The reason for this interest is demonstrated in several recent studies which reveal the significant impact that spatial cues have on individuals' behavior and can be consequently employed to increase retail performance, inform successful spatial designs and improve quality of life. Especially the places which are subject to purchase of goods and services are increasingly being conceived with their sensual characteristics. And multisensory design is getting much more important to enhance interaction and to intensify the sensorial experiences of people, related to the goods, services, spaces. Colors, lights, tactile properties of materials, temperature, humidity, odors, and sounds are increasingly considered with their physical properties, semantics and the way that they are perceived.

In line with this global trend, in last decades, the scientific society has seen the gap between individuals' experiences and the actions taken (in a conventional manner) to improve acoustic quality of environments. These conventional methods and actions taken were successful to a certain extent, especially regarding higher levels of noise exposure conditions (so called black areas), but do not offer any action for relatively lower levels of noise exposure (so called grey areas that are characterized with 55-65 dBA). It is estimated that 180 million people (roughly % 37 of EU 27 population) live in these grey areas where noise exposure is assumed to be acceptable and not harmful for individuals' health but still can cause serious annoyance that plays an important role affecting the overall well-being and quality of life of the exposed population. Noise annoyance is a multi-faceted concept where context-related perceptual factors play an important role as well as the noise level. Especially in these so called grey areas where the line between pleasant and unpleasant sound and consequently its effects on people become vague (Maffei et al. 2010). Noise annoyance may vary from one community to other due to these factors (Staples 1997; Lercher & Botteldooren 2006). Standard relationships and models, not considering the complex interactions that occur when people hear sounds - sounds recall memories and previous experiences trigger a multisensory processing which leads to identification of the source, finally form judgments as a function of the context in which the sound is heard - , can mislead the noise impact assessment when it is applied to different contexts, to different communities (Lercher et al. 2008). Thus ecological assessment of sound environments should take into account the variability among different communities or group of people exposed to noise and also the multisensory and interdependent nature of human perception.

In this context, soundscape research took on a new significance in sound related research field, since it involves not only physical measurements but also the

cooperation of human/social sciences, and it considers environmental sounds as a 'resource' rather than a 'waste'. Research into soundscapes encompass the entire context of the physical and psychosocial environment which often includes listening walks (soundwalks)(Adams 2008; Fiebig et al. 2010). The participation of local people (so called local experts) within soundwalks and social surveys is of vital importance, as their local knowledge is important in providing additional context on the area being studied (Schulte-Fortkamp 2010). This development of soundscape research is coming into prominence, pushing all non-visual senses of human to create an integral part of architecture, urban design and planning.

Soundwalks and social surveys taking place in real life settings offer significant advantages in order to get reliable and unprecedented insights into individuals' experiences in their environments. However, in general, they are costly, and not applicable to assess future scenarios (new projects). For this reason, usually, new methods are preferred for investigation in laboratory conditions. The biggest challenge in laboratory experimentation is to stimulate the participants' feelings and emotions (such as pleasantness, excitement, contentment) in order to have realistic reactions to the sonic simulated environment. In other words, in laboratory conditions, it is crucial to make participants experience sound and the complex environment (multisensory environmental stimuli) together (Otto et al. 1999). Conventional laboratory experimentation can not overcome this challenge since it focuses on just audio characteristics of a place and underestimates the cooperation between sensory modalities which plays a complex role on overall satisfaction of people. Thus, recently, several researchers worked on new methods employing high-end technology, like immersive virtual reality (IVR) systems, in laboratory conditions and focused on new user friendly interfaces to present audio and contextual information, and analyze participants' reactions to them. IVR systems offer satisfactory realism through high quality audio-video display and high level of interaction. The potentiality of various types of virtual reality systems in sound related studies is under study. Virtual reality systems can be utilized for dissemination of the results of noise maps (McDonald et al. 2009), soundscape design and urban design and planning (Brambilla et al. 2009; Fiebig & Genuit 2009; Drettakis et al. 2007; Jallouli et al. 2008; Curcuruto et al. 2010).

In this paper it is aimed to present the design of an innovative multisensory (audio-visual) evaluation technique that enhances soundscape laboratory studies and offers integration of soundscape approach and contemporary architectural and urban design practices. This technique employs immersive virtual reality and auralization technology for a realistic presentation of environmental stimuli in laboratory conditions. The tools to capture various objective and subjective psychological responses of individuals to evaluate satisfaction due to presented environment are also described within this technique. And a preliminary case study, which takes place in the historic neighbourhood Triana of Seville (Spain) and partially employs the multisensory evaluation system, is presented. The gained insights and possible future uses of the technique to support a more holistic urban design approach are explained.

2. Virtual reality and auralization

The term 'Virtual Reality' (VR) is defined in many ways since it serves wide range of activities; basically psychological therapy, technical training and education in numerous fields, social and professional networking, gaming, art and any kind of design activity including urban design. Consequently the term has gained a broader definition; VR is an environment generated in the computer, which the user can operate and interact with in real time. A contemporary and more specific definition of virtual reality is given by Burdea et al.(Burdea & Coiffet 2003), "Virtual Reality is a high-end user-computer interface that involves real time simulation and interactions through multiple sensorial channels, these sensorial modalities are visual, auditory, tactile, smell and taste". On the other hand, immersive virtual reality systems seek to give the user a sense of physically "being there" during virtual reality experience. These systems employ various output devices (effectors) in order to reproduce full spectrum of sensory information.

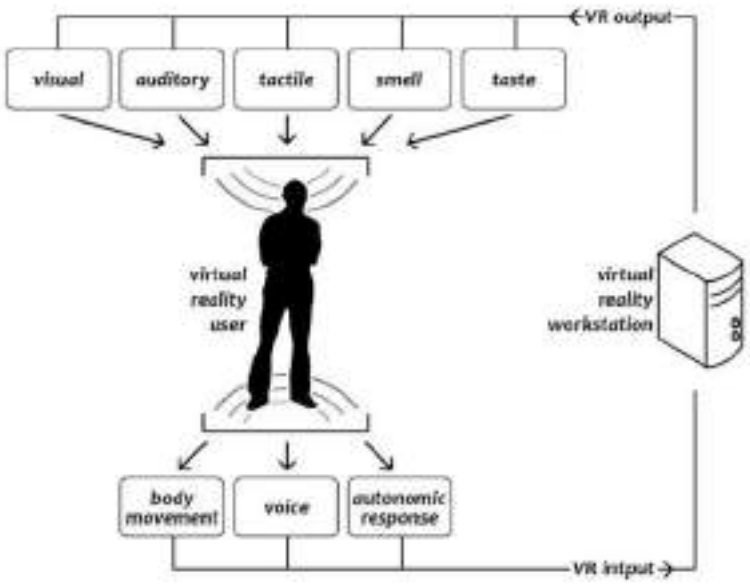

Figure 1. Range of possible input (sensors) and output (effectors) devices for a IVR system (adapted,(Biocca & Delaney 1995).

Realistic audio representation is important in the immersive virtual environment applications as it enhance the sense of immersion and spatiality. Due to high computational load of dynamic environments in virtual reality, audio has been a secondary issue after video. However, recently, scientific research is engaged in improving the auralization systems which is "the technique of creating audible sound file from numerical (simulated, measured, or synthesized) data" (Vorländer 2008a). Auralization techniques for indoor environments are notably advanced but for complex outdoor environments it is still an important challenge to achieve real-time auralization due to computational shortcomings. In order to lower computational load

of auralization for complex outdoor environments with relatively higher number of sources and higher level of interaction, perceptually plausible resulting sounds are usually aimed rather than physically correct results, in outdoor auralization processes (Tsingos et al. 2004; Funkhouser et al. 1999; Vorländer 2008b).

3. Methodology: Multisensory evaluation system

The proposed methodology, in its first step, involves audio-visual rendering processes to design virtual environments (VE) to represent different environmental conditions (e.g. existing situation and future projects). Second step, virtual reality immersion, is the presentation of the virtual environments to participants (end users) with use of IVR hardware. The final step, psychological assessment, is based on capturing and analysing objective and subjective reactions of participants due to presented virtual environments. The variations in reactions of the participants are interpreted with the variations in presented VEs' audio and video characteristics. In this way, useful and guiding insights of people can be integrated into the urban decision making and design processes.

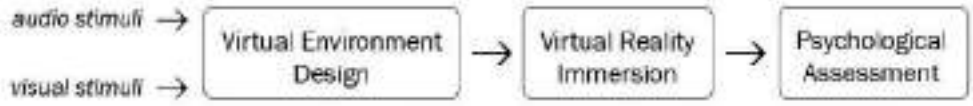

Figure 2. Scheme of IVR approach for multisensory assessment.

3.1 Virtual environment design

Audio stimuli design: The proposed auralization technique is based on an offline (not real-time) processing in order to avoid high computation load during the VR immersion. In this technique sound samples that represent sound sources in the virtual environment, are convolved with signal processing algorithms, in order to obtain auralized sounds for multiple receiver points which cover the possible walk area (e.g. grid-distributed receivers) and head orientation of the participant. These resulting auralized sounds are linked to the corresponding coordinates in the VE. Later, during the VR immersion, the body position and the head orientation of the participant, which is updated in real-time, determines which auralized sound files will be reproduced. In order to have a seamless reproduction of these sound files, linear interpolation is used when participant passes between predefined receiver points and when the participant has different head orientation angles than the predefined ones.

Visual stimuli design: The visual stimuli are designed in three steps: 3D modelling, texture mapping and IVR enhancement (Figure 3). In the first step 3D models of the desired environments are prepared using well-known software that enables 3D data (CAD, BIM or GIS) creation. In the texture mapping step, two series of images can be used to match to the prepared 3D model: in situ taken photos and/or rendered images (through texture baking). This helps to produce a visual result that seems to

have more richness than could otherwise be achieved with a limited number of polygons and since it eliminates necessity to use real-time shading, causes reduction in computational load during the VR immersion. In the third step, the prepared VR material (3D models, textures, sounds, etc.) must be put together to constitute the final VR application and this process of gathering must be done defining roles of each element, the interactions between these elements and the participant and basic physics of the overall VR environment.

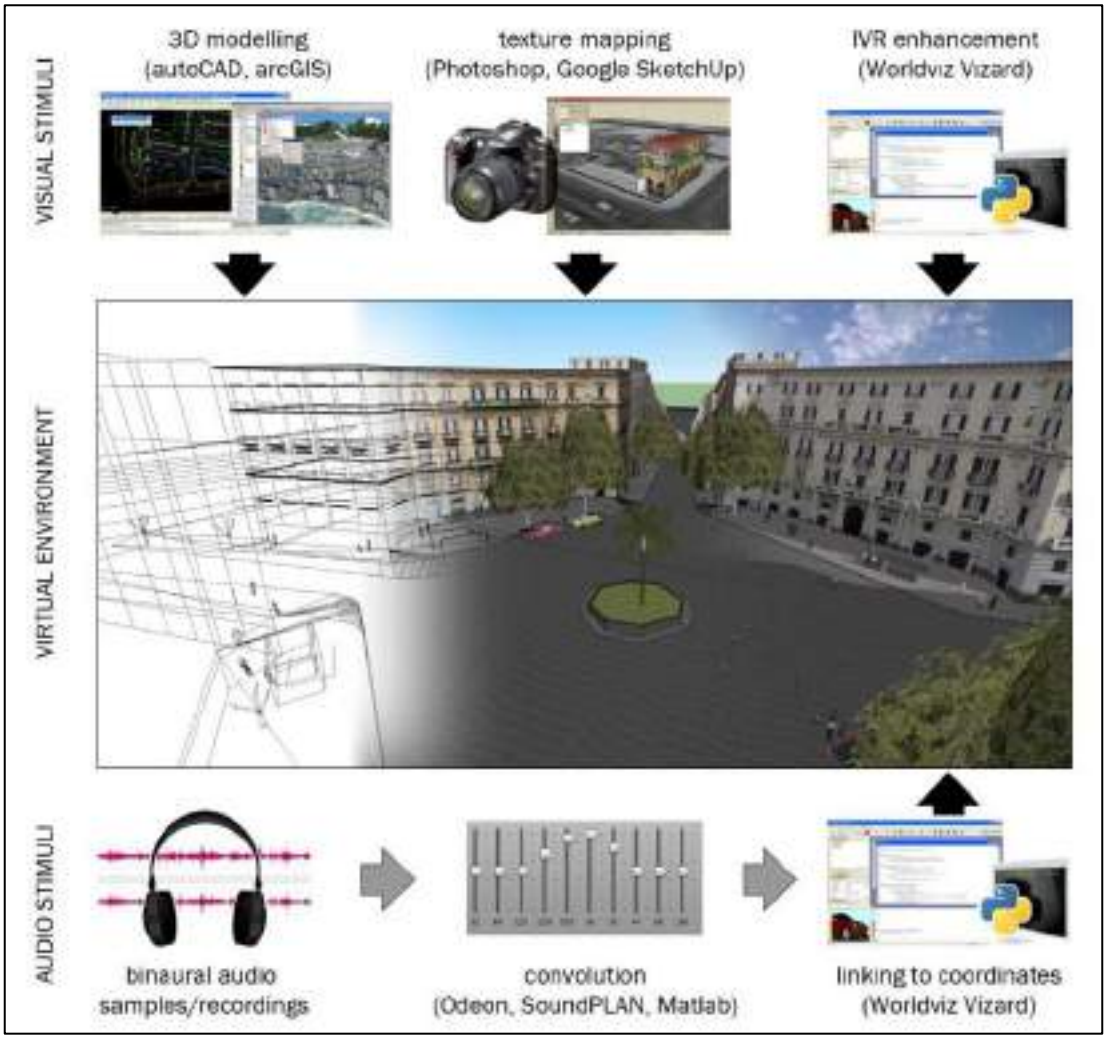

Figure 3. Virtual environment design scheme and preferred software by authors.

3.2 Virtual reality immersion

There is a wide range of effector and sensor hardware offering different levels of immersion and usage for such studies. The visual interfaces are the most advanced effectors of VR systems; they are supposed to provide images to the human eye that is "indistinguishable from that experienced in reality in terms of quality, update rate, and extent". Head mounted displays (HMD) and cave automatic virtual environment (projection on walls of a room-sized cube, a.k.a CAVE) systems are the

most accurate and well-known interfaces. The authors preferred to use a VR toolkit based on HMD which is more affordable and easier to deploy respect to CAVE system. The preferred VR toolkit employs two workstations; one to process motion tracking data and the other to be used by the operator to run VR applications. Visual stimuli is presented to VR user through nVisor SX60 head mounted display. The VR navigation is obtained by a position tracker system (Precision Position Tracker-PPT X4) with 4 optical sensors to track 3DOF position of worn markers. At least one marker is placed on HMD in order to track head position and additional markers can be used on different parts of the VR users body (like hand, arm, leg) regarding requirements of the VR experimentation. Additionally a 3DOF orientation sensor (InterSense Inertia Cube 3) is located on HMD in order to achieve 6DOF motion tracking (3DOF position and 3DOF orientation). The processed position tracking data, orientation data and the data from running VR application are merged by a video control unit (Stereoscopic SX) in order to obtain final video stimuli to be reproduced at HMD. The audio channel is processed by workstation and directly sent to the earphones (Pioneer SE-CL17-H) worn by the VR user. The data flow between workstations and optical sensors of the position tracking system is realized through a wired network employing a generic router. The system is tested and calibrated prior to each experiment session to get the accurate levels of presented audio and visual stimuli.

Figure 4. Immersive VR system of the Laboratory of Cognitive Science and Immersive Virtual Reality (CSVR) of the Second University of Naples.

Before the experimental procedure, in the recruitment phase it is important to pay attention to set criteria for inclusion or exclusion of people in the experiment.

According to the target of the study, the test subjects must be chosen in order to have results generalizable for a target end user group (of the studied project).

Figure 5. Test phase of psychological assessment.

The testing phase consists of different VEs (scenarios) prepared according to the aims of the case study. Also the duration of each scenario presented can vary regarding the objectives of the study. However in order to avoid obtrusive durations of the entire test, usually 3 minutes duration for each scenario is well accepted. To avoid any spurious effect deriving from sequence and order factors, the order of presentation of the scenarios should be quasirandomized. And, the order of the tasks (regarding psychological assessment) should be counterbalanced within each scenario and across subjects. Then, during each scenario, subject completes dedicated tasks and at the ending fills out the questionnaire (regarding psychological assessment).

3.3 Psychological assessment

The final step is designed to capture and interpret reactions of the users, employing various objective and subjective assessment measures. Subjective measures evaluate individuals' preferences regarding composing elements of the presented environment and overall satisfaction through questionnaires. Subjective reactions to the environments are assessed by means of dedicated questionnaires devised according to ISO/TS 15666:2003. Questionnaire is designed to be answered after the presentation of each VR scenario and the items (questions) in it are categorized in three groups regarding audio aspects, visual aspects and overall (audio and visual together) aspects.

On the other hand, especially when audio stimuli have an interfering character, they can cause decrease in comprehension of speech, in short term memory and executive functions. Also visual distraction can require higher levels of attentional resources. Such problems have a great influence on people's performance in their social and professional life. For this reason, in order to achieve a more complete evaluation, various objective measures (cognitive tasks) and speech intelligibility (how comprehendible speech is) which basically measure the burden of decreased cognitive capacity from environmental stimuli are introduced.

The captured variations in reactions of the users should be interpreted with the variations in presented scenarios' audio and visual characteristics using analysis of variance (ANOVA) calculations.

4. Case study: Triana – Calle San Jacinto

The proposed multisensory assessment method has been applied on case studies in order to see potential uses (basically for solutions in acoustics related issues) in architecture (Basturk et al. 2010; Maffei, Basturk, et al. 2011) and environmental decision making processes (Maffei et al. 2010; Maffei, T. Iachini, et al. 2011). The case study applications are varied with different scales and characteristics of environments.

In this case study (Basturk et al. 2011) the possible future audio and visual impacts of relevant legislative efforts of the General Directorate of Climate Change and Urban Environment of Andalusia (Spain) were depicted in virtual representation of "San Jacinto" street of Seville. It was aimed to test applicability of the method in public participation processes for this reason the multisensory evaluation method was applied partially just to prepare VR simulations of chosen conditions.

4.1 Preparation of the Virtual Triana

Several exploratory surveys have been carried out at different times of the day, in order to reveal the daily life dynamics as well as the built environment. These surveys are coupled with soundwalks, monitoring the acoustic character of the area and recording binaural audio signals. Photo and video acquisition were carried out in situ at the same time. After the exploratory surveys a representative part of the street (150 meters long pedestrian area) was chosen to be studied. And it is decided to prepare the VEs regarding three conditions; 1) the actual situation at daytime, 2) sodium-vapor lamp lighting at nighttime 3) LED lamp lighting at nighttime, all three accompanied with appropriate audio stimuli.

Figure 6. Scenes from calle San Jacinto.

The audio stimuli are prepared extracting representative tracks from the soundwalk recordings. For the daylight scenario a 2 minute long audio stimuli is extracted from

the soundwalk 18 February 2011, 14:00. The sodium-vapor lighting scenario has the audio stimuli extracted from the soundwalk 7 March 2011, 21:00. The LED lighting scenario has the audio stimuli extracted from the soundwalk 25 February 2011, 21:00. The three dimensional model of the study area is prepared and the images acquired in situ are mapped on the 3D model in order to depict existing daylight situation. Other two scenarios with LED and sodium-vapor lighting are simulated with appropriate lighting simulation software and resulting textures are mapped (texture baking) on the 3D model in order to present in final VR simulation. The chosen sodium-vapor light has 70 W power and 100 lm/W efficacy whilst LED light has 42 W power and 80 lm/W luminous efficacy. After that, the prepared visual stimuli are merged with corresponding audio stimuli in virtual reality application and dynamic components (people and cars) are added and programmed to act in a realistic way.

Figure 7. Snapshots of three prepared scenarios.

5. Discussion and future directions

The preliminary case study demonstrates the possible changes in urban environment due to the new regional regulation on an interactive virtual reality platform. The prepared simulations were influential for the local government and got positive feedback regarding its applicability. It is promising for further studies that can take advantage of intuitive and life-like presentation capability to achieve more democratic and transparent procedures in governing urban areas. The General Directorate of Climate Change and Urban Environment of Andalusia has been one of the first governmental bodies that consider such an innovative approach to evaluate urban environments that facilitates public information and participation obtaining public opinion to improve regulatory and decision making processes. A complete application of the whole multisensory assessment method is in consideration.

On the other hand, the presented multisensory evaluation technique offers an unprecedented understanding of perceived qualities of spaces. It is capable of detecting adverse effects of unsatisfactory qualities on general well-being and quality of life. And also, the technique facilitates to place the end user in the center of spatial decision making processes introducing a life-like interface. Thus, it both improves soundscape (especially in laboratory settings) studies and offers a tool that is capable of integrating interactive lights, tactile properties of materials, temperature, humidity, odors and surely sounds as well as other contextual aspects into architectural and urban design practices.

Today soundscape research step forward to emancipate architectural and urban acoustics from narrow noise control approach that grasps sound as a function of solely decibels. And it tries to piece together all sensory experiences and contextual factors in order to better understand soundscapes, to improve experienced qualities of environments through sound. Reminding Mirko Zardini's question "Is it possible to combine the different approaches to contemporary urbanism with a "sensorial urbanism," capable of offering a broader understanding of urban settings, interested in describing the character and atmosphere of places, and aiming to contribute to a new definition of public space ?"(Zardini 2005), we believe that soundscape approach is inciting a movement in architecture and urban design opposing the dominance of the eye and develops new tools to combine different approaches for a new *sensorial urbanism*.

URBAN REGENERATION IN TURKEY: THE CHALLENGE OF REGENERATING APARTMENT BLOCKS

Özgül Burcu Özdemir Sarı[1]

Abstract

For decades, urban growth and new housing production have been the priorities of Turkish urban planning and housing policies. This attitude could have been considered relevant and satisfactory at the earlier stages of urbanization. Currently, developing regeneration strategies to maintain and improve the standards of living and quality in existing urban environments is the major challenge of urban planning. Urban development and residential investment strategy of the public sector, however, is extensive housing production by means of new construction and urban transformation projects. Furthermore, urban transformation is reduced to physical redevelopment of squatter housing areas, decayed historical parts of the cities and more recently disaster prone areas. Consequently, improvement and redevelopment needs of the existing urban areas containing authorized housing stock are totally ignored.

This study argues that, beyond the concerns of current urban transformation efforts, the challenge of urban planning in Turkey is to regenerate the neighbourhoods of apartment blocks, which dominate the urban areas. Regeneration of apartment blocks is defined as a challenge in this study since almost all of this stock is privately owned, all types of repair-maintenance and rehabilitation activities are totally dependent on individual flat owners' decisions, redevelopment is difficult to undertake since it requires unanimous decisions of flat owners, and apartment blocks dominate the urban housing stock in Turkey.

Based on the findings of a recent research on households' reinvestment behaviour in apartment blocks of Ankara, this study provides a number of clues in designing urban regeneration strategies for neighbourhoods containing apartment blocks. Accordingly, (1) distinct urban environments require different types of tools and mechanisms of intervention, (2) physical component of regeneration is not sufficient alone to cope with multifaceted problems; social, economic, environmental, and cultural dimensions of regeneration could also be emphasized depending on the nature of problems in different neighbourhoods, (3) physical component of regeneration is not confined to redevelopment, investments for repairs-maintenance and rehabilitation of the existing housing areas could be complementary interventions, (4) public guidance and supervision is necessary to monitor tendencies of reinvestment as well as to trigger reinvestment capacities of households, (5) an

[1] Middle East Technical University, Ankara, Turkey – bozdemir@arch.metu.edu.tr

effective collaboration of public and private sectors, and resident households could provide viable regeneration strategies.

1. Introduction

For decades, 'urban growth' and 'new housing production' have been the priorities of Turkish urban planning and housing policies. This attitude could have been considered relevant and satisfactory at the earlier stages of urbanization. However, Turkey is experiencing a new phase of urbanization today, characterised by a reduced pace of population increase and slowed down rural to urban migration, where a surplus in housing stock exists (Özdemir Sarı, 2011). A major challenge of urban planning at this phase of urbanization is to develop regeneration strategies to maintain and improve the standards of living and quality in existing urban environments. Current urban development and residential investment strategy of the public sector, however, is extensive housing production by means of new construction, particularly on the periphery of major cities, and transformation of squatter housing areas and decayed historical parts of the cities which are very attractive due to their locational advantages. As a result of this strategy, annual housing production had artificially increased during 2002-2010, at an accelerated rate never observed in the last 25 years of Turkish urbanization history. Annual new housing construction reached almost to 850,000 units in 2010, which comprises nearly 4 per cent of the existing urban housing stock in Turkey. Furthermore, 'urban transformation' is reduced to physical redevelopment of squatter housing areas and decayed historical parts of the cities. Even more strikingly, Turkish housing policy is now on the verge of a 'bulldozer era' due to the current efforts of the public sector to transform disaster prone areas developing new legislation. In such a policy environment; maintenance, rehabilitation, and comprehensive redevelopment needs of the existing urban areas, particularly those containing authorized housing stock, are almost totally ignored by urban planning and housing policies in Turkey.

This study argues that, beyond the concerns of current urban transformation efforts, the challenge of urban planning in Turkey is to regenerate the neighbourhoods of apartment blocks. Nearly 70 per cent of Turkish urban households live in flats by year 2010 (TURSTAT, 2011). Almost all of the apartment stock is privately owned, and all types of reinvestments (investments for repairs-maintenance and rehabilitation) and redevelopment decisions are almost totally dependent on individual flat owners' behaviour in the free market. In this stock, decision-making power on buildings is unconditionally fragmented, minimizing the probability of producing joint decisions, neglecting the comprehensive or building level redevelopment needs in urban areas at future stages of urban lifecycle (Balamir, 1975). The above mentioned factors increase the difficulty of regenerating urban environments containing apartment blocks.

This study is organised in five sections including this introduction. In the next section, current concerns in the urban regeneration policies and programmes in Europe and in Turkey are briefly discussed. In the third section, an overview of the

Flat Ownership Law with respect to maintenance and demolition issues are provided, and factors that work against regeneration of apartment blocks are discussed. Findings of a recent research on households' reinvestment decisions in the apartment stock of Ankara are presented in the fourth section and based on these findings, a number of clues to regenerate neighbourhoods of apartment blocks in Turkey are presented. Final section of the study provides a number of conclusions.

2. Current concerns in the urban regeneration policies and programmes

Urban space is produced under distinct social, economic, political and technological circumstances. These circumstances change in time necessitating the transformation of urban space and thus design of planned interventions for the regeneration of urban areas. In Europe, urban regeneration policies and programmes have experienced various changes over the years and have been redefined numerous times. The first generation policies and projects emerged as deliberate efforts to get rid of the poorest slum areas in inner city, and were characterized by physical determinism and emphasis on the built environment (Carmon, 1997). Gradually, policies and programmes of urban regeneration became more sensitive to social and economic problems. In the Western European countries, for instance, slum clearance operations were followed by preservation of old historic buildings and housing rehabilitation (Skifter Andersen, 1999). Economic slowdown of the 1970s affected public policies and emphasis on economic development resulted in urban restructuring and revival of city centres (Carmon, 1997). Over the years, it became clear that physical interventions were not enough to cope with spatial concentration of physical, social, and economic problems. Integrated area-based approach to regeneration was emerged, particularly in the UK, as a solution to cope with multifaceted problems in urban areas simultaneously (Cameron et al., 2004). Currently, in many European countries there is growing interest in integrated area-based approach to urban regeneration.

Major support to integrated area-based regeneration model comes from the policies of the European Union (EU). Since 1990s urban dimension in EU policies are becoming more significant (Atkinson, 2001; Carpenter, 2006). Issues such as quality of life, safety, social inclusion, social equality, poverty reduction, better housing conditions and environmental sustainability are among the most discussed topics of the European urban agenda. In order to improve the living conditions of citizens in deprived neighbourhoods and to promote sustainable urban development, the EU has promoted the integrated area-based regeneration approach. Currently, within the context of integrated urban development and regeneration approach, EU policies emphasise economic growth and jobs, environmental aspects (i.e. energy efficiency and climate change), social exclusion, poverty, crime, integration of migrants and ethnic minorities, gender equality, demographic change, urban sprawl, architecture, culture and good governance (Piskorz & Goulet, 2009). In this framework, physical regeneration is considered together with social, economic, environmental and cultural aspects of urban life and development.

In Turkey, on the other hand, urban regeneration has become a current topic in the planning agenda particularly following the general elections of 2002. Legal documents and discussions in Turkey employ the term 'urban transformation' to refer regeneration policies and programmes. The 'Action Plan', declared by the government after the elections, highlighted 'prevention of squatter housing construction' and 'initiation of an extensive housing construction program' under the 'Urbanization and Settlement' heading of the plan (JDP, 2003). Housing construction was seen as a short-term solution to the unemployment problem in this period. To develop a legal framework for 'urban transformation', a series of legislation drafts were prepared, and most of them were enacted. However, these arrangements have been criticised by NGOs, academia, and by the different branches of Turkish Union of Chambers of Engineers and Architects on the grounds that these efforts were rent / profit-oriented, bypassing current legislations, and independent from the existing planning and urban development system and legislation (Özdemir-Sarı, 2010). Following the general elections of 2007, government declared a new 'Action Plan' which redefined the context of 'urban transformation' as 'urban renewal and squatter housing transformation' as part of the housing production process (JDP, 2008); yet, major dimensions of the policy remained unchanged. ***Displacement***, ***clearance and redevelopment***, ***large-scale and expensive public operations*** are the major characteristics of the current 'urban transformation' proposals and projects. Social and economic components of regeneration such as community participation or empowerment are totally ignored in Turkey (Özdemir, 2009). 'Urban transformation' is clearly reduced to transformation of squatter housing areas and decayed historical parts of the cities. As a result, improvement and redevelopment needs of the existing urban areas containing authorized housing stock are totally ignored.

In 2012, discussions gained a new dimension with the introduction of a new draft law concerning the transformation of disaster prone areas. As of May 2012, this draft law is on the agenda of the Grand National Assembly of Turkey and is expected to be enacted in the coming days. There are numerous points to be criticised in this draft law; however, the most significant aspects to be emphasized here are that (1) the entire country could be a subject of this law either as 'urban transformation area' or 'reserved areas for new urban development to be used for relocation purposes', and (2) Turkish housing policy is now on the verge of a 'bulldozer era' since major tool of intervention defined in this law is clearance and redevelopment.

In such a policy environment not only the social and economic components of urban regeneration but also maintenance, rehabilitation and redevelopment needs of the existing urban areas containing authorized housing stock are almost totally ignored by urban planning and housing policies in Turkey.

3. The challenge of regenerating apartment blocks in Turkey

This study argues that, beyond the concerns of current urban transformation efforts, the challenge of urban planning in Turkey is to regenerate the neighbourhoods of apartment blocks. Majority of the building stock in these neighbourhoods has been

produced within a short span of time without adequate technical supervision and ageing altogether (Balamir, 1975; 2002). Furthermore, sufficient standards in infrastructure, open spaces, green areas, etc. are not attained in most of these neighbourhoods. Before discussing why regeneration becomes a challenge in urban areas containing apartment blocks, it is useful to mention a number of points regarding the management and decision-making processes in apartment blocks.

In Turkey, apartment blocks dominate the existing urban housing stock. This stock is regulated through the 'Flat Ownership Law' (1965). The Law defines two main parts of the property as 'individually owned and independently usable parts' and 'commonly-owned parts' (independent and common parts hereafter). According to the Flat Ownership Law:

- **Maintenance of the independent parts**: Flat owners are compelled to maintain and preserve the architectural, aesthetic, as well as structural qualities of the property. On the other hand, this means that individual owners have rights to freely enjoy the control of investments in their own dwelling units / independent parts. They can do repairs and alteration freely in their individual flats, unless no damage is done to the main structure.
- **Maintenance of the common parts**: Flat owners together have the responsibility to undertake maintenance, preservation, retrofitting, and repairs. None of the flat owners is entitled to carry out repairs, construction, and paint in different colours without a written consent obtained from four fifth of the flat owners.
- **Urgent retrofitting of the main structure**: If there is an event of urgency confirmed by a court decision, for instance if the main structure requires urgent retrofitting, then consent of the flat owners is not sought.
- **Demolition of the main structure**: Demolition requires unanimous decisions of flat owners unless this operation is ordered legally as a safety precaution.

It is possible to identify a number of factors that work against regeneration of neighbourhoods of apartment blocks in Turkey. These are; (1) private ownership, (2) fragmented ownership structure, (3) lack of a management level at neighbourhood scale, (4) lack of public guidance, supervision, and funds, (5) extent of the problem.

1. **Private ownership**: It is not possible to ignore the question of agency in regeneration of apartment blocks. Almost all of the apartment stock, both owner-occupied and rented sector, is under private ownership. As explained above, all types of reinvestment activities and redevelopment decisions are reserved for the individual flat owners rather than public authority (excluding an event of urgency confirmed by a court decision). In other words, rehabilitation or redevelopment of the apartment blocks could take place only if flat owners decide to do it.
2. **Fragmented ownership structure**: In Flat Ownership system, decision-making power on buildings is unconditionally fragmented and the possibility of producing joint decisions is minimized (Balamir, 1975). Yet, as mentioned above, both maintenance of the common parts and demolition of the main structure require collective decision-making. As Balamir (1975) emphasize,

fragmented ownership structure in Flat Ownership system is to hinder realization of redevelopment decisions in the free market environment at future stages of urban lifecycle, leading large section of the Turkish cities into paralysis.

3. **Management level**: Flat Ownership Law defines management of individual building and building block. Lack of a management level at neighbourhood scale is an obstacle to consider regeneration as an opportunity to maintain and reorganize open and built spaces, social and technical infrastructure, etc. in neighbourhood environment. In other words, Flat Ownership system confines the content of regeneration to rehabilitation or redevelopment of buildings.
4. **Public guidance, supervision, funds**: Unlike European examples, no specific policy exists in Turkey to consider reinvestment processes and redevelopment in the existing housing stock, and there is no tool or mechanism to supervise or encourage flat owners' reinvestments (Özdemir Sarı, 2011).
5. **Extent of the problem**: Apartment blocks dominate the urban housing stock in Turkey. By year 2010, nearly 70 per cent of urban households live in flats (TURKSTAT, 2011). In other words, high-rise living affects wider sections of the society and urban areas compared to single-family housing. This means that acquisition of the decaying stock by the public sector or compulsory purchase measures to improve the quality of existing housing environments are unlikely.

Considering these factors, not only social, economic, and environmental dimensions of regeneration but also physical dimension of regeneration becomes a challenge in Turkey. Obviously, regenerating the neighbourhoods of apartment blocks is not a task that could completely be undertaken in the free market environment or by the public sector. Individual flat owners' investment capacity, decisions, and behaviour become significant in this context.

4. Households' reinvestment behaviour in apartment blocks: implications for urban regeneration policies

A recent research by Özdemir Sarı (2010), based on a household survey conducted in apartment blocks of urban Ankara during 2007-2008, displays a number of crucial findings which are relevant for the regeneration of neighbourhoods containing apartment blocks[2]. Accordingly;

- Substantial amount of capital is engaged in reinvestment work. Nearly 33 per cent of owner-occupier respondents and 28 per cent of tenant respondents were engaged in reinvestment activities in the year preceding the survey. Average annual reinvestment expenditures for owner-occupiers who carried out reinvestments were nearly 1650 Euro whereas it was 380 Euro for tenants.
- More than four fifth of the total reinvestment spending was realized in the owner-occupied sector. Tenants were less likely to engage in reinvestment activities, and their expenditures were small. However, no information was available on reinvestment expenditures of the owners in the rented sector.

[2] Refer to Appendix for details of the data source employed in Özdemir Sarı (2010).

- In the owner-occupied sector, circumstances of necessity and urgency were the determiner of reinvestment behaviour for almost half of the owner-occupiers. Owner-occupiers frequently engaged in and planned to undertake consumption enhancing investments. Reinvestments essential for the survival of the housing stock, however, were less often demanded. Tenants, on the other hand, were more likely to engage in reinvestments when it became inevitable.
- Among households who engaged in some type of reinvestment work, the share of households who employ consumer loans to finance reinvestment activities was only 4 per cent.
- Results also revealed that, for all tenure modes, the foremost obstacle to undertake planned reinvestments was the high costs of the reinvestment projects. For tenants, 'having the consent of the home owner' stood as a second major problem. Contrary to expectations, 'unavailability of skilled labour' was the third problem reported by owner-occupiers following the 'time constraints/having no spare time' to undertake reinvestments. On the other hand, 9 per cent of all respondents reported that the need for unanimous / collective decisions of flat owners in the apartment was a major obstacle to undertake the planned reinvestments.
- Furthermore, multivariate analyses of the survey data displayed that, for all tenure modes, **reinvestment works were less likely for** younger household heads, households having more than 40 years length of stay in the dwelling, households living in apartments where no reinvestment activity is observed in common parts, households who evaluated their dwellings as small-sized, and households who rated their neighbourhood environment as extremely poor or below the average. Moreover, **voluminous reinvestment expenditures were less likely for** households in the lowest end of the income scale, tenants, and households living in apartments where no reinvestment activity is observed in common parts.
- As a consequence, high rates of depreciation and loss of quality are expected to appear basically in the neighbourhoods where (1) lowest income households are agglomerated, (2) rented dwellings dominate the housing stock, and (3) apartment blocks are not maintained in good order.

1. **Lowest income households**: The study reveals that the lowest income households spend less for reinvestments compared to other income groups. Furthermore, there is a match between households in the lowest end of the income scale and lowest end of the housing stock in terms of dwelling age, dwelling size, and rental value. In other words, households who are unable / unwilling to maintain their dwellings already occupy the stock where deterioration is more likely due to aging and overutilization compared to other dwellings.

2. **Rental stock**: Empirical evidence displays that tenants' reinvestment expenditures are quite low compared to owner-occupiers' expenditures. Most of these expenditures undertaken by tenants are known to be for non-discretionary repair-maintenance works. Repairer tenants more frequently engage in painting, regular repair-maintenance, and repairs in electrical system or plumbing which are essential works for their own consumption.

Investigation of reinvestments by rental stock owners is required in order to understand the extent of disrepair in the rental stock. Yet, it is a fact that rental stock owners undertake reinvestment works with investment considerations only, either to secure their initial investments or to capitalize higher rental income where possible.

3. **Lack of repair-maintenance in common parts of the apartment**: Empirical results display that, repair-maintenance works undertaken by joint efforts of flat owners in common parts of the apartment block (particularly installations / infrastructure repairing) trigger individual reinvestment decisions and large scale reinvestment works. On the contrary, lack of these activities discourages households' reinvestments in their independent parts. In apartment blocks where rate of owner-occupancy is lower, flat owners abstain from maintaining common parts. This in turn decreases the likelihood of individual reinvestment decisions (both for owner-occupiers and tenants), and size of the expenditures (for owner-occupiers) in these apartments.

These issues identified above provide a number of clues in designing urban regeneration strategies for neighbourhoods containing apartment blocks. First of all, it is clear that ***spatial definition of the problem at local / neighbourhood level*** is inevitable. Experiences all over the world display that there is no single or standard solution to the problems in urban areas. Rather, distinct urban environments require different types of tools and mechanisms to intervene. Therefore, it is necessary to explore social, spatial, and economic characteristics of the area under consideration for regeneration prior to any intervention. For instance, as empirical findings display, both spatial concentration of the lowest income households and rental stock indicate to the likelihood of high depreciation rates and loss of quality in neighbourhoods. Although the observed problem in both cases is the depreciation of the housing stock and decline in neighbourhood quality, a global regeneration strategy to cope with physical deficiencies of the built environment could not achieve success in the long run. In the first case, where the problem stems from the inability of the lowest income households to maintain the lowest end of the stock, integrated regeneration strategies that include influential social and economic components along with physical regeneration could be remedies. In the second case, where the problem has its source in the disinvestment in rental stock, physical regeneration accompanied with policy measures for monitoring the reinvestments in the rented sector could provide solutions.

Secondly, ***integrated approach to regeneration*** is more likely to provide viable options. It is not feasible or operational to focus only the physical component of regeneration. Integrated approach including physical, social, economic, environmental, and even cultural dimensions of regeneration, where necessary, could provide feasible regeneration options. As in the example given above, if the reason of high depreciation rates in the housing stock and loss of neighbourhood quality is the failure of households to maintain their dwelling units due to income constraints, then redevelopment or rehabilitation of the built environment by the aid of public sector

would not be a solution alone in the long run, since reinvestment capacity of the resident households remains the same.

Another clue is that, ***diversified intervention methods under physical regeneration*** are essential. Physical component of regeneration does not only refer to redevelopment. Reinvestment in the existing housing stock and built environment is an indispensable component of physical regeneration. As Helleman and Wassenberg (2004) highlight, in the context of renewing large-scale housing estates in Europe, demolition is no longer a valid intervention method in most countries. Reinvestment and redevelopment interventions could be planned complementarily to achieve success in urban regeneration. It is a fact that at some stage of life-cycle, redevelopment is inevitable for building stock. As mentioned previously, demolition of the buildings under Flat Ownership Law requires unanimous decisions of flat owners (unless this operation is ordered legally as a safety precaution) and this is an obstacle for redevelopment. Therefore, first, strategies and models for redeveloping apartment stock are to be developed. Certainly, these strategies and models have to consider not only the individual building level but also interventions in the neighbourhood level. In addition to these, reinvestment strategies have to be designed. It is a fact that reinvestments could extend economic life of the housing stock, preserve asset values and ensure value increases, improve the standards of housing services and living environments, and help to adjust housing consumption with regard to the current needs and trends, etc. (Özdemir Sarı, 2011).

Moreover, it is clear that ***public guidance and supervision*** in reinvestment processes is an imperative. As mentioned previously, recent information displays that a substantial amount of capital is invested by households, particularly by owner-occupiers', in repairs-maintenance, and rehabilitation of the flats. Yet, findings display that there is a demand for consumption enhancing investments rather than the investments essential for the survival of the housing stock. This implies that there is a need for monitoring the tendencies of reinvestments so as to ensure the structural elements of dwellings are maintained regularly. Moreover, empirical findings mentioned above display that a number of household, dwelling, and neighbourhood characteristics discourage individual reinvestment decisions and size of the reinvestment expenditures. These findings suggest that policy measures are not only required for monitoring purposes but also for triggering reinvestment capacities of households who are unable or unwilling to reinvest their dwelling units.

Finally, ***a combination of financial resources*** is required in urban regeneration. Conditions described above display that regenerating neighbourhoods of apartment blocks is not a task that can be achieved solely by public or private sector investments. Regeneration policies and programmes have to be designed considering an effective collaboration of public and private sector, and resident households. Households' investment capacity is significant to maintain the quality and living standards in neighbourhoods, whereas public supervision and funding is essential to monitor and trigger households' reinvestment decisions in the existing housing stock.

Public and private sector investments in the neighbourhood, on the other hand, are required to maintain and increase the attractiveness of urban environments.

5. Conclusions

Currently, there is growing interest in integrated area-based regeneration approaches in many European countries. This model of regeneration is supported also by the EU policies to tackle physical, social, economic, and environmental problems in urban areas and to ensure sustainable urban development. On the contrary, current urban development and regeneration strategy of the public sector in Turkey depend solely on new housing construction and redevelopment to cope with the problems in squatter housing areas, decayed historical parts of the cities and more recently disaster prone areas. The major line of argument in this paper is that the challenge of urban planning in Turkey is to regenerate neighbourhoods of apartment blocks. As discussed in this paper, current circumstances and attributes of the Flat Ownership system display that not only social, economic, environmental dimensions of regeneration but also physical dimension becomes a challenge in Turkey. Recent research on households' reinvestment behaviour, on the other hand, provides a number of clues for designing viable regeneration strategies. Accordingly; defining problems and solutions spatially; considering social, economic, environmental, and cultural dimensions of regeneration, as well as the physical dimension; adopting reinvestment and redevelopment interventions complementarily; designing policy measures for monitoring reinvestment tendencies and triggering reinvestment capacities of households; and developing an effective collaboration between public, private sectors, and resident households could provide viable regeneration strategies. Regenerating the neighbourhoods of apartment blocks could be an opportunity for urban planners to reorganize and redesign urban environments in order to improve the quality of life in cities.

Appendix

The data source employed in Özdemir Sarı (2010) is a survey sample obtained through the 'Household Mobility in Housing Stock' project, a Scientific Research Project funded by Middle East Technical University. The sample of the survey was selected from the records of apartment blocks which were registered to Flat Ownership books in the Deeds Offices in Ankara. These records cover information related to buildings and individual flats in the central districts of Ankara metropolitan area namely; Çankaya, Yenimahalle, Keçiören, Altındağ, Mamak. The records were obtained from the local Deeds Offices of those districts and converted to a combined list ordered with respect to date of registration for a systematic sampling. Every 20^{th} record was selected (5 per cent sampling) in order to implement a household questionnaire. Every household in the surveyed buildings (regardless of mode of tenure) was encouraged to participate in the multiple-choice questionnaire. Households were not interviewed face-to-face, rather the questionnaire forms were distributed to the households and after a convenient time period a surveyor collected the questionnaires. More than 8000 households in approximately 950 buildings were visited. The response rate however remained approximately 25 per cent.

Urban Planners with Renewable Energy Skills – UP-RES

Arto Nuorkivi and Anna-Maija Ahonen,
Aalto University (Aalto PRO), Espoo, Finland
Mail: P.O. Box18000, FIN-00078 AALTO
Email: energy@nuorkivi.fi

Hanna Mattila and Timo Heikkinen,
Aalto University, The Centre for Urban and Regional Studies, Finland

Keywords: energy, emissions, climate change, education

Abstract

Missing link to energy and emissions

Traditionally, energy and emissions have not been integrated into the urban planning processes. Only in a very few planning schools in the world the spatial planners are educated with understanding on energy, and on renewable energy sources (RES) and energy efficiency (EE) in particular.

Relevance of the work to planning education

To fight Climate Change, however, such new understanding has become essential. The understanding may materialize in the following two ways:

- The energy experts and the urban planners shall start working together with all spatial development plans regardless existing or new building areas. In order to facilitate such co-working, training shall be provided to both types of professional to help them to understand each other.
- The training shall be extended to bachelor and master level education in parallel to the continued education of professionals.

UP-RES (Urban Planners with Renewable Energy Skills) Project as a part of the Intelligent Energy Europe framework programme provides pilot training to
spatial and energy planners in five EU countries as well as material support to other universities to adopt such training into their curricula.

The training material designed to other planning schools in Europe will be made freely downloadable in 10 languages by mid July 2012 on the web page: http://aaltopro2.aalto.fi/projects/up-res/materials.html

Methodology

During 2012, the pilot training is carried out in five European countries, namely in Hungary, Spain, Germany, U.K. and in Finland, the latter being the country of the coordinator.

The project work started with the competence and training needs analysis. Based on the analysis, the training concept was designed specifically for each country. Practical examples and best practice cases of combined spatial and RES planning have been collected and used in the pilot training. Real cases have been identified in which win-win situations have been achieved when both the lifecycle costs and the emissions could be substantially reduced compared to the traditional way of spatial planning. The pilot training is underway during the period Oct. 2011 – June 2012.

Pilot Training Approach

The core of the training is the structure comprising ten modules. Each module typcally comprises two days of training.

The module titles are as follows:

M1	SUSTAINABILITY CONCEPTS IN REGIONAL AND URBAN PLANNING: A HOLISTIC VISION
M2	ENERGY. FORMS - TRANSFORMATION - MARKET OUTLOOK
M3	ENERGY DEMAND REDUCTION STRATEGIES: POTENTIAL IN URBAN PLANNING
M4	ENERGY DEMAND REDUCTION STRATEGIES: POTENTIAL IN NEW BUILDINGS AND REFURBISHMENT
M5	ENERGY RESOURCES AND RENEWABLE ENERGY TECNOLOGIES
M6	ENERGY DISTRIBUTION: DISTRICT HEATING AND COOLING
M7	THE RIGHT SCALE FOR EVERY ENERGY CONCEPT: HEAT AND COOL DENSITY (DEMAND SIDE), POTENTIAL ON SUPPLY SIDE
M8	NEW MANAGEMENT CONCEPTS IN THE ENERGY MARKET
M9	ENERGY PLANNING
M10	NEW TRANSPORT MODELS AND URBAN AND INTER-URBAN MOBILITY

The above listed Modules will be described in the attached documents, including the objective, the main contents and the information sources available to design local training of the particular module.

Country Specific Differences

Designing and implementing the training heavily depends on the local circumstances, and therefore, has to be adjusted to the local needs and conditions. Therefore, various approaches were chosen in the five countries to implement the pilot training, as follows:

Finland:

- In Spring 2011 already, 7 one-day courses were organized in the cities of Espoo, Kuopio, Oulu, Turku, Tampere, Seinäjoki and Jyväskylä to market the long pilot training course.
- During Fall 2011-Spring 2012, a 9 months lasting long course of 8 modules of two days each was organized for 26 urban and regional planners.
- Moreover, a voluntary excursion of three days to Germany was arranged.

Hungary:

- By Summer 2011, 3 short courses were implemented.

- The long course with as much as 60 ECTS credits was organized during Oct 2011-July 2012rs.
-

Germany: ...

- Six short courses of 2 days each were organized in Germany with 182 participants in Dresden, Frankfurt, Munich, Hamburg, Chemnitz and Berlin.
- The long course of 9 months was expected to start in June 2012.

Spain:

- Four information days were organised in the Chamber of Architect's regional head-quarters in Girona, Tarragona and Barcelona
- The long course with 10 modules were implemented during Oct. 2011-June 2012. The long term course was structured in ten modules with an extension between 12 and 18 hours each.

United Kingdom:

- In total 5 short courses of 3 days each were implemented in UK by February 2012 but more expected later on.
- According to the project agreement, there will be no long courses in UK.

Structure of Training Material

The material at hand consists of the selected training materials of ten modules, for each of which a general description of the module objectives, approaches and the contents has been created. As annexes slides have been given to present some 3-5 key topics of the particular training module, some 300 slides altogether. Internet links have also been given for searching more information from the web in English language.

Methodologies of Training

In the pilot training several methodologies were applied, as follows:

- Sometimes a facilitator was chosen for each module to link the learned energy issues to urban planning
- Lectures were based on slides and discussions
- Excursions both locally and internationally were organized to best practice locations
- Exercises were carried out by the trainees in small groups and individually about issues combining RES and EE to spatial planning
- Distant learning was used to reduce the need of travelling and to save time
- Movies were shown to trainees such as, for instance, Inconvenient Truth, District Cooling,
- Expert panel, or expert clinic, advisory services were applied to support the trainees to carry out their exercises.

Example of Training Module

Here an example of the contents of a training module is presented. It has been a combination of team work, lecturers and an excursion, for example.

M5	ENERGY RESOURCES AND RENEWABLE ENERGY TECNOLOGIES
Fasilitator: N.N.	**13.-14.2.2012**
Time	**1st Day: Familiarization with RES**
9.00-9.15	Introduction to Module Topics
9.15-10.30	Presentation of RES technologies and applications
10.30-10.45	*Break*
10.45-12.00	Based on the presentation ,five groups of trainees search for information from Internet. One group specifically for solar electric, solar heat, wind, biomass and the fifth group for waste to energy.
12.00-12.45	*Break*
12.45-14.00	Five groups continue
14.00-14.15	*Break*
14.15-145.30	Presentation of the results of five group works
15.30-16.00	Conclusion
	2nd Day: Rural Energy Supply
9.00-10.30	Local economy: impacts of RES on rural economy and survival
10.30-10.45	*Break*
10.45-12.00	Off-grid village based on RES (Kempele, Finland)
12.00-12.45	*Break*
12.45-14.00	Agricultural waste to liquid fuel
14.00-14.15	*Break*
14.15-16.15	Excursion to a bio mass fuelled CHP plant

Expected outcome

In summer 2012, the UP-RES project has provided support to extend similar training of urban planners with renewable energy and energy efficiency skills to other planning schools in Europe by means of publishing training materials. These downloadable materials comprise:

- The module structure of training;
- Introductory reading of the general approach and the content of each training module;
- Sources in literature and internet for more detailed information; and,
- Some 300 slides and supporting texts as well as shared experiences

The material is available in 10 European languages such as:

- English
- Finnish
- French
- German
- Hungarian
- Italian
- Polish
- Romanian
- Spanish
- Swedish

From fall 2012 on, the material is expected help extend such training to other European planning schools that consider integral spatial and RES planning as an important approach to fighting Climate Change.

The material above is freely downloadable. However, we would need to keep record on how, where and when such material has been applied in order to report on the use to the project sponsors, primarily the EU.

POST DISASTER RELOCATION AND RESETTLEMENT PROCESS IN TURKEY

Binali TERCAN [1]

Abstract

Disasters are events that occur in uncertain periods of time and threaten a society or a relatively self-sufficient part of a society with major unwanted consequences. They are mostly unavoidable events coming in unexpected times. However, setting of pre and post disaster activities like mitigation, preparedness, response, recovery and development have very important roles in reducing the future hazard risks in disaster prone areas.

Resettlement after disaster or from disaster prone areas has been a major policy in post-disaster reconstruction, especially in developing countries. Resettlement can result in significant adverse impacts on the resettled population. Conversely, a well-planned and managed resettlement process can produce positive long-term development outcomes.

The major concern of this study is to make a critical evaluation of the relations and the role of planning in post disaster relocation process by examining the outcomes of previous different kinds of disasters and defining the importance of site selection and relocation in post disaster planning process, for reducing the future hazard risks in different examples of Turkey.

By this study it is exposed that, post disaster relocation processes are important for reducing future hazard risk in disaster prone area. Within these processes, site selection studies in urban and rural areas, relying on geological criteria are one of the most important steps. However, it is not going to be effective unless other criteria such as socio-cultural, traditional, economic, psychological, legal and institutional coordination are not taken into consideration systematically.

Keywords: relocation, resettlement, site selection, earthquake and disaster management.

1. Natural Hazards in Turkey

1.1. Introduction To Natural Hazards In Turkey

The Republic of Turkey is located within the sector bounded approximately by the. Latitudes 36°- 42° N and longitudes 26°-44° E occupying an area of 775,000 sq. km with a population of approximately 74 million. It lies between the Black Sea and the Mediterranean Sea, bridging Europe and Asia.

As a result of its geology, seismicity, topography and climate, Turkey is exposed to various kinds of natural hazards sometimes causing substantial losses of life and

*[1]Assist. Prof. Dr., Abant İzzet Baysal University, Department of City and Regional Planning, Bolu – Turkey.

property. The percentage of houses damaged by natural disasters in Turkey in the last 100 years is indicated in Table 1.

Table 1: % of the Total Number of Houses Damaged in Turkey by Natural Disasters During Last 100 years

Types of Natural Disasters	% of the Total Number
Earthquakes	76
Landslides	10
Floods	09
Rock Falls	4
Avalanches, Storms, Excessive Rain	1

Source: (AİGM,2001; BIB, 2000; Ergünay, 2007)Türkiye'nin afet profili

The data in this table indicates that of all types of natural disasters earthquakes represent the greatest hazard, causing about three-fourths of dwelling destruction and a higher share of fatalities and monetary losses. In the period since 1960 the impact of floods, landslides and rock falls has had a decreasing tendency as a result of regulating river flow and more effective land use planning measures. We can anticipate that earthquakes will engender the major natural threat that faces Turkey in the future (Table 2).

Figure 1: Earthquake Hazard Figure of Turkey

Table 2: Distribution of Population, Land Area. Industry and Dams with Respect to the Seismic Hazard Zones

Earthquake Zone	Population (%)	Surface area (%)	Major Industrial Centres (%)	Dams (%)
First degree (I > IX)	44	42	24,7	10,4
Second degree (I = VIII)	26	24	48,8	20,8
Third degree (I = VII)	15	18	12,0	33,3
Fourth degree (I = VI)	13	12	12,6	27,1
No Hazard Zone (I < V)	2	4	1,7	8,4

Source: Özmen, 2000

In Turkey the Disaster and Emergency Management is legally required, through Act No 7269, to serve the public in its needs for protection from consequences of all types of natural disasters, and to take all preventive and protective measures for this purpose.

1.2. Disaster Management System in Turkey

Historically Turkey has suffered significant losses of life and property due to earthquakes and other forms of natural hazards. This has led to the acquisition of long standing experience and the gradual evaluation of a centralised disaster management system, culminating in 1959 with Law No. 7269 entitled “Measures and Assistance to be put into Effect Regarding Natural Disasters Affecting the Life of the General Public. Despite three revisions and a substantial amendment in 1968 contained in Law No. 1051, Law 7269 still forms the blue print for the comprehensive approach to disaster response, planning and management now evident in Turkey. The basic aim of Law No. 7269 is to enable the administrative structure of the government to manage disasters in a timely and efficient way, so that Losses and human sufferings are minimised and rehabilitation can be implemented effectively.

1.3. The National Disaster Management Institutional Framework in Turkey

The process of institutionalizing natural disaster mitigation and disaster management planning in Turkey can be broken down into three distinctive periods.

1.3.1. The Pre-1944 Era

During the Ottoman times, the central authority responded to natural disasters by enacting post event assistance and relief measures on a case specific basis. There was little evidence of mitigation policies, instead there was a reliance on rapidly enacted

measures intended only to address the requirements of post-disaster periods: Following the Great Istanbul Earthquake of 1509 each household was awarded 22 gold coin and a central authority was established to organize rebuilding the 1070 houses that had collapsed. However, an edict was proclaimed prohibiting the construction of houses built on artificial fills, and of stone masonry buildings.

Even into the post-republic (1923) era there appears to exist no long-range or systematic policy for the reduction of disaster losses. Given the absence of policy there was of course no planning towards its realization. Any actions taken did not originate from a coherent policy designed to prevent damages from future earthquakes but were merely to dress wounds arising from any fresh catastrophe. Such an approach continued until a disastrous and sustained chain of earthquakes was unleashed by the 26th December 1939 event in the city of Erzincan with an average period of 7 months between events. 4 further major earthquakes occurred killing 43,319 persons and destroying 200.000 homes.

Although the rehabilitation measures in Erzincan were enabled with the instrument of a special law enacted specifically for that earthquake the government realized that a change of policy was needed. Recognizing that rebuilding collapsed houses did not constitute an adequate form of combating earthquake losses it was decided that legal and physical preparedness were essential ingredients towards reducing future losses. A law entitled Measures to be Put into Effect Prior and Subsequent to Ground Tremors', No. 4623 was passed on 22 July 1944. (AFEM,1994, pp.2)

1.3.2. The 1944-1959 Period

For the first time a longer term policy was enacted towards reducing the future vulnerability to earthquakes with the state assuming those responsibilities that could not be carried out by individuals. This included the requirement of the central government authority to make an assessment of the earthquake resistance of all public buildings: means to ensure that development and settlement programs were to take the earthquake threat into consideration and an understanding that technical expertise within Turkey needed to be strengthened: universities sent personnel abroad for technical experience and the Ministry of Public Works initiated education and training courses for engineers and technical professionals.

Institutionally The Ministry of Public Works and Settlement was made responsible for overseeing the implementation of law 4623 and to draw up national building codes. The ministry also established a technical unit called the "Technical Earthquake Services directorate." The outputs of this renewed thinking and the collaboration between government agencies, the Ministry of Public Works, and the universities included;

- Development of hazard Figures
- Earthquake design regulations
- Introduction of geological survey
- Establishment and better definition of mandates for Provincial and sub provincial rescue and relief committees.
- Bye-laws aimed at providing the principles for research and training in mitigation activities.

1.3.3. The Post-1959 Period

Law No. 4623 carried stipulations only in relation to earthquakes, and did not contain provisions for other forms of natural disaster such as floods, landslides, rock falls etc. which had become more prevalent during the decade from 1950. In response the national assembly passed a law in 1959 entitled "Measures and Assistance's to Be Put into effect Regarding Natural Disasters Affecting the Life of the General Public", No. 7269, which superseded the 1944 law. The basic philosophy of Law No. 4623, was maintained but its scope was widened to include other forms of natural disasters. The law created a new ministry called the Ministry of Reconstruction and Resettlement (Replaced in 1983 by the Ministry of Public Works and Settlement (MPWS). and, in effect. charged it with the mandate of coordinating and implementing all the states obligations to the citizens of the country in conjunction with natural disasters. Although regularly revised and substantially amended by Law No. 1051 in 1958, it in law 7269 which farms the basis of the Disaster Management system in Turkey (Erdik,1993).

An important shift occured in the disaster management structure of Turkey in 2009. A new department called "Disaster and Emergency Management Presidency" (DEMP) under Prime Ministry was established in December, 17 2009. Turkey is prone to major types of disasters.

Disaster management structure was governed by three main actors until 2009 in Turkey. They were; General Directorate of Disaster Affairs under Ministry of Public Works and Settlement, General Directorate of Civil Defence under Ministry of Interior and Turkey Emergency Management General Directorate under Prime Ministry. With the Law n.5902 issued in 2009, the activities of those three departments were ended and the new Presidency has become operative since 17 December 2009. Most of the duties of those three actors will be performed by DEMP. The law N: 5902 defines the central and provincial level structure of the new unit. According to this law there are six departments at central levels. In each city, there is a provincial disaster and emergency management directorate that is directly attached to the governor of the city.

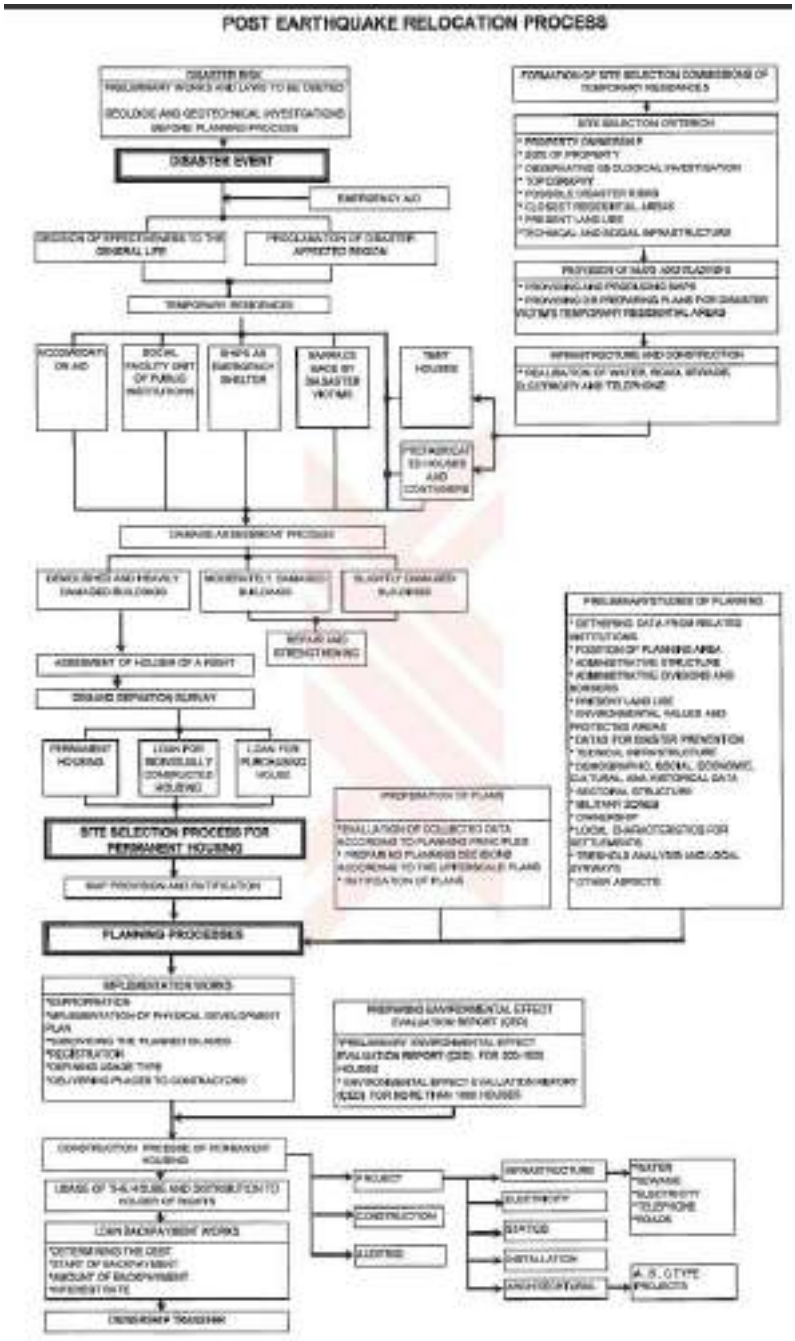
2. Post Earthquake Recovery Works and Relocation Process in Turkey

2.1. Damage and Need Assessment

When 17 August Marmara Earthquake happened, preliminary damage assessment processes had started immediately after the relief operations, synchronous with debris removal works (Figure 2). Parallel to these studies aiming at quick removal of the debris, the necessary activities to protect the legal right of the disaster victims pertaining to probable construction faults were carried out. According to the results of preliminary damage assessment, the initial tents erected to meet the urgent shelter need, field hospitals and kitchens serving hot meals were set up.

After the preliminary damage assessment, definite damage assessment works starts as preliminary damage assessment. Definite damage assessment results were listed and conveyed to the citizens as written announcement for one week. For five days objection time had given to the disaster victims. After that, objection acceptance and evaluation time take about one week. When the damage assessment of a building completed, demolition works start.

Figure 2 Post Earthquake Relocation Process



Source: Tercan, B., 2001

2.2. Provision of Temporary Housing

Several types of natural disasters (especially earthquakes) create a sudden and massive demand for alternative housing as a result of the widespread destruction of traditional and illegally constructed buildings.

According to the data taken from damage assessment groups, large scale temporary residential works are started.

There is an important time factor in solving the demand for shelter after disaster. Tents and other short-term solutions can usually be organized overnight, but large-scale camps of prefabricated buildings may take 8-10 weeks to plan, construct and assign units to families. Potential problems include financing the purchase of units and paying the labor required the logistics of transportation and the difficulty of acquiring land.

Starting from the initial stages of rescue and relief operations, the governmental efforts have been accompanied by voluntary initiatives both national and foreign in nature.

After August 17th and November 12th Marmara Earthquakes in Turkey, temporary residential problems were solved in many ways as indicated in (Figure 2). At first stages, the problem was solved by tents and barracks, which made by disaster victims. Then, most registered amount of the victims, were settled in tents. After relief operation, some of the disaster victims were settled to the ships of Greater Municipality of Istanbul and Turkish Navigation Administration Company. Others were settled to holiday villages of public institutions. The most expensive type of the temporary residents were prefabricated and container houses. The last groups of the disaster victims are supported by rent aid.

Self-Build Temporary Shelters: Most of the barracks made by disaster victims were settled just close to their demolished or damaged buildings. Although there is not a definite number about them, it is assumed that these are the most portions of the temporary residents of earthquake region.

Tent houses: Just after the earthquake, Turkish Red Crescent Association and other institutions distributed their tent stocks to the disaster victims. Because of the huge demand for tents, in addition to the donated and aid tents, The Ministry of Foreign Affairs imported 23.288 tents at first stage. (Başbakanlık;2000: 49) Totally 113.924 tents were distributed to the Marmara Earthquake Region.

Site selections, site surveys and ‘Tent City’ plans (Figure 3) related to aggregated (mass) tent residential areas, accomplished by the proposals of the Governorates and members of the Provincial Directorates of the Ministries.

During the site selection; Size of the area, distance to the settlement centre, location, ownership pattern (priority was given to the public ownership), infrastructure, geological land characteristics, land use and function in the existing plans, flood conditions, ground water level etc. were considered as selection criterions. (MoPWS, 2000, pp.17; Başbakanlık 2000, pp.53)

In order to take accommodation aid (100 million TL, about $150 in 1999), some of the disaster victims prolonged staying time in tent residents.

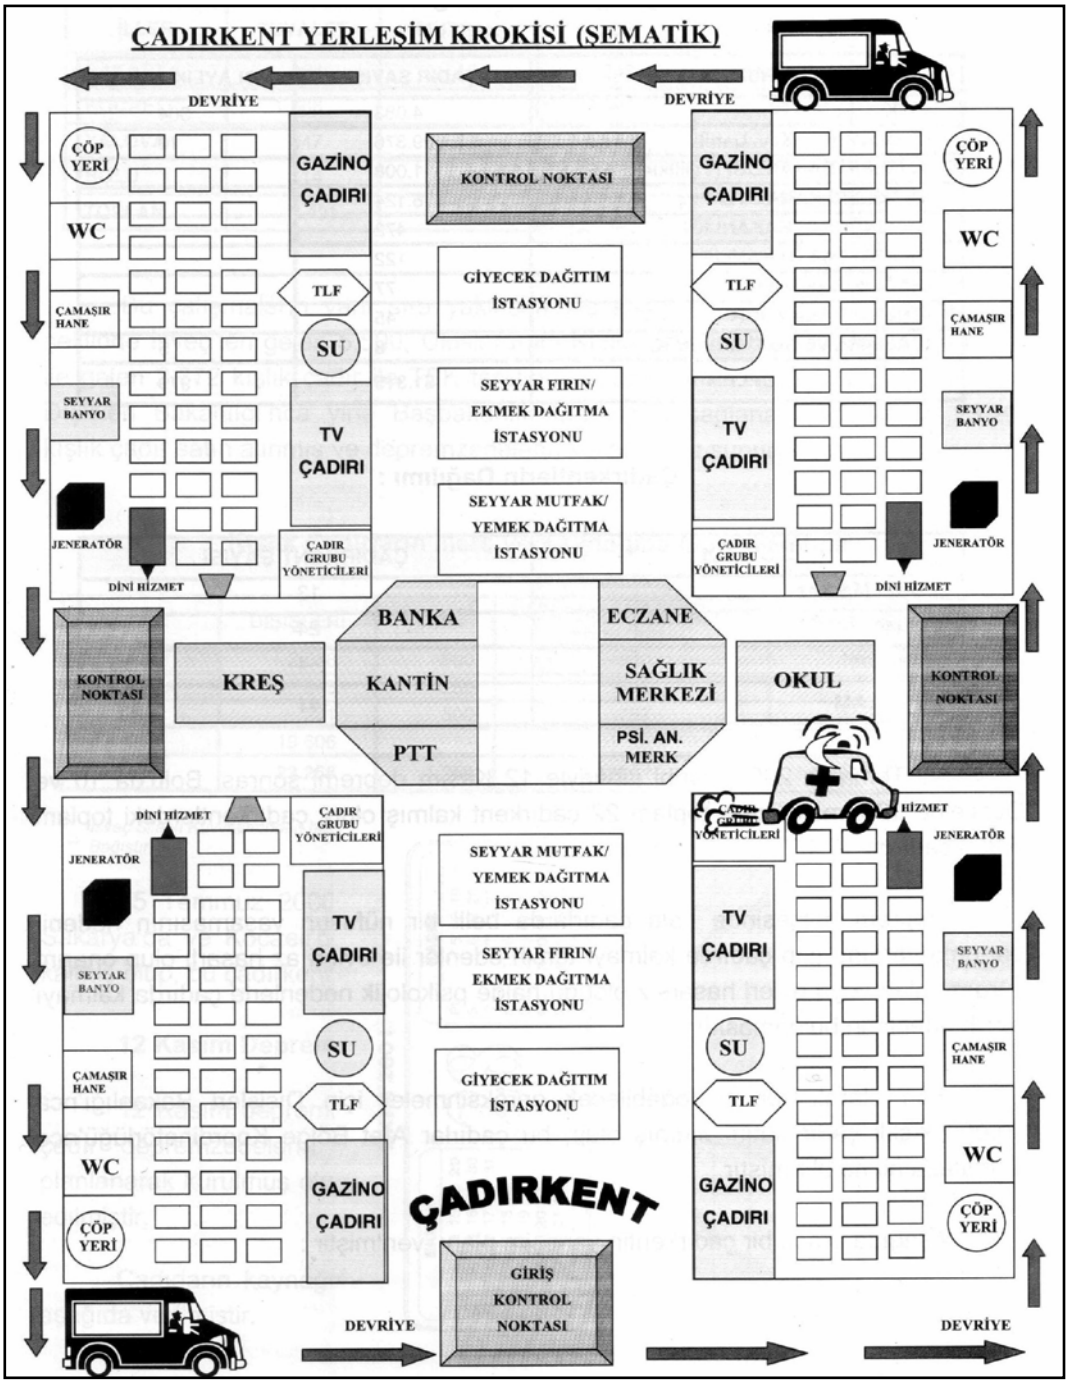


Figure 3: A Tent City Plan
(Başbakanlık,2000, pp.52)

Prefabricated temporary houses and containers: The government determined that people could be temporarily housed for the coming winter in prefabricated housing units. The Department of Public Works awarded contracts to 25 Turkish companies to produce and install approximately 26,000 of these units in the affected areas by the end of November, 1999 in Marmara Region. In addition, approximately 8,000 units were donated and erected by the private sector and foreign countries that included Japan, USA, Germany, Italy, Israel, Greece, Iraq, Russia, Czech Republic and the Cyprus Federation. Spain provided a soft loan in the amount of $400 million USD for use in purchasing housing and other goods from Spain. While several Canadian companies taught to participate in this work.

To define the number of the prefabricated houses a ‘demand definition survey’ had done by State Institute of Statistics and Ministry of Public Works and Settlement.

30 m2 prefabricated temporary housing units project was preferred. Site selection, site surveys for ‘Prefabricated temporary housing residential area’ plans were done, as tent cities, by the proposals of the Governorates, persons of the Provincial Directorates of the Ministries and municipalities.

The General Directorate of Bank of Provinces constructed all infrastructure works of the selected areas.

Ships as an emergency shelter: A few days after the August 17 Earthquake, ships of TDİ AŞ, ships of Greater Municipality of Istanbul and some private company’s ships were used as emergency shelter from August 26, till end of April 2000 for 1800 disaster victims.

Although, most of the ships were used for accommodation, some of them were serving health services for the injured peoples too.

Holiday villages and social facility units of public institutions: In addition to other temporary residential modes, some of the disaster victims were settled in Holiday villages and social facility units of many public institutions and Ministries. For those

mass disaster victims, 42.338 bed capacities were prepared. But only 5.257 person after 17 August Earthquake and 3.333 person after 12 November, totally 8.590 disaster victims were applied from all Marmara Region.

Government supported transportation, accommodation and feeding expenses. Also children of the disaster victims had had educational facilities.

Accommodation aid: According to The Disaster Law 7269, disaster victims whose houses were demolished, heavily damaged or moderately damaged, gains right to take accommodation aid although they are owner of the house or tenant.

In overall Disaster region, 119.418 families had taken 100 millions TL (about $150) as accommodation aid. (Başbakanlık, 2000 ; MoPWS, 2000)

2.3. Assessment of Holder of a Right (Beneficiaries)

Holders of a right assessment works have been made according to the 'Regulation About Assessment of Holder of a Right' of Law 7269. In assessment period, two things are very important. One is damage assessment result and the other is property ownership relation.

Assessment of holder of right processes began with a preliminary study about province, damage assessments results, guiding and participating the victims of disaster. Then demand and contracting application period started. This period took about three months. Assessment of Holder of a Right Commission was formed and this commission evaluated the applications in one month. Results of the applications were declared for one week and one week was given for objections. After the objections were evaluated in one month they were declared again. Conditions of some damage assessment and assessment of holder of a right, which are matter for the courts have not terminated.

Owner of a demolished or heavily damaged house or workplace gains the right of a new house or workplace, if he provides ownership conditions. Owner of a moderately or slightly damaged house or workplace gains the right of strengthening or repairing his house or workplace, also if he provides ownership conditions.

To clarify the number of houses by which method were going to be constructed, a 'demand definition survey' was made by State Institute of Statistics and Ministry of

Public Works and Settlement. According to this survey as shown in (Table 3) 5.248 of 13.895 victims of disaster who had heavily damaged or demolished houses became holder of a right and demanded a new house. 2517 victims of disaster who had heavily damaged or demolished houses as holder of a right, demanded to build his new house by himself. And 419 victims of disaster, who have heavily damaged or demolished workplaces as holder of a right, demanded a new workplace in the Province of Yalova.

Table.3: Holder of the right

2.3.1. Housing Tenure and Restoration Policy

There is a clear contrast between policies depending on housing tenure. There is a deep support for property owners while there is no policy at all for tenants

No policy for permanent housing is planned for those who lived in rented housing prior to the disaster. There is, in principle, no policy in Turkey to provide social rented housing. Some housing has been supplied as public official's accommodation and as a disaster measure in exceptional cases. Supply of social housing is not included in the general housing policy, so it is practically impossible to supply such housing on a mass scale after a disaster

A system to subsidize rent for the victims has been prepared. This is a temporary measure however and applied only to those who do not intend to live in temporary housing. There is no system to provide rent subsidy as a permanent housing measure.

In contrast, several measures are planned such as housing supply trough construction of new housing sites and provision of long-term loans with low-interest for those who own some real estate such as owner occupied housing. The development of new housing sites is limited to the disaster victims who has owner of the rights. Interest rate of the loan is planned at either zero or somewhere near zero, with a grace period of 2 years, and a term of repayment of 20 years. We have to be aware of the fact that

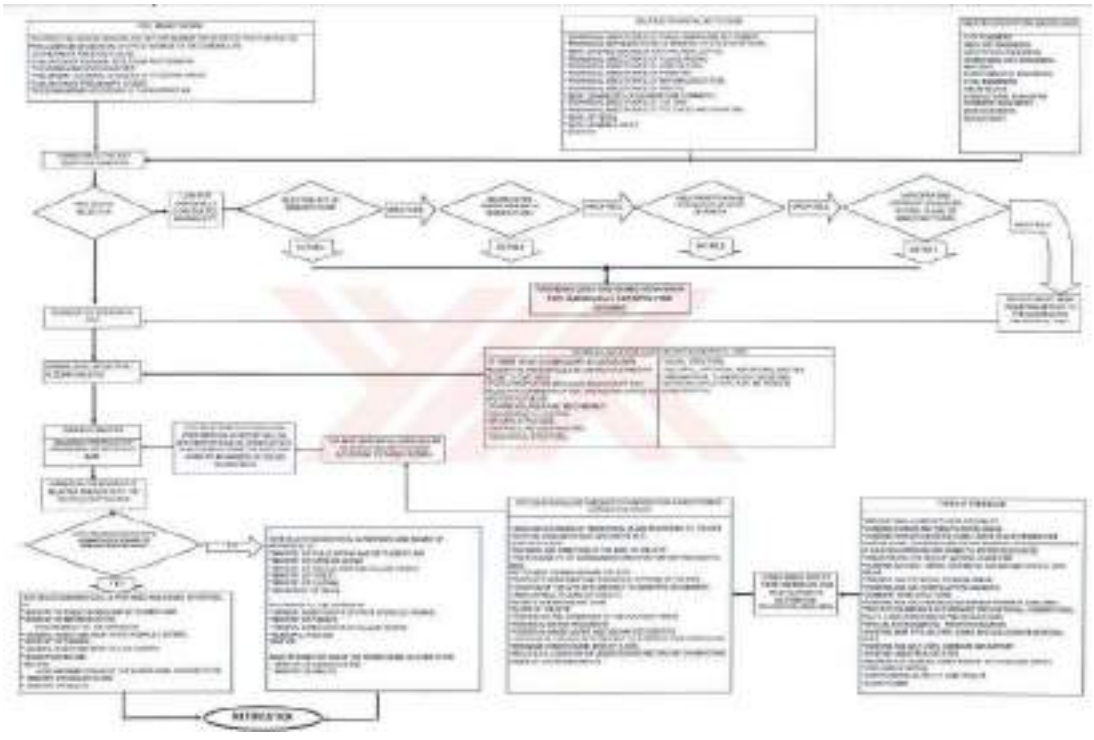
inflation has been high in Turkey since the end of the 1970s, meaning that eligible victims can acquire housing at a very low cost because their debt will decrease rapidly.

In many cases in Turkey, tenants are living in housing, which belongs to their relatives or acquaintances. There is a possibility that the circumstances of tenants will deteriorate due to a shortage of absolute number of rental housing units, a steep rise in the rental housing market and the collapse of the quake-affected tenant's income.

2.4. Site Selection Processes for Permanent Housing

For post disaster recovery works of Marmara Earthquake in 1999, by the help of General Directorate of Disaster Affairs, General Directorate of Technical Research and Implementation, General Directorate of Bank of Provinces, Municipalities and The governor(s) of the province(s) where empowered to organize preliminary works for site selection (Figure 3), according to the 16th article of Disaster Law (7269-1051: On Measures and Assistance to be Put into Effect Regarding Natural Disasters Affecting the Life of the General Public: May 25. 1959).

Figure 3: Site Selection Process of Disaster Victim Relocation Areas .



2.5. Provision of Figures and Physical Planning Processes

After the completion of site selection period, The General Directorate of Disaster Affairs had completed the geological and geo-technical studies on the urban development areas assigned by the General Directorate of Technical Research and Implementation. At the end of this study, permanent housing areas have been classified as “the areas with no need for a geo-technical study”, “the areas that need geo-technical studies”, and “the areas which should be used as green areas as the soil sedimentation is very hard”. Consequently, geologically and/or geo-technically unsuitable areas for habitation were developed.

2.5.1. Providing and Updating Base Figures for Relocation:

It is known that, like superstructure, Marmara Earthquake had affected many types of infrastructures. A linear strip about 160 km, which passes along many residential areas, was deformed between 0.6 m. and 2.6 meters. Province of

Because of this deformation, The General Directorate of Bank of Provinces updated all of the base maps of earthquake region by using GPS technology.

At first, the base maps of tent cities were prepared or updated. Then, base maps of prefabricated temporary residential areas provided. During the construction of prefabricated houses, base maps of suitable alternative areas of permanent residential areas were done. Between these alternatives, base maps of selected permanent residential areas were revised and presented for preparing development plans.

2.5.2. Upper Scale and Lower Scale Planning Studies:

Determination of permanent housing areas has started just after the completion of the studies related to allocation of land for prefabricated temporary housing. The main aim of the post earthquake planning activities undertaken related to permanent housing was to meet the housing need that has appeared after the earthquake, in the light of regional and rural development inputs of those

settlement areas which were considered suitable with respect to their soil and surface conditions, and data on damage level and eligibility for permanent housing. Within this scope, a dual approach including both new “Urban Development Areas” and “Settlement Areas of Disaster Victims” which were eligible for housing aid was adopted.

1/25 000 scale territorial planning studies, that determine the permanent housing areas on macro scale, have been prepared. Master and Implementation Plans, scaled respectively at 1/5 000 and 1/1 000 for the areas designated as the “Ministry of public Works and Settlement Implementation Areas” where dwellings for the beneficiaries according to the provision of the Law on Disasters will be located, are being prepared by either the General Directorate of Bank of Provinces and the General Directorate of Technical Research and Implementation, aiming at creating new, modern and self-sufficient residential units with adequate housing areas, pedestrian-traffic systems, urban green and recreation areas (parks, gardens for children, squares, etc.), technical and social infrastructure. (MoPWS, 2000, pp.29)

Out of the “Ministry of public Works and Settlement Implementation Areas”, where the Ministry had done implementation, the General Directorate of Technical Research and Implementation had controlled and ratified the plans prepared by the World Bank PIU.

1/25 000 scale territorial plans for the resettlement of disaster victims have been based on geologic and geo-technical ground studies by paying attention to spatial and social needs of the target settlements.

2.5.3. Expropriation:

After the process of site selection for permanent housing areas have finished, the expropriation studies started. General Directorate of Disaster Affairs and Prime Ministry PIU required for permanent housing and General Directorate of Highways required for the expropriation of service roads.

3.Conclusion

Although, no one knows where or when the next earthquake will occur, nobody has an idea of its scale or the number of people who may suffer from its consequences, nor whether it will happen in the city or in a rural area, we know that earthquakes are inevitable and they will come.

Governments and relief agencies, planners, engineers and geologists are striving to minimize their possible effects in seismic areas by surveying and implementing scientific methods to every step of the disaster hazard reduction and prevention process (Mitigation, Preparedness, Emergency Relief, Rehabilitation, and Reconstruction).

Reducing the risk of disasters involves activities such as improving the conditions of elements at risk, which either reduce or modify the scale and intensity of the threat faced.

To understand the nature and size of the risk for any society, we have to know both of the 'Hazard' and 'Vulnerability' (Disaster Risk = Hazard + Vulnerability).

Although risk reduction works (mitigation and preparedness) are often done before disasters, recovery process (relief, rehabilitation and reconstruction) after the earthquake disaster becomes a risk reduction work for the next earthquake. So the relocation gains quite importance in reducing the damages of the future disasters together with the aim of decreasing the current disaster damages.

The consequences of relocation itself may even be more harmful than the impact of the disaster. While a disaster may kill and injure many, disturb community organizations and economies and destroy infrastructure and dwellings, it rarely remove everything and structures of organization emerge from the rubble, often quite rapidly as the society undertakes the task of reconstruction.

On the basis of the preceding analysis of relocation experiences a number of conclusions can be drawn and lessons learned. The main conclusion is that too often relocations appear to have caused unnecessary suffering for the people involved. It is clear that any attempt to remove people from their existing physical, social and economic environment will have far- reaching implications for their lives. However, on

the basis of the more positive relocation experiences, it appears that negative implications can be limited if a number of conditions are fulfilled.

For this reason, site of reconstruction is one of the most important steps of the relocation process. Site selection can be done in two ways: selecting existing place of the damaged buildings or selecting a new residential area for reconstruction. If the situation is not surveyed well, both methods may have many advantages and disadvantages.

Involuntary resettlement often involves removal from an environment in which the society has evolved centuries old patterns of adaptation. This relationship to the environment may be based on economic, political or socio-cultural factors or a combination of any or all three. Economic dimensions such as soil fertility, resource availability, overall productivity or access to employment or labor resources; political factors such as territoriality, leadership structures and inter-group relations; and cultural factors such as the intimate (privacy) connections between environment and religion, cosmology, world view, and individual and cultural identity may all play significant roles in the relationships of a society to its land base and general environment.

It is for these reasons that many current researchers consider relocation must be avoided in development projects or minimized after the disasters. Otherwise, from the perspective of displaced people un-participated or forced relocation becomes a new disaster.

Unfortunately, the opportunity for participation in the decision-making by the relocates was in most cases rather limited, and this partially explains the lack of success.

Housing policy and urban planning in Turkey has been strongly characterized by centralization of power. Regarding the programs related to earthquake restoration, however, almost all power is temporarily transferred to the central government. This presents the problem of how they build up the relationships between the central government and municipalities, and between regional offices of the central government and municipalities.

Without agreeing with the national and regional development plans, by leaving aside planning discipline and thought, people have been encouraged to flow in the region which is known as settled on the earthquake region and the most important industry

region of the country, for to constitute cheap labor deposits in this region; coastal filling areas, fresh water reservoirs, productive agricultural areas, forests and plain lands have been opened for settlement and industry. In other words, plans have been prepared of the disaster existing, by being unplanned. Consequently, the planning precautions used to reduce the effects of natural disasters have been neglected, particularly during physical planning activities.

Nearly all of the central-government policies have encouraged private property house production and poor people who essentially have the need of residence have been put out of terms. Production of low-income housing, public housing and rental housing could not find any implementation area.

There is a clear contrast between policies depending on housing tenure. There is strong support for property owners while there is no policy at all for tenants. No policy for permanent housing is planned for those who lived in rented housing prior to the disaster, at least for now. There is, in principle, no policy in Turkey to provide social rented housing. Some housing has been supplied as public official's accommodation and as a disaster measure in exceptional cases.

However, it seems impossible for many prefabricated residential areas to turn back to the former use because of their infrastructures and bad effects to the environment. For additional permanent housing areas, the prefabricated residential areas were re-evaluated but most of them were not suitable because of their geological structures and ownership patterns.

If the site of earthquake-damaged buildings doesn't have any other disaster risks like flood, landslide, rock-fall, avalanche etc. relocation to a new site may also create many problems in the future.

Design of the houses also plays a very important role on occupancy. Housing design and construction are often blamed for the reaction towards or failure of post-disaster resettlement projects. Faulty construction and inferior materials in houses become quickly evident with use and create difficult living conditions, particularly regarding thermal protection in different seasons. Houses are cited as being too small for large rural extended families.

Traditional houses have evolved over time as functional to the needs of the household unit. The design of resettlement houses is often inappropriate for domestic activities, which require different kinds of spaces for different uses according to seasons. The design deficiencies of the state provided houses in rural areas of previous cases were modified by the occupants, in the form of alterations and extensions to them.

Construction materials of traditional houses are also very important for the seismic risk. Mud mortar, rubble stone masonry wall, flat earth roofed dwelling units are the most common houses in the rest of Eastern Anatolia.

This poor workmanship with poor mortar material resulted in total collapse of almost all the dwellings in Lice and the poor masonry workmanship caused the damage of cement-lime mortar masonry buildings as well. Construction of heavy roofs with inadequate connections to the walls and the generally poor quality wall construction caused total collapse of many houses and accounted for large losses of lives.

In many regions of Anatolia, it is unfortunately impossible to prevent large loss of life since there are houses with mud mortared rubble masonry walls and heavy flat earth roofs. For this reason, the aim should be the improvement of local housing construction practice.

Locations and specifications of these selected sites show that these areas are not selected after detailed surveys based on urbanization, environmental, infrastructure, property ownership and sociological principles. The institutional priorities had been omitted. In fact, even though these areas were selected only according to the geological criteria, there are still many speculations about their geological structures.

Consequently, by this study it is exposed that, post disaster relocation processes are important for reducing future hazard risk in an earthquake prone area. Within these processes, site selection studies relying on geological criteria are one of the most important steps. However, it is not going to be effective unless other criteria such as socio-cultural, traditional, economic, psychological, legal and institutional are not taken into consideration systematically.

Towards an adaptive approach to spatial development: insights from the 'leisuring' of landscapes

Stefan Hartman, MSc[1,2]

Keywords: adaptive planning, complexity theory, leisure landscapes, non-linearity

Abstract. The capacity to adapt has become a crucial property to sustain spatial and socio-economic development of a region, due to the impact of relative autonomously changing contextual circumstances (e.g. climate, economy, politics, demography, life styles) that impact and alter the way urban and rural territories are used, and which are to a certain extent beyond the control of planners. In this paper it is argued that, to avoid and mitigate negative influences that may perturb desirable situations, a degree of robustness is needed. Simultaneously, co-evolving and benefitting from new emergent situations requires a degree of flexibility. The 'adaptive capacity' to anticipate to autonomously changing circumstances relates to the ability to timely adjust the balance between robustness and flexibility. The paper is illustrated by the shift rural territories tend to undergo, especially in the vicinity of urban areas, increasingly becoming *leisure oriented landscapes.* Leisure-oriented landscapes are understood as multifunctional places: next to the more traditional land uses such as nature, agriculture and forestry land uses emerge that revolve around the qualities of space such as tourism, recreation, suburban and exurban living, and leisure. This paper aims to clarify how this shift comes about and discusses the impacts on spatial development, planning and decision-making. It is argued that for its development planners are confronted with a paradox: retaining essential spatial qualities that provide localities with potential for leisure-related developments requires robustness whereas flexibility is relevant to give room to the adaptive behaviour of actors trying to acquire a better 'fit' given local characteristics and dynamic contextual developments.

1. Introduction

The capacity to adapt has become a crucial property to sustain spatial and socio-economic development of a region, due to the impact of relative autonomously changing contextual circumstances (e.g. climate, economy, politics, demography, life styles) that impact and alter the way urban and rural territories are used. Space and place can, hence, considered to be constantly *out-of-equilibrium,* caught up in persistent process of *becoming* (De Roo et al., 2012). Planners become aware that development trajectories

[1] PhD researcher at the Department of Planning and Environment, University of Groningen, PO Box 800, 9700 AV Groningen, The Netherlands; e-mail: s.hartman@rug.nl
[2] Researcher at European Tourism Futures Institute, Stenden University, PO Box 1298, 8900 CG, Leeuwarden, The Netherlands

are not necessarily linear and predictable, but tend to unfold non-linearly as well. With non-linearity we mean that the object of planning (e.g. a neighborhood, city, region) is not only dynamic, it is moreover able to change in fundamental ways as will also be illustrated in this paper. Non-linearity implies there are to a greater or lesser extent uncertainties involved in how development trajectories unfold towards the future.

Such a perspective emphasizes the need for approaches that embrace uncertainty and offer anticipative strategies next to strategies aimed at reducing uncertainty. It emphasizes that planning needs to co-evolve along with the processes that drive spatial change, instead of trying to control and confine dynamics, and promote the capacities to manage emergent non-linearity. Hence, in a dynamic reality, regions will need to develop adaptive capacity that allows to reinvent themselves through the adapting of constituent elements, organization, institutions and their relations in response to dynamics. The lack of such capacity may result in negative (socio-economic, environmental) externalities and regional lock-in (cf. Grabher, 1993; Martin, 2010). As such, managing non-linearity requires approaches to spatial planning that stimulate the adaptive capacity of regions so to agilely deal with dynamics: a capacity that enables actors to simultaneously avoid and mitigate (potential) negative impacts on desirable trajectories as well as explore and benefit from the potentials of nascent or emergent novel development trajectories (e.g. to avoid lock-in situations).

This paper builds on an emerging body of literature that explores complexity theories, and aims to further refine these insights. It contributes by providing insight in to the mechanisms behind non-linearity and contributes to the existing body of literature on strategic spatial planning by discussing *adaptive* planning strategies. The paper is illustrated by the shift rural territories tend to undergo, especially in the vicinity of urban areas, increasingly becoming *leisure-oriented landscapes* (Slee, 2005; Woods, 2005). In these territories usages such as tourism, recreation, leisure and suburban and exurban living emerge next to the more traditional agriculture, forestry and nature. This shift, and ongoing dynamics, pose novel challenges for planners to deal with. Our aim is to better understand the impact and consequences of such non-linear development for spatial planning practices. Relating mechanism behind non-linearity, processes that drive spatial change, and spatial planning allows us to comment on stimulating the adaptive capacity of localities through spatial planning.

The first part of this paper provides a background on how leisure-oriented landscapes come about. We provide theoretical and conceptual support to better understand the coming about of non-linearity and the need for adaptive capabilities in the context of spatial planning (section two). This theoretical framework is used to clarify the emergence of leisure-oriented landscapes (section three). In the second part of the paper, conditions for (further) development are explored. Here, we draw on the theoretical insights presented and operationalize these insights in the context of leisure-oriented landscapes. Finally, we have the ingredients to discuss the co-evolution of planning

strategies, so to guide the process of emergent multifunctional, more leisure-oriented landscapes in their evolution.

2. Towards a dynamic-adaptive perspective on spatial development

The body of literature on adaptation and non-linearity increases in several fields that relate to spatial and economic development. Authors try to find sets of concepts and theories that allow them to describe the inherent dynamic nature of the phenomena they study. Fields that are addressed are, amongst others socio-ecological systems (Gunderson & Holling, 2002; Folke, 2005; Gerrits, 2008), socio-technical systems (Geels 2010, Geels & Schot, 2007), climate change (Pahl-Wostl, 2007; Gupta et al, 2010), socio-economic systems and evolutionary economics that focuses on the innovation of firms and industries (Simmie & Martin, 2010; Martin 2010; Boschma & Frenken, 2007) and complex adaptive systems (Wolfram, 2002; Holland, 2006). Generally the concept of adaptation is explained as a capacity to respond to multi-level change, and to improve systems to improved states or a better fit with their environments/contexts (e.g. Folke et al., 2005).

The interest in exploring the concept of adaptation relates to the desire to anticipate processes that drive change, but which take place on a contextual or macro level and are to a certain extent beyond the influence of actors that are influenced by them. The processes occurring at these abstract levels are considered having an autonomous character. Examples from the above mentioned fields are climate change (Gupta et al, 2010), exogenous socio-technical landscapes (Geels, 2010), external shocks (Martin, 2010) disturbance events, crisis and surprise stemming from external forces (Folke, 2005; Gunderson & Holling, 2002) and the external environment (Waldrop, 1992). To cope with such processes the constituents of a system (e.g. constituent parts, individual actors, organizations and governments) tend to respond by altering behavior, undertaking interventions and changing frameworks that govern their behavior. Hence, system change can be understood as a confluence of top-down, and bottom-up processes, partly autonomous in nature and partly consisting of planned actions, which simultaneously interact and influence one another.

To structure the interactions processes that make up for dynamics, multi-level perspectives are introduced. In this respect, Geels & Schot (2007) observe niches, regimes and ‘landscapes’ in socio-technical systems. In the context of socio-economic systems micro, meso and macro levels are distinguished (Dopfer, 2004). Holling (2004) introduces multiple levels of scale related to the panachy model (see also Gunderson & Holling, 2002). Interactions between levels of scale are considered persistent since macro and meso dynamics open up opportunities for micro-level (niche) developments. Simultaneously, micro level novelties (niches) can work their way up to the meso (regime) level and, potentially, to the macro (landscape) level. Change, therefore occurs as a result of being mutually receptive to multi-layered interactions (Geels, 2005; see

also Jessop, 2005) making it difficult to comprehend an entire system and to exactly calculate or predict the outcomes of system dynamics.

To relate adaptation to the coming about of non-linear development trajectories of territories, we will elaborate on theories about complex adaptive systems. The growing awareness that spatial developments is affected by multiple interconnected and interrelated processes that take place at different levels of scale, has led to the interest in exploring the scope of complexity theories in the realm of planning and spatial development (Urry, 2003; Allen, 2003, Batty, 2005; Byrne, 2005; Manson & O'Sullivan, 2006; De Roo & Silva; 2010; De Roo et al. 2012). Our main interest lies with the mechanisms that provide for the adaptive behavior of complex adaptive systems. Complex adaptive systems are open systems which neither show predicable linear behaviour, nor fully chaotic and unpredictable behaviour. Instead, their development can be understood as endless sequence of adaptation, re-organization whereby it moves, over time, towards different and new equilibria (which will never be fully reached). They are always to be out-of-equilibrium to a greater of lesser extent. Because equilibria tend to differ fundamentally from one another in terms of constituent parts and their relations, it is hence argued that complex adaptive systems evolve in a non-linear manner (Waldrop 1992; Phelan 1995).

The dynamic nature of complex adaptive systems is attributed to adaptive capacity of the constituent parts to self-organize. They are capable to endlessly reconfigure and realign themselves and their relations in response to contextual change, and in response to one another (Cilliers, 2000), due to feedback (evaluating, learning, scanning and interpreting information that comes from its environment) and feed-forward (predicting, planning) processes (Portugali, 1999; 2008). In other words, the constituents 'co-evolve' in response to one another (Garnsey & McGlade, 2006),

Local, self-organized changes, responding to (contextual, environmental) dynamics, build on historic events – they are path dependent – they do not necessarily imply a (linear) continuation of historical paths (Belussi, 1998; Van Notten, 2005). Patterns created in the past can be (gradually) changed and renewed as constituents 'adapt' to acquire a better 'fit' in response to one another and the possibilities and constraints stemming from the contextual environment (Holland, 1995; Cilliers, 1998, Folke et al, 2005). The 'adaptive properties' that allow them to perform such behaviour is an essential property to deal with the perturbations caused by (autonomous) dynamics. By reconfiguring and performing non-linear development, complex adaptive systems retain their capacity to adapt, crucial for 'survival' in future situations. Hence, it implies a certain degree of restlessness resulting from a persistent process of *becoming* (De Roo, 2012). These 'adaptive properties' are an appealing mechanism in the context of a persistently dynamic nature of spatial change as well as in terms of sustainability.

Studying adaptation in the context of spatial development

Inspired by the theoretical discussion provided above, we put forward a multi-layered analytical framework presented in figure 1 (cf. Hartman et al., 2011) to catch the planning issue as a composition of the material, organizational and institutional dimensions, which are interrelated and interact on various levels of scale, the macro, meso and micro. The framework differentiates three levels of scale to understand the persistently dynamic nature of spatial change, as a confluence of an autonomously changing context (macro-trends and events) and (self-organizing) responses and innovations at the micro level. The intermediate meso-level is referred to as the geographical scale at which functionally cohesive patterns emerge spatially, as a result of micro-macro interactions. From a planning perspective this is the level at which micro-level (self-organized) innovations can be related to developments elsewhere so to put them in a relational perspective, and to make it apparent whether planners' attention is required to stimulate or dampen its emergence or to enhance the interactions between the micro (local) and macro (global). As such, our analytical framework does not pursue a fixed geographical scale. Depending on the planning issue addressed the scale could vary in size (e.g. neighbourhood, city, urban region, network). The boundaries of the issue under study ('the spatial system') are likely to be pragmatic and normative (cf. Martin & Sunley, 2007). The framework as it is presented addresses a 'slice in time'. Considering this multi-layered analytical framework at various moments in time helps to clarify the evolving relation between emergent non-linear development trajectories and planning.

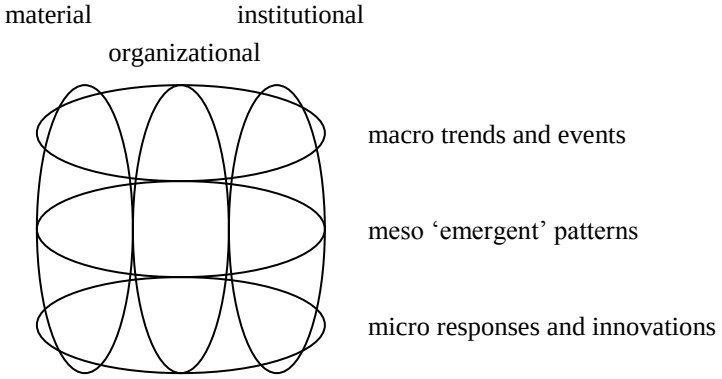

Figure 1: multi-level analytical framework (adapted from Hartman et al., 2011)

In the following sections the framework is used as a guide to clarify the emergence of leisure-oriented landscapes – as emergent patterns which become apparent at the meso level due to multilevel interactions. We clarify how the spatial transformations come about by relating local spatial dynamics and innovations to macro trends and events. The framework emphasizes that such material transformations (in a physical, morphologic sense) have an organizational and institutional dimension as well. The organizational

dimension refers to the actors involved and their coalitions who observe potentialities and are willing to undertake spatial transformations. The institutional dimension refers to formal and informal rules, cultures, customs, values and norms including political-administrative institutions and their interventions in terms of laws, guidelines, zoning plans, financial support and formal decision-making procedures (Healey, 2007). Adaptation can be seen as the (spontaneous) response, change and development of a system at the meso, being the result of interactions from and between the global and local and to which the system transforms, allowing a better fit (enhancing its connectivity and the potentiality of its connections) with its context and in between the global and local (compare Cilliers, 1998; p90; Folke et al. 2005).

3. The emergence of leisure-oriented landscapes

Urban areas and their surrounding countrysides become increasingly intertwined, forming urban regions. These countrysides go through a transition, becoming leisure-oriented landscapes to a greater or lesser extent. This transition manifests itself by actors introducing new functions and land uses related to tourism, recreation, leisure, sub-urban and exurban living and working that thrive by the *qualities of space*. We use the notion 'leisuring' to refer to the transformative processes of places associated with developments designed to serve residential, recreational and touristic demands (cf. Bunce, 2008). Guided by the framework presented in fig. 1, we aim to clarify that this shift unfolds rather autonomously as a confluence of processes coming from the 'outside' contextual environment and responses by local authorities and (policy) entrepreneurs.

The autonomous nature of this shift relates to persistent dynamics that stem from interactions between the macro (global) and micro (local). Places are constantly in motion due to the high interconnectivity of places and people, known as the network society (Castells, 1996), and the dynamisms that go with the fluidity of contemporary processes (see Bauman, 2000; De Roo & Silva, 2010). The increasing global interconnectivity and the relatively low cost of instant communication and high speed transportation, flows of people, goods, and thoughts are less influenced by distance as a limiting factor. The enhanced cross border interaction as the result of political-administrative action reinforces this trends, through organizations and institutions operating at the macro-level such as EU, NAFTA, WTO, UN, GATT (see McCann, 2008). Physically and virtually, networks stretch across the world. As a result 'cultures, economies, social worlds, politics and environments all become driven by logics of increasingly intense interconnections and flows, over larger and larger geographical scales' as it is well put by Graham & Healey (1999; p11). Consequently, at local, regional and even national levels actors are forced to move along with the processes they cannot influence directly (Urry, 2003). To continue to participate in the globally interconnected economy means actors (have to) conform and adapt to the international 'rules of the game'.

In this context, McCann (2008) observes that processes related to globalization makes spatial and economic development 'curved'. Employment tends to concentrate in urban areas where industries, services, logistics, and the development of knowledge and technologies cluster. However, simultaneously, throughout Europe (former) rural and peri-urban territories experience an influx of urbanites and visitors (recreating, visiting, living) as well as policies and regulations aimed at protecting landscapes, heritage, nature and other amenity values considered important by the (predominantly urban) society. This relates to the global shift to the service economy that is accompanied by people gaining more free time and disposable income (Antrop, 2005), by enhanced communication and mobility, and by society showing an increasing interest in nature, landscapes, (cultural and build) heritage and quality of life (Williams & Shaw, 2009). In response (policy) entrepreneurs adapt by adopting initiatives relating to tourism, recreation, suburban and exurban living, health care, wellness, and cottage industries.

The development trajectories of coutrysides are, consequently, fundamentally changed, when compared to their pasts, traditionally revolving around agriculture and nature. Moreover, farmers tend to (co-)adapt as well finding niches such as biological farming, energy production, the maintenance and development of nature, education, health care as well as activities related to leisure (wellness, recreation, tourism). These activities can offer relative advantages (Rogers, 2003) and can overtake the primary agricultural activity in time. However, whilst the relative economic importance of the agricultural sector is declining, it is nevertheless spatially and socio-culturally still quite dominant and important for retaining the characteristics and amenity value of localities (Slee, 2005). The changing circumstances have create societal and political *windows of opportunity,* (see Kingdon, 2002) strengthening the receptiveness to explore new paths of development.

For the emergence of leisure-oriented landscapes, important driving forces of change are confluences of factors such as demography, economy, technology, ecology and political-institutional and social-cultural aspects (cf. Gillespie, 2007, Johnson, Scholes & Whittington, 2005). Well-known composite macro-trends are (e.g.) globalization, urbanization, sustainability and climate change. Landscapes are reshaped morphologically and spatial-economically as market parties, governments, NGOs and individuals respond to multilevel changes, altering their behavior and actions, generating new developments to suit newly emerging societal needs. It is out of the interconnectedness and interactions between the global and the local, and the potentialities these contain, where new opportunities and issues continuously arise in a relatively autonomous manner. It can as such be argued indeed that landscapes evolve over time, a result of planned actions and unplanned events (Antrop, 2006).

As a consequence of interacting (f)actors on multiple levels of scales, together creating a highly complex process, planners have become aware that the way development trajectories unfold towards the future is at least partly uncertain (Albrechts, 2006; De

Roo & Silva, 2010). Dynamics can be(come) too complex to comprehensively understand and plan for (Healey, 2007). This should make planners modest with respect to their ability to control development trajectories of places (cf. Urry, 2003). Moreover, accepting that development trajectories evolve non-linearly, as systems adapt to changing circumstances, requires the material, organizational and institutional dimensions to co-adapt or co-evolve. It emphasizes the importance of adaptive capabilities to guide places in their evolution, and so to be able to profit from autonomously emerging opportunities and to avoid negative impacts.

Whereas some regions are capable to adapt to changing circumstances, others are not. Martin & Sunley (2006; p395) see that regions become locked into paths of development and over time lose dynamism, whereas others are able to avoid this danger by 'reinventing' themselves through the successive creation of new development paths (see also Garud & Karnøe, 2001; Martin & Sunley, 2010). In tourism literature, this is also referred to as the life cycle approach (see Butler, 1980). In the absence of reinvention, the danger of getting in to a lock-in situation increases (Grabher 1993; Arthur; 1995, Martin, 2010). In lock-in situations the potential of new, alternative developments may not be recognized as they may be only 'weak signals' (Ansoff, 1975), and consequently suppressed in favor of vested activities, that are established and have proven themselves in the past (Geels, 2005). As a result regions may become highly specialized and potentially become less resilient (Simmie & Martin, 2010) and 'victims of their earlier success' (Boschma & Lambooy, 1999; p416) especially when a spatial-functional lock-in is reinforced by a cognitive and/or political lock-in (Grabher, 1993; Hassink, 2010). The ability to deviate from a vested development trajectory is then constrained by rigidly retaining traditional spatial patterns, policies, strategies and institutional settings that once supported economic growth in an area but do no longer. In the following section we characterize leisure landscapes to distinguish conditions for development and discuss consequences for material, organisational and institutional dimensions.

4. Characterizing leisure-oriented landscapes

The becoming of leisure-oriented landscapes, implies that the meaning and values attributed to landscapes change fundamentally (Buijs et al, 2006). Landscapes are no longer confined to the production of food and fiber, or to nature. Landscapes are also interpreted as commodities, utilizable for tourism, recreation, living purposes. They serve as means that offer potential for development or as a décor for producing experiences (cf. Pine & Gilmore, 1999). For leisure-related occupancies, explicitly subjective aspects matter such as aesthetics, authenticity, identity, sense of place and belonging (amongst others Tuan, 1977, 1990; Relph, 1976).

The importance of amenity and experiential values is also related to changes in the field of tourism, recreation and leisure. Enormous growth has been realized in these sectors, and it is expected to do so in the future (see UNWTO, 2011). The innovations in communication and transportation technology improved the action radius of people, and

reinforced the accessibility of places and the competition between them. The result is an increase of dynamics and diversity, and initiatives diffuse over urban as well as rural areas. Entrepreneurs tend to specialize and develop niches to deal with the competitive nature of the industry (Brinkhuijsen et al., 2007). On the one hand, tourism and recreation become more intense and active. On the other hand, experiences are sought that are more extensive, revolving around relaxation, tranquility, culture, identity, spirituality, etc. Overall, the products, services and places are not only chosen for their functional value only but increasingly so for their experiential value (Pine & Gillmore, 1999).

Similarities can be found in the housing sector. For living, people tend to diffuse over wide geographical surfaces settling in the urban, peri-urban and rural areas in search for the experiential values that fit their life styles. The urban cores provide high density, highly dynamics places. The city's edges offer the benefits of both the urban and its countrysides, where developments are known as suburbanization. In addition, exurbanization is coined to describe the phenomena of 'very-low-density, amenity-seeking, post-productivist residential settlements in rural areas', wherein the inhabitants 'have deliberately chosen the rural landscape as a setting for their homes' (Taylor, 2011; p324). Agian, landscape amenity and experiential value are important factors. Bruegmann (2005) adds that these low-density areas lay beyond the suburbs but are still an integral part of the urban system. Similarly, rural areas face an influx of highly specialized, small businesses (e.g. consultants, architects, designers, artists, webmasters) that operate in supra-regional or international networks (so-called cottage industries by Tordoir, 2010).

In the context of place and landscapes, the physical dimension requires planners to take into account not only the functional, tangible aspects of a place, but also intangible, hedonistic aspects (Buijs et al, 2006) that provide for a sense of place and belonging (Steele, 1981). Relevant are the presence and accessibility of natural (nature, ecology, landscape) and built environment (infrastructure, heritage) as well as their aesthetics, identities, authenticity and uniqueness. Moreover, initiatives depend on the availability of experiences, creating a need for things to do and interesting stories about places, people, culture, histories made available in interesting ways (e.g. events, technologies). For experiencing, giving and deriving meaning, being crucial aspects of leisure, less tangible aspects may be more important than physical ones (Caalders, 2002; Metz, 2002). These observation opts for more integrative, holistic approaches that revolve around landscape amenity and spatial quality, compared to approaches that deal with sectors (e.g. nature, infrastructure, housing, water) individually.

How the development of leisure-oriented landscapes become spatially manifest, and the extent to which, is shaped by the way people perceive *cognizable* sets of biotic and abiotic elements in *expressive* terms (Keulartz et al., 2004): what do we like, what do we find ugly, exciting, adventurous, safe, or what makes us find belonging in a place? These

perceptions attached to or derived from elements provide people with the incentives for visiting, living or establishing tourism businesses, or refrain them from such actions. As such, perceptions are important for providing a place with potential for leisure-related developments. Perceptions are also relevant since they shape how places and their future development trajectories are judged normatively (Keulartz et al., 2004): what elements should be preserved or protected and what elements may be adjusted, transformed and added? To address such questions the notion *spatial quality* is introduced (Rapoport, 1970; Moulaert et al. 2011). Spatial quality can be attributed to (sets of) factors, (amongst others) as a means to describe the elements that are perceived as conditions for making a place worth visiting, living in, starting businesses in – i.e. the aspects that provide localities with potential for leisure-related developments.

5. A planners' adaptation to stimulate the 'leisuring' of landscapes

Although leisure-oriented initiatives can offer formidable potential for spatial and socio-economic development, it can also be(come) a force that shapes the physical and socio-economic landscape negatively. The impact of spatial interventions can differ greatly, ranging from low-impact being in symbiosis with its (natural) environment to high impact developments that transform landscapes and benefit from a location but do not contribute to enhancing landscapes. A spectrum is put forward in figure 2 to capture this range of relations between leisure and landscape more conceptually (see Hartman et al., 2011; Cadieux & Hurley, 2011).

At one end interventions can be positioned that revolve around development and taking opportunities for (socio)economic development. This refers to developments that emerge in or near attractive places, where functionality is dominant and the focus is mainly on economic returns over the enhancement of landscape qualities. Brinkhuijsen et al. (2007) observe that these can take parasitic forms, when relations with their surroundings are purely functional, and matter mostly in terms of location. To indemnify places from (potential) negative perturbations, a traditional planning approach is to spatially separate different types of land use through zoning (Hartman & De Roo, 2009; Hartman et al., 2011). At this extreme, we can position places that are devoted predominantly to development to support leisure complexes (e.g. hotels, B&B's, theme parks, bungalow parks) as well as suburban neighborhoods, business parks and agricultural or silvicultural production.

At the other end interventions can be put that respect preserving place-based qualities and mitigating risks of disrupting these qualities. Leisure-oriented initiatives can be considered incompatible with nature and heritage when it causes deterioration. In addition, as is also described earlier, impacts may be considered negative when hampering the development abilities of agriculture (e.g. limiting up scaling, rationalizing landscapes) and forestry (e.g. co-use, amenity values) and alter rural communities (gentrification, exclusion) and lifestyles (Theobald, 2005). Through planning perturbing developments may be completely avoided or limited to low impact initiatives to protect

particular landscapes or activities. At this extreme, localities may be positioned that revolve mainly around nature, landscape or heritage, as a result of protective measures (Holmes, 2006; 2008).

The extremes mainly serve a conceptual purpose, because in reality landscapes hardly consist out of functionally separated land uses. As Holmes (2008), rightly notes many places are more or less multifunctional (also see Evans et al. 2002, Wilson, 2001). Moreover, spatially separating functions runs in against the autonomous development of emergent leisure-oriented landscapes: a process of actors trying to utilize the potentialities of landscapes and translate them into marketable activities by linking macro processes (changing life styles, increasing demand for leisure) to local characteristics (place-based qualities). Hence, stimulating leisure-oriented landscapes concerns developing the gradient in between the extremes, revolving around synergies between preservation and adaptation (figure 2).

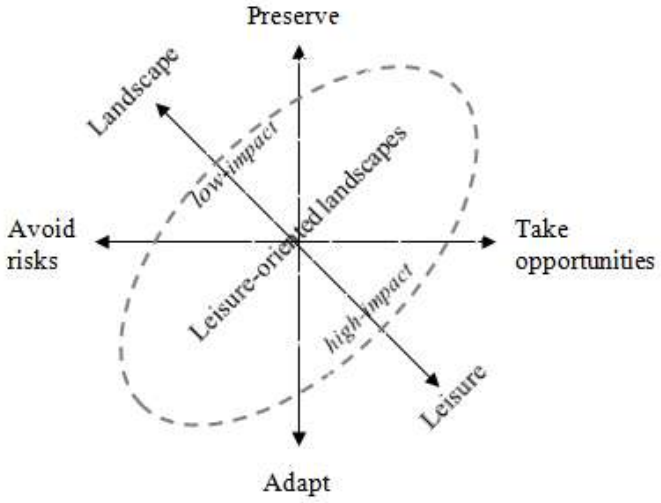

Figure 2: leisure-oriented initiatives in relation to landscape and carrying capacity

In this context, planning is important along to two lines (which relate to the extremes on the continuum that are set out in fig. 2). First, interventions to retain in the past acquired spatial qualities that are important for providing places with potentialities to attract visitors, inhabitants and (leisure-related) businesses. This emphasizes the need for a degree of *robustness*. Second, interventions to adapt places in order to co-evolve along with contextual, societal dynamics i.e. adding new functionalities to existing landscapes and building, introducing new types of land use or transforming places more fundamentally so to acquire a better fit between the local and the contextual. This emphasizes the need to promote a degree of *flexibility*.

- A degree of **robustness** represents a focus on *being*: interventions aim at preserving and sustaining in the past acquired spatial qualities. Potentially disruptive impacts are avoided or mitigated in order to minimize negative impacts so to preserve and protect expressive factors perceived as important for (future) leisure-related developments. A place its (perceived) carrying capacity determines whether and in what form developments are possible.

- A degree of **flexibility** represents a focus on *becoming*: interventions focus on utilizing as well as transforming pre-existing landscape elements (to a greater or lesser extent) so to enhance, expand existing qualities or introduce alternative, novel spatial qualities that provide a better 'fit' with current and expected future societal demands. Although these processes of adaptation may build on earlier developments – path dependencies – the focus leans towards deviating from historic development trajectories, stimulating non-linearity.

From a complexity perspective, emphasizing the persistency of dynamics, planners are challenged to balance the degrees of robustness and flexibility. Whereas robustness is needed to adhere to certain qualities and development trajectories, a sole focus on robustness may inhibit the capacity to adapt to changing circumstances and result in negative locked-in situations. Flexibility is needed to co-evolve along with contextual dynamics and provide room for the innovative, self-organizing behavior actors. However, a sole focus on flexibility ('laissez faire') may result in chaotic situation that negatively affect development potentialities for the future. Balancing robustness and flexibility is a strategic planning and decision-making issue that requires ideas about and perspectives on place-based amenity values, and where improvements can be realized. Moreover, processes driving spatial development will (likely) change over time, resulting in the emergence of new perceptions on the use and development of space, giving rise to novel land use claims, and the submergence of traditional ones. What constitutes spatial quality is temporal in time and place as it is dependent on actors that have an interest and on their perception – which can both change in time. The balancing act is therefore an iterative process of monitoring, adjusting and adapting perspectives on carrying capacity, spatial quality and development.

6. Reflection: towards an adaptive planning approach to spatial development?

In this paper we have illustrated that, from a planning perspective, the transition territories undergo becoming leisure-oriented landscape occurs in a relatively autonomous manner. To guide these territories in their evolution, this paper has illustrated the need for the co-evolution of material, organisational, institutional dimensions in order to anticipate multilevel processes that drive spatial change. Moreover, in this context, we observe that there is a need for adaptive planning approaches. Adaptive planning refers to (strategic) planning approaches that stimulate

the adaptive capacity of places, enabling regions to timely anticipate to emergent non-linearity.

To discuss adaptive planning approaches to spatial development, we focus on the mechanisms behind the processes that drive spatial change. Here, we draw on insights from complexity theories and complex adaptive systems in particular. The emergence of leisure-oriented landscapes adds to these insights that managing spatial dynamics and non-linearity requires planners to constantly balance robustness and flexibility. On the one hand they are burdened with the task to guard over a degree of robustness in order to sustain the development opportunities of places and societies towards the future. For leisure-oriented landscapes a degree of robustness is needed to sustain spatial qualities of places, and avoid and mitigate negative impacts. However, on the other hand, anticipating dynamics and non-linearity provides an argument not to become too robust, and for planners to stimulate a degree of flexibility as well. This is a paradox planners are confronted with.

Combining these insights we can deduce several conditions for managing non-linear development. First, the importance of self-organisation which refers to the adaptive behaviour of actors trying to acquire a better 'fit' given local circumstances and macro trends. Their actions may serve as guides for how development trajectories unfold towards the future: a continuation of historic paths or the emergence of alternative paths? Second, the importance of feedback and feedforward processes (see Pahl-Wostl 2007; Walker et al. 2002; Portugali, 2008). Feedback encompasses identifying emerging and 'submerging' developments, trends and issues. It allows recognizing the potentialities of niche developments, and assessing whether to support or constrain them. To formulate criteria for assessment, feed-forward processes are crucial. This refers to the efforts that revolve around exploring possible and desirable future states, and the subsequent strategic planning actions and interventions that are considered needed to capture opportunities or deal with potential issues (cf. Van Dijk, 2011; Myers & Kitsuse, 2000).

What are the implications for planning? Feed-forward processes are important for stimulating robustness: creating ideas, perspectives and (formal) strategic visions about potential and desirable future states and appointing crucial factors (e.g. spatial qualities) that need to be retained or adapted (compare fig. 2). In the context of leisure-oriented landscapes, governance structures become appropriate constellations to incorporate multiple actors and (policy) sectors involved as well as to take in to account intangible factors (Hultman & Hall, 2012). Moreover, trend watching and monitoring (e.g.) economic, demographic, environmental and political change at various levels of scale help to observe processes that indicate or inhibit non-linearity. It is about reflexivity: recognizing early (warning) signals indicating processes of self-organisation and emergent new development trajectories, and the submerging land uses and the danger of negative locked-in situations. This revolves around feedback to identify when regions

and planning systems tend to become too robust, whether to simulate flexibility, and whether to adapt dimensions (fig. 1).

Stimulating flexibility benefits from (purposefully) linking macro trends and events to micro responses, requiring room for experimenting and self-organisation that may lead to alternative development trajectories that deviate from the past. Actors need to learn and become aware how new initiatives can offer relative advantages (see Rogers, 2003), how they help cope with unfolding urgencies, under which conditions development emerges, and which (alternative) approaches and strategies are required. Micro-initiatives by the actions of innovators and early adopters can serve as (small scale) trials or experiments that empower actors to observe and showcase their 'relative advantages' over others in terms of e.g. socio-economic development or impact on the environment. The awareness of relative advantages can provide incentives and mobilize resources to further explore potentialities. It could increase the receptivity to adapt organizational and institutional dimensions, when conditions for development require to deviate from past trajectories, routines and approaches (Geels, 2005; Martin, 2010).

The (case of the) emerging leisure-oriented landscapes illustrates that adaptation can be a contested process. Stimulating robustness, revolving around preserving factors important for the quality of space, can be inconsistent with simultaneously stimulating flexibility, allowing for actors, societies and regions to acquire a better fit (to co-adapt) to changing circumstances. Nevertheless, crucial to managing non-linearity is to support multiple development trajectories: not to fully specialize but to keep multiple options open for future development trajectories, so to agilely shift when beneficial or necessary (for example specialized diversification, Pike et al., 2009; smart specialization, McCann, 2011; related and unrelated variety, Frenken et al., 2007; pluripotential, Hartman et al., 2011). The dynamic reality, spatial development is a persistent process of adapting, experimenting, innovating, evaluating and learning. Developing the adaptive abilities to do so is likely to become increasingly important, given the (contextual, largely autonomous) forces driving local and regional spatial dynamics.

Past and present of the development of mega transport projects (MTP) in Greece: changing paradigms, priorities, challenges and outcomes

This paper reviews the history of infrastructure development in Greece with special reference to transport and mega transport projects. This review starts from the late 19th century and extends until today trying to trace the major political, economic and social challenges that have historically influenced the formulation of MTPs in the country. We propose a periodisation according to broad periods related both to socio - political change and changes in the priorities of the country that reflect the transformations of the accumulation regime, thus combining principal political and economic eras affecting the planning, funding and delivery of construction infrastructure and consequently MTPs.

The emphasis is placed largely in the periods after late-eighties, which we regard as the most insightful for analysing the formulation of the present context of planning and delivery of large-transport projects. The analysis of the current context is then supported by a subsequent discussion on the specific institutional, legal and funding circumstances that are relevant to the development of MTPs. The paper concludes with our reflections on today's relevant harsh dilemmas and questions, regarding the MTPs that are in the construction and planning phase, given the relative severity of broader challenges such as EU governance, privatization, financial globalisation, car-dependency, modern technology, environmental protection and the economic and institutional sustainability of the state.

Past and present of the development of mega transport projects (MTP) in Greece: changing paradigms, priorities, challenges and outcomes

1. From the 19th century to the 2nd WW

Greece, when becoming an independent country in 1830, was already considerably lagging behind the western European world which was already half way through the first industrial revolution. Technical progress thanks to the stream of inventions was going on giving birth to new systems of infrastructures for most human activities. Steam was already in action since the beginning of the 18th century, and put in to industrial duties in the textile factories from the last third of that century. Portland cement was already invented in 1824 while the lathe was invented in 1830, the year Greece gained officially its independence. Steam engines and trains had started from 1825 and the gas lighting of London had taken place during 1812-1820.

The new country, during the first half of the 19th century, had to organize and efforts were put to plan and construct the capital, Athens. It was not until the late 19th century that the construction of the first major infrastructure projects started. The first wave of infrastructure development in Greece took place mostly under the Trikoupis[1] governments during the late part of the 19th century.

According to Tsokopoulos (1999), the major construction works in the end of the 19th century and in the beginning of the 20th, comprise railways and road works, the construction of the Corinth canal, electrification, the water system of Athens, Construction (rearrangement) of the Port of Piraeus, and the reconstruction of Thessaloniki (after the 1917 fire). Haikalis et al (2002) add the exsiccation of the Kopais Lake, and the construction of important buildings. This first wave of infrastructure works the so-called Trikoupis projects established the pre-conditions for the industrial spring of the mid-war period that was swiftly interrupted by the later developments (Minor Asia disaster of 1922 and 2nd World War).

The Trikoupis projects, especially the railways programme, expressed the efforts to build a modern and cohesive state. It is to be noted, of course, that at the time transport was only railways. For the early part of the twentieth century, Kafkoula and Vitopoulou (2002) note that exemplary projects of the period from the first world war until the Metaxas Dictatorship (1936-1940) such as the reconstruction of Thessaloniki and other Northern Greece cities (mid-thirties) had been planned and carried out by the Ministry of Transport (which was responsible for planning and public works). They add that the well-staffed ministry had developed confidence in planning knowledge and tools which did not completely vanish after the extreme political conservatism that overrun the country after 1945. Yet, in terms of major transport projects no mega projects were planned during the first half of the twentieth century after the Trikoupis wave.

[1] Harilaos Trikoupis was prime minister of Greece during 1875, 1880, 1882-85, 1886-1890, 1992-1993, and 1893-1895.

2. The Period of Intensive Rehabilitation (1948-1962)

Between 1945 (or 1948: end of civil war) and 1962 the main infrastructure projects were those related to the rehabilitation of the country after the 2nd WW and the civil war that followed. Greece suffered most from the German occupation (1941-1945), and its entire infrastructure was practically destroyed. Just the destroyed buildings in the whole of the country accounted for 23.3% of the entire building stock (Haikalis et al, 2002: 51). So besides the development challenges that most countries had to face, Greece had to deal with the particular problems that had been created by the Nazis.

The effort for rehabilitation included the reconstruction, construction and resurfacing of the road network, the reconstruction of the rail networks, the clearance of the Corinth canal from the remainders of the blown rail bridge and from train coaches thrown into it by the retreating Nazis, the construction of a new generation of bridges, the construction and reconstruction of ports, the irrigation works of Athens and Thessaloniki, the construction of hydroelectric dams, the further electrification, the expansion of the telephone network, as well as important defence works. Especially the construction of the large hydroelectric dams, the planning and construction of which gradually passed on to Greek hands became crucial for the development of the country and of the construction sector.

The whole enterprise was financially supported by Marshall Plan and by AMAG (American Aid to Greece, until 1953, when the devaluation of the drachma took place and monetary stability started to be achieved), in the form of aid or loans. *From 1953 the projects continued under a dynamic programme of the Ministry of Public Works, while by virtue of the programme many local contractors, often lacking capital themselves, were also set up in business (Munkman, 1958: 193-201)* (Skayannis, 1990: 165).

The post war infrastructure wave, the rehabilitation of the country, lasted until 1962, and marked the rise of a new branch of Greek economy the one of construction capital. Despite the debates on the development trajectory[2] of the country and the efforts made for re-industrialization, little was at the time achieved in the field of manufacturing industry, while due to the pressing needs construction proliferated. It is very indicative that four economic plans were made and none of them worked, as the real economy had taken its own track.

Construction developed along two lines gradually comprising two fractions of capital: one of housing to cover the vast new needs and one of 'contractors' (often being small and lacking the means) to undertake public works, as the vicious circle of urbanisation started to feed infrastructure.

The big construction activity was conducted via centrally controlled projects and combined many aims at the same time (e.g. civil, military). In the absence of

[2] see the Zolotas-Varvaressos debate and the positions of Batsis

significant manufacturing growth, the new post civil-war regime of accumulation was infrastructure biased (Skayannis, 1990). The corresponding infrastructure of this particular stage was one of extensive provision of the very basic infrastructures where there was no space for a limited number of mega projects, but for a number of major projects instead. As far as transport is concerned, road building was the main issue serving the emerging market and the socio-spatial integration of the country. All infrastructures built served as a necessary precondition for the next stage of industrial production take-off.

3. The Period of Intensive Accumulation (1962-1973)

During the first part of this period (1962-1967), public infrastructure kept its pace (completion of various works) but did not really increase its magnitudes. The demand for housing increased rapidly. The most significant infrastructure projects were important road works (such as the Athens-Thessaloniki National Road) and land reclamation projects including drainage and flood preventing works, as well as the National Airport of Athens, and several power stations (including hydroelectric dams). In a few occasions the Greek construction companies collaborated with non-Greek western companies.

During the second part of this period (military dictatorship of 1967-1973), the economy utilised its already built infrastructure. A substantial part of construction was sustained by the building of huge hotels (Benas, 1976: 293).

Construction capital progressively tended to be centralised: in 1972, there were 624 companies. Six of them together with their satellites had 29% of the sector's working capital, while between 1967-1973 when the sum of profits of all companies reached 6 bill.drs, five of them alone accounted for 3.3 bill. drs (TEE Bulletin, No 838:20, cited in Benas, 1976: 297). As a result, and despite its powerful presence in most parts of the economy, foreign capital did not manage to decisively control the 'technical companies'. In 1972, it controlled only 0.7% of the technical firms' total assets (Giannitsis, 1978: 200).

Evidently, there has been a process of transformation from a small scale craft-like production to a more organised, large scale and industrial-like one. This concentration and centralisation is pointed out by Tarpagos who argues that an oligopolistic nucleus was formed in the construction activity, which, by the end of the period, reached its limits in the domestic market and pursued an 'imperialist' expansion abroad (Tarpagos, 1985: 105).

At the public finance level, there was an attempt to apply a restricted version of Keynesianism via public spending in conjunction with the need to complete territorial integration that would effectively lead to market and economic integration. This made construction and other public works play a prominent role. In Greece it may be that the most unifying social element of the construction activity (including housing sustained by rampant urbanization) has been its role as a stimulant of the

economy, partly because of the backward linkages and partly because of the rest of the effects that generate a 'virtuous' cycle.

It was during the first part of this period that the developmental necessities led to the construction of a mega transport project of the period, the 'National Road' linking the major cities of Patras, Athens, and Thessaloniki, extended to the northern border of Evzonoi (PATHE). This link actually materialized the renowned 'S' shape of the Greek development axis[3]. Yet at the same time, the optimism of the private car (and all related interests) signalled the termination of urban tramways in Athens and the first visualisation of the Athens metro (1962 Smith study).

The 'National Roads' (highways) along with some technically advanced bridges constituted the major transport projects of this period. These projects had not been the result of comprehensive planning methods and procedures. Serious cost overruns and delays were taking place due to inadequate studies which in many occasions were not taking into account the full range of relevant technical and financial risks. There are cases where the needed additional and supplementary works were not anticipated in the studies, geological studies were not prepared, the expropriations were not finalized (and proved to be very time consuming and expensive for the state) and also cases where lack of adequate financing halted the progress of the projects (Haikalis et al, 2002: 84). The attempt of developing Egnatia[4] Motorway in 1971 illustrates the transition of the intensive accumulation period to the period of crisis. In 1971 the dictatorship, in an effort to overcome international economic isolation, signed a contract with the US company 'Mac Donald' for the study, financing, and project management of the Egnatia motorway. According to the contract, the construction would be done by Greek companies. After substantial segments of the road were tendered, the US company decided to exit the contract. A Greek consortium of 12 companies undertook the study and construction of the project. The consortium invested significant amounts to mechanical equipment in order to cope with the technical difficulties of the project but the democratic government after 1974 decided to halt the project and direct funding mainly to defence projects. Some of the contactors faced severe financial problems due to the investments that had already done and other focused their activity to Middle East and Africa in order to be viable and keep their activity in Greece (Haikalis et al, 2002: 84).

The legal, political and institutional context together with the urgency of infrastructure upgrade did not leave space for the involvement of stakeholders in the decision making. There are signs that decision- making was strictly taking place at high levels of government under non-transparent procedures especially during the dictatorship. The Greek socio-political context of this era (and later as well) was

[3] For the history, the meaning, and the 'political economy' of 'S' see P.Skayannis, 2009.
[4] Egnatia (after the name and the footprint of the Roman Via Egnatia) connects the west (city of Igoumenitsa) to the east (city of Alexandroupolis) of Northern Greece. In the Roman times, it was connecting Durrës with Byzantium (Constantinople, today's Istanbul).

underpinned by a quite unease and at the same time distanced relationship between the State and citizens. Politicians together with some high-level public servants have played the most decisive role in the planning of major projects. Moreover, environmental concerns were not high rated in the agenda, if not missing at all.

4. The Period of Crisis and After (1974-1981)

The economy since the 1974 recession was facing serious difficulties because of the unfavourable international situation (1973 oil crisis), the dictatorship's catastrophic policies that led to the Cyprus crisis (1974) generating the need for increased defence expenses.

The crisis resulted in a drastic restructuring of the production structure of the country (smaller manufacturing units, switch to traditional branches) and a decisive switch of Greek construction capital to overseas activities. As a result, during this period, due to a) the reduced public investments which previously sustained construction, b) the reduced urbanisation rates which previously sustained the excessive investments in housing, c) the over accumulation in the broader construction sector in the previous period, and d) the reduction of the opportunities for investment in manufacturing industry, there was a considerable expansion in the private sector's construction activity abroad. This was one of the major responses of the Greek local and cosmopolitan capital, especially the infrastructure geared one, to the (post crisis) worsening conditions of accumulation within the country (Skayannis, 1990).

Eventually, there were more than 70 fairly large Greek companies engaged in design and execution of construction operating in the Middle East and North Africa, mainly Saudi Arabia and Libya, 15 of which very large (Koutsoyannis, 1984: 135-6). The budget of some companies was virtually multiple of the budget of the Public Investment Programme of the Greek State (Tarpagos, 1985: 108-11).

Given the situation described, the state did not proceed to any major public infrastructure investments in the transport sector, neither organised any major transport projects, besides point interventions in the urban centres.

5. The first period of PASOK[5] (1981-1986)

During this period, PASOK tried to achieve a modernisation of capitalism employing Keynesian tools and bringing about a limited level of welfare state regulations previously non-existent. Consequently, such policies bore a high risk of public deficit increase, endangering the economy. The state investments meant to assist the valorisation opportunities of local capital, not only in manufacturing but also in the traditionally strong infrastructure field, did not suffice to regenerate economic

[5] PASOK: Pan-Hellenic Socialist Movement, led by Andreas Papandreou. It won the October 1981 elections.

activity at the desired level. A growing deficit in the public sector has, since that period, been observed.

In 1985 the government negotiated the terms of a loan with the EEC. The terms were based on a 'stabilisation programme' less strict than what an IMF one would have been. It was an austerity programme that managed to destroy the then existing social consensus around the PASOK government.

Under these circumstances, the government in 1986 announced the 'six grand projects'. Most of them were already under consideration in one way or another. They appeared in the Regional Development Programme 1986-1990 that was submitted to the EEC in early April, 1986 (*Eleftherotypia*, 4/4/1986: 39; *Ta Nea*, 4/4/1986: 18). However, they were advertised as such in early February 1987. These projects are: 1) the new Athens airport in Spata, 2) the Athens metro, 3) the motorways programme, 4) the diversion of the Acheloos river, 5) the Rio-Antirio suspension bridge, 6) the electrification and modernisation of the railways (see *Ta Nea*, 11/2/1987: 16; *To Vima*, 15/2/1987; *Ta Nea*, 21/2/1987: 11; *To Vima*, 25/2/1987: 25) (P.Skayannis, 1990: 191).

So in its second phase, based on the EEC guidelines, PASOK, attempting to stimulate the economy and escape the minimal investment situation, tried to manage the crisis with a) strict incomes policy; b) a macro-economic regulation based on austerity packages; c) a resort to large scale construction under a considerably different legal framework facilitating 'conglomerates' of design and construction firms, and d) further infrastructure provision policy with increasing emphasis on self-financing of the projects, a pretext for a certain kind of privatisation. These were accompanied by the adoption of a pro-EEC perspective and efforts to re-establish links with foreign capital. So, the initial attempt to establish a regulation based on quasi-keynesian policies by linking wages to the cost of living, crashed in the absence of investments and the slowdown of output, only to be slightly reversed by the virtual neo-liberal stabilisation programme of the last period, based on the EEC guidelines.

The coming neo-liberal approach became also evident in the case of transport construction projects. Kaltsounis (2004) refers to a particularly interesting case during the 1980s which was the attempt to establish a public authority that would undertake the design, construction, operation and maintenance of the major road network of the country on a self-financing basis using credit capital. The Ministry of Environment, Planning and Public Works (MoEPPW) formed a working committee to investigate the potential of such a venture and the National Road Fund (authority responsible for toll collection in Greek roads) conducted pilot studies which showed very promising results regarding the self-financing possibilities of the entire national road network. At the same period other relevant studies showed that the users of the road network would be willing to pay in tolls adequate amount to sustain the viability of the planned public authority. The reason for this was that the existing road network was in such bad condition that users would pay up high tolls to use a better

network given also that the consumption ability of the population by that time had been significantly increased. However, the international economic climate of deregulation and free competition had already been dominant. Moreover, the emergence of easily moving private capital and know-how on transport PPPs around the world brought a neo-liberal stance on the issue. The idea of a public authority as initially envisaged was abandoned and instead the promotion of a concession-based type of road development started being planned.

6. The CFS periods (1986–1993, 1994–1999, 2000–2006) and the Olympics: The overdue realization of the contemporary MTPs in Greece

A third wave of large infrastructure development of Greece was mature to happen and was made possible with the EEC Community Support Frameworks (CSF) (the beginning of this wave was marked by the, previously mentioned, repeated announcements of the six grand projects by A. Papandreou, in the 80s). Before the CFSs all major transport projects were entirely financed by public funds and in many cases the delayed realization of many major projects was due to the lack of available capital.

The period from 1984 to 1993 (Integrated Mediterranean Programmes and CSF I) was marked by small scale interventions rather that major infrastructures. The first CSF gave Greece a chance to advance on management, especially through the positive reaction of the private sector. The rigidities and inflexibility of the public sector left a lot of gaps in economic and bureaucratic management and the first CSF was only partly successful.

However, the EEC[6] Structural Funds' reform in 1988 qualified Greece as a full Objective 1 status country and gave the opportunity to the country to maximally benefit from the significantly increased EEC funding. According to the new set up, a National Plan is submitted by the government to the EC in support of its request for aid from the Structural Funds. The official agreement between the Commission and the Greek state on the amount and form of EU assistance for the National Development Plan takes the form of a CSF. The above process of preparing a comprehensive development plan in order to claim structural aid has been an extremely important exercise for the Greek state. This procedure forced the Greek government to approach the transport sector in a more strategic way and to start putting in the pipeline major transport interventions in the view of substantial inflow of EU funds.

In the early nineties the flagship study "*Greece 2010*" commissioned by the Ministry of Economy and Finance (to be used as feedback into the National Strategic Development Plan for CSF II) took a strategic view on transport planning considering the European and international dimension of transport development. The study (MoEF, 2005) identified the priority transport axes for the development of the

[6] On 1 November 1993 with the Maastricht Treaty, EU succeeded the EEC.

country's Highway network. Their development was combined with major investment projects in points of access (ports, airports) and secondary transport networks. Starting from late eighties but essentially in 1990 and 1991, a great effort took place at the MoEPPW in order for all priority MTPs, which had been identified and incompletely studied in the past, to be finally realized. Designs and studies were completed and the final decisions were made with outstanding effectiveness, compared to the past. Also, for the first time new methods of procurement, management and financing were studied and introduced for Mega Transport Projects (MTPs) such the Athens Metro, the new Athens International Airport, the Attiki Odos, the Rio-Antirio Bridge and the Egnatia Motorway (Papaioannou & Peleka 2006). The tendering, negotiating and procurement process of all those projects essentially took place within the period from 1991 to 1996. They were all developed with the heavy support of CSF II and CSF III funds, either by private sector consortia through PPPs (concession-type for the case of Rio-Antirio Bridge and Attiki Odos and joint – venture PPP for the case of new Athens airport) or by project-specific public companies operating under private sector rules, governing all phases of project development (Attiko Metro, Egnatia).

The implementation of the CSF II transport programmes was the first crucial test in dealing with large-scale projects. However, the Greek state's implementation mechanisms proved inefficient in many cases causing substantial delays in the programmed works of the pre-mentioned MTPs (MoEF, 2005). In any case, the second, and the third CSFs (1994-1999 and 2000-2006) performed better due to the experience gained in-between. The urgency of the Olympic projects (and the continuous exhortation of the Olympic Committee to speed up) gave a major chance to Greece to improve effective planning measures and complete works on time (see evaluation reports of the CSFs). So the Olympic Games together with the availability of funding worked as a window of opportunity for Greece to advance with projects that were lying in the drawers and were seen with inhibition by the administration for a long time. For example, the Athens metro had been initially proposed by the renowned 'Smith Study' (1962), but never really started until it became an Olympic must. However, it is important to note that a) the delays have been alleged to be 'artificial' so that the 'urgency' could force to assigning projects to specific firms that could cope with urgency and pressure, and b) that projects were speeded up by the Hellenic Olympic Committee and the collaborating Ministries by bypassing the law and even by violating Rights and court decisions, or employing special new legislation, just for this matter.

This wave of MTPs significantly contributed to the radical restructuring, consolidation and growth of the construction sector. The large magnitudes required, led to important mergers and acquisitions so that the domestic construction sector could stay in the game either undertaking MTPs by themselves or by establishing consortia with major international players in the MTPs market. The opening and strengthening of the infrastructure market in Greece was further reinforced by the large privatization shift in MTP development. The involvement in transport infrastructure became more attractive since projects became larger, more technically

demanding and more importantly because profits for private firms could be made from long-term exploitation of transport projects and not only from construction.

During the period of the first three CSFs, Greece gradually switched from the target of internal integration to the target of European Integration. In the first CSF there was no prioritization of quality or sustainability, and the works were spread all over the country in order to satisfy urgent needs and to meet political obligations. The second CSF (1994-1999) gave priority to 'heavier' interventions, in the form of big transport projects, targeting by and large the improvement of transport infrastructure in the Athens metropolitan area. The railway programme came again as one of the priorities, while new forms of partnering with the private sector emerged. During that period, a great effort took place in order to improve the organization, the procedures and the institutions for planning, studying and implementing large projects in the transport sector. New authorities were established to study, procure, and execute large projects (such as Egnatia SA, Ergose SA for the construction of rail projects) but also new organizational structures within the public administration to undertake EU requirements for prioritizing and monitoring EU funded projects (Christofakis, 2007). In the third CSF (2000–2006), a major funding stake targeted again the big transport infrastructure projects such as the Thessaloniki Metro, the continuation of Egnatia and PATHE. Also, a further shift towards partnering with the private sector took place. The major transport PPPs that had been initiated before 2000, such as Athens International Airport, Attiki Odos, Rio–Antirio Bridge were completed in the period before 2006 and a number of new (fourth wave) large transport PPPs were envisaged, planned and studied within the third CSF.

7. A recent generation of MTPs and the post-2008 economic recession.

The post-Olympic optimism and the sense of 'achievability' within the 'ecosystem' of MTPs' advocates in the country had fueled a momentum which was to be kept in the era thereafter. This was manifested by the great number of new MTPs that, by 2008, were either procured or (most of them) already in initial phase of their construction (MoEPPW, 2007; Petroutsatou, 2012). Those projects were the Thessaloniki Metro, the Thessaloniki Submerged Tunnel and the Concession Programme of Major Greek Highways consisting of the Ionian Corridor, the Central and Peripheral Peloponnese Corridors, Segments of PATHE, and Central Greece Corridor E65 (MoEPPW, 2007; Petroutsatou, 2012). The total costs of the above projects was estimated to be more than €9 billion, while except the Thessaloniki Metro all other projects were procured through BOT type concessions (MoEPPW, 2007). The completion of the construction of those projects, according to the contracts' provisions was between (depending on the project) 2011 and 2014 (Petroutsatou 2012; Ypodomes 2012).

In early 2008, the forecasts, despite the deepening of global financial crisis which could affect the country's fiscal responsibilities, were still optimistic (BMI 2008). However, one year later, the picture was quite different. The severe downward trend in construction that started in 2007 was forecasted to continue while the activity in

the infrastructure sector in the meanwhile had been very little. Large PPPs that were in the pipeline such as the Thessaloniki's Submerged Tunnel and the Port concession were abandoned and others that were being planned started appearing as rather unachievable. As the global financial crisis was deteriorating and liquidity was dying up in the financial system, the public debt and the budget deficits were severe threats to the Greek economy and major constraints on the attempts to implement stimulus plans through infrastructure development either through public investments or private PPP capital (BMI, 2009). In the next years, again, progress remained marginal in all major transport projects. The delivery of Thessaloniki Metro was postponed to 2015, instead of 2012 which was the initial contracts' delivery time. The expansion programme of Athens Metro was, as well, progressing very slowly and eventually stalled due to the SIEMENS scandal. Also, the future of the motorways concession programme started appearing very uncertain given the inability of the government to continue the funding at the initially planned pace, the serious expropriation delays (they were programmed according to the contracts to finish by 2009), the decreasing toll revenues (which according to the concession contracts was planned to partially fund construction) and the obvious expression of reluctance by the banks to keep injecting money into those large road PPPs (BMI, 2010, Petroutsatou, 2012). For example, in this context the construction of E65 stopped.

In 2010 the country faced an acute insolvency threat and agreed to receive a financial support of 110 billion from IMF, EC and ECB, with a repayment period of 5 years (Law 3845). After almost two years, in early 2012 and with the country not having at all escaped the insolvency danger, a new bail-out of additional financial support and a mechanism of alleviation of debt repayment obligations was agreed (Law 4046). According to the above agreements, the government has to implement unprecedented austerity measures and reforms which also directly affect the funding, ownership, management and operation of enterprises and projects in the transport sector. Due to the strict targets and the tight inspection of the lending bodies (IMF, EC), during the two years' period a number of relevant developments have speeded-up (some of them not so successfully due to unions' opposition and the lack of effectiveness of the responsible government bodies), aiming at (quickly) reducing expenditure and enhancing revenues. Those quite unpopular developments that are being planned to be promoted in a 'fast-track' mode, have caused big protests and are strongly criticized as neo-liberal, lacking a strategic long-term approach and ignoring democratic values and practices. Indicative of the new policy orientation is the restructuring of the Hellenic Railways Organisation (Law 3891) and the reform of public transport organizations in metropolitan Athens (Law 3920), which both aim at consolidation, privatization of a great number of activities and operations, cutting lines, increasing fares and transfer of employees to other state organizations. Other indicative developments include the Privatization Action Plan regarding Ports and the regional airports concessions (MoEF 2010).

As far as other specific MTPs are concerned, the most crucial remarks have to do with:

- The intention to privatize the operation of Egnatia (and increase toll fares) so as the, currently public and loss-making multi-billion highway (which also suffers from serious traffic decrease due to the economic recession and the fuel price increase), to stop burdening heavily the state budgets (*Agelioforos* 8/12/2010; Ypodomes Portal*).*
- The serious delays in the construction progress of the Thessaloniki Metro and the extensions of Athens Metro (related to the SIEMENS scandal), and the delays in programmed tenders of their new lines. Those delays are related to budget constraints but also to archeological and contracting issues that diachronically delay such projects in Greece (MoI 2010b; Ypodomes potal).
- In 2010, the Extension of Attiki Odos adapted to a new alignment that was more environmental friendly, economical and compatible with the revised Regulatory Plan of Athens/Attiki (RPA-2021) which was under preparation (GRReporter 2010; ORPA 2010). However the most recent updates from media reveal that the major Greek construction companies seem to have successfully lobbied with the Ministry for another alignment which ignores the restrictions of RPA-2021 (esp. the connection between the old and the new international airport). The new project is a highway network in Attiki region of a much higher budget than any other proposed in the past (Ypodomes portal). Media also comment that the conflict of RPA-2021 with this new project has led to the resignation of the former president of ORPA (Ypodomes portal) and the halting of the procedure for the RPA-2021 to be filed for voting in the parliament.
- The New airport of Heraklion in Crete is intended to be redesigned to be smaller and more economical and thus more attractive to sponsors that will bid in a tender of a Joint-venture PPP with the Greek state. An initial tender in 2010, based on the original designs and specifications has not been successful after two postponements of the bids opening (Reuters News 2011b; Ypodomes portal).

During this last period of MTPs development in Greece, there is an apparent trend towards implementing large transport projects through various forms of PPPs and privatization, the governments intending to further push ahead towards this direction. However, despite these strong ambitions towards seeking private investment in transport, the present macro-economic, political, social and institutional context in Greece makes investors and banks quite disinclined to enter into contracts which they perceive as very risky.

The case of the highways PPPs that are currently under construction is very illustrative of the above mentioned context which comprises not only the new challenges and risks that the recession has brought about but also the diachronically persisting institutional and managerial impediments. These projects have experienced huge delays and budget overruns due to the lengthy expropriation procedures, alterations of the project design due to archeological excavations and public utilities arrangements (Lambropoulos, 2010; Petroutsatou, 2012). Such delays fall into the

responsibility of the public sector (according to the concession contracts) and give the right to the banks and the concessionaires to impeach the contracts. The public sector, on the other hand, despite its intentions to implement new legislative and institutional mechanisms (for speeding up environmental consents, expropriation procedures and archeological excavations) to combat delays, has not moved much towards this direction, yet. In addition, it is important to note that the recession has caused serious traffic decline (less economic transactions, increase of petrol retail prices, etc). In addition, more (around 14%) austerity-hit road users have been refusing to pay tolls (Reuters News 2011a). In this context, banks have suspended funding for those road MTPs (Reuters News 2011a; Lambropoulos, 2010) causing almost an absolute stagnation in the projects' progress.

With the aim of providing a stimulus in the economy and a positive impact on employment, the government and the EU are currently negotiating on a mechanism that will allow Greece to re-allocate its 2007-2013 Structural Aid to support infrastructure investment (BMI 2012). Those funds are aimed to support a 're-set' in the road PPP contracts in combination with the introduction of reduced toll fares (which will make transport affordable in the current recession conditions) and concession extensions (Reuters News 2011a).

8. Some general remarks

Apart from the specific comments that add to the discussion in each of the sections of this paper, we can draw some broad conclusions from the historical evolution of MTPs development in Greece. It is apparent that, to a great extent, MTPs are realized in waves. This means that MTPs are realized in "bundles" and also that there are always long periods of relative low MTPs' magnitudes between the waves' peaks. Apparently, within those long periods certain conditions and generators lead to the emergence of the waves. However, despite the fact that MTPs' waves need long times to be realized, they are always interrupted by very severe circumstances such as wars, dictatorships and harsh financial crises. As a final point, it also appears that MTPs' waves go along with general infrastructural waves while MTPs are almost always regarded as the "flagship" ones. A further research would be required to see if to what extent and in what way the infrastructure construction waves in Greece are linked to cyclical economic crises of national and international capital.
