Planning methods are regarded as a "controlled sequence of purposeful operations in order to solve problems" (Schönwandt and Voigt 2005: 772). These sequences are deliberately designed; planning methods require personal, financial, and temporal resources, and an organisational and legal framework. Hence planning methods at least implicitly include an idea of their mode of operation and of desired impact. The outcome and impact of planning methods appear at different levels: shaping the results of the three stages; influencing the application of subsequent methods; modifying "Approaches" and "Institutions" of the "Planning World"; facilitating certain "Interventions" that eventually change the "Settings". In that sense planning methods only indirectly impact the "Outcomes" of planning.

This basic definition points to a broad spectrum of procedures that reaches far beyond standardized or legally regulated operations (Fürst and Scholles 2004). Planning methods are permanently enhanced in an on-going process of variation and modification in order to cope with the changing challenges of spatial planning processes.

When taking the issue of impact as a starting point for the research in planning methods, these methods necessarily comprise purposeful events of communication. On our understanding, communication is a

prerequisite to all planning methods. In our research approach we consider only those methods that are directed to a recipient and in that way exceed spontaneous informal two-person or group communication. We restrict the project to medial and public informal communication. An expertise left on the shelf or a simulation tool run only within the walls of a design office, are cut off from audience. In this respect they are incomplete planning methods. Instead these tools have to be set within more complex sequences of operations that in the end also address stakeholders.

In our research project we distinguish planning methods according to different characteristics of communication: format, recipient and degree of interactivity. Planning methods can be shaped by a single communicative event or a sequence of different communicative events that are deliberately linked to one another.

When the “Planning World” applies and carries out planning methods it simultaneously initiates individual steps of communication within the “Planning World” and between the “Planning World” and the “Life World”. Planning methods stimulate the communication process within and between the two worlds. Current communication theory conceives communication as a system that exceeds linear cause-and-effect. Instead back coupling is an important feature (Merten 1999: 114-117). When applied to our research approach, feedback that can be understood as outcome and impact of purposefully applied planning methods.

Planning methods’ analytical and visual ingredients

Beyond the basic communicative challenge, planning methods require further skills and capabilities of spatial planners. We hypothesis that analysis and visualisation make up basic buildings blocks, that in their various formations define the outcome and impact of planning methods. Analytical and visual skills can be regarded as ingredients in more complex “sequences of purposeful operations” (Schönwandt and Voigt 2005: 772).

Analysis points to a systematic search process that aims to gain new knowledge on real world planning situation. Planning methods can be regarded as analytical when they apply scientific research methods and their practical and hands-on modifications. This includes a rich repertoire of scientific research methods ranging from quantitative to qualitative empirical methods as well as non-empirical interpretative methods. By this definition, analysis is no longer restricted to the “empirical-analytical” paradigm of social sciences (Hermann, Heye and Leuthold 2004) or the “analytical philosophy of science” (Boesch 1989). Analysis as basic building block of planning methods should not be put on a level with “linear thinking“ or “scientism“ but potentially embraces further research approaches such as systems theory, phenomenology and hermeneutics (Boesch 1989). In our research project we focus on three basic criteria of analysis: methods and techniques, the connection to communication – analysis as something on-going or as a result – as well as the method of assessment of the analytical results.

Visualisation in the narrower sense applies to the utilisation of pictures as a visual exemplification of a fictional or real situation or matter within planning methods (Sachs-Hombach 2005). In spatial planning typical visual media include maps, plans, blueprints, GIS-visualisations, renderings, photographs, sketches, drawings, mock-ups or diagrams. We restrict visualisations to medial images and ignore their real and mental dimension (Förster and Thierstein 2008). Visualisations are linked to communication as an event or a result. Visualisations as a result gain their weight within planning methods from communicating visual products. In this case the act of visualising is not part of the communicative event. Visualisation as a presentation technique has the ability to – better – communicate certain planning contents. When visualisations emanate from the act of visualising within planning methods, they can be regarded as an event. The action of visualising happens simultaneously with the communicative event. The event of visualising can be both analytic and creative in nature.

The complementary nature of the three building blocks AVC

Today planning theory and practice acknowledge that spatial planning calls for a broad range of different skills and capabilities (Harris 1999; Dangschat, Frey and Hamedinger 2008). However, the evolution of planning theory in the last 60 years is characterized by a sequence of so called "turns" – each of which can be interpreted as the emphasis of certain skills to the detriment of others. The emphasis of the role of analytical or visual or communicative skills within planning theory's turns illustrates the specific capabilities and limitations of each of these skills. For this reason we hypothesise the productive combination of AVC.
Analytical skills are of central importance in the attempt to make spatial planning more scientific early in the 1960s. There is much focus on the study of cause and effect of the built and social environment (Hall 1996; Albers 2004, 2006; Davoudi 2006). When acknowledging the limitations of systems analysis and system optimisation in the 1970s, planning theory is looking for a much more differentiated integration of analytical skills in political as well as design processes (Kunz, Reuter and Rittel 1980; Kunz and Rittel 1984; Harris and Batty 1992; Salama 2008). The turn to "evidence-based planning" from early 2000 capitalizes on analyses as a means of persuasion and engaging planning actors (Böhme and Schön 2006; Faludi and Waterhout 2006). This approach is criticized as follows: the action of analysing cannot be separated from assessing and designing (Harris 1996; Davoudi 2006); therefore analyses have to be embedded in the process of interaction and communication of the different planning actors (Böhme and Schön 2006; Faludi and Waterhout 2006); the interpretation of analytical results demands a creative and iterative process in which visualisations may play an important role (Aring and Sinz 2006; Primas 2008).

Visualisations are fundamental to the understanding of planning as a design-oriented discipline. This goes back to its origins in architecture and engineering. In particular, the synthesis work of spatial planners implies a basic design component that cannot be treated scientifically (Rittel 1988; Hall 1996; Harris 1996; Albers 2004, 2006). Visualisations offer important support to the design process (Rittel 1988; Hacker 1999; Sachse 2002). The creative momentum is also necessary for creating strategies, concepts or plans; in each case the visualisation of spatial patterns and structures is of central importance (Aring and Sinz 2006; Davoudi 2006; Zonneveld 2007; Dangschat, Frey and Hamedinger 2008). The approach of "evidence-based planning" makes use of visualisations to communicate analytical results (Böhme and Schön 2006; Faludi and Waterhout 2006; Zonneveld 2007). Communicative or cooperative planning identifies pictures and visualisations as a means of fostering comprehensibility, clearness and vividness of planning contents as well as awareness among relevant actors – all of this is constitutive in activating stakeholders and players in spatial planning (Faludi 1996; Healey et al. 1999; Salet and Faludi 2000; Fürst 2005; Boelens 2006; Faludi and Waterhout 2006; van den Berg 2006; Zonneveld 2007).

The consideration of communication as a basic skill for spatial planners can be found in the argumentative planning model (Rittel and Webber 1973; Kunz, Reuter and Rittel 1980) and the approach of collaborative / communicative planning (Healey 1992). In this model, planning deals with political and design problems (Rittel and Webber 1973; Harris 1999; Zonneveld 2007). The turn to communicative issues in planning can be traced along the following keywords derived from planning theory and practice: planning is directed towards a process instead of a plan; "governance" in place of "government" as part of a cooperative approach to planning; urban development as a collective process of cooperation and coordination that includes as many players as possible. When broken down into a set of concrete skills that spatial planners need, these approaches require information, cooperation, moderation, mediation, management, bargaining (Healey et al. 1999; Faludi 2000; Salet and Faludi 2000; Knieling, Fürst and Danielzyk 2003; Fürst 2005; Boelens 2006; Heinelt 2006; Knieling 2006; Nadrowski and Wachten 2006; Reiß-Schmidt 2006; van den Berg 2006; Friedmann 2007; Selle 2007; Davoudi 2008; Dangschat, Frey and Hamedinger 2008). Criticism of the one-sided emphasis on communication points up a lack of attention to planning content, deficient expert knowledge of planners (Hall 1996; Huxley and Yiftachel 2000; Schönwandt 2006; Selle 2006) as well as the shortcomings of the creative momentum (Albers 2004, 2006).

This brief synopsis of AVC's roots in planning history shows that AVC emanates from different traditions and working cultures in planning theory and practice. Today these skills form a repertoire that can be drawn on according to the planning problems that have to be tackled – beyond one-sided preferences (Schönwandt 2002; Altrock, Huning and Peters 2004; Fürst 2005). Nevertheless, we would argue that AVC's synergies and complementarities are investigated insufficiently in today's planning research.

3. Meta-analysis of planning literature

The first empirical module of the research project is based on the meta-analysis of international planning literature of the last 10 years. This module points to the exploration of the "space of possibility" of AVC's interplay. The objective is to generate hypotheses that can be tested in real case studies. Based on the primary research question, three questions are examined within the investigation. The first question points to the outcome and impact of planning methods that comprise the skills AVC; the second question focuses on the interplay of AVC within planning methods; the third question investigates external influence on the outcome and impact of methods as well as on the interplay of AVC. The latter includes the three steps within Schönwandt's basic scheme for planning, the different spatial scales of the respective case studies, and the different disciplinary backgrounds of the authors of the scientific articles.

3.1. Meta-analysis – methodology

The meta-analysis is restricted to articles in international peer reviewed planning journals in the period 2000-2011. A systematic screening is carried out along the following criteria: 1) the articles report on the application of planning methods in a real case study; 2) the particular planning methods contain the basic skills communication and/or analysis and/or visualisation; 3) the case studies are located in the Western World; 4) the authors judge the effects – outcome and/or impact – of applied planning methods. The articles report on impact studies, arranged more or less systematically, of planning methods with AVC. The primary quality criterion is the peer review process.

The screening process started with a Boolean search in international search engines that revealed over 2400 findings. These findings were reduced stepwise to 40 articles that feed into the qualitative content analysis. The selection proceeded with 1) a rough selection of nine per cent of all articles by screening title, abstract and keywords 2) a fine selection of 35 per cent of the remaining articles by systematically perusing the abstracts 3) carrying out the content analysis with 152 remaining articles and filtering another 75 per cent that did not fit the predefined criteria. The fine selection included articles from 53 peer review journals that were reduced to 19 journals in the final selection (see table 1).

Table 1: Planning journals and respective articles in the selection process from fine selection to final selection.

Learning from the omitted papers

During the screening process we evaluated the reasons for removing articles from the hit list. This provides valuable considerations for the state of research in planning methods. The fine selection by perusing the abstracts omitted 65 per cent of the initial selection of articles. The applied evaluation scheme integrated the criteria 1) presence of planning methods and 2) their application in a real case study. The evaluation produced the following results: The most important reason to leave out articles is the absence of a real case study while most of the articles are actually devoted to planning methods. In the chosen period of investigation plenty of scientific literature can be found on planning methods. Only a small part of it, however, deals with their application in planning practice. The rest of the articles presumably focus on theories, techniques, and formula of planning methods.

During the content analysis three quarters of the selected articles did not fit our criteria for delineating the effects of applied planning methods. Fundamental reasons for exclusion were:

- Planning methods lack application in a case study or, when actually applied in a real case, they lack a receptive audience. Therefore the effects and impact of planning methods cannot be observed (Affisco 2000; Anderson, Meaton and Potter 1994; Bell 2001; Carlsson-Kanyama et al. 2008; Dortmans 2005; Fenster 2009; Gertler and Wolfe 2004; Guhathakurta 2002; Hermann 2009; Janssen, Goosen and Omtzigt 2006; Lange and Hehl-Lange 2010; Lange 2001; Luz 2000; Malczewski et al. 2003; Newcombe 2003; Nye and Rydin 2008; Robinson 2003; Sanoff 2008; Sheppard 2006; Vervoort et al. 2010; Walker, Bourne and Shelley 2008; Hanewinkel 2009)
- Planning methods are derived from planning theory and respective articles focus on the development of a theoretical concept for planning methods without application in practice (Alshuwaikhat and Nkwenti 2002; Ball 2001; Beers et al. 2010; Bourne and Walker 2005; Rauschmayer and Wittmer 2006; Renn 2006; Selin 2006; Sheppard 2005).
- Authors focus on techniques and detailed procedural steps of planning methods. They are looking for optimisation and improvement of planning methods for given functions and do not examine their effects in a real case (Appleton and Lovett 2005; Bryan 2003; Dockerty et al. 2006; Jessen 2005; Jetter and Schweinfort 2010; Joerin, Thériault and Musy 2001; Konisky and T.C. 2001; Novakowski and Wellar 2008; Özkaynak and Rodríguez-Labajos 2010; Shaw et al. 2009; Talen 2000; Tansey et al. 2002; van de Kerkhof and Wieczorek 2005).
- Articles only deal with the application of methods in planning practice descriptively (Dühr 2003; Jenssen 2010; Özdemir, Basal and Aslan 2010).
- Planning methods are described in respect to their functions as ex-ante supposed impacts instead of ex-post effects (Celino and Concilio; Finn, Hopkins and Wempe 2007; Garrod 2003; Jacob 2006; Kok 2009; Lange, Schroth and Wissen 2003; Wiek, Binder and Scholz 2006)
- Authors point to the implementation and realisation of planning methods with regard to feasibility, acceptance, and comprehensibility to the addressee without assessing the effect of the methods on the planning process (Ben-Zadok 2009; Jankowski 2009; Lord and Hincks 2010; Palerm 1999; Renn 2006; Sheppard and Meitner 2005; Smith 2002).
- Planning methods are assessed from a normative perspective without looking at their effects in a real case (Bond, Palerm and Haigh 2004; Buchecker, Hunziker and Kienast 2003; Carr and Halvorsen 2001; Chilvers and Burgess 2008; Palerm 1999).

This brief summary of main reasons for omitting articles from the meta-analysis illustrates the current need for research on planning methods. In the last few years scientific literature has over-emphasised the dimensions of technique, formula, function of planning methods to the detriment of studying the actual effects and impacts of planning methods in planning practice.

Selected Database

The selected 40 articles for the meta-analysis come from a broad variety of international journals (see table 1); its authors cover a broad range of different disciplines involved in spatial planning (see table 2). The analysis of disciplines is based on the first authors' education and current field of activity as well as the journal specialism. More than half of the articles have two or more disciplinary backgrounds as indicated by the multiple mentions in table 2.

Discipline (multiple mention)	Number of journal articles
Urban and regional planning	11
Landscape planning	8
Environmental sciences and planning	8
Spatial development and planning	8
Geography	7

Hydrology / water management	5
Administrative sciences	4
Political science	4
Landscape ecology / human ecology	3
Forestry	3
Architecture	3
Geology / geo sciences	2
Transport planning	2
Social scieneces	2
Planning theory	2
Screenwriting	2
Agronomy / agricultural sciences	1
Urban design	1
Tourism	1
Agrology / soil science	1
Number of mentions	**78**
Number of disciplines	**20**

Table 2: Disciplines included in the meta-analysis.

The aggregation of theses different disciplines in the four classes 1) planning disciplines, 2) natural and engineering sciences, 3) social sciences and 4) design gives rise to the following picture: 88 per cent of all articles have a link to planning disciplines – no surprise in our research project. 45 per cent of the articles have a background in natural and engineering sciences. These disciplines seem to claim raised demand and efforts for effective planning methods in spatial planning practice. Only 15 per cent of all articles have a background in design disciplines including urban design, architecture and landscape architecture. How is this to be interpreted? The quality criterion of peer reviewed planning journals might be a significant bias for the different disciplines: design disciplines might publish in these journals less frequently than other disciplines as they have a stronger focus on planning practice. Another assumption is the minimal involvement of design disciplines in the planning issues captured in our literature review.

The case studies in the selected articles range from sector planning issues like transport, water, climate change and tourism to more comprehensive, strategic planning issues. 47 per cent of the articles engage in case studies at the spatial scale of municipalities and cities, 40 per cent tackle regional planning cases and a minority of 13 per cent of the articles report from European planning cases.

The content analysis of the chosen scientific articles is carried out along a coding scheme (see figure 3); coding and its qualitative analysis are computer-assisted. The starting point of the coding process is the identification of planning methods; secondly, these methods cause effects that can be attributed to the different stages within Schönwandt's basic scheme for planning; thirdly, the presence of the basic skills AVC within the coded methods is recorded.

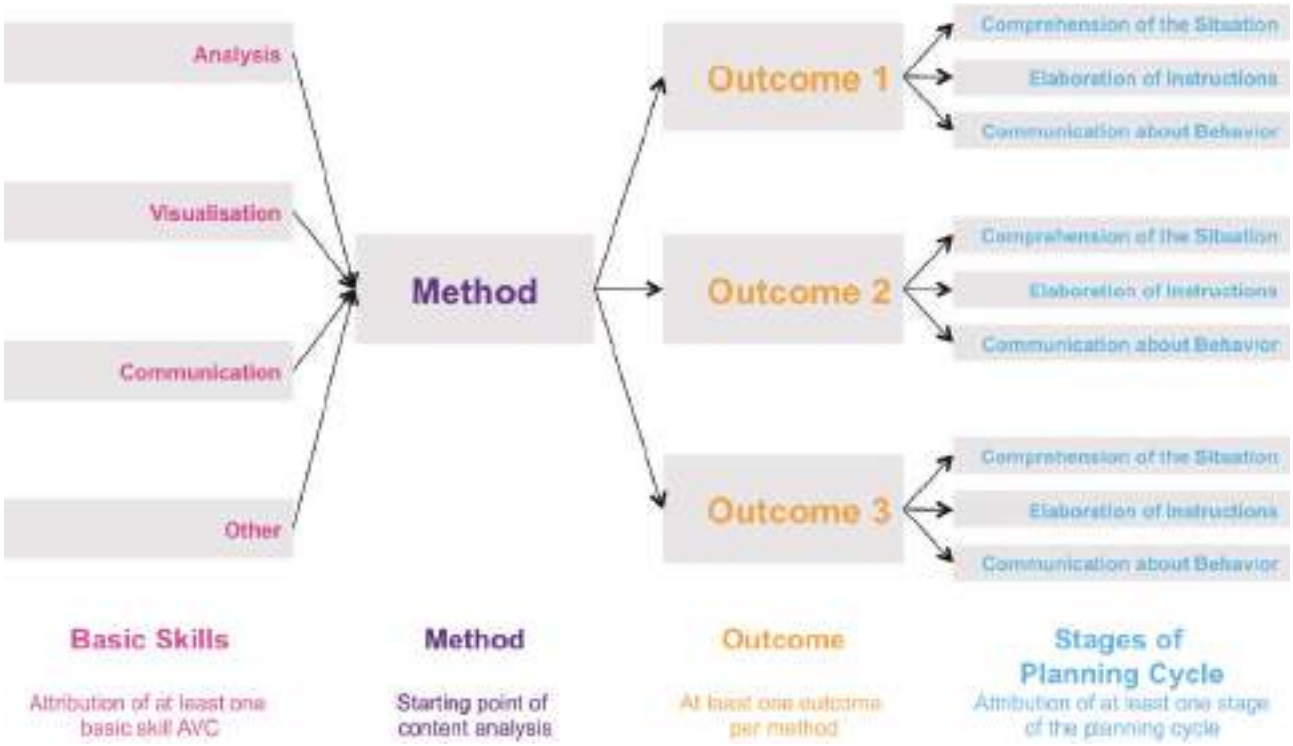

Figure 3: Coding scheme of the content analysis.

The approach of a meta-analysis based on journal articles entails the difficulty that it is not possible to verify the articles' underlying data and its assessment criteria. Moreover, scientific approaches and methods vary from article to article. Nevertheless we regard our approach as adequate to outlining a preliminary "space of opportunities" of AVC's interplay and in this way to conduct an initial test of our general hypothesis.

3.2. Meta analysis – findings

In the subsequent sections we will summarize the results of the meta-analysis. We will focus on research questions one and two. Research question one is:

What positive effects on spatial planning do planning methods that apply the skills AVC generate?

The content analysis assigns 178 codes for effects of planning methods that are subsequently categorised to 27 effects (see figure 4) in a multi-level qualitative analysis process. Effects appear in all three stages of the planning process "Comprehension of the Situation", "Elaboration of Instructions", and "Communication of Behaviour" (see figure 5) and have strong reciprocal effects (see figure 6). The meta-analysis cannot analyse the long-term impacts of these effects to the actual goal achievement of the case studies. The recorded effects should rather be interpreted as impacts that the authors' of the scientific articles perceive and suppose. With the 27 categorized effects, the meta-analysis indicates weighty expectations of spatial planners with regard to the outcomes and impacts of planning methods that apply AVC.

Figure 4: 27 individual effects of planning methods with AVC arranged according to frequency in the study sample of 40 scientific articles.

In the content analysis each of the effects is characterized by a bottom-up definition out of the journal articles. In this paper we extract five out of 27 definitions.

Involvement of laymen

→ ***Laymen and affected parties are involved***

Planning methods support the involvement of a broad range of actors from the “Life World” that are predominantly non-professionals: citizens, involved parties, residents, users, and different groups of stakeholders. These actors are integrated in the planning project at different levels of intensity: from information to active participation in the processes of data interpretation or solution finding. This integration makes use of everyday and local understanding and knowledge, of attitudes and mind-sets, issues and concerns, experience, expectations, users’ perspectives, new approaches and arguments.

(Al-Kodmany 1999; Antunes, Santos and Videira 2006; Berchtold and Krass 2009; Frittaion, Duinker and Grant 2010; Lewis and Sheppard 2006; Schroth, Wissen and Schmid 2006; Söderström and Zepf 1998; Van Herzele 2004; Van Herzele and van Woerkum 2008; van Vliet, Kok and Veldkamp 2010; Ward 2001; Wright, Duncan and Lach 2009)

Spatial context

→ ***Spatial and territorial patterns, orientation and context are incorporated***

Planning methods convey and communicate visual and spatial relationships, connections and patterns as well as invisible, hidden functionalities and correlations. They support the spatial and territorial specification

and concretisation of planning content and the relation to spatial context. They thereby strengthen the link to the everyday life situation of the planning actors and involved parties and foster the comprehensibility of spatial patterns and relations. They take into account perception of space and spatial images of the concerned actors, support spatial orientation in the planning area, and territorial awareness among the stakeholders.

(Al-Kodmany 1999; Aring and Sinz 2006; Berchtold and Krass 2009; Böhme and Schön 2006; Lewis and Sheppard 2006; Söderström and Zepf 1998; Van Herzele 2004; Van Herzele and van Woerkum 2008; Wright, Duncan and Lach 2009)

Collaborative solution finding

→ ***Solutions are developed collaboratively with the actors of the "Life World"***

Planning methods support the integration of the actors of the "Life World" into the process of generating solutions. They enable the step-by-step development of the solution in a process with different actors and support stakeholders and non-professionals of the "Life World" in proposing solutions. The methods allow for a collective authorship of solutions, improving those solutions through the integration of new perspectives and approaches and facilitating the formulation of practical solutions through affected parties.

(Al-Kodmany 1999; Berchtold and Krass 2009; Deelstra et al. 2003; Frittaion, Duinker and Grant 2010; Sandercock 2003; Schroth, Wissen and Schmid 2006; Söderström and Zepf 1998; Van Herzele 2004; Van Herzele and van Woerkum 2008; Ward 2001)

Complex relationships

→ ***Comprehension of complex relationships is fostered***

Planning methods help structuring and surveying unclear, complex relationships. They support a broad and comprehensive understanding of planning content and foster integrated thinking and system comprehension. They enable the comprehension of spatial functionalities, qualities and problems as well as cause-and-effects amongst the protagonists of the "Planning World" and "Life World".

(Antunes, Santos and Videira 2006; Berchtold and Krass 2009; Frittaion, Duinker and Grant 2010; Jensen et al. 2000; Lewis and Sheppard 2006; Mayer et al. 2005; Van Herzele 2004; van Vliet, Kok and Veldkamp 2010)

Implicit knowledge

→ ***Implicit knowledge of actors and stakeholders is integrated***

Planning methods support the integration of implicit, tacit knowledge that is linked to individuals. That includes subjective assessments, perceptions, and experience – with or without spatial reference. Actors and stakeholders contribute their implicit knowledge, make it explicit and thus support the structuring of problems, assessment of problems and solutions as well as integrated thinking. They localise need for action and potential in city quarters, cities or regions, and introduce new points of view.

(Al-Kodmany 1999; Antunes, Santos and Videira 2006; Berchtold and Krass 2009; Frittaion, Duinker and Grant 2010; Golobic and Marusic 2007; Hasse and Milne 2005; Schroth, Wissen and Schmid 2006; Söderström and Zepf 1998; Van Herzele 2004; Van Herzele and van Woerkum 2008; van Vliet, Kok and Veldkamp 2010

Interplay between the individual effects – interdependency network

Planning methods have the ability to simultaneously initiate different effects. In the study sample planning methods on average trigger 4.8 individual effects. This leads us to the interpretation that planning methods are deliberately implemented to simultaneously generate such effects that mutually depend on or reinforce one another. In this way the individual effects interact in an interdependency network. We carried out a quantitative social network analysis that looked at the inter-linkages between the 27 individual effects of the study sample. The formal network analysis helps – from the perspective of the study sample – to identify the key levers for enhancing the effectiveness of spatial planning processes.

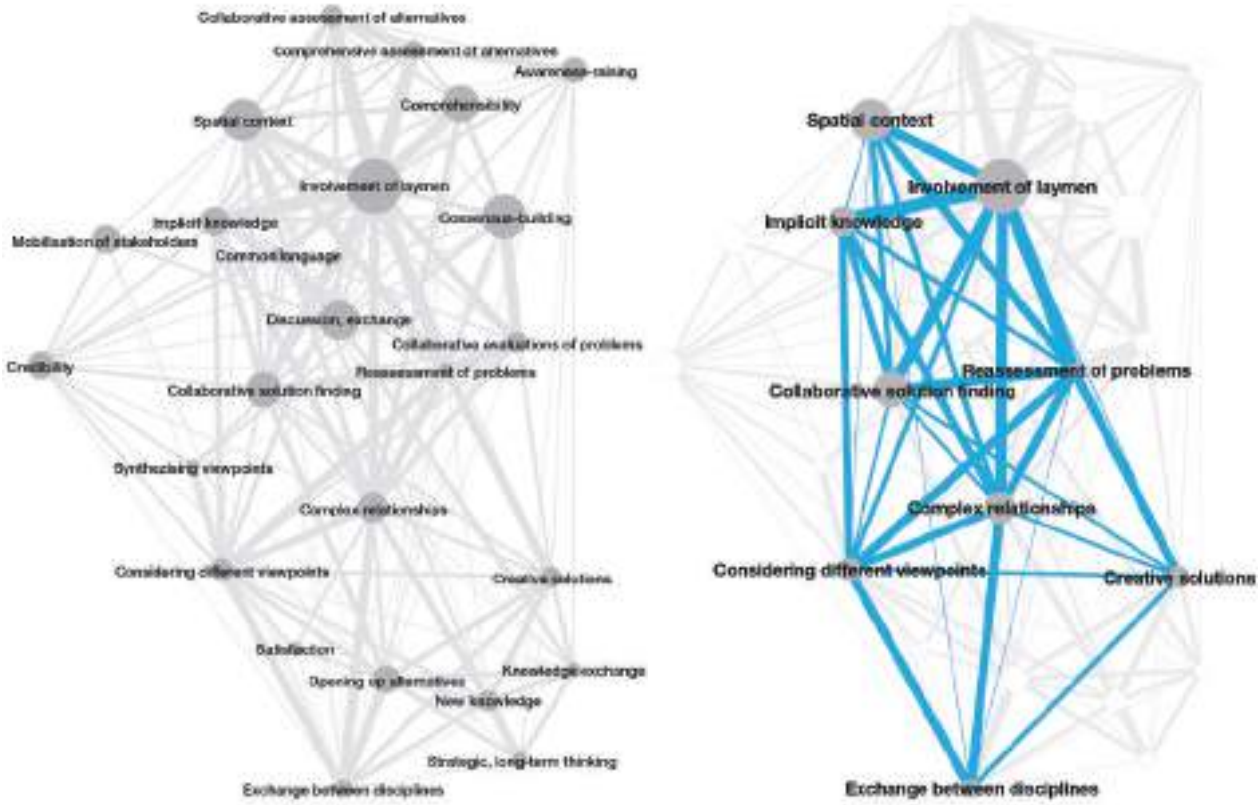

Figure 4: interdependency network of planning methods' individual effects of in the study sample, illustration of all linkages (left) and filter of the most important linkages (right).

The position and relation of an individual effect within the interdependency network demonstrates the importance of an effect for the goal achievement of the study sample's planning projects. The network features a main node "involving laymen" and a secondary node "complex relationships" that are in close exchange. The effects "spatial and territorial dimension" and "implicit knowledge" have a connecting function between these two main nodes.

Effects in the steps of the basis scheme for planning – "specialists" and "generalists"

All coded effects of the study sample feature information on the stages of the planning scheme. This attribution is based on information provided in the journal articles along a rough assessment framework. Consequently the classified 27 effects can be analysed with respect to their approximate position within the scheme of planning (see figure 5).

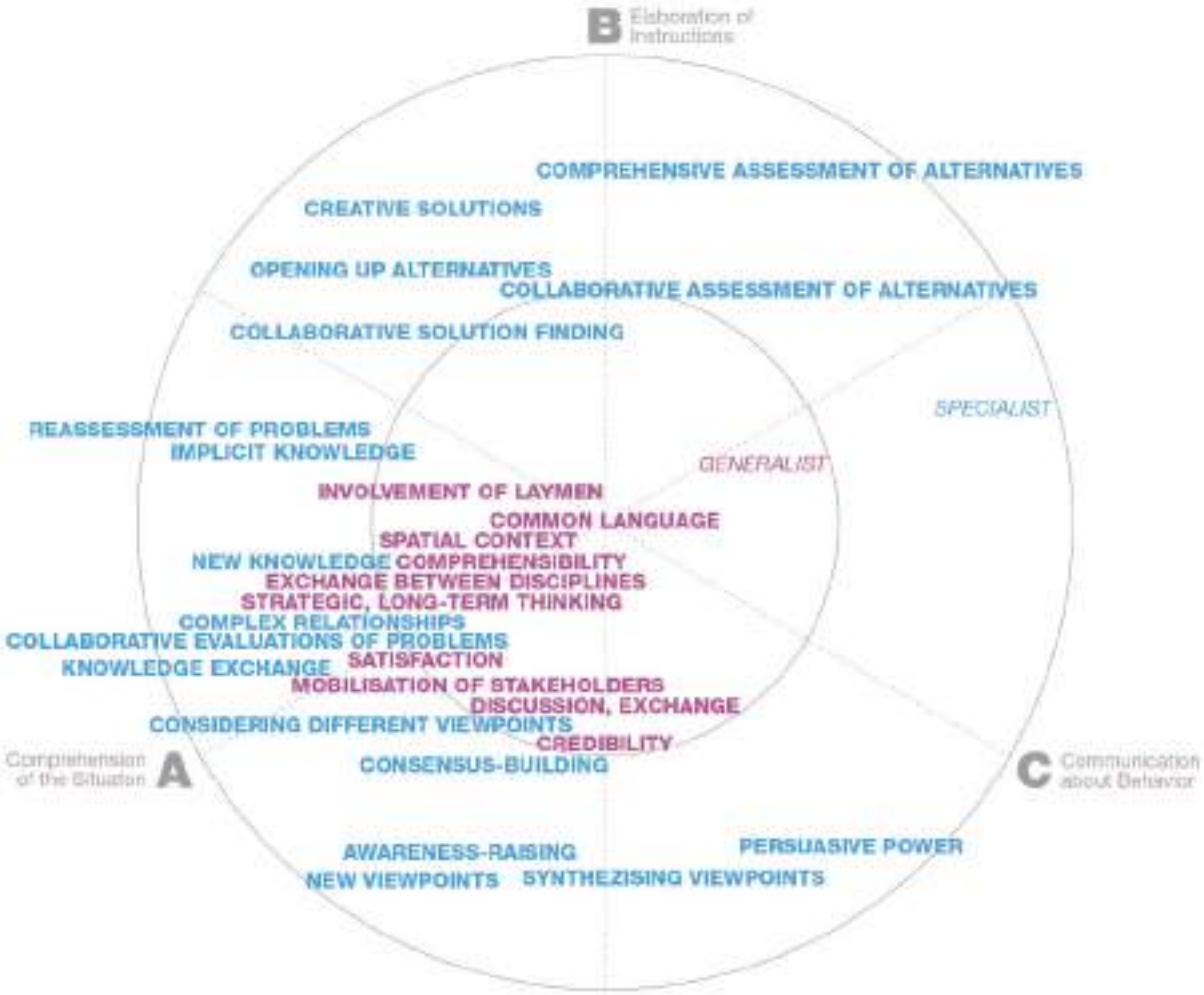

Figure 5: Classification of individual effects of planning methods within the scheme for planning – ranging from “specialist” to “generalist”.

“Specialists” are those effects that primarily operate in the individual stages of the planning process “Comprehension of the Situation”, “Elaboration of Instructions”, and “Communication of Behaviour”. “Generalists”, on the contrary, are effects occurring in all three stages of planning.

This brief and sketchy overview of the results of the meta-analysis related to research question one can be summarized as follows: planning methods with AVC form a dense network of a broad range of expected effects that apply to all three stages of the planning cycle. Although our research approach inevitably captures a diversified understanding of planning methods’ effects, outcomes and impact, we suggest that the AVC approach comprises a suitable scope of skills that significantly determine the potential impact of planning methods.

Research question 2 investigates the interplay of AVC within the planning methods:

How and to what extend does the interplay of AVC contribute to the planning methods’ positive effects?

The meta-analysis shows that the broad range of suggested effects features significantly different characteristics of the basic skills AVC and their respective interplay. The analysis leads us to postulate that the stronger AVC are linked up to one another the more effective the respective methods are. The 27 categories of presumed effects show clearly different profiles in their ACV ingredients (see figure 6). That means that the basic skills AVC, by their complementary nature, add value to spatial planning processes.

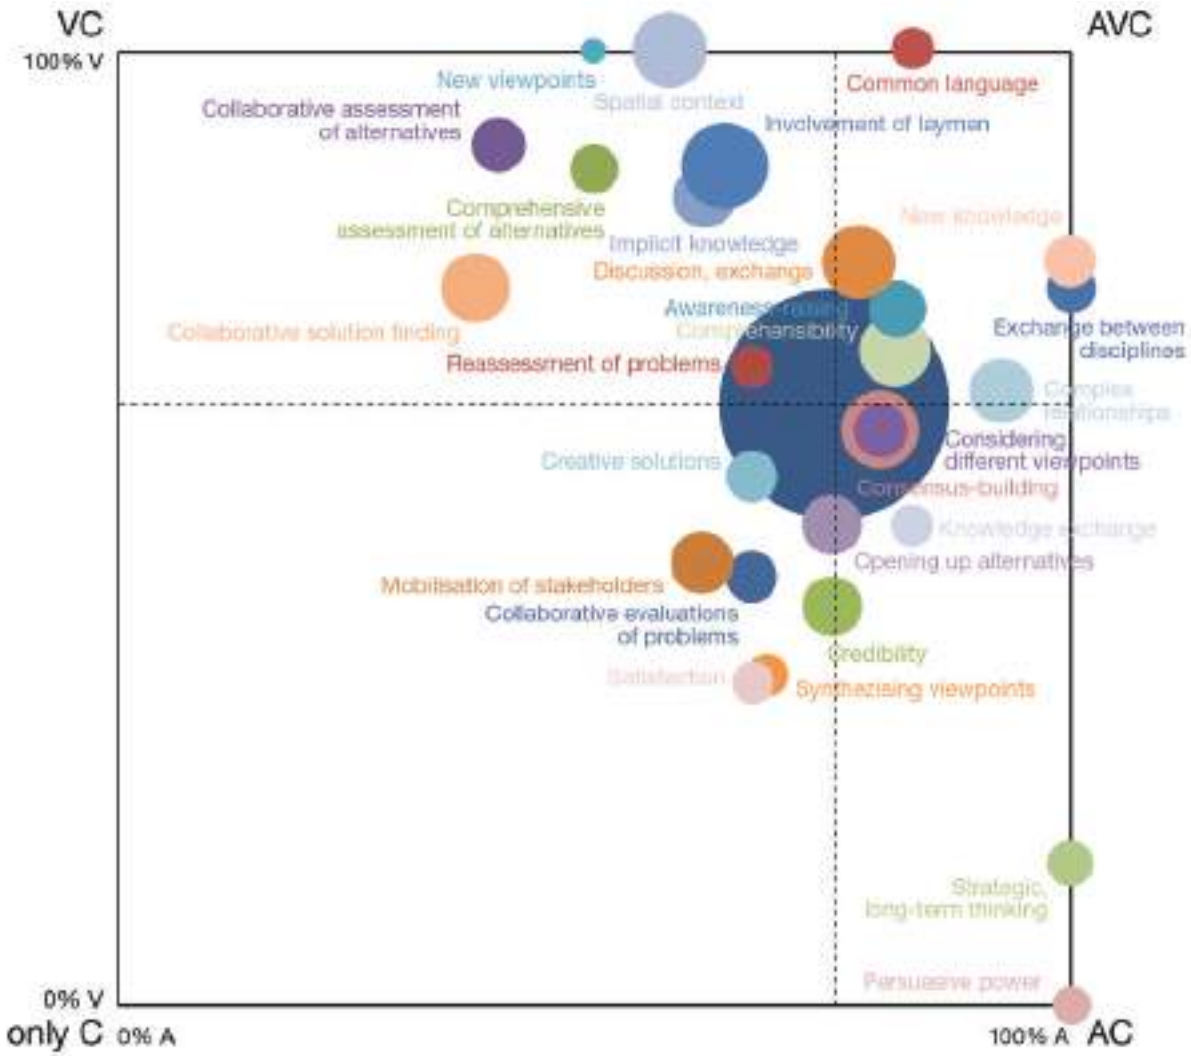

Figure 5: Characteristics of AVC interplay of the different categories of presumed effects within the study sample.

The coding scheme allows correlation of the defined effects with the basic skills AVC that are part of the applied methods. Figure 5 shows the results of the quantitative analysis of AVC ingredients within the 27 categories of effects. The size of the circles indicates the frequency of the effects within the 40 journal articles. The circles' position on the x-axis refers to the portion of analysis within the respective methods; the position on the y-axis reflects the portion of visualisation. Effects that are dominated by predominantly analytical methods, visual methods or a combination of both clearly can be depicted.

The meta-analysis further investigates the relation between the structure characteristic of AVC in planning methods and their attributed effects. Altogether eleven key findings can be drawn from this detailed qualitative study. These findings will here be listed only; further explanation about individual findings can be drawn from Förster and Thierstein 2011 (Förster and Thierstein 2011).

1. The basic skills AVC create positive effects through complementarities and synergies (see figure 5)
2. The interplay of AVC fosters the interdependency network of planning methods' positive effects
3. The interplay of all three skills AVC within planning methods is particularly effective
4. Planning methods that are exclusively based on communicative skills are less effective
5. The interplay of different communicative events within planning methods fosters their positive effects
6. Face-to-face communication is more effective than medial communication
7. The higher the methods' degree of interaction the more effective are the methods

8. Analyses show higher effectiveness when closely linked to communication events
9. Complexity and complementarity of analytical methods fosters planning methods' effectiveness
10. The deliberate design of the process of interpretation and evaluation of analytical results increases effectiveness of planning methods
11. Making use of complementary visualisation techniques improves the positive effects within planning methods.

The analysis reveals clear correspondence between input of AVC and the effects of the methods applied. Despite a number of limitations of our meta-analysis and the study sample, AVC obviously affects the impact of planning methods on the goal achievement of the planning projects. We worked out structure characteristics of analysis, visualisation and communication as well as of their interplay that seem to play an important role for effectiveness of planning methods.

4. Discussion and conclusions

There are a number of important limitations within the meta-analysis: 1) the selection of scientific articles exclusively from peer-reviewed journals entails the bias of considered disciplines and case studies; 2) the meta-analysis focuses only on positive effects of planning methods, their unintentional side-effects are not analyzed; 3) the articles report on the positive effects of planning methods; however, the empirical basis of the authors' findings cannot be assessed; 4) the latter is especially critical when some articles report on effects of planning methods with low priority because the articles focus on other issues.

4.1. Expert workshop and interviews

In order to validate our findings from the meta-analysis we carried out an expert workshop in October 2011 as well as a series of expert interviews with planning practitioners from Munich. The aim was firstly to discuss individual findings from the meta-analysis; secondly to assess the conceptual foundations of our research project and thirdly to check the relevance of our approach and overarching hypothesis from planning research and practice. The participants in the expert workshop and expert interviews were chosen from academia as well as from planning practice from German-speaking countries; a number of planning practitioners from the Munich metropolitan region were included.

The content analysis of the group discussion in the expert workshop reveals four central perspectives on the intermediate results of our research project. These perspectives are based on clusters of arguments closely used together during the discussion. In each perspective the need for further research is indicated.

Specifying our understanding of planning and planning process

The presentation of the concept and intermediate results of our project evoked a lively debate about our underlying understanding of the notion and concept of planning. With Schönwandt's basic scheme for planning we introduced a broad understanding of planning that is not restricted to a particular application – concerning scale, topic area, time horizon or institutional context. Correspondingly, we used multi-faceted case studies in our meta-analysis. In the group discussion participants argued that this broad understanding was too vague and that we therefore cannot learn much from this variety of very different case studies. Some experts point to the great importance of the institutional context on spatial planning that restrains cross-case learning in our study sample. One participant argues that our level of abstraction with regard to spatial planning is too high and hence useless. Another contribution to the discussion favors a restriction of the research project to the comparison of similar and hence more comparable planning cases. A group of participants questions the separation of the three preparatory stages "Comprehension of the Situation", "Elaboration of Instructions", and " Communication of Behaviour" that involve the "Planning World" from the sections "Interventions", "Setting" and "Outcomes" of the "Life World". The contribution of

professional planners should not be restricted to these three stages as outcome and impact of planning projects are substantially determined by its implementation in the “Life World”. The conception of our project deliberately distinguishes the thought process – i.e. the three preparatory stages – from the implementation process. There is still conceptual work to be done in order to specify our understanding of planning process in respect of the applications of the methods on the one hand and their outcome and impact on the other hand.

Deepening the understanding of AVC and examining the role of framing and conceptualising

A number of participants found it difficult to clearly understand the concept of the basic skills AVC. We use the three terms in a specialized sense. On the one hand, participants’ spontaneous reactions to the term visualisation expand the concept to mental images and symbols as well as to all kind of methods that appeal to the senses such as excursions, mobile workshops, literature or sounds. On the other hand, the definition of visualisation is regarded as too extensive as it includes very different kind of phenomena. A central point in the discussion on the basic skills relates to activities such as framing, conceiving or conceptualising. Participants and interviewees argue that the triad AVC should be expanded to these kinds of skills. This remark points to a conceptual problem which we still have to tackle. Firstly we consider AVC as basic skills in order to frame, conceive or to conceptualize alternative solutions. Of course, some additional competencies are needed, such as creative skills. Some of the articles in our study sample refer to collective creative techniques. On the other hand we conceive planning methods as closely linked to media or group communication. In this regard, we neglect those creative techniques that are related only to one person or an internal work group and do not directly address the recipients of the methods.

Elaborating a framework of AVC’s impact that also considers the time axis

The third view of the results of the first research module concerns the analyzed effects of the planning methods. One participant argues that with our database of scientific articles we have collected only impacts that the authors assume instead of factual impacts of planning methods. Zech refers to the fact that many planning practitioners with expertise in the evaluation of planning methods are not used to publishing in peer-reviewed journals. Hence our database is biased. This is certainly true and the interpretation of the results must take account of the logic and rules of scientific publication practice. In addition there is a conceptual problem when assessing the effects of planning methods from a literature review. Each author – at least implicitly – has a different understanding of output, outcome and impact of the methods that she describes. The question is, to what extent does our meta-analysis really capture the impact of planning methods? To clarify this question we need to further conceptualize the idea of the output, outcome, and impact of planning methods on the time axis and with regard to the basic scheme for planning.

Investigating the role of context for the success of planning methods

When further elaborating a concept of impact we also have to specify the role of the context of this impact. Despite the correlation between AVC interplay and the effects of planning methods as shown in figure 5, the meta-analysis cannot elaborate on cause-and-effect between the skills and their respective impact. All workshop participants clearly recognize the importance of the context within which planning methods are applied. The context includes the different stakeholders with respective background knowledge and concerns, organisational structures, financial and human resources, balances of power, legal framework, etc. In order to choose case studies for our second research module we still have to refine the idea of context. The context varies in each planning case and it is important to be aware of the dependent and the independent variables that influence the impact of AVC within spatial planning methods.

4.2. Conclusions

In our paper we presented the intermediate results of an ongoing research project. Based on a conceptual framework, we carried out a first empirical research module and validated the results in an expert

discussion and expert interviews. Although significant need for further research is identified and important conceptual as well as empirical work still has to be done, we consider our approach and our preliminary results as highly relevant for current spatial planning research and practice.

The activity of spatial planning is often regarded as a black box. Beyond the single planning case there is little transferable knowledge on how to effectively design and apply planning methods. This kind of knowledge is most likely found with experienced practitioners. With its empirical orientation, the research project aims to learn systematically from current planning practice. A broad cross-case perspective has been applied in the literature review of the first empirical research module; the second research module will deepen its findings in three focused case studies based on the analysis of primary documents and in-depth interviews.

With the expected results we hope to stimulate the discussion on the financial, temporal and personal resources of planning methods as well as their legal framework. Furthermore, the consequences for planning education will be outlined.

MEASURING PERFORMANCE OF KNOWLEDGE TECHNOLOGIES THAT AIM TO SUPPORT STRATEGY MAKING

Case of Urban Strategy

Dr. Marco te Brömmelstroet
University of Amsterdam, Nieuwe Prinsengracht 130, 1018VZ Amsterdam
0031 20 525 4149 | marco@transport-planning.eu

1. INTRODUCTION

There are a large number of computer based systems that aim to support integrated land use and transport planning; more than 100 in the Netherlands alone (Al 2005). These so-called Planning Support Systems (PSS) have been developed since the 1970s and are still continuously improved. In a recent survey among land use and transport planners in the Netherlands we found that, just as in almost all planning fields, these instrument fail to support an important phase of planning where land use and transport should come together; the strategic planning phase (Te Brömmelstroet 2010). Figure 1 lists the reasons that were found to block the widespread use of these tools in daily practice of integrated land use and transport strategy making.

Figure 1 Bottlenecks for PSS in integrated land use and transport strategy making (% of respondents (124) that think it is a (highly) problematic.

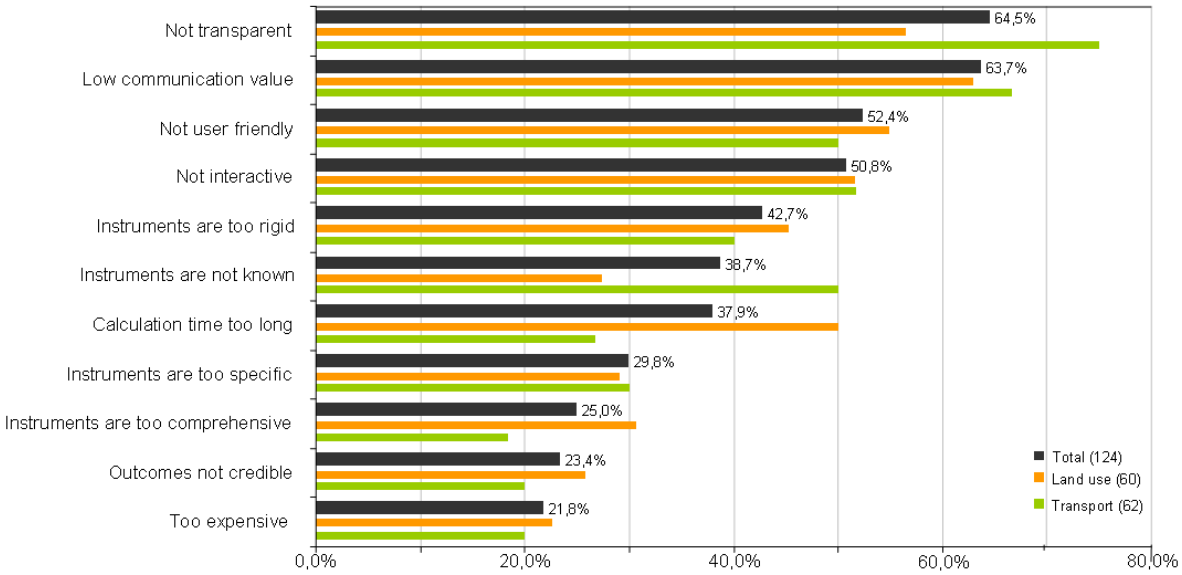

Figure 1 shows that it are mainly soft characteristics that hamper widespread use of PSS. Transparency, low communication value, user friendliness and interactiveness are seen as (highly) problematic by more than half of the respondents. There is no shortage of ideas to bridge what has been coined the implementation gap. Some of these focus on improving PSS software by adding new functionality: PSS that are more integrated (i.e. What If developed by Klosterman 1999), more interactive (i.e. Urban Strategy developed by TNO 2011) or more user-friendly (i.e. UrbanSim developed by Waddell 2002, 2011). Others focus more on the hardware, such as Maptables (see Vonk & Ligtenberg 2009) and other visual gadgets. Then there is the process-oriented line that focuses on bridging the human gap between the potential end-users and the PSS developers with more participative, iterative PSS development structures (i.e. Lee 1973; 1994; Te Brömmelstroet & Schrijnen 2010; Vonk 2006).

In this publication we report on the first family of solution strategies; a more interactive PSS software package. We have experimented with a state-of-the-art PSS called Urban Strategy that has been developed in the Netherlands in recent years. The goal of this experiment was to find out if urban Strategy enabled a bridge over the PSS implementation gap. To do so, we first need to define how we measure usability or use of a PSS (section 2). Then, we describe the set up of the experiment (section 3). Before concluding the report and discussing implications of our findings in section 5, we report the outcomes of the experiment (Section 4).

2. ASSESSING USABILITY OF PSS

Recently we have developed a instrument that enables us to structurally test if improvement strategies for PSS are successful (Te Brömmelstroet, 2011). It is based on the idea that PSS have (one of) two main goals: First, improving planning *processes* by structuring them better and/or making them more interactive, integrative and participatory. Next to that PSS aim to improve the *outcomes* of these processes (e.g. strategies, plans and projects) by providing relevant knowledge and facilitating a design-analysis loop: 'linking knowledge to actions in the public domain' (Friedmann 1987). Especially in strategic planning this link is particularly problematic. Couclelis asserted that strategic planning

> "is a hopelessly complex human endeavour. It involves actions taken by some to affect the use of land controlled by others, following decisions taken by third parties based on values not shared by all concerned, regarding issues no one fully comprehends, in an attempt to guide events and processes that very likely will not unfold in the time, place, and manner anticipated" (Couclelis, 2005; p. 1355).

The subject of strategic planning is often referred to as 'wicked problems' (Rittel and Webber, 1984), for which there are no clear-cut answers or solutions. It is the development of the capacity to deal with these problems, rather than final solutions that is the general aim of strategic planning. Planners here (should) aim to become aware and learn to cope with complexity and the "unknown unknowns" (Taleb, 2007) instead of collecting knowledge to reduce it/them.

Both aims of PSS are being translated into a multidimensional framework. Based on academic literature on ideational output (e.g. Dean et al. 2006) we operationalise the quality of the outcome in the dimensions *novelty*, *workability*, *relevance* and *specificity*: i.e. a good planning outcome is novel, workable, relevant and specific. Based on academic work on Group Model Building (Rouwette et al. 2002) we operationalise the quality of the process in the dimensions *reactions*, *insight*, *commitment*, *behavioural change*, *communication*, *shared language*, *consensus*, *system changes*, *further use of modelling* and *efficiency*.

The dimensions are then translated into statements. The once for process are presented in table 1 and are rated by the participants themselves. The once for outcome are presented in table 2 and are rated by external raters.

Table 1 Dimensions of outcome and their operationalisation

Dimension	Operationalization	Measure statements (9-point Likert scale, asked to external raters)
1. Novelty	1a. Originality	The strategy is ingenious. The strategy is imaginative. The strategy is surprising. The strategy is novel
	1b. Paradigm relatedness	The strategy is radical. The strategy is transformational.
2. Workability	2a. Implementability	The strategy can be easily implemented.
	2b. Acceptability	The strategy is socially acceptable. The strategy is legally acceptable. The strategy is politically acceptable.
3. Relevance	3a. Applicability	The strategy clearly applies to the stated problem.
	3b. Effectiveness	The strategy will solve the problem. This is an effective strategy

4. Specificity	4a. Completeness	The strategy can be decomposed into independent subcomponents. The strategy covers who The strategy covers what The strategy covers where The strategy covers when The strategy covers why The strategy covers how
	4b. Implicational explicitness	There is a clear relationship between the recommended action and the expected outcome.
	4c. Clarity	The strategy is clearly communicated with regard to grammar and word usage. The strategy is easy to understand

Table 2 Dimensions of process and their operationalisation

Dimension	Operationalization	Measure (statements on Liker scale; asked to participants)
5. Reaction (I)	5a. Enthusiasm	I have a good feeling about the session The session resulted in valuable results
	5b. Satisfaction	The session was successful. I am satisfied with this session. I am confident that the group solution is correct
	5c. Credibility	The results of the session offer real solutions for the problem The results of the session are based on correct assumptions on the underlying system
6. Insight (I)	6a. Insight in problem	My insight into the problem has increased. The session has given me more insight into the relations between the elements that compose the problem. It is clear to me what the causes of the problem are. I now have more insight into the processes that play a role in the problem. The session has given me insight into the possibilities that my organisation has in 'steering' the problem. The session resulted in new insights.
	6b. Insight in assumptions	My understanding of the opinions of the other participants about the problem has increased. I understand how other participants in the session perceive the problem. I better understand the proposed solutions of other participants in the session.
7. Commitment (I)		I support most of the results that were drawn during the session. I will communicate the results of the meeting in front of other members of my organisation. I will try to convince others in my organisation of the importance of the results.
8. Behaviour (I)		I will use insights from the session in my daily planning practice
9. Perception of Communication (G)		The process has given me insight into the opinions and ideas about the problem of other participants.
10.Perception of development of shared language (G)		During the sessions we have developed a shared professional language During the sessions a platform emerged that supported the sharing of ideas
11. Perception of consensus (G)	11a. On problem	We have reached a shared vision of the problem. The results integrated diverse opinions and ideas of the

		participants. We were able to reach a consensus on the problem.
	11b. On goals	We have reached a shared vision on the goals
	11c. On strategies	We have reached a shared vision on the possible solutions
12. Perception of cohesion (G)		I had a strong sense of being part of a group The session brought me closer to the other participants We experienced conflict during the session There was conflict about the task we had in the session
13. Efficiency gains over traditional method		The session was time efficient We were able to perform the work with less effort than in regular sessions We were able to perform the work in less time than in regular sessions We were able to do more in the same time compared to regular sessions

3. SETUP OF THE EXPERIMENT

3.1 Intervention: Urban Strategy PSS

TNO started around 2005 with the development of a PSS – Urban Strategy (Borst et al. 2007; 2009a; 2009b) – specifically aiming to bridge the existing flexibility- and communication bottlenecks. Urban Strategy aims to improve complex spatial planning processes on the urban- and regional level. To do this, different computer models are linked to a central database and interface to provide insights in a wide area of urban indicators and maps. The effects of interventions in infrastructure, land use, build objects and their functions can be calculated and visualized. Because the PSS is able to calculate fast and present the results in an attractive 1D, 2D and 3D visualisation this can be used in interactive sessions with planning actors.

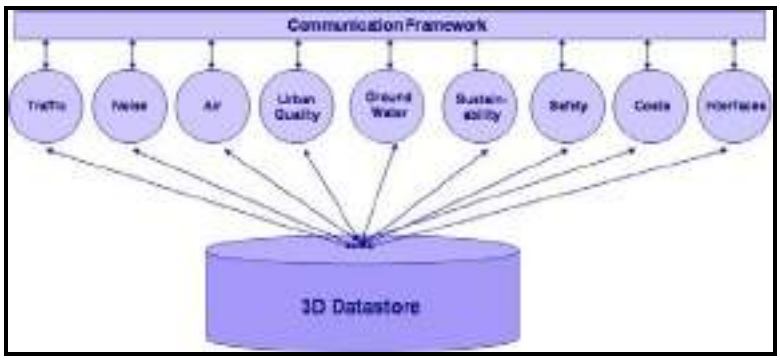
Starting point for Urban Strategy is the use of existing state-of-the-art and legally accepted models. To link these existing models a number of new elements were developed:
- a database with an uniform datamodel;
- interfaces that show a 3D image of the modeled situation, indicators and that offer functionality to add interventions;
- a framework that structures the communication between the models and the interfaces.

3.2 Mechanisms: how does Urban Strategy bridge the PSS implementation gap?

The goal of Urban Strategy is to enable planning actors in workshop sessions to communicate their ideas and strategies to the PSS and to learn from the effects that are shown. This interactivity calls for fast calculations of all the model and fast communication between all elements. For this, the models were enabled to respond on *events* (urban interventions from the participants in the workshops. A new software architecture was developed to have all these elements communicate (figure 2).

Through this increases speed and the wide variety of models that are linked together, the PSS aims to be highly flexible in offering answers to a large number of questions that a group of urban planning actors can have.

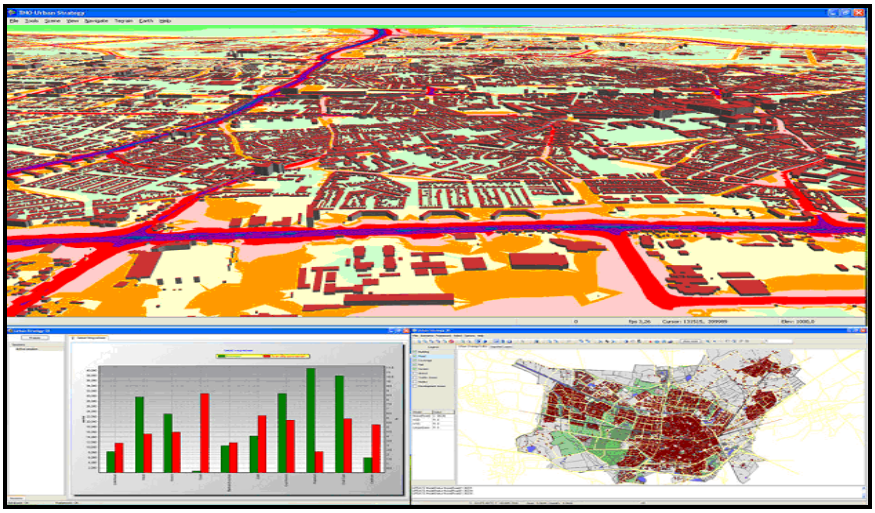
Figure 2 Schematic overview of communication architecture of Urban Strategy.



The 3D interface generates, based on objects in the database, a 3D digital *maquette* of the urban environment. To this, different information layers can be addes, such as air quality contours, noise contours and groundwater levels. Also, the objects can be colored according to their characteristics (function, energy use, CO2 emissions, number of inhabitants, etc). The 2D interface can be used by the end user (or operator) to add changes to the database. Objects can be added or removed, their location can be changed and the characteristics of the object can be changed. The 1D interface shows

indicators that are calculated by all the models that are included. Examples are the percentage of noise hindrance, group risk in an area or the contribution of types of objects to CO2 emission.

Figure 3 The three interfaces of Urban Strategy



3.3 A two group treatment experiment

Together with TNO we organized two sessions in which the usability of Urban was tested. For this we set up a typical urban planning problem: where to allocate a large number of new houses and jobs from an accessibility point of view in the western part of Rotterdam (appendix I). The groups were told that their results would be assessed on novelty, workability, relevance and specificity (the dimensions of table 1).

We invited seven second year Urban Planning students from the University of Amsterdam based on their excellent performance in the course '*Planning voor Ruimte en Mobiliteit*' in 2010. They represented future planning practitioners that deal with planning challenges such as the abovementioned. The seven students were randomly split into two small groups. Each group was then asked to find the best solution for the proposed urban planning problem.

Both groups were treated in a similar way. They each got 70 minutes to process the information n on the problem, get acquainted with Urban Strategy and then come up with a solution for the planning problem. First they were asked to individually read the assignment. After they signaled that they read it, Ralph Klerkx started to introduce Urban Strategy to the group. In 10 minutes, he showed the functionality of the instrument and what can and cannot be done with it. After this introduction Ralph guided the groups in finding solutions for the planning problem. A TNO colleague did the hands-on work of translating the interventions of the students into Urban Strategy and starting the calculations to show the effects of certain interventions.

After a small number of iterations (planning interventions and seeing their effects) both groups had to draw up an integrated land use and mobility strategy for the region

Next to the support by Urban Strategy (the PSS and the support by Ralph and his TNO colleague) the groups had pens and paper to their disposal. Also, a number of maps of the area were printed on A3 size and positioned on the table. Both groups used these maps to present their strategy and added a written explanation to it.

4. TWO SESSIONS OF STRATEGY MAKING

The two groups applied a different strategy making style. In this section we will shortly describe the most notable differences and similarities

4.1 Group 1 (4 persons)

The first group consisted of four male urban planning students with a background in land use and mobility studies. The group started with an introduction to Urban Strategy by Ralph. 1 of the participants asked questions about the OD matrix and the network that is used to calculate effects.

The strategy making started from a bottleneck point of view (the bridges are congested, this needs to be solved). There is one person that takes the lead in the process while another responds to the ideas of this person. The response is mostly done based on information in the maps (by pointing to them). When the group wants to start testing the first idea of a housing strategy they ask if they can see the zones that are used to calculate the effects because they want to use this as their scale of reference (i.e. 25.000 new houses in one zone, more detailed allocation not a question in these kinds of strategic questions). Urban Strategy is adapted to show these zones. The group then asks many questions about what they exactly see in the maps. They keep a very analytical stance in the process. They keep asking questions about the limits of the models behind the results. Although they test some of their assumptions and share their tacit knowledge, they are showing a lack of confidence in the results. They only used Urban Strategy to look at traffic intensities (mainly on the bridges) and stayed on a very abstract level of detail. In general this group followed a design – evaluate – design – evaluate approach.

4.2 Group 2 (3 persons)

The second group consisted of three male urban planning students with a background in land use and mobility studies. During the introduction of Urban Strategy one participants asks clarification on the legend that is used in the traffic intensity map. Another participant asks questions relating to the borders of the model: what can(‘t) it do?

The strategy making is started as an individual exercise. The participants started to individually think, look and draw. The first idea that is put to the test is the extension of the road network to connect the new tunnel. With this, the group hopes to solve some of the congestion and externalities of the east-west corridor through the city. During the drawing of this new road in Urban Strategy, the system created several errors. In the end, the system had to go back to the starting position, because the network was not functioning properly any longer.

5. OUTCOMES

5.1 Quality of outcome

The total number of participants (7) and groups (2) are too small to make significant statements about the effects of Urban Strategy. We also did not have a control group of students that dealt with the planning problem in a business-as-usual scenario (i.e. no support from a PSS). However, the results are still offering valuable insights.

Three experts (PhD students in the area of integrated land use and transport planning) were asked to rate the outcomes of the two groups (the two integrated land use and transport strategies). They were asked to rate the statements in table 1 on a seven point Likert scale. Table 3 shows the average of the six scores (three raters times two strategies) on all statements and on the four dimensions.

Table 3: Quality of the outcome

	Score	**Group 1 (4p)**	**Group 2 (3p)**	**N**
Novelty	**3,6**	**3,4**	**3,7**	
Originality	**3,0**	**2,5**	**3,6**	
The strategy is ingenious	*2,8*	*2,5*	*3,0*	*4*
The strategy is imaginative	*3,5*	*3,0*	*4,0*	*4*
The strategy is surprising	*3,2*	*2,7*	*3,7*	*6*
The strategy is novel	*2,7*	*1,7*	*3,7*	*6*
Paradigm relatedness	**4,2**	**4,3**	**4,0**	
The strategy is radical	*3,7*	*4,0*	*3,3*	*6*
The strategy is transformational	*4,7*	*4,7*	*4,7*	*6*
Workability	**3,9**	**2,9**	**4,2**	
Implementability	**3,4**	**3,0**	**3,7**	
The strategy can be easily implemented	*3,4*	*3,0*	*3,7*	*5*
Acceptability	**4,1**	**2,8**	**4,3**	

The strategy is socially acceptable	~~*3,0*~~	~~*1,0*~~	~~*4,0*~~	*3*
The strategy is legally acceptable	*4,3*	*3,5*	*5,0*	*4*
The strategy is politically acceptable	*4,0*	*4,0*	*4,0*	*4*
Relevance	**3,1**	**2,5**	**3,8**	
Applicability	**3,4**	**3,3**	**3,5**	
The strategy applies to the stated problem	*3,4*	*3,3*	*3,5*	*5*
Effectiveness	**2,9**	**1,8**	**4,0**	
The strategy will solve the problem	*3,0*	*2,0*	*4,0*	*4*
This is an effective strategy	*2,8*	*1,5*	*4,0*	*4*
Specificity	**2,9**	**2,5**	**3,4**	
Completeness	**2,9**	**2,6**	**3,2**	
The strategy can be decomposed.	*4,8*	*4,0*	*5,5*	*4*
The strategy covers who	*1,0*	*1,0*	*1,0*	*6*
The strategy covers what	*4,3*	*3,7*	*5,0*	*6*
The strategy covers where	*5,3*	*5,3*	*5,3*	*6*
The strategy covers when	*1,2*	*1,3*	*1,0*	*6*
The strategy covers why	*1,7*	*1,0*	*2,3*	*6*
The strategy covers how	*1,8*	*1,7*	*2,0*	*6*
Implicational explicitness	**2,5**	**1,3**	**3,7**	
There is a clear relationship between the recommended action and the expected outcome.	*2,5*	*1,3*	*3,7*	*6*
Clarity	**3,3**	**2,7**	**3,8**	
The strategy is clearly communicated	*2,8*	*2,0*	*3,7*	*6*
The strategy is easy to understand	*3,7*	*3,3*	*4,0*	*6*

* The statements that were rated by half of the (less than) raters (*grey*) are excluded from the calculations.

In a lack of a control group the only reference point that we have is an expected average. Following this, we could state that each score under 3,5 is relatively bad and above 3,5 is relatively good. The average aggregated score for the quality of the outcome is 3,3. However, there is a large difference between the two groups (resp. 2.8 and 3.8).

The dimensions novelty and workability are rated as good, although only slightly above average (resp. 3,6 and 3,9). There are also a very limited number of statements that score relatively good. On average the two strategies are rated as relatively radical (3,7) and transformational (4,7) legally and politically acceptable (4,3 and 4,0) and decomposable (4,8), especially into what (4,3) and where (5,3)

The lowest scores are related to the sub dimensions originality (3,0), effectiveness (2,9), completeness (2,9) and explicitness (2,5). The expert raters have low rates on the statements for ingeniousness (2,8), novelty (2,7) and effectiveness (2,8). They also think that there is too little information in the strategies on who (1,0), when (1,2), why (1,7) and how (1,8).

5.2 Quality of process

To assess the quality of the process the seven participants were asked to rate the statements from table 2 on a seven point Likert scale. This again means that an average score above 3,5 equals a relatively good score and below 3,5 a relatively bad one. Although the number of participants is too

low to show significant patterns, all dimensions show a positive result. The overall aggregated average for the quality of the process is 4,0.

Table 4: Quality of the process

	Score	Group 1 (4p)	Group 2 (3p)	N
Reaction	**3,6**	**3,1**	**4,3**	
I have a good feeling about the session	5,3	4,5	6,3	*7*
The session resulted in valuable results	2,7	1,8	4,0	*7*
The session was successful	4,3	3,3	5,7	*7*
I am satisfied with this session.	4,6	4,3	5,0	*7*
I am confident that the group solution is correct	3,1	1,5	5,3	*7*
The results of the session offer real solutions for the problem	2,3	2,0	2,7	*6*
The results of the session are based on correct assumptions on the underlying system	2,6	2,8	2,3	*7*
Insight	**4,2**	**4,2**	**4,3**	
My insight into the problem has increased	4,7	4,8	4,7	*7*
The session has given me insight into the possibilities that my organisation has in 'steering' the problem	5,0	5,0	NoData	*1*
It is clear to me what the causes of the problem are.	4,0	3,3	5,0	*7*
I now have more insight into the processes that play a role in the problem	4,5	5,0	4,0	*6*
The session has given me more insight into the relations between the elements that compose the problem.	4,3	4,5	4,0	*7*
The session resulted in new insights	4,7	5,0	4,3	*7*
My understanding of the opinions of the other participants about the problem has increased	3,8	3,7	4,0	*6*
I understand how other participants in the session perceive the problem	4,3	4,0	4,7	*6*
I better understand the proposed solutions of other participants in the session.	3,6	3,0	4,0	*5*
Commitment	**4,4**	**3,3**	**5,0**	
I support most of the results that were drawn during the session	4,4	4,0	5,0	*7*
I will communicate the results of the meeting in front of other members of my organisation	4,5	4,5	NoData	*2*
I will try to convince others in my organisation of the importance of the results	1,5	1,5	NoData	*2*
Behaviour	**5,0**	**5,0**	**5,0**	
I will use insights from the session in my daily planning practice	5,0	5,0	5,0	*6*
Perception of communication	**4,0**	**3,3**	**4,7**	
The process has given me insight into other people's opinions and ideas about the problem	4,0	3,3	4,7	*6*
Perception of development of shared language	**4,1**	**4,1**	**4,2**	
During the sessions we have developed a shared professional language	3,9	3,8	4,0	*7*
During the sessions a platform emerged that supported the sharing of ideas	4,4	4,5	4,3	*7*
Perception of consensus	**5,1**	**4,5**	**5,8**	
We have reached a shared vision of the problem	5,3	5,0	5,7	*6*

The results integrated diverse opinions and ideas of the participants	4,4	4,0	5,0	*7*
We were able to reach a consensus on the problem	5,3	5,0	5,7	*7*
We have reached a shared vision on the strategic goals	5,1	4,3	6,3	*7*
We have reached a shared vision on the possible solutions	5,1	4,3	6,3	*7*
Perception of cohesion	**4,9**	**3,7**	**4,1**	
I had a strong sense of being part of a group	5,7	5,3	6,3	*7*
The session brought me closer to the other participants	4,7	4,0	5,7	*7*
We experienced conflict during the session	(-) 2,6**	(-)2,5	(-)2,7	*5*
There was conflict about the task we had in the session	(-) 2,4	(-)3,0	(-)1,7	*7*
Perception of efficiency gains	**3,9**	**4,6**	**4,3**	
The session was time efficient	3,9	4,3	3,3	*7*
We were able to perform the work with less effort than in regular sessions	*3,3*	*6,0*	*2,0*	*3*
We were able to perform the work in less time than in regular sessions	*5,0*	*4,0*	*6,0*	*2*
We were able to do more in the same time compared to regular sessions	*4,7*	*4,0*	*6,0*	*3*

* The statements that were rated by less than half of the participants (*grey*) are excluded from the calculations.

** The statements with a minus are negative statements (the lower the rate, the better the score).

Of the dimensions, the perception of consensus has the highest score of 5,1. However, there are large differences between the two groups. In the first group of four persons this was rated with 4,4 and in the second 5,8 The participants were especially content with the shared vision (5,3) and consensus (5,3) on the problem. If we look to the separate statement, it is noteworthy that the participants rate the "sense of being part of a group" highly (5,7).

On the negative side, the participants think that the sessions do not offer real solutions for the problem, rate the value of the results fairly low and also doubt if the results are based on correct assumptions about the land use and transport system.

6. CONCLUSIONS AND IMPLICATIONS

Although these two treatment groups only give us some first insights, we can already identify some interesting directions. It seems that Urban Strategy in its current form has difficulties in supporting integrated land use and transport strategy making on the urban scale.

6.1 Conclusions relating to the measurement framework

In this report we have operationalized the goals of PSS (to improve planning) into a measurement framework of two multidimensional concepts: the quality of the outcome (rated by external experts) and the quality of the process (rated by the participants). All parameters were measured on a 7-point Likert scale.

Since we have not yet measured a control group, it is difficult to state what the value of the framework is. The differences that occur between the two groups (both underwent the same treatment) might hint to the fact that the reliability of the indicators is weak. It can also indicate that the composition of the group of participants has a strong influence on the measured indicators.

Especially in some of the statements that were rated by the external experts, a high standard deviation was found, indicating that measurement validity can be weak. We will have to do a more in-debt analysis on these specific indicators and see where this lack of agreement comes from.

6.2 Conclusions relating to Urban Strategy

From the first results of this experiment, it seems that Urban Strategy in its current form has very little positive effect on the quality of the outcome (3.3) and quality of the process (4,0) of integrated land use and transport strategy making. Observations of the sessions strengthened this finding. It seemed that the scale and level of detail are currently not well tuned to the demands of the land use and transport strategy makers. Also, the kind of indicators used (IC maps, noise areas) are not well suited for the kind of questions that are asked in this planning domain.

APPENDIX I

Vervoersplanologische uitdaging

Rotterdam West (zie kaart 1) kent tot 2030 een grote ruimtelijke- en mobiliteitsopgave. Zo moeten er in het gebied ruimte worden gevonden voor een groot aantal nieuwe inwoners en banen. Ook de omgeving van het gebied is vol in ontwikkeling, met als voornaamste verandering de aanleg van de Tweede Maasvlakte in het westen. Deze opgave resulteert in een enorme druk op het wegennetwerk van de stad, omdat goederen moeten worden afgevoerd en tegelijkertijd de inwoners en arbeidsplaatsen bereikbaar moeten blijven.

Strategie rondom nieuwe oeververbinding

De Stadsregio Rotterdam denkt momenteel aan het creëren van een nieuwe oeververbinding in het gebied als oplossingsrichting voor dit complexe vraagstuk, waarbij er 2 mogelijke varianten worden onderzocht (zie kaarten 2 (verkeer), 3 (lucht) en 4 (geluid)). Dit is ook het startpunt van jullie opdracht. Jullie worden als vervoersplanologisch team gevraagd om een integrale ruimte- en mobiliteitstrategie te maken voor het gebied. De opgave dient met de volgende zaken rekening te houden:

- Er moeten 25.000 nieuwe inwoners en 25.000 nieuwe banen worden toegevoegd aan het gebied
- De strategie moet ervoor zorgen dat het mobiliteitssysteem goed blijft functioneren, ook na uw interventies.
- Bij het maken van de strategie moeten jullie rekening houden met leefbaarheidsaspecten (met name geluid en luchtkwaliteit)

The Intention of Residents in Urban Renovation

-A case study in Tainan, Taiwan

Hsiang-Leng CHEN[1], Wei-Ju CHANG[2], Ko-Wan Tsou[3]

Abstract

Recently, urban Renovation became one of the most important strategies for the government to implement urban regeneration. It more focuses on improving community environment or buildings. The government had tried many different ways to encourage people to participate in urban renovation projects, such as tax exemption, floor area incentive, and subsidies. However, despite of its great promotional effort, the government had not seen results. Thus, this research set out to reveal the key factors which can influence the intention of residents in urban renovation.

A conceptual model of this study was built in two steps. First, social cognitive theory, theory of planned behavior, and technology acceptance model were applied to analyze residents' behavior in urban renovation. Second, key impact factors which influence the intention of residents were revealed through literature review and pilot text. Once the theoretical model was built, a questionnaire was designed based on the model to understand the intention of Tainan residents. Structural equation modeling was then applied to survey result to modify the conceptual model in order to estimate the most likely relationships between the variables.

There are two major accomplishments in this research. First, a conceptual model of resident's intention in urban renovation was built. The key impact factors are personal attitude, perceived usefulness, neighbors, residential dissatisfaction and perceived ease of use. Researchers can apply this model in different studies to reveal residents' intention in urban renovation. Second, the results of the structural coefficients show

[1] Post-doctoral researcher, Department of Urban Planning, National Cheng-Kung University, Taiwan. Email: z10010058@email.ncku.edu.tw
[2] Research assistant, National Cheng-Kung University, Tainan, Taiwan. Email:weiju@mail.ncku.edu.tw
[3] Professor, Department of Urban Planning, National Cheng-Kung University, Taiwan. Email:uptkw@mail.ncku.edu.tw

that residential dissatisfaction and personal attitude were identified as the most important factors to influence Tainan residents' intention. In addition, people are more concerned about the quality of community environment than the buildings themselves. Thus, Tainan city government should implement projects from a neighborhood or local community. Furthermore, not only tell residents how many subsidies the government can provide but also show them how much the urban renovation project can improve their environment.

1. Introduction

In the context of urban regeneration (UR), governments generally seek to implement policies aimed at improving the social and physical environment. Moreover, it is an important issue for promoting a sustainable city (Roberts& Sykes (*2000*) ; Wallbaum .et al , 2011) Unfortunately, these policies usually fail, or have unsatisfying results (Mathers .et al,2010). Many studies have tried to explore the reasons behind the unsatisfactory results of such policies, most of past studies focused on improving the policy or providing more incentives. However, residents play a more and more important role in urban regeneration affairs. A UR project cannot be succeed without resident's support (Gullino, 2009; Chen, 2009). However, the factors that influence residents' intention in urban regeneration still remain relatively unclear. Thus, this research set out to reveal the key factors which can influence the intention of residents in UR.

In Taiwan, urban renovation became one of the most important strategies to implement urban regeneration since 2009. It more focuses on improving community environment or buildings. The government had tried many different ways to encourage people to participate in urban renovation projects, such as tax exemption, floor area incentive, and subsidies. However, despite of its great promotional effort, the government had not seen results. Comparing with other UR policies, local residents play the most important role in urban renovation project. Residents can be the main developer, and implement the project without any other private sectors. Thus, it is an appropriate example to understand the intention of the resident.

2. Model development

This part will start from reviewing the theories utilized in this study and then outlines the model development. Finally, the hypotheses and conceptual model was built to reveal resident's intention in urban regeneration

2.1 Theoretical background

In the literature that utilizes psychological behavior theory in modal choice research, the theory of planned behavior (TPB, Ajzen, 1985) has been widely used in predicting and explaining intended behavior across a variety of disciplines. Moreover, the technology acceptance model (TAM) is among the most commonly employed theories for examining the new technology acceptance (Davis, 1989). Recently, it applied to exam people's intention for the new policies. Below are some details of above three theories.

Theory of Planned Behavior (TPB)

The TPB provides a useful conceptual framework for dealing with the complexities of human social behavior. Ajzen (1991) proposed the TPB to improve the explanatory power of Theory of Reasoned Action (TRA) by adding the construct of perceived behavioural control, in order to address the limited when TRA dealing with behaviours over which people have incomplete volitional control. The TPB is based on the proposition that an individual's behavior is a direct function of behavioral intention and perceived behavioral control. Intentions are themselves shaped by attitude (toward the behavior), subjective norms and perceived behavioral control (Ajzen, 1991). The three determinants of behavioral intentions are each based on an underlying belief structure: behavioral, normative, and control beliefs. In their respective aggregates, behavioral beliefs produce a favorable or unfavorable attitude toward the behavior; normative beliefs result in a perceived social pressure or subjective norm; and control beliefs give rise to perceived behavioral control with regard to performing the behavior (Fishbein & Ajzen, 1975). Taken together, attitude toward the behavior, subjective norm, and perceived behavioral control translate to the formation of a behavioral intention which is the immediate determinant of actual behavior (Heberlein & Black, 1976). In keeping with Ajzen's model of the TPB, Figure 1 shows how attitude toward using a self-issue and return

system, the subjective norm, and perceived behavioral control affect users' intention to use it. Over the years, support for TPB as a model of general social behaviour came from many studies. Recently, it has been applied to predict and explain people's intention of public policies.

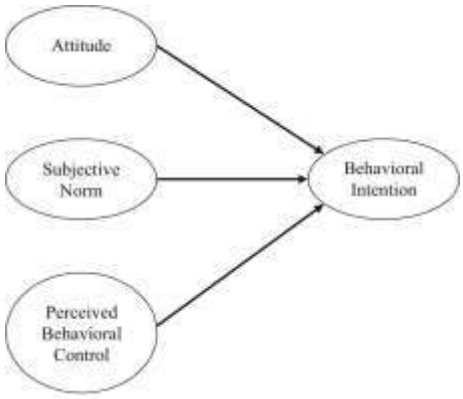

Figure 1. TPB model (source: Ajzen, 1991)

Social Cognitive Theory (SCT)

SCT explains how people acquire and maintain certain behavioral patterns, while also providing the basis for intervention strategies (Bandura, 1997). Evaluating behavioral change depends on the factors environment, people and behavior. SCT provides a framework for designing, implementing and evaluating programs (figure 2).

Environment refers to the factors that can affect a person's behavior. There are social and physical environments. Social environment include family members, friends and colleagues. Physical environment is the size of a room, the ambient temperature or the availability of certain foods. Environment and situation provide the framework for understanding behavior (Parraga, 1990). The situation refers to the cognitive or mental representations of the environment that may affect a person's behavior. The situation is a person's perception of the lace, time, physical features and activity (Glanz et al, 2002). The three factors environment, people and behavior are constantly influencing each other.

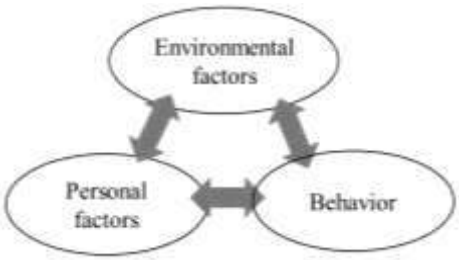

Figure 2. SCT model

Technology acceptance model (TAM)

In the technology adoption context, the technology acceptance model (TAM) is among the most commonly employed theories for examining technology acceptance (Davis, 1989). The appeal of TAM lies in that it is both specific and parsimonious, and displays a high level of predictive power with regard to technology use. TAM suggests that perceived ease of use (PEOU) and perceived usefulness (PU) are the two most important factors in explaining technology use. PEOU is the perception that a particular system or technology is easy to use, whereas PU is the degree to which an individual believes that using a technology will enhance his or her performance (Davis, 1989; Ajzen,1986; Ajzen & Madden, 1986; Chen & Chao,2010). The introduction of an urban renovation strategy in urban regeneration can be viewed as a new policy from the residents' perspective. Therefore, this study also applied TAM to build up a theoretical model.

2.1 Conceptual model

TAM and TPB are social psychology theories and applied to predict people's behaviour. The reason for including TAM and TPB is that both models are extended from the theory of reasoned action (TRA), but have different foci, making the inclusion theoretically compatible and potentially complementary(Fishbein & Ajzen, 1975). Comparing with the SCT, these two theories more focus on the personal and social factor, but not deeply consider the physical environment factor which is an important issue in urban regeneration (urban renovation). In order to provide an suitable model to reveal resident's behavior in urban regeneration policies, above three theories are applied to build up a theoretical model as figure 3.

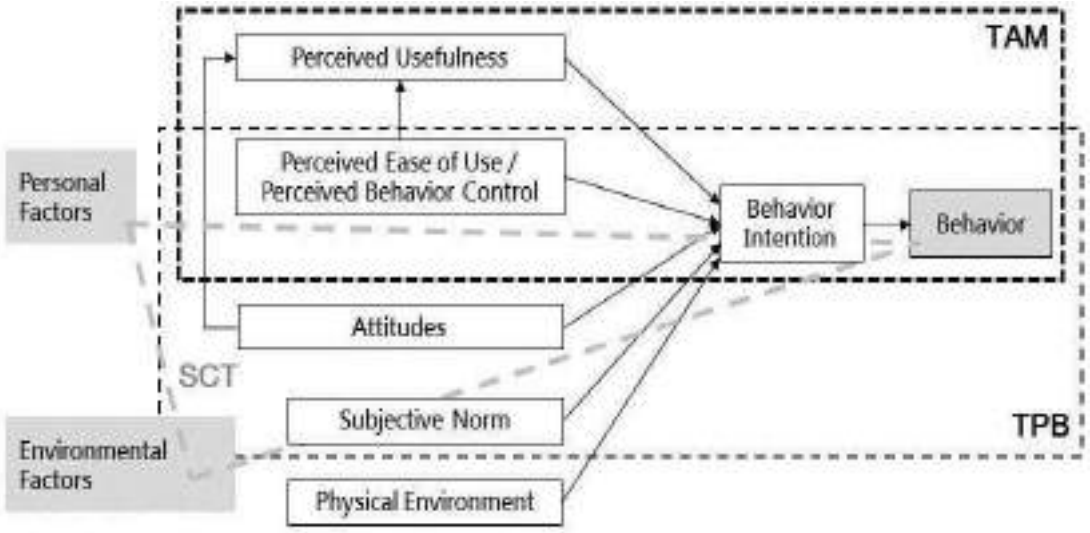

Figure 3. Theoretical model

2.2 Hypotheses and conceptual model

Based on the theoretical model, the conceptual model (figure 4) and hypotheses (H0~H7) were established to reveal the relationship between the key factors and resident's intention. Intentions capture the motivational factors that drive a person to perform a behavior (Ajzen, 1991).H0 was omitted from this model because urban regeneration is at very beginning stage and difficult to find enough sample who had moved into the implement stage. Moreover, the role of intentions on actual performance has been reported to be a strong predictor of actual usage (Ajzen,1991；Venkatesh et al., 2003).

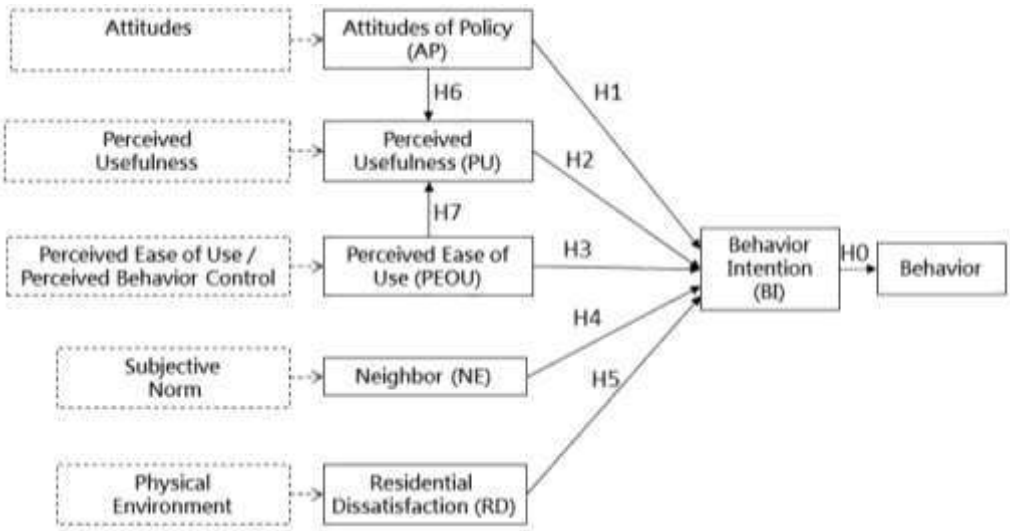

Figure 4. Conceptual model

H0. Behavior intention (BI) has a positive effect on behavior.
H1. Attitudes of policy (AP) has a positive effect on behavior intention
H2. Perceived Usefulness (PU) has a positive effect on behavior intention
H3. Perceived Ease of Use (PEOU) has a positive effect on behavior intention
H4. Neighbors' intention (NE)) has a positive effect on behavior intention
H5. Residential dissatisfaction (RD) has a positive effect on behavior intention
H6. Attitudes of Policy (AP) has a positive effect on perceived usefulness (PU)
H7. Perceived ease of use (PEOU) has a positive effect on perceived usefulness (PU)

3. Analysis and Results

3.1 Data collection

The questionnaire survey was conducted to collect data from residents who live in the regeneration area[4] in Tainan during April to June of 2011. A total of 216 questionnaires were distributed and 181 useful samples yielding an effective response rate of 83.7%.Out of all respondents 42.0% were female, 58.0% male. A majority of the respondents were the 3~5 people family (70.1%). While 8.8% of the respondents indicated their annual household income was less than NT$240,000 (around US$8,000), 83.4% reported their annual income was within the range of NT$240,001–NT$350,000 (around US$11,667), and 7.7% reported annual income of more than NT$1,350,000 (around US$45,000).50.3% response live in business district and 49.7% in residential district. A majority of the respondents' house has been built over 21 years (79.2%) so it is reasonable to implement urban renovation in these areas.

3.2 Measurement development

A survey questionnaire with all the measures was developed using items that were validated from previous studies. A pre-test was carried out with randomly selected residents in Tainan regeneration area. Based upon feedback from a pilot sample of 102 residents, the questionnaire was revised to improve clarity and reliability. Moreover, the Kaiser-Meyer-Olkin (KMO) of variables under 0.6 was eliminated from the questionnaire. According to the hypothesis model, the questionnaire is designed in six main parts in order to collect the data for RD, PEOU, NE, PU, BI, and

[4] Regeneration area is pointed by the Tainan government which normally are the older or poorer area in the city.

AP. Likert scale was applied to measure the first 4 parts and nominal scale was applied to measure resident's behavior intention of urban regeneration.

3.3 Reliability and Factory analysis

Reliability refers to the consistency of a measure and Cronbach's alpha is often applied to test whether it produces consistent results under consistent conditions. The higher the score, the more reliable the generated scale is. Nunnaly (1978) has indicated 0.7 to be an acceptable reliability coefficient. Most of the coefficients are over 0.8 (table 1) and it indicated that internal consistency is acceptable. Only the coefficient of PEOU is lower 0.7 which meaning its two questions are not consistency. However, both urban regeneration knowledge and economical ability are very important in urban regeneration issues. Thus, the two questions are still applied in the questionnaire.

Table 1. Cronbach's alpha values for all measures

Measures	Cronbach's alpha
Attitudes of policy	0.831
Perceived Usefulness	0.863
Perceived Ease of Use	0.384
Neighbours	-
Residential dissatisfaction	0.816
Behaviours Intention	0.921
whole	0.837

Factor analysis

Factor analysis is a collection of methods used to examine how underlying constructs influence the responses on a number of measured variables. The KMO measures the sampling adequacy which should be greater than 0.5 for a satisfactory factor analysis to proceed. According to the test results, the KMO measure is 0.809 and the Bartlett's test of sphericity is significant which indicate that it is appropriate to apply a factor analysis for the data.

A preliminary CFA was then conducted. As all factor loadings in table 2 are over 0.5 and the variance explained of each factor is over 50%, it indicate the factors can explain the data and analysis the latent variable (Hair et al., 1992).

Table 2. Exploratory factors analysis results

Factor	Question	Eigenvalue (factor loadings)	Variance explained (%)
RD	Neighborhood conveniences	0.62	58.105
	Neighborhood safety	0.66	
	Neighborhood appearance	0.78	
	Housing appearance	0.72	
	Housing safety	0.68	
AP	Idea of urban regeneration	0.83	85.544
	Government's urban regeneration policies	0.86	
PEOU	Urban regeneration knowledge	0.46	61.908
	Economical ability	0.52	
BI	Barrier-free facility improvement	0.84	76.621
	Public infrastructure improvement	0.88	
	Neighborhood appearance improvement	0.92	
	Housing appearance improvement	0.85	
	Housing structure improvement	0.75	
NE		_	_
PU	Housing interest	0.90	78.949
	Neighborhood interest	0.81	
	Economical interest	0.78	

3.4 Structural model and hypothesis tests

According to Table 3, error variance are positive, T-test are significant, most of the factor loadings are between 0.5 to 0.95, and the standard error is low. All above test result shows that the fitness of model is acceptable.

Table 3 Fitness judgments

Test	Result	Fitness
Error variance	All positive numbers	Yes
T-test	Significant (over 1.96)	Yes
Factor loadings	Most of the factor loadings are between 0.5 and 0.95. Only urban regeneration knowledge of PEOU is only 0.46.	acceptable
Standard error	low	Yes

Discriminant validity, which assesses whether individual indicators can adequately distinguish between different constructs, is ensured if the square root of Average Variance Extracted (AVE) for each construct is greater than the correlation between that and all other constructs in the model (Fornell & Larcker, 1981). The correlation matrix in Table 4 indicates that the square root of AVE (shown in gray background along the diagonal) of each construct was higher than corresponding correlation values for that variable in all cases, thereby assuring discriminant validity.

Table 4. Result for the test of Discriminant Validity

	AP	PEOU	NE	PU	RD	BI
AP	.878					
PEOU	.000	.180				
NE	.000	.000	.947			
PU	.370	.107	.000	.578		
RD	.000	.000	.000	.000	.374	
BI	BI	.056	.115	.207	.173	.379

3.5 Hypotheses testing

Based on the previous test, the initial model was modified as figure 5 in order to improve the fit. Compare with the initial model, the PEOU only has a directly positive effect on PU and has an indirectly positive effect on BI through PEOU.

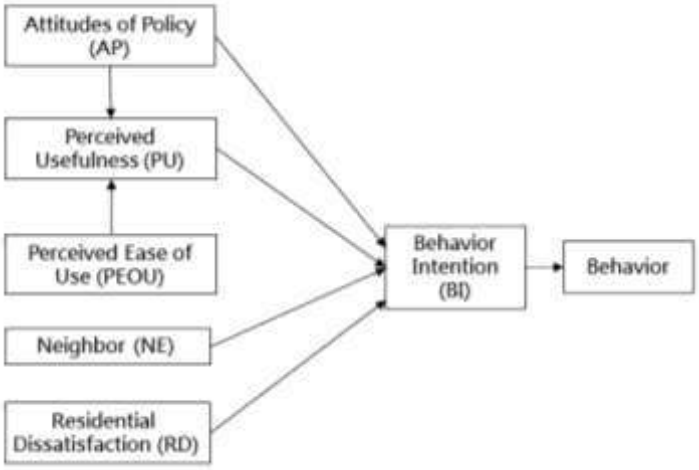

Figure 5.Modified mode

The modified mode was text by SEM and the result of T-test is significant. Figure 6 is the result of path analysis. Only the coefficient of PEOU and NE is lower but others are acceptable.

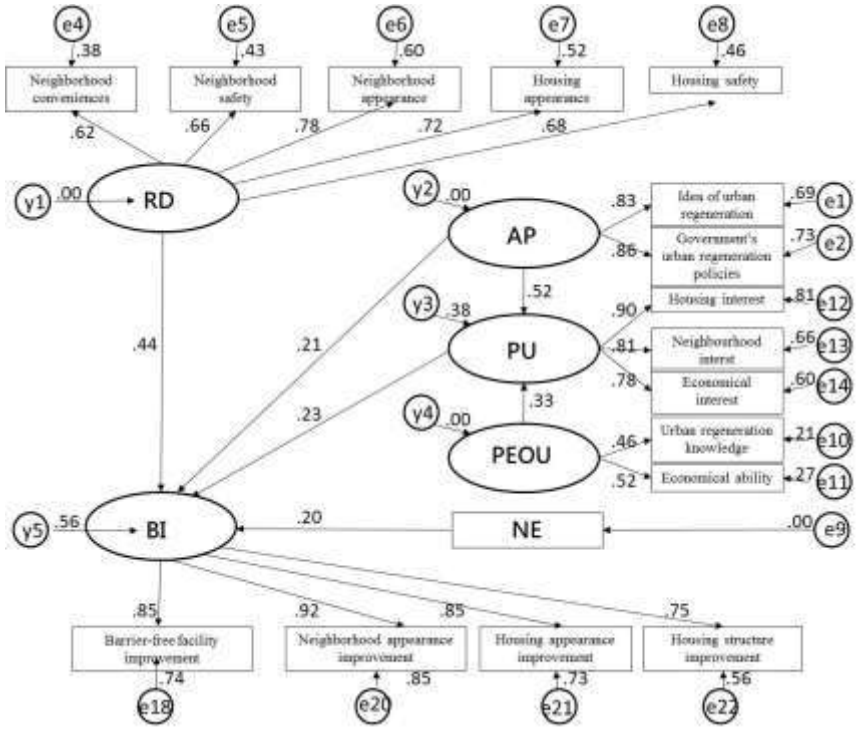

Figure 6. Path diagram of the modified model

Table 5 is the result of the path analysis. AP, PU, NE, and RD have direct effect on BI. RD has a highest effect on BI (0.44), follow are AP (0.41), PU (0.23), and NE (0.20). Moreover, AP and PEOU have indirect effect on BI and the result is 0.52 and 0.33. It indicates that AP and PEOU have direct effect on PU, and effect BI through PU.

Table 5 Path analysis

Path relationship					Direct	indirect	whole
AP	→	BI			.401		.522
	→	PU	→	BI		.121	
PU	→	BI			.232		.232
PEOU	→	PU	→	BI		.078	.078
NE	→	BI			.206		.206
RD	→	BI			.445		.445

5. Discussion and conclusions

There are two major accomplishments in this research. First, a conceptual model of resident's intention in urban renovation was built. Second, the results indicate the important factors to influence resident's intention in urban regeneration.

A conceptual model of residents' intention in urban renovation was established

The key impact factors are personal attitude, perceived usefulness, neighbors, residential dissatisfaction and perceived ease of use. Also, the questions for measuring each factor were sieved out by literature review and pre-test. Furthermore, the modified conceptual model (figure 5) indicates the fitness relationship between the factors. Researchers can apply this model in different studies to reveal residents' intention in urban renovation. The government officers can utilize the model to test the new urban regeneration policies before implement.

The results of SEM indicate the key factors to influence Tainan residents' intention

The results of the structural coefficients show that residential dissatisfaction and personal attitude were identified as the most important factors to influence Tainan residents' intention. In addition, people are more concerned about the quality of community environment than the buildings themselves. Thus, Tainan city government should implement projects from a neighborhood or local community. Furthermore, not only tell residents how many subsidies the government can provide but also show them how much the urban renovation project can improve their environment.

Territorial effects of climate change on Europe's regions

Johannes Lückenkötter, Stefan Greiving, Christian Lindner[1]

Abstract

Climate change and its effects on Europe's regions are highly political issues. The European Commission and its member states, as well as regional and local governments and civil society organizations are exploring and debating how to adapt to the projected climatic changes. It is clear that Europe's regions will be affected differently and will also have different means available for adapting to climate change. Thus territorially differentiated adaptation strategies are necessary. However, there are hardly any studies that employ a territorial perspective to the issue of climate change impacts and adaptation in Europe. Most studies are strictly sectoral in outlook. But what is needed, from a policy-making perspective, is a cross-sectoral assessment that provides an evidence base for regionally differentiated, tailor-made adaptation strategies.

The paper presents the methodology and key findings of the recently concluded research project ESPON Climate.[2] The project conducted an integrated climate change vulnerability assessment with a prime territorial focus. Building on a widely accepted conceptual framework the study used ten climate change variables based on the CCLM climate model, 19 sensitivity indicators and 15 adaptive capacity indicators to calculate the climate change vulnerability of 1,350 European regions. The results are presented as maps and discussed from a pan-European perspective.

One of the core findings is that Europe's climate change vulnerability runs counter to territorial cohesion. The assessment indicates that climate change would deepen the existing socio-economic imbalances between the core of Europe and its Southern and South-Eastern parts because many economically lagging regions also are the most vulnerable to climate change.

Finally, implications and options for EU and regional policy making are discussed. For example, the project's findings could inform the allocation of EU funds that would provide targeted financial assistance to regions that are projected to be severely affected by climate change and also have low adaptive capacity. This would ultimately contribute to a more balanced territorial development of European regions. The paper concludes with methodological reflections and a careful outlook.

[2] The project was conducted within the framework of the ESPON 2013 Programme and was partly financed by the European Regional Development Fund. This paper does not necessarily reflect the opinion of the members of the ESPON Monitoring Committee.

1. Introduction

Climate change is a high profile political issue in Europe with a distinct territorial dimension. For example, in the "Europe 2020 Strategy for smart, sustainable and inclusive growth" (COM 2010) the EU took up the challenge of climate change and set ambitious targets for greenhouse gas emissions, renewable energy use and energy efficiency. Likewise the Territorial Agenda 2020 (EU 2007) regarded climate change and environmental risks as very important and as containing both challenges and potentials for territorial development. Finally, the EU White Paper "Adapting to climate change: Towards a European framework for action" (EC 2009) explicitly related climate change to territorial development in Europe and called for a planned response.

But such a systematic response to the development challenges of climate change requires an appropriate evidence base. Many European studies have until now focused on different types of impacts of climate change. The focus has usually been on very specific impacts or on particular sectors. While these studies contributed to the overall understanding of climate change mechanisms in Europe, their findings have seldom been transferable or comparable between sectors or between regions. What was missing was an overall, cross-sectoral assessment of climate change that would allow European policy-makers to understand the diversity of climate change impacts and develop territorially differentiated adaptation strategies at the European, national and regional level.

Taking up this challenge, this paper presents findings of the EU financed research project ESPON Climate, which conducted an innovative, integrated and pan-European climate change vulnerability assessment with an explicit territorial focus.

2. Concepts and methodology

2.1 Conceptual framework

The ESPON Climate project is based on a conceptual framework that is widely used in the climate change and impact research community (see Figure 1). According to this framework rising anthropogenic greenhouse gas emissions contribute to global warming and thus to *climate change*. This anthropogenic contribution runs parallel to natural climate variability. The resulting climate changes differ between regions, i.e. each region has a different *exposure* to climate change. In addition, each region has distinct physical, environmental, social, cultural and economic characteristics that result in different *sensitivities* to climate change. Together exposure and sensitivity determine the possible impact that climatic changes may have on a region. However, a region might in the long run be able to adjust, e.g. by increasing its dikes. This *adaptive capacity* enhances or counteracts the climate change impacts and thus leads to a region's overall *vulnerability* to climate change.

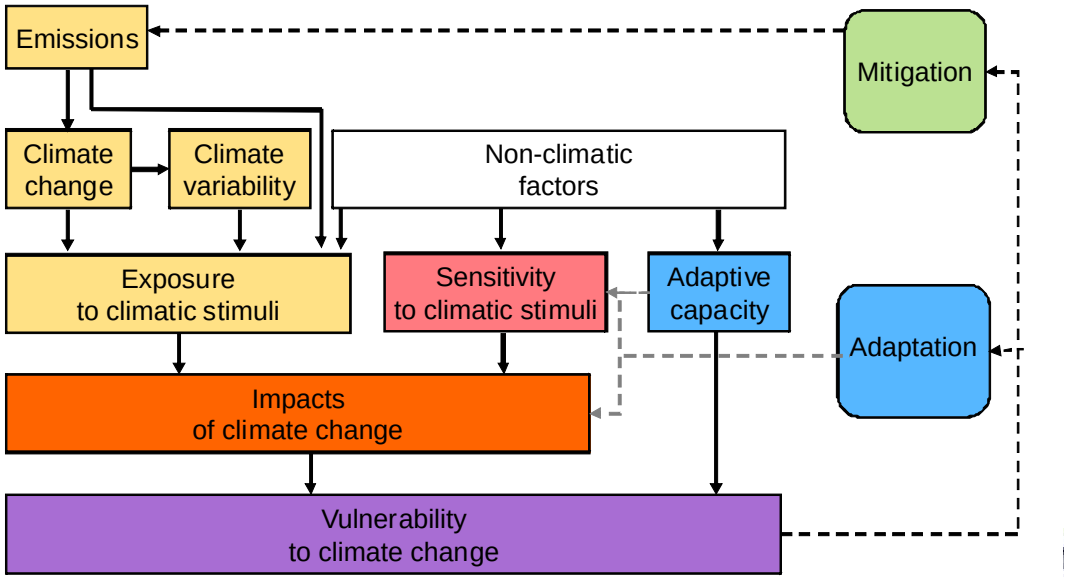

Figure 1: Conceptual framework (adapted from Füssel & Klein, 2002, p. 54)

In order to provide a clear basis of understanding these key concepts are further defined below:

Table 1: Definitions according to Füssel & Klein (2002) and IPCC (2007)

***Exposure*:** The nature and degree to which a system is exposed to significant climatic variations.
Sensitivity: The degree to which a system is affected, either adversely or beneficially, by climate related stimuli. The effect may be direct or indirect.
***Impacts*:** Consequences of climate change on natural and human systems. Depending on the consideration of adaptation, one can distinguish between potential and residual impacts.
Adaptive capacity (or adaptability): The ability of a natural or human system to adjust to climate change (including climate variability and extremes) to moderate potential damages, to take advantage of opportunities, or to cope with the consequences.
Vulnerability: The degree to which a system is susceptible to, or unable to cope with, adverse effects of climate change, including climate variability and extremes. Vulnerability is a function of the character, magnitude, and rate of climate variation to which a system is exposed, its sensitivity, and its adaptive capacity.
Mitigation: Climate change mitigation refers to all human attempts to mitigate the effects of climate change.

2.2 Methodology

Following this framework the ESPON project's methodology consisted of five main components (see Figure 2 for a graphical overview).

The *exposure analysis* focused on the climatic changes as such. It made use of existing projections on climate change and climate variability from the CCLM climate model, whose results have been used, among others, by the 4th IPCC assessment report on climate change. Using the IPCC climate scenario A1B (Nakicenovic et al. 2000) the ESPON Climate project aggregated data for two time periods (1961-1990 and 2071-2100) for eight climate stimuli.[3] River flooding and sea level rise were added as two immediate 'triggered effects' of these climate stimuli.

Each region was then assessed in regard to its climate change *sensitivity*. For each sensitivity dimension (physical, environmental, social, economic and cultural) several sensitivity indicators were developed. Each of the 19 sensitivity indicators[4] was calculated in absolute and relative terms and then combined. This integrates two equally valid perspectives on sensitivity: While relative sensitivity (e.g. density of sensitive population) is advantageous from a comparative point of view, the absolute sensitivity (e.g. absolute number of sensitive inhabitants) is more relevant from a policy/action point of view.

Exposure and sensitivity were then combined to determine the potential *impacts* of climate change. The analysis thus focused on what would be the result if climate change took place unrestrictedly and impacted on the regions without further preparation. For determining impacts each sensitivity indicator was related to one or more specific exposure indicator(s). For example, heat sensitive population (persons older than 65 years living in urban heat islands) were related to changes in the number of summer days (above 25°C), while forests sensitive to fire were related to summer days and summer precipitation. After determining the individual impacts, all impacts of one dimension were aggregated. The impact values of the five sensitivity dimensions were finally combined to one overall sensitivity value.

This aggregation of the various impact dimensions (and later the integration of exposure, sensitivity and adaptive capacity) raises normative issues induced by the theoretical framework. At these stages of the assessment process weighting takes place, for even if no weighting is deliberately performed, this then amounts to simply giving equal weights to each object. This weighting ultimately refers to cultural

[3] Exposure indicators used by ESPON Climate related to change in annual mean temperature, frost days, summer days, winter precipitation, summer precipitation, heavy rainfall days, snow cover days and evaporation.

[4] Sensitivity indicators used by ESPON Climate related to roads, railways, airports, harbours, thermal power stations, refineries, settlements, coastal population, population in river valleys, heat sensitive population in urban heat islands, NATURA 2000 protected areas, occurrence of forest fires, soil organic carbon, soil erosion, museums, cultural World Heritage Sites, energy supply and demand, agriculture and forestry employment and GDP, tourism comfort index and tourist beds.

beliefs and political preferences, e.g. how one values human lives in comparison to economic damages. The ESPON Climate project decided to address these normative issues openly and conducted a Delphi survey among the members of the ESPON Monitoring Committee, which represented the European Commission, 27 European countries and four Partner States. Committee members were asked to propose individual weights for all relevant stages and dimensions of the assessment (see results in Table 2).[5]

Table 2: Weights resulting from the Delphi-based assessment

Sensitivity		*Adaptive capacity*	
Cultural sensitivity	0.1	Economic resources	0.21
Economic sensitivity	0.24	Knowledge and awareness	0.23
Environmental sensitivity	0.31	Infrastructure	0.16
Physical sensitivity	0.19	Institutions	0.17
Social sensitivity	0.16	Technology	0.23

A third major component of the project was the assessment of *adaptive capacity* in regard to climate change, i.e. the economic, socio-cultural, institutional and technological ability of a region to adapt to the impacts of a changing regional climate. This could mean preventing or moderating potential damages but also taking advantage of new opportunities. Several indicators were developed for each of the five major dimensions of adaptive capacity. The 15 individual indicators were subsequently combined for each dimension and finally aggregated to an overall adaptive capacity. This aggregation was again conducted on the basis of the Delphi survey results.

To determine the overall *vulnerability* of regions to climate change the impacts and the adaptive capacity to climate change were combined for each region. The underlying rationale is that a region with a high climate change impact may still be moderately vulnerable if it is well adapted to the anticipated climate changes. On the other hand, high impacts would result in high vulnerability to climate change if a region has a low adaptive capacity.

Mitigation is also highly relevant for territorial development and cohesion since climate policy implementation and the transition to a low-carbon society will have differential effects on sectors and regions. Mitigation measures, even implemented at the regional level, will not have significant effects on regional climate but only contribute to an overall reduction of global climate change. Therefore the project's mitigation analysis could only determine the mitigation capacity of each region but cannot determine what effect this would have locally or regionally.

Finally seven *case studies* at the trans-national, regional and local level cross-checked and deepened the findings of the pan-European assessment and explored the diversity of response approaches to climate change.

[5] The survey yielded equal weights for exposure and sensitivity as well impact and adaptive capacity.

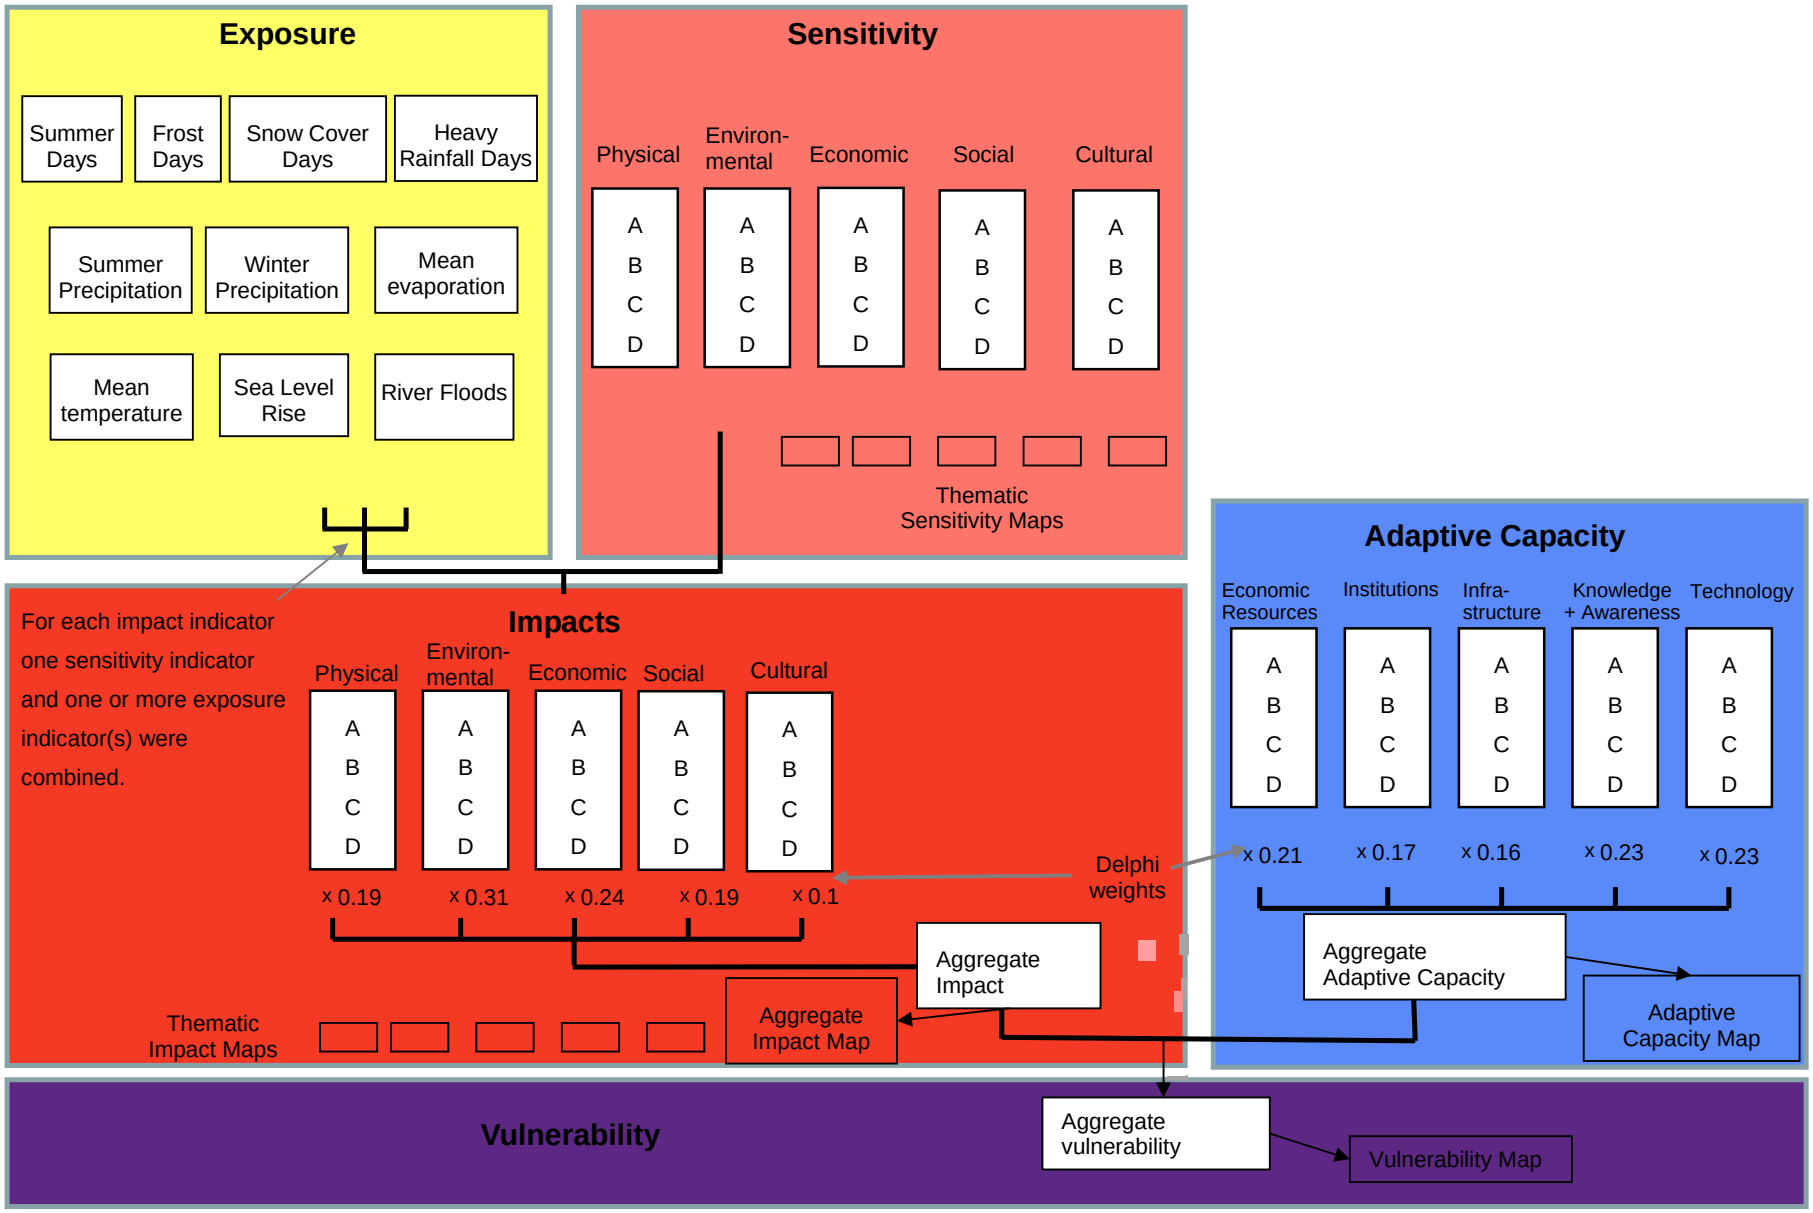

Figure 2: Overview of the ESPON Climate vulnerability assessment methodology (Greiving et al. 2011)

3. Main results

This section presents key outcomes of applying the methodology described above. For a full presentation and discussion of individual exposure, sensitivity and impact indicators one may refer to the Scientific Report of the ESPON Climate project (Greiving et al. 2011). Instead this paper focuses only on aggregated results regarding impacts, adaptive capacity and vulnerability to climate change.

The project's findings regarding impacts of climate change may be grouped into impacts primarily caused by extreme events (flooding and heat) and those caused by changes of average climate conditions. The former group consists of potential physical, cultural and social impacts (see maps in Figure 3).

Potential **physical impacts** relate to physical structures such as settlements, roads, railways, airports, harbours, thermal power plants and refineries. These structures are especially sensitive to flood events. Consequently, the adjustment of coastal storm surge heights with the projected sea level rise accounts for most of the high impacts in north-western European regions bordering the Atlantic Ocean (sometimes exacerbated by fluvial and pluvial flooding). Projected increases in river flood heights are responsible for regional 'hot spots' in Italy, Slovenia and Hungary. However, large parts of Europe may not expect significant impacts on their infrastructure resulting from climate change. In fact, physical structures in some central and southern European regions may even experience less climate-related impacts due to decreasing precipitation in these regions.

The potential **cultural impacts** of climate change focused on tangible cultural assets, because intangibles like norms and attitudes were considered part of the adaptive capacity of a region. More precisely ESPON Climate analysed what impact the projected climatic changes may have on the 350 UNESCO World Heritage Sites and ca. 20,000 museums in Europe. Not surprisingly the impact patterns for these cultural assets resemble those for infrastructures and settlements: The high impacts in Italy, Slovenia, Slovakia, Hungary and northern France, Belgium, the Netherlands, parts of Denmark and Finland are a consequence of the projected increase of flood hazards and the density of cultural sites in these regions. On the other hand, cultural assets in some Central European regions, especially in Poland, would benefit from decreasing flood hazards.

The potential **social impacts** of climate change relate to Europe's population, which is also mainly sensitive to extreme events that are driven by climate change: coastal storm surges exacerbated by sea level rise, increases in river flood heights, increasing flash floods, but also increasing heat events. Sensitivity to these changes is a matter of location, age group distribution, but also the density and size of urban areas that create urban heat island effects. Hence the social impact patterns again largely resemble those of physical impacts, because population centres are also concentrations of buildings and infrastructures. The highest impacts are primarily flood related and are projected for urban agglomerations on the Belgium, Dutch and Norwegian coasts as well as the city regions around Barcelona, Venice and

Ljubljana. In addition, southern Europe would be more affected because of the more compact urban form of its cities and greater increases in hot summer days. In contrast, the population of most non-coastal areas of Europe is potentially not or only marginally affected by climate change and some regions are even projected to have positive impacts due to declining flood hazards, e.g. in Poland and Portugal.

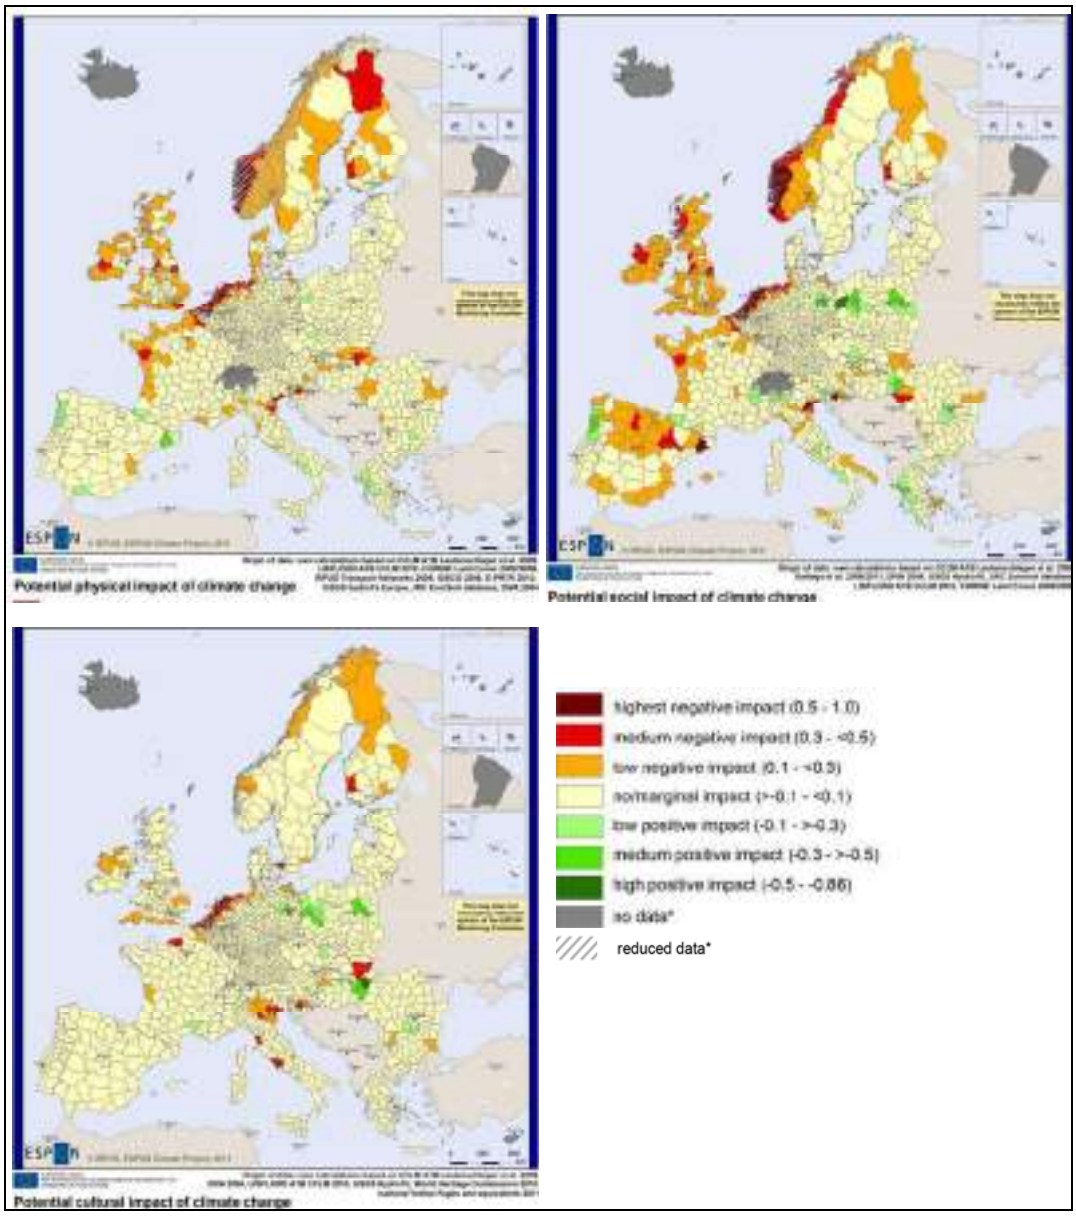

Figure 3: Potential physical, cultural and social impact (Greiving et al. 2011)

The second group of climate change impacts relate to changes of average climate conditions. In contrast to more robust sub-systems that are primarily affected by extreme events like e.g. floods, the economic and environmental sub-systems are sensitive even to creeping climatic changes (see Figure 4).

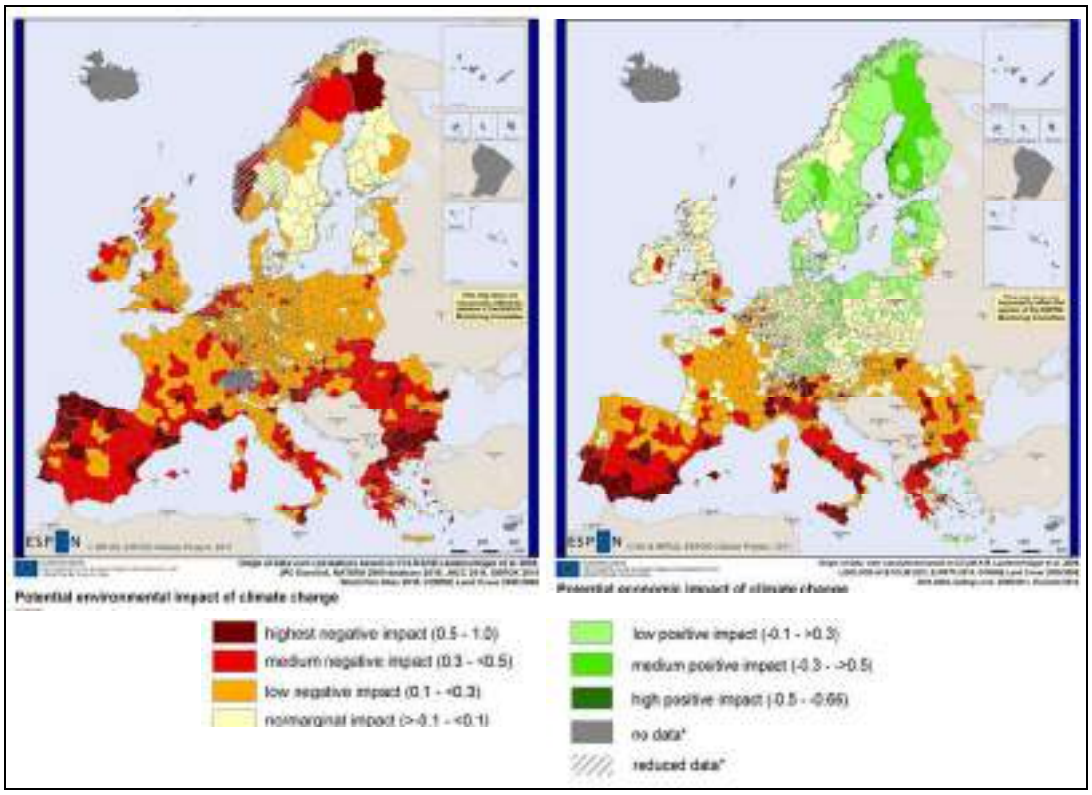

Figure 4: Potential environmental and economic impact (Greiving et al. 2011)

The potential **economic impacts** of climate change were analysed in regard to especially climate-sensitive economic sectors, namely agriculture and forestry, energy production and consumption as well as summer and winter tourism. Overall the economic impacts of climate change show a clear south-north gradient: many Central European regions and almost all Scandinavian regions are projected to have positive impacts, while almost all southern European regions would experience negative impacts. This is largely due to the economic dependency of large parts of southern Europe on (summer) tourism and agriculture. Both sectors are projected to be negatively impacted by increasing temperatures and decreases in precipitation, whereas the environmental conditions for agriculture in north-eastern Europe tend to improve. In addition, energy demands would rise in the south for cooling purposes and decrease in the north due to less heating. Finally, the Alps as a premier tourist dependent region can be identified as an impact 'hotspot', which mainly results from the projected decrease in snow cover days.

The potential **environmental impacts** that were analysed relate to protected natural areas, soil organic carbon content and the propensity of soil erosion and forest fires.

The overall findings show that for these environmental variables negative impacts are projected for almost all European regions. But the highest negative environmental impacts are expected in the north and south of Europe. In southern European regions the drier and hotter climate is projected to increase the likelihood of forest fires and to also degrade soil conditions in mountainous and coastal areas. The severe environmental impacts in northern Scandinavia are mainly due to very large protected areas where any climatic change (in this case warmer and wetter climate) is considered as negatively affecting the specific ecosystems under protection.

Moving beyond sectoral impact assessments was a defining feature of the ESPON Climate project. In a first step the sectoral impacts were aggregated and then combined with the capacity to adapt to climate change, which yielded the potential vulnerability (see maps in Figure 5).

ESPON Climate's cross-sectoral **aggregate potential impact** results exhibit the following general patterns: coastal regions are projected to be negatively affected, because their high concentrations of physical, economic, social and cultural assets would face increasing flood hazards. Southern European regions are expected to be negatively impacted because their hotter and drier climates severely worsen conditions for their populations, economies and natural environments. Highly negative impacts are therefore projected for southern Europe's agglomerations and tourist resorts along the coasts. But inland mountain regions that are dependent on agriculture, forestry and winter and/or summer tourism would also be highly affected. In contrast, many central, eastern and northern European regions would face virtually no negative impacts or would even experience positive impacts of climate change – mainly due to marginal climatic changes or projected decreases in river and flash floods.

The **adaptive capacity** was defined by indicators on knowledge and awareness, economic resources as well as technological, infrastructural and institutional capacity to adapt to climate change. For example, national and regional governments may or may not have developed climate change adaptation strategies that serve as the basis for sectoral and cross-sectoral development policies (cf. Greiving and Fleischhauer, 2012). Interestingly, mapping the overall adaptive capacity yields an almost inverted pattern compared to the impact map: Most regions for which climate change impacts are expected to be the most severe (mainly in the South) are in fact the least aware and capable to adapt to these impacts.

Finally, combining impacts and adaptive capacity leads to the **potential vulnerability** to climate change in Europe. The vulnerability map seems to mirror the territorial pattern of potential impacts, but with an even more pronounced South-North gradient. This is due to the high adaptive capacity in Scandinavian and Western European regions, which partly compensates for the potential impacts projected for these regions. On the other hand, in the Mediterranean region and in South-East Europe, where medium to high negative impacts are expected, the ability to adapt to climate change is generally lower thus resulting in even higher levels of vulnerability. The overall most vulnerable types of regions are: (1) Coastal regions

with high population and high dependency on summer tourism, (2) mountain regions with high dependence on winter and summer tourism, and (3) agglomerations with high population density, where *inter alia* the problem of urban heat is more severe.

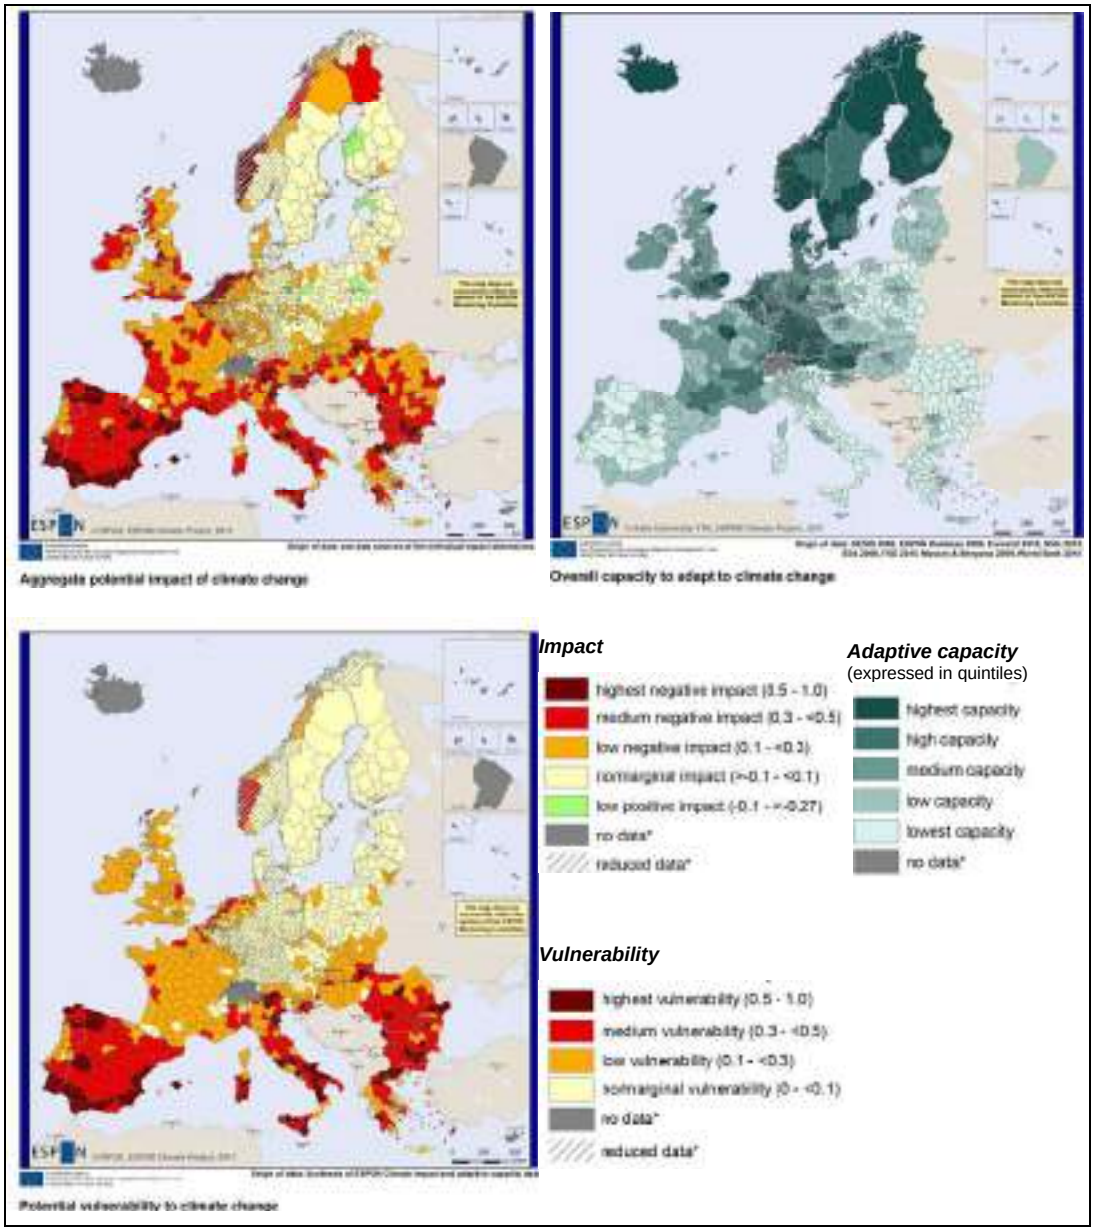

Figure 5: Potential aggregate impact, adaptive capacity and vulnerability (Greiving et al. 2011)

4. Conclusions

The ESPON Climate project constitutes the most comprehensive pan-European climate change vulnerability assessment to date. The project provides not only regionally specific results but also aggregated, cross-sectoral findings that lend themselves to high-level European policy-making. In contrast, most existing vulnerability studies have a sectoral focus and lack a clear territorial focus. However, several new EU-funded research projects are currently being conducted that also employ an integrated methodology for assessing climate change impacts, adaptation and vulnerability. But these projects (e.g. ClimSAVE, RESPONSES and MEDIATION) will only conclude and deliver their final results by the end of 2012 and 2013 respectively.

4.1 Climate change and EU development policies

ESPON Climate created a comprehensive pan-European evidence base needed for a climate change responsive European territorial development policy. For example, ESPON Climate demonstrated that Europe's climate change vulnerability exacerbates territorial differences and poses additional challenges to ensuring cohesion. The assessment indicated that climate change will probably deepen the existing socio-economic disparities between the core of Europe and its southern and southeastern parts because many economically lagging regions there are also the most vulnerable to climate change. Most likely these imbalances will even increase in the future: the current economic and financial crises in Greece, Italy, Spain and Portugal are reducing both individual and collective adaptive capacities. And in eastern Europe severe demographic changes like massive outmigration and ageing are projected to continue, which would further increase regional climate change sensitivity and decrease adaptive capacity levels (e.g. an older regional population is more sensitive to heat and less able to adapt to climate change).

ESPON Climate's methodologies and results could possibly become part of an evolving policy support tool that would enable policy-makers at European, national and regional level to (a) identify regional 'hot spots' with projected high impacts and weak capacity and devise appropriate support and response mechanisms, (b) develop a more strategic and climate change responsive approach to territorial cohesion, (c) identify especially vulnerable (sub)sectors and then mainstream climate change adaptation in the respective sectoral policies, (d) develop territorially differentiated adaptation strategies that take into account the regional variations in regard to climate change exposure, sensitivity, impact and adaptive capacity and (e) coordinate and integrate sectoral policies with a view to preventing potential negative climate change impacts and capitalising on positive development opportunities.

4.2 Critical reflection and outlook

It has to be kept in mind, however, that the ESPON Climate project is based on only one climate forcing scenario (A1B), one global circulation model (ECHAM5/MPI-OM) and one regional circulation model (CCLM) due to time and financial constraints and the fact that Europe as a whole needed to be covered. Furthermore, long-term socio-economic development trends that influence future regional sensitivities to climate change could hardly be integrated in the assessment (only some demographic scenarios could be tested based on data from the ESPON project DEMIFER). Thus the project's results have to be seen as a vulnerability scenario, which shows what Europe's future in the wake of climate change *may* look like (based on current knowledge, data and particularly assumptions), and not as a clear-cut forecast.

Reflecting on the project's methodology a number of key features and challenges are apparent. First of all the project used a generally accepted conceptual framework and on this basis was able to operationalise a coherent vulnerability assessment methodology. Nevertheless, the selection, calculation and aggregation of the individual indicators involves not only scientific knowledge, but also normative decisions on what aspects of such concepts as climate change, sensitivity or adaptive capacity are to be captured and assessed. In addition the choices of indicators are also shaped by the availability and quality of statistical data. Lastly, most of the indicators finally used in the project are made up of several input variables. The construction of such composite indicators is challenging as it involves different choices on selection of data, normalisation procedures, weighting schemes and aggregation methods (cf. Saltelli, Nardo et al. 2004).

Despite these inevitable challenges the prospects for major advances in the field of integrated vulnerability assessments in Europe are encouraging. The European projects mentioned above (ClimSAVE, RESPONSES and MEDIATION) will soon conclude their research and it will be interesting to analyse how their results will compare to the results of the ESPON Climate project: whether they will reinforce, complement or contradict each other. But also comparing and learning from the comprehensive methodologies that these projects are currently developing will cross-fertilize the scientific research in this field. Furthermore, ENSEMBLE datasets that combine climate projections based on several climate models are now available and can be used to drive assessment models like the one presented in this paper. This makes impact and vulnerability assessments less dependent on one climate model and thus makes their results more robust. As regards data availability the new online platform CLIMATE-ADAPT provided by DG Climate Action (http://climate-adapt.eea.europa.eu) facilitates sharing of research results and data on climate adaptation and enables further integration and dissemination of climate change focused research.

VULNERABILITY ACROSS SPACE: A FOCUS ON THE UNDERLYING MECHANISMS

Galderisi A.[1], Ferrara F.F.[2]

Abstract

Vulnerability is widely recognized, both in scientific literature and institutional documents, as a key-component of risk, crucial for improving risk knowledge, assessment and management. In the last decades, vulnerability has been largely investigated according to different aims and disciplinary perspectives: nevertheless, the challenge for integrating current approaches has to be still faced and many gaps related to vulnerability understanding and measuring have still to be bridged.

Despite some scholars have clearly outlined that "vulnerability rests in a multi-faceted coupled system with connections operating at different spatio-temporal scales" (Turner et al. 2003), till now vulnerability is often represented as a static and crystallized feature of elements/systems or, according to Roberts et al. (2009), "as a static factor" rather than a process, neglecting in such a way the significant changes affecting both its facets and the relationships among them over time and across space. Hence, a clear idea of the path to be followed for analyzing and measuring the time and spatial dependency of vulnerability (Birkmann, 2006) and for grasping its dynamic nature is still missing.

For long, vulnerability has been associated, up to an absolute identification, to the concept of damage even though, according to a shared interpretation, it can be more precisely defined as "the characteristics and circumstances of a community, system or asset that make it susceptible to the damaging effects of a hazard" (UNISDR, 2009). The UNISDR glossary (2009) highlights that vulnerability concept includes numerous aspects - arising from physical, social, economic and environmental factors - and that it significantly varies over time, but does not emphasize the variability of vulnerability, and of its different aspects, across space despite the entity and the far-reaching dimensions of the consequences produced by such a variability, as largely shown by recent disasters.

Even if different from each other, the concepts of vulnerability and damage are closely related and the recognition of damage patterns may represent one of the key-tool for in-depth analyzing some aspects of vulnerability not sufficiently investigated up to now. Accordingly, Cochrane (2004) states that "damages are displaced geographically and temporally". Therefore, looking at the different phases following the impact of a hazardous event, might the analysis of the spatial distribution of damage help us to better understand factors and mechanisms able to induce a displacement of vulnerabilities across space?

The present work aims at answering this question; in detail, grounding on some case studies, an overview of the main spatial mechanisms that can favor the displacement

1 University of Naples Federico II, Dipartimento di Pianificazione e Scienza del Territorio, Naples, Italy - galderis@unina.it

2 AIAT – Italian Environmental Engineers Association - floriana.ferrara@gmail.com

and the change of vulnerability across space and some hints devoted to an in-depth conceptualization of the spatial dynamics of vulnerabilities will be provided.

1. The dynamics of vulnerability

Hazards are generally recognized as spatial phenomena: spatial patterns of hazardous events as well as damage distribution in space have been an important concern of scientific literature in the disaster field. On the opposite, despite some scholars have clearly outlined that "vulnerability rests in a multi-faceted coupled system with connections operating at different spatio-temporal scales" (Turner et al. 2003), the dependency of vulnerability on time and space seems to be still hard to grasp.
Nowadays, vulnerability is widely recognized as an intrinsic feature of elements and systems: the UNISDR glossary provides a definition of vulnerability as "the characteristics and circumstances of a community, system or asset that make it susceptible to the damaging effects of a hazard" (UNISDR, 2009), emphasizing that the concept includes numerous aspects, arising from physical, social, economic, and environmental factors and that it may significantly vary over time. Nevertheless, the UNISDR definition does not lay stress on the variability of vulnerability and of its different aspects across space, despite the entity and the far-reaching dimensions of the consequences produced by such a variability, as largely demonstrated by recent disasters.
Moreover, although at present territorial, social, economic systems are widely recognized as complex systems, continuously varying over time and across space, and vulnerability interpreted as an intrinsic feature of such systems, the latter is still now, surprisingly, often considered "as a static factor that modifies the amount of loss caused by threats" (Roberts et al. 2009) and approached as a state, rather than as a dynamic process developing over time and across space.
Due to such a prevailing approach, factors and mechanisms that may induce or contribute to the displacement of vulnerability across space have not been exhaustively investigated.
As an example, "risk transfer" processes have been up to now analyzed mainly in respect to the financial mechanisms (Benson and Clay, 2004; Arnold, 2008), such as insurances, and defined as "the process of formally or informally shifting the financial consequences of particular risks from one party to another whereby a household, community, enterprise or state authority will obtain resources from the other party after a disaster occurs, in exchange for ongoing or compensatory social or financial benefits provided to that other party" (UNISDR, 2009).
In some cases, risk transfer processes have been also investigated in relation to the "time" factor (Etkin, 1999). On the opposite, an effective conceptualization able to explain the displacement of vulnerability in space is still missing.
In detail, what has to be in-depth investigated are factors and mechanisms that, by acting as "drivers" of vulnerabilities across the space, can lead to different damage distribution.
As it will be better highlighted through the following case studies, factors and mechanisms inducing a displacement of vulnerability across space vary according to the type of vulnerability at stake in that, for example, the ones that may induce a

transfer of physical vulnerability across space can be different from those which may determine a transfer of other aspects or facets of vulnerability.
Therefore, for our purposes, two "facets" of vulnerability will be mainly considered: physical vulnerability, which can be referred to "the fragilities that can lead to physical disruption and harm when facing the stress provoked by a given hazard" and systemic vulnerability, which can be referred to the susceptibility of elements and systems to be indirectly damaged, as a consequences of their functional or economic relationships with the hit elements and systems (Ensure Consortium, 2011). According to such definitions, it is possible to state that physical vulnerability is strongly hazard-related ("vulnerability to hazard" as a form of stress) whereas systemic vulnerability, weakly or indirectly dependent on hazard, can be interpreted as a "vulnerability to losses". The stronger the interdependencies among systems and system components are, the more relevant the "systemic vulnerability" is. Therefore, by a scale perspective, physical vulnerability can be analyzed on the hazard scale, according to its distribution across space, whereas systemic vulnerability has to be investigated on different geographical scales, depending on the functional and economic linkages between elements and systems (Polsky et al., 2007; Bonadonna et al., 2011).
Grounding on these considerations, two main mechanisms able to induce a displacement and in many cases a change of physical and systemic vulnerabilities across space will be here investigated: propagation and transfer.
Both the mentioned mechanisms can be referred to the shift across space of physical vulnerability due to the propagation or transfer of hazard factors. Furthermore, transfer mechanism is also useful to understand how systemic vulnerability, due to the interdependencies among elements and systems which characterize the hit territorial system, reveals itself at different geographical scales, moving from a local up to a regional or a global level. It is worth noting that the dynamics of vulnerability across space largely depend on the context, which is always crucial in vulnerability analysis (Anderson-Barry and King, 2005; Roberts et al. 2009). Social, economic, environmental as well as spatial and functional organization of the hit territorial systems, indeed, not only characterize the different facets of vulnerability but will also influence their dynamism across space.
Propagation and transfer mechanisms may develop very quickly or in a long time span, giving rise to huge and unexpected effects over areas significantly wider, sometimes very far from the one directly hit by the hazardous phenomenon. In other words, such mechanisms might determine a final distribution of vulnerabilities and, consequently, of damages significantly different from the one resulting in the immediate aftermath of the hazardous event.
The term "propagation" suggests, for analogy to some physical phenomena (e.g. sound, light), the existence of a "mean" allowing the spread across space of vulnerability or, better, of the factors that determine vulnerability. Therefore, the term propagation may be referred to the spread of a given phenomenon from an element or an area to a contiguous/adjacent element or area "by contact" or, even, from an element/area to another element/area, although not contiguous, thanks to the "connecting" action of a specific mean (e.g. air, water).

The spread of vulnerability, and namely of physical vulnerability across space, is very often a direct consequence of hazard propagation. Such consideration is not surprising, since, as mentioned above, this aspect of vulnerability is strongly hazard-related.
Hazards can propagate through different means, involving elements and/or systems not directly hit by the hazardous event and, consequently, determining new vulnerabilities, increasing the overall damage and influencing spatial distribution of both vulnerability and damage. Nevertheless, even though spatial distribution of hazards is generally investigated, the potential propagation of hazards, despite its relevance into vulnerability analysis, is often neglected mainly in case of na-tech hazardous events (Galderisi et al, 2008).
On the opposite, the identification of potential elements or factors able to spread hazards across space may allow us to recognize new or different exposed targets, highlighting the need for investigating their vulnerability and for singling out the most appropriate scale for developing vulnerability analysis.
The concept of transfer differs from the propagation one in that while the latter is generally referred to the widening in space of the impacts of a given hazardous event, capable to affect areas or elements characterized by spatial continuity (in that elements or areas are contiguous or linked to each other through a mean), transfer can be the result of reverberation effects and can involve elements or areas not contiguous or spatially linked to the place of occurrence of the hazardous phenomenon.
Transfer mechanisms overcome the concept of spatial proximity, in that the presence and the continuity of a mean does not represent a key-requirement as in case of propagation mechanisms.
As mentioned before, transfer mechanisms can be referred both to physical and to systemic vulnerability. The displacement of physical vulnerability is generally due to a transfer of hazard factors across space, whereas the shift of systemic vulnerability from one area to another is generally due to functional and economic interdependencies among elements and systems located in the hit territorial context and other placed in other contexts, not directly hit by the hazardous events.
It is worth noting that propagation and transfer mechanisms do not exclude each other: they can occur contemporarily and, according to the well accepted idea that vulnerability is a “multifaceted” concept, they can also turn one “facet” of vulnerability into another, qualitatively and quantitatively different from the previous one.
The above mentioned mechanisms will be more in-depth analyzed in the following paragraphs through different case studies, focusing on the occurred damages interpreted as the result of hazards and vulnerabilities of exposed elements and systems. In detail, the Baia Mare (2000) and the Katrina (2005) disasters will be shortly described for clarifying how hazard propagation and transfer mechanisms may induce a displacement of physical vulnerability across space. More attention will be devoted to the transfer mechanisms due to the interdependencies among elements and systems, looking at the earthquake occurred in 2009 in the Abruzzo region (Italy) and at the eruption occurred in 2010 in Iceland: both of them largely emphasize how pre-existing functional and economic relationships among elements

and systems located at different geographical scales may induce a displacement and a change of vulnerability across space, turning in many case physical vulnerability at local scale into systemic vulnerability at upper scales.

2. Transfer and change of vulnerability across space: case studies

2.1 Hazard propagation and transfer: effects on dynamism of vulnerability

The Baia Mare accident

The disaster occurred in Romania, near to Baia Mare village, in 2000 represents a clear example of hazard propagation through a "mean", capable of extending the effects of hazard to a wider area as well as to involve new, and potentially vulnerable, elements located in areas far from the hazard source, inducing an increase in the overall vulnerability to the hazardous event.

In the mentioned case, toxic substances, namely the cyanide used by the Aurul company to remove precious metals from the tailing, were released into the Lapus River; then these substances travelled downstream into the Somes and Tisza rivers into Hungary, before entering the Danube. The cyanide was carried out by the river waters from the source placed in Romania, to Yugoslavia and Hungary, putting at risk the water supply of more than 2 million of Hungarian citizens. The concentration of toxic substances was supposed to significantly decrease along the path from Romania to Hungary, with less and less impacts on environment and population. Unfortunately, conversely to what was more likely, the presence of "ice on the rivers and low water levels in Hungary delayed the dilution of the cyanide, increasing the risk of municipal water supplies" (UNEP/OCHA, 2000).

Only the prompt action of the local authorities avoided serious damage to the water supply of the two largest cities along the Tisza river, Szolnok (120.000 inhabitants) and Szeged (206.000 inhabitants).

In such a situation, river water was the "mean" responsible for hazard propagation: hence, new vulnerable targets were involved and the consequences of a supposed localized event, in terms both of direct and indirect impacts, extended over areas very far from the one directly hit, affecting natural resources (such as the flora and fauna of the central Tisza river), population, economic activities and organization of the emergency response (involving different national States, different organization and so on) of different countries too. Therefore, the propagation of hazard through the river water has induced a propagation of physical vulnerability across space and, in the meanwhile, it has also determined a change of vulnerability, from the physical vulnerability of the heterogeneous targets directly or indirectly affected to the social and institutional vulnerability arising from the threat to the water supply and to the need for local authorities in different States to deal with such a threat.

Figure 1 - Vulnerability propagation due to hazard propagation. (Source: own elaboration)

The Katrina Hurricane

Although rare, a displacement of physical vulnerability may occur also as a consequence of hazard transfer. A paradigmatic example in this line of thought is the Katrina Hurricane which hit the city of New Orleans in 2005. After the hurricane broke the levees of the Mississippi river, the immediate task for National and Federal Authorities was to drain out flood water from the city. The latter indeed, being placed below the sea level, was characterized by a not fully effective natural water drainage. The amount of flood water to be removed was accounted for about 114 billion liters. In the immediate aftermath of the event, also due to the accident to the Murphy Oil, flood water rapidly become a mixture of toxic and organic substances (Sheikh, 2005). Therefore, the water drainage presented a number of significant concerns. Lake Pontchartrain and Mississippi river were the two potential receptors of the flood water. Due to the fact that the latter was the main source for drinking water supply of the city, Local Authorities decided to pump waters into the Lake Pontchartrain. Furthermore, the treatment of flood waters before pumping them was not possible, due to the lack of full treatment technologies in place and the need for a quick drainage of the water from the urban area. Thus, Local Authorities decided to pump flood waters from the city towards the mentioned Lake that is a water body relatively close to the city itself and connected through the Lake Borgne to the Gulf of Mexico (Fig. 2).

Figure 2 – The area around New Orleans affected by hazard transfer. (Source: National Academies Press, 2009)

Due to the importance of the Lake and of its surrounding as natural ecosystems, the Lake – highly polluted as a consequence of the numerous sources of chemicals and organic substances – had been already interested since 2000 by recovery interventions, under the responsibility of the Environmental Protection Agency (EPA) and Pontchartrain Basin Restoration Act Program. Thus, before Katrina, fisheries and touristic activities were largely developing on and around the Lake.
According to the Congress Report (Sheikh, 2005), after the operations of pumping-in, the Lake, despite the relevant efforts for its environmental recovery, had received in few days the equivalent of several years of urban runoff. Kilic and Aral (2006) estimated that the Lake would have required about 80 years to recover from the stress created by the pumping of polluted waters after Katrina.
Summing up, the release of toxic substances into the Lake Pontchartrain and the consequent pollution of the Lake itself can be considered a "man-made" phenomenon of hazard transfer: by involving new targets, namely the natural ecosystem of the Lake, a transfer of physical vulnerabilities occurred accordingly to hazard transfer which, as in the previous case, has turn into other facets of vulnerability (for example the economic one, due to the loss of economic activities which were largely developed around the Lake).

2.2 Functional and economic interdependencies: effects on dynamism of vulnerability

The Abruzzo earthquake
The Abruzzo earthquake, occurred in central Italy, with a 5.8 local magnitude (APAT, 2009), on the 6th of April 2009. It caused the death of 298 people, 1600 injured, the destruction of the historical centre of L'Aquila – the main city of the Abruzzo region –and severe physical damages in other minor centers located in an area identified as "the crater" (PCM, 2009) for a total toll of over €10 billion.

Looking at the earthquakes experienced by Italy over the last century, after Messina (1908), L'Aquila has been the first big urban center[3] severely hit by a seismic event.
By an engineering perspective, L'Aquila was characterized by a high level of physical vulnerability to earthquake, due to a prevailing stock of ancient masonry buildings.
By an urban planning perspective, even if the city core of L'Aquila is a medieval center, its development has been quite atypical. The growth of the city has not occurred, according to a traditional "core-periphery" model, around the historical city but according to the model of a modern "city region", even if concentrate in a quite small territory. This means that urban growth has occurred through the development of numerous hamlets and villages, quite distant from the city center but strongly related to it from a functional and economic point of view (Fig. 3). In some cases, these small villages are formally recognized as districts of the city. More precisely, the growth of the city mainly occurred after the Sixties, when the Highway A24 connecting L'Aquila with Rome was built up. In the Master Plan approved in 1975, and still in force at the time of the earthquake, 4.200 ha of new residential and industrial settlements were included and all of them have been realized. Thus, between the 1951 and the 2001, the population grew from 54.633 to 68.503 inhabitants, while the urbanized areas from 500 ha (the area of the city core) to 3.100. Thus, the urban development has entailed the establishment of a monocentric urban model characterized by a strong dependency of the new developments on the city core, the historical city, where most of the institutional, administrative, commercial activities and an important university pole were concentrated.

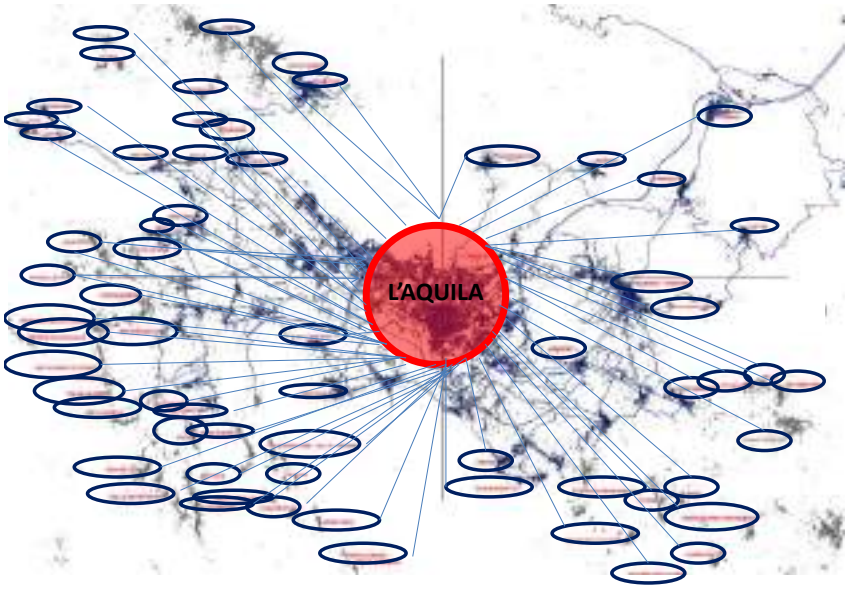

Figure 3 – The city-core and the near villages and hamlets which form the L'Aquila City Region. (Source: own elaboration)

3 72.988 inhabitants in 2008. Source: http://www.comuni-italiani.it/066/049/statistiche/recenti.html

Thus, the historical city, which represented the most physically vulnerable area to a seismic event, played a primary role in functional and economic terms for a significantly wider geographical area.
In detail, in terms of institutional and administrative activities L'Aquila was home to the Court of Law, the Cadastre, the Prison, the Regional Council. These buildings, mostly placed in the historical city, have suffered severe structural damages or collapsed, as in the case of the Palace of Government, head office of the Prefecture that is also the public body in charge of coordinating activities during an emergency phase. As a consequence, the prefecture was prevented from meeting these specific commitments included in its institutional competences.
Moreover, in the historical center of L'Aquila, numerous commercial and touristic activities (bars, hotels, restaurants, accommodation facilities), also due to its touristic attractiveness at regional and national level, were placed. After the earthquake, such area, due to safety problems related to the risk of collapse for parts of heavily damaged buildings, was declared as "red zone" (Fig. 4). Such a declaration has induced the interdiction to access for all citizens and, in turn, the paralysis of the incomes of all people having their source of livelihood in the red zone.

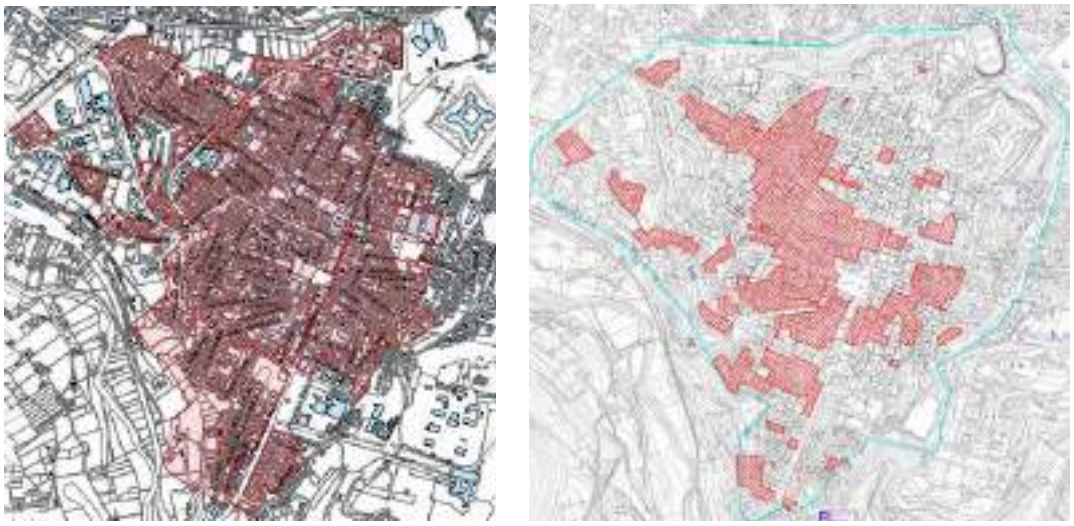

Fig. 4 – Boundaries of the red zone (December 2009 – August 2011) (Source: http://www.comune.laquila.gov.it/pagina52_zona-rossa-della-citta.html)

Apart from commerce and tourism, before the earthquake, economic activities in L'Aquila were mainly related to building sector, real estate, ITC, manufacturing that provided goods and services to other small Municipalities of the crater whose economy was, on the contrary, mainly based on agricultural activity, hunt and forestry (CRESA, 2009).
Lastly, L'Aquila was famous for being an important university pole. University was very important for the city both in terms of identity - being the most ancient University in the Abruzzo Region and also one of the most important in Italy - and for its economic significance. About half of the 27.000 students enrolled at the

L'Aquila University before the earthquake were non-residents (CRESA, 2009), which means that they were the main users of numerous services and economic urban activities, such as local transport, accommodation facilities, commercial activities and so on.
After the earthquake, the registrations at university have decreased and only some adopted contingency measures, such as the promotion of free public transport and free fees for students, have prevented the collapse of a well-established economic activity. Nevertheless, the identity of the city, by this perspective, has been seriously jeopardized.
Furthermore, relevant damages to tourism and to private small enterprises have been recorded in the city core, with ripple effects reverberating from the local scale up to the regional one. As mentioned before, functional and economic damages represent an indirect consequence of the hazard itself, in that rather than related to a "vulnerability to hazard", namely to the earthquake, which generally reveals itself at the hazard scale, they are generally related to interdependencies among elements and systems which pave the way to a "vulnerability to losses" at wider geographical scales.

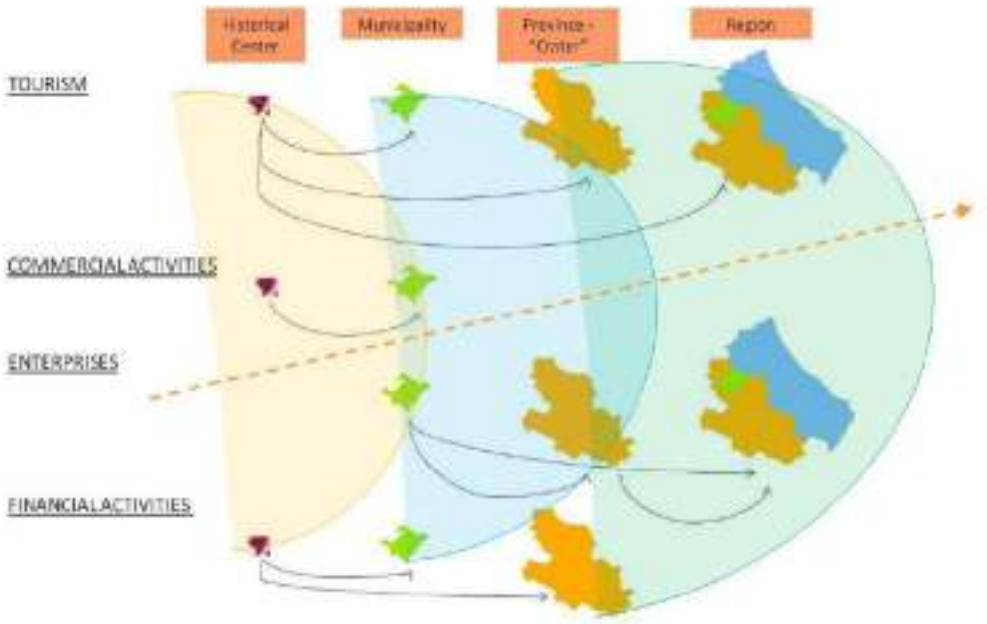

Figure 5 - Transfer of vulnerability across space due to functional and economic interdependencies. (Source: own elaboration)

To sum up, the important functional and economic role of a (small) physically vulnerable area to earthquake (the historical center), due to the concentration of numerous and important activities, and to the interdependencies between the city center and wider geographical areas, has induced a transfer of vulnerability from a sub-municipal, municipal level up to the regional one and, in the meanwhile, has determined a change in the prevailing facet of vulnerability, in that physical

vulnerability at local scale has been turned into a systemic and economic vulnerability at wider geographical scales (Fig. 5).
Furthermore, it is worth stressing that the persistence of an interdicted "red zone" in the historical center of L'Aquila induces also an extension of the time needed for an effective recovery and a likely worsening of the conditions which have determined the vulnerability to losses, with the effective threat of widening vulnerability factors far beyond the involved area.

The 2010 Eyjafjallajökull eruption
Iceland is a well-known volcanic area, with about 130 volcanoes. The last significant eruption of the *Eyjafjallajökull* happened on the 14th of April 2010, after a previous and less intensive episode occurred some days before. The eruption was characterized by a high explosiveness index coupled with a significant production of ashes. Chester et al. (2001) underline that the scale of the potential consequences of a local hazardous event mainly depends on "the strategic position of the threatened city within the economy of a country and/or region". This is not the case of Iceland that has neither a "core" position nor an important economic role in the European and in the global context. Nevertheless, the impacts of the hazardous event have been very relevant because a strategic activity in the globalized world economy, namely the air transport of freights and people, has been affected as a consequence of the propagation of hazard through the air space (Galderisi et al., 2011).
According to a physical analysis of the phenomenon, in the immediate aftermath of the eruption and in the following days, a cloud of exceptionally fine-grained ashes was driven toward Central Europe. Ash particles may induce relevant failures in engines, in essential systems of aircrafts (e.g. sensor systems, hydraulics) and external aircraft components such as pilot windscreens that may become largely non-transparent. Concerns about safety condition led to the closure of large portions of European air space, including some strategic airport as London and Paris over the week 15-21 April. So, on the one hand, the air traffic of some important hubs, connected to each other, were suspended, interrupting in this way the provision of important services at global level; on the other hand, the use of a "global shared" resource, the air space, used as a physical mean for covering the distance from one city to another, was interdicted.
The cancellation of flights across Europe affected about seven million passengers (Oxford Economics, 2010) and has entailed, only for European flights companies, economic losses for $2.6 billion in GDP. What initially seemed to be only an inconvenience for passengers (e.g. tourists, businessmen) and commercial activities soon showed the dimension of a planetary trouble especially by an economic point of view. The effects of the crisis extended indeed far beyond the direct impact on the air transport industry (Oxford Economics, 2010). Due to the closure of air space, significant secondary impacts have been recorded too, so that a "butterfly effect" for the Icelandic eruption has been largely mentioned.
One of the most severely damaged sectors by the air space restriction has been the import-export one. In Europe, most of the export "made in Italy" of fresh fruits (mainly strawberry), mozzarella cheese and flowers was interrupted, whereas in

Africa, relevant repercussions on exports have been reported in Kenya due to the fact that this country normally exports up to 500 tonnes of flowers daily, the 97% of which is delivered to Europe. Therefore, Kenyan farmers have been forced to dump stocks of fresh food and flowers destined for European consumers and, according to Kenya's Fresh Produce Exporters Association Daily Nation, the loss for local producers of flowers, fruit and vegetables has been US$ 3 millions a day as a result of flight cancellations to Europe (Oxford Economics, 2010). The same amount has been estimated for market losses related to flower export to the EU from Latin America and mainly from Ecuador and Argentina. Referred to the import-export sector, the Japanese carmaker Nissan announced a one-day suspension of production of three of its models too, because of the impossibility to import relevant components from the Irish Republic (BBC, 2010).
Other relevant failures, with consequent further economic losses, have been determined by the cancellation of political and business meetings, of relevant cultural and sporting events and also by the delays to services of air mail companies.
As comprehensive data, the total impact on global GDP caused by the first week's disruption amounts to approximately US$ 4.7 billions (Oxford Economics, 2010).

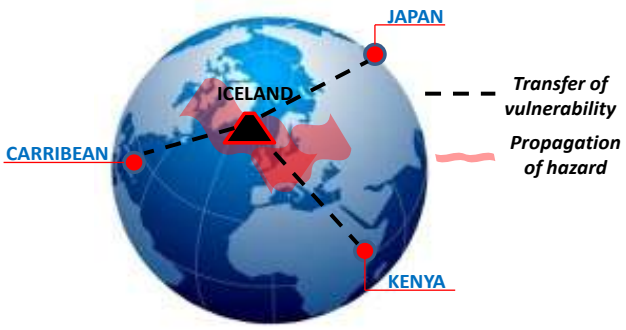

Figure 6 - Transfer of vulnerability across space due to hazard propagation combined with functional and economic interdependencies. (Source: own elaboration)

The Icelandic eruption has clearly demonstrate that the consequences of local hazardous events occurring in places which hold a strategic position within a wider economic context or which affect activities characterized by a key role in the global economy may induce damage which reverberate on areas very far from the hazard source, also at a global scale.
In detail, the propagation of the volcanic ashes - due to the features of the eruptions and to the meteorological conditions - has triggered a transfer and a change of vulnerability: physical vulnerability of airplanes to ashes has been turned into a systemic vulnerability of all the activities (airline industry, people mobility, commercial activities, business, etc.) depending on air flights. The latter vulnerability has been turned again into an economic vulnerability of enterprises or national economies depending on those activities (Fig. 6). The transfer of vulnerability has been clearly favored not only by the hazard propagation but, mainly, by the existence

of well-established functional and economic interdependencies, which allow to overcome the boundaries of any physical contiguity.

3. Conclusions

Hazardous events generally induce significant multi-scale and cross-scale effects: thus, an effective vulnerability analysis has to look far beyond the area directly hit by a hazard, taking into account factors and mechanism which may favor the displacement across space of the different facets of vulnerability.
Up to now, spatial patterns of hazardous events as well as damage distribution in space have been largely investigated. On the opposite, factors and mechanisms inducing a displacement of vulnerability across space are still hard to understand and foreseen.
In this paper, some hints for a conceptualization of the spatial dynamics of different facets of vulnerability have been provided, focusing on propagation and transfer mechanisms, interpreted as "drivers" of physical and systemic vulnerability across space. Propagation mechanisms can be referred to the spread of a given phenomenon from an element or an area to a contiguous/adjacent element or area "by contact" or, even, from an element or an area to another element or another area, although not contiguous, through a specific mean (e.g. air, water). Transfer mechanisms can be referred to effects of reverberation, able to involve elements or areas not contiguous or spatially linked to the place of occurrence of the hazardous phenomenon.
Moreover, according to the Ensure Project, physical vulnerability has been defined as a "vulnerability to hazard", whereas systemic vulnerability has been interpreted as a "vulnerability to losses". Such a difference has allowed us to deepen the discussion on propagation and transfer mechanisms, highlighting how dynamics of physical vulnerability are mainly related to propagation and transfer of hazard across space; whereas dynamics of systemic vulnerability largely depend on interdependencies among elements and systems. These mechanisms may develop very quickly or in a long time span and may occur separately or contemporarily; furthermore, they can turn one "facet" of vulnerability into another, qualitatively and quantitatively different from the previous one.
In detail, the Baia Mare (2000) and the Katrina (2005) disasters have clearly highlighted how hazard propagation and transfer mechanisms may induce a displacement of physical vulnerability across space; the Abruzzo earthquake (2009) and the Iceland eruption (2010) have allowed us to explain how pre-existing functional and economic relationships among elements and systems located at different geographical scales may induce a displacement and a change of vulnerability across space, turning in many case physical vulnerability at local scale into a systemic one at upper scales.
All case studies have been analyzed grounding on damage distribution which, being the result of hazards and vulnerability of exposed elements and systems, has contributed to a better understanding of spatial dynamics of vulnerability. Case studies have clearly shown how, as a consequence of propagation and transfer mechanisms of the different facets of vulnerability, physical as well as functional or

economic damage may affect areas even very far from the hazard source and significantly wider than the one directly hit by hazard itself. Involved areas cannot be confined to the areas immediately surrounding the hit one and they are not necessarily contiguous to it; they can be very wide, depending on the existence of a mean able to propagate hazard, to the role of the affected area or the affected element/system in a wider geographical context, and on the interdependencies among vulnerable elements and systems. These findings open the way to the matter of the appropriate scale for carrying out vulnerability analysis, in that the focus on the hazard scale may lead us to underestimate important aspects of vulnerability and of its dynamics across space: systemic vulnerability, indeed, largely depends on the interdependencies among systems and their components and, as a consequence, the width of the related investigation area has to be determined according to the specific context.

Key words: Permeability, networks, Turkish homeowners, deprived neighbourhoods

One of the major debates in the context of urban cohesion focuses on so-called context effects: Living in deprived areas can have negative effects on the life chances of inhabitants (Galster et al., 2010). Empirically, however, it is still unclear *to what extent* the spatial context (the neighbourhood) influences the economic and social prospects of local residents. The degree of permeability of a neighbourhood, in terms of residents' access to external resources, therefore seems to be an important clue to the power of neighbourhood-related contextual effects. The context or *foci* of interaction outside the neighbourhood might be an important resource to strengthen the functional, social and symbolic integration of the local population. Nevertheless, the bridging potential of networks of residents outside their neighbourhood is still insufficiently explored in urban research. Nor do approaches to neighbourhood renewal focus appropriately on such external or inter-neighbourhood linkages.

The underlying research question is: Which linkages outside disadvantaged neighbourhoods (looking at the context of the city and beyond) have such a bridging power? Interactions and institutions governing trans-neighbourhood movements or interactions are discussed at three different levels. First, we look at individual or group networks within the city, second, the bridging power of local institutions such as schools is discussed, and finally, discourses on the neighbourhood which contribute to either the strengthening or weakening of existing boundaries are explored.

Introduction and outline of the problem

Various studies, especially in the US-American context, indicate the disadvantaging effects of disadvantaged neighbourhoods (Galster, 2008). Although empirical findings suggest neighbourhood effects in the USA (see for an overview Dietz, 2002), equivalent effects in Europe are to date unclear and are thought to be slight (Schönwälder, 2007; Doff, 2010; see for critical discussion: Farwick, 2009; van Ham et al., 2012). What is, however, clear, is that particularly disadvantaged districts are usually characterised by a high proportion of immigrants (Friedrichs and Triemer, 2008; Doff, 2010). Thus immigrants are especially affected by spatially concentrated poverty.

The influence of place of residence on the likelihood of inclusion forms an important background to neighbourhood-based renewal in European cities. The need for spatially focused policies is also confirmed in the fifth cohesion report of the European Commission (EC, 2010b, p.187). In Germany as in other countries (e.g. the

Netherlands, France and the USA), the social mixing of disadvantaged neighbourhoods is a programme objective (Münch, 2009; Beauftragte der Bundesregierung, 2007, p.113; Doff, 2010, p.4). It is thought that the presence of middle-class households in these neighbourhoods will have a "healing" effect.

But why are the results of investigations into context effects in European and also in American cities not always clear-cut and, indeed, at times even contradictory? Lupton (2003) mentions a number of factors that complicate measurements and evaluations in this field. First, the measurement of neighbourhood-related contextual effects is influenced by the choice of spatial investigative unit: the results of analysis can be expected to vary with the choice of spatial scale (e.g. the block, the neighbourhood, the district). Farwick (2009) emphasises, for instance, the significance of the immediate neighbourhood for the effective measurement of the formation of networks and intercultural contacts. Second, the effects are more or less pronounced according to the group being observed, particularly the social positions and ethnic origins of residents are of relevance here (Galster et al., 2010). The "sensitivity" of individuals and groups to the parameters of the neighbourhood thus varies.

Particularly households of higher social position are less restricted to their proximities in the structuring of their everyday life (Savage et al., 2005). Such spatial differentiations in practices have been empirically proven in the work of Wellman (1979) using the example of individual networks. It can thus be assumed that residents use individual "bridges" into other spatial contexts to access resources and to compensate for the disadvantaging effects of the neighbourhood. In the US-American context, Zelinsky and Lee (1998) discuss the "heterolocalism" of migrants, expressed in social and spatial multi-situatedness.

In addition to these processes of boundary crossing and bridging *out* of the neighbourhood, various pieces of research show that residents construct small-scale boundaries and practise processes of social distinction *within* the neighbourhood. Empirical studies have thus contributed to a "disenchantment" with mixing strategies by demonstrating the existence within neighbourhoods of these small-scale separate worlds of residents of differing social positions (Atkinson, 2006; Watt, 2009). These small-scale dissociation processes can mean that even when households of higher social position reside in a neighbourhood they do not necessarily compensate for neighbourhood effects.

In addition to the composition of the population of a neighbourhood and the "granularity" of the mixture there are thus other factors to consider when evaluating context effects. In this paper we argue that residents' bridging to the outside and their construction of boundaries within are important indications of the permeability of neighbourhoods and thus the strength of neighbourhood effects.

Permeability of neighbourhoods: constructing boundaries and bridges

The concept of the **permeability** of neighbourhood boundaries refers to the simultaneousness of **boundaries** and **bridges**. The permeability of neighbourhood

boundaries can vary with direction, point in time, individual or group of individuals. The construction of boundaries on the one hand, and boundary crossing using bridges out of the neighbourhood (or, alternatively, into the neighbourhood) on the other hand, can provide indications of the "permeability" of neighbourhood boundaries. This perspective can creatively augment the analysis of neighbourhood-related contextual effects.

The proportion of disadvantaged residents in an urban district thus only provides limited information about the chances of integration for its inhabitants. Neighbourhoods with comparable proportions of immigrants and disadvantaged population groups (measured according to the proportion of recipients of transfer payments) can take on quite different functions in the urban context. They may be an arrival and orientation space, a transit space for the mobile, or a place to stay for the mobile and immobile. The resources available to the residents of a neighbourhood are, we argue, significantly influenced by the degree of permeability of a neighbourhood. We therefore supplement and broaden the analysis of neighbourhood effects with discourses on physical, social or symbolic boundaries and bridging.

Boundaries and the construction of boundaries

"Neighbourhoods often have sharp boundaries, either physical or atmospheric, but the layers of neighbourhood life are like an onion with a tight core and a loose outer skin" (Power and Wilson, 2000, p.1)

Of interest for our research is the perception of boundaries and the process by which the boundaries are produced and reproduced (bordering) or changed (boundary change: Tilly, 2004a). Individuals move around in a complex web of "hierarchical borders" (Newman, 2003, p.22) and play with numerous group affiliations and identities. In the context of boundary studies Newman (2003, p.20) recommends examining "bottom up" processes in the sense of the everyday practices of residents of neighbourhoods and "top down" processes focusing on the role of institutional actors. Newman draws attention to various levels of analysis for boundaries. As well as examining physical boundaries and the perception of boundaries from the residents' perspective, he suggests considering the significance of semantics (discourses, representations, images, story-telling). Finally he mentions the so-called "management mechanisms" that structure boundaries through forms of governance and institutions and distributions of power.

The production and reproduction of boundaries is thus based on the attitudes and actions of different actors, networks, institutions and media discourse (Lamont and Molnár, 2002; Zerubavel, 1991, 1996; Newman, 2003). These are included in our research design in the dimensions *institutional*, *social* and *symbolic* bordering and further developed with reference to their respective physical-spatial dimensions.

Boundaries, however, have two sides. Thus in line with the perspective taken, they do not always act in a limiting fashion. Boundaries simplify the overall view and aid orientation. In the same way, social boundaries are also drawn by individuals, helping them to orientate themselves in urban space. Simmel (1995/1903) points out

that the blasé and distant attitude typical of city dwellers enable them to live together in a heterogenic urban space. Bordering is thus particularly important for individuals in heterogenic contexts. A broadly based investigation from the Netherlands also indicates the significance of small-scale boundaries *within* neighbourhoods for the explanation of middle-classes remaining in disadvantaged neighbourhoods (Wittebrood and Permentier, 2011).

Living in such districts thus seems to be possible for many middle-class households because they develop an emotional distance to the local problems and demonstrate little loyalty to the neighbourhood. The study from the Netherlands mentioned above establishes that the importance of upwardly social mobile and middle-class households for districts needing renewal should not be overestimated. Interestingly, the investigation discovered differing trends. Considering residents of Netherlands origin, it was primarily middle and higher income households that moved out of neighbourhoods needing renewal, while middle income households with an immigration background moved into these neighbourhoods (following appropriate urban renewal measures).

Boundaries can also create space for interactions. At boundaries transition zones and borderlands can develop, offering opportunities for contact and forums for exchange and interaction. This dimension should also be taken into account.

Bridges out of the neighbourhood context

Decisions by households on where to locate emerge from the interaction between external framework conditions (the housing market is especially relevant here), and the resources and preferences of the household itself. That an individual resides in one particular neighbourhood does not, however, necessarily mean that the action spaces of that individual are primarily oriented on the neighbourhood space (Pinkster, 2007). As early as 1935 the psychologist couple Muchow and Muchow used the differentiation between "spaces of action" and "spaces of possibility" to draw attention to the difference between the space *in which* a person *lives* (the allocated space of possibilities), the space that the person *experiences* (the space of actual experiences, influenced by the individual's biography) and the space *that* the person *lives* (in the sense of behavioural use dependent on range of movement). These multiple "spaces of possibility" are differently formed by individuals according to their resources, preferences and external restrictions (Muchow and Muchow, 1998).

In particular, people in higher social positions find themselves interacting in multiple spatial contexts (from inner-city to transcontinental) (Savage et al., 2005). Savage et al. differentiate between, on the one hand, situative belonging in the context of daily routines and everyday practices and, on the other hand, closer bridging linkages, for instance to "best friends", that may also be located outside the individual's neighbourhood. These linkages of inhabitants beyond the neighbourhood boundaries are also important for explaining their local sense of belonging: "Most residents talk about their local belonging in terms of the connections which it allows with other places and its convenience for everyday life" (Savage et al., 2005, p.204).

Based on the understanding of bridging and bordering described here, the following section focuses on the refinement of possible research questions and discusses dimensions of analysis for the permeability of neighbourhoods.

Initial considerations for the investigation of permeability

The significance of boundaries within neighbourhoods and bridges leading outside them brings us to the question of the *permeability* of neighbourhoods. We assume that households of higher social position remain particularly in disadvantaged neighbourhoods that are characterised by permeability to the outside.

The permeabilities and boundaries of a neighbourhood can be observed and investigated from various perspectives. Alba and Nee (2004, p.29) point out that boundaries gain significance only through the perceptions and everyday practices of individuals and groups: "The effect of a social boundary is to mark a categorical distinction that the members of a society take into account in their everyday activities and on which they align their orientations and behaviour (...) Such boundary constructions aid orientation and at the same time contribute to the ignorance of each group about the real living conditions of the others". It thus seems worthwhile examining the permeability of a neighbourhood from the perspective of the individual, his or her everyday practices and affiliations. This shows which boundaries are relevant for the structuring of the everyday life of residents of the neighbourhood, for their social mobility and also for their group affiliations and spatial belonging.

It seems important to capture in more detail the spheres of action and multiple situatedness of individuals both outside and within the neighbourhood. Our line of argument is thus based on an understanding of space in which space emerges "as the result of the human capacity for synthesis, as a kind of synopsis of the individual 'places' through which the locally divided is brought together in a simultaneous connection, in a spatial framework" (Läpple, 1991, p.37).

In the first place, the intention is to empirically investigate, from the perspective of individuals/households, which bridging and bordering is undertaken by people of higher social position in disadvantaged neighbourhoods.

Our thesis is: The continued presence of middle-class households is distinguished by characteristics of bridging *out* of the neighbourhood and bordering *within* the neighbourhood.

- Households of higher social position that remain in disadvantaged neighbourhoods exploit resources outside the neighbourhood and so can individually compensate for the disadvantaging effects of the neighbourhood. Their bridging and also their experience of boundaries give important indications to the permeability of the neighbourhood.
- The continued presence of households of higher social position in disadvantaged neighbourhoods is accompanied by small-scale processes of dissociation from other social groups. In this way their individual resources

> are of little benefit to other residents and the extent to which neighbourhood effects are cushioned by their continued presence is limited.

Expressed in somewhat exaggerated terms, this could be said to mean that only the dissociation within and the bridging out of the neighbourhood can explain the continued local presence of middle-class households. How though are pertinent findings on the practice and perception of individuals to be gathered so as to give indications about the permeability of neighbourhood boundaries? In our opinion it is worthwhile considering three different analytical levels. The permeability of neighbourhoods can:

- be institutionally anchored (e.g. through an international school, through a firm's network, through the accessibility of various submarkets on the housing market),
- be individual in nature (in the form of action spaces, networks of friends or family), or also
- be symbolic or discursive, acting upon groups and spaces in the form of boundary constructions.

These three aspects are further differentiated and specified in the following discussion.

Institutional contexts

Institutional contexts can significantly promote the social upwards mobility of residents of disadvantaged neighbourhoods. In particular, educational institutions with their accessibility and quality influence the systemic integration and social inclusion of residents. Thus the international studies of PISA (Programme for International Student Assessment) and PIRLS (Progress in International Reading Literacy Study) reveal that academic success in Germany is more closely associated with social origin than in all other participating countries (Konsortium Bildungsberichterstattung, 2010). Especially students with immigration backgrounds from socio-economically disadvantaged circumstances, who often live in disadvantaged neighbourhoods, are impacted by these deficits (Baur and Häussermann, 2009).

Educational institutions thus support residents in their social participation and functional integration – or through their structures and mechanisms can exclude groups or individuals. Indications for the permeability of neighbourhood boundaries can therefore also be captured through institutionalised forms of bridging or, indeed, exclusion. The accessibility of such structures is influenced not only by spatial accessibility but also by knowledge about such facilities and the "felt" permeability.

Educational institutions as institutional contexts play a key role not only for permeability in the functional sphere (individual social mobility). They are also significant for social interactions. Educational institutions play an important part in the process of communitisation of children and parents. Empirical work by Savage et al. (2005) shows that in the course of starting a family new coalitions and groups are formed and that educational institutions can take on a binding or a dividing function

here. Watt (2009, p.18) demonstrates that the educational orientation of family households is a key driver for removing to suburban districts. How then do middle-class households that remain in the neighbourhood choose the appropriate educational institution?

Wellman and Wortley (1990) also confirm the significance of contacts made in the context of school, work and free-time. These contexts have a particular quality for contact-making because they enable regularity, so that a routine can develop in the meetings or exchanges. Such contacts are more than occasional chance encounters, and they also offer an important basis for testing images of the other, and thus for the symbolic construction of boundaries or permeabilities (see further discussion below).

In addition to the institutional accesses that neighbourhood residents exploit outside their neighbourhood, it is also important to discover how accessible and attractive institutions such as schools or also other infrastructure/meeting places *in* the neighbourhood are for visitors from the outside. Which institutions in disadvantaged neighbourhoods are regularly sought out by actors that live outside the urban district in question?

Social networks

A further factor influencing the context effects of disadvantaged neighbourhoods is the form of the social networks of its residents. In particular, the significance of networks that extend beyond the boundaries of the neighbourhood should be more closely investigated. Wacquant (1998, p.27) points out that a concentration of social networks *in* disadvantaged neighbourhoods can hinder or even prevent the upward social mobility of residents: "Ties that bind and keep you down". Filsinger (2010, p.23) also observes the danger for inhabitants of segregated districts of a long-term limitation of social circles to their place of residence: "It is decisive whether enough exchange relations exist to allow linkages to be made".

Granovetter (1973) draws attention to the particular strength of "weak ties" that offer residents of disadvantaged neighbourhoods important support, allowing them to access information that is outside the reach of their own peer group. These networks extend beyond the boundaries of the neighbourhood and are associated with bridging capital: "They are wide ranging and are likely to serve as bridges across social boundaries" (Blokland and Noordhoff, 2008, p.107). Bridging is also in this context dynamic. The production or change of social boundaries is a central part of social interactions: "People everywhere organize a significant part of their social interaction around the formation, transformation, activation, and suppression of social boundaries" (Tilly, 2004a, p.213).

It is thus meaningful to investigate the bridging and/or bordering strength of individual networks in disadvantaged districts. Middle-class households are judged to possess particular strength in this context. The bridging character of such social networks can also create social corridors between places and spaces: "Just as places are connected to other places through the organisation of a network of the imaginary, so one´s network of best friends connects you to other places" (Savage, 2005, p.151).

Early network analyses (see Wellmann, 1979) already confirmed the increasing differentiation of the spatial and social relations of households, a differentiation that went hand in hand with developments in communication and transport. Nauck (1988) argues, for instance, that ethnic concentrations and close access to family networks has little significance for the choice of place of residence for migrants to German cities. Farwick (2009, p.225) similarly draws attention to the declining coherence of local social community. This thus opens up the possibility that the importance of spatial proximity to ethnic neighbourhoods with their infrastructure, sites of crystallisation and chances of contact may be disappearing.

Schnur also refers to forms of individual networks that cross neighbourhood boundaries. He calls neighbourhoods "Fuzzy Places" in recognition of their indistinctness: networks are both "a bit inside" - in the form of neighbourhood contacts - and at the same time "a bit outside" - in the form of, for instance, transnational social networks (Schnur, 2008, p.41). From a network perspective neighbourhoods can thus be described as "clusters in the rather sparse, loosely bounded structures of urbanites' total networks" (Wellman and Leighton, 1979, p.385).

Network theory is a good way to approach the question of which contacts a person maintains, how these are shaped, and where they are spatially located. The significance of neighbourhood for social relationships is discussed in three polarised models (see Wellman and Wortley, 1990; Hennig, 2007). Thus the "decline of community" thesis argues that neighbourhood has limited significance for the existence or creation of social contacts. In contrast, the "community saved" thesis states that the neighbourhood is still of great value for social contacts. The wish for social control and the self-selection of households into certain neighbourhoods leads to the survival of "community" (see Pahl, 1991). Finally, the "community liberated" thesis suggests that primary relationships are still of great significance but that these are no longer embedded in localised "communities". Wellman and Wortley find proof for this third thesis: "Routine contact at work and the widespread use of automobiles and public transit mean that people do not have to live nearby to see each other often" (Wellman and Wortley, 1990, p.568).

Symbolic bordering and permeabilities

The third analysis dimension that can provide indications of the permeability of neighbourhood boundaries is symbolic bordering and bridging. People define "self" and "other" in order to draw up categories that reduce the complexity of everyday life. "The essence of a border is to separate the 'self' from the 'other'. As such, one of the major functions of a border is to act as a barrier, 'protecting' the 'us insiders' from the 'them outsiders' (…)" (Newman, 2003, p.14). Only through the process of bordering are we able to develop activity routines and to enter into social relations with others (Jenkins, 2008, p.27).

Reuber (1995, p.63) draws attention to the importance of boundary construction that results in a better "readability" of neighbourhoods and that thus functions as an framework for orientation in daily activities and also as a memorable space for

residents: "Easily perceived boundaries at the edges of a district as well as between homogeneous, closed subareas promote the small-scale and the transparency of the physiognomy".

The extent to which a space is determined by the power of one group also influences encounters between individuals and groups. Savage et al. (2005) argue that it is not enough to reduce understandings of dissociation mechanisms to the old-established residents of a neighbourhood on the one hand and the newcomers on the other hand (see also Elias and Scotson, 1994, on the established/the outsiders). Rather these dissociation mechanisms are related to different groups, contexts and also concrete places according to individual residential biographies and worlds of experience.

Atkinson (2006) uses the example of the middle-classes to discuss the deeply anchored quest for like-with-like spatial association and the accompanying process of symbolic dissociation from the "others". The negative image of the urban district (re-)produced by media and discourses in the city does not, however, match the social position of the middle-classes that remain there. Thus small-scale dissociation processes become highly significant in positioning a household in comparison to other social groups. Watt (2009) uses the concept of "selective belonging" to draw attention to these many small-scale contexts of local belonging. Based on their own empirical investigations, Blokland and Van Eijk (2010) confirm the limited interaction between different social and ethnic groups.

Tilly (2004b) discusses the significance of "stories", the telling of which contributes to the communalities of "us" and constituting of "the others". This can express itself through the "badmouthing" of particular spatial subareas of an urban district. Verbal constructions of boundaries ("power of naming") were discussed early on by Bourdieu (1991) as a mechanism for safeguarding status, and were illustrated by Watt (2009, pp.14f) using the example of a suburban residential area. Watt draws attention to the reproduced discourse of fear and uncertainty that divides the small residential area perceived as being safe and status-worthy from its surroundings. In this way households of higher status seeking to belong, dissociate themselves from the surrounding stigmatised urban district and thus save their image ("managing the spoiled identity", see Goffman, 1986). Wittebrood/Permentier (2011, p.104) also draw attention to the strategy of small-scale dissociation by middle-classes who remain in disadvantaged districts.

As well as using small-scale processes of dissociation middle-class households can also position themselves in relation to symbolically important locations outside the neighbourhood by using bridges. Such bridging processes provide indications about the permeability of a neighbourhood and its "external image".

Planned research project

Building upon the arguments outlined above, we plan in 2012-2013 to conduct an empirical study on the permeability of segregated neighbourhoods. The study should investigate more closely the linkages, including those that extend beyond the neighbourhood, used by middle-class households both with and without immigration

backgrounds. The aim of the research is to trace down these bridges out of the neighbourhood, so that conclusions can be drawn about the permeability of the neighbourhoods and the power of context effects. In addition, indications about networks or about social and spatial boundary construction *inside* the neighbourhood should be gained.

The empirical work is planned in two steps. In 2012 an explorative investigative research design will empirically test and modify the research assumptions. In a further step the aim is to conduct a larger comparative study in an international context. Case-studies should investigate segregated inner-city districts in various conurbations.

The explorative investigation will be conducted in a German city with a research focus on the German and Turkish middle-class. A qualitative survey of a total of ca. 30 middle-class households of German and Turkish origin is planned.

Key research questions:

- What is the significance of the neighbourhood in the perceptions of residents, which other linkages and also boundaries do they experience?
- Which **bridges** out of the neighbourhood are formed by middle-class households of higher social position that remain in segregated districts? How are these spatially manifested?
    - Individual social linkages (e.g. friends)
    - Institutionalised linkages (e.g. attending school outside the neighbourhood)
    - Belonging to groups and spaces, (re)production of media discourse (dissociation from the "bad areas")
- Which differences between German and Turkish households can be observed? What is the significance of linkages back into the neighbourhood of those that have moved out?
- Which social, institutional and symbolic **boundary constructions** by Turkish and German households within the neighbourhood can be observed? How are these spatially manifested?
- What are the implications of the identified bridges and boundaries for the assumption that middle-class households have a positive effect on "the neighbourhood", that is in terms of social cohesion, role-models, stigma, etc.

Abstract

The urban climate effect already poses a challenge in several cities as it leads to the formation of heat islands and therefore to an increase of the morbidity and mortality rate. Due to climatic changes, these effects are expected to increase. However, the consequences of climate change may be reduced by introducing appropriate adaptation measures to cities.

Spatial planning is regarded to play an important role in adapting cities to climate change as it influences the spatial configuration, type and degree of development of buildings and land use, as well as landscapes and green spaces. But especially the uncertainty and the complexity of climate change confront spatial planning with growing challenges and the difficulty to make and justify decisions. Therefore, local experts from Stockholm (Sweden) and Rostock (Germany) lack a basis for decision-making within spatial planning.

The Climate and Land Use Change-model (CLUC-model) can support spatial planning when making decisions with regard to climate change. The model focuses on the interactions between land use and surface temperatures and on the specific air conditions within cities. It allows to project urban temperature differences with regard to different assumptions of (future or planned) land use/land cover and its specific characteristics. Analysing the input parameters of the CLUC-model, spatial planning mainly can influence five parameters: the specific heat of concrete, the average mass of concrete, the building mass per unit of built land, the roughness length and the evaporating fraction at surface. Being aware of the relevance of these five parameters, spatial planning can contribute to the future temperature conditions.

Summarizing, the CLUC-model can support spatial planning in projecting and evaluating adaptation measures by assessing different future land uses and spatial patterns. Therefore, it can serve as a decision-support tool for spatial planning with regard to climate change.

1. Introduction

The average annual air temperature in large cities is 1 to 2 °C higher than in the immediate surrounding area – in mega cities differences of more than 10 °C can be determined at certain times (Oke, 1973). In the context of climate change, this could present a growing problem for mankind since rising temperatures may also increase the intensity and frequency of the formation of heat islands. Since over half of the world's population was city-dwellers in 2010 and this tendency is growing (Crossette, 2010), the urban climate effect may impact on an increasing number of people worldwide in the 21st century. More severe consequences can be expected concerning future climate change in metropolitan areas than in their surrounding areas (Früh *et al.*, 2011). If societies are not prepared for such changes, morbidity and the mortality rate will increase due to the consequences of a higher heat load (Souch and Grimmond, 2004), an example of which occurred in France in the summer of 2003 (Filleul *et al.*, 2006). It is assumed that the number of summer days (days with maximum temperature $\geq$ 25 °C) and hot days (days with maximum temperature $\geq$ 30 °C) will increase in many regions (Früh *et al.*, 2011), and hence in the areas where people suffer from thermal stress (Souch and Grimmond, 2004).

However, these consequences of climate change may be reduced by introducing appropriate adaptation measures to cities. Spatial planning is regarded to play an important role in adapting cities to climate change as it influences the spatial configuration, type and degree of development of buildings and land use, as well as landscapes and green spaces. Especially the uncertainty and the complexity of climate change confront spatial planning with growing challenges and the difficulty to make and justify decisions.

The article is based on the evaluation of literature and interviews with local experts in the City and Region of Stockholm (Sweden) and the City and Region of Rostock (Germany). In both regions, semi-structured interviews were carried out with local representatives of the departments for spatial planning, landscape planning and environment as well as of the regional planning administration.

As one possible approach to support decision-making within spatial planning, this contribution introduces the Climate and Land Use Change-model (CLUC-model). The model explores the impacts of climate change and land use on surface temperatures as well as the interrelations between them. It is examined in which way the model can support spatial planning when taking decisions and it is planned to evaluate it for Rostock and Stockholm.

First, the focus is on the topic of adaptation to climate change within spatial planning (chapter 2). In chapter 3, the functionality of the CLUC-model is presented. Following this, we discuss how the application of the CLUC-model in planning processes could support spatial planning decisions to influence the future temperature conditions in cities (chapter 4). The contribution concludes with the possibilities as well as the limitations of the model with regard to spatial planning.

2. Adaptation to climate change within spatial planning

There is a broad consensus that both mitigation and adaptation to climate change are needed with regard to climate change (e.g. Davoudi *et al.*, 2009; Alberti and Blanco, 2009; Intergovernmental Panel on Climate Change (IPCC), 2007). Within spatial planning, both tasks are considered to be parts of the broader task of climate change planning (Wheeler *et al.*, 2009). Whereas mitigation has long played an important role, adaptation to the impacts of climate change is attracting increasing attention within spatial planning only for some years. In the European Union, the 2001 report by the Intergovernmental Panel on Climate Change (IPCC) is considered providing an important impetus for tackling the topic of adaptation to climate change (Termeer *et al.*, 2009).

The role of spatial planning in adapting to climate change is based on the spatial relevance of both the impacts of climate change and potential adaptation measures (Biesbroek *et al.*, 2009; Fleischhauer and Bornefeld, 2006). For example, a rise in sea level or increasing temperatures could affect cities, necessitating changes in the current land use or influencing decisions on future land use. Since spatial planning influences the spatial configuration, type and degree of development of buildings and land use, as well as landscapes and green spaces, it has an important role to play in adapting to climate change impacts.

However, adapting to climate change confronts spatial planning with growing challenges. These challenges are mainly attributed to the high level of uncertainty, to the dynamic and the long-time horizon of climate change and to the high complexity of cities and regions (Reese, 2011; Hallegatte, 2009).

The uncertainty of climate change is seen as a pivotal challenge for spatial planning (Hall, 2009). Results from empirical studies in Stockholm region (Sweden) and Rostock region (Germany) reveal that local experts assess uncertainty being one of the most important challenges for spatial planning with regard to climate change. Even if planning always had and still has to deal with uncertainty, local experts confirm that climate change seems to exacerbate this problem. In their opinion, climatic changes are more difficult to predict than other future developments. As climate scenarios contain a wide range of potential climatic changes, they are considered to be too vague and imprecise to develop adaptation strategies and measures. Thus, uncertainty is not only about climatic changes, but also about measures and strategies for spatial planning (i.a. Davoudi *et al.*, 2009; Hallegatte, 2009). Otherwise, spatial planners in Stockholm and Rostock are aware that

uncertainty cannot be completely eliminated and that they have to find possibilities to integrate uncertain impacts of climate change within spatial planning.

Another challenge can be seen in the dynamic and the long-time horizon of climate change. On the one hand, climate change exceeds the traditional planning horizon that often focuses on the next ten or 15 years (Ritter, 2007). Nevertheless, spatial planning has to consider climatic changes already now as planning decisions influence the spatial structure over a long period of time. Local experts from Stockholm and Rostock emphasise that this is not a completely new challenge as planning always had and has to deal with long-time developments. Within the fields of landscape planning or flood protection, the time horizon is up to 200 years.

On the other hand, climatic changes are characterized by high dynamics (Hallegatte, 2009; Schuchardt and Schirmer, 2005). Local experts in Rostock point out that the dynamic of climatic changes is even more challenging than the long-time horizon. Decisions made today have to be compatible with the current as well as the future climatic conditions: „For an architect, it is not more difficult (nor more expensive) to design a building adapted to the climate of Cordoba than to the climate of Paris. But it may be more difficult (and more expensive) to design a building adapted to both" (Hallegatte, 2009, p. 241).

Furthermore, spatial planning has to deal with the complexity of cities and regions. Interventions such as adaptation measures have manifold impacts that have to be considered while designing adaptation measures and strategies (Aerts *et al.*, 2012). Local experts in Stockholm and Rostock are aware of this complexity and consider climate change as a "very complex and complicated phenomenon".

Despite these challenges, spatial planning has to decide on future developments. This raises the question how adaptation measures and strategies can be justified. Due to the uncertainty and the long-time horizon of climate change, local experts lack a basis for decision-making as they estimate the existing climate scenarios being too weak and imprecise. Taking for granted that climate scenarios will remain uncertain (Hallegatte, 2009), the question arises which methods and processes can serve for decision-making within spatial planning (i.a. Hallegatte 2009; Overbeck et al. 2008).

In the following, we present a model that could support spatial planning in decision-making.

3. The CLUC-model

The Climate and Land Use Change-model (CLUC-model) focuses on the interactions between land use and surface temperatures and on the specific air conditions within cities that differ from those in the surrounding countryside. The so-called urban heat island (UHI) effect describes the phenomenon of differing temperature between urban areas and their immediate surrounding rural areas. These differences are

primarily generated in urban areas due to large-scale building structures, sealing and emissions from transport and industry.

The CLUC-model explores the impacts of climate and land-use change scenarios on surface temperatures. While causes for temperature differences within urban areas are well understood, it is difficult to map and quantify the spatial configuration of these (Smith *et al.*, 2011).The model allows to project urban temperature differences arising from specific land covers and their specific properties (for instance rate of vegetation cover, impervious surfaces or building height). To do so, the model combines two elements: Climate change scenarios and different types of land use. The climate change scenarios are based on global and regional climate models (downscaled to the city scale). By using different types of land use as input to the model their specific effects on the surface temperature can be compared. There are similar spatial and temporal patterns between air and surface temperatures, although most of the time they do not have exactly the same values (Arnfield, 2003). Surface temperatures vary more (Lowry, 1988) whereas air temperatures are nearly identical across an immediate landscape due to mixing of air (Brown and Gillespie, 1995). The correlation with microscale site characteristics like sky view factor is stronger (Eliasson, 1996) and surface temperatures are less dependent on the unpredictability of wind speed and direction (Whitford *et al.*, 2001). It can serve as a measure of mean radiant temperature and therefore is a significant factor in determining human comfort (Matzarakis *et al.*, 1999).

The surface temperatures are quantified using an energy exchange model previously developed (Whitford *et al.*, 2001) from the urban climate model of Tso *et al.* (1991) and adopted for example for Manchester (Gill, 2006). It is based on following energy balance equation (Figure 1):

$$R = H + LE + G + M$$

R...net radiation flux; balance between incoming and outgoing energy at the surface
H...sensible heat flux due to convection; transfer of heat energy from surface to atmosphere by air movement
LE...latent heat flux due to evaporation; quantity of heat energy released by the surface due to change of state (evaporation)
G...Conductive heat flux into the soil; quantity of heat energy transferred within and between bodies of matter (soil)
M...heat flux to storage in the built environment; quantity of heat energy stored in the built environment

The model solves equations for the terms in the energy balance simultaneous and expresses the balance in terms of the surface and soil temperature (T_o and T_s).

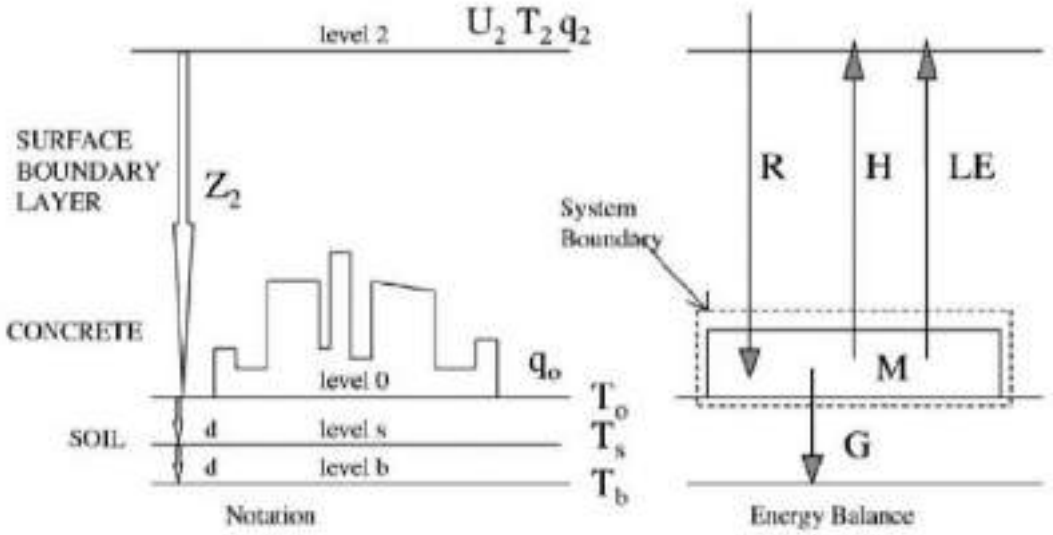

Figure 1. Framework of the energy balance model (Whitford et al. 2001, Tso et al. 1991)

For further explanation of the differential equations see for example Gill (2006) and Tso *et al.* (1991). The process of solving the differential equations during the different time steps is as follows (Gill, 2006):

1. Initial estimate for dawn air and soil temperatures
2. Dawn temperatures as initial conditions for differential equations over the sunny period and simultaneous equations are solved, solutions are taken as sunset air and soil temperatures
3. Sunset temperatures become initial conditions for differential equations over night and simultaneous equations are solved, solutions are taken as midnight air and soil temperatures
4. Midnight temperatures become initial conditions for differential equations over pre-dawn period and simultaneous equations are solved, solutions are taken as the next dawn air and soil temperatures
5. Dawn temperatures from previous day (1.) are compared with new dawn temperatures (4.), if results are unchanged to 3 decimal places no further iterations are carried out, otherwise new dawn temperatures (4.) become initial conditions for 2. and another iteration follows

The surface and soil temperatures are plotted over time and the maximum and minimum temperatures are provided by the model (Gill, 2006). Some input parameters for the model, like air density and specific heat of air, are adopted from previous studies (Table 1). Others are adapted to specific conditions in the case studies of Rostock and Stockholm. Meteorological parameters have to be changed for the assessment of a hot, cloud-free summer day in present and future climate and will vary with different climate scenarios.

Table 1. Input parameters for the energy exchange model (after Gill, 2006).

Parameter & notation	**Unit**
Specific heat of air	J/kg/°C
Density of air	kg/m^3
Thermal conductivity of soil	W/m/°C
Specific heat of soil	J/kg/°C
Density of soil	kg/m³
Specific heat of concrete	J/kg/°C
Latent heat of evaporation	J/kg
Average mass of concrete	kg/m²
Building mass/unit of built land	kg/m²
Roughness length	m
Height of surface boundary layer (SBL)	m
Wind velocity at SBL	m/s
Air temperature at SBL	°C
Specific humidity at SBL	-
Evaporating fraction at surface	-
Soil depth	cm
Soil temperature at depth 2d	°C
Reference temperature	°C
Hours of daylight	h
Sunrise time	h
Sunset time	h
Peak insolation	W/m²
Night radiation	W/m²

Referring on these input parameters, the CLUC-model allows to project urban temperature differences with regard to different assumptions of (future or planned) land use/land cover and its specific characteristics. By changing the input parameters, it is possible to model the impact of different land use scenarios on surface temperature.

4. The CLUC-model as decision-tool for spatial planning

With regard to spatial planning, the crucial question is how the application of the CLUC-model in planning processes could support spatial planning decisions to influence the future surface temperature in cities. To do so, two major questions arise: First, which parameters can be influenced through spatial planning? And second, what can spatial planning do to influence these parameters and therefore the surface temperature within cities?

Looking at the input parameters of the CLUC-model (Tab. 1), spatial planning mainly can influence five parameters:

(1) The parameter ‘specific heat of concrete’ can be changed by using other materials for buildings, streets or places. The higher the specific heat of the materials is, the higher is the capacity to store or carry heat.
(2) Another factor is the ‘average mass of concrete’ that also varies according to the building materials. The temperature is influenced by the specific heat storage mass.
(3) Spatial planning can also influence the ‘building mass per unit of built land’. It mainly depends on the height of a building and the building materials. Higher buildings have a higher building mass and therefore contribute more strongly to increase the temperature.
(4) The ‘roughness length’ describes the surface structure of a city that includes the height of the buildings, the density of an area and the spatial configuration. The lower the buildings and the density, the lower the roughness length and the increase of temperature.
(5) Finally, the temperature is determined by the ‘evaporating fraction at surface’. A lower degree of sealed surface, and therefore a higher evaporative fraction, results in a lower heat effect on the surrounding area.

Being aware of the relevance of these five parameters, spatial planning can contribute to the future temperature conditions. As the urban temperature depends on several other parameters that cannot be influenced by spatial planning (as for example the specific heat of the air or the hours of daylight), there are no generally appropriate measures or strategies to decrease the surface temperature. Therefore, it is very important to take into account the local conditions and their development. By projecting the surface temperature for different land uses, the CLUC-model can support spatial planning in order to make well-founded decisions.

With the help of the CLUC-model, different spatial developments could be compared. Suppose an inner-city area that should be redeveloped: The alternatives are either some flat but extensive buildings or one high building and a small park. By entering the specific data (as well as all the other parameters) into the CLUC-model, the temperature rise for this area can be calculated and the two developments can be compared. Against the background of the uncertainty and the complexity of climate change, the CLUC-model can serve as a decision-support tool for spatial planning.

5. Conclusion

Summarizing, the CLUC-model can help to project the effects of changes in land use and building patterns – and therefore of potential adaptation measures – with regard to climate change. The particular added-value of the model is that it integrates future climatic changes as well as potential changes in land use and building patterns. Therefore, it can support spatial planning in several respects:

(1) The model reveals the complex and manifold effects of planning decisions on the future surface temperature.

(2) As the model considers both future land uses and future temperature conditions, it facilitates spatial planning to analyse the interactions between these two components.
(3) By integrating different future temperature conditions, the model provides an opportunity to take into account the whole range of potential climatic changes.
(4) Furthermore, the model allows projecting the effects of different land uses and spatial patterns on the surface temperature. The comparison of different spatial developments can support spatial planners when taking decisions.

Obviously, modelling the effects of planning measures cannot release spatial planning from its duty to define objectives and set priorities with regard to future developments. In addition, the model cannot show differences in air temperatures due to for example inner-urban wind corridors and shading by trees. However, the CLUC-model can support spatial planning in projecting and evaluating adaptation measures by assessing different future land uses and spatial patterns. Therefore, it can serve as a decision-support tool for spatial planning with regard to climate change.

THE CONCEPT OF INTEGRATION IN SPATIAL PLANNING : AN EXPLORATION

F.M. van Straalen [1]

Keywords: Integration, Spatial Planning, The Netherlands

Integration has become a central standpoint in planning practices in Europe. Several researchers (e.g. Nadin,2007; Vigar, 2009) incorporate the notion of integration in spatial planning. Nadin (2007) distinguishes spatial planning for traditional land use planning by its ability to encourage long term strategic visions, bring together and integrate policies, support sustainable development and improve cooperation between stakeholders and society. Vigar (2009) even argues in his article on integrated spatial planning that integration and spatial planning can be considered tautological concepts.

In the Netherlands the concept of integration has taken shape via the ambitions of the national government, in the 2006 spatial memorandum (Ministry of Housing, Spatial Planning and the Environment et al., 2006). To operate the ambition 'integrated spatial development' was introduced as a new planning process, a process designed to deal with several planning issues at the time, including integration (see Louw et al, 2003; Boelens and Spit, 2006). As a result of the economic set-back, many of the integrated spatial development projects in the Netherlands have come to a standstill, mainly due to their integrative, large-scale, and therefor costly character. As a result, discussion amongst professionals arises whether or not such (regional) development projects will be possible in the (near) future, and how these projects can be completed in integrative ways.

Although integration is a key concept in spatial planning, the actual meanings of the concept in relation to different planning processes and in different views of stakeholders are still vague. This paper explores the different meanings of integration in spatial planning / spatial development processes. Previous designed frameworks for integration (e.g. Healey, 2006; Kidd, 2007; Vigar, 2009) will be used to conceptualize the meanings of integration in spatial planning. Furthermore, and based on the frameworks for integration, the paper assesses the comprehensiveness of the integration concept in spatial planning, thereby taken into account that not all planning objectivesrequire integrative planning processes. The Dutch integrated planning practice will be used as exemplifying case study.

1. Introduction

Integration has become a central standpoint in planning practices in Europe. Multi-functionality, complexity, coordination, and partnership are concepts often mentioned in connection with integration in planning processes. Although these concepts do not automatically reflect an integrated planning practice, they are used as signifiers to show the necessity of integration in planning projects. To have integrated planning practices is considered to be natural, sometimes even fashionable, obligatory, and the road to successful planning practices. The apparent role of integration in planning is revealed in studies of several researchers. Vigar (2009) argues that integration and spatial planning can be considered tautological concepts. A thought reflected in the definition of spatial planning of Nadin (2007, p. 43), who distinguishes spatial planning from traditional land use planning 'by its ability to encourage long term strategic visions, bring together and integrate policies, support sustainable development and improve cooperation between stakeholders and society'. A definition filled with the signifiers of integration: integrated policy, cooperation between stakeholders, strategic visions, etc. Vigar adds that spatial planning can be considered a holistic form of land use planning.

Although different researchers (e.g. Scharpf, 1996; Eggenberger and Partidário, 2000; Healey, 2006; Kidd, 2007; Vigar, 2009) have studied the concept of integration, there is no universal definition of the concept of integration. When looking at integration in planning practice, different stakeholders give different meanings to the concept and use different signifiers to point out integration in planning processes (cooperation, policy integration, complexity, partnership, synchronisation, etc.). Furthermore, different Dutch stakeholders questioned the role and necessity of integration in planning projects during interviews, pointing out the complex and time consuming character of integrated planning processes.

This paper explores the concept of integration in both planning literature and practice. The paper addresses different meanings of integration in spatial planning, the ability of integration to function as umbrella-term (Healey, 2006) for several other concepts related to planning, and the necessity of integration in planning processes. Central questions in this paper are: what is integrated spatial planning and is the umbrella-term integration comprehensible in planning practice? Previous designed frameworks for integration (e.g. Healey, 2006; Kidd, 2007; Vigar, 2009) acted as setting to conceptualize the different meanings of integration in spatial planning. Furthermore the frameworks helped to form signifiers for the analysis of planning practice. The paper subsequently assesses the ability of integration to function as an umbrella for several planning concepts, such as coordination, participation, etc.; thereby taken into account that not all planning objectives might require integrative planning processes. The Dutch regional planning practice is used as exemplifying case. Via a series of interviews with stakeholders in Dutch integrated planning processes and officers of regional governmental authorities, integration in planning processes was studied. In the final sections of this paper the necessity and implications of integration in spatial planning will be discussed.

2. Integration and spatial planning

Although integration has become a key concept in planning, the meaning of the concept varies. In different planning processes, stakeholder use different definitions and formats integrative planning practices. Furthermore different researchers, who studied the concept of integration in planning, have composed different frameworks for the concept, and its forms, aspects, dimensions or types (e.g. Healey, 2006; Kidd, 2007; Vigar, 2009). Healey (2006) studied policy statements in the English planning system and divides the policy statements in types of integration and their meanings. Kidd (2007) has drawn on the relation between health and planning, and created a detailed framework of different forms of integration in spatial planning. Vigar (2009) focused on the evolution of integrated spatial planning in UK territories. He chose to analyse spatial planning via the notion of governance lines, a form of horizontal and vertical integration. Although the different researchers have made different frameworks, elements of their frames overlap (see figure 1 and 2 for the frames of Healey and Kidd). The notion of horizontal and vertical integration, for instance, is found in the studies of all researchers. Vigar took this dimension of integration as basic grid, while in the framework of Kidd horizontal and vertical integration are part of the subdivision of territorial integration, the same applies to the frame of Healey where horizontal and vertical integration are part of co-ordination. One could argue that Vigar focuses on a specific dimension of integration, related to governance, coordination and the integration of policy and action.

Table 2. A framework of integration in spatial planning

Sectoral	Cross-sectoral Integration	Integration of different public policy domains within a territory.
	Inter-agency Integration	Integration of public, private and voluntary sector activity within a territory.
Territorial	Vertical Integration	Integration between different spatial scales of spatial planning activity.
	Horizontal Integration	Integration of spatial planning activity between adjoining areas or areas with some shared interest.
Organisational	Strategic Integration	Integration of spatial planning with other strategies, programmes and initiatives within a territory.
	Operational Integration	Integration of spatial planning with the delivery mechanisms in all relevant agencies within a territory.
	Disciplinary/Stakeholder Integration	Integration of different disciplines and stakeholders within a territory.

Figure 1. Kidd's framework for integration in planning (2007)

Table 5.1 Meanings of 'integration' in recent policy statements about the English planning system

		Type of integration	Meaning of integration
A		Co-ordination	
	A1	Aligning	Fitting in to other policies and strategies
	A2	Co-aligning	Mutual adjustment among diverse strategies
	A3	Multilevel co-aligning	Mutual adjustment both vertically and horizontally
B		Framing	
	B1	Widening a policy frame	Extending an existing frame to encompass a new dimension
	B2	Creating a new frame or vision	Developing a new policy focus and discourse
	B3	Creating a place-focused policy frame	Focus specifically on place qualities and spatial organisation
C		Linking policy and action	
	C1	Policy and delivery	Connecting policy assertions to specific delivery mechanisms
	C2	Regulation and investment	Linking principles governing land use regulation to those governing development investment
D		Linking multiple actors	
	D1	Involving	Drawing the community and key stakeholders into plan-making processes
	D2	Sharing knowledge and ideas	Drawing on and developing knowledge with stakeholders
	D3	Sharing ownership	Developing a shared commitment to the content and legitimacy of a plan/strategy

Figure 2. Healey's framework for integration (2006)

Both Healey (2006) and Kidd (2007) have created a detailed framework to define integration and specify its signifiers. Healey distinguished four main types of integration: co-ordination, framing, linking policy and action, and linking multiple actors. The framework focuses on specific actions to be taken to integrate policies in planning practices. Kidd distinguished three main types of integration: sectoral, territorial, and organisational integration (or co-operation). This framework focuses on the different sectors or places in which integration can take place. Although both researchers took a different viewpoint on integration in spatial planning, their frames partly overlap in terms of signifiers, focussed either on input (actors, organisations) or output (policy, implementation):

- Participation and cooperation (integration of stakeholders and initiatives)
- Spatial scales (vertical integration, redistribution of power, decentralisation)
- Adjoining areas (horizontal integration)
- Policy design (integration of disciplines, programs, policies, and strategies)
- Policy implementation (integration of sectoral activity)
- Policy design to implementation (integration of policy and action)

Both Healey (2006) and Kidd (2007), as well as Vigar (2009), view the signifiers as concepts important to successful spatial planning processes, joint under the umbrella of integration. While the researchers urge the necessity of integration in planning processes, they emphasize the need to be specific with the form of integration sought for in a planning process. Vigar (2009) questions how far integration can be pursued in the contemporary governance landscape. In relation to integration, Vigar refers to the principle of meta-governance and bottom-up planning. This has allowed for a wider variety of stakeholders in planning processes and has redistributed power in planning practices via processes of bottom-up planning and decentralization. Over all, planning processes have become more complex and fuzzy, making it more difficult to be integrative in planning practices. Vigar also points out the positive of this situation. New planning issues such as sustainability and renewable energy are more easily plugged in, and meta-governance allows for flexible alliances of stakeholders and planning processes. Healey (2006) concludes that different actors in planning processes first need to be able to identify their own objectives and their need for cooperation, before integrative projects can commence. Kidd (2007) argues the different facets of integration might more easily be understood in planning practice, than the actual use of integration as key concept. Although Kidd adds that integration only takes place if different sectoral policies are combined in spatial planning, and spatial planning adds to different sectoral policies.

To summarize, planning has become more holistic and complex. To deal with different issues in planning practice, integration has emerged as a concept to be able to organize successful planning processes with multiple stakeholders, different (level) planning authorities, and different views, strategies and policies of stakeholders. Although integration is important, to be able to grasp the meaning of integration in planning practice, the integration-umbrella has to be split in different, more easily understood, concepts regarding policy and stakeholders in planning processes. Furthermore, stakeholders have to identify their objectives for integration as specific as possible in the beginning of planning processes, to be able to reach an integrative planning process.

In the next sections of the paper the Dutch planning practice in explored, to assess whether or not the meanings of integration in planning processes were defined in the beginning of projects, and whether or not integration is understood as an important part of a more holistic and complex planning practice. The signifiers, as specified in this section, helped to identify integration in planning practice and have been used to analyse policy documents and interviews with stakeholders in integrative planning processes and officers of regional planning authorities.

3. The Dutch regional planning authorities in context

The regions discussed in this paper, the provinces, are the middle level governmental bodies in the Netherlands. The Netherlands have twelve provinces, which are considered institutionalized planning authorities. Because the Netherlands is a relatively small country, the Dutch provinces are also small in comparison to, for example, the German or Spanish regions. Although they are small, they face similar problems concerning governance as larger regions in Europe. In order to reach their objectives and mobilize their resources, they have to overcome divisions between different levels of government and public and private stakeholders. Regions have to 'formulate and mediate their interests in the intergovernmental arena' (Benz and Eberlein (1999).

The Dutch provinces have played a role in planning processes since the 1920s (Bosma, 1993), when regional infrastructure became a planning objective. In the 1950s the role of the provincial planning authorities increased when land consolidation was added as regional planning objective, although the national government was a dominant actor in preparation and implementation of land consolidation schemes. During the 1990s the role of provinces in policy-making and planning projects increased due to decentralisation of responsibilities and tasks from the national to provincial governmental level. The provinces started acting as mediator between national policy design and local policy implementation and gained a permanent role in planning projects crossing municipal border. Besides realizing desired land uses, landscape quality and effective policy implementation became provincial planning objectives. In 2004 the national investment fund for rural areas (*Investeringsbudget Landelijk Gebied*) was decentralized to the provinces, making the provinces accountable for the implementation of the National Ecological Network and the related land consolidations. As a result provincial planning authorities became active participating stakeholders in planning processes. Besides regulation and coordination of policies and projects, they were actively involved in integrated planning processes, including (strategic) acquisition of land and risk full investment in projects. (Van Straalen et al., in review)

4. Dutch integrative regional spatial planning

Although integration or integrative projects have been part of the Dutch planning tradition for a longer period of time, the concept of integration was formally introduced as objective of the national government in the 2006 spatial memorandum (Ministry of Housing, Spatial Planning and the Environment et al., 2006). To implement the objective, 'integrated spatial development' was introduced as a new planning process. Integrated spatial development had to deal with several different planning issues, including integration, transparency, openness, and participation (see Louw et al, 2003; Boelens and Spit, 2006). The concept might be best understood in relation to the explanation of new emerging patterns of governance, as referred to by Kidd (2007, p.163): *"... an emphasis on openness and transparency, broad*

stakeholder engagement and consensus building in policy development and delivery. The potential benefits to public policy of a discursive approach, bringing multiple perspectives together, are of course reflected in the extensive collaborative planning literature (e.g. Healey, 1997)". The concept of integrated spatial development as such, was seen as cure to many planning issues, although the content of the concept unclear. Different reports, such as a guide to integrated spatial development *(reiswijzer gebiedsontwikkeling,* e.g. Ministry of Housing, Spatial Planning and the Environment, et al., 2007), had to provide for and facilitate new integrated planning projects.

As selected planning level for optimum integrated planning, the Dutch regional planning authorities – eager to prove themselves as mediator between national and local planning levels – started many integrated spatial planning projects in which integration was expressed as objective to guaranty the success of the projects. In many of these (cross-municipal) projects, cooperation was sought between province, municipalities, and private stakeholders, in some projects even national government became involved as stakeholder. Furthermore different land-uses where combined in these projects and cost-recovery schemes where set up to redirect funds from profitable to non-profitable parts of the projects (see De Wolff and Spaans, 2010).

As a result of the economic set-back, many of the integrated spatial development projects in the Netherlands have come to a standstill, mainly due to their integrative, large-scale, time-consuming, risky, and therefore costly character. Discussion amongst professionals arose whether or not such (regional) development projects will be possible in the (near) future, how these projects can be completed, and if integration of objectives, policies, and stakeholders in projects is still possible (see for instance Ministry of Interior and Kingdom Relations, et al., 2011).

5. Integration in Dutch regional spatial planning, a stakeholder perspective

As shown above, the economic set-back, and its unwinding, has influenced planning practices. As a result planners and governmental officers have taken a reflexive attitude towards the planning practices started before the crisis when, in the words of an interviewee, 'everything seemed possible'. As part of a larger project concerning spatial planning and land policy in the Netherlands, interviews took place with different stakeholders in integrative planning processes and different officers of regional planning authorities (the provinces), in the period 2009 to 2012. One of the topics addressed in these interviews was integration in planning projects, sometimes introduced by the interviewer, sometimes brought up by the interviewee before a question was asked on this topic. In this paper the analysis of these interviews is used to explore the meanings and roles of integration in Dutch regional planning processes, according to planning practice. The signifiers mentioned in section 2 of this paper were used as framework for analysis of the interviews:

- Participation and cooperation (integration of stakeholders and initiatives)
- Spatial scales (vertical integration, redistribution of power, decentralisation)
- Adjoining areas (horizontal integration)
- Policy design (integration of disciplines, programs, policies, and strategies)
- Policy implementation (integration of sectoral activity)
- Policy design to implementation (integration of policy and action)

The different interviewees all had different ideas of integration in spatial planning. Some of the interviewees asked for a clarification or definition of the concept before addressing the question, others explained their idea of the concept, still others referred to the concept without explaining their ideas, using integration as general concept. In all interviews the interviewees where given the opportunity to explain their ideas of the concept, before the interviewer would address the concept (as umbrella-term).
Most used terms in relation to integration where complexity, participation, and integrated implementation of different land uses. Officers of the regional planning authorities often mentioned the relation to landscape quality, as 'glue' between different land uses, the possibility to integrate land uses and planning projects on a cross-municipal scale, and cost recovery within projects as additional perceptions.

One interviewee emphasized the possibility of regional planners to choose an area oriented viewpoint, as meaning of integrated policy implementation. The ability to look through a lens of planning processes, instead of having a sectoral lens. This gave the interviewee the advantage to combine funds, planning tools, and planning objectives of different stakeholders involved in the planning process. In the view of this interviewee integration or integrated spatial development was a tool to implement planning objectives such as the objectives of the investment fund for rural areas. Some of the other stakeholders had the same notion of integrated spatial development as tool, while other interviewees had a different view. In the view of this second group of interviewees integration was an objective to be met in planning processes. As a consequence some interviewees viewed integration as opportunity to improve processes, while other viewed it as an obligation, sometimes interfering with other planning objectives.

One interviewee referred to the a phrase of national government from the 2006 spatial memorandum (Ministry of Housing, Spatial Planning and the Environment, et al. 2006), "*decentralised if possible, centralised in necessary*", in which decentralised planning processes are preferred. The interviewee stated '*sectoral if possible, integrative if necessary'*, relating to the complexity of integrative planning processes and favouring straight forward land use planning. One interviewee adds to this statement by highlighting the possibility to overrule municipalities via a regional zoning plan, possible since the new Spatial Planning Act of 2008. This offers the provinces the possibility to implement national or regional planning objectives without the cooperation from or by excluding a municipality opposing the implementation. Although most interviewees would opt for cooperation with

municipalities and state this form of planning would damage the relationship between municipalities and provinces, this would simplify planning processes.

In relation to the previous point, different interviewees relate to the complexity of integrative planning processes in which several stakeholders are involved. Often these processes are time consuming, because all stakeholders have a voice in the design and implementation of the project. In some planning projects private stakeholders or different ministries involved in a project of national importance, cooperate and are represented as a group by one person. According to an interviewee the advantage of this form of cooperation in the simplification of complex processes with multiple stakeholders. However, the different representatives have to spare more time for consultation with the other members of the group, not necessarily speeding up the process. Although a high number of stakeholders might lengthen processes, the involvement of many stakeholders in planning processes is seen as a natural occurrence of more integrative or governance oriented planning projects. One interviewee refers to the concept of depillarization in the Netherlands, resulting in smaller groups of stakeholders, more groups of stakeholders and individuals, and more independent voices. According to this interviewee we should not confuse the involvement of multiple stakeholders in planning processes and the concept of integration in planning. The first is a (no-stoppable) natural occurrence, the latter being something to actively strive for in processes or to use as a tool to improve the effectiveness of planning processes.

6. Discussion and conclusion

Overall interviewees did not have a straightforward definition of integration in planning processes, but referred to the same signifiers as the frameworks of Healey (2006) and Kidd (2007); although integration was mentioned more often in relation to policy implementation and the involvement of multiple stakeholders, than in relation to the integration of policies. Furthermore, in relation to horizontal and vertical integration, the regional planning officers often referred to policy integration within the own organisation and in cross-municipal projects, but the synchronisation of policies between provinces is less often mentioned. In relation to the aim of Dutch national government - although the national government recently collapsed and elections will be held in September 2012 - to decentralise the responsibility for spatial planning and the development of nature to the provinces, the synchronisation of policies related to planning becomes more important. Linked to the reasoning that borders are merely social constructs and expressions of power relations (Allen et al., 1998; Paasi, 2010), provinces or in general stakeholders integrating policies should be aware of these power relations and if possible redistribute power to be able to integrate policy design and implementation.

When assessing the meaning of integration in spatial planning, there is a deficiency between planning literature and practice. In relation to the observation of Kidd (2007), the fuzziness of the notion of integration, planning practice might benefit

from a clear separation of different form, dimensions, or aspects of integration. Interviews have shown that the meaning of integration differs between stakeholders involved in the same planning process or at the same planning level, making it harder for them to cooperate, integrate policies, or implement policies in an integrative manner. Concepts such as coordination, cooperation, cross-border projects, synchronization of policies speak to the mind of interviewees and might more easily spark integrative planning processes, than the vague, or rich, concept of integration.

As for the (future) role of integration in planning processes, integration is there to stay. From the perspective of planning literature, integration is a natural part of a more holistic spatial planning. From the perspective of planning practice, integration is not a necessity when opting for traditional (land use) planning projects and integration complicates planning processes. However, interviewees have shown the dedication of planning practitioners to integration and integrative planning processes. The interviewees point out the strengthening role of integration and participation in integrative planning processes, leading to stakeholders who understand each other, share interests and might more easily seek cooperation in future planning projects. Interviewees also hint at the necessity of policy integration to benefit effective planning projects; although future integrative projects would be of a smaller scale, compared to those prior to the economic setback.

7. Future research

After studying the meanings and role of integration in planning processes, and concluding integration is a viable part of planning practice, a new research aim emerges. This paper mainly viewed integration in planning practice from the perspective of planning output and input from stakeholders. Future research could focus on the conditions for integrative planning processes. This research should not only focus on the resources of stakeholders and the power distribution between stakeholders, but should also focus on laws and regulations enabling or disabling integrative planning processes.

HOW TO MAKE DEVELOPMENT PLANS SUITABLE FOR VOLATILE CONTEXTS

Ward Rauws[1], Matthew Cook[2], Terry van Dijk[3]

Abstract

A Complex Adaptive System (CAS) approach enables a dynamic view of how spatial systems evolve, considering spatial development to be a product of multiple and interrelated drivers for change. These processes typically have a remote causality and progress in a non-linear fashion. Those promoting CAS within the realm of spatial planning suggest it can help planners to gain an enhanced understanding of spatial change and find alternative ways of guiding spatial development. However, little attention has been given to the implications of remote causality and non-linearity on planning practices in general and development plans in particular. While development planning is a dynamic process, development plans have been criticised for exhibiting increasing rigidity during their lifetime and therefore offer limited utility to effective spatial planning. From a CAS perspective, this rigidity is particularly problematic since it requires planning strategies that are flexible enough to productively co-evolve with spatial dynamics. Meanwhile, development plans are widely recognized for their capacity to set direction, unite initiatives around a shared vision and the certainty they provide for landowners, project developers and citizens. Therefore, this paper explores with help of a case study some of the issues and tensions which may arise if the CAS approach is promulgated further and leads to significant changes in the design and implementation of development plans. It shows how CAS-based principles for developments plans may enhance the adaptive capacity of urban environments, but can also undermine other features of development plans. Additionally, some alternative skills are requested from planners when strengthening the adaptive capacity becomes a central aim.

Key words: adaptive capacity, complex adaptive systems, flexibility, development plans, Blauwestad

1. Introduction

Complexity science is now viewed by a number of authors to provide considerable utility in understanding and planning the spatial (e.g. Allen 1997, Batty 2005, Portugali, 1999; Webster, 2010). Portrayed as complex adaptive systems (CAS), spatial dynamics are understood to evolve in response to changes in their context, e.g. a city in response to a financial crisis or to environmental changes. However, a

CAS's evolutionary behaviour is dynamic and difficult to predict as responses to changes in context are non-linear and emergent (Holland, 1992). Seen in this way, spatial development is discontinuous and often involves unforeseen change, rather than smooth progression (Portugali, 2006). Therefore a CAS approach describes dynamic processes of spatial development and highlights a situational perspective; spatial issues cannot be seen as unchanging, a-temporal and independent of their context (De Roo, 2012).

While for a number of years complexity science has been drawn upon to theoretically understand and artificially model spatial dynamics, only recently has it been used to suggest alternate spatial planning practices (see Alfasi & Portugali, 2007; Portugali, 2010, Rauws & De Roo, 2011; chapters from De Roo & Silva, 2010). This paper seeks to contribute to this growing body of research by exploring the implications of understanding spatial dynamics as CAS on spatial planning practices with particular reference to development plans.

Development plans are a well established, central tool of current planning practices; they are official documents produced by local and regional authorities to guide and regulate land use change (Healey & Shaw,1993; Kaiser and Godschalk, 1995). However, development plans are known to exhibit increasing rigidity during their lifetime and therefore are flawed for effective spatial planning under circumstances with a high degree of uncertainty (see e.g. Booth, 1996; Staley & Cleays, 2005; Larsson, 2006). Underlying drivers of spatial development, such as technological innovation, socio-economic and lifestyle trends, and also local demands and capacities frequently transform spatial configurations faster than development plans are able to deal with.

Development plans are often not sufficiently responsive as they set out a predefined trajectory of change. While the aim of planning is to support the making of better future places, most development plan designing processes take the current physical, economical and institutional configuration as fundament. As this configuration can considered to be fluid, it results in development plans that do only partly match the dynamic 'reality'. Some argue they often exhibit increasing rigidity as they are formalized and are consequently ill prepared for societal, economic or ecologic change experienced during their implementation and/ or completion. According to Alfasi, (2006) and Staley & Claeys (2005) the rigidity of development plans can discourage further spatial innovation and obstruct bottom-up development initiatives. In addition, Larsson (2006) and Van der Valk (2002) argue that the strong determining power of development plans can lead to bureaucratic situations in which matching the dynamic reality and the rigid plan is time-consuming. In other words, it is argued developments plans tend to lack the flexibility to co-evolve with emerging changes.

From a CAS perspective, such rigidity of development plans is particularly problematic. A CAS approaches requires flexible development plans that have capacity to productively co-evolve with spatial dynamics, to effectively mediate and respond to contextual changes and evolutionary dynamics as they emerge. However, also and importantly, development plans are widely recognized for the certainty they provide for landowners, project developers and citizens (Neuman, 1998). Indeed,

they are important as they stimulate and direct spatial developments and engender investor confidence.

Therefore this paper considers what the CAS perspective may mean for development plans. Although the production of development plans include various dimensions (Conroy & Berke, 2004), we concentrate on the visionary product − the design – as an effective instrument to spark urban change (Neuman, 1998). We focus on development plans for district level (5-15 years) since they incorporate the challenges of variety of actors involved due to their size an high level of uncertainty, due to their time span, while often incorporating concrete implementations measures next to strategic goals. It is asked how the capacity of these particular development plans to incorporate the temporality and dynamics of spatial relations and functions might be enhanced while the certainty current development plans provide to engender investor confidence can be retained. Additionally, we question how such plans may help to improve the adaptive capacity of areas in development. This way, the paper explores some of the issues and tensions which may arise if the CAS approach is promulgated further and leads to insight in the required changes in development plans and indeed planning practices more generally.

This paper is divided into five sections. First, the key concepts of CAS are briefly discussed, exploring how CAS portrays reality and subsequently what kind of consequences this perspective could have for planning and governing the spatial. The second section contains a review of a development plan in the Dutch planning practice. We analyse in what sense the rigidity of a development plan can be problematic and what sources for rigidity in this particular plan can be identified. The third section discusses what consequences a CAS approach might have for drafting and implementing development plans aiming for more flexibility. It is concerned with the fundamental questions can be raised when the structuring capacity of plans and the aim for adaptive capacity promoted by a CAS approach a brought together. Taking this one step further, section four identifies possible lessons for planning practitioners on how CAS-based principles for designing and implementing development plans may increase the flexibility of these plans and the adaptive capacity of areas in development. The paper concludes with carefully exploring the considerations and challenges that planners could be confronted with when the CAS approach would further penetrate planning theory and practice.

2. Complex Adaptive Systems and a Perspective of Becoming

Already some time ago planners moved beyond the idea that they can design en shape spatial development through solely technical rational approaches. Due to the work of amongst others Simon (1957), Lindblom (1959) and Davidov (1965), the limitations of these approaches became apparent, showing the incompleteness and selectivity of information and the influence of political or power-driven motivations on decision making next to rational ones. With the communicative turn in the 1990s, increasing attention is given to the context dependency of spatial issues and the plurality of perceptions, preferences and values of actors involved in planning processes (Healey, 1996, 2003; Innes, 1995). Moreover, the idea of spatial issues being embedded in a multiple and overlapping networks gained momentum inspired by Castells work on the Network Society (1996). Due to these various factors highlighting the context dependency and multiplicity of spatial issues alternative

perspectives are explored to enhance our understanding of spatial change in attempt to support planning innovation.

Various scholars suggest complexity adaptive system (CAS) thinking may provide planners with an interesting set of concepts which could help to further develop a dynamic perspective on spatial developments. During the 1990s Batty and Longley (1994), Allen (1997) and Portugali (1999) showed the relevance of mechanisms of change based on CAS is discovering new patterns of emergence in cities. In the years that followed, this research has been refined and also extended for example consensus building (Innes & Booher, 2010), city development and property rights (Webster 2003, 2010), transitions in urban-rural integration (Rauws & De Roo, 2011) and, governance and decision making (Gerrits, 2008; Portugali, 2010, De Roo & Rauws 2012,). A central argument to all of them is that a CAS approach helps understanding unexpected transformations as the heart of spatial issues, instead of seeing them as exceptions or failures. Below we discuss the CAS approach and explore how it may cast the design of development plans.

Those inspired by CAS argue it provides a straightforward critique on the Newtonian world, assuming a world of knowable entities independent of time. CAS are embedded in and contributing to non-linear processes of change producing out-of-equilibrium states (Wolfram 2002). From a CAS perspective the world is considered to be in a state of constant flux. It provides a perspective on spatial dynamics being time and space related resulting in continuously evolving realities.

CAS are open systems, evolving through interacting contextual and internal processes (Portugali, 2006; Wolfram, 2002). It is argued that their continuous adaptation is on one hand the result of contextual interferences triggering reconfiguration in the attempt to create the best possible 'fit' with its environment. At the other hand, CAS are suggested to have internal mechanisms of adaptation referred to as self-organisation. These are processes in which the constituents of a system (individuals actors, informal coalition and organisations) alter their behaviour, undertaking actions that result in a jointed efforts to change frameworks that constitute their behaviour. The self-organising aspect is that new structures, patterns and organisations that may arise, altering these frameworks, from actions between various actors in the system without external coordination (Heylighen, 2008). In sum, the evolution of CAS can be understand as mixture of top-down and bottom-up processes, including planned an unplanned actions, which continuously create feedback and feed forward loops (Lewin, 1992) influencing one another.

This mixture of top-down and bottom-up processes creating feedback and feed forward loops results in emergence. This behaviour is not limited to a system itself, since a system is considered to be open. Therefore the process of continuous adaptation effects other systems as well. This phenomenon of interrelated systems is known as 'nested systems'- "cases are in themselves complex systems which are nested in, have nested within them, and intersect with other complex systems (Byrne, 2005 p. 105)". It does not necessarily mean they are ordered in an hierarchical way, as spheres of influence can go across such categorisations. The concept of nested systems emphasizes the interdependency of processes of change and the dynamics CAS cause while being infused by others.

The CAS approach portraits a dynamic reality that evolves to a large extent autonomously as a result of interrelated processes. Both planned and unplanned actions are considered to be part these processes, the path of development, however, presumed to progress in a non-linear way. The CAS approach puts forward a perspective of 'becoming', in which visioning, designing and decision making on planning situations should not only be sought in 'being' but should be considered as a part of on-going trajectories of change. It suggests in many situations predictability is low and uncertainty high, and challenges planners to accept remote causality between planned interventions and their outcomes.

What kind of consequences would CAS imply for planning in dealing with this fundamental uncertainty? According to Bertolini (2010, p.93) planning needs to 'seeks a solution through the identification of robust measures – to enhance the resilience of the system – and options which can and should be left open – to enhance the adaptability of the system'. De Roo & Rauws (2012) suggest planning should move to more adaptive strategies based on a 'situational understanding' of socio-spatial phenomena, taking into account how planned an unplanned developments meet, intersect and overlap together becoming manifest in a certain time a place influencing (perceived) possibilities and limitations for planning interventions.

If such views on planning would be implied, what then would be the consequences for development plans? Although exploratory, applying a CAS approach seems to suggest that development plans should incorporate mechanisms that enable the spatial system under concern to co-evolve successfully with a transitioning spaces and places, including permanently redefined demands over time and space. Seen this way, rigidity is a serious treat to productive planning and development plans may have to improve their flexibility.
The next section explores the issue of rigidity and its consequences on a more practical level analyzing a development plan in Dutch planning practice.

3. Rigidity pitfalls for development plans – challenges in practice

In this section we draw on development plan Blauwestad to explore the possible implications for development plans when rethought in the light of a CAS approach. Blauwestad, located in the Northern part of the Netherlands, is a comprehensive development including a diversity of functions to be realised. Although it does not represent all development plans in Dutch planning practice, similar kind of plans, such as 'Meerstad' (Van den Brink et al. 2006) and 'Wieringerrandmeer' (Woltjer & Al, 2007; Woltjer, 2008), have been designed. More importantly, it is part of a category of development plans that may not be pursued it its current form if a CAS approach gains more influence on planning.

Before analysing Blauwestad in-depth, we first briefly explain some key aspects of the Dutch planning system to provide insights in the function of development plans in Dutch planning practice. The Dutch planning system is foremost a legislative rather than a political system and heavily emphasizes protection and legal security (Janssen-Jansen & Woltjer, 2010). In this system development plans have an important role as they are a central tool in guiding future development. Development plans are intensively prepared by public planners, including participation of private

and civil actors as there is a deep rooted believed in consensus building (Van de Valk, 2002), often leading to a comprehensive designs which are then formalize and carefully followed during completion. As a consequence, the potential to negotiate the scope and substance of developments is limited (Janssen-Jansen & Woltjer, 2010).

3.1 Blauwestad

The development plan for Blauwestad (Blue city) was designed to give a new boost to a region that experienced both demographic and economic decline. The plan comprised an area of 1450 hectares with dominantly rural activities. It is part of a region that has a rich and economically successful argicultural history (Hidding, 2002). During the 1980s, however, the vitality of the region was declining. A part of the agricultural plots remain unused due to EU policies, industrial sites closed down and as a consequence unemployment was increasing, causing young and highly educated people to leave the region (Dammers et al., 2004;Bekkers & Moody, 2006).

A broadly shared sense of urgency raised support for a large scale spatial intervention, resulting in development plan Blauwestad. Development plan Blauwestad has emerged from the initial ideas of two local actors they displayed in 1989 and is eventually developed by PPP (public-private partnership) that planned to invest in total 82 million Euros (NRK, 2010)[4]. It is a grand vision and has been lauded on its integral approach combining economic development, housing, nature and leisure development, and water management measures (winner "Gouden Piramide 2005", national prize for 'inspiring commissioning'; nominated World Architecture Festival 2008 category 'Nature').

The heart of the plan is a man-made lake (800 hectares) on former agricultural land. In and around this lake, the construction of about 1200 luxury mansions (later on this was raised to 1480) with a minimum price of 300.000 Euros was planned (NRK, 2010). It was expected that building these high end properties, by making developers investing a share of the profit in the common structures, would largely cover the costs for creating the lake. This way, building houses would generate both the funds for the lake, the nature development. And at the same time it was expected to stop the outmigration of highly educated people and invite wealthy families from other regions of the Netherlands to migrate to this area giving a boost to the regional economy (Stichting Blauwestad, 1997; NRK, 2010). The project was expected to deliver 400 temporal jobs and 400 structural new jobs (Dammers et al, 2004) The lake would also make the region a touristic center for the North of the Netherlands as well as help solve some serious water management difficulties in the region (Roggema, 2010). The realisation of the plan started in 2004.

[4] Including acquisition of the land. In 2010 the total costs were increased to a total amount of 785 million Euros (NRC, 2010)

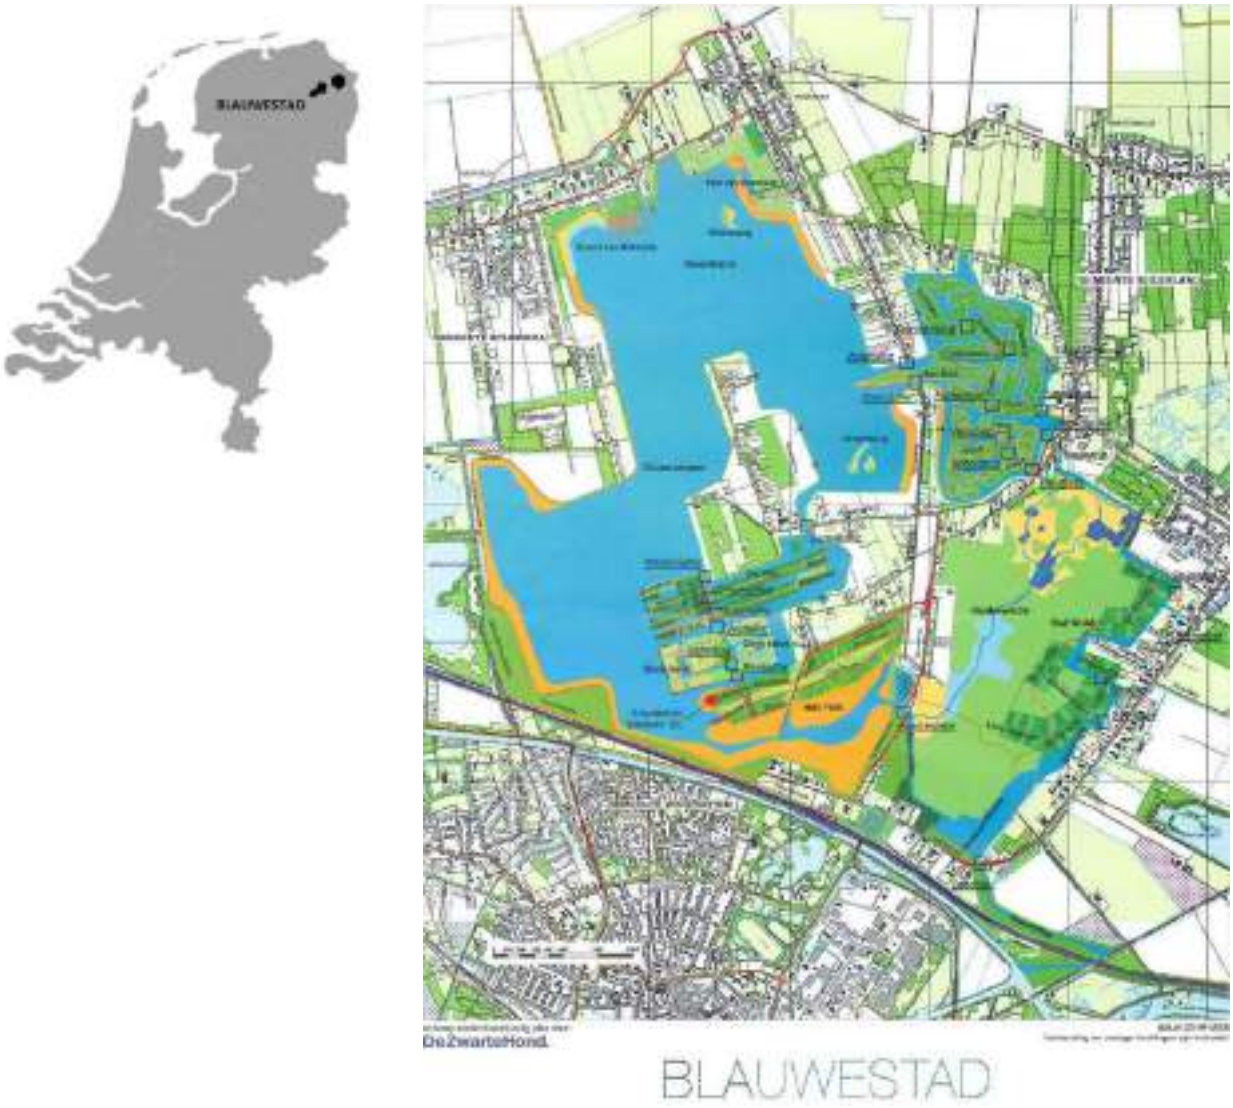

Figure 1: Development plan Blauwestad including an artificial lake on former agricultural land (800 hectares) and several thematic neighbourhoods for the construction of 1480 luxury mansions.

However, things evolved rather different than originally planned. The investments needed for completion of the plan were higher than expected (NRK, 2010). Therefore, the private project developers have been granted permission to build an additional 280 houses and to use the profits of this extra quota to address the financial shortfall (NRK, 2010). More serious is that the estimated demand for luxury houses appeared far above the real demand. Planners expected an inflow of house buyers from outside the region, presuming much higher prices and low supply elsewhere and ICT to make people footloose, enabling them to even run their business in the Randstad region, 200 kilometres away. These expectations did not materialise – not in the years before the financial crises and certainly not after.

Initiatives to loosen the strict design regulations were not accepted by the regional authorities as they would damage the desired image of luxury living in a high quality environment (NRK, 2010). However, the reputation of the project with its peripheral location was increasingly becoming one of failure and the sale of plots for private

housing construction almost came to a full halt. “The idea of moving to Blauwestad is almost similar to emigrating to another country” was the general tendency (NRK, 2010 p.110). Aggravating this, the few potential buyers could not move in because they had difficulties selling their current house due the stagnation of the national real estate market as a consequence of the financial crisis. This in turn caused the heart of the plan, a district called ‘the village’ designed to include local shops and other community services, to remain unconstructed as the lagging development around it caused neither the funds to be available, nor the residents to spend their money there.

In 2007 two of the three participating private developers quit and the financial risks to the public parties involved have increased substantially. In 2009, the PPP was dissolved and the regional government had to take the financial loss (28,8 million Euros) and full reasonability and financial risks for completing the plan (NRK, 2010). In 2010, with only 183 of the eventual 1480 plots are sold (Provincie Groningen, 2010), the development plan was adjusted, extending the duration of implementation and rescheduling the expected number of plots sold each year from 150 to 40 (Provincie Groningen, 2010).

3.2 Sources of rigidity in Blauwestad

Surely, the development plan for Blauwestad can be considered as a powerful vision. It was able to bring together a diverse set of stakeholders around an innovative and inspiring new future for an area in decline. Meanwhile, the recent progress that shows the difficulties that can arise when the initial development strategy needs to be adjusted due to changing circumstances. We will review development plan Blauwestad to find the essence of its rigidity.

Why was Blauwestad so vulnerable to various types of changes? Primarily, the plan included an integral development strategy that first required upgrading the spatial qualities of the site, before rest of the plan could commence. Therefore, high upfront investments had to be made (118 million Euros by public actors, NRK,2010) for acquiring the land, constructing the road infrastructure to the building plots, and constructing the artificial lake. This was considered necessary to put the area on the map, before a single plot would be sold and the first house could be built. The upfront investment, and the interest rate making this amount grow, was to be recouped later on by developing houses.

A sound balance sheet demanded a minimum amount of plots to be developed yearly and a certain final number to cover the at least the public investments. The balance was tight - raising 73 million[5] Euros from the profits of 1480 houses means collecting 50,000 Euros per house on average, when leaving out interest rates on the investment and excluding 32 miljoen of subsides (NRK, 2010). Slower development, other types of land use or lower final numbers would automatically result in a financial loss. Moreover, the full construction of the lake, street grid and even the street-lighting in advance set the spatial design for a long period.

This resulted in a rather prescriptive real estate program, focused on attracted wealthy people from both regional as national market. Especially the group from outside the region was expected to give a boost to the region’s economy. The

[5] In 2009 this was already increased to 118 million (NRK, 2010)

feasibility of this strategy was soon considered to be doubtful. The projected 1480 high end plots was massive compared to the limited national demand on luxury housing (RIGO, 1995). Moreover, only 28% of the plots sold until 2007 in Blauwestad was bought by people from outside the Northern part of the Netherlands (Companen, 2006 p.65). The other plots are obtained by regional house owners, who could afford high investments and of which a part delayed their investment anticipating on the construction of the Blauwestad (Companen, 2006). Thus, the supply was exceeding the demand and part of the investments in the region were redistributed instead of new investments were attracted.

It led to a financial lock-in that caused the development's rigidity. It might have been a master plan, with room for reconsideration of parts of it. But the high investments made it impossible to reconsider the remainder of the plan – future choices were taken hostage as they had to recoup the investments. The financial burden and, in addition the set spatial design, dramatically constrains the range of choice, causing high vulnerability to changes in context.

4. Discussion: are flexible development plans desirable?

In exploring the possible relevance of a CAS approach for the design of development plans, we have assessed the Blauwestad development plan. It has illustrated when a development path can become rigid, the development plan's contribution to this process, and, accordingly, what challenges can arise. The question we concentrate on in this section is whether more flexible plans, as a CAS approach seems to suggest, would help to prevent these situations and could strengthen the adaptive capacity of a development area.

4.1 Tensions between making plans and seeking adaptiveness

However, we first need to critical asks ourselves what tensions could emerge when one would argue to increase the flexibility of development plans. A CAS approach, how appealing and elegant in a theoretical sense, can raise a number of rather fundamental questions when it is tried to apply in planning practices. Complexity thinkers implicitly draw the use of planning into question, in the very logic of their argument (Portugali, 2012, p.55). Therefore we pose three counter questions to a CAS-approach for development plans below.

Question 1 would be: *How flexible can a plan be, without ceasing to be a plan?* In the flight from the rigidity of plans, a CAS approach would opt for maximum flexibility. But a 'flexible plan', in its ultimate consequence, is an oxymoron. When all future actions are possible, open to consideration on points in time to come, by definition that means we don't have a plan. We can't set out a course of action and at the same time declare that course completely relative and open for reconsideration at any time.

Not only would it be semantically impossible, it would also discard all benefits from agreeing on a course of action. Despite the downsides of rigidity, we cannot ignore the structuring, stabilizing and synergizing role of development plans enhancing the robustness to overcome external pushes and internal stresses. In general plans are designed to represent current strategic choices with regard to possible futures (Hopkins, 2001). Thus, in order to steer spatial change, planners have to organise a

coherent set of actions across a range of interdependent actors. That is the purpose and right of existence of plans: they align interests and actions in situations of dispersed power. As Hoch (2009) explains 'plans offer provisional accounts of future outcomes that users intend to accomplish by changing the relationships represented in the current urban situation' (p.236). Making plans flexible may equal re-inviting uncertainty and mistrust, resulting in loss of performative power.

Hence, a balance must me struck between the adaptive capacity and the certainty development plans contribute to. In CAS metaphors: there is a tension between the degree of flexibility and robustness. Therefore, discussing flexible plans has to consider the loss of being able to unite across actors and mobilise concerted action. How flexible can we be without loosing all?

Question 2 would be: *Is it possible to foresee all alternative trajectories?* A consequence of adopting a CAS approach can be that planners should aim for flexible plans so unexpected future situations can be accommodated without costly redesign and rebuilding. Although a potentially valuable intention, given the need for efficiency and the dynamics of contexts for plans, a complication arises.

Is the implicit assumption that we need to anticipate on changes with high degree of unpredictability in context not fundamentally a paradox? When we make spaces in such a way that alternative uses may be already considered in the design, it implies that we foresee and define these alternative uses already. At the same time, we dismiss the possibility of planners being able to predict the future, so this would be a contradiction. We cannot design in such a way that *any* no matter how unthinkable future need would be accommodated, because every design will accommodate some uses and render space unsuitable for others. So, on what basis is decided what particular range of flexibility is aimed to achieve in designing a development plan?

Question 3 would be: *On what scale do planners want adaptive capacity and where not?*
In urban landscapes the capacity to adapt is never absent. And neither is structure and planning. Even in highly regulated planning systems, room to self-organize exists on the scale of people's daily walking patterns. People together create new routes, reconfiguring the urban fabric (see Helbing, 2001). At the same time, also highly chaotic spatial processes produce rules. The formal and informal rules that come into existence in illegal settlements and refugee camps are illustrations.Such processes can be explained as enslavement; due to information compression order parameters emerge, enslaving other directions of progress (Haken, 1983; 2000).

Does adaptive capacity in the context of development plans, then, mean we just wait what the joint result of individual or small-group actions will amount to? Or is the production of plans a spontaneous result of self-organization already? There will always be openings for diversity and alternative paths of development, within a certain web of regulations that pose boundaries to that freedom. Every planning system, as well as every plan, is a temporary agreement on where these limits are. Therefore, we consider regulating structures, such as development plans, to be to some extent *a product of* self-organisation, and for sure *a precondition for* self-organisation, rather than the opposite of self-organisation. Structures are a precondition because although they may be blamed for setting limits, they by doing

just so, also define spaces allowing freedom of action - structures and actions are countermoulds (Giddens, 1984).

Conclusively, spatial change is self-organised and self-structuring at the same time - on different levels and moments. We cannot, and do not need to, choose on which particular level planners should remove all planning barriers for self-organisation and which not. In the context of design postulating specific futures Marshall (2012) rejects the choice between designing or not, stating that '…any settlement or built environment will feature design somewhere, at some level: and so the question becomes an argument of scale.' (p.204). Key to this paper is how combinations of structuring aspects and room of self-organisation can be integrated in development plans on district level to strengthen the adaptive capacity of these environments.

4.2 A framework for development plans

What kind of framework for development plans would allow combinations of structuring aspects and room of self-organisation in development plans? Let us start by stating development plans do have a vital role in inducing desirable spatial change. They can have both a persuasive and prescriptive role. While the latter potentially limit the flexibility of the plan and could be reformulated with help of CAS-based principles, the first has to be safeguarded.

Captivating grand visions remain crucial to reveal shared values and devise innovative ideas that blend seemingly contradictory demands and as such trigger initiatives (Rauws en Van Dijk, forthcoming). However, planners may need to relinquish ambitions for comprehensive large scale designs. In an attempt to retain the persuasive capacity of a plan while increasing its flexibility during implementation, we suggest both can co-existence. Though, on different levels of planning. The visionary elements should be considered on strategic level. Converting a persuasive vision into concrete implementation measures needs to be done on operational level. Here the CAS-based principles are required to guarantee the adaptive capacity.

Operational decisions should not have the same level of ambition as the vision has. This does not mean to separate plans a created, but the persuasive and prescriptive elements are valued on different levels. Of course, the two levels are intertwined, strategic and operational elements of the plan feed into each other. Nevertheless, distinguishing the two within a plan may help the actors involved to acknowledge the implications of the unknown futures they are confronted with realizing a development, despite its possible synergizing and mobilizing effects and innovative ideas. In the next section is discussed how CAS based principles can connect both level and respectively their visionary elements and implementation measures.

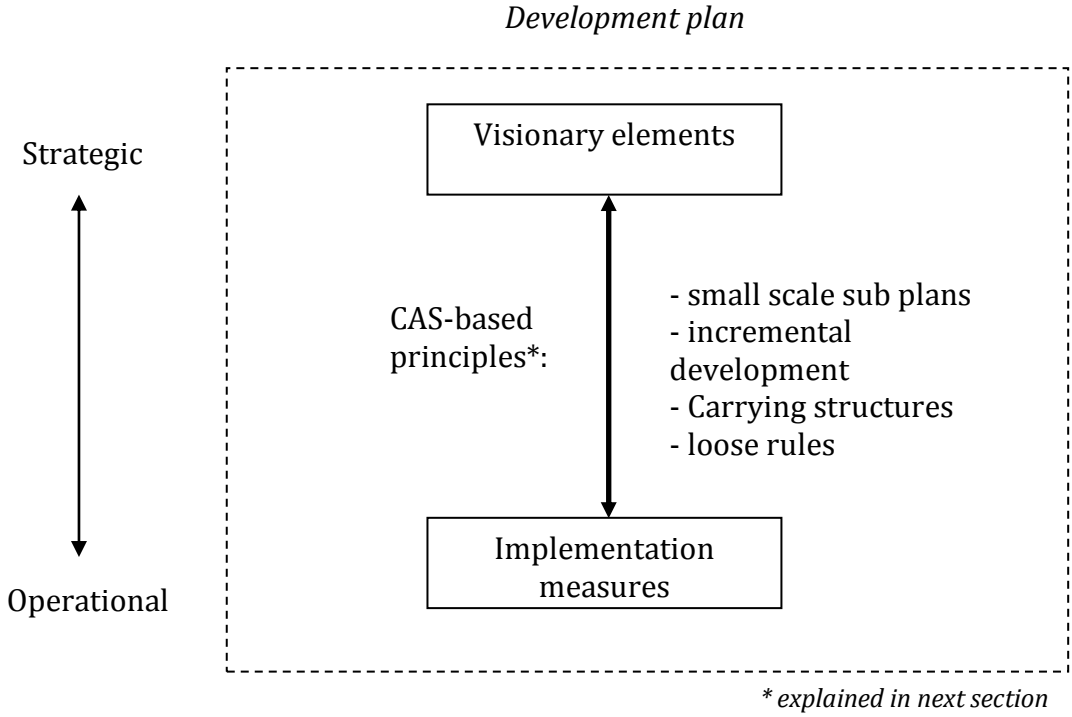

Figure 2: A framework for flexible development plans. CAS-based principles can help to link the visionary elements and concrete implementation measures in such a way the adaptive capacity is strengthened.

5. Practical design principles for flexible development plans

When we focus on strategic decisions are made operational and how CAS-based principles may help to strengthen the adaptive capacity of an area, several preliminary lessons for planners can be deducted. The example of the Blauwestad development plan reveals the essential pitfalls of rigidity. Backed up by practical implications found in current literature, this is what CAS may mean for development plans.

First of all, the main flaw of the Blauwestad was not its visionary ambition or its end-state image that it pursued. Uncertainty does not mean we should stop making plans. On the contrary, plans help create sense of urgency, direction and agreement (Rosenhead, 2001, Albrechts, 2004). Blauwestad might have made it just one of many plans that turned out not to be viable, unrealistic under altering circumstances, necessitating it to change plans and try other ways. But in the case, unviability has led to serious implications.

The pitfall of the Blauwestad plan was not drafting an ambitious plan *on paper*, rather it was the massive pre-investments *physically and financially*. Making a plan is an innocent act. But embarking on an overambitious operational program of investments resulted in serious challenges later on. Doing these investments made it difficult to (i) develop in a much slower pace, (ii) change the future land use, (iii) refrain from implementing part of the plan. Dramatic changes in context of Blauwestad, showed the necessity of a combination of these three measures.

Concretely, adaptive capacity, on the specific level of scale of development plans on district level, is best secured when they meet the following principles:

- The overall plan, in its implementation phase, is composed of multiple independent smaller scale plans. From a CAS approach a mosaic of self-sufficient small plans would be preferred over large scale plans (see also Alfasi & Portugali, 2004). Large scale plans have a long time span due to their size, making contextual changes (political, economic, societal) very likely. The small scale plans cover a relatively short time period, making them less susceptible to change. In addition, aiming for a degree of self-sufficiency of these small scale plans causes them to be less dependent on the success of other developments in the area.
  In case of the Blauwestad a division into in a number of sub-plans would have meant an increased functionality of compartments in future situations were other sub-plans are developed with a delay or even aborted. The risk of high upfront costs would have been limited.
- Incremental development Related to the first principle, integrating an incremental development strategy in development plans could be suggested from a CAS approach. It means evaluating former steps (i.c. small scale plans) to enhance next steps, building on successes. At the same time incremental development creates opportunities to include newly emerge contextual trends and self-organised initiatives.
  With respect to the Blauwestad an explicit incremental strategy may have led to an approach with more attention to learning and adjustment. As such failures of one sub-plan would not have impeded the reconsideration of initial choices made for the next sub-plan.
- The development plan may need to install carrying structures required to make the small scale projects possible. These are frameworks that support and connect the, to a large extent considered, autonomously emerging initiatives for further development (see also Hartman et al. 2011). The notion of 'carrying structures' originates from ecology and expresses the population level of a certain species supported by the life infrastructure present conditions of the ecosystem, e.g. quantity of food, habitat and other (Xu, 2008). In a similar way we can refer to carrying structures in urban settings, such as road and public transport networks, blue-green networks, or data networks. These can function as frameworks self-organised initiatives can easily link-in to, increasing opportunities for initiatives to emerge and therefore contribute to a vital urban system. When these structures are expensive (as the lake in Blauwestad was), the carrying structure can be divided in independent parts, so that pre-investment comes in stages.
- For the smaller projects define loose rules based on core objectives instead of detailed regulations. A set of basic, general and often qualitative rules defined within a development plan, such as 'mixed use' or 'energy neutral', is meant to guide development of an area. This is in contrast with detailed, quantitative and narrow defined rules on how objective are supposed to be met, as from a CAS perspective this may undermine or not recognise the opportunities created by self-organised initiatives. Initiatives which include ideas that do contribute the area's potential but cannot be realized within existing set of rules as they are, following a CAS approach, derived from the 'being' insufficiently taking into account the 'becoming'. In contrast, loose rules do not try to cover all possible

urban forms, not do they advocate any particular way of living (for similar kind of discussion see Alfasi & Portugali, 2007). Loose rules guide future development paths and embrace diversity in further evolution instead of regarding it as a risk which needs to be reduced as much as possible.
The tight financial balance and a predetermined group of future inhabitants, causing strict standards, defied flexibility to co-evolve effectively with a changing context Blauwestad was embedded in. In constrast, loose rules possibilities to adjust to and make use of the opportunities that arise fitting with the general aim of the development are widened. In case of Blauwestad loose rules such as 'low dense living in open space' and 'water-oriented development' could have been defined while leaving options open for multifunctional land use, architectural variations and flexible plots sizes increasing the adaptability of the development plan.

The introduced principles can help in designing more flexible development plans that strengthen the adaptive capacity of an development area. However, one could argue that a principle such as a incremental development strategy may undermine the inviting capacity of the plan. In case of Blauwestad the construction the lake at once, the future living environment for potential house buyers becomes real. Also at major sites that need newly installed highway access or public transit, this problem occurs. Some investment may be inevitable to spark the development at all. Still, when risks are so large, a phased gradual installation should be considered. With regard to the Blauwestad this could for example have meant the smaller access roads were only constructed or upgraded after a minimum level of traffic has been reached and the location for and scale of shops and other services was not predetermined, but tuned on the speed and scale of housing developments.

When major pre-investments are nonetheless considered to be inevitable, massive investments such as the creation of a big artificial lake can still done when actors agree this the only way forward. However, they need to accept the risk of the limited futures paths this investment might fit in with or the unexpected effects it may have. Therefore investments may not return in the form of planned profits and adjusted without doing new investments again. Thus, doing such investments should be guaranteed losses can be taken. Put differently, the degree of flexibility in development planning is a choice and therefore attached risks should be presented as a choice as well.

However, not only the financial viability, but also the political approval to development plans is likely to be compromised by loose rules. As Sager en Ravlum (2005) showed, politicians have difficulty limiting political authorisation processes to a strategic level, that focus on the general outline of plans instead of their details. Questions raised by their electoral body often leads politicians to feel the need to engage in discussions about details to secure the interests of their voters. Therefore, loose rules would at least require efforts of planners in convincing politicians to stick to strategic level decision making in particular. In addition, when developments are guided by loose rules, what uncertainties arise for investors and who is responsible for deciding whether proposed initiatives fit the development plan? The starting point should be maximum transparency in advance about the requirements initiatives need to meet. This should avoid that initiatives are frustrated by requirements faced later on in the development process.

Hence, some practical lessons about how the adaptive capacity of the Blauwestad could have been strengthened are identified. Taking a CAS approach have resulted in a set of criteria that allow planners to create flexible development plans without disregarding their visionary power.

6. Conclusion

To conclude, reviewing the development plan of Blauwestad from a CAS perspective learns us about the 'why' and 'how' of flexibility of plans. Strategies have to be included to design development plans that enable an area to co-evolve successfully with changing contexts.

The Blauwestad development is an innovative and persuasive design postulating a new future for a region in decline. A design that was apparently able to unit numerous actors around a shared vision and motivated them to work jointly on a more regional transition. This capacity can, at least partly, be ascribed to the comprehensive design. However, this comprehensive design turned out to have limitations when the implementation of the Blauwestad plan evolved differently than expected. As those adopting a CAS approach would argue, a situation that by planners should be considered as rather normal instead of exceptional due to dynamics behaviour of spatial systems and their environment.

A CAS approach presents a way of understanding of spatial development that steps away from the Newtonian world view that still seems to dominate today's planning practice. Planning scholars exploring the implications of CAS thinking, argue it provides interesting concepts that help to further develop a dynamic perspective on spatial developments and their underlying processes. Moreover, it is suggested a CAS approach would require a shift of attention from the 'being' to the 'becoming', meaning planning issues have to be considered as part of on-going trajectories of (non-linear) change.

What that means to the design of development plans we explored in our paper. Complexity theorists that address planning take a number of positions toward reality and the role of plans, that can easily be misunderstood or exaggerated, as if planning has no function at all. And CAS thinking does imply a number of internal tensions, as we saw in Section 4. However, by applying a CAS approach we can learn that incorporating a degree of flexibility in the design of development plans may help to strengthen the adaptive capacity of environments.

Three main lessons can be derived from this paper. First, designing a development plan requires a distinction between visionary elements and implementation measures incorporated in the plan. A development plan contains both, as the first refers to the capacity of development plans to provide an appealing, uniting and mobilizing future image while the latter contains concrete designs for realizing this future. Each of the aspects requires attentions from planners and although they are interrelated different qualities can be attached to them. The overall idea is that visionary elements are needed to set direction and inspire actors, while implementation measures are needed to ensure initiatives in line with the vision can be realized but also that alternative development paths remains open.

If a distinction between these two main components of a development plan is not made properly, rigidity is a serious risk. This turned out to be the case in the Blauwestad, as in the development plan visionary elements of the plan were insufficiently linked to implementation measures that would guarantee a degree of flexibility while appreciating the desired future the plan puts forward.

Second, CAS-based principles can help to link the visionary elements and implementation measures within a development plan. The principles provide a set of strategies by which visionary ideas can be translated into operational strategies while strengthening the adaptive capacity of an area. We have distinguished five principles: small sub-plans, incremental development, carrying structure and loose rules. The combination of these principles results in development plans the do provide a direction of development and, in addition a degree of certainty, while enlarging opportunities for incorporating unexpected change. Therefore, CAS-based principles can assist in making a successful link between the two aspects.

Third, when major pre-investments that reduce the flexibility of a plan are nonetheless considered to be inevitable, these can still done when actors agree this is the only way forward. However, they need to accept the risk of the limited futures paths this investment might fit in with or the unexpected effects it may have. Put differently, the degree of flexibility in development planning is a choice and therefore attached risks should be presented as a choice as well.

As illustrated with the principles above, a CAS approach to development plans should respect the values of making plans, but focuses on implementation mechanisms that allow reconsiderations in the future. They enable the plan under concern to co-evolve successfully with a transitioning spaces and places, strengthening the adaptive capacity of the development area. Acknowledging planning is part of world in constant change, the crucial task for the planner becomes to balance flexibility and robustness taken in the account the both space- and time-related conditions. This paper has shown development plans can become a helpful tool in this process.

Dwellings and generational change in owner communities

Annette Spellerberg[1]

Abstract

The ecological, social and demographic change is a major challenge for suburban residents. Within a research project titled "Residential Property for Generations" a specific form of suburban area with privately owned homes in owner communities was analysed. By means of organised group self-help, the future homeowners took part in the building of their homes with thousands of working hours each. Most of these settlements were founded in the 1950th and 60th and are characterized by small houses, huge gardens for self-supporters and small stables for chickens, rabbits or pigs. The families created strong neighbourhoods and tight communication structures, bundled in clubs and associations.

The objective of the research project was to investigate if these owner communities may easier cope with urgent future tasks than other suburban residential areas, although inhabitants grew significantly older. The question is how neighbourly help, the modernisation of buildings to meet modern standards, or the generation change is managed. Within the research project inhabitants of five owner communities in Rhineland-Palatinate were analysed and advised in terms of the solution of future tasks. A survey on housing conditions, neighbourhood, and social activities as well as a participative processes "Zukunftswerkstatt" (foresight) were conducted.

Results show that inhabitants of these dwellings have strong bonds towards their homes, strong neighbourhoods still exist, and help is given to single handed elderlies. On the other hand investments in buildings are deferred to future generations. Two thirds would like to pass on the dwelling to their offspring, but in fact houses are sold on the market, because parents, children and grandchildren live in different places.

Rhineland-Palatine as a rural state in Germany focuses on home owners as actor to preserve resources and save energy. The project was funded to analyze to which degree these owners show a higher affinity towards energetic modernization than typical single home owners. Despite information, guidance and advice in the context of the research project, the constellation of the single family remained in the centre of decisions. In the same time participation processes supplied evidence that these seniors engage very actively in their neighborhood. Still these seniors (61 years old in average) take matters into their own hands and form an active part in their city – unfortunately this potential often is unrealized. In this regard the examples are good examples that could be regarded as a role model.

1. Introduction

In the postwar decades with their increasing affluence for the population, residential property developed particularly on the outskirts of cities, in the communities surrounding towns or in rural areas. These small expansions of communities happened in several stages by adding detached one family houses and are regarded as the prototype for urban development of owner-occupied homes in the Federal Republic. (Jessen, Simon, 2001, p. 353). With the increasing age of the residents and the homes, these homeowner communities are currently facing great challenges. As the Federal Institute for Research on Building, Urban Affairs and Spatial Development (BBSR) points out in a study, the quarters of the 1960s and 1970s with their high percentage of single family homes is not as such problematic. But due to the quality of this kind of urban housing with its poor infrastructure and the expected demographic development, this type of dwelling will be facing various challenges in the years to come (BBSR, 2009, p. 18). Current challenges and future tasks of areas dominated by detached family homes include energy conservation, adjusting the buildings to modern needs, ensuring that seniors are adequately provided for, plus coping with the generation change.
This essay will present the results of the practice-based research project "Residential Property for Generations. Sustainable Development for Owner Communities", in which a particular kind of residential community was studied. In those communities, the future residents organized mutual support groups to construct their homes. Five of these homeowner communities organized in the Verband Wohneigentum (homeownership association) Rhineland-Palatinate were observed in detail and counseled regarding the solution of future tasks.

1.1 Owner Communities in Transition

The movement for single-family home ownership goes back to the year 1918. In order to improve the living conditions of the poorer population and low middle class, the state passed a number of laws (e.g. Reichsheimstättengesetz - Reich homestead law of 1920) thus providing the prerequisites for the construction of small residential estates and small residences. During the early years of the homestead and small holding movement veterans, people disabled or damaged by the war, war widows as well as families with many children were the target group for establishing healthier living conditions. Apart from participating in the construction of homes, self-subsistence through cultivating gardens and keeping small domestic animals was an important issue of the residential movement. The communities are therefore characterized by comparatively small houses, annexes to the buildings and large gardens (Hafner, 1996, pp. 559-561; Kuhn, 2001, p. 195; Rauch, 2010, p. 21). During the Weimar Republic, however, only about 20,000 such properties were realized (Hafner, 1996, p. 559).

Even during the reign of the National Socialists, such small communities were established. However, the focus of construction activities shifted from large cites to small and middle sized communities in sparsely populated areas or regions close to borders. Gardening and keeping small animals played an important role in terms of subsistence economy. In general, the housing policy of the National Socialists aimed at (re-)rooting the people. In contrast to the propaganda (100,000 privately owned homes annually), only a total of 140,000 such homes were built (Harlander, 2001, p. 261). In the "Third Reich", these small housing estates and homesteads became an important part of the Nazi family ideology and they were placed in the context of the national socialist blood and soil ideology. During this period, the small estate and homestead movement opened up towards the middle class in order to raise private funds. In addition, racial issues and party membership played a role in the selection the future homeowners (Hafner, 1996, pp. 584-585; Harlander, 2001, pp. 258-259).

During the times of housing shortages in the 1950s and 1960s, the construction of small suburban residential areas boomed, building on the traditions of the Weimar Republic. After the war, organized mutual support was a prerequisite for lower and middle-income groups to be able to afford homeownership. For setting up the usually standardized, compact homes in the suburbs, the future owners had to make a personal contribution, which often amounted to 1,500 to 2,500 hours of construction work. The planning and construction of the suburban residences was handled by a builder, frequently a residents associations or nonprofit building societies. Through mutual support, the future residents often established close contacts before even moving in, resulting in strong ties with the place and close neighborhood relationships (Hafner, 1996, pp. 567-568; Jessen, Simon, 2001, p. 356; Szypulski, 2008, pp. 117-118).

In 1935, the "Deutsche Siedlerbund" (German Settler association) was recognized as the sole representative of all homeowners. In 2005, it was renamed Verband Wohneigentum (homeownership society), as the term "Siedler" (settler) had almost vanished in spoken German – at least in the context of living in the Federal Republic. It now focused on the future. The Verband Wohneigentum currently has 370,00 members, making it the largest association of homeowners in Germany, and it supports the funding for constructing and acquiring homes and ensures that owner occupied homeownership is preserved.

As in other areas dominated by single-family homes, the owner communities organized in the Verband Wohneigentum are facing major challenges. The one and two family homes of its members are for the most part only insufficiently equipped with amenities for the needs of their aging residents. When the homes were built, the speedy creation of living quarters had top priority; living standards appropriate for old age were not an issue. Therefore, many of the existing homes in these residential communities have an increased need for modernization if one wants to meet standards appropriate for seniors (Szubin, 2009). In addition, the homes need to be adapted to modern energy standards.

In many homeowner communities, a generation change will take place shortly or has already begun.
As there are currently no new communities built on organized mutual support, local residents associations and owner communities are facing new tasks. The percentage of first time home owners will dwindle steadily due to age, and new home owners, without the experience of mutual support groups during the construction phase, will have to be integrated into existing communities. In addition, there is a trend that owner communities regard themselves as institutions for consumer rights. They provide legal and financial counseling, and give advice on gardening, energy efficiency and barrier-free living. Other important future tasks of residents associations are (Uertz, 2010, p. 17): preventing vacancies, improving the living quality in the residential areas, strengthening local networks, as well as joint economizing (e.g. purchasing cooperatives or sharing equipment and facilities).

2. Background and rationale

As in more typical suburban areas, the owner communities, organized in the association "Verband Wohneigentum", are facing major challenges. Many inhabitants of the first generation live in their houses for decades – people and houses, both grew older, resulting in a homogenous, quite old age structure of residents. Offsprings themselves count about 50 years of age and live in their own houses and in different areas. And second-hand single-family-homes exceed the number of households which are likely to buy them, because in Germany the fertility of the population dropped far below replacement level. These kinds of dwellings probably are not accepted any longer. In most cases they were enlarged, but many require investments, need reconfigurations and reconstructions. Time consuming garden maintenance may be an obstacle as well.
The key question of the project was, if this kind of living – very traditional on one hand but very modern on the other hand – can be a role-model to solve problems of "normal" suburban areas, such as social engagement, overcoming lack of services or energetic modernization. We analyzed these settlements from a variety of viewpoints, including ecologic, economic, social and urban development considerations.

- Social aspects: The percentage of first time home owners will decrease steadily due to cohort effects. New home owners, without the experience of mutual support and construction will have to be integrated into existing communities. Are neighborhoods negatively affected? Are residents able to interact adequately and integrate new population groups, new households in different stages in their lifecycle, different values and lifestyles?

- Economic viewpoint: Are the settlements at risk of abandonment, deterioration and devaluation? Do the owner communities face problems like vacancies?
- Urban development: Political actors and spatial planners try to reduce land consumption and strengthen existing settlements. We wanted to know if these quite homogenously built houses, as well as compact and green quarters can be preserved - despite generation change, problems of infrastructure and possibilities for redensification.
- Ecological viewpoint: The project was funded to analyze to which degree these owners show a higher affinity towards energetic modernization than typical single home owners. Finally, they are used to collaborative construction work - maybe residents think about economy of scale.

The aim was to work on concepts and strategies for future development of these owner communities together with the inhabitants. Active participation and willingness to act during the process were crucial for success in this applied research project. It was conducted by a team of sociologists, ecologists and urban planners from the University of Kaiserslautern. [2] Social aspects are in the focus of this paper.

2.1 Methods

The project concentrated on five communities (Figure 1), located in the cities Boppard, Lahnstein, Wittlich and Worms as well as in the smaller village Waldböckelheim (county Bad Kreuznach).

Figure 1. Pictures of owner communities:

Public Green in Wittlich

Original structures in Boppard

Missing infrastructure in Lahnstein

In the empirical research, mixes methods were combined: In December 2009 a standardized survey on housing, satisfaction with housing conditions, neighborhood, activities and generation change was conducted. In Lahnstein oral interviews were added. Needs, potentials and deficits within the

[2] We are indebted to the Ministry of Finance and Ministry of Environment of Rhineland-Palatinate who financed the project. Thanks a lot also to the head of the association "Verband Wohneigentum", working as gatekeeper in the project.

settlements could be identified. Furthermore, a workshop in each community took place: "How shall our neighborhood look like in20 years?" in order to develop projects according to specific needs (Spring 2010). In a third step expert talks with local politicians and planning departments were conducted, in order to get information on the municipal perspective (Autumn 2010). And finally, we collected data on a fine-grained regional or municipal basis. Here, I will concentrate on the survey and some impressions of the participation processes.

3. Results

3.1 Survey on housing, neighborhood, and social activities

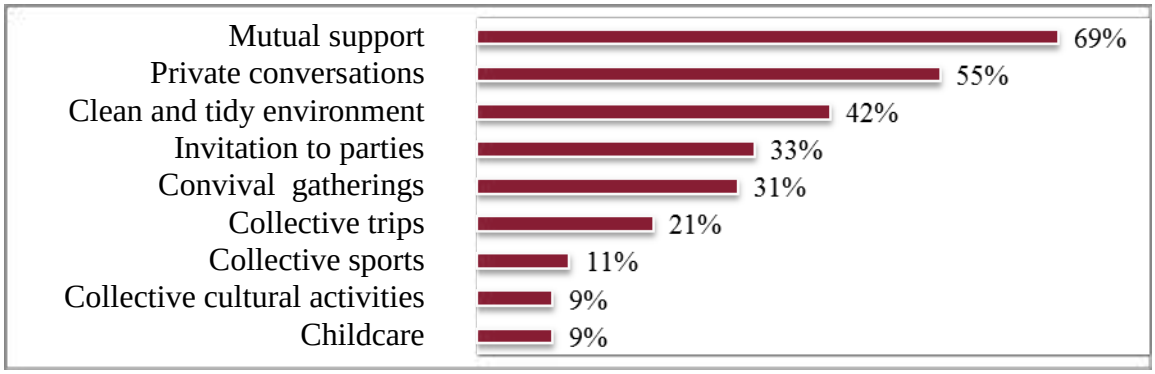
All of the households (n=528) got an information sheet in advance, followed by a standardized questionnaire "Living in owner communities". 233 persons participated in the survey, which means a satisfying return rate of 44 %. In Worms 33 % sent the questionnaire back, whereas in Lahnstein 74 % did so, reflecting different interest levels.
The average age of respondents was 61 years, with a range from 27 to 90 years. These home owners are much older than the average of the population (43 years). According to the higher age groups, most of the respondents live alone (14 %) or as a couple (57 %) in their homes. Dependent children live only in one out of five households (average in Germany). More men (63 %) then women (37 %) answered, who eventually felt as head of the household more often. The educational and income levels are quite disperse, 39 % finished school with a lower degree and 36 % with the highest level "Abitur". Within older persons lower levels dominate, whereas in younger age groups higher levels can be found. This result can be interpreted as a first indicator for the attractiveness of these settlements for the middle classes.
According to the age structure a generation change takes place, depending on construction age, having reached the oldest of settlements. New inhabitants move in with different lifestyles, habits and experiences. This may affect the neighborhood, common activities, and civil engagement. The question "Did you buy, inherit or built your house yourself?" aimed towards generation change (Table 1).

Table 1. How did you or your family get your house?

	Total	In single settlements
Built myself	51 %	Boppard: 46 %; Lahnstein: 89 %; Waldböckelheim: 82 %; Wittlich 17 %; Worms 32 %
Bought	36 %	
Inherited	13 %	

Still, half of the residents built their homes by themselves. One third bought it and 13 % got it by heritage. In Lahnstein nearly each respondent is member of the first generation of owners, whereas in Wittlich, which was founded in the 1930s, the generation change took place already. Only five out of 23 built the house themselves. Two thirds would like to pass on the dwelling to their offspring, but in fact houses more often are sold on the market, because children and grandchildren live in different places. This is a crucial factor, why investments in buildings are deferred to future residents.

Table 2. Activities with neighbors

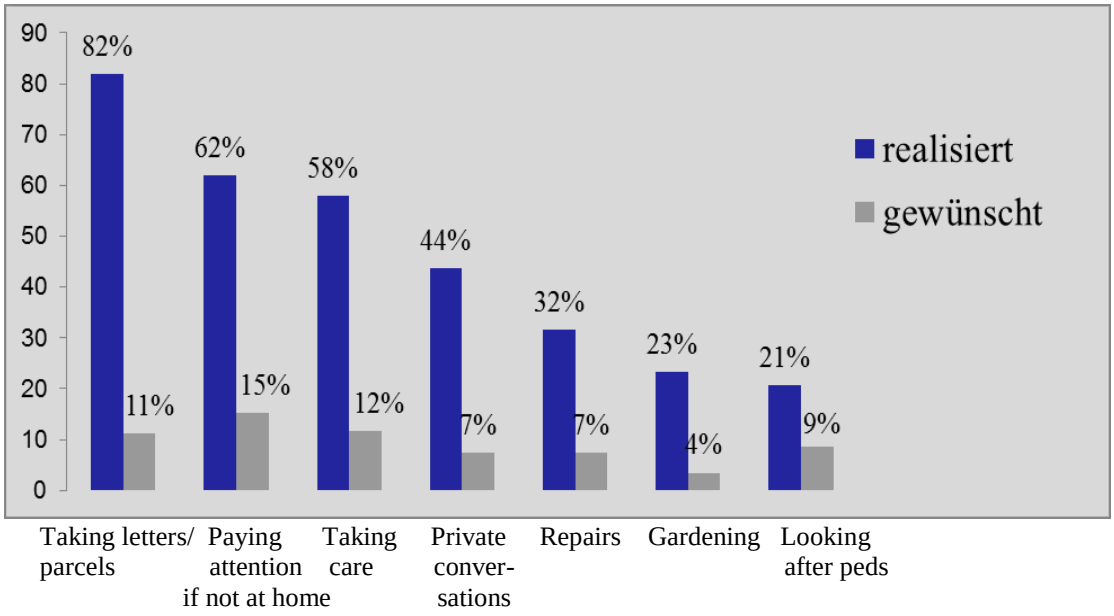


Neighborhood and community are an important potential for mutual support (Table 2). Strong neighborhoods are very much demanded because of the ageing population and lack of services in cities and villages. On the individual level good neighborhoods are regarded as central for individual integration and social cohesion.

More than half of the residents see their neighbors daily or several times a week. Three quarters say, neighborhood is as vital as it was decades ago, which is seen as an important factor for quality of life. These bonds support neighborly help, as the figure shows. More than two thirds pronounce mutual help, more than 50 % talk to each other on a very personal basis, four persons out of five look for secure and proper environments.

But if you ask people, which support they like from their neighbors, you face the situation that normally they do not want to depend on their direct neighbors (Table 3). Most people in Germany like a friendly, helpful, but more distant neighborhood. Professional services are preferred more often, because they don't violate the principle of reciprocity and help to avoid the feeling of shame, when people can't give back what they get from neighbors.

Table 3. Neighborly support: What they do and what they like



These settlements organize themselves in clubs. Nowadays, only one third of the residents are active member of the "settlers' club" – the typical form of community in these suburbs. Half of the respondents support the opinion that these clubs are important, but one third is only a passive member or no member at all. The importance of these clubs is higher in neighborhoods with first owners and accordingly in higher age groups (40 % of the older respondents are active member, but only 20 % of the younger ones).
This kind of suburb has a long lasting tradition, but modernization has taken place. Leisure activities highlight the modernization of these suburbs. Most frequently the homeowners spend their time with computers, 47 % use them on a daily basis, followed by visits of relatives, friends or neighbors. Handicraft, doing arts or visiting theaters are quite uncommon.
Facing the pluralization of life styles and leisure activities, it is more difficult to organize activities suitable for many. The association "Verband Wohneigentum" is facing the task of having to recruit new members who are less interested in existing communities than in individual benefits and "elective affinities". Accordingly, company, fun, doing something together and personal activity are the main motives to participate in active engagement for the settlers' club. Altruistic motives like solving problems or felt responsibility for the community are not mentioned.

First Conclusion:
The five communities studied are characterized by active neighborhood support and diverse communal activities. However, it can be observed that neighborhoods, due to the generation change, are now frequently understood in a neutral and pragmatic manner, similar to other suburban residential areas. It

is therefore not surprising that younger people are less interested in an owner community than older people. Community is often perceived as something you share with other individual residents who have similar interests, i.e. activities are more likely to take place with individuals or small groups. In larger residential areas it is generally not easy to maintain the social cohesion. Civil engagement in clubs can be found if people like companionship and recognize an increase in personal happiness and subjective wellbeing.

3.2 Participation processes: Perspectives of owner communities

Figure 2. Participation process

This form of participation process, called "Zukunftswerkstatt" (foresight) is divided in three parts, a phase of critique on actual living conditions, a utopian phase and a phase, in which concrete projects are developed. Residents of the owner communities discussed weaknesses and chances of the suburbs under the motto “How shall our neighborhood look like in twenty years?”.
In one community a roofed place came to the fore, in another a meeting point with café was discussed, in a third traffic problems came up, in a fourth, communication and information were seen as weak points. And in Lahnstein – the oldest but most active community mobile services, a place to play boule and a citizens’ bus or dial a bus service shall be installed. The community got in contact with nexus-institute (Berlin; cooperation supported by the Ministry of Economy RLP to implement citizens‘ buses). They spread out information and organized a meeting and a discussion with the city council. Despite all efforts, politicians rejected the plans – for unknown reasons besides expected disturbance and disorder.
In May 2012 the author and the team of researches evaluate the ongoing processes and the effect of the project. Besides we include three more settlements to compare those communities with others that got no input from academics.

4. Conclusion

Owner communities were created at a time of need to provide the poorer classes with family friendly housing. Joining them entailed considerable

personal contributions towards the construction of the homes and a commitment to self-subsistence by operating kitchen gardens and keeping small animals. Many of the floor plans have been adapted to the changed needs and the gardens are now considered a hobby, in keeping with their initial concept of providing a place for self-fulfillment, physical activity, as well as shaping and expressing esthetic concepts.

The high standard of quality of life in the owner communities studied here results in a high degree of satisfaction with the living conditions. Vacancies are thus quickly filled because of the way the communities were planned with their open private and public spaces, which in turn are associated with opportunities for personal development, so that, despite the relative age of the houses, there are no sustained vacancies to be observed. An aging population and having to cope with the generation change is a key challenge for many owner communities but so far this has not been a central issue in the residents associations.

Workshops for developing ideas for the future have shown that particularly the older owners are very active in developing new ideas and realizing them. Older people in communities have a potential that can inspire communities – if there is organizational support. Experts rate the feasibility of project ideas developed in those workshops as high. In addition, the representatives of local administrations und local politics have promised to support the realization of various projects.

Raising the awareness of various communal and statewide political actors for the owner communities was among the objectives of the ExWoSt-Project „Wohneigentum für Generationen“ (homeownership for generations). On a state and federal level, the project made an impact with a final symposium where experts lectured on suburbanization and energetic sanitizing and presented their own project findings. The relevance of the topic was underlined with the minister of Rhineland-Palatinate in charge of financing and construction (Dr. Carsten Kühl) and the mayor of Koblenz (Marie-Theres Hammes-Rosenstein) who both gave brief welcoming speeches. The entire board of the Verband Wohneigentum was present as well as city representatives for the owner communities and owners.

The special case of “owner communities“ exemplifies that practical and political actors on different levels are dealing with the project’s issues, especially with the sustainable development of individual properties and certain suburban residential areas, as well as the future of honorary volunteer work. Rhineland-Palatinate, characterized by its rural environment, focuses on owner occupied homes as an energetically sustainable housing stock. The project was funded with the aim of finding out whether organized owners were more likely to carry out energetic sanitation work than owners in classic residential areas. As it turned out, despite the information, counseling and help provided in the framework of the research project, the owners’ personal situation, even in owner communities, is of greatest importance. Despite favorable conditions in the communities, such as mutual support in the neighborhood, organizations

and associations, the individual financial scope as well as the age and the family circumstances determine the concrete willingness to act, and only to a lesser degree the life in a comparatively homogenous community. The project also demonstrated that owners of homes - even at a higher age – are very active and committed to supporting their area of residence. This potential includes a large, hardly called upon potential for new ideas and their realization. Thus the selected case studies might function as a role model.

Lessons learned looking at sustainability:

- Inhabitants of these dwellings have strong bonds towards their homes, strong neighborhoods still exist, and help is given to single handed elderlies.
- An aging population and generation change is a key challenge for many owner communities but so far this has not been a central issue in the residents associations.
- Foresight workshops have shown that the older owners are very active in developing new ideas and realizing them. Older people in communities have a potential that can inspire communities – if there is organizational support. These seniors (61 years old in average) take matters into their own hands and form an active part in their city – unfortunately this potential often is unrealized.
- In the same time, the association and clubs are changing: More and more owner communities regard themselves as institutions for consumer rights, not as active neighborhoods. They provide legal and financial counseling and give advice on gardening. Some communities fall apart and change into a usual suburb. Larger communities face the biggest problems and those with very old-fashioned actors.
- Because of place identity and place building the residents want to pass over their dwellings, but in fact that are unrealistic plans. At least they maintain family capital by selling the property.
- On some roofs we find solar panels, new heating systems were installed, old windows replaced, etc., but only a few owners started energetic modernization.
- To sum up, place making, place identity and strong social bonds are the main assets of these settlements. It takes some time, financial support and some effort, until owner occupied homes form a substantial part of an energetically sustainable housing stock.

FROM CULTURE OF THE PLAN TO THE CULTURE OF PLANNING: THE RELEVANCE OF THE STRATEGIC PROCESS IN THE DEVELOPMENT OF SPATIAL PLANS. THE EXPERIENCE OF THE MUNICIPAL MASTER PLAN FOR ALMADA.

José Antunes Ferreira[1] Jorge Gonçalves[2]

Keywords: Territorial change, Spatial Plan, Municipal Master Plan, Strategic approach

Abstract

The shortcomings of functionalist planning in an economic and social context as volatile as today's have been recognised for some time now. This volatility does not fit well with rigid spatial planning standards, particularly with relation to the uses attributed to land. In some cases the planning tools are rendered obsolete by reality, meaning that plans have to be suspended, altered or even completely revised. The arrogance of thinking a plan can unilaterally determine the future is supplanted by the constantly changeable and uncertain reality, affected, as it is, by many other variables and not only the decisions imposed by the Plan.

The failure of this more rationalist/positivist paradigm is reflected not only in the limitations of formal plans but also in the emergence of informality, with varying degrees of legality, as an alternative strategy, seeking a renewed capacity of anticipation of the future (through greater understanding) and flexibility (through more open planning tools and new governance modalities).

The recognition of the existence of life cycles in cities and territories and the need to prolong more favourable periods and combat periods of depression constitutes a huge challenge for classic planning, all the more so in the context of acute national financial crisis, with all the turmoil, uncertainty and vulnerability that brings for the cities and territories.

[2] CESUR-IST, Lisbon, Portugal - jorgeg@civil.ist.utl.pt

A significant contribution to this change in paradigm would seem to be the incorporation of more robust strategic thinking on land management tools, with a view to giving them more quality and efficiency.

As an illustration of this renewed look at planning we propose the process for the Revision of the Master Municipal Plan for Almada (Portugal) and, in particular, the description of the strategic reflection that took place, with the ultimate goal of furthering the development of proposals for a more intelligent plan with a successful future.

By articulating political principles expressed by the local council in various documents, the orientations by the planning instruments approved at the national, regional or local level, the various diagnostics carried out (namely, for the revision of the Municipal Master Plan itself) and more strategic or sectorial plans, it was possible to outline a set of anchor resources, challenges, supra-local strategic guidelines and municipal development lines. All this information, which was not always convergent in terms of options, was condensed into dimensions of concern that gave rise to strategic lines and pro-positive vectors of action.

From this initial work of observation and systematisation of trends and orientations one then advanced to establishing objectives that are two-fold: end objectives (the desired end results) and intermediate objectives (intermediate goals contributing to the end objectives). Land management planning is thus changed from being an end in itself to an instrument that will help create the appropriate matrix for achieving the objectives that are essential for local development.

1. Territorial management instruments dimensions from absence to inevitability

Territorial organization form, either agricultural or urban, evoking only the most common dichotomy present in land planning practice, comprise the spatial expression of the societies that embrace them. Even when the image we come across is not the most pleasant or corresponds to our current stadium of development.

In our understanding another certainty is equally challenging for consideration, is that as western societies, got internally more complex, by means of hierarchy power build up, of new regulatory mechanism and new lobby groups, that are always searching for minor adjustments or profound changes, many times appealing to ideologies as a support stick, territory was also being "produced" with an equal complexity degree. This new reality, demands adequate control instruments, that where barely, or almost never achieved.

Pressure management striking upon the territory, as in other collective life situations, end up by historically revealing existing conditions dependency, instead of appearing as a proposal for a new relation chart amongst existing spatial dynamics.

Thus, the absence of autonomy, the excess of dependencies and the time rapture between the problem´s arousing and its confrontation by land planning policies, as we can nowadays observe, has ended by having consequences in the territory global image quality.

Another two indispensable ingredients for a better interpretation of territory dynamics can be joined: on one hand, the geographic conditions that, in the Portuguese case, register an overwhelming internal difference.

It would be fastidious to enumerate, all the multitude of differences affecting the territory, but that can easily understand the limitations of a legal, generalized and normative chart, to be applied on a mass scale, with everything benchmarked and simplified;

On the other hand, the cultural-historic conditions, in many cases, in intense collaboration with previous topic, that ended up by dragging a distinctive image into the territory, self revealing of its equal singularity of how societies see the world and themselves. Once again the legal chart shows inflexibility that worsens their differences assumption, or even, their identity assertion.

All these reality faces, combination, visible in the space ends up by expressing different ways in different spaces, but with some common points, amongst others: huge urbanized area, services infra-structures deficiencies, and problems in equipment offer and supply.

"*Hard-planning*" understood as a central administration answer to urban planning problems, privileged the present moment in time in generating an answer, that is, the objective solution for the "here" and "now". It proposes a barely negotiated future, with very little changes for different places.

We can then understand, within this spirit that, in pioneer legislation on urban planning instruments in Portugal (Law-Decree 208 of 26th may 1982 and Law-Decree 69 of 2nd March 1990), the future is an absent idea.

In current legislation (Law-Decree 380 of 22.09.1999, altered by Law-Decree 316 of 19.09.2007, with current text, given by Law-Decree 46 from 20.02.2009), the same expression appears over two dozen times, which is revealing of the paradigm change that occurred in the past 3 decades. In order to adequately illustrate this change, it is worthwhile to do a contents analysis exercise of the 3 referred decrees.

Fig. 1 | Law-Decree 208/82:Textual analysis

Fig. 2 | Law-Decree 69/90: Textual analysis

Fig. 3 | Law-Decree 316/2007: Textual analysis

The evolution is clear and it suggests a path that goes from a protagonist placed upon the Plan and in Plans, to another in which Plans overcome the Plan, and finally it starts to appear land planning, territorial management instruments (No sense here?). It appears that a new type of speech emerges with new legislation.

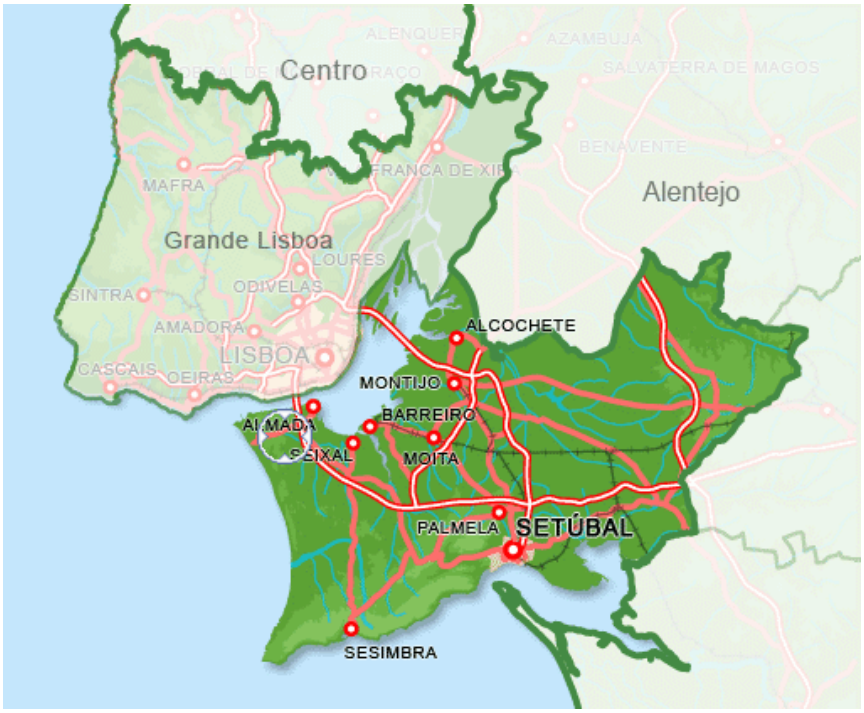
All this change reveals a particular attention with the future and a compromise with communities and activities, in a tendency for *soft-planning* exercise. To reflect over the future, to equate available resources, to select a desirable scenario and programming necessary measures to attained its goals, started to legitimate the manner for planning, mobilizing its actors.

2. Almada's Municipal Master Plan (PDM) revision: short chronicle on ongoing changes

2.1. Regional changes

In the almost two decades that occurred, since the first Almada's municipal master plan, many were the transformations that occurred, both in the municipality, as well as, in Lisbon´s metropolitan region. They reflected in the territory occupancy, in its relationship with surrounding areas, and in its standing relative position to Lisbon´s metropolitan area (AML) context, and especially with Setubal's Peninsula.

Fig. 4 | Almada in Setubal Peninsula



As a matter of fact, we have not only assisted to a profound change in the economical grounds of the municipality and of the peninsula – where the large heavy industry, which attained its identity since the fifties to the seventies, gave way to new modern and technological more advanced industry plants, as well as the speedy development of the services sector -, but also, many of the long discussed proposals were accomplished, namely in the areas of territorial infra-structures, in its endowment of public services and collective facilities, in its accessibility and transportation, at the same time that urban and suburban areas were developed, which benefited from the meanwhile achieved improved accessibility

From the development of a new logistics and industrial area, enhanced by "Auto-Europa" facilities compound, to the consolidation and reinforcement of the tourism and leisure vocation, of significant parts of the Setubal Peninsula – such as Sesimbra, Aroeira and Arrábida -, to the construction of Vasco da Gama Bridge, the railway crossing over the river Tagus, the South of Tagus Tramway system, or by the upcoming of new secondary cores, associated to the main Peninsula's urban centres. Many were the changes verified in this south side of Lisbon´s Metropolitan Area.

Even if in relation to the recent past, it is not difficult to identify the occurred changes, and which impact they had on the territory and its inhabitants, on the other hand, the prospective exercise associated to its own urban planning practice, demands a bigger reflection and framing, in relation to its main factors – endogenous but most of all exogenous. This have influenced the social systems, economics and urban planning evolution, that in itself, conditioned and explained the territorial occupancy, as well as, influenced the strategic

options, that the Municipality in a willingly exercise decides to assume for an orientation of the council's future.

In this context, it's important above all, to explicit which were the main changes that occurred, and which developments can be expected at AML and Setubal's Peninsula level, which might have decisive impact in Almada's council, whether in reference to the exogenous conditions of its own changes, and as to its positioning and relative weight amidst this metropolitan system.

At the structural changes level, it is necessary to enhance those that, in the economic sector scope, have obtain a motor role for the Peninsula's economy – with its consequent change of workplaces location, and its interchange with the exterior – as the ones that resulted from accessibility improvement, that were observed meanwhile, in certain areas of this peninsula territory, at the same time as degradation of these access condition developed in these areas where historically had begun the urban occupancy of the sixties and seventies from last century.

Thus, while old industrial riverside locations rotted, and ended up by disappearing – launching into unemployment tens of thousands of labours, as well as a myriad of middle and small subsidiary firms -, we watched the strengthening of the logistics sector, of the big commercial trade surfaces, and the implementation of new, more advanced technologic based industry.

The production concept of "*just in time*" were adopted, and the aim moved into exporting, immediately transferring outside AML a large amount of supplies and manufactured products – demanding therefore, bettered and more regional and international accessibilities -, as well as inducing a close location of part of its national components production. Hence the fast and accentuated location transfer that was verified in locations of the main Peninsula's industrial activities, which are currently dwelling mainly in the Coina, Paio Pires and Mitrena's areas, in disadvantage to verified in precedent locations as Almada, Seixal, Barreiro and Montijo.

On the other hand and more recently, with the possibility of construction of a new road-train Tagus crossing between Beato and Montijo, it will not only, transfer the gravity centre relationship of both river shores to the eastern side of Almada, as well as it will create new urban expansion areas. Taking advantage of new accessibility conditions to Lisbon´s centres – example of which, is the Parque das Nações- and for the remaining north area of AML – as such as the services and technologic campus, located along the Cascais motorway accesses -, and of the new building products offer. It is believed that new building fronts will be able to channel for themselves a significant part of the demographic growth and the migration moves amidst the AML.

In a similar way, if the opening of the railroad service in 25th April bridge, enhanced the capturing of new residents for the stations nearby influence areas - despite many times needing to complement with the automobile -, its extension to the Pinhal Novo and Setúbal,

opened new possibilities of residential inhabit for those who work in the new services job centres of Lisbon city.

2.2. Local dynamics

Resulting from the combination and overlapping of these change factors, Almada's council lost part of its foremost role, in Setúbal's Peninsula relationship with Lisbon, whirling into its interior and its direct area of influence - above all noticeable throughout the axis defined by the EN 10 route -, and at the same time would strengthen its secondary centrality functions in the AML context, thanks to its equipment and services offer development, and to the strengthening of innovation and university educational cores, that got fixed in the north side of the council, between Pragal and Monte da Caparica

On the other hand profiting from its extensive Atlantic beach front, the municipality equally reinforced its role in the AML leisure area, which explains to a certain extent, the consolidation of illegal genesis urban areas, and its progressive transformation in first residence urban areas, in association with tourist and leisure developments, of which the Aroeira area is an example.

However if the if the movement of urban occupation gravity centre from the Tagus river south shore moved towards east – due to the new entrepreneur locations with bigger workmanship contingency, and the new Lisbon accessibility made available by the Vasco da Gama bridge, and its accesses network – the inertia associated to the historic legacy at territorial urban occupancy level, throughout the route EN 10 axis, is still determinant in the geography and daily travel intensity between the two Tagus shores; albeit as far as pendulum travelling manner, its proportional importance has diminished faster that it could be expected.

The automobile traffic steadiness on 25th April bridge, of approximate 170 thousand vehicles per day, along with the continuous growth crossing the Vasco d agama bridge- currently around 65 thousand vehicles per day and per direction – it's a tendency clear sign.

This trend will for be sure endorsed, by the new Lisbon airport sited southwest of the Alcochete shooting range, by the development of the great AML logistic hub at Poceirão, and by the suburban railway service expansion, between Lisbon and Tagus south side to the town of Bareiro.

They are all factors that will accentuate the economic weight of the eastern side of Setúbal's peninsula, and potentiate there the urban obsolete and unqualified industrial spaces renovation, as well as the capture population and jobs. As a result it constitutes a true challenge to Almada's traditional role in AML context that, oblige the re-equation of its future as a metropolitan secondary centrality.

In this scope, it assumes particular importance the approved PROTAM strategy, in re-centring the AML around the Tagus estuary and promoting a true two shore city, multi-cored and diversified in its urban offer trend.

Indeed, if the new transport and logistics infra-structures, as well as the location of more dynamic economic activities, and more qualified job – that will naturally follow the new accessibility and the new foreseen structuring locations – pointing towards the eastside Peninsula area, role reinforcement amidst the AML. The territorial vision entrusted in the AML's Territorial Regional Master Plan (PROTAML), restates the necessity of relationship endeavour between the two Tagus riversides, there where they are more intense today and where they were historically strengthened.

Almada, whilst one of the main Setúbal Peninsula Council in demographic terms, in its offering of high hierarchy facilities and qualified employment, is currently in a structuring turning point, relative to its AML role, especially in the Setúbal Penisula.

To do this, the gains already obtained must be counted upon, in terms of centrality, of its urban environment qualifications, in the offering diversity that it has in its leisure area, and in the modernization of its local governance, leveraging these differentiating factors and relative advantage in relation to other Peninsula councils.

This has to be achieved, through some blockages and shortcomings resolutions, that currently exist in accessibility, identity and social cohesion, and qualification of leisure and tourism areas of, as well as, decisively betting in the development of its University Innovation Campus, and in deepening administrative efficiency and proactive attitude of the municipality.

3. Drawing Almada's Master Plan Startegy

3.1. Inspiration sources for the Municipality strategy

Planning strategy do not differ much from the usage of the same concept in the fields from where it was imported, heartening the fact that the strategy should be above all be, in the starting conditions of the thinking and reflective act – intrinsically and environmental -, and conceiving a acting form in a variable tempo horizon, but mostly in middle/long run. With identical understanding Chandler (1962), Hax and Majluf (1988), state that a strategy, is the determination of the basic, long run objectives of an entity, the adoption of adequate actions and the resources provisions to meet those aims.

But the strategy conception process, for raw-material can be found in various fields, more unstable or more stabilized, from whom it derives the inspiration for conceiving preparation of the future. This is naturally by definition uncertain. It's triggered by powerful forces, that nobody even those involved can be totally controlled. It is also true that for organizations, it is given the chance, the possibility of in-loco moulding those dynamics, from their internal past resources and dynamics. The above mentioned authors enhanced the relevance, of aims, means and resources provision.

Thus it's necessary to underline the close relationship between territory and its external context, close or farther, in one which one contains the controllable difficulty forces, from the current standing-point in which are, and another, containing available forces to condition

and re-orientate them. In this case, it will be the territory planning, and the territorial management tools to promote that reorientation that it is desirable to define.

We are not dealing with the future or at least with its determination. As Inneraty states (2010), “a good society must be unpredictable, respectful of its own limitations” (p.221). It also does not mean to aspire to a future for which it certainly lacks the conditions for it to be achieved, but to aspire to an uncertain plausible future

Here at stake, so it seems, is the territorial positioning and its actors, against the identified dynamics, which can be translated in a strategic vision, where choices of future direction paths are made.

In Almada’s municipality case, many are the contributions to be considered as “inspirational source”, deriving from work widely developed in several fronts – political, urban, economical -, and what it matters now, is to make it directional compatible, into a converging and mobilizing idea. It is demanded, then, in first instance, its systemization, and form detail to evidence them, and make them useful, for a clarification work of a strategic thinking.

Anchorage resources, constitute identified elements in different Almada’s territorial incident documents (plans, studies, as built), as potentially interesting to development mobilizing strategies. They can already participate in existing dynamics or yet to explore, since their aim is to rethink its integration form in the drawing processes in such a way as to increment synergies produced among all. We have to remember that in economics, resources are designated by those factors that combine are able to generate value in the production of goods and services. These, in a classical economic perspective, are assets, land and work.

They can be physical aspects, such as the extensive low and sandy seaside front or the accessibilities, or cultural and social such as demography dynamics, metropolitan centrality or the value of the landscape.

Anchorage resources

Immaterial resources

- metropolitan centrality
- Human resources
- Landscape
- Life quality
- Cultural and associativety dynamics
- Citizenship

Phisical resources

- Sea and river front
- Higher education facilities
- Enviromental resources
- Culture, sports and leisure

- Touristic projects
- Inovation and technology activities
- Accessibilities and transports systems

The challenges, being still nevertheless an essence problem, demand for its overcoming the mobilization of efforts and several resources, but also an expectation that this overcoming will produce gains for local or urban development. On the contrary, failure in its straight dealing will bring negative consequences, of a bigger or lesser magnitude.

Challenges are present in all fields of reality, but have differentiated levels of attainment difficulty, translated in organizational, financial and timing demands. The before mentioned resources, constitutes, also as catalytic for these challenges answers, which can be organized in four fundamental dimensions:

Territorial

- Supra-regional structering projects
- Climatic alterations adaptation
- Inter-council reinforcement ties, through public transports
- Inter-council mobility / road system structuring
- Urban system requalification
- Public spaces qualification

Social

- Population keepingness
- Empty habitation park utilization
- social-culture integration

Economic

- Job promotion
- Economical base diversification
- Activity innovation and knowledgement technology reinforcement
- Tourism activity broadening and qualification

Governability

- Natural and technologic risk prevention
- Illegal genesis Urban Areas requalification and resolution
- Municipal environmental structure execution and management
- Governability /Management adaptivety

Between the two presented levels – anchorage resources and challenges – one needs to consider another political nature contribution body, that emerge from team program, with leading responsibility on council territorial management. All in all, this program's contents,

aware of existing conditions, both in the internal and external level, proposes a way, or willingly, **development axis.** This nevertheless will constitute answers to its "negative".

Development Axis (Council's guidelines)

"More Almada"

- Urban renovation and social-economic development
- Environment, biodiversity and energy
- Urban mobility, accessibilities and public areas
- Education, learning, qualification, knowledge and youth
- Culture, sports, solidarity and safety
- Information, participation and governability
- Public service modernization and improvement

PDM's starting aims

- Strengthening balance of Council's role in the Region
- broadening Council's economic basis
- Natural and built environment improvement
- Social-cultural development and professional learning
- Council's image development

Inicio de segunda parte da tradução

Se estes elementos fazem parte do reconhecimento alargado da matriz territorial que pode suscitar o posicionamento de Almada perante o horizonte de vigência do Plano Director Municipal revisto não podem deixar de ser consideradas as orientações de âmbito supra-municipal que emanam de Instrumentos de gestão territorial legalmente aprovados e em vigor, e que directa ou indirectamente têm de ser integradas na análise nesta análise prévia.

If these elements are part of territorial matrix enhanced acknowledgement, that can incite Almada's positioning in face of the revised Municipal Master Plan valance reviewed horizon, can not be

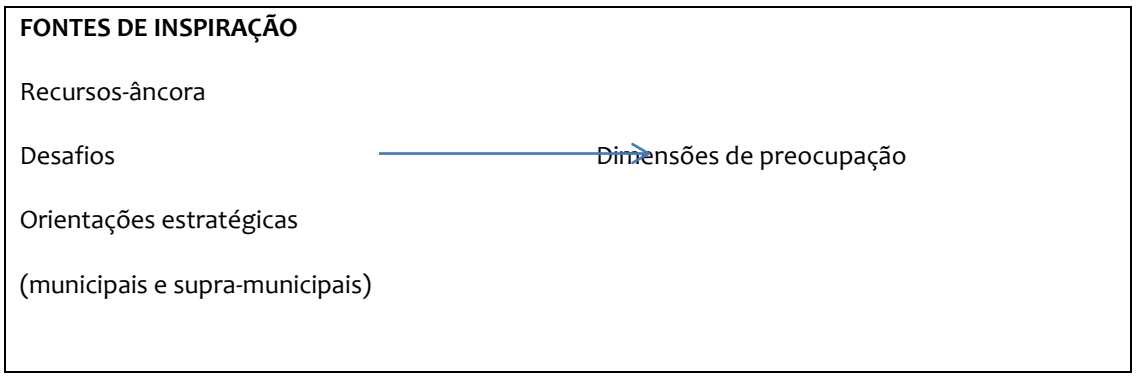
- Conectividade, Competitividade e Cosmopolitismo;
- Polinucleação e Compactação;
- Sustentabilidade Ambiental e Sintonia com a Natureza;
- Dinâmica de Coesão Social e de Qualificação;
- Governabilidade e Governança;
- Reorganização do sistema metropolitano de transportes;
- Ordenamento dos diferentes usos e actividades especificas da orla costeira;
- Valorização e qualificação das praias;
- Desenvolvimento de actividades específicas da orla costeira;
- Defesa e valorização dos recursos naturais e do património histórico e cultural.

Como se pode observar ver a informação é extensa, desigual na sua natureza e nos seus propósitos, mas relevante para a estabilização de um quadro de preocupações-chave que estabeleça o pano de fundo para o desenvolvimento de um espaço estruturado de enfrentamento e onde o território tenha o natural destaque pelo instrumento em que tudo isto está integrado. As designadas dimensões de preocupação acabam por ser a condensação operacional do trabalho de levantamento feito nesta fase.

Dimensões de Preocupação

- Potencial Humano
- Dinâmica Económica
- Afirmação Regional
- Qualificação Ambiental
- Qualificação Territorial

Assim, o processo até aqui percorrido pode apresentar-se esquematicamente do seguinte modo:



3.2. From concerns to strategies

The condensation process that resulted in the dimensions of concern resembles a tree structure that we will see, will evolve into a double-arborescenc estructure, upstream and downstream of the process. As it turned out, these concerns are generally consistent with the political and technical issues raised above but also with the locative resources, initiative, human and institutional.
This articulation is intended to strengthen the idea that attention should focus on topics for which there were only identified resources are sufficient reasons as well able to support their understanding and coping. In other words, the formulation found seems to be able to achieve the desired objective and cover the field of possibilities, not excluding any significant area. Apart from this lack hindsight now realize what to do with it. This is not a strategic plan but "only" a plan that admittedly meant to emphasize this strategic dimension to frame a comfortable and credible framework for the development of this instrument.

Thus, these dimensions of concern came into direct connection to the strategic lines without the mediation of a vision as this is well formalized in the frameworkof the Municipal Plan (Decree-Law 380/99 republished by Decree-Law no. 46th/ 2009 of 20 February): "Art 69th., 2 - Plans municipal planning lay down rules on land use, defining models forecast development of human settlement and organization of urban systems and networks and, in appropriate scaleparameters of land use and ensuring environmental quality. Article 84, 1 - themunicipal master plan establishes a strategy of territorial development, themunicipal policy on spatial planning and urban and other urban policies,integrates and articulates the guidelines established by the instruments ofterritorial management national and regional level and establishing a model of spatial organization of the municipal territory. ".

The following strategic lines that give the dimensions of concern are:

· More businesses and jobs. Seizing new opportunities

· More people, better integration

· Better public transport, better mobility

· Improved urban environment, rehabilitating and structuring the built environment

· promotion of environmental values and landscape

The difference between concerns and strategies are in fact the first to exalt the problem and said a second approach to address this assertion. Understandingthe strategic line would be enough to "feed" the work of operation necessary todisaggregate into strategic vectors that point to specific issues where it isimperative to act and is still advancing with the end-objectives that match what you would like to have in order for each of problems:

- More businesses and jobs. Seizing new opportunities
entrepreneurship| Objectives purpose: To promote employment, promote the creation and support of business

Locate economic activities | Objectives-end: Boosting the economy, ensureterritorial competitiveness

Leverage local resources | Objective-end: Valuing indigenous resources

- More people, better integration
Education, Training, Qualifying | Objective-end: Raise the level of qualificationsof the resident population

Attracting new residents | Objectives-end: Increase the resident population

Integrating classes and generations | Objectives Worm: Enhancing the social integration

- Better public transport, better mobility
Develop inter-district council accessibility | Objective-end: Improving theinfrastructure and public transport service

Improving mobility intra-district council | Objective-end: Improving mobility and connections

- Improved urban environment, rehabilitating and structuring the built environment
Urban centres structuring | End-means: to promote urban areas re-qualification

Urban space rehabilitation| End-means: to promote historic centres rehabilitation and revitalization

- Better environment and landscape framing

Endorse the municipal ecologic structure | Aims-end: endorsing the municipal ecologic structural consolidation

Improve and protect views | Aims-end: endorsing the minimization of environmental impacts, improving views and focal points

3.3. Process procedure

The land management instrument – Municipal Master Plan – shows as documental contain "Article 86th , 1 – the municipal master plan is constituted by: a) Regulation; b) Urban plan representing the organizational area model of the council's territory, in accordance, with structuring systems, and land qualification, and yet planning operative units and defined management; c) Restrictions plan, identifying passages and current public utility restrictions that can constitute limitations or impeachments to any specific usage form." (Law-Decree 380/99, of the 22nd September, republish by Law-Decree 46/2006, of 20th February). Such demands end up by giving a especial delicacy, to the work in obtaining the strategic lines, in such a way that, it can be unveiled in credible and concrete actions to be participated, in a stimulating way in the remaining steps of the Plan elaboration.

As this process is still far from its conclusion, being still in a developing stage, there are limitations to be taken into account, namely the current actions that are not yet possible to safely define. The action/project demands a timing detail level, amidst hierarchy, governability, financing, articulation, and so on, that in the current phase it is impossible to define.

However, understanding that strategic lines though mobilizing and well intentioned, would be excessively vague to instigate a substantive discussion in the form of a procedure of enlarged participation, one should, without compromising any of the aims, to find a formula, that would help to deepened the reflection process, and helped in the identification and construction actions exercise.

This formula ended up in the definition of aims that have the merit of having sufficient detail, instigate discussion without yet stating actions, but that are sufficiently near to them.

The “Aim” figure encloses a large complexity, but it is generally accepted that it is about a end or finality that was determined by the process ambit, that should be obtained or achieved by means of an integrated project. In the particular case of the Almada´s Municipal Master Plan revision, it was considered useful its segmentation in two types (to which it is necessary to add the means-end, dealt in previous paragraphs):

Starting aims

Are those who permitted to sustain the beginning of the RPDMA process, and which will be recalled at the process finish, in order to evaluate the obtained answer levels. They are thus programmed aims in the sense that they will constitute guidelines for the Plan’s elaboration.

- Reinforce Almada’s role while a AML secondary centre and a main Setúbal’s Peninsula urban site within de “two riversides city” context.
- To create the necessary conditions for university campus, and council’s innovation development, promoting new trades land fixing and the inter-relationship with developer’s fabric and supporting its internationalization.
- Upgrading the leisure and tourism offer, of which the “Costa Polis” is a fundamental element and enhancer of new initiatives in this domain – in the sense of deepening the council’s vocation as a big area for leisure within the AML context.
- Consolidation and upgrading of the council’s ecologic net, in order to, guarantee its sustainability, in such a way that it will contribute for the environmental improvement of the urban spaces that is crosses.
- To better neighbourhoods urban environment, as well as, its lesser valued urban centres, in order to strengthen or giving them, their own identity, enabling their development in a close-by urbanism, and a more coherent and solidarity social livelihood.
- To contribute to the main problems resolution of existing accessibilities, both in relation to the AML’s north riverside – in particular with Lisbon -, as with several of the council’s areas, and its immediate surroundings, in a sustainable mobility perspective, that focus not only in accessibilities and transportation systems, but also in those urban aspects that will condition urban mobility.
- To deepen council’s urban management capacity, in the sense of increasing its efficiency, and municipal’s competence to guide the urban development process, and establishing structuring partnerships with the State and private enterprise for action and project achievements for the municipality, bearing in mind the acquired experience with the current PDM, and its innovating aspects at urban balance and private participation level, in territorial infra-structures and in its contribution for provisioning the municipality with collective facilities.

Aims - means

They are instrumental to obtain its end aims (referred previously), willing to participate in their various success. It was possible to organize all the universe of aims-means, in five

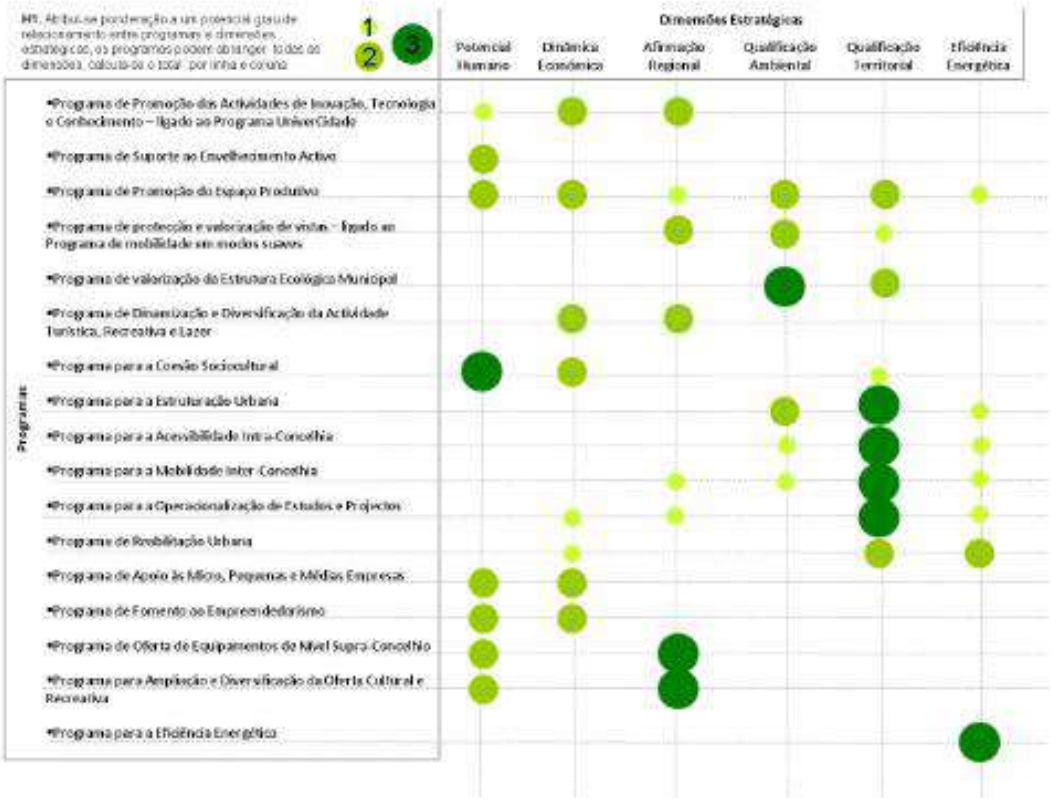
dimensions (related with strategic lines): Economic Endeavour, Mobility Structuring, Social Cohesion, Urban Spatial Structuring, and Landscape Environment Improvement.

Each of these aims can participate in one, two, three or even four programmes simultaneously as it can be seen in the below figure.

Fig. 5 | Methodology of general structure

It totals, 17 programmes, which cover all considered central areas for social territory qualification, inter-acting them with defined strategic dimensions as we can see below:

Fig. 6 | Matrix of strategic dimensions and programs



4. Conclusion

Producing a territorial strategy it is a complex exercise, which should be done tailor made, with should take into account its resources, actors, and existing problems. Not however withstanding its pertinence for a planning process, and above all for a planning that tries to surpass the here and now, unprepared for a future full of uncertainties.

Obviously the followed path could be different, investing in scenarios, and debating more ambitious plausible futures with the community. However, the process is not yet closed, and it can now, after the scheduled public discussion, verify its necessities of deepening, enlarge or only to adjust.

What matters is that planning is not anymore an end in itself, becoming through this methodology, a potent tool ensuring a future that musters everybody for its daily construction

Effect of introduction of fire prevention facilities on fires in Ottoman Istanbul

Masaru TANAKA, Yukio NISHIDA and Makoto TSUJIMOTO[1]

Abstract

Many fire incidents and urban-fires occurred in Ottoman Istanbul, but today we no longer face such kind of disasters.

This research analyzed records of 151 fire incidents and urban-fires from the year 1478 to 1918 in Ottoman Istanbul, paying attention to start points, burnt areas, damaged scales and calendar date of each fires with the help of GIS database in order to clarify factors that had reduced fire incidents. Subject area is set inside of the zone surrounded by the Golden Horn Inlet, Theodosian Walls and Marmara Sea.

Reduction of the numbers of fires should be attributed to enhancement of either 1) fire proof ability of each buildings through rebuilding following destruction by fires or decay by time, operated by building codes (e.g. the 1848 building code), or 2) fire fighting ability depending on both fire fighting organization (e.g. establishment of autonomous fire fighting section in 1868) and fire fighting equipments (e.g. Real Davud's introduction of fire pump to the Ottoman Empire around 1720 or installment of fire ponds in the city started from 1794).

[1] Center for Fire Science and Technology, Tokyo University of Science
1-14-6 Kudankita, Chiyoda-Ward, Tokyo, 102-0073, Japan. ketz@yk9.so-net.ne.jp (TANAKA)

So, paying attention to such epoch making years as 1720 (i.e. introduction of fire pump), 1795 (i.e. the next year of the start of installation of fire pond) we counted the numbers of fire incidents per annum before and after each epoch making years.

The numbers of fire incidents occurred in all over the subject area (151 fires recorded) had not been reduced after the installation of fire ponds mentioned above. Regarding fire incidents started in or around the Grand Bazaar (in Turkish, Bedesten, 13 fires recorded), the numbers per annum declined to 1/5 after 1795, when they had started to install fire ponds in the grounds of Beyazid- and Nuruosmaniye- Mosques which are just next to the Grand Bazaar. Also those started in or around the district of Odun Gate, infamous for its vulnerability (30 fires recorded), declined to 60% per annum after 1795 compared with before.

So, those fire ponds installed in the premises of large mosques in the center of the city prevented fire from growing larger to some extent, but, as the urban fire streams proceeding through the vicinity of those fire-ponds-installed mosques was not reduced, fire fighting ability at that time seemed to be inadequate to settle down large scaled fires.

Of course we should conclude that such reduction of fire incidents can not be attributed only to the installments of fire ponds but also to other reasons combined together, but at least we can say that it was the biggest effect to reduce the numbers of fire incidents concerning those area which could protect themselves with extinguisher facilities, composed of fire pumps, fire ponds and fire fighters.

Keywords: fires, Ottoman Istanbul, fire proof ability, fire fighting ability, planning history

1 Introduction

1.1Background and purpose of the paper

Istanbul is a prominent mega-city embracing around 9 million population and 13.1 million including its suburbs in 2010. The city, suffering from its 256 fires during the years 1478-1918 according to the description by Mustafa Cezar, 2002 (the 11th Chapter, pp.354-445), has developped contemporary urban spaces after repeated destructions and constructions like Edo (old name for Tokyo). This paper aimed to 1) organize the information on the history of fires in Istanbul, 2) grasp characters of each fire and 3) consider historical background of the change of those characters, based on the above-mentioned book.

1.2 Method of the research and accuracy of data

The subject area (Fig.1) is the historic peninsula of Istanbul, that is, the area enclosed by the Theodosian Walls, the Golden Horn Inlet and the Marmara Sea. Within the 256 fires mentioned above, fires broke out in this area were 151 and 25 of them were recorded with the information how they spread out gradually.

We built up GIS database of these fires with the help of the Google-Map and the Mapinfo (GIS application soft) and considered characters of fires and their (characters') change referring to other books appropriately.

Cezar described location information of each fire with the names of city wall gates, localities, large-scaled buildings or streets. In case there were few information

Fig. 1 Subject Area (source:Baedeker)

Tab.1 Historic Events concerning fire fighting and fire-proof structure

Year	Event
1701	Reconstruction of the Grand Bazaar into masonry structure
ca.1720	Introduction of hand-pump extinguisher
1794	Installation of fire ponds (first phase)
1811	Installation of fire ponds (second phase)
1826	Independence of fire fighting organization from military power
1848	First building regulation system introduced
1864	Complete prohibition of wooden structure

to identify the location of ancient localities or streets exactly (pinpoint) (but at least got some hints), we assumed their mid-section to be the starting-points or spreading-routes of fires.

And, we drew spreading-routes with polyline style linking each building or locality said to be destroyed by fires. Even in case Cezar did not describe plural spreading-routes respectively, we drew those routes separately when we judged rationally that there should have been existing plural routes.

Thus, this database standing on Cezar's description is NOT SO accurate enough to measure burnt-areas or length of spreading-routes, we mainly have done qualitative analysis (location information).

The analysis was undertaken according to the 3 eras set by two epoch-making events; introduction of fire-pump by Real Davud (French-born Naval Engineer served for Ottoman Navy, introduced hand-pump extinguisher. Cezar, 2002. pp.356-357.) around 1720 and the first time installation of fire ponds starting from 1794 (Cezar, 2002, p.416) (Tab.1).

2 Analysis

2.1 Overview of outbreak of fires

2.1.1 Transition of the numbers of fires

Tab.2 Fires broke out in Istanbul in each era

	Period (year)	Years	Population (thousand)	Numbers of Fires	(among which spreading route identified)	Average fires per annum
First Era	1478–1718	241	620	36	8	0.15
Second Era	1720–1784	74	640	72	15	0.97
Third Era	1788–1918	122	820	44	10	0.36
Total	1478–1918	440	N/A	151	25	0.34

Tab.2 shows round numbers of population of Istanbul (Chandler , 1987.) and numbers of fires in each era. Average numbers of fires per annum occured during the second era (0.97) is more then 6 times as many as the first era (0.15). Behind this phenomenon, there must have existed concentration of population and commercial- and industrial-functions to urban space, but at the same time we should presume that such records from newer period should outlive easier (securely) than those from older period.

And, in spite of such presumption, the average fires broke out in the third era (0.36) is less than half of the second (0.97). It depicts certain reasons restrained fires to break out, for sure.

2.1.2 Transition of outbreaks of fires by months

Fig. 2 shows numbers of fires broke down by months. Comparing the proportion of the numbers of fires occurred in each era by months, we may describe that during the first era, the proportions of such months as August, September, April, May, and March are high in descending order, but during the second, that of July, March and June rise (position of April and May stay similar to the former era) and instead August and September fall. During the third era, July and June continue to have large proportion, but on the other hand April and May used to be prominent during the first and second fall.

Thus, “fire concentration season” differs in each era; during the first era, it is from spring through high summer till late summer; during the second, spring till

early summer; the third, early summer till high summer.

According to the meteorological data (provided by the research assistant F. Korhan Yelkenci, belonging to the General Astronomy Division of the Astronomy Department of the University of Istanbul) observed in 2010 just below the Beyazid Tower (Former Fire-Watch-Tower under Ottoman period, located in the site of the so-called “Former Palace”, later turned into the Ministry of Army and then to the University today), the average relative-humidity (Fig.3) records the lowest in May and the second lowest in August, so the high proportion of May in the first and second eras and that of August in the first and third eras are convincing, but the falls of that of May in the third era and that of August in the second are not. There must

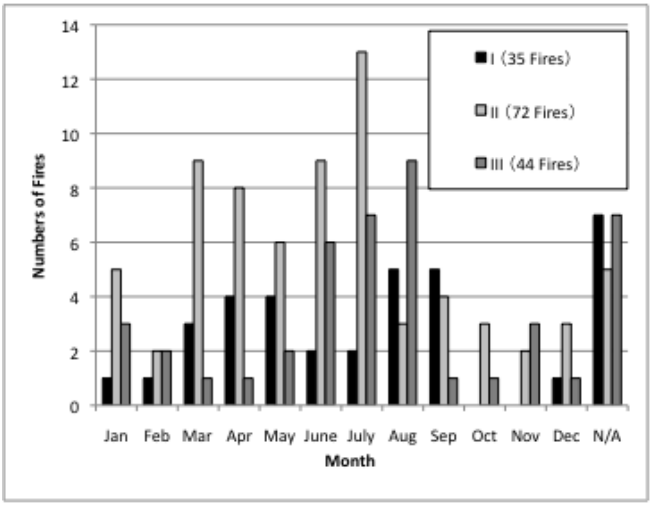

Fig.2 Numbers of Fires broke down by Months

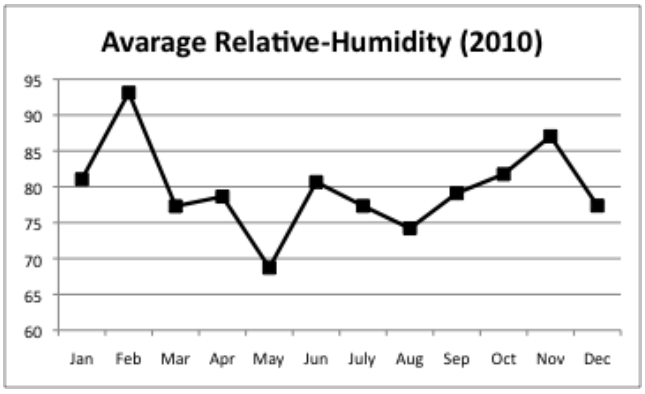

Fig.3 Average Relative-Humidity observed in Istanbul in 2010, (source: original data courtesy of Mr. Yelkenci)

be some other reason which cannot be explained by the actual meteorological data.

2.2 Onsite analysis of outbreak of fires

2.2.1 Outbreak locations

Fig.4-6 shows outbreak location of fires.

During the first era (Fig.4), fires broke out in Topkapi Palace and in its vicinity (the First Hill, "**A**" in the following sentences), the Grand Bazaar and the Old Palace together with its vicinity (the Second and the Third Hill, "**B**"), the commercial sea port facing to the Golden Horn Inlet (Eminonu, "**C**") and such residential districts also facing to the Inlet as Cibali, Fener and Balat inhabited by Greek, Armenian and Jewish people ("**D**"). Only one fire broke out on the Seventh Hill ("**E**").

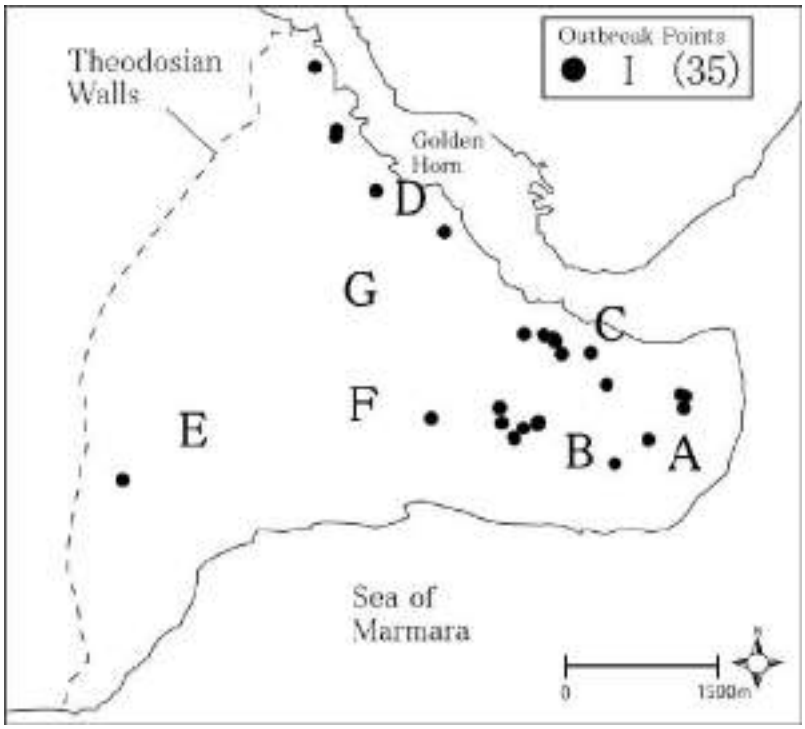

Fig.4 Outbreak Points of Fires during the first era (1478-1719)

The contrast between **D** and **E** may be attributed to the facts that 1) Non-Muslim people were restricted to live in smaller house than that of Muslim people (Kuban, p.355.,), 2) **E** was occupied by Muslim people and their houses were composed of several buildings scattered around in premises (Kuban, 2010. p.240.) and 3) large area of **E** was occupied by the so-called Kulliye, that is, a complex of buildings for various benevolent services for local community (Kuban, 2010. pp.313-314.).

During the second era (Fig.5) , more than 6 times as many fires per annum broke out as during the first. The occurrence status of fires around **A** did not change, but numbers broke out around **B**, **C** and **D** increased. Among them, Balat District in **D** gained population density more because of absorbing those Jewish people eventually being forced to move out from **C** for the construction of New-Mosque (Yeni Camii) at the end of the 16th century (Kuban, 2010. p.69.). And, fires broke out to the west of **B** (in the vicinity of the saddle-point formed by the Third and the Forth Hills over to the sea of Marmara, "**F**"), in the vicinity of Conqueror's Mosque (Fatih-Camii) (the Fifth Hill, "**G**") or in the Marmara side of **E** (Samatya District) came to be

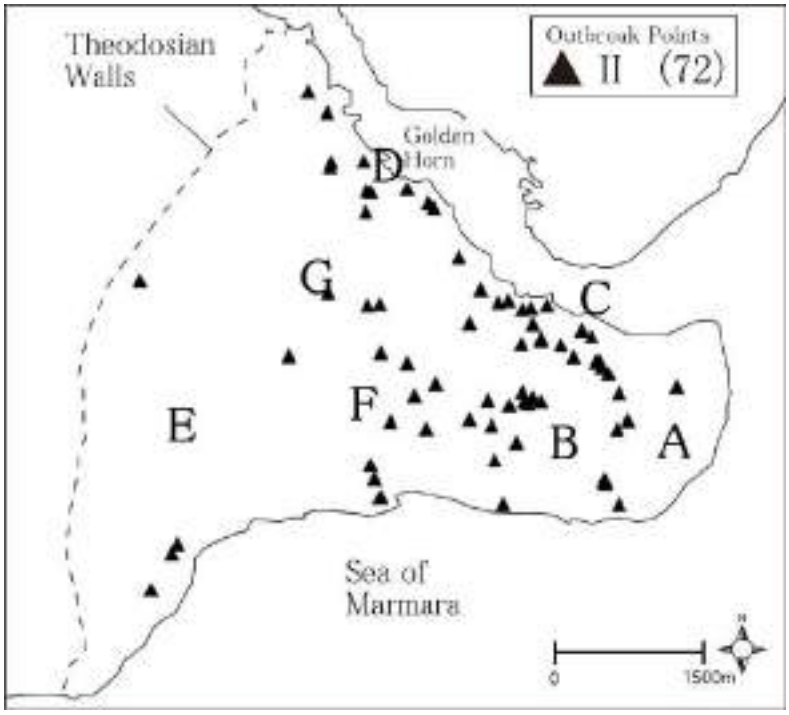

Fig.5 Outbreak Points of Fires during the second era (1720-1794)

observed. In this era, in **F** and **G**, such markets founded by Ottoman Sultan Mehmet II (the Conqueror) as Sultan pazari Market and Sarachane Market were thriving because of the trade expansion between Balkan Peninsula and Istanbul (Kuban, 2010. p.281.).

During the third era (Fig.6) , the numbers of fires per annum decreased by less than half of the former. Fires occurred similarly in **A**, **B** and **D**, but less occurred in **C** and **F**. In 1794, authority installed fire ponds in **B** (in the premises of the Beyazid and the Nuruosmaniye Mosques), **C** (in the premises of the New and the Suleymaniye Mosques) and **F** (in the premises of the Laleli Mosque). In 1810 they installed fire ponds again in **C** (in the premises of the Suleymaniye Mosque) and **F** (in the premises of the Sehzade Mosque) and newly in **A** (in the premises of Sultanahmet Mosque) and **G** (in the premises of the Conqueror's Mosque) (Kuban, 2010. p.418.). Regarding **C** and **F** equipped with fire ponds dropped frequency of fires, but on the other hand, **B** also equipped with fire ponds could not drop the frequency.

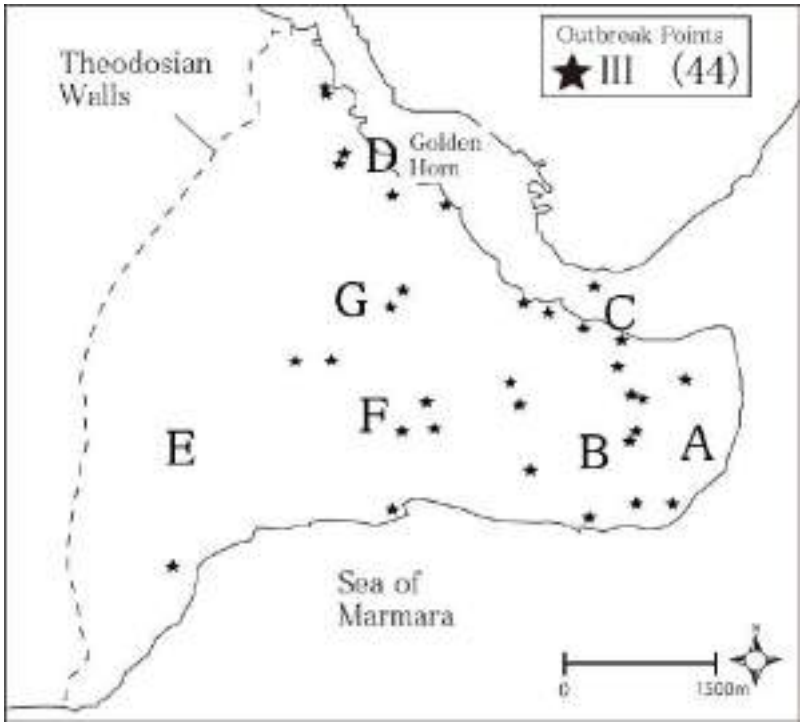

Fig.6 Outbreak Points of Fires during the third era (1795-1918)

2.2.2 Spreading route

Fig.7-9 shows spreading routes of fires recorded in each era. Triangle- or Star-shaped points depict start of each fire and polylines extending out from those points show spreading routes.

No spreading route is recorded during the first era (Fig.7).

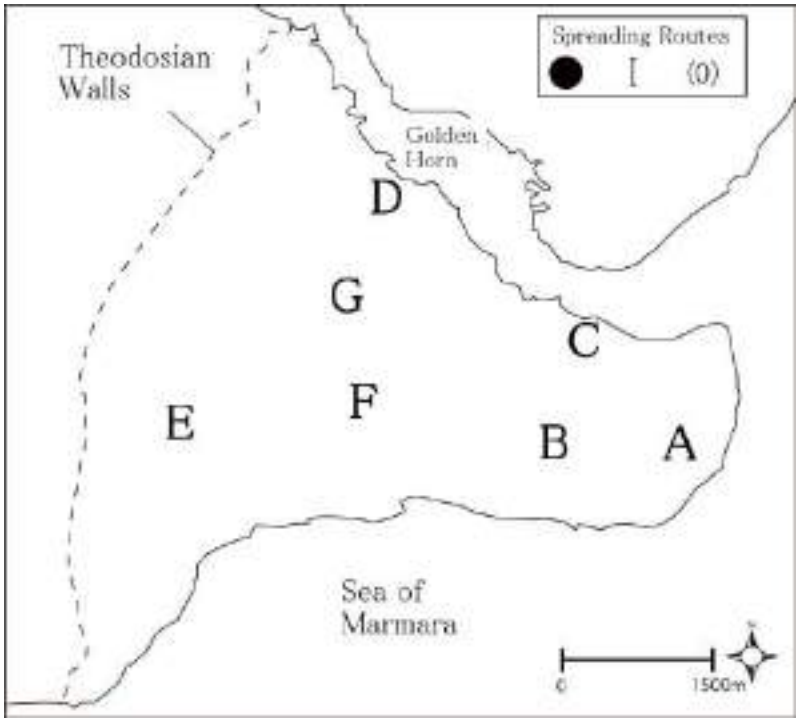

Fig.7 Spreading Routes of Fires during the first era (1478-1719)

During the second era (Fig.8), half of the fires recorded with spreading routes were generated in **C** and **D** facing to the Golden Horn Inlet. This may be attributed to such facts as 1) **C** and **D** were densely inhabited and flourishing for their commercial and industrial functions, 2) **D** was not equipped with fire ponds and 3) the prevailing wind observed in almost all months comes from the Golden Horn Inlet (Fig.10 shows wind-rose chart, made from the meteorological data mentioned above).

During the third era (Fig.9), the numbers of fires with long-spreading-routes

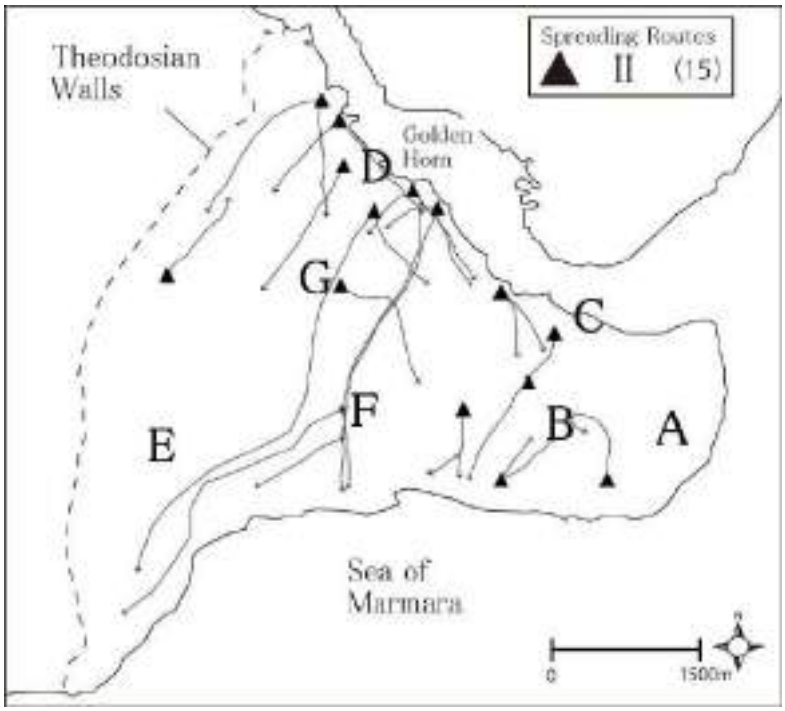

Fig.8 Spreading Routes of Fires during the second era (1720-1794)

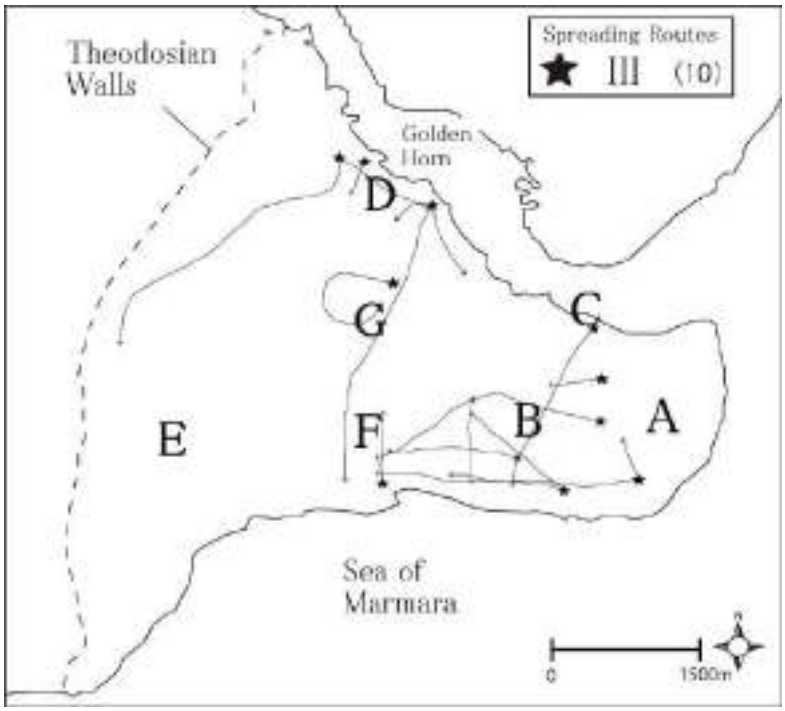

Fig.9 Spreading Routes of Fires during the third era (1795-1918)

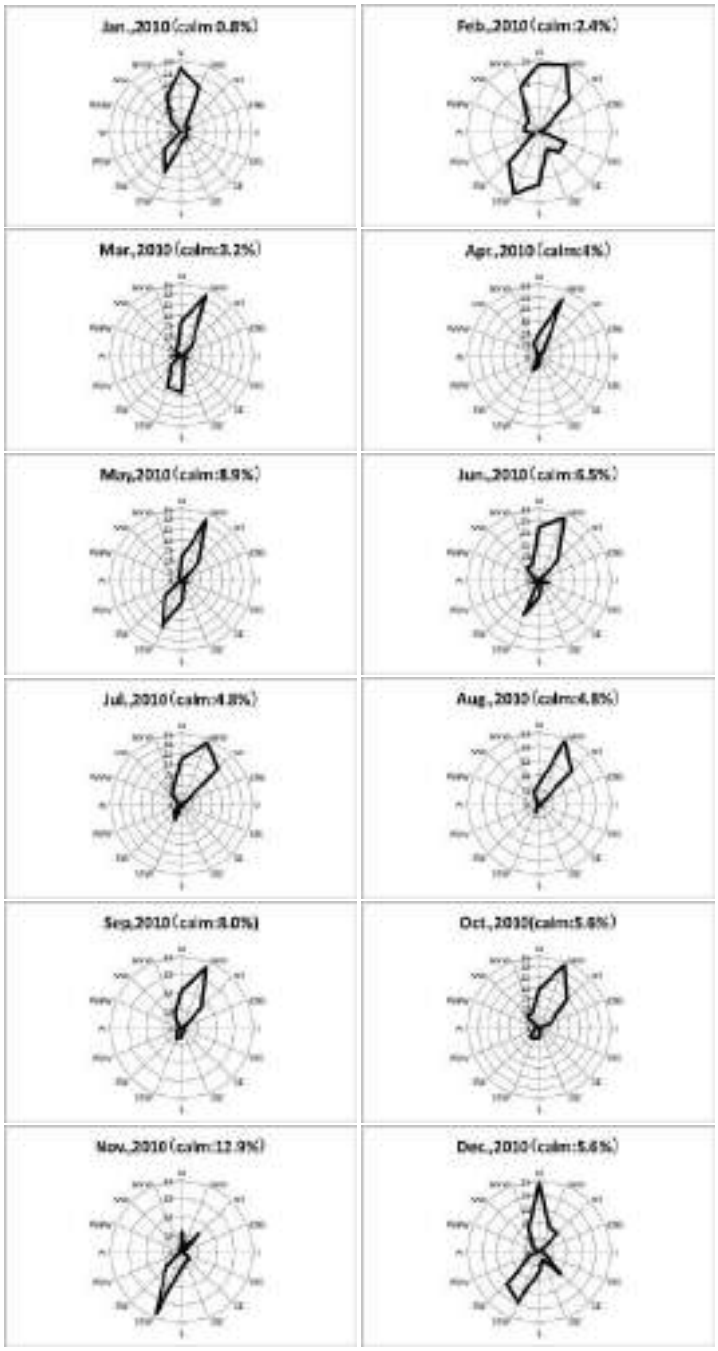

Fig.10 Wind-Rose Chart in 2010 (data: courtesy of Mr. Yelkenci)

derived from the minority district facing to the Golden Horn Inlet declined (though still occurring).

E, less suffered from outbreaks of fires, also less damaged by those spreading

fires (though, Samatya District inhabited by Armenians and Greeks burnt). This may be interpreted as the result of being low building-coverage ratio mentioned above, similar to the fact that those fires broke out in the premises of Topkapi Palace tend not to grow larger.

2.3 Start of Building Regulation and its Effect

2.3.1 Development of Building Regulation

According to the description by Celik (Celik, 1986. pp.51-54) (Tab.3), the first systematic Building Regulation (Ebniye nizamnamesi) together with Building Declaration (Ebniye beyannamesi) were issued in 1848. They defined “Kargir” or masonry structure and started to control height of building in accordance with whether it hwas to be built in masonry (less than 22m) or wooden (less than 16m) structure.

Then, in 1864 Government issued a decree saying that henceforth they

Tab.3 Development process of building regulation after 1848

	Concerning fire-proof construction	Concerning height	Concerning street classification	Concerning (improvement) of infrastructure	Acknowledgement
1848 Regulations (Ebniye Nizamnamesi) and Declaration (Ebniye beyannamesi) for Buildings	Introduction of definition of Kargir (masonry)	Kargir structure, less than 22m; wooden structure, less than 16m	3 classes	Large vacant land area, small building lots, development permission for plots or open fields	
1856	Urban redevelopment of Beyoğlu after the Great Fire of Pera				
1863 Street and Building Regulation (Turuk ve Ebniye Nizamnamesi)			5 classes		
1864 Government Decree	Prohibition of wooden structure within the territory of the Capital City, except for those installed with Kargir Fire Wall				
1865	Establishment of the Commission for Street Improvement, commencement of street-widening projects and urban redevelopment of Beyoğlu after the Great Fire of Beyoğlu				
1868	Planning of the New Street Network				
1875 Regulations on Construction Methods in Istanbul (Istanbul ve Belde-I Sebsede Yapılacak Ebniyenin Sureti-I Inşaiyesine dair Nizamnamo)	Complete prohibition of wooden structure in the Inner Zone and prohibition of them in the Outer Zone, except for those equipped with Fire Wall				Part of the area linking Aksaray-Unkapanı-Azapkapı-Galata-Pera-Ortaköy was the Inner Zone, West, the Outer Zone
1882 Building Law (Ebniye Kanunu)		Introduction of the regulation for height of building in accordance with width of street	5 classes	Introduction of the Torla Rule (Infrastructure reorganization in case of fire causing damage of more than 10 buildings)	

source: Celik, Zeynep. 1986. The remaking of Istanbul: Portrait of an Ottoman City in the Nineteenth Century. University of Washington Press. pp.51-54

prohibited wooden structure except for those buildings installed with Kargir firewalls. This prohibition developed into another phase in 1875 ; 1) wooden structure was completely prohibited in the inner part of the capital city (eastwards from the axis connecting Aksaray- Unkapani- Azapkapi- Sisli/Pera- Ortakoy till Bosphorus Strait) and 2) prohibited unless it equipped itself with masonry firewalls in the outer part (westwards from the axis mentioned above).

As for height-control, Building Law (Ebniye kanunu) issued in 1882 introduced regulation for height in accordance with width of streets running in front of those buildings.

Thus, gradually Ottoman capital gained ways to regulate the size and volume of buildings composed of flammable materials for the sake of suppress fires.

2.3.2 Fires after the enforcement of masonry structure

Now focusing on those fires occurred after the definition of Kargir structure in 1848. In the subject area, 22 fires broke out after 1848 and interestingly enough most fires came out from the same or neighboring places as the former ones.

Tab.4 shows fires I) occurred in the same district (premises) as the precedents and II) occurred (possibly) in the neighboring area or in the same point of the precedents, after 1848.

Among the former ones Samatya (No.1 of Case I) was destroyed before the enforcement of Kargir obligation in 1864 and again in 1882. Hocapasa (No.2 of Case I) and Sublime-Porte (No.3 of Case I) caught fire after 1864 and, as for Hocapasa, the name never came out to the history of fire henceforth, but Sublime-Porte again (Feb., 1911), though it is not a good case to study more because of its special characteristics.

Tab.4 Places suffered from fire after 1848 more than twice

I) Fires occurred in the same district (premises) as the precedents after the 1848 Regulation

	Name of place	Month/Year	Note
1	Samatya District	Aug.,1852 and Jul.,1882	After the fire in1852, Obligation enforced.
2	Hocapasa District	Aug.,1865 and 1865 (no further info.)	After the enforcement of Obligation Fire occurred.
3	Sublime Porte (Babiali or Grand Vizier's Office)	May,1878 and Feb.,1911	After the enforcement of Obligation Fire occurred and another one occurred later.

II) Fires occurred (possibly) in the neighboring area or in the same point of the precedents after the 1848 Regulation

	Name of place	Month/Year	Note
1	Sultanahmet	1852 (no further info.)	After the fires in1852 and 1880, Obligation enforced and another one occurred later.
	Ahirkapi	Jun.,1860	
	Ishakpasa	1912 (no further info.)	
2	Koska and Laleli	Jun.,1855	After the fires in1855 and 1856 Obligation enforced and an other one occurred later.
	Aksaray	Nov.,1856	
	Uzunsarsi (spread over from)	Jul.,1911	
3	Fener and Kiremit	Apr.,1881	After the fire in1861 Obligation enforced and another one occurred later.
	Balat	Jul.,1911	
4	Fener and Kiremit (double-count)	Apr.,1881	After the fires in1881 and 1883 Obligation enforced and another two occurred later.
	Halicilar	Dec.,1883	
	Circir (spread over from)	Aug.,1908	
	Sultansolin	Jun.,1918	
5	Gedikpasa	Sep.,1865	After the enforcement of Obligation fire occurred and another one occurred later.
	Uzunsarsi (spread over from) (double-count)	Jul.,1911	

Among the latter ones, there are some cases which seem to be interesting; chatching fires more than twice after the enforcement of Kargir structure. It implies the possibility that even reconstructed buildings with Kargir structure might not to be able to stop fires to occur, as the vicinity of Sultanahmet (No.1 of Case II) and Gedikpasa (No.5 of Case II) in which people were obliged to rebuilt their buildings with full-Kargir structure (another possible interpretation is that the precedent did not touch the places which followers burnt down, or, Ottoman officials were not so keen to let people keep the regulations).

2.3.3. Historical tendency and the effect of regulation

Another question is whether such new regulations set by Ottoman officials had

clear effects on stopping the tendency of fire till then, or not.

Tab.5 shows fire history in the areas shown on Tab.4.

As for Hocapasa (No.2 of Case I) , though many high officials serving for Sultan lived in at that time, it was caught fires 7 times and destroyed every 10-20 years until the third quarter of the 18th century and twice let Sublime-Porte burn down (No.3 of Case I), but as we saw above after the fire in 1865 it never caught fire. This fact may be attributed to the effect of regulation for structure, but also to the possibility that high officials followed Sultan's move to Galata/Pera side of the city (Celik,pp.38-39) and so population and building densities might go down.

In the vicinity of Uzuncarsi, Gedikpasa and Grand Bazaar (No.3 of Case II), that of Fener and Balat (No.4 of Case II) and that of Laleli, Koska, Aksaray and Langa (No.5 of Case II), though in deed they each occupy vast territory of the city, people experienced several fires .

About the vicinity of Uzuncarsi, Gedikpasa and Grand Bazaar (No.3 of Case II), 5 fires occurred with interval of 30 years in the 18th century. Though installed with fire pond in the premises of Nuruosmaniye Mosque in 1794, the quarter suffer 3 fires and one after the enforcement of Kargir in 1864. So, as we saw macro-scope study at 2.2.1, frequency of fire seems not to decline.

But, in the vicinity of Fener and Balat (No.4 of Case II) and that of Laleli, Koska, Aksaray and Langa (No.5 of Case II), the numbers of fire decline clearly around the end of the 18th century. The former suffered 9 fires till the end of the 18th century and never to be equipped with fire pond and after the turn of the century 4 (during the 18th century 6 with interval of ranging from 2 to 30 years, and during the 19th century 3 with interval ranging from 13 to 50 years). The latter, though just next to barracks of Jannisary Troops obliged for fire fighting till 1826, suffered from 9 fires

		Jul.1811 (Langa)
		Aug.1833 (from Cibali to Langa)

till the end of the 18th century and after being equipped with fire pond at Laleli Mosque, 5 (during the 18th century 7, and during the 19th century 4, though both periods show similar range of interval).

It is hard to distinguish the possible effect of building regulation over fire-prevention from that of installation of fire pond, but in the vicinity of Fener and Balat, fire pond was never installed.

3 Conclusion

This paper reveals such facts as 1) the numbers of fires once increased till the end of the 18th century and then started to decrease around the same time as the installation of fire ponds, 2) originally, spring to summer seasons being short of rainfall occupied larger proportion of months in which fires broke out, but after the period of installation fire ponds the proportion of spring season fell, 3) as population and commercial- and industrial-functions were being concentrated on gradually, fire risk had risen, but the numbers of fire broke out decreased after the installation of fire ponds in such densely-inhabited or thriving commercial- and industrial- districts, 4) half of those fires recorded with their spreading-routes started from the Non-Muslim Districts in which space of living inevitably condensed, 5) even after the enforcement of masonry and fire proof structure called Kargir within the city territory in 1864.

Still, we should pursuit accuracy of consideration with the combination of fire, calendar, wind-rose chart and relative-humidity as well as concrete density of population and implementation of building regulation at that time.

Climate regulation provided by street trees - examples from Gothenburg, Sweden

Sofia Thorsson and Fredrik Lindberg

Department of Earth Sciences, University of Gothenburg, Box 460, SE-405 30 Göteborg, Sweden; Email: sofia.thorsson@gvc.gu.se

Trees has shown to be an effective measure for reducing heat stress in high latitude cities in summer, especially in dense urban areas (e.g. Lindberg and Grimmond 2011). During the day the cooling effect provided by trees is foremost due to shading, i.e. evaporative cooling is of less importance. In summer deciduous trees (foliated) block 95-98% of the direct solar radiation and in winter (un-foliated) 45-53% of the direct solar radiation (Larsson 2011, unpublished results). This means that trees provide significant shading both in summer (desired) and in winter (undesired) (Thorsson 2012). In order to design better cities and mitigate heat problems, quantitative information on the shading effect of street trees is required. This paper presents the influence of street trees (amount, location, size etc.) on the outdoor thermal comfort in the high latitude city of Gothenburg, Sweden. The shading effect of street trees on a neighborhood scale is analyzed using the SOLWEIG-model (2.2 version) (Lindberg et al. 2008, Lindberg and Grimmond 2011). The model simulates spatial variations of 3D radiation fluxes and mean radiant temperature (Tmrt) as well as shadow patterns in complex urban settings. Model evaluation shows good agreement between modelled and observed values of Tmrt as well as shadow patterns (Lindberg and Grimmond 2011), which shows that the SOLWEIG model is an appropriate tool to quantify the influence of vegetation on Tmrt and shadow patterns within the urban environment. The SOLWEIG model is designed to run using a user friendly interface which makes it possible for practitioners and planners as well as researchers to make use of the model in a climate planning perspective. The results presented in this paper highlight a number of possible climate sensitive planning practices for urban areas at the local scale.

Keywords: Mean radiant temperature, SOLWEIG, urban vegetation, shadow patterns

User perspectives in housing: the relevance of 'habitus'

Barry Goodchild [1]

Abstract

During the past few years, the implementation of national carbon reduction targets in the UK has led to an enormous amount of research has been undertaken on the design and use of the home in relation to energy consumption, especially in relation to low energy homes. The aim of this paper is to show the relevance of concepts of habitus to sustainable (and unsustainable) patterns of consumption and in doing to call for more qualitative, interpretative research in this field. It is acknowledged that different approaches have different strengths and weaknesses and the demands of methodological pluralism requires that these be mixed together. However, a full understanding is only likely to arise if priority is given to qualitative understandings, at the very least as a framing device for subsequent quantitative studies.

The aim of this presentation is to show that a pragmatic interpretation of 'habitus', albeit one grounded in the history of the concept, can provide a way into understanding energy use in the home and other related aspects of sustainable housing and by extension sustainable planning. In particular, the aim is to show how habitus can help bridge the gap between different methodological approaches, for example those based on the individual and society and those based on quantitative and qualitative sources.

Planning is concerned, as we are repeatedly told, with sustainable development. However, sustainable development is unlikely to get very far without a parallel concern with sustainable consumption, that is to say, how people use the environment in which they live. Habitus starts with processes of consumption, though it has implications for development. Developers work on the basis of habit in organising their work (Binder 2012). In relation to consumption patters, however, habitus has the merit above all of dealing with the obvious characteristic of sustainable homes- their novelty. The scale of carbon reduction envisaged by current targets implies a new relation between people and

This paper draws on work undertaken with Aimee Walshaw and Fin O'Flaherty. However, the present author takes responsibility for the contents. The paper is also work in progress and is likely to be modified in the future.

the homes they live. Carbon reduction implies investment in the older housing stock, the adoption of new types of dwelling with new types of heating and ventilation systems and, in most cases a more self-conscious relationship between the occupants and their home so that they understand how best to manage these new systems

As a result, the promotion of low energy/ low carbon housing represents a departure in the conventional way in which people think about and act in relation to their homes. It involves a break with old habits. What then does the theory of social habits and habitus say about strategies to promote sustainable consumption?

1. Routinisation and habit

Habitus is a mainstream concept in sociology, though one that is open to more than one interpretation. A common assumption in sociology is that, without shared, stable and generally taken for granted assumptions, our sense of social and personal identity begins to break down. Routines emerge from the every day life and from work and give a sense of structure to the world. Giddens (1984b xxiii) comments, for example: 'Routinization is vital to the psychological mechanisms whereby a sense of trust or ontological security is maintained in the daily activities of social life.' (xxiii) Ontological security means a sense that the world is as it should be on the basis of expectations. Routinization also involves taking reality for granted and therefore as unproblematic and unquestioned. It represents reality under normal circumstances (Schutz 1962, 220, 273).

Routines and routinization in turn imply habits and 'habitus', a bundle of habits. The term itself requires a brief explanation. Habitus, as understood in in social theory in Britain is associated with Bourdieu and is considered predominantly as a theory that seeks to understand the impact of society on the individual. The term predates Bourdieu, however. It goes back at least to the late 19th and early 20th centuries and emerged from a specific school of philosophy called phenomenology- the study of phenomena as encountered. Phenomenology is literally the application of 'logos' (thoughtfulness and language) to any phenomenon (object, person or environment) precisely as it is given (encountered) or experienced (Giorgi 1997, 237: Van Manen, 1984 4). Put like this, phenomenology looks obvious, even trite. It is not. Whereas conventional Western philosophy separates the subject from the object and, in doing so, implicitly endorses a positivist philosophy of science, phenomenology insists on the unity of human experience as encompassing both the subject and the object.

As such, habitus has a more ambiguous, richer meaning than is offered merely by Bourdieu. Habitus encompasses both the individual, the concern of phenomenology and social structure, the concern of sociology

2. Habitus as biography and structure

Phenomenology is concerned with human experience and how this interacts with the lived world, the world of everyday life. For Husserl ([1948] 1973, 122), the founder of phenomenology, previous experience does not disappear without trace. It continues '*in the form of a habitus*, ready at any time to be awakened anew by an active association' (italics in the original). Habitus as conceived by Husserl is therefore a product of a person's biography, their previous experience (Frère 2005). Bachelard ([1958] 1994, 14) uses similar language in analysing the house, above all the childhood house as a 'group of organic habits'. Equally, however, most interpretation of phenomenology do not exclude the possibility of conscious thinking reflecting on and either refining or changing habits and routines. Bachelard (1994, 67) comments, for example, 'consciousness rejuvenates everything, giving a quality of beginning to the most everyday actions'. Finally, The treatment of perception by Merleau Ponty ([1945] 2002, 39) is similar. 'Perception is a "hypothesis" that the mind evolves to 'explain its impressions to itself….. It is an interpretation apparently immediate, but in reality gained from habit corrected by reasoning.' The crucial words are 'corrected by reasoning'. Habit, as the routine performance of actions influences perception but this is always also influenced by conscious decisions.

Later, the concept of habitus was taken up by Bourdieu to refer to the likely persistence of similar practices (or patterns of behaviour) amongst people in a similar socio-economic situation. Habitus, according to this latter definition, is 'a set of acquired characteristics which are the product of social conditions and which, for that reason, may be totally or partially common to people who have been the product of similar social conditions' (Bourdieu 2005, 45). Habitus so defined is a form of social space, moulded by the social conditions of which it is a product. It is based on a combination of cultural capital (for example educational levels) and economic capital, including status in the labour market and, in this latter respect, is generally considered an aspect of class. In addition, habitus is a 'classificatory device' (Bourdieu 1998: 8) that enables the identification of different groups according to different tastes and life-styles and that can be mapped in terms of 'real' physical space, for example through spatial variations.

Habitus as social space is distinct from habitat, an aspect of physical space, but in the work of Bourdieu ([1993] 1999, 128), habitat and habitus are assumed to reinforce one

another, for example through patterns of residential segregation. In this context, habitus has been understood, perhaps misleadingly as defining 'sense of place' (Hillier and Rooksby 2005). Habitus, the routines that people follow in their daily lives, define their sense of place and *vice versa*. Places and social practices interact with one another. Further different groups tend to live and congregate in different parts of a city, either because of constraints or of active choices within the market. Those with choice seek out places that best meets their aspirations and requirements for cultural capital, as reflected in the twin and sometimes conflicting aspects of an attractive urban amenities and good schools (Bridge 2006)

If, however, habitat and habitus are mutually reinforcing, where is the individual? In some interpretations, the answer is nowhere. The individual disappears, except as the performer of a set of previously determined behaviour patterns. Habitus involves no apparent conscious intention, as in the following paragraph, and change in habitus is likely to be slow. It is a 'system of dispositions …. or a system of *long-lasting* (rather than permanent) …. structures of perception, conception and action' (Bourdieu, 2005, 43) (italics in the original). In other interpretations, in contrast, individual consciousness reappears. In the words of Bourdieu (1990, 64 and 81) 'if one is to adapt to .. indefinitely varied and never completely identical situations' .. habitus must be 'a source of invention, but only within certain limits.' Habitus can never be static, because society is not static. In any case, the multiplicity of different situations in contemporary society leads to the individual experiencing different social worlds at different stages in their life and multiple identities.

In other words, the earlier biographical concept of habitus, of habitus as being modified by experience and learning, remains, embedded within the socio-economic situation that the individual finds himself or herself (Frère 2005).

3. Understanding variations in consumption

These two meanings of habitus, biographical habitus on one hand and structural habitus do not coexist with one another easily in terms of theoretical consistency. Full integration of the two meanings is probably impossible. Their value is to express the ambiguities of 'real life' situations and to offer alternative, complementary explanations and understandings of how people use buildings, spaces and places and of whether their use in sustainable or not.

Studies of energy use provide an example. Different people vary considerably in their use of energy in the home, even when building standards are similar. How might this be explained and understood?

A full answer would draw on both biographical and structural habitus. A biographical explanation and understanding would look at how expectations and routines have been developed over time, from the personal experience of particular users. It would also explore the processes through which individuals are able to learn routines and learn how to change those routines. Learning implies the potential for change. A structural explanation and understanding would point to the way in which different groups and types of individual, classified notably by age, income and life-style (ethnicity and educational level, for example) have different tastes, different ways of interacting with the world and, most importantly, differential access to good quality, easily heated housing. A structural explanation would also suggest that social distinctions are an essential part of consumption and life-styles, even if these change over time, for example as a result of technological innovation.

The distinction applies equally to theories of change in relation pro-environmental behaviour (or change in favour of sustainable consumption to use the language of practice theory). Biographical habitus is consistent with those theories of change that seek to prioritise the individual- through so-called nudging, manipulating the situation in which people find themselves and so changing the assumptions of daily life (Thaler and Sunstein 2008: Allcott and Mullainathan 2010). Nudging means using a series of behavioural levers or 'cues' to encourage consumers to consider sustainable life-styles and patterns of consumption. The 'cues' are potentially diverse and include the energy labelling of products; changing the default settings in domestic equipment and the introduction of smart meters for energy and water. (By definition, nudging excludes compulsion, and measures that involve significant changes in economic incentives.)

In contrast, structural habitus implies a concern with the range of products and technologies available in society at any given time and the historical evolution of those products in relation to mass consumption. It means the state driving forward promising energy saving products out of their specialist, experimental niches into the mainstream. Zero carbon homes provide the best example. Zero carbon homes were initially developed by innovative individuals and communities and then promoted in the mainstream by government through a mixture of experimental subsidies and the threat of regulation. Mainstreaming has not been completely successful, mainly owing to the cost implications, however (Goodchild and Walshaw 2011).

Finally, both individual and structural habitus imply a concern with an intermediate level of communities and voluntary work by communities. In this context, two further theories of change are available; namely

- community marketing, involving an assessment of which particular changes are most likely to be accepted, the identification of barriers that mitigate against their take-up and the use of moral pressure, personal contacts and promotion of personal and community targets (McKenzie-Mohr et al 2012)
- community development, involving individuals in voluntary activities on the assumption that this increases understanding of environmental issues, generates a commitment to local environmental campaigns and 'spills over' into other innovative action (Seyfang & Smith 2007).

Of these three levels of intervention, measures targeting the individual are the easiest to implement from a political viewpoint, as there are no apparent losers. Change proceeds through persuasion and a so-called 'feelgood' factor that is supported by an attitudes, behaviour choice or 'ABC paradigm'. If only governments could change consumer preferences, sustainable patterns of consumption would emerge spontaneously. In the usual sociological approach, represented, for example by Shove 2010, views consumption patterns as being locked into a persistent socio-technical system involving relationships between life-styles, routines and dominant cultural assumptions.

The criticism is probably correct. A focus on the individual alone overestimates the ease of change, ignores the way in which the most obvious forms of consumer education have already been undertaken and also ignores historical precedents. historical studies of life-styles and technologies suggest that patterns of consumption change relatively slowly, over decades and are conditioned by a mutually supportive interaction between daily routines, largely taken-for-granted technology and infrastructure and dominant cultural conceptions of what is desirable and undesirable (Shove 2003: Owens and Driffill 2006). The replacement of horse drawn urban transport by motor vehicles (Geels 2005) or the replacement of open fires by central heating provide examples. In both cases, technology and life-styles changed together in a process of 'coevolution'. The implication is that innovation has to incorporate both the users and the producers of goods, services and infrastructure (Geels 2004) and that, as a result, policies have to be long term and ambitious. Indeed, in some ways, policies for sustainable development involve more substantial change than those associated with the growth of motor vehicles or central heating, both of which emerged along with the grain of modernity- more speed of movement and more comfort in the home. Sustainable consumption in contrast seeks at least to reverse or qualify these tendencies.

However, it is wrong to suggest that the advocates of the ABC approach are unaware of the limitations. For example, P. Stern (2000), an advocate of psychological approaches, notes that the ABC approach only works when contextual factors are not too strong to override personal choices. Contextual factors include habits and routines, household economic constraints and the available infrastructure.

4. Conclusions: Habitus and method

Whatever the broad strategy, the choice of measures presupposes some process of selection and evaluation. In this a combination of quantitative and qualitative methods is necessary. Habitus as a classificatory device implies statistical techniques to establish the main lines of division. Likewise studies of domestic energy consumption require the identification of variations in energy consumption for specific types of property. In this, research can draw on conventional surveys already undertaken, so long as these enable the identification of specific properties and households. Quantitative methods, subject to the availability of data, are also relevant in tracing progress over time.

However, the most distinctive aspect of habitus, irrespectuve of whether biographical or structural, is its use of qualitative methods. Habitus rests on routines and often taken for granted assumptions. Exactly for this reason, the assumptions of practice are not always revealed in the context of a conventional questionnaire, capable of simple quantifiable answers. Direct questioning risks generating misleading answers, 'don't knows' or incredulity (Allen 2005: Flint 2011, 81-2). Extended discussion, for example in a focus group, indirect methods such as diary keeping and visual methods (using photographs to stimulate responses or giving respondents a camera may, nevertheless, be more fruitful in generating insights (Walshaw, Goodchild and O'Flaherty 2012). Visual methods are, in any case, particularly valuable in helping people express their views and feelings about places and landscapes (Knowles. & Sweetman 2004).

Further, habitus and by implication other similar approaches based on phenomenology (even indirectly) have another implication that requires qualitative interpretations to be given priority. The concept of habitus applies as much to researchers and planners as to the subjects of a research project or initiative. No-one escapes the tendency to think or to act according to routines and habits. This background of routines and habits cannot be ignored, but it can be controlled through an exposition of the traditions and theories within which the research and the researcher is operating.

PUBLIC PLANNING IN THE ENTREPRENEURIAL CITY – THE BO01, MALMÖ, AND BRUNNSHÖG, LUND, IN SWEDEN

Ana Mafalda Madureira
Blekinge Institute of Technology, Sweden
e-mail: amm@bth.se

Abstract

Recent research has argued that due to a turn in urban policy towards entrepreneurial forms of urban governance, the scope and influence of urban planning conducted by public actors is changing and even decreasing. Entrepreneurial City approaches are employed by the municipality to promote local economic development through improvements on place attractiveness, and often rely on urban renewal and design, associated with businesses approaches such as branding, marketing, speculation and risk taking. The goal is to create neighborhoods that will attract companies and specific types of inhabitants (creative, young urban, entrepreneurial) to reside and work in the city or neighborhood. Business approaches are thus invading the field of public sector urban planning, and setting the context within which it occurs. The group of people involved in the planning project is fragmented and multifaceted. However, although the influence of public planning might be apparently watered down with the involvement of different stakeholders in the planning project, this paper will argue that instead, in practice, public authorities and planners remain influential and crucial actors in urban development projects as initiators of (re)development projects, when they bring in financial incentives or lease out the plots for development, or when they add to the project political legitimacy and bring around the table different actors that would otherwise be less likely to join forces.

This paper discusses this turn towards entrepreneurial urban governance approaches and its influence over the practice of public planning, from an urban governance perspective. It looks at one urban renewal project in the city of Malmö, and one project of urban expansion in the city of Lund, in Sweden. A case study approach is followed, using official documentation and expert interviews with developers, public planners and other municipal officials. The paper indicates that the setting in which public planning occurs

is marked by fragmentation (in actors involved, goals, and financial means) and decentralization. These Entrepreneurial cities are managed as companies, trying to promote an image, develop a brand or sell a neighborhood. This influences how public planning can work with public spaces and in conceiving a city for "the public". The projects' goals find parallel in the aims of other planning projects occurring throughout the city, but can this be a coincidence of the type of landscapes that planning projects are looking for, or is it a sign that there is still a comprehensive overview of urban planning for the city? It concludes with a discussion on how public planning is adjusting to the changes in urban policy and governance. The paper contributes to the discussions on how the practice of planning is influenced by the influence of neoliberalism and a turn towards entrepreneurial urban governance.

1. Introduction

The term "Entrepreneurial", in the concept of "Entrepreneurial City", is borrowed from the field of Business Administration and Economics, and is linked to an approach to urban policy and local economic development that is inspired by practices of the Corporative and Business Administration worlds. This approach is considered to represent a shift (Harvey, 1989; Swyngedouw, 2005; Cochrane, 2007), whereby local governments are steering away from traditional activities linked with the local provision on welfare and services, and adopting a more proactive and outward-oriented approach to promote local economic development, characterized by risk-taking, inventiveness, promotion-seeking, and profit motivation as guiding local policy-making (Hubbard and Hall, 1998. The case of Malmö, in Sweden, was analyzed by Dannestam, 2009). The city is entrepreneurial because the actors involved in urban policy adopt businesses approaches such as branding, marketing, speculation and risk taking to urban policy-making. The city is developed as a brand and a product that can serve as a setting for creative and innovative companies to invest in, for new inhabitants, especially the highly skilled and educated ones, to reside in, and for private investors to invest in real-estate or to create new businesses. The municipality is regarded as a firm and the city its product for sale, and policy makers as managers looking for new business opportunities, ways of promoting its own product, new business partners willing to invest and develop the product.

The term was first coined to describe urban policies pursued within a context of neoliberalization of urban policy in the US and the UK, and following the critics and dismiss of the Keynesian Welfare State (Cochrane, 2007). It is not related to a decline of the role of public authorities in urban policy and development, or to the simple replacement of the role of the public by the private sector. Instead, what is pointed out is a change in how public and private sectors interact within urban development projects and policies, particularly within a context of inter-urban competition (Shimomura & Matsumoto, 2010; Jessop, 1998).

Entrepreneurial cities are also a result of institutional reforms that go beyond the global scale of economic transformation, and the adoption of discursive practices that promote entrepreneurship and an entrepreneurial-oriented position by a wide range of social actors, from policy makers and private investors, to workers and ordinary citizens (Painter, 1998; Jessop, 1998; Hubbard, 1996; Brenner & Theodore 2002a and b; Smith 2002).

Much has been written about the implications of this turn towards entrepreneurial forms of urban governance for urban policy making (Hubbard and Hall, 1998; Cochrane, 2007; Healey, 2006) and the public sector (Montin, 2000; Elander & Strömberg, 2001; Swyngedouw et. al. 2002, Hohn & Neuer, 2006; MacCleod, 2011). However, the strong

emphasis of these strategies on interventions over the physical landscape of a city or neighborhood implies greater attention to what is being done by public planning, as the field that formally takes charge over urban planning in the city. Studies focusing on the implications of this turn for the practice of public planning are fewer (although see McGuirk & MacLaran, 2001; Gualini & Major, 2007; Tasan-Kok, 2010) and tend to approach these implications from the stand point that this turn signifies a decrease in the scope of influence of public planning (McGuirk & MacLaran, 2001, Elander & Strömberg, 2001).

This paper will discuss this entrepreneurial urban governance approach and its influence over public planning, by focusing on the characteristics of this turn from a governance perspective, and how public planning is adjusting to the changes in urban policy and governance. It emphasizes that although the influence of public planning might be apparently watered down with the involvement of so many stakeholders in the project, in practice public authorities remain influential actors in urban development projects as initiators of the projects, when they bring in financial incentives or lease out the plots for development, or when they add political legitimacy and bring around the table different actors that would otherwise be less likely to join forces in the project.

The paper is informed by a series of expert interviews and analysis of documentary evidence, plans and reports, in order to build a review of the urban governance structure built around the projects and what tasks and responsibilities planning had within this structure.

The cases selected represent most-likely cases (George & Bennett, 2005) of large-scale urban development projects influenced by an entrepreneurial approach to urban planning. Municipalities in Sweden are taken as cases, as there is a heritage of planning involved in delivering public welfare that might alter the perspective of the planners involved in the project and/or strengthen their negotiate position with regards to the private sector positions.

The Bo01 is a most-likely case because it is the site of an international housing exhibition held in Malmö, in 2001. The old harbor area was reconverted into an exhibition stage, in a case of urban renewal used to create a new image for the city, from industrial city in decline, to Knowledge-industry city. Nowadays, the area includes residential and office spaces, public parks and recreational areas, and hosts a new Media and IT profiled university and several knowledge-intensive companies.

Brunnshög is an urban expansion project currently under way in Lund. The location of the National Electron Accelerator Laboratory for Synchrotron Radiation Research (MaxIV) and of a European Spallation Source (ESS) facility in the area gave the impetus for the municipality and developers to turn their attention to Brunnshög. The aim is to create a new district for the city that combines the characteristics of the medieval city

center with an environment that attracts new companies and investments, and contributes for ideas to be shared between the professionals that will work and reside in the area.

In both cases external events are the engine behind the area transformation – a housing exhibition, and the establishment of research facilities. Urban development is used to create a district of the city where knowledge-intensive companies, entrepreneurial activity, and the creative class (Florida, 2002) are key goals. The municipal planning department is a key actor, which would be expected of planning projects in Sweden.

The following section introduces the main characteristics of an entrepreneurial approach to urban policy and what this might imply to the practice of planning in the public sector. Potential challenges posed by this entrepreneurial approach to public planning are discussed. The subsequent section outlines and analyses the cases in light of the governance approach taken. A final conclusion and discussion will highlight challenges of an entrepreneurial turn to urban governance for public planning.

2. Public planning in the Entrepreneurial City

Entrepreneurial city approaches to urban policy are frequently portrayed as representing a turn in urban policy-making "from government to governance" (Harvey, 1989; Hubbard & Hall, 1998) meaning that, in Western countries especially after WW2 policy-making and implementation were done by strong publicly elected bodies, while nowadays governance structures bring together public and private actors to the field of policy making and implementation.

By governance, it is understood here inter-organizational networks (Rhodes, 1997), where a wide range of actors, from the private, non-profit and public sectors, come together to participate in the development and implementation of a project. This network of actors creates the capacity to act, by pulling together resources towards a commonly defined goal (Hill & Hupe, 2002). These resources can also include the definition of framework conditions and ordered rules for collective action, and focus on governing mechanisms such as grants, contracts and agreements that do not rest solely on government authority and sanctions (Milward & Provan, 1999: 3).

The turn from government to governance is discussed by scholars as developing to the decentralization in public administration and government (Montin, 2000), and resulting of an ideological (Jessop, 2002) or opportunistic (Swyngedouw et al. 2002) turn in policy-making towards neoliberalism (Harvey, 2005). For Khakee and Barbanente this governance approach is characterized as a turn "*from unidirectional, hierarchical control to control through networks … [where local politics] to a larger extent than previously, tries to create premises for development by attempting to coordinate various*

resources" (Khakee & Barbanente, 2003: 185) This derives in a greater complexity - of levels of intervention, players, funding sources, goals, accountability.

In a context of urban governance, Harvey understands that nowadays decisions about interventions over different spheres of the city are made in a multi-actor context. For Harvey, urban government is not the appropriate expression to classify the processes surrounding the management of the urban area and the relations between the actors involved in this management. Instead, urban governance is a more suitable expression, as *"the real power to reorganise urban life so often lies elsewhere [that not the government] or at least within a broader coalition of forces within which urban government and administration have only a facilitative and coordinating role to* play. *The power to organize space derives from a whole complex of forces mobilised by diverse social agents."* (Harvey, 1989: 6).

Public sector urban planning is faced with the dilemma of working with the tools and representatives of the private sector, in public-private teams that do not, necessarily, have in mind the needs of the city inhabitants, and are instead focused on specific project goals (Campbell & Fainstein, 2003. Burkitt & Whyman, 1994). The change in the direction of planning practice is also discuss by Montin (2000), who points out that traditional local planning used to be responsible for the regulating land-use, while nowadays its role is focusing on providing the means for development opportunities. From a regulator, planning has transformed into an enabler of pro-growth strategies. The public planner not only plans for the location of housing and workplaces, but also for houses and work environments with an image that attracts specific types of inhabitants and companies.

Policy-making and implementation under an Entrepreneurial city approach took a turn towards focusing primarily on single projects. Swyngedouw et al. (2002) discussed the turn from a comprehensive approach to planning (that they called the plan) to a more time, space and resources constrained approach (that they called the project). These planning projects captured a segment of the city and worked with that segment in view of the socio-economic and political objectives of the multi-actors governance structure that was created around the project. Often poorly integrated within the wider urban processes of the city and its planning systems, these types of projects are characterized as one-off ventures decoupled from their context and from the planning projects of the wider municipality – a piece-meal approach to urban development. One could also see this turn as an unavoidable consequence of the growing importance of Public-Private Partnerships and negotiative planning (Cars, 1992). A project based-approach would be more easily tuned to comply with the interests of the stakeholders involved and to deal with the necessary time and financial constraints imposed. Additionally, it allowed urban planning to develop through several individual projects with inter-project coordination developing through a series of adjustments and agreements between various actors (Khakee & Barbanente, 2003: 187).

The challenge for entrepreneurial urban governance is how to create integration within this fragmented landscape of projects, actors, goals and sources of funding. Is it possible for such a heterogeneous project team to develop a unified image for the neighborhood/ city that is to be renovated? One could also argue that the strength of the current landscape of urban projects lies exactly on the fragmented character of the coalitions of actors behind these projects. A fragmented and temporary set of actors cooperating within a project opens up possibilities for learning and exchange of knowledge and experiences to occur across interest groups that might not, in other situations, meet and cooperate. This fragmented style of governance is also supportive of a growing attention to the characteristics of place, as the territory is the common denominator behind these partnerships.

Figure 1 summarizes the main characteristics of this turn in urban policy making, emphasizing its potential influence over planning.

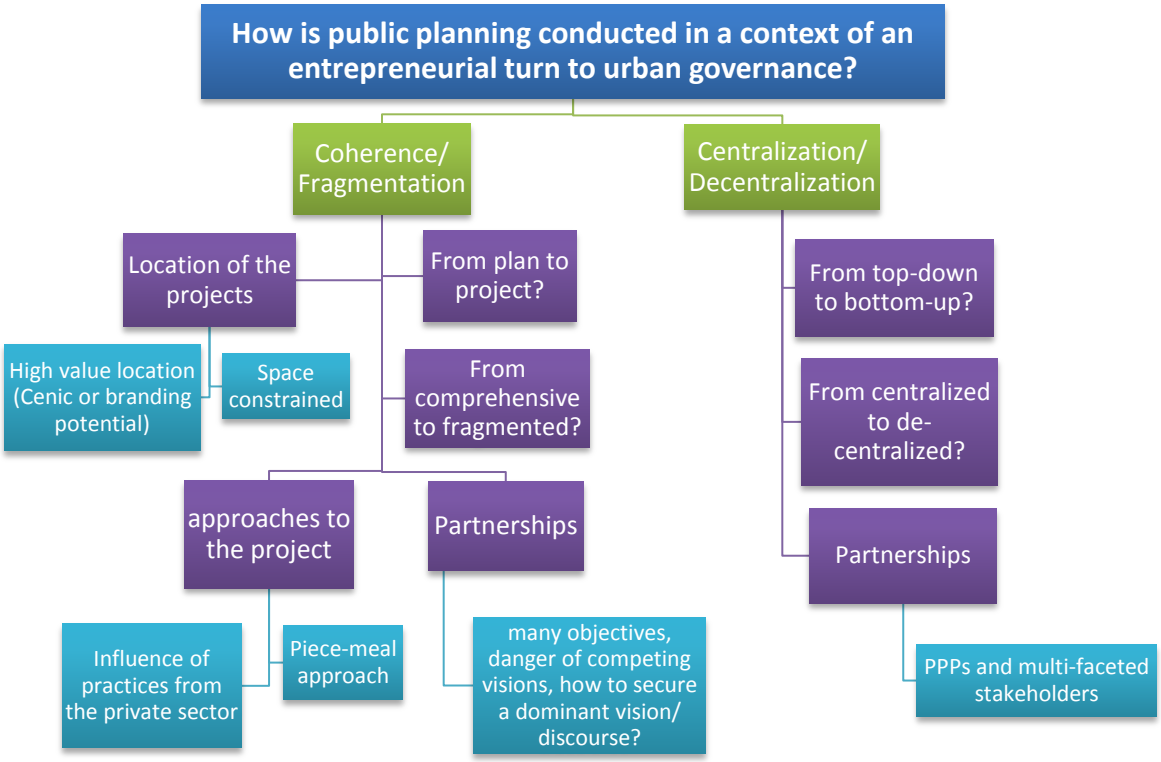

Figure 1

In recent years, scholars have focused on challenges for public planning practice, derived from this entrepreneurial approach. Tasan-Kok (2010) discussed how the complexities of multi-actor governance influenced the implementation of urban regeneration projects. She highlights that, in a multi-actor context, there are conflicting interests and competing aims coinciding in the project, not necessarily limited to differences between public and private actors' objectives, but also between different private actors. There are also limitations posed by the persistence of hierarchical relations that hinder the emergence of plural forms of leadership, while simultaneously area-based agencies are set up to oversee the projects, replacing or shadowing the traditional tasks of the planning department (Tasan-Kok, 2010; McGuirk & MacLaran, 2001). The need for coordinated action and quick responses is jeopardized in such hierarchical structures.

There is a general lack of overview of how the project fits or is complemented by other projects happening throughout the city (Swyngedow et al 2002). As McGuirk and MacLaran state "because the greater part of the development activity is led by the private sector and remains dependent on its profitability criteria, such a reliance inevitably emphasizes the imperative of maintaining a corporate ethos and adopting modes of planning practice which continue to be appropriately supportive of property capital." (McGuirk & MacLaran, 2001: 439) This also justifies why aims and goals change according to market conditions.

Tasan-Kok (2010) and Gospodini (2010) stressed the design-oriented character of these Entrepreneurial City projects, with urban design emerging as an added tool to promote the new district and the city.

The corporate imperative, the fragmented governance structure, and changing goals frame some of the challenges for planning under this entrepreneurial approach - how to ensure continuity and interconnectivity between different projects or within the same project across time?

3. Case studies

The Bo01 was an International Housing exhibition under the motto of "*City of Tomorrow"*. The exhibition was held in Western Harbor, a former industrial area, scarred by the presence of shipyards gone bankrupted, and a SAAB industrial complex, shut down during the 1980s. To host an international exhibition in a location where the industrial tradition of the city was most visible served the dual purpose of renovating an abandoned area, and build a new image of the city, associated with Innovation, Creativity and Sustainability, instead of the traditional image of a blue-collar city of heavy industrial production, hit by severe unemployment and decline.

Parallel to this project, the city center was being renovated and a new university college had been established in the city, also located on Western Harbor. The Öresund Bridge opened in 2000, representing the physical connection between southwest Sweden and mainland Europe, and there were plans to build a city tunnel that would further strengthen the role of Malmö as a regional center and extend its commuting area. The residential district of Augustenborg was also focus of a project to become a more attractive, sustainable and multi-cultural living environment. Three of Bo01's overarching goals - sustainable living, to strengthen the image of Malmö as a place to live and to invest in, and the redevelopment of a new district of the city - were supported by parallel projects throughout the city.

Brunnshög is located in the NE of Lund, in an area that has been pinpointed for expansion since the Comprehensive Plan of 1991. It is bordered by the neighborhood that hosts Ericsson, the highway E22 and to where the labs MAXIV and ESS will be built in the near future. To the east there is a large park and to the south, the mainly residential neighborhood of Östra Torn. Location is a fundamental problem with the urban development in Brunnshög, as it is physically cut off from the city by the E22, the IDEON Science Park, and Lund Tekniska Högskola (LTH). The idea to expand the city towards the NE has existed since the mid-90's and plots had already been allocated to some of the larger developers (Interview Dalman). However, the disadvantage of being "first movers" in an area that is not particularly attractive for investment had detracted the interest of developers (Interview Flycht). There was also lack of clear political vision to what would become of this area. It took an external actor – the decision to locate the ESS and MaxIV labs in the area – to re-start the process. Suddenly the project gained political importance: "The whole world will have some expectations about Lund, will have their eyes on Lund, and nothing is happening in Brunnshög. So we have to make sure that we have something there." (Interview Dalman).

Other planned projects directly support the goal of creating a lively and attractive district in Brunnshög. A tram connection (Lundalänken) has been under discussion and is considered an important element for the image of urbanity to be created in the district (Interviews Dalman and Flycht); an energy vision is being developed by Lunds energy in partnership with the municipality, ESS, MaxIV and VaSyd, to capture the heat produced by research facilities and use it as district heating for the city, thus contributing for the sustainability emphasis of the project; Brunnshög is placed in the continuation of the "Road of Science", an initiative to brand a corridor that comprises the university area, IDEON, the university-hospital, Brunnshög, ESS and MaxIV as a knowledge-intensive area. The university and IDEON are also discussing the possibility to add more diversity of uses to the area now occupied by LTH and IDEON, adding other services, commerce and housing. The rehabilitation of the central station area, including the connection with Lundalänken, is also planned, as is the construction of a congress center next to the central station, to operate in partnership with the one in Malmö (Interviews Dalman and Flycht).

Table 1 illustrates the governance structure of each project, highlighting the position of the planning department.

Table 1- Governance structure of projects

	Bo01	**Brunnshög**
Main Stakeholders	Municipality, (Departments of City Planning, Real Estates, and Parks and Streets) SVEBO (Boverket + 10 Swedish municipalities) Developers' group	Municipality Project group Lund North-East *Developers
Responsibility of planning department	Quality Programme Detailed and comprehensive plans Communicating with developers Preparation of master plan, together with head architect of Bo01AB Solutions for soil decontamination, eco-cycle, green structure and traffic	Plan Program Detailed and comprehensive plans Project overview and management Contact with developers and politicians
Responsibility of developers	Buildings and interior architecture and design Individual sustainability solutions Keep standards from Quality Programme	Buildings and interior architecture and design (Unclear as the detailed plan has not yet been adopted)
Input from other stakeholders/ consultants	LTH –environmental standards and techniques Sydkraft –local renewable energy	ESS and MAX IV – demands over traffic, physical structure, equipments Lunds Energi and Vad Syd – energy vision
Main investment sources	Local Investment Programme (LIP) Malmö Municipality SVEBO Developers European Union	Lund Municipality (attempts for State financing of tram) Developers

Between Coherence and Fragmentation

Fragmentation as discussed in Entrepreneurial City literature, was a result of the public-private partnerships that meant a wider diversity of funding sources, actors putting claims on the project, and of ways of working (Khakee & Barbanente, 2003; Swyngedouw et. al. 2002), with the municipality striving to coordinate various resources (Khakee & Barbanente, 2003; Tasan-Kok, 2010)

In the case of Brunnshög and Bo01, public-private partnerships are also the norm, and inevitably there were conflicting and even antagonist perspectives on how the two districts should develop. The most frequently mentioned example in the interviews was traffic and limits to parking in the areas. In the case of these two projects, public planning kept a key position in the negotiation table, by inviting other stakeholders to join in the processes early on, in order to have time to build a common approach and aim for the neighborhood. It also tried to ensure a coherence of the aims of the individual project with the visions for the city and other planning projects happening in parallel (Interviews Reepalu, Dalman).

One such example of how public planning tried to build a common platform of understanding between the different stakeholders was the elaboration of the Quality Programme for the Bo01, which set the environmental standards for the area. The task was the responsibility of the municipal planning department, but they invited the developers and the architect from Bo01AB to partake in the process: "The interested developers have been invited to participate in the work of the Quality Programme. This was ready before the purchase of land and was a part of the agreement for land purchase. However, at the end of the exhibition it was concluded that the developers that had actively been involved in the preparation of the Quality Programme were more aware of its role to guarantee the environmental standards, while those developers that had not been involved in the preparation of the Quality Programme considered the document useful for the aesthetic and marketing of the area". (Person, 2005: 48)

From the public planning perspective, there is no turn from comprehensive planning towards fragmented projects (Swyngedouw et. al. 2002; Khakee & Barbanente, 2003). In the case of Bo01, the project did step out from the standard process of public planning (interview Johansson and Blucher) but this was related to the existing specific time constraints, and to the demands of an International Housing Exhibition. Additionally many of the environmental standards pioneered with Bo01 and the procedures developed for it were later extended to other planning projects in Malmö (Interviews Johansson and Andersson). The Bo01 project was fully in line with the vision of the Municipality to build a new image for Malmö, associated with knowledge economy activities and sustainable living (Interviews Johansson, Blucher). "[Bo01] reached out to be a part of the city. It's a wonderful meeting place for people from all over Malmö (…). This created a very good example for changing the image of the city "(Interview Reepalu)

In the case of Brunnshög, the project gets renewed attention at a time when other projects are developing across the city with similar goals. "So many things coincide. (…) now plans are being made to develop the city central station and increase its capacity and link it to the tram. [There are other plans] for a new congress center [and the university hospital] wants to open up their area to the adjoining city. (…) So everything is happening at the same time and this is very rare when it comes to planning". (Interview Dalman)

Regarding the project location, Bo01 grew in a high scenic value area, with branding potential. "[this area] is connected with the green and beach areas and the housing area to [the south] which was also seen as a higher status area. The Bo01 was to become part of this corridor "(Interview Johansson). "The location was attractive because it was close to the city center, in a peninsula and close to the sea (…) had the sight of the newly built Öresund Bridge" (Interview Blucher). "The use of small plots and many developers introduced diversity and small scale to the neighborhood, in order to give an image of a more central urban neighborhood. (Interview Reepalu).

In the case of Brunnshög the connection to the city center is being shaped by the urban design of the area. Instead of the larger plots and wide streets and squares of the initial plan, the current proposal introduces a structure that resemble the medieval urban pattern of the city center. Also emphasized is Lundalänken, to overcome the idea that Brunnshög is far from the center.

Regarding the approaches to projects, the influence of the private sector is poorly seen during the planning process due to two factors: first, the slow housing market situation in both cases led the developers to assume a reserved position. For Bo01, Malmö Stad had to convince developers to participate by waving them with favorable lease contracts for the municipally owned land: "[Malmö Stad] said 'if you [the developers] don't take part in this then you won't take part in the development of this city when we [get our city back on its feet]. We own most of the land for building in this city, so they knew that they must be in good relations with us" (Interview Reepalu). In the case of Brunnshög, the developers are still hesitant to engage in the process because it is not yet clear whether the lundalänken will be built, and which plots will be assigned to which developer. Also the area does not have the same initial potential as Bo01. (Interview Flycht)

Secondly, the use of small plots and a wide variety of architects and developers was an idea originating from the Bo01AB architect and the municipality, in the case of Bo01, and from the municipality, in the case of Brunnshög. Developers are usually working with larger plots and one developer per plot. This approach was thus in both cases municipally-driven. This was made possible due to the specific demands of the housing exhibition – experimenting with new ways of creating a sustainable urban area – and with the demands of Brunnshög – bridge the character of isolation and distance from the center, and create an environment where people meet and interact in the public sphere. These approaches have been difficult to replicate in other projects (Interview Johansson). The singularity of the approaches pioneered in these projects enforces the idea of a piece-meal approach to the planning projects, but not of a private actor influence over how planning is conducted.

The vocabulary used by public planning to discuss the approaches followed during the project often derives from the business and private sector world: "Bo01 also helped to create quite an innovative **"toolkit"** for development and planning. This toolkit was based on the quality programme, which endeavored to employ a holistic approach but also gave **criteria**, detailed **objectives** and directions for more sustainable solutions, e.g. concerning energy efficiency, source separation of waste, greenery and biodiversity, but also for the more elusive quality of human sustainability." (Person, 2005:20. Emphasis added)

Between Centralization and Decentralization

In the process of directing responsibilities at local level, and of extending public-private partnerships, some authors noted the emergence of area-based agencies replacing or overshadowing the public planning agencies (McGuirk & MacLaran, 2001). In the case of Bo01, the creation of the Bo01AB allowed informal procedures and networks to be developed parallel to the action of the planning department. It was an organization focused on the exhibition area, where different actors came together to define what was best for the exhibition, but where the city officials also had a voice. The agency was not formally responsible for the planning of the neighborhood, as formal licenses were the responsibility of the planning department (Interview Reepalu). However, Bo01AB acted as an influential consultant – its main architect designed the layout of the neighborhood, discussed the public spaces with municipal officials, was consulted for the Quality Programme, chose the architects and building projects. Thus, although legally the planning tasks were kept with the municipality, informally the frequent meetings with the agency and the coincidence of the demands of the exhibition with the needs of the urban development made the agency an influential actor in the planning process.

The municipality, in both cases, was also the one taking the initiative for projects and for inviting other stakeholders to participate. Therefore, one cannot talk about a turn from a top-down process towards a bottom-up, as the municipal planning monopoly is still maintained.

Nevertheless, the decentralization of responsibilities towards area-based agencies such as Bo01AB, and to developers for compliance in implementing environmental standards, the financing limitations imposed by the State, and the coexistence of multiple sources of funding within the same project means an increasingly complex setting within which public planning operates. Even though it remains in a leading role, the tasks of mediating, facilitating and coordinating between the multi-faceted actors of the partnership become increasingly important.

Reactions in the practice of planning in the entrepreneurial city

The context in which these two projects happen provides public planning with a degree of freedom of experimentation. In the case of Bo01, planners could experiment with a different process of involvement with stakeholders that joined in the negotiations at a much earlier state. It was also possible to push forward environmental standards and regulations, and urban design proposals that would not otherwise be accepted by developers. The context of a housing exhibition, time constrains, the existence of a specific exhibition theme, made way for experimenting with ideas and practices. In the case of Brunnshög, the international attention and willingness to show something daring and new are allowing the group of planners involved in the project to also be more daring and creative in their proposals for the design of the neighborhood, and for how to involve the citizens and other stakeholders. This unusual setting also means there are no fixed practices and instead the group of stakeholders is exploring new ways of acting as they go along (Interviews Blucher, Johansson, Larsson, Dalman).

The interviewees were asked about how the project stakeholders had reacted to the challenges posed by the project itself, be it through implementing new practices, routines, images, developing bridging concepts, etc. In the case of Bo01, one of the new aspects was the establishment of Bo01AB, set up to ensure that the exhibition was ready in time and that its standards and aims were met. This agency included only public actors, was leading the process of organizing the exhibition, and was a key consultant in the urban development project itself. (Interviews Reepalu, Blucher)

Bo01AB consisted of people sharing a planning background and/ or interest. This is probably one of the reasons why the layout proposed to the area was different from what was the standard at the time for city planning in Malmö and in Sweden. This was something innovative at the time, only possible due to the particular momentum created by the housing exhibition, the interest of developers in working in such a high visibility project and to try to recover from a string of bad years for the housing market; and because those involved in the project shared a common language – that of planning and urban development. (Interviews Larsson, Rosberg, Blucher)

The existence of a core-project group in Bo01AB ensured that the goals of the housing exhibition were met and that there were no divided loyalties. However, from the side of the municipality, the organizational set-up was more complicated, with the heads of the main departments involved having to decide together on issues related to Bo01 and Malmö Stad. This meant that sometimes the politicians were called in to make a decision, or that the issue had to be extensively debated until a decision was made. This absence of a clear head taking decisions in Bo01, from the municipality side, was one of the problems highlighted (Interview Dalman). Nevertheless, Bo01AB, the developers and the municipality met frequently, in formal and informal meetings, to discuss the progress of the project.

For Brunnshög, the organizational setting was different. Learning from the experience of Bo01, but also from other projects, there was a core-project group set-up within the municipality, led by Eva Dalman, who is the ultimate decision maker within the group, and is also part of the steering committee where politicians are involved. The project group sits in a common office, in a different building from the rest of the municipality. There are no divided loyalties and it makes the informal meetings and conversations easier to happen (Interviews Dalman Abrahamsson). However, it does have the disadvantage that the project appears disconnected from other planning projects happening in Lund, as there is a single project team, as opposed to different people involved in various projects simultaneously. Additionally, the interaction between projects and sharing experiences becomes harder (Interview Abrahamsson).

For the Bo01 project, the developers were grouped in a developer's group, led by the then Head of planning department – Mats Olsson. This meant the group of private interests and investors had a voice in the project organization through the person of a public officer and planner. The idea of inviting Mats Olsson to be head of the developer's group came from Ilmar Reepalu. Until recently, Mats Olsson had worked in the private sector and had good connections with the developers. This was considered an advantage in a time when the housing market was insecure and the developers were hesitant to being involved in high risk projects (Interview Reepalu). These were also the reasons why, in Bo01, the developers were invited to join in during the early stages of the project design. (Interview Dalman).

In Brunnshög, the developers are not yet cooperating as a group of similar interests, although the project group has already approached the developers to form a single group and discuss among themselves (Interview Flycht). However, the planning process is still in the beginning, with no detail plan approved. Additionally there are reservations regarding the economic viability of investing in Brunnshög, which makes the developers hesitant to commit when it comes to dates and standards for the development. What is clear is that the involvement of the developers so far has been standard - they have been kept informed of the status and development of the project, but have not been involved in the design of the project. (Interview Flycht).

At Bo01 the Quality Programme was developed as a tool to secure the environmental standards for the housing and the public areas, and the compliance of the developers. The Quality programmes are not new to the municipality. Although the Quality Programme was a responsibility of the Planning Department, the developers and Bo01AB were also involved, together with other external consultants. The Quality Programme was included as a compromise in the land-allocation contracts, and functioned as a concrete guideline for the sustainability vision for Bo01. *À posteriori* it was concluded that those developers that had been actively involved in the definition of the quality programme, were also more aware of its importance as a safeguard of

environmental standards and regulations, an assurance that their competitors, other developers, were also subject to the same standards. (Persson, 2005)

The perspective that Brunnshög is developing for researchers and highly educated people is not shared by the project group, although they recognize that there is a special attention placed over how this group of users might use the neighborhood (Interview Dalman and Abrahamsson). For the developers, however, it is the presence of the research facilities, and consequently the type of users that might use the neighborhood - researchers, students, university people – that brings the special character to the area. This is the unknown card that for developers, if well exploited, will contribute to the attractiveness of Brunnshög as a district to live and invest in. The emphasis on sustainability is important, but what is truly innovative with Brunnshög is not the sustainability emphasis, as was the case in Bo01, but the closeness to the ESS and MaxIV. (Interview Flycht)

4. Conclusions

This paper started from a premise that has been widespread in literature that there is a turn in how urban policy is conducted. In the process, a new entrepreneurial governance setting is framing the conditions in which public planning is conducted. A question for debate is whether there is a turn under way in how public planning is conducted under an entrepreneurial approach towards urban development. A second question would be how public planning is adapting to it.

In the cases analyzed here, the role of the public actor remains central. It is the backbone of the project, getting it off the ground collecting the necessary partners for the project to come through. The developer's influence is different from that in the 1960s. What has changed is the importance given to how the market will react, what the market expects from the development. In that sense, one could say that it is not the developers' taking over the projects, but the expected market needs and demands taking over it. The market is an abstraction of the demands over what housing and office spaces should offer.

In Sweden, the public sector has traditionally held a monopoly over housing provision and planning matters, so it would be expected that this role remains strong nowadays, despite being changed by financial constrains from the municipality that push public planning to think on return-on-investment issues and on how best to secure that there are indeed investors for the housing developments. The public is essential as a middle-man between developers. Developers are competitors amongst themselves. Public planning is expected to lay concrete rules and standards that developers have to follow, visions for the district, and ensure that everyone involved keeps up with their end of the bargain – create a level playing field.

In the projects analyzed here, there were competing ambitions for the neighborhoods from the different stakeholders. However, there is a dominant vision, centered on sustainability, innovation and the knowledge economy, emerging in both cases. The discourse is politically supported and materialized in the initiatives taken throughout the city. The sustainability discourse is particularly interesting, as it encloses a paradox. On the one hand, studies have shown that in the implementation of sustainability strategies a broad community involvement is essential to guarantee the success of the strategy. On the other hand, the projects in discussion here exclude the wider community, through the justification that there actually was no one living in the neighborhood prior to the urban development (Bo01) or by arguing that the inclusion of inhabitants would add too much confusion to the organization of the project (Brunnshög). Nevertheless, sustainability opens up an opportunity for developers to see a business opportunity (especially in Bo01), it offers a back-bone against which to try informal or not regulated approaches to citizens involvement (Brunnshög) and can be what grants a holistic perspective to the development and keeps the perspective of what is the "public good", a base-stone in the practice of public planning, and that should be kept even in an Entrepreneurial City project.

It is the challenge of how to include the "public" in the Entrepreneurial city projects that deserves further attention by researchers concerned with the practices of public planning under conditions of neoliberalism and entrepreneurial approaches to policy and planning. This challenge raises issues of how these projects might be contributing to the development of segregated cities, and how public planning is supporting the dominant socio-economic groups and ideologies against socio-economic groups and economic and cultural activities that become excluded from these entrepreneurial cities and neighborhoods.

List of interviewees

Tobias **Abrahamsson** – Project coordinator for citizens involvement at Brunnshög. 12.03. 2012

Pernilla **Andersson** – Project Manager at Malmö City Hall. 18.05.2011

Gösta **Blucher** – former head of Bo01AB. 22.02.2011 and 20.09.2011

Eva **Dalman** - Project Manager of Brunnshög. 20.01.2012

Staffan **Flycht** – Business Development at Skanska. 14.03.2012.

Bertil **Johansson**- Senior planner at Malmö City Hall. 07.03 2011

Christer **Larsson** – Head of Planning department at Malmö City Hall. 27.02.2012

Ilmar **Reepalu** - Malmö mayor and member of board of Bo01AB. 20.03.2012

Göran **Rosberg**- Information Officer at Malmö City Hall. 03.03.2011

HistoriCity: PRESERVATION OR REVITALIZATION PLANNING TOOLS?

António Ricardo da Costa[1], Mariana Seara Paixão[2], Jorge Gonçalves[3]

Abstract

Presently, cities continue to focus most of their concerns in territory qualification and have enhanced their role in promoting social and economic development of the territories in which they exist.

Therefore, it is urgent to address the challenges related to the preservation of fundamental heritage values and the need to revitalize historic centers, by giving them new features and repopulating them. As a consequence we require policies that are able to preserve and manage the pre-existing while adapting it to the present time, and, even harder, to future times.

The concept of heritage, in its connection with the historic centers, has been changing over time, as has been the social perception of the value of this resource. The heritage policies of urban renewal have been also adapted to such changes. International charts and documents reveal the conceptual diversity that justifies the interventions in these places regarding their role of contemporary architecture and urbanism. So, at a time when everyone looks with anxiety and concern to the future, it is important to reflect on the past and the received heritage, seeking the most appropriate answers to the planning and to a creative and integrated strategic management of the historic centers in the contemporary city.

Historic centers are reference places in the urban space, because they have a double role of memorial testimony and of generators of cultural, economic and social dynamics which are determinant to the cohesion and qualification of the contemporary city. However, often times inherited urban fabrics are affected by the limitations of the heritage policies which, for being too general and based on theoretical and abstract conceptual frameworks, have difficulty incorporating the specifics of each area of intervention and neglect the formulation of criteria and specific intervention methods to each case.

[1] Universidade Técnica de Lisboa – Instituto Superior Técnico, Lisbon, Portugal – arcosta@civil.ist.utl.pt
[2] Universidade Técnica de Lisboa – Instituto Superior Técnico, Lisbon, Portugal – m.seara.paixao@gmail.com
[3] Universidade Técnica de Lisboa – Instituto Superior Técnico, Lisbon, Portugal – jorgeg@civil.ist.utl.pt

The purpose of this communication is to provide a comparative reading of the levels of urban renewal allowed by the planning and management tools in the present in selected historic centers, and trying to evaluate the different policies adopted for the preservation of this heritage, especially with regard to their ability to adapt to a sustainable future.

Consistent with these principles the allowed actions of renewal are typified, which enabled the construction of a matrix that relates the impact of interventions in the historic urban landscape to the degree of adaptation to the demands of contemporary buildings. This allowed to deduce, then, the expected level of urban renewal in the historic centers selected for analysis.

This conceptual and methodological body was the support for the analysis of the current situation of four reference historic centers of in Portugal. The historic centers of Évora, Porto and Guimarães, which are World Heritage Site since 1986, 1996 and 2001, respectively, were selected for this study. It was also considered Baixa Pombalina in Lisbon, whose candidacy was submitted as World Heritage Sites in 2004. These historic centers register different ways of thinking and intervene on the built heritage, realized in the differences in their planning and management tools.
This reflection is a contribution not only to interpret the effects of different planning tools in the architectural interventions in the historic centers in study, but also to peer trends and results and thus raise the discussion on the role that the different heritage policies assume to the reanimation of these places which have strong identity valences.

In the background plays the challenge of combining heritage preservation with a greater capacity for change through the integration of new urban heritage policies.

Keywords: Historical Center | Planning Tool | Urban Renewal | Heritage | Urban Planning

1. Introduction

Cities are still concentrating within, territory qualifications worries, and have seen their role reinforced, on the social and economical development promotion of themselves.

It is urgent to tackle the challenges related to the safeguard of heritage fundamental values, along with the need for revitalization of historic centres, giving them new functionalities and residential attractions.

Consequently it is demanded that pre-existence management policies capable of their preservation, are at the same time, adequate for present and future challenges. Heritage policies dictated by current planning instruments, represent the conservation strategy adopted by each historic centre.

The aim of this paper is to provide a comparative reading of urban renovation levels, made available by current management and planning instruments, in emblematic Portuguese historical centres classified by UNESCO, as World Heritage Sites.

We will be looking to evaluate the different policies adopted for this heritage preservation, especially concerning its adaptability capacity for a sustainable future. Namely what measures in which historic centres urban conservation is seen as a site historicism maintenance process (spatial relationships, traditions, memory), and simultaneously designed to catalyze new spaces upgrading its palimpsest value, that the city is.

2. Historic centres: conceptual evolution and heritage policies

2.1. Concept developed up to 1st World War

The urban heritage concept was altered with time in its articulation with historical centres, in accordance to this resource of social perception value.

Urban renovation policies adjusted to its own herded heritage evolution in accordance with its respective era, social characteristics, culture, economics and policies.

In this evolution we can emphasize three distinctive phases (Ashworth, 1994): preservation, conservation and heritage. Preservation was the first phase for these policies and incided on buildings looked upon as monuments, selected by beauty or age criteria. The constructions were preserved by legal imposed protection from specialists, which identified its relevance as cultural goods (Tiesdel et al, 1996).

2.2. Concept developed between World Wars

20th century modern movement upholds a radical approach for the intervention and resolution of historical city's problems. Its destruction and reconstruction according to modern principles was then proposed, not giving especial importance to the pre-existences, as exemplified by Voisin Plan (1925) conceived for Paris city by Le Corbusier.

However, simultaneously radically opposed concepts started to emerge to this approach of facing the inherited city. We underline the works of Gustavo Guiovanni who developed the *minor architecture* concept, meaning, a monument conception, viewed not anymore as an isolated spatial piece, but with a surrounding essential for its understanding (Choay, 1982). In his vision the historic city was a monument, because of its topography, landscape character, and the set of built typologies.

It is after the 1st world war that the historical centres intervention considerations intensify, because it became imperative, a fast answer for the rebuilding of the destroyed cities. The Italian Giovannoni gave an important contribution, for this reflexion, in formulating the *urban heritage* concept, considering the historical city as a density of relevant values. One asset that should be preserved through protection laws as it already existed for isolated monuments (Aguiar, 2007).

2.3.Concept developed after the 2nd World War

It is only in the sixties, a strong economical recuperation period after the 2nd world war, that renovation methodologies in historical centres were implemented for the first time in Europe, such as the *Plan de Sauvegarde et Mise en Valeur do Marais* (1969) in Paris, and Bolonha's Historical Centre Regulating Plan (1969) (Tung, 2001).

These places were degraded both physically, and at a social, cultural and economic level, enabling the change for a second phase of urban conservation policies, *the conservation*, magnifying its attention aim to urban sets (Ashworth, 1994). Its goal was to better the physical environment, such as housing, and at the same time, solve the social problems of the resident population.

General heritage safeguard international documents show us a diversity of conceptual evolution that justified in these places, the intervention as to the role of contemporary architecture and urban planning.

Thus, when everybody anxiously looks with preoccupation to the cities future, it is important to reflect over the received heritance of the past, searching the most adequate answers for planning and strategic integrated management and creative of the historic centres in the set of the contemporary city. This international orientations mirror the worries and distinctive attitudes towards the preservation and conservation of historic centres as a resource and legacy for future generations.

Five relevant international documents can be identified.

i) Nairobi's recommendation (UNESCO, 1976) determines that the historical set and its surrounding are a coherent hole, but identifies new constructions as a threat that could destroy the set's character (* consulted in (Lopes e Correia, 2004);

ii) Resolution 813* (CE, 1983) assumes as a guide rule the need to integrate contemporary constructions in historic sets, in order to give continuity to the architectural tradition and building a future European heritage (* consulted in (Lopes e Correia, 2004);

iii) Washington's Charter* (ICOMOS, 1987) identifies as a guide rule that the historical sets safeguard, should be carried out through social and economical coherent development policies, and defends the preservation of urban forms, of the built and empty spaces relationship, building's form and function(* consulted in (Lopes e Correia, 2004);

iv) Burra's charter (ICOMOS, 1999) for the first time identifies a larger conservation concept, "*Conservation* means all the processes of looking after a place so as to retain its *cultural significance*" (art.1.4) which "means aesthetic, historic, scientific, social or spiritual value for past, present or future generations." (art.1.2).

v) Vienna's memorandum (UNESCO, 2005), which is not a final chart or document for urban development, but a consensual transition element amongst world entities, identifying as guide line the acceptance of the city's building process as an integrated part, defending the heritage conservation and simultaneously its modernization strengthening its identity and social cohesion. Hence, contemporary architecture should complement the existing urban historical landscape as a fundamental strategy.

Historical centres today are treated by the third phase of urban renovation policies, *the heritage*, which occurred when they came under a market orientation (Ashworth, 1994). The architectural legacy started to be looked as a consumer selected product, and managed by current market demands. The past is molded to answer contemporary needs (Nasser, 2003). It has become an urgent necessity that conservation and urban planning have a symbiotic relationship that will bring harmonious cities development (Cohen, 2001).

Historic centres are becoming reference places in the urban space, as they carry a double achievement of being a memorial witness, as well as, a generator of cultural, economic and social dynamics, crucial for the cohesion and qualification of the contemporary city.

However the urban net legacy is many times penalized by the heritage policies limitations, that by being too general, and established by abstract conceptual theoretical tables, have difficulty in incorporating each intervention area singularities, not caring for the formulation of criteria and adjusted methodologies for each case.

Planning in historical sites resides nowadays in the dictum between preserving the past by its intrinsic value, and the transformation necessity, answering to the values of a restless for innovation, inclusion and culture seeking society. As such, if urban areas do not have the ability to change, they will end up stagnating in the set of the urban fabric (Larkham, 1996).

"Conservation is a complex process of managing the tensions between continuity and change in the city, and its main aim is to manage the cultural character and identity of the city" (Liu, 2011, pp.23). Hence urban conservation is a political decision; it is the management of urban change.

3. Evaluation of clearness and renovation levels capacity of planning instruments in emblematic Portuguese historical centres.

The fact of having explicit rules minimize bureaucracy and maximizes margin of interest in the projects, thus boosting economies, population flows, services and cultural programs to these historic centers through a clear and objective management of urban renewal, i.e. of the process of change.. That can result in a gradual and rigorous transformation that leads to the preservation, revitalization and sustainable development of these heritage tissues.

The following conceptual and methodological body constitutes, a situation analysis matrix, of four reference historic centres in Portugal. The Évora, Oporto and Guimarães historical centres, World Heritage respectively since 1986, 1996 and 2001, have been selected. Lisbon's Downtown (Baixa Pombalina), whose World Heritage request was delivered in 2004, was also considered.

The current planning and management instruments for these historical centres, reflect different ways of thinking and intervention on built heritage enabling us to understand the different policies adopted for the conservation and renewal of these world heritage urban places.

For the comparative analysis of these planning instruments, were defined as parameters the rules that represent the urban renewal actions allowed on historic fabric buildings.

With this set of parameters a matrix can be built that enables to evaluate the urban renewal levels established by planning instruments in each historic centre, and it enables a comparison amongst them afterwards.

Factors were defined:

i) direct impact in the historic centre image:

- in elevations to preserve:
  (1) original design,
  (2) traditional technologies and materials,
  (3) colours.

- in roofs to preserve:
  (1) geometry/original volumes,
  (2) traditional technologies and materials.

ii) buildings adaptation levels to new necessities:

- in internal typology to preserve:
  (1) original typology
  (2) forbide joining of territory
  (3) maintain the use of traditional technologies and materials
  (4) forbide car parking provision
  (5) regulation of structural reinforcement.

3.1.Évora's Historic Centre

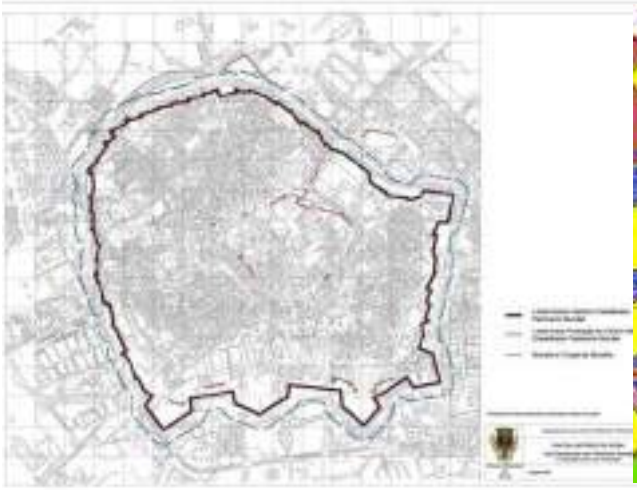

Figure 1: Plan with the delimitation of Évora historic centre classified as World Heritage. The historic center protection zone is not still legally defined, only the walls protection zone is defined. Source: Évora City Council.

Figure 2: Localization of the areas where is permitted new constructions in Évora historic centre. Source: Part of the PUE zoning plan.

3.1.1. Plan Type and Management Entity

In this historic centre, the planning instrument that regulates urban renewal is the "Évora's Urban Plan (PUE, 2000), produced by Évora's City Council (Figure 1).

3.1.2. Criteria and Levels of Intervention

This plan does not establish intervention categories in historic centre buildings, that is, a building intervention strategy with different levels of freedom. Évora's Urban Plan (PUE), identifies the sites were new construction is foreseen or allowed (Figure 2).

The new constructions range from, green spaces (landscape) support facilities, kindergartens, facilities next to exterior of the city's wall, to four building groups for housing or hotel use. In these later buildings, the adopted rules are the same applied to expansion housing areas, sited outside the historic centre. Parameters such as, usage, number of apartments and storeys, net usage ratio, internal clear-height, plot dimension, distance to neighbour buildings, and number of parking places to be created, are defined.

In new constructions as well as in alteration or expansion works, restrictions are implemented only on elevation and roof design:

- in **elevations**: imposition is made on the composition of finishes material usage, and the color range possibilities to be used – the traditionals. Color and material for window and door frames is also imposed, whilst imposition for technical support equipment such as, solar panels and air conditioning equipment is withdrawn;

- in **roofs:** the materials allowed to be applied are imposed.

Demolition here is not seen as an option. New construction replacing demolition is only applicable, when the existing building's advanced state of decay, enables its recovery, or when location is identified as being for new construction, regulated by the Urban Plan. As an urbanistic instrument it has aspects that end up being emphasized – urban regulations and external finishes - lacking references to issues such as internal changes in built spaces (Table 1).

3.2. Oporto Historic Centre

Figure 3: Plan with the delimitation of Porto historic centre classified as World Heritage and its protection zone. Source: www.igespar.pt [04/04/2011].

3.2.1. Plan Type and Management Entity

In Oporto's historic centre the built heritage intervention management is run by *Porto Vivo – Urban Rehabilitation Society* (SRU), whom since 2004 produced strategic documents for each block, assuming each of these as an intervention unit (Figure 3).

These strategic documents (DE) establish the foreseen and authorized works in each building, safeguarding the minimum sanitarian and habitability conditions.

The DE has law enforcement power over the building, and has to be followed both by public and private dwellers. The foreseen interventions were produced by the joint work of *Porto Vivo – SRU* with *Instituto de Gestão do Património Arquitectónico e Arqueológico* (IGESPAR).

3.2.2. Criteria and Levels of Intervention

Porto Vivo – SRU's strategy covers an extended range of worries placed both on the survey and diagnosis of the existing condition, and in the procedures for the intervention management, as well as in the rights of each involved entity in the urban rehabilitation process and the construction quality (quality and sanitarian environment, energy efficiency, construction and functional security) (Table 2).

Table 2: Intervention criteria in Oporto's historic centre.

1. Intervention thecnological aspects	- understand and respect existing building, the primitive technologies, and if not possible assure that new technologies are compatible with the old ones; - intelligent exploitation of the existing elements: re-use them to reduce cost and obtain more sustained solutions.
2. Urban Elevations	- maintain and qualify, through consolidating operations, repair and cleaning (reposition of original elements by withdrawing unfitting elements.
3.General typological resolution	- in profound or deep interventions, maintain elevation, and main building side walls, renewed threshold at the same level of existing, in order to maintain relationship between external openings and internal spaces; - in deep interventions there are typological reformulation operations, in the scope of plot definition, internal spatial room alteration, horizontal and vertical distribution common areas alteration, with the introduction of lifts, equipments and services demanded by current legislation.
4. General criteria for technical interventions	Aims to whatever level of intervention: - respect as much as possible for building's insertion environment ; - general rehabilitation and anomalies correction, by means of building's quality increment, with focus on structural safety and fire risk; - abide current demands for new construction whenever possible; - Primitive elements upgrading, with authenticity, safeguarding their compatibility with new intervention elements.
5. Securing of main demands	a) structural safety: - new structures (reinforced concrete, metal or steel) creation of new vertical communications; - traditional timber structures (ensure fire safety, acoustic insulation and waterproofing in water areas); - reinforce foundations and seismic resistance; - balance choices in economic aspects, base on the buildings state.
	b) safety against fire risk: - risk reduction measures of fire starters and fire spreading (established or to be established by the Firemen's Office) - ensure fire partition barriers and stable levels to fire.

	c) hygrometric thermal comfort: - (new construction or deep intervention) uphold thermal comfort passive systems , to reduce heating thermal charge, through good insulation and minimize cooling active systems (air conditioning); - (existing construction rehabilitation or light interventions) reinforce roof thermal insulation, renewal of degraded opening's frames (thermal bridges); - insulation reinforcement (roof, opening frames, double glazing, lowering thermal bridges, bettering night ventilation systems).
	d) acoustical comfort - (new construction or deep intervention) fulfillment of current demands; - (existing constructions), sound insulation between storeys (ceilings and/or roofs) and between plots, reinforcement and insulation of opening frames; - intervention on buildings private or common noisy equipment.
	e) healthcare of conveniences and kitchens - employment of ventilation, water supply and drainage, necessary equipment; - washable, waterproof and resistant finishes
	f) services and infra-structures: - application of rainwater drainage, telecommunications, active security and gas systems, as well as other services imposed on new constructions
	g) durability and economics: - pragmatic attitude in solutions choices, as to cost and acceptable durability, through control and critical continuous assistance in all project phases.

Source: *Ponte Nova*, PBDE, Annexe II

These interventions criteria definitions to which urban renewal projects have to comply, try to conduct the various intervention aspects, in an efficient manner, for a global satisfaction of the pretended aims in Oporto's historic centre rehabilitation process.

The *Porto Vivo-SRU*, with a deep knowledge of its intervention area, and in order to clarify its intervention criteria in the historic centre buildings, has also established three building intervention categories: light, medium and deep (Table 3 and Figure 4).

Table 3: Intervention levels in Oporto's historic centre

Light Intervention	- Reasonable Building's conservation state; - intervention is not allowed, unless certain point in time, in the main constructive solutions and systems; - repair and/or rehabilitation works on buildings do not require relocation of users, and does not interfere with inresidents daily life;
Medium Intervention	- light intervention works; - repair or substitution of timber works and opening frames; - repair and eventual reinforcement of some structural elements, mainly floorings; - general repair on roofs, internal and external walls, internal and external finishes; - substitution of electrics and hydraulics services and improve the common parts; - upgrading formal environmental and functioning conditions of spaces (kitchen, bathrooms (ventilation systems, water supply/drainage and equipment)) in accordance to current legislation.
Deep Intervention	- includes light and medium intervention works; - need to intervene deeply in the construction system, in the typologic organization and distribution (may alter number of plots, and the building's function); - implies demolition and reconstruction. Intervention on: structural level, vertical and horizontal circulation areas, building's materials and finishes, forcing the coexistence of different systems and materials; - Can imply temporary relocation for the building's residents

Source: *Ponte Nova* Strategic Document Base Plan, Annexe I.

Figure 4: Elevation of proposed intervention, Mouzinho da Silveira Street.
Source: Strategic Document to Ponte's Nova Intervention Unit.

From the intervention criteria analysis established by *Porto Vivo – SRU*, we can apprehend that (Table 4):

-in **elevations** the original design is to be maintained.
-in **roof**, the maintenance of its geometry/volumetry is imposed.
-as for **internal typology**: the structural reinforcement, that is, the intervention method on building structures is regulated.

3.3. Guimarães Historic Centre

Figure 5: Plan with the delimitation of Guimarães historic centre classified as World Heritage and its protection zone. Source: Guimarães City Council.

3.3.1. Plan Type and Management Entity

In the historic area of Guimarães is the Local Technical Office (GTL) the responsible for managing the interventions in buildings (Figure 5). This entity has a threefold objective of maintaining the population, provide better living conditions and preserve / restore the heritage values of authenticity. The GTL advocates a logical maintenance and minimal impact through the use of skilled local labor, materials and traditional techniques.

3.3.2. Criteria and Levels of Intervention

This office classifies interventions according to two categories (Table 5).

Table 5: Intervention levels in the historic centre of Guimarães.

Light Works	Deep Works
Repairing the roof, eaves, window frames, painting elevations or introduction of sanitary facilities.	Interventions in the structure and interior organization.

Source: Guimarães City Council.

This office elaborated the Regulation for Intervention in the Urban Center and History of Guimarães (RICUH, 1994), which requires multiple constraints for urban renewal. The RICUH requires:

- in **elevations** have to keep: the design and original materials. It is imposed that they have to be towed, or stone, at the level of finishes. The window frames have their own taxes, as well as the stone, sills and railings, paint and color - always replacing the traditional design and colors, with restrictions on materials allowed in each of these elements.

-in **roofs**: are prohibited slabs of concrete and changing the number of waters. Structured roofs are permitted only wood and covered with tile. The type of tile is chosen depending on the time of construction of the building and must be maintained according to the eaves original design. The downpipes and guttering must be of galvanized sheet metal, painted and equipped.

-concerning **internal typology**: the inside walls should be preserved whenever possible. Tax is to be towed, or stone, at the level of finishes. The floors should be in line with the remaining balance of the building and under the guidance of IGESPAR. Only in cases where there is extensive restructuring of buildings is that it allows the creation of firewalls and the double walls, including a fire resistant material in its air-box.

From this document emerges that the historical center of Guimarães is no place for the introduction of contemporary architectural values (Table 6).

3.4 Baixa Pombalina, Lisbon

Figure 6: Plan with demarcation of the area proposed for World Heritage and its protection zone. Source: Candidacy File of Baixa Pombalina to World Heritage.

Figure 7: Plan with the demarcation of the area of intervention of the PPBP. Source: PPBP.

3.4.1 Plan Type and Management Entity

For the Baixa Pombalina specifically, entered into effect, in 2011, the Detailed Plan for the Safeguard of the Baixa Pombalina (PPBP), the foreground of this nature to come into effect in Portugal, prepared by Lisbon's City Council (Figure 6 and 7).

This plan aims to protect the urban area that resulted from the implementation of the innovative plan, at urban, architectural, cultural and social level, undertaken as a consequence of the great earthquake of 1755.

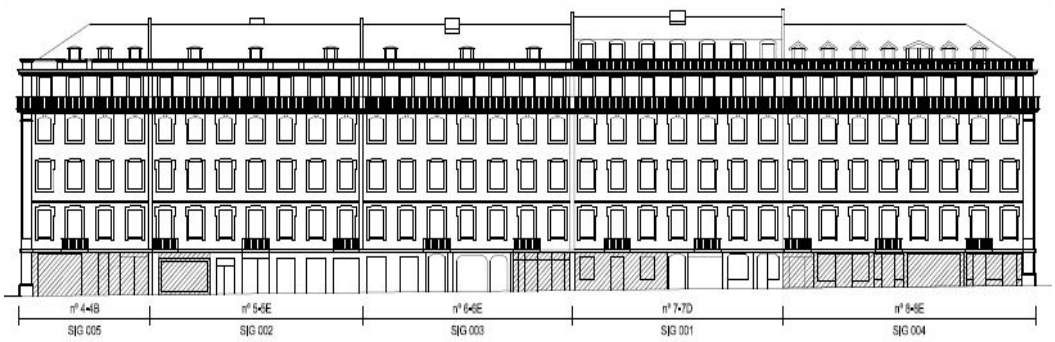
With a strong abstraction in the geometric design and against the nobility and clergy taste who saw their social position disfavored with the metric uniformity induced by Eugénio dos Santos' Plan, "... the Baixa Pombalina open the way for the introduction of modernity in Lisbon with high quality of design and sense of the future" (Costa and Lobo, 2010, pp. 33). "The Baixa Pombalina inaugurated the systematic application of measures arising from a hygienist concern, being striker of the hygienist ideal of the eight hundred. Similarly, the concern to build a city for all, where the formal and conceptual concerns of the elites do not take primacy also makes this plan a precursor of the ideas that have permeated the work of almost all pre-planners and urban designers of the XIX century" (Costa and Lobo, 2010, pp.36).

3.4.2 Criteria and Levels of Intervention

Thus, the PPBP to preserve this heritage as a strategy adopts four distinct ways of acting on the buildings (Table 7).

Table 7: Ways to intervene in buildings.

To remove	To replace the metric of openings	To reformulate	Possible increase of volumetry
Removal of elements and / or harmful floors in terms of structural and conceptual;	In situations in which are relevant to maintain the rhythm of the facade, this has been distorted both by the closure of openings, or by their tampering, so it requires the replacement of the metric;	Volumetric change in form or material of the elements highlighted, in particular the removal of floors when the existent volumetry is a factor of formal or structural imbalance of the block in which it operates;	When the existent volumetry is a factor of structural or formal imbalance in the block in which it operates.



Figueira's Square

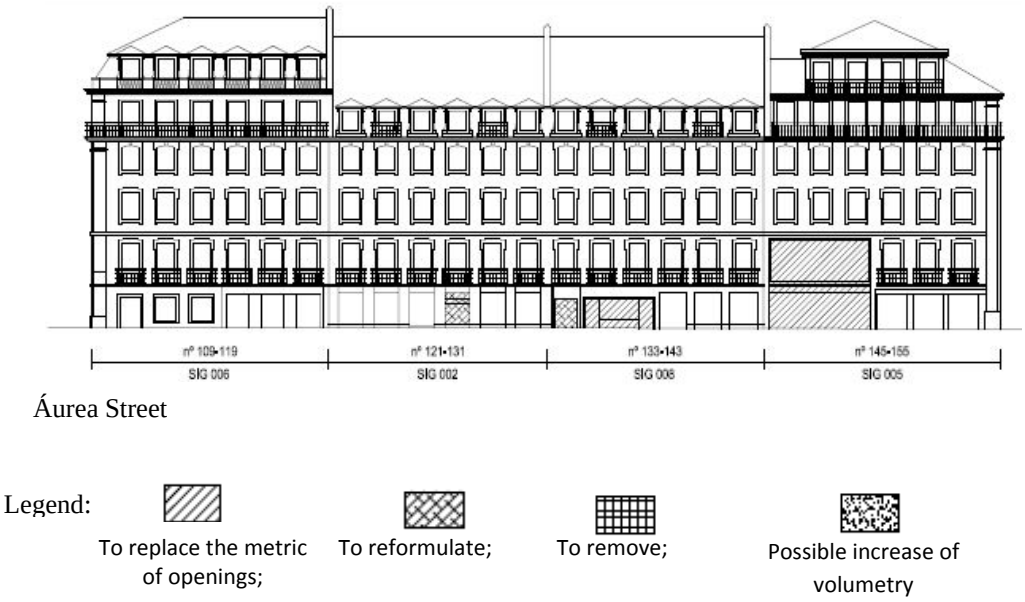


Figure 8: Interventions permitted on the elevations of Figueira's Square and Áurea Street. Source: Annex I, Regulation of the PPBP, Block Q6.

The PPBP regulates in detail the possible interventions in the buildings at the level of the elevations, roofs, structural elements, interiors and the demolition work, providing reconstruction works with or without preservation of the façade.

In the **elevations** only is allowed changes to improve the structural behavior of the building, to replace metrics, rhythms, and original materials, to strengthen the structure, in terms of seismic safety of the building, and it is permitted the removal of inadequate coatings or without cultural value.

In **roofs** only are allowed interventions that do not change the geometry, the form and original materials. These can only be changed when in an advanced state of degradation, to correct anomalies, take dissonant elements and materials, improve living conditions in the attic and to do small changes in building's height under this Regulation. To these modifications it is imposed that the roof respects the characteristics of adjoining properties and preserve the elements of historical or artistic value. Are not allowed new flat roofs and it is imposed the use of red clay in pitched roofs, among other impositions as equipment installations for the harnessing of solar energy, for example.

For the **structural system** is required a previous report when the intervention involves the structural elements, which must review the parts that matter to the proposed work such as foundations, main walls of masonry, the front walls, floors and roof. In the PPBP is also proposed a classification of the structural condition of

the building (good, fair, poor). The art.25 of the Regulation specifies the rules for the intervention in structural elements according to the state of conservation of the structural system of the building obtained in the previous report.

Are also included in the regulation of PPBP rules on the **typology**, and is authorized its total change when buildings don't present historic and artistic values, but when they hold these values, whatever the time of construction (Pombaline, Neoclassical, or previous) only are allowed partial works, with the aim of improving functional and housing conditions (introduction of toilets, kitchens and elevators). It is not allowed to do basements, unless they are bound to keep equipment and technical means necessary for functional rehabilitation and safety of the buildings (Table 8).

Table 8: Baixa Pombalina Urban Renewal.

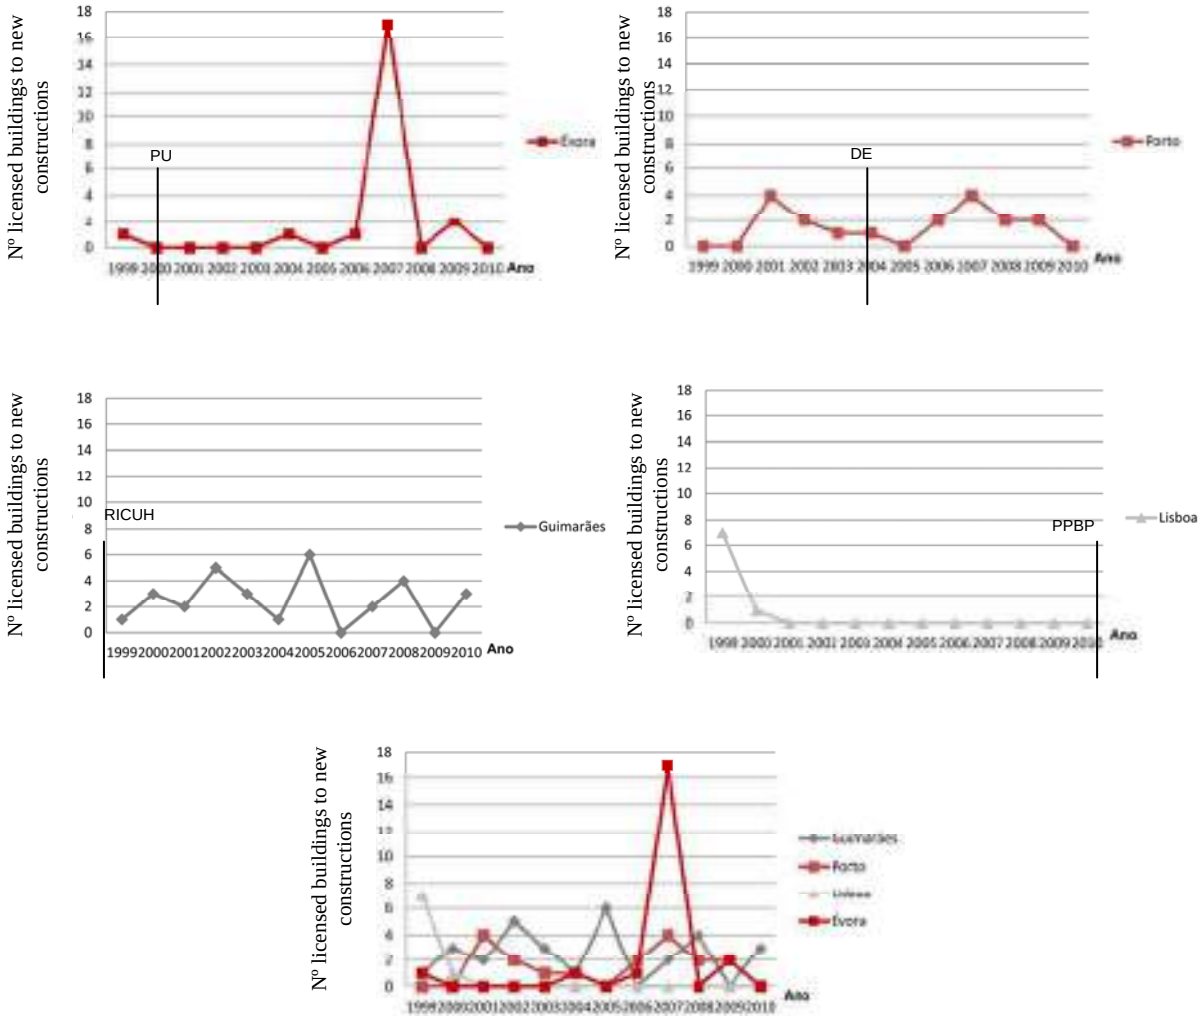
4. The Practice – Statistic Data

To understand the link between the theoretical plans into effect and its practical application, it was collected the statistic data regarding the *Licensed buildings (No.) by Geographic localization, Type of project (new construction and extensions / alterations and reconstructions) and destination of the work (family housing and other); Annual* for the period between 1999 and 2010, available on the National Statistics Institute (INE).

It was possible to obtain this information to the area of the historic centers in study because the delimitation of the World Heritage Area encompasses and coincides with the boundaries of the administrative districts. Thus: Historic Centre of Évora (parishes: Sé, S. Pedro, S. Antão, S. Mamede), Historic Centre of Guimarães (parish: Oliveira do Castelo), Historic Centre of Porto (parishes: Sé, S. Nicolau, Victoria, Miragaia), Baixa (parishes: S. Nicolau, Madalena, Mártires, Sacramento (St. Justa and S. Paulo are bordering parishes to the area candidate for World Heritage, but they are not representative because they have few buildings within that perimeter)) (Figure 9).

Figure 9: Licensed building in the historic centers under study. Source: *Licensed buildings (No.) by Geographic localization, Type of project (new construction, and extensions / alterations and reconstructions) and Destination of the work (family housing and other); Annual* National Statistics Institute (www.ine.pt [02.23.2012]).

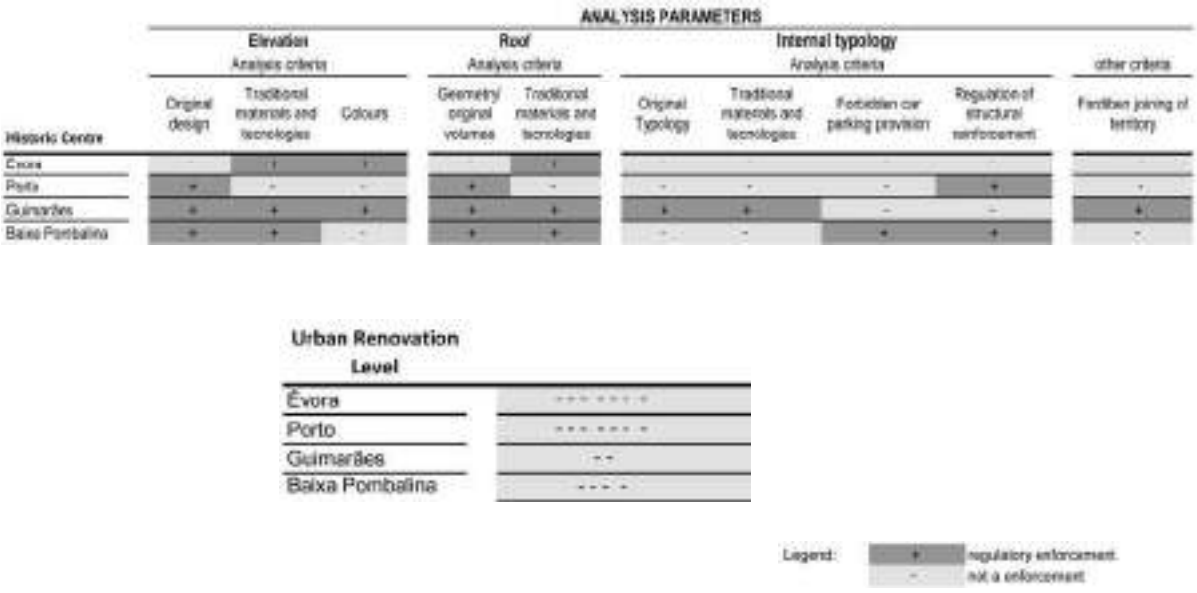


Analyzing the available information and crossing it with the date of entry into effect of the planning instruments in each case study we can see that these documents did not have a consequence on the renewal dynamics of historic centers. The number of licenses for renovation of buildings was almost always close to zero in all the centers studied historical centers, whether its planning tools has been approved before or during the studied period. Thus we can realize the long way to go with additional measures, incentives and more effective strategies in urban renewal planning for the revitalization of these urban fabrics.

5. Conclusion

This reflection is a contribution not only to interpret the effects of the different planning tools in the architectural interventions in historic centers, but also to peer results and trends. Thus it raises the discussion about the role that these various policies assume through the planning tools to the urban conservation and renewal, i.e. in the revitalization of these places which possess strong identity valences.

Table 9: Comparative Urban Renewal Matrix.



Comparatively we can see that (Tables 9):

- the planning tools that allow greater urban renewal are the strategic documents in Porto and the PPBP in Lisbon.

- In the historic center of Porto the strategy developed by *Porto Vivo - SRU* is based on the deep knowledge of the buildings, preserving in its exterior the original design and aesthetic, but allowing contemporary interventions that benefit the whole. The strategy followed by *Porto Vivo - SRU* allows a deeper intervention inside the buildings, with the aim to provide the standard

conditions of habitability for contemporary people that want to live in these places without losing comfort.

- Although the PU in Évora conveys the same level of urban renewal of the historic center of Porto, we are not facing the same situation. The PUE does not present a strategy with different categories of intervention in the buildings. This happens in other historical centers: Porto - light intervention, medium intervention, deep intervention; Guimarães - light works and deep works; Baixa Pombalina- to maintain, to reformulate, to replace the metric of openings and possible increase of volumetry. In the historic center of Évora there are no systematic rules of intervention for the various urban renewal factors identified in this study. The fact that there is only a Plan of Urbanization (PU) to regulate the operations of buildings in the historic center does not help the existence of specific rules for intervention in buildings, because by nature the PU has a inadequate scale to the planning of the historic areas;

- In the PPBP, we can see that it allows a large urban renewal, and its application strategy is thought to regulate the various factors of urban renewal identified in this study. It has an approach similar to the one developed by *Porto Vivo - SRU* with the strategic documents.

- The RICUH in Guimarães reflects a reduced possibility of intervention with contemporary values. Almost all parameters must remain as the original features of the buildings. In our interpretation this shows that the strategy of perpetuating the past values, believing that contemporary architectural values would reduce the artistic, social, cultural values and the economic development acquired by the place so far.

- Through this study we can understand that the latest Portuguese planning tools, the strategic documents in Porto and the PPBP in Lisbon, are the most complete. They cover, for example, how to intervene on the building's structural system and they also point out objectively the constraints relating to the factors of façade design, roof and internal typology.

- We can say that the relationship between the intervention policies explicit in the planning tools and the real transformations are not direct. This may be seen by the number of licenses given to the renewal of buildings in period after its planning tools entry into force (section 4).

As suggested by the Vienna Memorandum (UNESCO, 2005) in the management of political intervention in the historic centers must exist as a principle the acceptance of change as part of the construction of the city, not only advocating the preservation of heritage, but also and at the same time, the upgrading in order to strengthen the identity and social cohesion. After the analysis of the mentioned planning tools it can be seen that are the strategy documents in Porto and the PPBP in Lisbon, those who best embody the idea of conservation and modernization explained by the Vienna Memorandum.

SUCCESSFUL INITIATION AND COORDINATION OF MOBILITY MANAGEMENT – EXPERIENCE OF THE GERMAN ACTION PROGRAMME "EFFICIENT MOBIL"

Mechtild Stiewe [1], Conny Louen [2]

Abstract

Even though Mobility Management is more and more seen as a suitable approach to meet the challenges of mobility and transport, a nationwide and top down strategy has been missing in Germany so far. The action programme "effizient.mobil" of the German Energy Agency (dena) (runtime 01/2009 – 12/2010) funded by the Federal Ministry for the Environment (BMU) is the first attempt to go a more systematic way to foster Mobility Management strategies and implementations. So far more than 100 municipalities and companies got free of charge consulting that led to a specific concept taking the framework conditions into account. The ILS-Research Institutes for Regional and Urban Development and the ISB-Institute for Urban and Transport Planning are assigned with both the evaluation of processes and the estimation of effects.

The evaluation concentrated on all relevant processes in both of the action levels of the program, namely the level of regional initiation, application and coordination of mobility management measures and the level of individual consulted cases. A mix of qualitative and quantitative methods was used for this. Firstly, ongoing project activities could be documented and analysed. Though it was possible to follow developments and to discuss them with all stakeholders in the current process. This offered the possibility to optimize certain parts of the program. Secondly, success and inhibition factors could be derived for the different programme levels.

An assessment tool for effectiveness of the internal mobility management concept was developed to estimate the CO_2 reduction of the planned measures based on extensive surveys and concepts. The programme offered the possibility to display the traffic-related benefits of mobility management to the consulted cases for consulting the traffic-related cases for the benefits of internal mobility management by uniformly collected basic data.

So the motives for a confrontation with the issue of mobility management can be explained better. For example it can be stated that the worse the quality of location,

[1] Research Institute for Regional and Urban Development gGmbH – mechtild.stiewe@ils-forschung.de

[2] Institute for Urban and Transport Planning, University of Aachen - louen@isb.rwth-aachen.de

the more specific mobility related motives lead to participate in the programme "effizient mobil". Otherwise the car share at the journey to work is lower, the greater the prior experience with the subject of mobility management is. Based on these results evidence for action and influence factors for implementation of mobility management in companies can be derived. The results show that e.g. especially cycling and public transport are considered because here the enterprises have the largest existing knowledge and experience. Measures that affect the working time regulations were rarely observed and not internally designated. Especially in combination with the location of the sites and the existing accessibility the question is, what does this mean for the willingness of implementation.

1. Introduction

Even though Mobility Management is more and more seen as a suitable approach to meet the challenges of mobility and transport, a nationwide and top down strategy has been missing in Germany so far. The action programme "effizient.mobil" of the German Energy Agency (dena) (present runtime 01/2009 – 12/2010) is the first attempt to go a more systematic way to foster Mobility Management strategies and implementations.

It is funded by the Federal Ministry for the Environment (BMU). It aims for a further dissemination of Mobility Management, as this concept is so far mainly implemented on an ad hoc basis. The programme supports the uptake and the effective implementation of Mobility Management, both within the municipalities and for different sites and organisations. Effective structures shall be established which support a better institutional anchoring and a better integration into suitable strategies and programmes. So far more than 100 municipalities and companies got free of charge consulting that leads to a specific concept taking the framework conditions into account.

As examples prove, Mobility Management is effective. To help this instrument to its breakthrough, however resilient and comparable data is needed. Therefore an important aim of the Action Programme was, to accurately evaluate the effects. On the one hand, the outcomes of as much of the 100 Mobility Consultations as possible were to be analysed quantitatively: Which potentials for traffic relocation and CO_2 reduction do the drafted measures hold? Realistic description after all influences the counseled company's and municipalities' willingness to implement the concepts. As the whole Action Programme also Mobility Management is based essentially on communication, coordination and networking between relevant actors, on the other hand it was important to study the quality of the corresponding processes: which steps had been taken to activate multiplicators and possible users of Mobility Management and how did it work?

Table 1. Definition of Mobility Management

Definition Mobility Management

Mobility Management (MM) is a concept to promote sustainable transport and manage the demand for car use by changing travellers' attitudes and behaviour. At the core of Mobility Management are "soft" measures like information and communication, organising services and coordinating activities of different partners. "Soft" measures most often enhance the effectiveness of "hard" measures within urban transport (e.g., new tram lines, new roads and new bike lanes). Mobility Management measures (in comparison to "hard" measures) do not necessarily require large financial investments and may have a high benefit-cost ratio.

Source: European Platform on Mobility Management (EPOMM), developed by the EU Project MAX: Successful Travel Awareness Campaigns and Mobility Management Strategies

A special focus is laid on possible CO_2-reduction of these measures. It is estimated by analyzing the mobility concepts and data about the staff's mobility behaviour and the current site characteristics and quality of available mobility options.

In detail the programme aims at the following:

- Initialisation and encouragement of conceptual design and implementation in order to support concrete Mobility Management strategies and measures on the municipalities' level as well as on the site level.
- Creation of a nationwide network of stakeholders to concentrate the knowledge and to use it for an area-wide implementation of Mobility Management.
- Anchoring of the subject in politics and the public
- Evaluation of the effects on a structural and organisational level and development of a standardised method and tools to estimate the excepted CO_2-reduction of the programme.

The ISB-Institute for Urban and Transport Planning and the ILS-Research Institutes for Regional and Urban Development are assigned with both the evaluation of processes (mainly ILS) and the estimation of effects (mainly ISB). The evaluation concentrated on all relevant processes in both of the action levels of the program, namely the level of regional initiation, application and coordination of mobility management measures and the level of individual consulted cases. A mix of qualitative and quantitative methods was used for this. Firstly, ongoing project activities could be documented and analysed. Though it was possible to follow developments and to discuss them with all stakeholders in the current process. This offered the possibility to optimize certain parts of the program. Secondly, success and inhibition factors could be derived for the different programme levels.

2. General Approach of the Evaluation of the processes

The main subject of the evaluation which takes place throughout the whole project duration are the processes on the scale of regional coordination and individual consultation. The aim is to analyse and document the according activities in the Action Programme as well as the anchoring on-site. Building on that, success and inhibition factors for a successful implementation, promotion and distribution of Mobility Mangagement have to be derived and clues for the transfer into permanent structures have to be developed. A mix of qualitative and quantitative methods was used for the evaluation of the counseling. On the scale of the 15 regional networks, the effectiveness of the coordination offices for the regional networks in regards to their networking capabilities and the dissemination of the concept of Mobility Management is analysed. On the scale of the 100 consultations an emphasis lies on the analysis of the collaboration between counselors and counseled companies. A survey of all mobility advisors and beneficiaries will generate findings about factors of success in the consultation processes.

On several events for information potential Mobility Management actors could be approached and activated. In total about 2,200 actors could be reached on 80 events during the action period. Particularly city councils, transportation companies and chambers of industry and trade turned out to be important supporters.

As other important subjects for a promotion of internal Mobility Management the companies name their employee's mobility as the most important field of work, followed by business trips. Regarding municipal Mobility Management the priority lies at the intra-administrative anchoring.

3. Motivation of companies for taking part in the Action Programme "*effizient mobil*"

The recipients are asked to provide information about their most important reasons or their motives for an application for „effizient mobil". The response categories were derived from the previous guided interviews. Additionally further motives could be named in the category „Other" (see Fig.1).

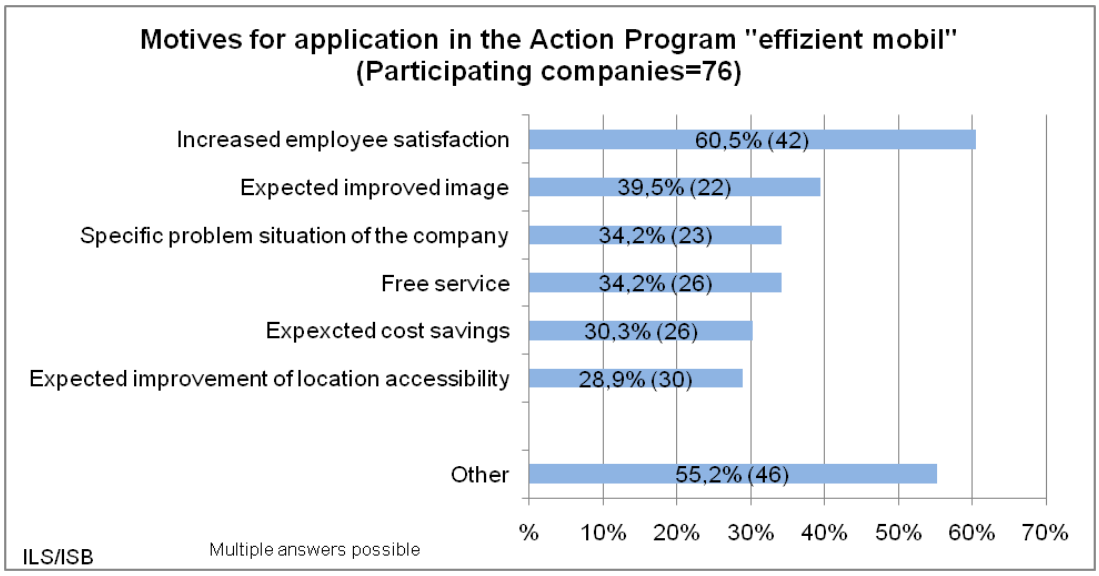

Figure 1. Motives for the application in the Action Programme “effizient mobil”

The most common answer is the increase of employee satisfaction. Of altogether 76 recipients 46 companies or organisations name this motive. This is a result, that can be retrieved from other studies as well (ILS et. al 2007: 11 f.). Second comes the expected improvement of the image. So companies focus on two motives that are not directly in connection to the subject of mobility. Another important role belongs to the specific problem situation of the company and hereby indicates a mobility-related motivation. In more than 55 % of the cases further motives were named in the category „Other“. It turned out that Mobility Management is a contribution to the protection of climate and environment – and with it also CO_2 – are further important aspects. In the municipalities mobility-related motives like specific problem situations and a positive influence on modal split clearly dominate the answers.

3.1 Estimation of need for action

Looking at the question how high the need for action regarding Mobility Management in the companies is estimated, it becomes clear that consulters estimate the need for action explicitly higher than the recipients.

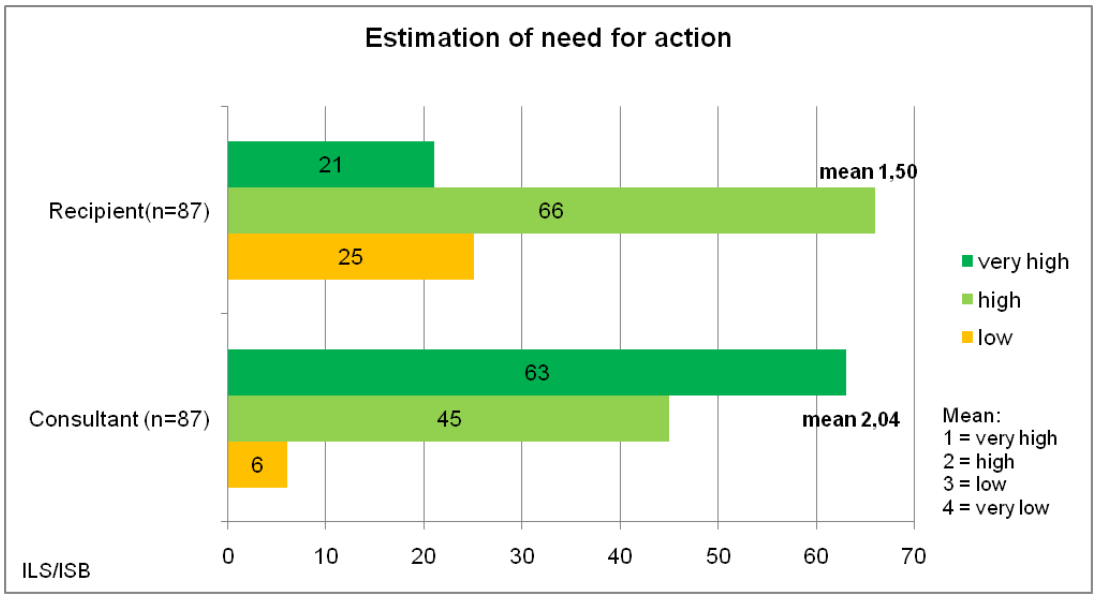

Figure 2. Estimation of need for action

Thereby generally need for action is seen in multiple fields of action. In particular cycling and public transport are named quite often by the consultants as well as the recipients. They consider the introduction of a jobticket as a particularly important task. The consultants consider the subjects parking space, employee traffic and optimising service trips as fields with a high need for action (see Fig. 2).

This different estimation can be also explained by the low or even non existing experience of many companies regarding Mobility Management at the beginning of the Action Programme „*effizient mobil*“. So 29 % of the companies said that they were widely unfamilar with Mobility Management. In 58 % of the cases at least a basic understanding existed.

A standardised survey addressed the companies as the receivers of initial consultation. 82 % of the addressed evaluated the quality of consultations as very good (1) or good (2). The average result was at 1,97 which meant „good“.

Even though the majority of the recipients – according to their own statement - had already taken single measures before the beginning of “*effizient mobil*”. Mostly named here were measures regarding public transport. Especially jobtickets were widely spread among the companies. But also measures in cycling like building parking areas played an important role.

Asked for the willingness for implementation of the suggested measures, more than 60 % of the answering companies named a very high or a high willingness. In connection to that, 71 % - among them every single municipality – that also during implementing the concept additional consultation is needed.

4. Estimation of the potential of CO_2 reduction

Mobility management is a concept to promote sustainable transport by the use of "soft" measures like information, communication, organisation and coordination, as well as an accompanying marketing. Thereby different fields are distinguished. Mobility management for cities and regions is mainly strategically. At this level measures aim to create the basis for further mobility management measures, linking the policy level with the management level in order to ensure the support of the responsible authorities or management and create new offers like car sharing or new public transport tickets. Mobility centres offer intermodal information about travel options. Mobility management for target groups or locations develops concepts based on the individual demands and conditions of the group or location, e.g. mobility packages for new citizens. Accordingly mobility management in companies focuses mainly on employees. Measures aim at the promotion of environment friendly transport modes such as adjusting the public transport schedules to the working time at companies, establishing job tickets or participate in action programmes such as "Cycling to work"[3].

Within the framework of the project the development of a method to estimate the CO_2 reduction focuses on mobility management in companies, because most of the mobility management concepts within the programme are made for companies. Due to the strategically focus of mobility management for cities and regions the benefit of these concepts cannot be estimated by the reduction of CO_2.

The base for the development of a standardized assessment of soft measures and the estimation of CO_2 reduction for these measures is complex. On one hand mobility management combines many different measures, which have different effects and can be combined in different ways in concepts in order to adapt the services to the specific individual needs and demands. On the other hand there are just a few mobility management measures or concepts which have been verified due to their effect on modal shift. Examples for scientific evaluated measures are the Dialogue Marketing Campaigns for New Citizens[4] or the mobility management for companies at Infineon in Dresden[5].

Mobility management measures have effects on different target fields (see Fig. 3). With the aim to promote the environment friendly transport modes and an efficient use of the existing transport systems mobility management provides an important effect on the environment. By shifting trips from cars to environment friendly transport modes noise exposure, pollutant emission, land consumption and separating effects on people´s living space can be reduced. Also health serves as another target field of mobility management. The modal shift from car use to non-motorized transport leads to more exercise and therefore to a better health. By the number of

[3] ILS, ISB (2000)
[4] ISB (2009)
[5] PGN, BiP (2003)

accidents due to transport modes it is possible to describe the safety of transport. As each mode has a different accident rate modal shift has an impact on safety. In addition mobility management has an influence on costs. If trips are shifted from car to environment friendly transport modes, on the one hand the measures can lead to decrease mobility costs of people. On the other hand companies or authorities need to carry the costs of the measures.

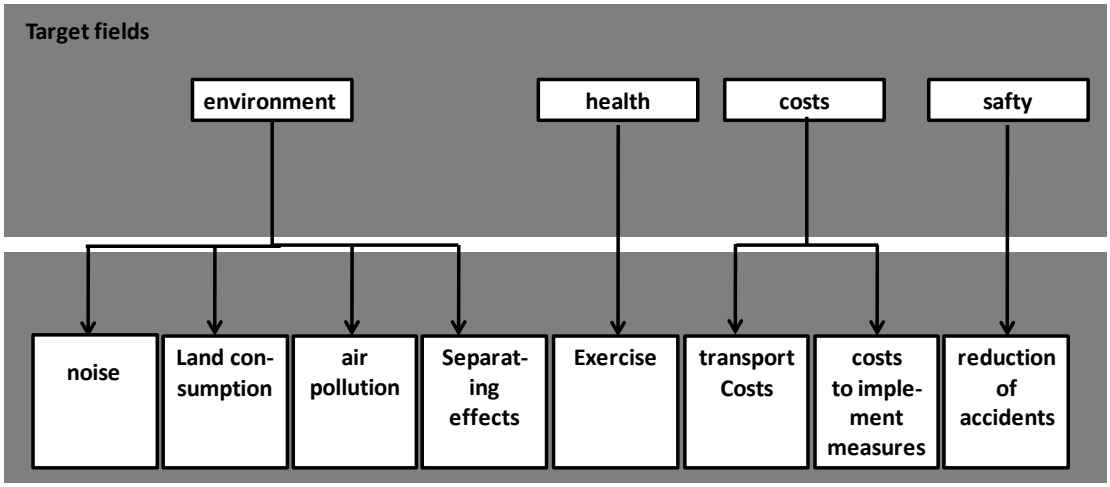

Figure 3. Target fields of Mobility management

In order to point out the positive outcome of mobility management on the climate within the framework of the project the focus is on the estimation of CO_2 reduction.

4.1 Method to estimate the CO_2 reduction of mobility management measures

The estimation of the potential of CO_2 reduction of trips to and from work is based on the reduced distance travelled by motorized private transport. The kilometres of motorized private transport are calculated by today's distance travelled and the estimated distance travelled after the implementation of the measures proposed in the concept. The change in CO_2 emissions by public transport is more difficult to calculate because there is no information about the occupancy rate in public transport in the different regions. Therefore it has been neglected in this method.

Today's distance travelled by motorized private transport is calculated by the distance between residence and workplace of the employees and their use of motorized private transport. The estimation of the distance travelled made by motorized private transport after the implementation of mobility management measures is based on the collected data of conditions of location and surroundings and the travel behaviour and opportunities of the employees. Figure 4 shows an overview of the steps of the estimation. In a first step a theoretical potential is determined. This is defined by the proportion of car-users that could be shifted to different modes of transport, based on their personal conditions. The conditions of

the location determine the level of this potential which can be obtained by the measures proposed in the concept.

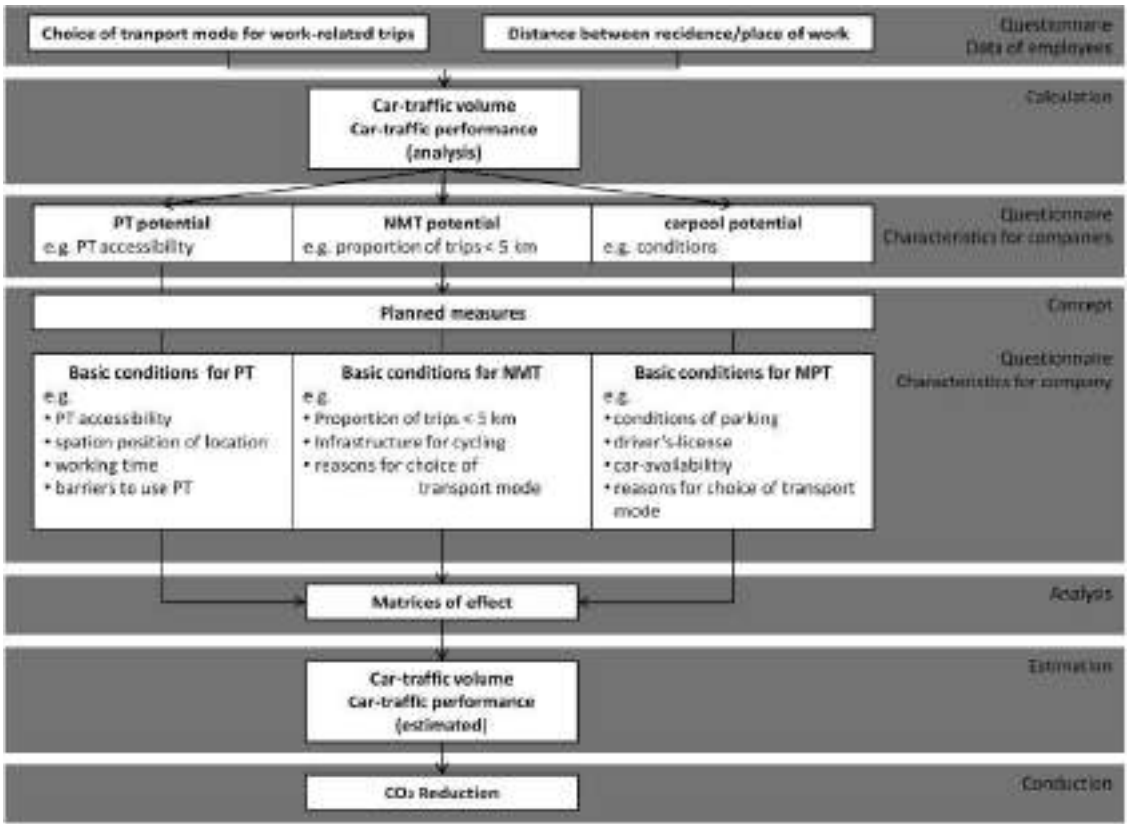

Figure 4. Overview of the estimation

5. Results of the theoretical potential

Based on the employee survey about 53,000 people can be identified, who use a car for their trip to and from work each day. About 28% of these people cannot be shifted to either environment friendly transport modes or car pooling due to their individual circumstances. The majority of the remaining car users, 33%, could be shifted to public transport. In addition about 13% could be shifted to public transport if the travel time with public transport could be reduced due to measures improving the public transport supply (additional PT potential). The theoretical potential of non-motorized transport is about 6%, this seems to be relatively low compared to today's car-users (cf. Fig. 5). But it shall be taken into account that the potential of non-motorized transport is based on a distance of max. 5 kilometres between residence and workplace. This distance may be considered to be, manageable by bike especially for those who are used to go by car to and from work each day.

The theoretical potential of those people, who use a car between one and three times a week for their trips to work, is rather similar. But in comparison to the high proportion of daily car users only a small number of people drive to work 1-3 times a week by car, therefore only daily car users are depict in the following analysis.

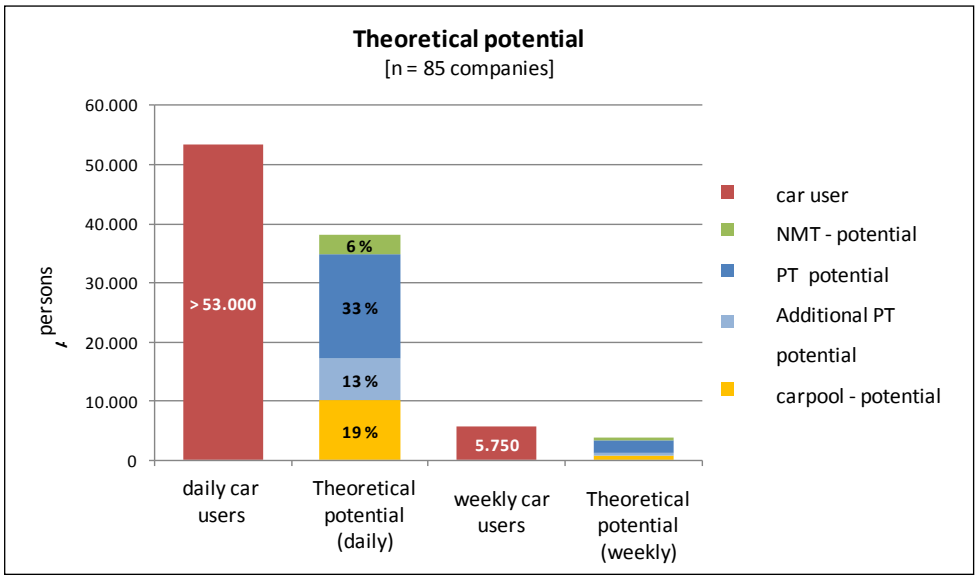

Figure 5. Results of the theoretical potential

Car-drivers who are employed at a company in an urban area or in the periphery could be easier shifted to non-motorized transport than those who are employed in rural areas. Due to the lack of public transport offer, in rural areas only few car-users could be shifted to public transport, however they could be shifted to car pooling (cf. Fig. 6).

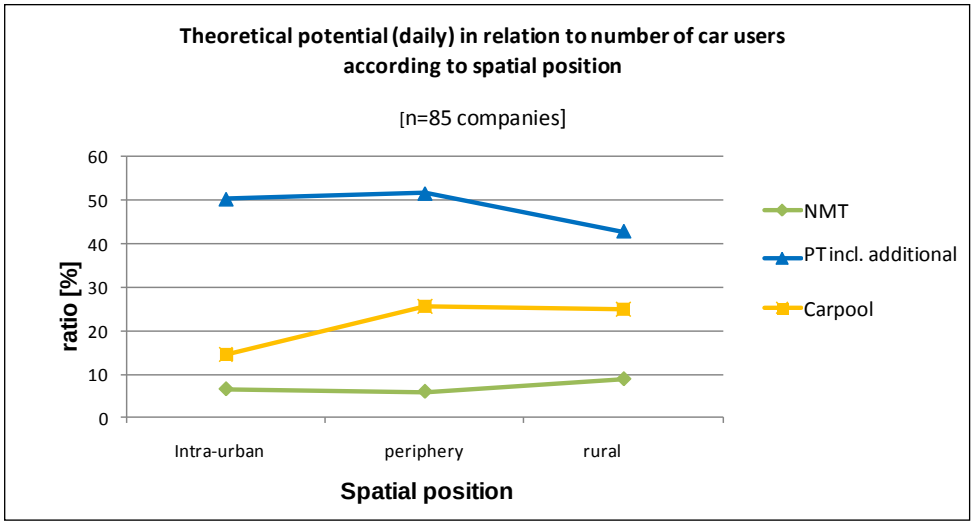

Figure 6. Results of the theoretical potential – acc. to the location

The level of the theoretical potential which can be obtained by the proposed measures depends on the quality of location for each transport mode. The better the public transport quality of a location and the higher the restriction of motorized private transport is, the higher is the proportion of the theoretical potential that can be obtained. The calibration of this method is made on basis of evaluated examples.

Since there are just few examples available which have been evaluated it is necessary that the calibration continues with further empirical data.
The analysis of the 85 concepts shows that on an average 26% of the theoretical potential can be obtained (see Fig.7). Averaged 119 daily and 17 weekly car users of each type of location are shifted.

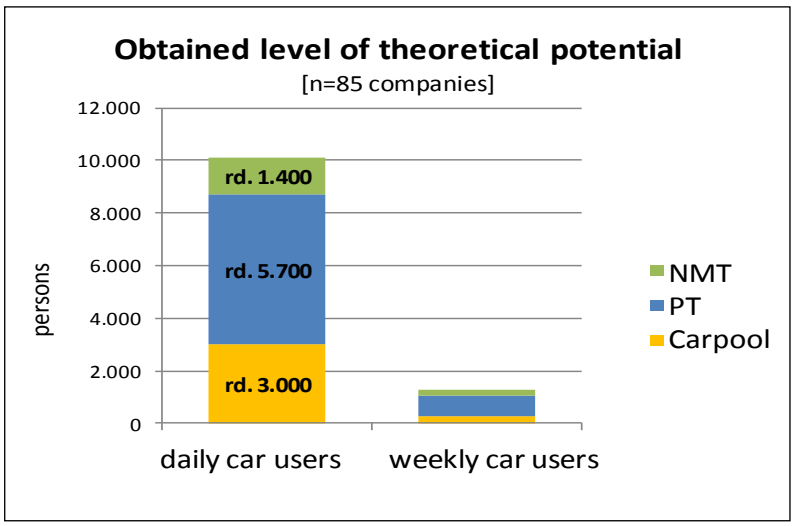

Figure 7. Part of the theoretical potential which can be obtained

To determine the reduction of CO_2 the estimated reduction of car distance travelled is multiplied by an average CO_2 value for cars (177 g/km).

A full implementation of the concepts of these 85 evaluated companies would lead to an average CO_2 reduction of 0.19 t/a for each employee and an average reduction of 248 t/a for each company. The total CO_2 reduction of these 45 companies is about 23.000 t/a (see Fig. 8).

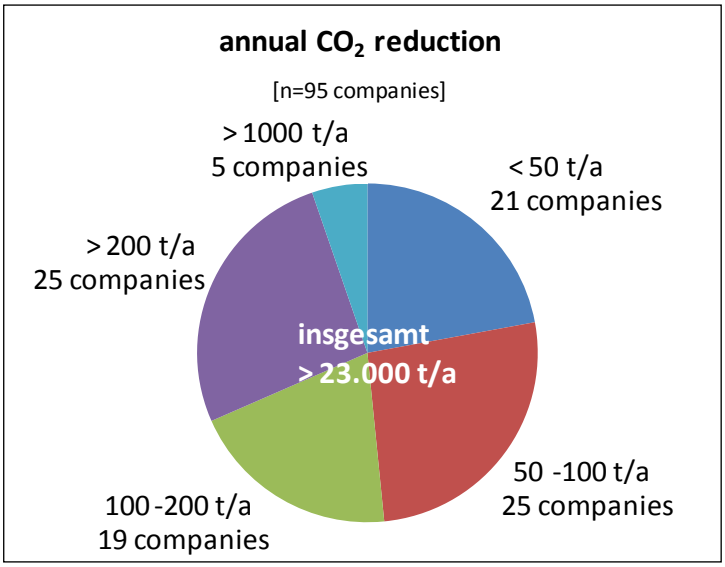

Figure 8. Annual CO_2 reduction

More than half of the recipients declare a high willingness to implement the measures proposed in the concept (see Fig. 9). Because among them are companies with a high potential of cutting down CO_2, 70 % of the cumulative CO_2-reduction potential (which means over 16.000 t) could be achieved with a "very high" or "high" possibility according to the recipients' data. In about 22% of the cases (according to the recipients) the willingness for implementation is "low" to "very low". In these companies there is a reduction potential of a little less than 3.000 t. Anyway attention should be paid to the fact that almost one quarter of the recipients did not provide any data to this topic.

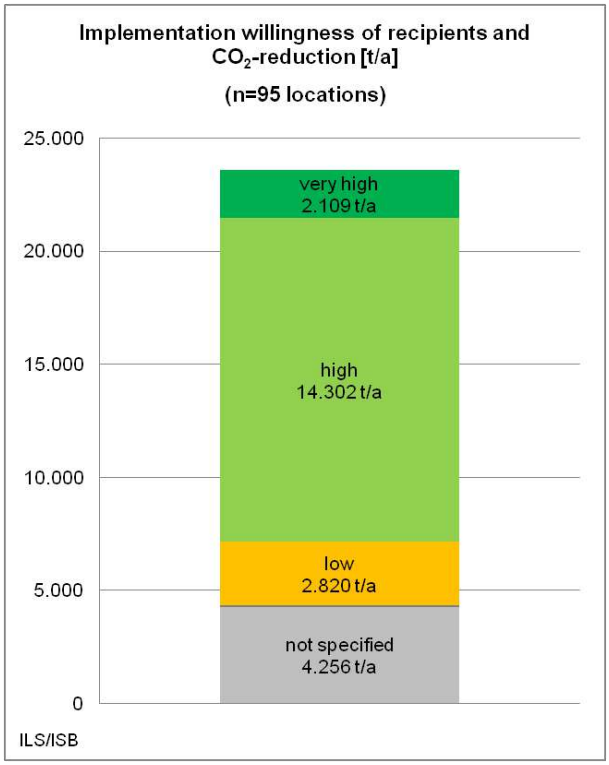

Figure 9. Implementation willingness of recipients and CO_2-reduction

6. Conclusion and Perspective

By extrapolating the data obtained it can be seen that there are, in the companies surveyed, in all some 53.000 people driving to work by car. Some 28 % of these cannot use other forms (public transport / car pools) due to their individual circumstances. However, 72 % could, at least in theory, shift to other means of transport. To what extent this potential is tapped is dependent on the proposed measures and on the locational quality of the alternative means of transport. An analysis of the 85 concepts showed that on average 26 % of the theoretical potential is being tapped.

As mentioned at the beginning it is not possible to calibrate all possible combinations of locations and measures with existing examples, since there is only little

knowledge about the effects of mobility management measures so far. Therefore the different combinations of measures may, with regard to their potential of shift, only be classified roughly. In general it may be said that there is only little empirical data available, so that the presented method needs to be developed with additional data. This data needs to be generated.

As a result it can be stated, that through the Action Programme „effizient mobil" a number of actors could be activated, regional structures were successfully initiated or rather strengthened and new incentives for Mobility Management in Germany were given. Anyhow at stabilising and implementing support is still needed.

NEW SOCIAL HOUSING POLICY IN URBAN CHINA: EVIDENCE FROM CHONGQING, NANJING AND CHANGZHOU

Mingye LI

Abstract

Launched in the 1980s, China's urban housing reform sparked considerable interest and gave rise to a burgeoning literature. Thirty years later, in spite of improved living conditions of urban inhabitants, soaring house prices have made affordability an imperative problem, especially for middle-and low-income households. In response, the central government began to promote social housing program by establishing ambitious housing development schemes in the late 2010s. This paper aims to examine the role of the new social housing policy at both a national and local level. Adopting a theoretical framework based on productivist welfare capitalism in East Asia, we argue that the new social housing policy in urban China fits into the framework of the productivist model in which social policy is subordinate to the overriding policy objective of economic growth. The pertinence of this integration is supported by the pro-growth urban governance patterns under China's transitional economy. This argument is then verified by the investigation at both a national and local level. At a national level, the social housing policy is closely related to the economic circumstance, especially the situation of real estate market. At a local level, the investigation in three representative cities-Chongqing, Nanjing and Changzhou indicates that besides taking care of a limited number of the poorest urban households, newly built social homes are largely used to ensure the smooth running of urbanization and urban renovation, and to attract both migrant labor and a highly qualified workforce, with the objective of maintaining economic growth and stimulating local competitiveness.

Key words: social housing urban China social equity economic growth

1. Introduction

Launched in the 1980s, China's urban housing reform sparked considerable interest and gave rise to a burgeoning literature (Wu, 1996; Wang & Murie, 1996, 1999; Wang, 2000; Huang & Clark, 2002; Zhao & Bourassa, 2003). According to these accounts, the reform was carried out progressively and a transitional period between the socialist public housing system and the market-oriented housing system can be identified. During this period, transitional compensation policies, such as the sale of

public-sector housing at a low price and issuing housing coupons, the assignment of social housing were adopted in order to promote the housing reform and improved the housing conditions of urban households. Alongside with these policies, two major types of social housing were introduced to Chinese cities-affordable housing (*jingji shiyong fang*) and low-rent housing (*lianzu fang*) in the 1990s. From 1998 to 2002, the floor space of newly constructed affordable housing represented more than 20% of the total floor space of residential buildings started in the same period (China statistical yearbook 1999-2003). Although the initial objective of covering 70-80% of urban households was not achieved, the investment in affordable housing reached a peak in this period (Stephens, 2010; Wang & Murie, 2010).

The circular letter[1] of the State Council issued in 2003 marked a turning point in social housing development in China. It announced that the real estate sector constituted 'the pillar industry of the national economy' and 'commercial housing rather than affordable housing was designated as the housing type of the majority of urban households'. This policy rapidly had impacts on the investment in affordable housing. Between 2005 and 2008, the development of affordable housing sharply declined, which represented less than 7% of the total floor space of residential buildings (China statistical yearbook 2006-2009). As for the low-rent housing, its target group remained very small and in cities implementing this policy fewer than 5 per cent of households benefited (Wang & Murie, 2011). Till 2011, households who benefited social housing system were estimated to only 7-8 per cent of the total urban population (National Bureau of Statistics of China). At the same time, commercial housing prices have been soaring. The average price of commercial housing increased by 103.6 per cent from 1997 to 2007 (National Bureau of Statistics of China). Taking into consideration location factors, the housing price in some regions increased several times (Ye et al, 2010). Housing unaffordability, combined with the increasing income gap, has become an acute problem in Chinese society.

To make amends, the central government declared its intention to promote a social housing policy in the circular letter[2] issued in 2007. At the end of 2008, in order to cope with the global crisis, the Chinese government announced a 4-trillion-yuan stimulus package[3], including the investment dedicated to social housing development.

---

[1] Circular letter on Promoting a Continuous and Healthy Development of the Real estate Market

[2] Several opinions of the State Council on solving the housing difficulties of urban low-income households

[3] A decision of stimulus package estimated at 4 trillion yuan (about 570 billion U.S. dollars) was announced by the State Council on November 9, 2008. It would be spent over the next two years to finance programs in 10 major areas, such as low-income housing, rural infrastructure, water, electricity, transportation, the environment, technological innovation and rebuilding from several disasters, most notably the May 12 earthquake. Source: http://news.xinhuanet.com/english/2008-11/09/content_10331324.htm

In the following years, the objective of social housing development has become more and more ambitious; from a programme aiming to protect 7.5 million low-income urban households with housing difficulties in 2009[4] to a scheme to build 10 million social housing units in 2011[5], culminating in the five-year-plan of a total of 36 million social housing units between 2011 and 2015 and the objective to cover 20% of the urban population by social housing by 2015. This change in the Chinese government's attitude towards social housing policy has attracted the attention of scholars in the housing field (Ye et al, 2010; Chen et al, 2010; Deng et al, 2011; Wang & Murie, 2011). Some contributions provided a global view of housing policy evolution at a national level, and several studies focused on the example of large cities as Beijing and Shanghai (Ye et al, 2010; Wang & Murie, 2011; Chen et al, 2010). Yet, very few empirical studies have been conducted to examine the evidence from different regions of the country.

This paper attempts to reach a better understanding of the role that the new social housing policy has played at both a national and local level. Following the introduction briefly presenting the context of the new social housing policy, section 2 discusses the conceptual framework based on the idea of productivist welfare capitalism in East Asia and its application to Chinese experience considering the pro-growth urban governance pattern under China's transitional economy. Section 3 examines the objectives and principles of social housing policy at a national level as well as the position taken by the central government facing the changing economic circumstances. In section 4, the implementation of social housing policy at local level is examined through the examples of three representative cities-Chongqing, Nanjing and Changzhou, which suggests that social housing policies carried out by municipal governments are closely linked with local industrial and urban development strategies.

2. A conceptual framework based on productivist welfare capitalism

Social housing studies are underpinned by theories developed for welfare state and social policies. Esping-Andersen (1990), based on the Western experiences, classically identified three welfare models i.e.: liberal, corporatist and social democratic systems. This analysis has dominated the contemporary understanding of welfare capitalism in advanced capitalist societies (Ronald, 2007) and provides a powerful framework for a comparative analysis (Holliday, 2000). Barlow & Ducan (1994) and Kemeny (1995) extended this approach to housing policy research, which to some extent compensated Esping-Andersen's failure to pay attention to housing (Malpass, 2008). The identification of typology forms a mainstream approach to comparative housing research, which provides a means of understanding the different

[4] Source: The government annual report (2009)

housing systems and major economic and social factors that shape them.

In the 1990s, capitalist East Asia, emerging as major economic powers, attracted scientific community's interest in the field of social policy, which gave rise to a burgeoning literature (Castell, 1992; Deyo, 1992; Jones, 1990, 1993; Kwon, 1997; White & Goodman, 1998; Doling, 1999; Holliday, 2000). Their aim was to complete the theoretical framework originally based on Western capitalism. Most of these works deal with the example of Japan and the *little tigers*: South Korea, Hong Kong, Singapore and Taiwan, and introduced a distinctive welfare model called "East Asian welfare model". Roughly speaking, there are two explanations supporting this idea. The first is a cultural explanation which emphasized on the 'oriental culture' or Confucianism based on strong kinship tie (Jones, 1990, 1993). The second explanation focuses on the 'productivist' feature of social policies which are subordinate to country's economic development (Holliday, 2000). In accounting for the evolution of family pattern and relationship under the rapid economic growth and urbanization in these countries, the 'productivist' explanation rather than the cultural explanation is more relevant.

Holliday (2000) developed the productivist model by following Esping-Andersen (1990)'s approach. He added a fourth criterion to Esping-Anderson's three criteria ('the quality of social rights, social stratification, and the relationship between state, market, and family') used to classify the three systems. That is the 'subordination to other policy objective'. By applying this criterion, Holliday considers that a productivist world with social policy subordinated to growth-oriented economic policy is distinguished from the liberal, corporatist and social democratic systems. Other accounts based on experience in East Asian countries (Deyo, 1992; Ku, 1995; Doling,1999) hold similar opinions- in general the role of social policies as with all other parts of the corporate plan, is to further the economic goals of the nations.

However, most of research focusing on East Asia was reluctant to include Chinese experience. This was probably due to China's socialist regime and the economic gap with other industrialized countries. Nevertheless, on the one hand, China's fully-fledged marketization led its economy to a capitalist system; and on the other, the country's rapid economic growth during the last thirty years has narrowed the gap with other industrialized countries in terms of economic development.

Indeed, a few recent works attempt to fill the gap by placing the Chinese housing system in a theoretical framework and in an international context. Considering China's hybrid status as a developing country as well as a transition country, Stephens (2010) used the European transition countries as comparators against which to assess China's evolving urban housing system. In view of this, the conceptual framework of the market-housing model was adopted as part of broad framework of transition. Nevertheless, although China and the European transition countries initially had a similar starting point in the housing system i.e. the state enterprise or

east European model of housing; they have experienced different transition after 1989. The different political and economic contexts make the comparison less convincing. Wang & Murie (2011) provides a comprehensive picture of the new social housing provision system in China since the housing reform in the early 1980s. After comparing it with both former socialist countries and East Asian systems, the authors conclude that China is neither following the pattern of change experienced by former socialist state systems in Europe nor those in other East Asian countries or rapidly developing economies, but a distinctive system experiencing with alternative ways of complementing housing market provision. They believe that the recent introduction of the concept called 'basic housing right' and the government's backing in basic housing provision indicate that the government supported housing might again become accessible to a wide range of social and economic groups. However, the concept of 'housing right' adopted by Western welfare states focusing on citizenship might be difficultly to put into be practice by Chinese officials who tend to privilege pragmatic policies oriented to economic growth. Besides, Wang and Murie's analysis of the practice of the new social housing provision system in China is mainly based on the example of Beijing. As it is under central government pressure, and has more political and economic resource than other parts of the country, the capital is a special case in the implementation of social housing policy.

In this paper, we argue that Chinese experience is not a distinctive system but fits into the framework of the productivist model of East Asia. The pertinence of this integration is supported by the urban governance patterns under China's transitional economy. The concept of 'developmental state' which was initially used to refer to the East Asian's newly industrialized countries (Deyo, 1992; Kwon, 1997; Goodmen & Peng, 1996) has been widely applied to urban studies in China. At a national level, the state legitimizes itself by prioritizing development (Wu et al, 2007); and it is more than a market regulator, but market builder and market actor (Wu et al, 2007; Wu, 2010). In particular, the state's intervention is strong in the real estate market with the objective of maintaining its stability and prosperity. Considering the decentralization in the course of China's economic reform, some scholars have applied the concept of 'developmental state' to the local level. Zhu (2004, 2005) describes China's local governments as economic interest groups with their own policy agenda, and thus the local developmental state. Wu (2002) argues the transformation of China's urban governance towards entrepreneurialism. In order to stimulate economic growth, local governments are zealous in promoting urban and industrial development which are seen as two major drive forces of Chinese cities, while tend to put social policy in second place. In terms of social housing policy, we can also identify its subordination to both urban and industrial strategies designed by local decision-makers. On the one hand, newly built social homes are largely used to ensure the smooth running of urbanization and urban renovation; on the other hand,

social housing schemes in some cities aims to attract migrant labor or a highly qualified workforce according to the demands of local industrial strategy and so that to stimulate economic growth and enhance local competitiveness.

3. Social housing policy at a national level

In 2003, the real estate sector was said to be the pillar industry of the national economy, since then its status has never been modified. This sector contributed approximately 1-2% to the GDP growth rate of the nation which varied between 8-11% in recent years (Zhang & Xuan, 2011). Its importance to national economy lies not only in the increasing value of real estate which reached 1185.43 billion yuan in 2007, but also in its driving force in the industries of steel, building materials, as well as in the development of financial industries(Ye et al, 2010). In view of this, to combat the soaring housing price, the central government had to face a dilemma. On the one hand, it sought to deflate the real estate bubble and to reduce social conflicts caused by soaring housing prices; on the other hand, the state is concerned about the stability of the flourishing real estate sector which constitutes the driving force of the national economy.

The central government's dilemma was reflected by the sudden shift of housing price regulations issued between 2005 and 2008. The state began to take measures to slow down the rise in housing prices in 2005. Since then, a series of housing price regulation policies[6] were issued. Nevertheless, the shift occurred when the real estate market was hit by the global crisis in second half of 2008. The central government came to the "rescue" of the market by lowering the interest rate of mortgage loan, reducing transaction tax, and requiring smaller down-payments. These measures deviated from previous policies aiming to cool down overheating market, and finally led to another wave of housing price inflation.

In the following years, soaring housing prices continued to be an acute problem. In this context, the central government embarked on social housing development in 2007 by launching a series of huge development schemes. This actually provides a way to resolve the dilemma. According to the Ministry of Housing and Urban-rural, the social housing policy intends to achieve several economic and social objectives[7]: firstly, to expand domestic demand and to maintain a steady economic growth; secondly, to improve people's living condition and to share the achievements of the Reform and Opening-up; thirdly, to promote social equality and political stability. In

[6] Opinions of the State Council on stabilizing the real estate price issued in 2005, Opinions of the State Council on the adaption of the structure of housing provision and the stabilization of the real estate price issued in 2006

[7] Source: Report on Theories and Practices of Housing Security published by the Ministry of Housing and Urban-rural Development in 2011

the Annual Reports of the Government (2009-2011), the policy concerning social housing development has been included in the measures to promote the healthy and steady development of real estate market. This means that the provision of social housing is deemed to be a housing price regulation tool to cool down the overheating residential property markets. At the same time, the ambitious social housing development scheme could be a new driving force to further economic growth, especially in the context of the global crisis. This explains one of the reasons why bricks and mortar subsidies rather than housing allowance have been chosen at a national level. Moreover, since 2010, the central government has taken tough action to cool down the overheating real estate market. As a result, price growth has been slowing down and the volume of transactions has been falling since early 2010. The substantial investment in social housing development could compensate for the decline on the property market. The floor space of 10 million of social housing units announced to start in 2011 (supposing the average floor space of social housing units is 50 m²) would be equal to 38.7% of the total floor space of housing started in 2010 which reached 1 293 million m² (China Statistical Yearbook 2011). Finally, the aim to reduce housing inequalities is related to the government's concern to make the state more legitimate, stable and supportive, rather than to incorporate the ideology of 'housing right' prevailing in western welfare states. Indeed, for a state which has adopted the productivist concept, the continuous economic growth is the best way to maintain social stability, since a slowdown in economic growth is more likely to hit the most vulnerable population and to arouse social discontent.

Concerning the typology of social housing and the corresponding target group, three types of housing have been designated at a national level: low-rent housing targeted for low-income urban households, affordable housing for low-and middle-income urban households and the newly established public rental housing for the lower-middle-income urban households as well as for the migrant workers and young graduates providing the local financial situation allows to do it. It should be noted that urban household means households with local family registration (*Hukou*). Besides, there are other social housing types which are not strictly stipulated by the state, for instance, commercial housing at moderate price (*Xianjia fang*) and housing for renewal of shanty area. The former one was introduced in 2006[8], aiming to make housing more affordable, and has been carried out mainly in large cities as Beijing, Guangzhou, etc. where high housing price is combined with strong housing demand. The latter one concerns the housing units used to host original residents after

[8] There is no exact definition of commercial housing at moderate price. It was introduced after the promulgation of the Circular Letter related to adjust the housing supply structure and stabilize the housing price in May 2006, which advocated building size-controlled and price-controlled commercial housing. Source: Ding & Chen, Housing system of middle income group and study on price-controlled housing policy, Reform, No.167, 2008(1)

demolishing squatter settlements and old dilapidated houses in old city. Regarding the conditions of application, such as household income, housing floor space, each local government determines the qualifying conditions according to the local situation.

Table 1 Scheme of different type of social housing in 2011

Types of social housing	Low-rent housing	Affordable housing	Public rental housing	Housing for renewal of shanty area	Commercial housing at moderate prices	Social housing in Total
Scheme	1 650 000 units	1 100 000 units	2 270 000 units	4 150 000 units	830 000 units	10 000 000 units
Percentage	16.5%	11%	22.7%	41.5%	8.3%	100%

Source: compiled by author according to the discourse of M. Jiang Weixin Minister of Housing and Urban-rural Development in the 23th session of the eleventh Standing Committee of the National People's Congress (NPCSC)

As shown in the Table 1, in the social housing development scheme in 2011 announced by the Ministry of housing and urban-rural development, the most housing units lie in the housing for renewal of shanty area, followed by the public rental housing; while the previous principal type, affordable housing, accounts for only 11% of the total scheme and the low-rent housing for the most vulnerable people accounts for only 16.5%. This implies that the 'social housing' is actually a broad term which contains a considerable number of housing units for renewal of shanty area, including housing used to relocate expropriated households in the process of urban renewal. This should be understood in the context of a rapid urbanization and vigorous urban renewal in China which constitutes a very important context of social housing policies in urban China. The large number of rural population moving to cities has resulted in substantial housing demand. Yet in the urban-rural dualistic structure of Chinese society, rural migrants have been excluded for a longtime from the urban social security, including social housing. Moreover, in the process of urbanization and urban renewal, local governments use expropriation[9] tools to expand or restructure urban space. Consequently, large numbers of land-expropriated rural and urban households need to be rehoused and paid damages.

[9] China adopted a dual land tenure system under which land ownership is independent of land use rights. The urban land is owned by the state, called 'State Land', while the rural land is owed by rural collectivities, called 'Collective Land'. The municipal government holds the power of expropriation of collective land and state land as well as the attached objects (above-ground buildings, crops, etc.)

4. Social housing policy at a local level: evidence from Chongqing, Nanjing and Changzhou

We assess in this section the different measures taken by three representative municipal governments in implementing social housing policies.

Since China is such a large country with considerable disparities between regions, it is not quite feasible to conduct an exhaustive investigation. Thus, we have chosen three cities-Chongqing, Nanjing and Changzhou- in our analysis at local level. These three cities, each with a different administrative status, different demographic size, and respectively located in the foreland and hinterland of the country provide a relatively complete picture in terms of social housing policy practice (see Figure 1, Table 2). In addition, the first-tier cities like Beijing and Shanghai have not been chosen in our study, since they have been addressed by most of urban research in China, yet their special status cannot represent the general situation of the country.

Chongqing

Chongqing is considered as a model city in implementing social housing policies. It introduced affordable housing in 1998 and low-rent housing in 2002. In 2009, the municipal government announced the aim to achieve the largest public rental housing stock in the country. In 2010, this objective started to take shape by the announcement of an ambitious scheme to build 40 million m² of public rental housing in three years. One year later, approximately 30 000 households were protected by this scheme. At the same time, according to the municipal social housing policy introduced in 2011, the other two systems: low-rent housing and affordable housing were to be integrated into the public rental housing system by setting different rent levels.

Active public rental housing development corresponds to the propaganda of the municipal government to restore the socialist color of the Communist Party. This policy is actually one of the pillars of the 'Chongqing model' aimed at a common prosperity enshrined in socialist ideology, which seems contradictory with the productivist concept.

The public rental housing system in Chongqing is characterized by its broader target compared to the national criteria. The former covers not only urban households with local *Hukou* but also the migrant population with housing difficulties. Precisely, all inhabitants over 18 years of age working in the urban area of Chongqing, with no housing or with housing which has a floor area per person less than 10 m² are eligible to apply for social housing. Recent graduates, migrant workers who have no accommodation in the city are also eligible to public rental housing. The municipal government has set the quotas for each type of population in which migrant workers represent 50% of the target group (see table 3). And a survey[10] conducted on 26,127

[10] Source: Information published by the department of communication of the municipality of Chongqing on the website www.people.com referred in August 2011.

beneficiaries of public rental housing in Chongqing in 2011 shows that these quotas were basically achieved with 43% urban households, 41.3% migrant workers and 15.7% recent graduates.

Table 3 Proportion of different targeted groups of public rental housing set by the municipal government of Chongqing

Groups	Urban residents	Recent graduates	Migrant workers, including migrant farmers
Proportion	30-40%	10-20%	50%

Source: Liu, 2010

In terms of the income ceiling, the criterion has been removed in 2011 in order to achieve a broader social objective of the policy. Since then, housing difficulties has constituted the major condition of applying for public rental housing rather than the income level[11]. Yet for migrant population, an employment contract is necessary for the application. In this case, the criteria could be simplified to 'having job, with no accommodation'.

Based on the investigation carried out in Chongqing, we can identify two types of public rental housing in Chongqing: the first one is the residential area open to all of the three groups of applicants; the second one is the public rental housing located in industrial parks, dedicated to migrant workers.

Kangzhuang meidi and *Minxin jiayuan* are two public rental housing residential areas of the first type. Built in 2010, both are characterized by large size of community (about 50 000 dwellers for each residence), moderate apartment size (between 30 to 80 m²) and high density (high-rises with over 20 floors).

Xiyong microelectronics industrial park, located 30 kilometers west of the city center, provides the public rental housing dedicated to migrant workers. In 2011, 1.2 million m² of public rental housing were built in the park. At the end of 2012 it will host a total of 100 000 employees[12]. It is actually a collection of dormitories rather than a real residential area. Four employees share one room. And each room is equipped with two bunk beds, cabinets and an air conditioner, which means a relatively low level of comfort and a lack of privacy. Yet its proximity to workplace allows the employers to better manage their staff who often work long.

As we can see, the social housing policy in Chongqing emphasized the accommodation for migrant workers who had been excluded from the urban security

[11] Source: http://finance.chinanews.com/house/2012/02-17/3675490.shtml

[12] Source: http://www.chinanews.com/estate/2012/01-05/3582728.shtml, referred in January 2012

system for a long time. On the one hand, this policy does reduce the housing inequality, since most migrant workers have housing difficulties in the city; on the other hand, the social housing programme aims to attract migrant workers who constitute the major labor force of Chongqing. This consideration is related to the city's industrial development strategy.

In 1997, following to the National Western Development Plan, the city of Chongqing was separated from Sichuan province and became the fourth direct-controlled municipality of the country (the other three are Beijing, Shanghai and Tianjin). In this context, Chongqing has become the growth pole in central and western regions of China. However, with a large rural population and a tradition of heavy industry, the per capita GDP of Chongqing amounts to only 40% of that of Nanjing and Changzhou and the average per capita income for urban households in Chongqing is only 66 % of that of Nanjing (see Table 2). In order to narrow the gap with the economic level of coastal cities, the municipal government adopted an industrial upgrade strategy whose aim is to move away from the traditional heavy industry to the modern light industry following consumer demand, such as, the production of electronic devices. This strategy takes advantage of the opportunity that manufacturers initially located in the coastal area of the country are looking for lower cost of land and labor force in hinterland. The provision of public rental housing to migrant workers in industrial parks together with other preferential local policies intended to encourage these companies to move to Chongqing. As a result, several electronic component makers, including Foxconn Electronics (*Hon Hai*), the world's largest maker of electronic components, built their new plants in Xiyong microelectronics industrial park in Chongqing in 2009. To such an extent that the social housing policy plays a role which goes beyond the basic sense of social security, but contributes to the local industrial development.

Nanjing

The city of Nanjing introduced the social housing policy in 2002. Today a multi-target and multi-system housing policy has been developing with the provision of low-rent housing, affordable housing, public rental housing and commercial housing at moderate prices[13]. In 2010, the municipal government launched four mixed social housing schemes with a total floor space of 10 million m², including 76 000 units of social housing. It is composed of 61 000 units of affordable housing, 10 000 units of public rental housing and 5 000 units of low-rent housing. Moreover, in the following five years, the government aims to build 90 000 units of public rental housing and 80 000 units of affordable housing. From these programmes, we can see

[13] In Nanjing, the commercial housing at moderate price is designated for expropriated households.

that affordable housing and public rental housing are the major types of social housing in the provision.

The low-rent housing system is designated for the poorest households in Nanjing. To target this population, the national system of urban minimum subsistence allowance was used. In 2009, there were 2.9% of urban households in Nanjing that received the urban minimum subsistence allowance. Among these households, those who have housing difficulties are eligible for low-rent housing. However, till 2009, there have been only 2200 dwellings in low-rent housing, which was far from being sufficient. As a result, housing allowance was adopted to complete the system. In 2010, from 22,000 households eligible for low-rent housing, approximately 90% received housing assistance instead of accessing low-rent dwelling. Even so, the total households covered by the system accounts for only 2.2% of urban households in the main city (*shiqu*) of Nanjing in 2010.

Affordable housing has been the dominant social housing type in Nanjing. Till 2010, in total 106 437 affordable apartments have been provided, which was fifty times as many as the provision of low-rent housing units (not including the housing allowance). Yet we need to analyze this system by examining the beneficiaries.

Indeed, since 2004, a large part of affordable housing has been assigned to land-expropriated rural households and house-expropriated urban households (see table 4). However, the non-expropriated low-and middle-income beneficiaries accounted for a very small share. According to statistics from the Municipal Bureau of Social Protection and Home Ownership of Nanjing, the proportion of affordable housing granted to land-expropriated households amounted to 73.2% in 2004 and stabilized at around 70-90% between 2004 and 2008. The percentage of those granted to house-expropriated urban households represents approximately 15%. In spite of a slight increase since 2007, the proportion of those granted to low-and middle-income households reached only 8.7% in 2008.

Table 4 Assignment of affordable housing in Nanjing (2002-2008)

Year	Quantity of affordable housing assigned to low-and middle-income households		Quantity of affordable housing assigned to house-expropriated urban households		Quantity of affordable housing assigned to land-expropriated rural households		Total	
2002	1539	52.0%	386	13.0%	1033	34.9%	2958	100%
2003	2511	40.4%	1301	20.9%	2407	38.7%	6219	100%
2004	803	12.8%	883	14.0%	4601	73.2%	6287	100%
2005	269	2.4%	1486	13.3%	9453	84.3%	11208	100%
2006	175	1.2%	2259	15.3%	12285	83.5%	14719	100%
2007	296	1.8%	1946	11.6%	14558	86.7%	16800	100%

2008	1905	8.7%	3447	15.7%	16647	75.7%	21999	100%
Total	8244	9.2%	13460	14.9%	68346	75.9%	90050	100%

Source: Municipal Bureau of Social Protection and Home Ownership of Nanjing

Moreover, among the 61 000 units of affordable housing programmed in the four projects of social housing, 35 000 units were designated for land-expropriated rural households, 16 000 units for house-expropriated urban households and only 10 000 for low-and middle-income households.

The priority given to land-expropriated rural households could be explained by the rapid expansion of the urban area of Nanjing. In the process of urbanization, expanding the urban areas has become the principal means of obtaining factors of production for local governments by reorganizing spatial resources (Wu, 2006). Municipal governments have been zealous in transforming the vast rural areas into industrial parks and new towns. Thus, expropriation of farmlands and homes of rural households constitutes a precondition of such projects. Yet in the urban-rural dualistic structure of Chinese society farmland has been considered as the most important social security of the rural population. In order to promote the urban development and to avoid social conflicts, the municipal government of Nanjing took the task of rehousing the land-expropriated rural households.

As for expropriation in urban areas, it is driven by urban renewal and development. In Nanjing, as in many other Chinese cities, a large number of urban renewal projects are underway. Municipal governments, who have gained instruments of urban planning and expropriation, effectively hold the power of urban renewal planning. Subordinate to the local development strategy, renewal projects have led to a transformation of urban space. Old dilapidated houses downtown are being expropriated and original residents are relocated to the peripheral areas where land is much cheaper. Land use rights of downtown areas are transferred to real estate developers for more profitable projects, such as office buildings or high-quality residences, which provided the municipal government with substantial transfer income[14], one of greatest sources of revenues for the local exchequer. The local government uses this revenue to invest in the development of urban infrastructure, as well as facilities for education and healthcare, so as to increase the city's competitiveness. In Nanjing, many affordable housing schemes located in the periphery were used to rehouse expropriated households. As shown in Figure 2, the inner city has been almost encircled by affordable housing schemes, except for the

[14] Municipal governments, delegating the ownership the State land, assign the land use rights to land users, who shall in turn pay fees for the assignment thereof to the State. Source: Interim regulation of the People's Republic of China concerning the assignment and transfer of the right to the use of the state-owned land in the urban areas, 1990

western part which crosses the Yangtze River. The four newly started schemes followed the existent urban spatial structure, which tend to lead to higher level of social polarization.

Figure 2 Location of social housing residential areas in Nanjing in 2010

Source: The managing committee of social housing development in Nanjing

Xingxian Jianyuan and *Jingming Jiayuan* are two typical affordable housing residential areas in Nanjing. Located in the peripheral areas, each of them hosts around 6500 expropriated (rural or urban) households, approximately 20 000 dwellers. Built in 2006, the residential areas have already showed some signs of deterioration. This is due to the non-payment of maintenance fee. Many dwellers refuse to pay the maintenance, since they are not satisfied with the expropriation and the relocation process in which they had no say in terms of the relocated destination and the levels of indemnity. As for rehoused rural households, although they have gained an urban status, they still have difficulties in integrating into urban society. With no job, many of them let their affordable housing in order to get a rental income. As a result, despite of the rules prohibiting leasing affordable housing, approximately one third of dwellers in *Xinxian Jiayuan* residential area are tenants.

The municipal government included the public rental housing in the local social housing system in 2010. In terms of the target group, besides lower-middle-income urban households, the groups called 'highly qualified professionals', 'young talents' and migrants were introduced. For the 90 000 units of public rental housing programmed in the next five years, 10 000 units were designated for 'highly qualified professional' and 50 000 for recent graduates (including young talents) and migrants workers. The redefinition of target group of public rental housing also corresponds to the local development strategy of Nanjing.

According to the 12th five-year plan in Nanjing, the city aims to become a National Innovation City by 2015 and to transform 'made in Nanjing' into 'innovated in Nanjing'. One of the measures is to promote high-tech industries, such as pharmaceutical chemistry, information & communication, etc. To do this, the municipal government made five human resource plans[15] supporting this strategy. An aim to attract more than 220 000 highly qualified individuals by 2015 was fixed in the 12th five-year plan of the city. Nanjing, as the educational center in southern China, possesses a large number of universities and colleges, and is a potential city of innovation. However, each year many promising graduates decide to start their career in first-tier cities such as Beijing and Shanghai which are considered to provide more opportunities for young talent. Faced with this situation, Nanjing prompted greater investment in 'human capital', including the investment in public rental housing for the young talented population in the hope of reinforcing its competitiveness.

Changzhou

Despite its medium size, Changzhou is a pioneer in social housing policies in China. In 2007, it was one of the first cities to put the public rental housing system into practice; in 2009, it replaced the provision of affordable housing by giving housing allowances for the purchase of a dwelling. The experimental approach is probably due to its location in coastal parts of the country where the policy makers are more open-minded than those of the hinterland. Accordingly, a market oriented ideology in favor of homeownership is reflected in the social housing policy in Changzhou.

[15] *Zijin* Human Resource Programme provides funding for 10 top talented persons (and their teams), 100 leading talented persons (and their teams) and 1000 much-needed talented individuals. *Zhongshan* Young Talent Programme aims to build 20 bases for 500 young talents to start undertakings each year and provides them with funding. *Jinling* famous Artist Programme aims to provide funding for 100 talented artists. Modern Service Industry Programme aims to introduce 5000 talented persons. Highly Qualified Technician Programme aims to train 15 000-20 000 innovative technicians. Source: 12th five-year plan of Nanjing

At present, the city possesses three types of social housing systems: low-rent housing, affordable housing (with housing allowance for the purchase of a dwelling) and public rental housing.

In Changzhou, the low-rent housing system is also intended for the poorest urban households who have housing difficulties. Between 2000 and 2010, 7 212 households benefited from this policy, of which 1 444 households accessed low-rent dwelling, 5 768 households received housing allowance. The coverage rate (including beneficiaries of housing allowance) is approximately 2.3% of the total urban households in the main city (*shiqu*) of Changzhou.

Affordable housing had been the principal social housing type in Changzhou. Till 2010, approximately 12 000 households enjoyed this system. The shift from the provision of affordable housing to housing purchase allowances occurred in the context of economic crisis of 2008. The crisis had a significant impact in the local real estate market: the sales of commercial housing decreased by more than 20%, the stock of new commercial housing for sale reached more than 13 million m². Meanwhile, the income of households tended to decline. Consequently, about 40% of eligible households for affordable housing gave up their right to purchase due to financial difficulties. To overcome this problem, the municipal government phased out the provision of affordable housing and introduced the housing purchase allowance in early 2009. Each eligible household was provided with an allowance of 80 000 yuan for the purchase of their dwelling on the market. In 2011, the allowance reached 100 000 yuan per household. As a result, more than 6 000 households applied for the allowance during the first six months after the introduction of the system, which was five times as many as those in previous years. The statistics collected by the municipal government from 3 120 beneficiaries show that the average floor space of the dwelling purchased by these households reached 94.5 m² and the average purchase price of per dwelling reached 378 000 yuan. In the following phase, the sales of commercial housing have increased by 65%. This means that the measure effectively tackled the decline of housing consumption during the period of crisis. Nevertheless, this policy caused controversies. Mostly because it actually ‘rescued’ the local real estate market during the crisis and prevented housing prices from declining which has made housing more unaffordable for the poorest households.

In 2007, Changzhou was the leader in introducing the public rental housing policy. It also developed two types of public rental housing: one type is the public rental apartment designated for low-and lower-middle income households with local urban *Hukou* as well as households called ‘new urban citizens’ (*xinshimin*) with housing difficulties; the other type is the dormitory designated for recent graduates and migrant workers with housing difficulties. Here, households of ‘new urban citizens’ refer to those without local *Hukou* but who worked in Changzhou for more than three

years under a formal employment contract. This population is considered as more likely to become permanent residents of the city. For this reason, the term ‘new urban citizen’ replaced the pejorative term ‘migrant’.

The public rental housing residences in Changzhou are characterized by their moderate size and lower density compared to those of Chongqing and Nanjing. The two investigated residential areas *Huakang jiayuan* and *Huasheng jiayuan* host about 700 dwellers for each. Compared to the social programmes of Chongqing and Nanjing mentioned before, the social residential areas are integrated into a mature residential zone and have a lower density (building six stories high), thus posing less risk of social polarization. Nevertheless, recently, due to budget cuts, the municipal government is considering replacing the property subsidies for public rental housing (apartment type) by housing allowance.

Public rental housing in industrial parks is mainly used to host migrant workers. In addition of the dormitories dedicated for migrant workers here called ‘blue collar dormitory’, another form of public rental housing, the so-called ‘white collar apartment’, was introduced in the Exportation and Processing Park of Changzhou (see Figure 3). In contrast to the ‘blue collar dormitory’, the ‘white collar apartment’ has more comfortable facilities: larger surface, the rooms are fully furnished and equipped. It is used to host managers who work regularly in the park. The provision of this kind of apartments helps to reduce the companies’ budget used for hotel expense for managers thus making the industrial park more attractive.

In recent years, with the acceleration of industrialization in hinterland cities, Changzhou, as other cities in the Yangtze Delta region, has been experiencing a shortage of migrant workers. Unlike the migrants in the previous generation,

nowadays, young migrant workers have more choice in terms of their working destination. They began to ‘vote with feet’. Instead of leaving their family and working in coastal regions, more and more of them choose to work in factories in their own regions or other regions in the hinterland. Although the salary is lower than that in coastal regions, the cost of living is lower as well. This change may have an impact on the local industry in coastal cities such as Changzhou whose economy is still based on the manufacturing industry. In view of this, the local government of Changzhou is favorable for improving the living conditions of migrant workers in industrial parks. Meanwhile, many companies are motivated to develop dormitories for their employees so as to attract low-cost labor force. As a result, the local government and the companies jointly contribute to investing in these projects.

5. Conclusion

This paper has attempted to reach a better understanding of the new social housing policy in urban China by placing it in a framework of productivist capitalism welfare in East Asia. This integration is supported by the ‘developmental’ urban governance patterns under China’s transitional economy in which both the central and local governments place a top priority to economic development, productivity and competitiveness. By using this framework, we can identify the productivist features of the new social housing policy which can be summarized in three aspects: first, being subordinate to economic growth; second, investment-oriented social welfare; third, ‘workfare’ (work-for-your-welfare) policy.

These features are reflected at both a national and local level. At a national level, the social housing policy closely related to economic circumstances It has been given a regulatory role for the residential property market; and been used to stimulate national economic growth during the global crisis. It is undeniable that the new social housing policy has some security elements and the massive development of social housing will improve the housing conditions of part of urban households with housing difficulties. To some extent, it helps to reduce housing inequality in response to the adoption of an idea of ‘harmonious society’ by the Communist Party in 2006. However, the aim is to establish legitimacy, stability and support for the political regime, rather than to ensure citizenship as is the principle of social housing policy in western welfare states.

At a local level, besides taking care of a limited number of the urban households with the lowest income, social housing policy is subordinate to local urban and industrial development which constitutes two principal driving forces of local economy in the context of China’s transitional economy. In order to ensure the smooth running of urbanization and urban renewal, social housing units are used to relocate expropriated urban and rural households. By doing this, local governments seek to

restructure urban space and to obtain more productive resources. Moreover, social housing schemes of some cities have included migrants, young graduates, even highly qualified professionals into the targeted groups, because these groups constitute the productive working class of the Chinese urban society. This is a kind of human capital investment related to local industrial strategies: the local governments have identified the industrial sectors which are essential to local interest and then ensure high levels of investment and preferential supporting policies, including the provision of social housing.

Finally, several questions are raised about the future of social housing development in China: the intense schemes in peripheral areas could result in social polarization and segregation; the targeting determined by the productivist concept is not always consistent with a social objective, and this could produce social injustice; the budget cuts of local governments could eventually hold back social housing development.

SMART USE OF SPACE
How to deal with the growing pressure of urbanization in Flanders

Els Terryn, Ann Pisman, Thomas Verbeek, Georges Allaert[1]

Keywords
smart use of space, spatial policy, reuse of space, previously developed land (PDL)

Abstract
Due to urbanization, Flanders, the northern part of Belgium, is one of the most densely built and inhabited regions in Europe. The growing pressure of urbanization is expressed by an increasing built-up surface. Projections indicate that 30 to 50 per cent of the area of Flanders will be built-up in 2050 (Poelmans, Van Rompaey & Batelaan, 2010). To slow down this urbanization trend, a more sustainable spatial development with less use of undeveloped land has to be considered. In the framework of the Spatial Policy Plan Flanders 2020-2050 this principle is translated into the concepts of 'smart' and 'careful' use of space, related to the 'Three R principle' of waste management: reduce, reuse and recycle. Translated to spatial planning objectives, the growing pressure on greenfield areas should be reduced and existing structures should be reused and recycled by constantly reusing them.

This article presents the results of a research for the Flemish Spatial Planning Department and focuses on the localization of reusable space, the stimulating and obstructing factors, its potentials and the integrated implementation in spatial policy. Currently, there is no 'tool' to locate reusable space and the majority of new developments still focus on greenfields. Firstly, the study introduces the idea of 'reuse of space' in Flemish spatial planning. Contrary to the restricted definition of the concept in the field of brownfield development, in this research reuse of space is defined broader than merely the development of contaminated sites. The concept has more resemblance with the term previously developed land (PDL): "land or premises which have been previously used or developed and are available for use with or without intervention" (Ganser & Williams, 2007, p.603). Secondly, the potentials of reusing space are analyzed through different case studies and the amount of reusable space in Flanders is quantified in a GIS-analysis. Finally, in order to implement reuse of space in spatial policy, the resulting data are used to construct different spatial typologies in Flanders, based on the potential reusable space.

The research shows that focusing on previously developed land can be a method to reduce the growing pressure on greenfield sites, resulting in less use of space.

1. Introduction: Sustainable spatial planning in Flanders

Flanders, the northern part of Belgium, is coping with a growing urbanization. A large transformation in land use from open space (agriculture) to urbanized land takes place, which makes it one of the most urbanized regions in Europa. This transformation results in a fragmented urbanizing pattern and an increasing built-up surface. The proportion of built-up land is significantly higher in Flanders than in the neighboring countries (Poelmans and Van Rompaey, 2009; Poelmans et al., 2010). Today, more than 25 per cent of the Flemish area is developed and according to the different scenarios, this will increase up to 30 to 50 per cent towards 2050.[2] This leads to a growing pressure on undeveloped areas.

If we want to find an answer to this increasing pressure, we should learn to cope in a sustainable way, with the available space in Flanders. In the Spatial Structure Plan for Flanders[3], the concept of sustainable spatial planning has already been introduced: *"a development that meets the needs of the current generation without compromising the ability of future generations to meet their own needs"* (Vlaamse Overheid, 2011 - own translation). As a follow-up for this structure plan, the department of Spatial Planning of Flanders is now preparing the new Spatial Policy Plan Flanders 2020-2050[4] (BRV). In this policy plan, the concept of sustainable spatial planning is translated into the concepts 'smart' and 'careful' use of space. The preparation of the Green Paper for this BRV proposes to let Flanders evolve into a region in which the total amount of built-up land won't increase. With this proposal, they take part in the ambitious objective of the European Commission to run down the additional use of undeveloped land in the European region to zero. At the same time, Flanders has to cope with a population growth from 6.3 million people in 2010 to 7.5 million people in 2050. Consequently, one of the main challenges in spatial policy in the coming years will be to tackle the expected growing pressure on undeveloped land in a sensible way.

Although different studies on the theoretical concept of reuse have been carried out, less attention has been paid to the implementation of reuse in practice. The objective of the study at hand on reuse of space[5], subject of this article, was to provide inspiration to introduce and translate the concepts 'reuse of space' and 'reversible space' into the future spatial policy (BRV) (van Acker et al., 2012). The reuse of space (in addition to intensive and reversible use of space) can be one of the main thoughts for offering living and working space in Flanders in the future.

[2] Percentage of built-up land in surrounding countries: The Netherlands 11.5%, France 5%, United Kingdom 7.5%, Germany 8%
[3] Ruimtelijk Structuurplan Vlaanderen (RSV).
[4] Beleidsplan Ruimte Vlaanderen (BRV).
[5] The study 'Slim Ruimtegebruik door hergebruik en omkeerbaar ruimtegebruik' (Smart use of space by reuse and reversible use of space) was conducted by TRITEL and the Center for Mobility and Spatial Planning of Ghent University, under the supervision of the Flemish Department of Spatial Planning, Housing Policy and Immovable Heritage.

In this article a theoretical framework for 'reuse' as a part of 'smart use of space' is explored. Furthermore, in order to implement reuse of space in the Flemish spatial planning policy, a tool to locate and quantify the amount of reusable space in Flanders is proposed and the categorization of different spatial typologies of reusable areas with a selection of 'hotspots' is introduced.

2. Theoretical framework: Reuse of space within the context of smart use of space

The translation of a more sustainable spatial development into the concept of smart use of space with a focus on reuse of space, asks for a further exploration of the different concepts.

Smart and careful use of space

Careful use of space is defined by Van Den Broeck et al. (2010) as the active and critical use of space to prevent wastage (economical use of space) and to solve wastage (reuse, joint use and new use of space, with renewable sources and materials). It takes into account the carrying capacity of an area and its context and goes beyond individual needs in order to create public added value. This definition is related to the principle of 'reduce - reuse - recycle' as will be described later.

Literally, reuse is described in the Oxford Dictionary as "*use again or more than once; the action of using something again for the second or further time"*. It is not possible to translate this definition unambiguously into a context of spatial planning. Therefore, the next paragraphs try to explain related words and definitions.

Reduce - reuse - recycle

The conceptual framework and the principles of sustainable spatial development have strong parallels with the sustainability principles that were created for waste disposal. By analogy with the principles of waste management, the 'Three R-principle' (reduce-reuse-recycle), also known as 'the ladder of Lansink'[6], may be utilized to reduce pressure on greenfields. If we apply the 3R-principle in the context of smart use of space, in order to do more with the existing built-up space and consequently stop further urbanization, we can describe the basic principles as follows. In the first place (reduce), additional activities should always find a place within the existing and available urban area. By bringing activities in close proximity to each other or even interweave them, possibilities arise for multiple use of the same space. As a result, the demand for space, which leads to a pressure on new undeveloped areas or greenfields, is reduced. Secondly, the reuse opportunities of well-located but insufficiently used space should be maximally utilized (reuse). This is not an easy task, because of the many practical difficulties that are involved with the transformation of existing buildings or decontamination of soils. Nevertheless, through a consistent policy in terms of reuse, brownfield development could be made

[6] The ladder of Lansink is named after the Dutch Politician Ad Lansink, who introduced this method of working in 1979 in the Netherlands.

more competitive compared to greenfield development. Thirdly, we must encourage forms of reversible space (recycle), especially in cases where new open space will be developed. This means that space is conceived as recyclable, with future possibilities to return to an original condition.

Adaptive Reuse and Previously Developed land

In the context of architecture and urbanism, the concept 'adaptive reuse' is used for reuse of industrial heritage. Peter Suzuki defines it as follows:

> *"Adaptive reuse, […] refers to the rehabilitation of a building/set of buildings or district for a use, or uses, different from what the original purpose(s) of the structure/structures or neighborhood had been."* (Suzuki, 1996, p.562)

He describes adaptive reuse as the counterpart of 'demolition in the name of urban renewal', one of the two options for 'previously-developed land' (PDL). In the Planning Policy Statement of London on Housing, following definition is used for PDL:

> *"Previously-developed land is that which is or was occupied by a permanent structure, including the curtilage of the developed land and any associated fixed surface infrastructure."* (Communities and local Government: London, 2006, p.26)

The initial use of this definition has often led to confusion. Although not intended, agricultural land and private gardens were part of the description. This is the reason why the definition is revised in more recent policy documents. In this way, a better definition is given by Ganser and Williams (2007): *"land or premises which have been previously used or developed and are available for use with or without intervention".* To extend this definition, the authors emphasize that the focus is on built-up space.

Brownfield - Greenfield

Reuse is often named in combination with brownfield development. During the last decade, the definition of brownfields has evolved from contaminated areas to a broader definition of underutilized, sometimes contaminated, formerly developed areas.

> *"In common usage brownfields refer to previously developed land or derelict, encompassing a range of sites in terms of size and location."* (CABERNET, 2010)

In this way, the concept has resemblance with the previously-developed land defined by Ganser and Williams. The definition in the Flemish policy documents is similar to the definition of CABERNET. The decree on brownfield development of the Flemish Government states that these wastelands or brownfields have a potential to reuse, but it involves considerable development costs. For this reason, investors and project developers prefer greenfields to brownfields (Vlaamse Overheid, 2007). In the

broadest sense of the Flemish brownfield policy document, brownfields are thus ‘reusable areas’.

Reuse

In the context of sustainable spatial development in Flanders, reuse is one of the methods to cope with the available (free) space. Complementary to reducing the demand for space, it is another method to decrease the development of new (undeveloped) space. The term reuse as used in the study 'Smart use of Space', therefore encompasses more than just the development of contaminated sites, but refers to the broadest definition of brownfields as reusable areas.

Reuse can therefore be defined as using existing built elements, structures or buildings for new or similar functions or destinations, mainly in built-up or developed areas. It is essential that by reusing space, no new (greenfield) areas are used and that it remains possible to reuse space again in the future (reversible use of space). From this point of view, reuse is one of the strategies to achieve a smart or careful use of space.

3. Localization and quantification of the amount of reusable space

Despite several studies on sustainable spatial development and reuse, today, the majority of new developments in Flanders are still focused on undeveloped space or greenfields. If we want to change this policy, it is necessary to be able to indicate and locate reusable space. The remaining part of this article focuses on a tool to locate and quantify reusable space in Flanders and on a way to implement reuse of space in spatial policy. Besides indicating reusable locations, we also try to indicate the reuse potentials. How likely is it that reuse will function at this location? What are the preconditions? This will result in a reuse potential map for Flanders.

Adaptive reuse potential

Shen and Langston (2010) present an interesting study on the reuse potential, introducing the concept ‘adaptive reuse potential’ (ARP) to measure the reusability of buildings. They make a difference between the useful and physical life of the building stock and propose an integrated model to predict the potential reusability of buildings on a micro scale and to advise policymakers on how to deal with it.

To give an ARP score to a building, a number of data (building age, any refurbishment, prediction of physical life of the building, ...) have to be available, which makes this mapping impossible on the scale of Flanders. However, the application of the ARP score could help with assigning a priority to the different buildings with high reuse possibilities that should be taken into account by the policymakers. Thus, when the reusable space is located, in particular the reusable buildings, calculating the ARP score could be a next step.

Localization and quantification of reusable space in Flanders

In order to develop a method to identify reusable space in Flanders, the hot-cold method of Eric Frijters and Atelier Verborgen Land, introduced in the publication 'Tussenland' (2004), can give inspiration. In their research, a list of indicators that indicate the occurrence of one type of wasteland, intermediate land[7], is compiled. These indicators are included in 'condition maps' reflecting conditions which stimulate intermediate land (warm conditions) or hinder the emergence of it (cold conditions). If these 'warm' and 'cold' maps lay on top of each other, an overall picture of 'hot areas' and 'cold fronts' emerges. These maps show the possibility of existence of intermediate land in gradations from white to red. The redder, the more possibilities for intermediate land to emerge. The methodology used in this book is intended to track intermediate land, but with the right adjustments it can be used to locate reusable land.

Screening: hot-cold analysis

The hot-cold analysis in the study at hand on reuse of space is a cartographic tool to locate and quantify interesting reusable areas in Flanders based on GIS analysis. Similar to the methodology described in the publication 'Tussenland', different condition maps are the result. The selection of areas eligible for reuse is formed by several steps.

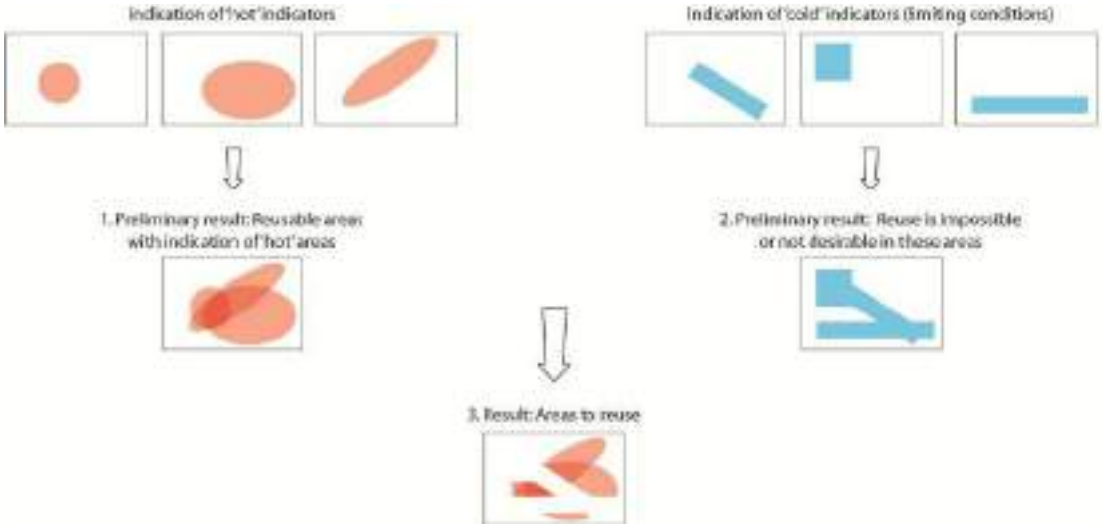

Figure 1. Hot-cold analysis: diagram

At first the hot indicators are presented, an indication of all areas that may be reused (figure 1 - point 1). In a GIS environment, several data layers were collected and represented. By giving a certain transparency to the layers, those places with different 'hot' indicators on top of each other are represented darker. In this way, 'hot areas' appear in which different indicators point to high reusability potentials. Examples of these data layers are empty buildings, contaminated land, architectural

[7] Intermediate land is a kind of wasteland, lying between city and countryside. It has characteristics of both, but cannot be reduced to one of them (Frijters, 2004).

heritage, mining areas, etc. Then, cold indicators provide limiting conditions: in these areas, reuse is impossible or not desirable (figure 1 - point 2). The related GIS data are merely based on nature conservation and development, flood risk, ... A part of the area that was first marked as reusable (point 1), is therefore excluded (figure 1 - point 3). We can illustrate this way of working with an example: in the first phase all contaminated sites are selected as reusable and form a 'hot' layer. Then nature reserves are designated as non-reusable areas; new developments for which nature must yield, are -in accordance with the spatial policy- not desirable. The contaminated areas lying in a nature reserve will therefore not be part of the areas to reuse.[8]

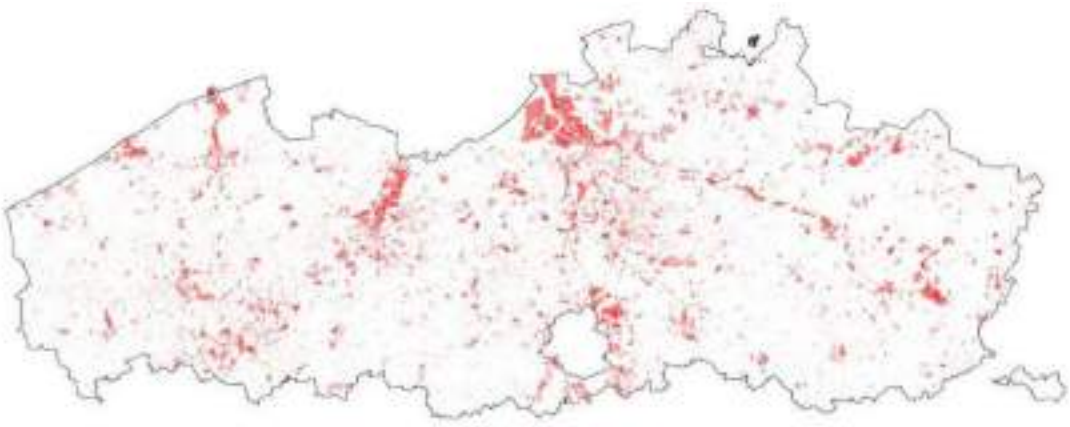

Figure 2. Areas with a high reuse potential in Flanders

The result of the hot-cold analysis is a map of Flanders, with an indication of the areas in which reuse is possible. A distinction is made between areas without opportunities to reuse and areas with a low or high reuse potential. Figure 2 shows the areas with a high potential for reuse. This is about 10 per cent of Flanders. The darker the area, the more factors that indicate potential reuse. The zone that isn't filled in in figure 2 has a lower or even no reuse potential.

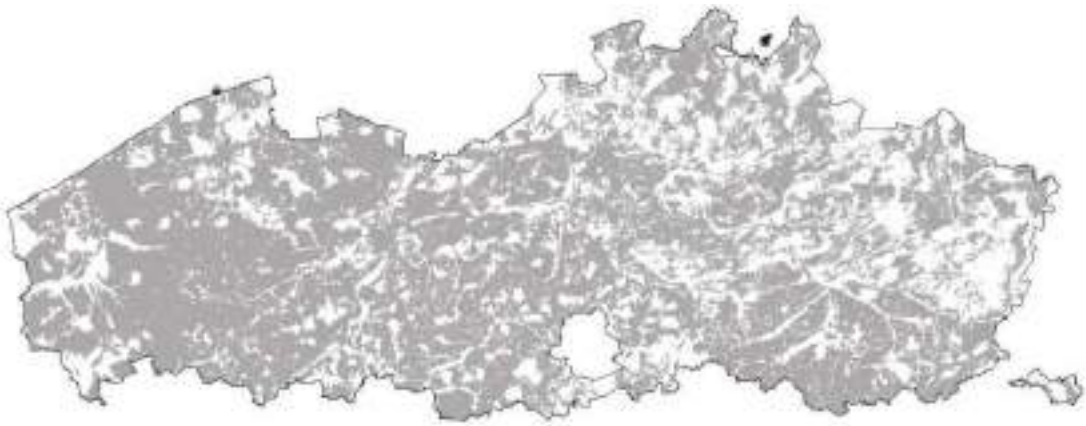

Figure 3. Areas with a lower/no reuse potential in Flanders (gray/white)

[8] This is in line with the reuse definition: reuse is situated in built-up areas.

The distinction between low and no reuse potential is made in figure 3. The gray-colored areas (approx. 63 per cent of Flanders) on this map have a reuse potential, but this potential is lower than for the colored zones on figure 2. The white colored zone in figure 3 was identified as 'cold indicator' (figure 1) and is therefore not reusable. Table 1 shows the reuse potential in Flanders, with a distinction between areas without potential to reuse and areas with a low or high reuse potential. We can conclude that 72.5 per cent of Flanders is reusable in a certain way.

Table 1. Reuse potential in Flanders in hectares and in proportion to the total area

Reuse potential	**Area**	**% of Flanders**
Reuse is impossible or not desirable it these areas (white on figure 3)	373.691 ha	27,50 %
Areas with a low reuse potential (gray on figure 3)	850.900 ha	62,63 %
Areas with a high reuse potential (figure 2)	134.174 ha	9,87 %

Analysis on a micro-level: potentials of reusing space

This screening with a hot-cold analysis indicates reuse possibilities in varying degrees. In a second step, nine case studies were analyzed at the micro level in order to check the screening.[9] The reversibility and reusability profiles were examined, in order to start a research by design (with the desired development in the framework of smart use of space). We do not discuss this analysis on a micro-level in this paper, but focus immediately on the conclusions. Are the areas, indicated as reusable on the Flemish level, also reusable in reality? In most cases they were. If the selection in the general screening was not successful and as a consequence reuse was not appropriate, this could be reduced to three reasons: missing data, opposing factors from the context and terrains that were not immediately available. The case study makes clear that the localization and quantification of reusable area by means of a hot-cold analysis on a scale of Flanders is valuable, but that not all potentially reusable space is (immediately) reusable.

4. Implementation in spatial policy

Ganser and Williams describe that

> *"Urban brownfield sites are a major planning concern across Europe, and most European countries have strategies to reuse them. […] However, approaches developed to tackle these sites vary considerably."* (Ganser and Williams, 2007, p.603)

They admit that the definitions of brownfields are progressive, but in reality the national policies just focus on restricting pollution and decontamination. Integrated

[9] Three cases at a regional level (the 19th century developments of Ghent, the region of Kortrijk-Waregem and the basin of the Rupel) were selected, with three micro-cases in each regional case.

strategies are rather the exception. Schulze Baing compares different policies and admits that

> *"only for a few countries, namely the UK, France, Germany and Belgium, brownfield land and brownfield regeneration has been identified as a national issue, […]."*(Schulze Baing, 2010, p.25)

Flanders, as a part of Belgium, has indeed a brownfield policy, but the sites that are dealt with are merely contaminated sites. Reuse of space, broader then only contaminated areas, is still not adopted in Flemish Spatial policy. After localization and quantification of reusable space in Flanders, it is thus necessary to make some suggestions how to use these results in spatial policy.

Flanders aims at a more sustainable spatial planning with less use of undeveloped land or greenfields. Reuse is one of the strategies to achieve this target. With the current spatial instruments, nothing obstructs a broad implementation of reuse. However, it is evident that not the total amount of reusable area (as mentioned in table 1) can be considered now. Therefore, the study categorizes the areas in Flanders with a high potential on reuse (figure 2) in different spatial typologies, with specific reuse potentials, and selects some 'hotspots' for reuse to stimulate reuse of space (figure 4).

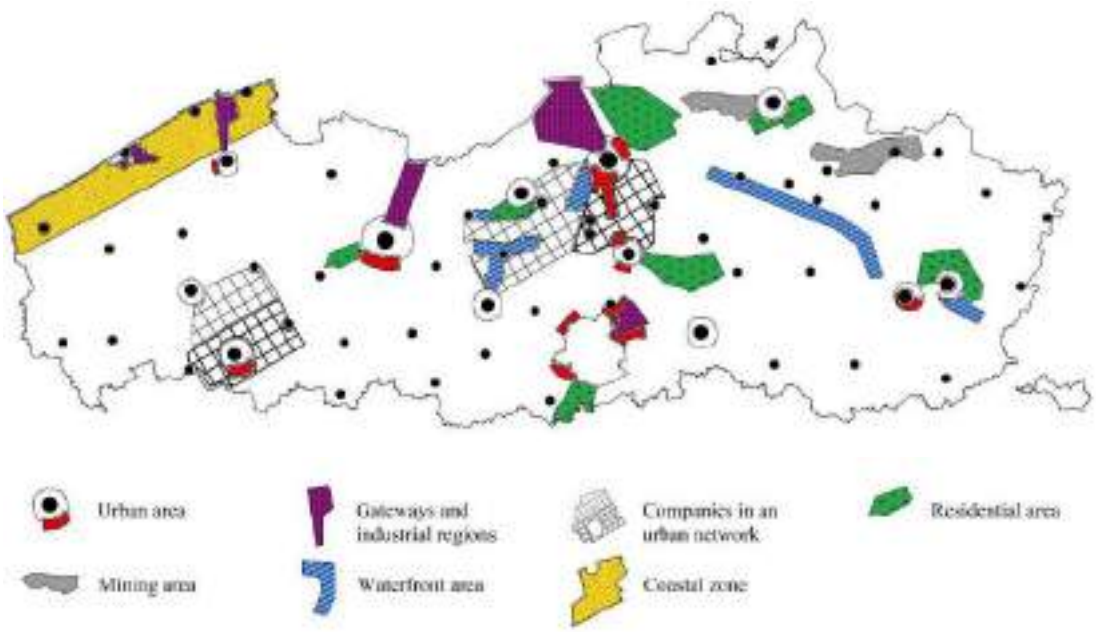

Figure 4. Different spatial typologies of reusable space in Flanders

By categorizing the reusable area, the findings and outcomes can be put together more easily. For example in urban areas (and especially in the city center), reuse is particularly applicable to the level of buildings. Cultural heritage plays an important role in this typology. Typical elements are churches, chapels and monuments, mainly (re)usable for public functions (library, museum,…). In this category, reuse is already a common phenomenon. One city learns from another and some realizations in one city can trigger other cities.

Next to the categorization of different typologies of reusable space, the study offers the possibility to select ‘hotspots’ of reuse to transform the theoretical analysis into realization. Hotspots were defined as areas with the highest reuse potential and with policy priority. This concept of selecting hotspots is in line with the ‘brownfield covenants’ in Flanders. These covenants are used by the government to make agreements with developers and investors (with some juridical, administrative and financial advantages) in order to promote the development of brownfield areas. Similar to these covenants, we suggest the development of charters between the Flemish government and the different actors to promote reuse of space in important reusable areas (hotspots). To determine which reusable areas are eligible to be selected as a hotspot, a yearly updated list can be set up. This list can be linked to the action program of the new spatial policy plan as mentioned before.

5. Conclusion

With the expected population growth in Flanders, the growing pressure on greenfields will not decrease. At the same time Flanders wants to evolve towards a region in which the built-up area no longer increases. Reuse is one of the crucial keys to keep offering space in this context.

The study reveals that by focusing on reuse, it is possible to reduce the extra demand of space without letting it form a threat on societal developments. From the hot-cold analysis we can deduce that there are many reusable places in Flanders. Moreover, the analysis shows that only 27.50 per cent of Flanders certainly cannot be reused (table 1).

To what extent can we reduce or even stop the use of greenfields in Flanders with the principle of reuse of previously developed land? More than 25 per cent of the Flemish space is built-up and projections indicate that without a specific spatial policy, 30 to 50 per cent of Flanders would be built-up by 2050. This means an increase in built-up surface of about 5 to 25 per cent of the Flemish area. By focusing on reuse in the approximately 10 per cent of space with a high potential for reuse, in theory it is possible to limit the increasing hardening at 15 per cent instead of 25 per cent. In the most ideal scenario, it would even be possible to reduce the existing built-up space with 5 per cent by 2050 (instead of an increase of 5 per cent).

This assumption should be nuanced; most likely this scenario can’t be achieved just by applying reuse. This paper is therefore primarily an argument to deal more carefully with the available space and to change the state of mind. The results of the GIS analysis should be understood as a support of this idea instead of exact calculations. The main lesson that can be learned from the analysis is that we can do more with less use of undeveloped space in Flanders, .if we deal ‘smarter’ with the available space.

EUROPEAN LANDSCAPE CONVENTION. POLICY AND PLANNING INNOVATIONS

Angioletta Voghera [1]

Abstract

The landscape valorisation is a central objective in Europe, since the approvation of the European Landscape Convention (Council of Europe, ELC, 2000). ELC gives centrality to the sustainability strategy, stimulated the development of an innovative system of policies aimed at protecting natural and cultural heritage of the landscape, managing and planning the landscape as a framework of the population lifestyles, as an expression of regional and local identity and diversity, and as an important resource of social-economic and territorial development. The Convention introduces in the pan-European context a reference strategy for action in order to disseminate a common approach in different landscape planning traditions, aimed at valorizing the landscapes for the sustainability of the territories.
The paper discusses the legislative innovations, policies, plans, design methodologies which were developed by various countries during the ten-year period following the approval of the ELC. The recent landscape policies and implementation approaches can be traced to the interaction between European guidelines and historical tradition of heritage protection, planning and management of each Country. In this direction, the paper analyzes the approach, the criticity and the recent results of policies, programs and projects for the valorisation of landscape identity and quality of some countries (as The Netherlands, Great Britain, Germany, Austria, Denmark, France, Spain and Italy). This comparison outlines the role of the different landscape cultures in respect of their tradition of protection of the natural and cultural heritage and with reference to the spatial planning, highlighting the role of heritage for the socio-economic development. The analysis will also evidences: the individual track of each planning culture developed to implement the Convention; the relation among landscape planning and other planning; the role of participation to define policies and projects to enhance identity; the interrelation among different levels of landscape planning; the relation between landscape planning and the projects. It will also describe participative landscape governance and urban design tools aimed at valorize the local identity integrating development and conservation especially in small towns.

1. Introduction

The European Landscape Convention (ELC, 2000) has been ratified by 31 member countries of the Council of Europe (by 23 member countries of the EU). The ELC stimulates development of a set of integrated landscape protection, planning and management policies as a framework embracing the life of the populations, an expression of identity and diversity, a resource for sustainable

[1] Assistant Professor in Urban and Regional Planning and Urban Design at the 2 Faculty of Architecture, DIST, Politecnico di Torino- angioletta.voghera@polito.it

development (Déjeant-Pons, 2006; Jones et al., 2007). It introduces a pan-European reference framework for actions aimed at: basing recognition of identity and landscape values on the populations (art.6c, ELC, 2000; Jones, 2007; Jones and Stenseke, 2011); constructing new values, moving from the protection of significant sites to participation of local municipalities in valorising all types of landscapes (art.5 c, ELC, 2000); integrating landscape valorisation in territorial, economic and social policies (art. 5d, ELC, 2000).

In Europe over the last decade, actions have been taken to support social, cultural, political and economic identity as developed also according to the European Landscape Convention (ELC, 2000).

Many initiatives, international researches and policies in Europe have followed, stressing different aspects of European landscape (Antrop, 2006). Natural (Wascher, 2000), rural (Dramstad and Sogge 2003; Parris 2004; Claval 2004), multifunctional land use (Brandt and Vejre 2004; Mander and Antrop 2003), historical and archaeological (Fairclough and Rippon 2002; Van der Knaap, Van der Valk, 2006) issues has been addressed in many studies and researches, but a transdisciplinary consideration of landscape is caused by the ELC in order to define protection, management and planning policies for the heterogeneity and complexity changes and thus also processes and functions in the landscape.

In this view the paper will try to discuss:

1. What are the influences of the European policies on the landscape? How and if the European level, that has not competence on landscape, could contribute to ELC territorial applications? How to square the system of landscape planning introduced by the ELC with European territorial policies?

2. What are the major innovations of the ELC as compared to national and regional legislation in the countries represented in the study? How do the ideal types of the southern European sectorial system of landscape planning and management and the northwestern European system compare?

3. Which are the major innovative approaches in landscape systems that can be traced to the ELC?

2. ELC and European policies

The innovative scope of the ELC is however hampered by the absence of a European Union landscape policy that, today, is an aspect that undermines its application.

The strong importance of landscape in Europe was already given in the First (Dobríš) Assessment of Europe's Environment: "The richness and diversity of rural landscapes in Europe is a distinctive feature of the continent. There is

probably nowhere else where the signs of human interaction with nature in landscape are so varied, contrasting and localised. Despite the immense scale of socio-economic changes that have accompanied this century's wave of industrialisation and urbanisation in many parts of Europe, much of this diversity remains, giving distinctive character to countries, regions and local areas" (Stanners and Bourdeau 1995). So in the EU the need of a specific landscape policy is strongly evidenced.

Although the EU is not competent for landscape matters, the concept of landscape introduced by the ELC is considered only in part in EU strategies and Laws. The art. 191 of the European Union Treaty affirms the objective of "prudent and rational utilisation of natural resources" which is common to European Landscape Convention and the principles of precaution and prevention prescribed should also apply to landscape policies (Cartei, 2011). In the absence of a specific policy, in the European policies landscape is considered prevalently in terms of effects and impacts (such as transport sector policy, measures for energy, …), that should be controlled and contrasted by specific actions. Only recently landscape is considered a development factor, but landscape importance and value was identified in general in relation to specific aspects (economic, ecological, aesthetic, social, …) in a sectorial way.

The landscape is influenced to a major extent by Community territorial policies, which influence localisation of activities in the territory and generating transformations of the landscape. Community actions with more direct fall-out on the landscape include: the policy of socioeconomic cohesion; transport sector policy; environmental policy; common agricultural policies (CAP); measures for energy; measures for tourism.

The cohesion policy aims to monitor socio-economic imbalances that could be exasperated by completion of the single market, addressing the territory with targeted plans, actions and structural funds. The structural funds for the 2007-2013 planning period are directed towards enhancing competitiveness and developing the local economy, generating long-term effects on landscapes. So far, the EU has dedicated very little attention to these effects. The relationships between the new infrastructures, territory and landscape are, in fact, observed considering the critical issues they generate, reflected in environmental assessments that analyse the positive effects in terms of accessibility, and their negative repercussions on the environment and the landscape.

Adopting various strategic instruments and measures, the policy for the environment, directed towards sustainable development, focuses on management of natural resources and of biodiversity that are important landscape values (reflected mainly in Directives for the protection of natural habitats and of migratory species). In fact, the VI European Program for the Environment (2001, 2007) identifies measures for establishing new relationships between the environment, and government of the territory includes the landscape on the axis of "biodiversity" actions, intended to valorize functioning of the ecological systems.

From the market liberalization with the decoupling of subsidies, the CAP was promoting overproduction and causing – directly or indirectly – severe impacts on European agricultural landscapes (Potter & Tilzey 2005), such as: intensification, pollution, erosion, overuse of water resources, and the loss of natural habitats and value cultural landscapes especially in northern Europe. From the 1999, common agricultural policy tried to reflect an integrated concept of rural development, considered to be an "instrument for establishing a coherent, long-lasting context for the socioeconomic and environmental future of rural areas". From this perspective, the landscape is deemed to be a development factor, necessary to guarantee the multi-functionality and the modernisation of agricultural economy through diversification of activities. The rural policy contributes to consolidate the conceptualization of multifunctional landscapes evolved recently in Europe around the recognition that agriculture produces commodity outputs (e.g. food, fiber and fuel) as well as various non-commodity outputs for society (habitat, scenic values, recreational opportunity, jobs, regional identity). So in this view we can define such landscapes as "providing multiple environmental, social, and economic functions in a given area of land, taking into account the interests of landowners and users" (Lovell and Johnston 2009, p. 214) and social needs.

The European Spatial Development Perspective (ESDP, 1999) expresses an innovative consideration of landscape, proposing a strategy for Europe inserted in a framework of sustainability and linking European spatial policies for infrastructurisation of the territory to urban development, safeguarding and management of the landscape, the protection of nature and of biodiversity.

Considerable stress is laid on European landscapes and on the more representative and sensitive areas to be managed with integrated policies. The concept of landscape that emerges from the ESDP is undeniably interesting and pro-active as it does not simply view the landscape as an "object" influenced by the effects and impacts of territorial policies but considers this to be the basis of a European and local collective identity (Pedrazzini, 2005; Röhring, 2011).

Although a separation remains between "natural" and "cultural" landscapes, the dynamic vision of the landscape that seeks to weave new relationships with planning and government of the territory is interesting.

However, two scarcely integrated concepts of landscape can be still observed in Community strategies:

— The landscape as an eco-mosaic, i.e. as the connective tissue of natural or para-natural habitats, able to promote systems of useful connections for combating the fragmentation of the landscape that threatens biodiversity (IUCN, 2003).

— The "socio-cultural" dimension of the landscape (Gambino, 2008) in policies for rural development and cohesion. In accordance with the latest UNESCO strategies (ICCROM, 1998; UNESCO, 2005), these policies are considerably

broadening the categories of excellent "cultural landscapes" to also include systems able to attract tourists, investments and inhabitants.

These two different concepts also influence national policies, especially in the countries that have a not integrated way to manage territory and natural and cultural landscape (such as the Mediterranean countries as Italy, Spain, France, see p. 3). In the absence of competencies, strategies, and ad hoc financing, activation of the ELC is now assigned to countries that are setting up initial experiments in a diversified and as yet fragmented framework.

In this view the research is focusing on the landscape culture in each country so that the results achieved by activating the ELC can be interpreted, and EU wide visions and strategies developed out of shared knowledge and the methods of acting on and in the landscape.

3. European visions for the landscape

The application of the ELC on the territory, in the various national approaches and results, is the expression of a new social recognition of landscape values and correlated administrative commitment. Furthermore, it is also the effect of a process of "Europeanization" of landscape policies, in two directions: as a top-down effect of European strategies that produce regulatory indications or policies on a national scale (Knill and Lehmkuhl, 1999) or as an influence for the mobilization of states in the construction of international strategies ("bottom up approach"; Börzel and Risse, 2000). The ELC is in fact a soft law (Bulmer and Radaelli, 2004), proposing a common model of governance for CoE member states – adhesion to which is "voluntary" - defined by discussing and exchanging experiences (Prieur, 2004).

There are the following requirements needed to give territorial application to the ELC:

— Legislative innovations inspired by the ELC and/or national strategies to define goals for reinforcing the landscape resource and cooperation between stakeholders, promoting and/or monitoring quality (such as established national and/or regional observatories);

— Actions for community involvement and empowerment in order to create public projects to promote social awareness;

— Developing new projects for landscape based on assessment to analyse the dynamics, characteristics, values and negative values and to establish common goals for enhancement;

— Landscape coherence in territorial policies and the sector at various administrative levels (vertical and horizontal integration);

— Subsidiarity, which requires the definition and implementation of actions starting with the local perception of landscape (bottom-up), in accordance with the European Charter of Local Self-Government (CoE, 1985).

The ELC envisages two interwoven levels of application: the adhesion of the states, and the construction of a common national policy in regional contexts (top-down), with strategies and practices shared by the population (bottom-up).

So the following paragraphs describe the landscape cultures and systems identifying the specific evolution aspects in some study cases relating them to the above key aspect of the ELC application.

4. Cultural landscape approaches

This paragraph discusses the landscape culture in the study cases, referring it to some ideal types models, such as the southern European sectorial system of landscape planning and management and the northwestern European system.

Today, landscape is a central theme of international cultural, social and political innovation (IUCN, 2004), inspired by ELC. The ELC has in fact inspired recent innovations in the legislative framework, strategies, plans and projects for landscape of many countries, integrated with "landscape traditions" reinforcing the historical-cultural roots relevant to protection, planning and management, as well as providing guidelines for experimentation in ways sometimes far from the cultural origins. The roads taken by the counties are the result of participation and the reciprocal fertilization between countries discussing the ELC innovations.

North European countries of Germanic-Anglo-Saxon origin (Voghera, 2004, 2006) such as Austria, Germany, the Netherlands, Denmark and Great Britain have been developing actions for the protection of landscape heritage with territorial policies since last century; while France, Spain and Italy - countries with Central-Mediterranean historical-cultural root (Voghera, 2004, 2006) – have drawn up landscape protection policies separated from territorial development and planning. These last nations in fact created, through the development of their legislative framework, a separation between the management of land uses for settlements and landscape conservation. This separation has produced distinct and non-interrelated management tools: territorial planning and safeguard restrictions.

The root also has its own particular terminology.

In the Germanic-Anglo-Saxon world, the term landscape (Landschap in the Netherlands, Landschaft in Germany and Austria, Landscape in Great Britain, …) means cultivated land. In Germany the term also indicates a close relation between the rural territory and local political-institutional and social culture; in fact in these countries "landscape referred both to the conditions and character of the land as well as to the policy within which the people's shaping of the land occurred" (Jones, Howard, Olwig, Primdahl & Sarlöv Herlin, 2007). Venturi Ferriolo (2003, p.24) mentions that the term was used as far back as the 9th century to indicate a juridical-administrative system based on the common identity of those living in the Landschaft. The idea of Landschaft corresponds to the Aristotelian idea of Polis, a territorial area of cultivated land and settlements, in view of the resident population, and visited daily.

In Central-Mediterranean culture however, the term paysage, paisaje, paesaggio (landscape) derives from paese (land-town). The Latin root of paese is pagus, the boundary stone sunken in the ground to mark a limes, the boundary between two properties and systems. From pagus derives pagensis – the root of paese (land or town) – a built-up settlement, which can be distinguished in its structure, form and function from the rest of the territory.

In this sense, landscape refers to the way man inhabited and organized the land (Jackson, 2003).

The terminological roots of Landschaft and pagensis, correspond to opposite interpretations of territory and landscape as a social representation (Turri, 2006), as well as different management models.

If landscape is a selective process with which a society demonstrates how it meets its needs (Morris, 1954), the Germanic and Anglo-Saxon world puts the emphasis on the environmental and territorial resources that the population makes sparing use of in order to live, while the Mediterranean interpretations put the focus on man.

In this sense, landscape is an excellent window for interpreting the culture of a society and understanding the way in which it defends its resources today.

The ELC places landscape at the centre of territorial government, with regulations, strategies, plans and projects on the basis of these cultural roots. Today, the different historical roots correspond to more operative governmental actions in the Anglo-Saxon world and more conservative actions in the Central-Mediterranean culture, as described in the following paragraphs that compare the study cases to the ELC application key aspects (see 2.2.); many cultural and operational indications of the ELC are a traditional feature of the Austria or Germany landscape approaches. Although they have not ratified the ELC yet, they work in the landscape according to the ELC aims.

In fact the Council of Europe has identified The Netherlands and Great Britain as countries in the forefront of its activation by the Council of Europe, (CoE, 2010, Table 1 and 3). Dealing with the ideal type of landscape culture they are (such as in the paragraphs 3):

— Interpreting the approaches taken by legislative, procedural, and planning tradition in guiding the landscape project;

— Identifying innovative instruments to evaluate, finance, and plan the landscape in order to help the EU and other countries to activate a process of landscape policy reform in line with the ELC.

4.2.**The ELC application**

This paragraph will compare the major ELC innovations to national and regional legislation in the countries represented in the study. The declinations and the different speeds with which countries implement the ELC are due to the diversity of European landscapes, all of which cannot be planned and managed in the same way at the various administrative levels involved in landscape government (starting with national and local responsibility), and the tradition of management

(See Table 3). It may be useful to consider some questions that represent useful "windows" for interpreting different cultural roads and results:

— The ratification of the ELC;

— The historical origin of landscape policies;

— The legislative, strategic and operative competence for the implementation of quality goals;

— The definition of "ad hoc" laws, created and/or revised in accordance with the ELC;

— The definition of new analytical tools and tools for action;

— The integration at various governmental levels of landscape and territorial policies;

— The consideration of landscape quality as the goal of territorial and sector policies;

— The social perception and participation in establishing goals and scenarios.

4.2.1. **Ratifications**

The ratification of the ELC is the first step in the experimentation of innovative actions, chiefly aimed at defining synergies for collaboration between public and private stakeholders for the promotion of awareness and the development of new landscape tools. These actions are necessary to reinforce the landscape quality of the territories and to promote reciprocal fertilization between the demand of the territories and the societies concerned (bottom-up), creating a national (top-down) vision, to obtain common and shared results from strategies and policies.

Ratification should be followed by programmatic and legislative innovations from the countries, with the corresponding differentiation in the cultural approach of the regions, adapting and integrating decisions taken at a higher level. The objective of the ELC and the states is to develop and consolidate relations between the various levels. The differentiation between the regions helps explain the "formal" non-adhesion to the ELC of Austria and Germany, who have been working for landscape on the basis of the ELC since the 1960's, but have not ratified the same at a federal level. The ratification of the ELC in fact, requires considerable national and/or federal powers, with legislative competence and/or competence in the management of territory and landscape.

4.2.2. Competencies

Different administrative fields of competence can be some of the most useful elements for interpreting recent experimentation with the ELC.

In Great Britain, the Department for Environment, Food, and Rural Affairs (Defra) ratified the ELC in 2006. Defra, Natural England and English Heritage are the principal institutional stakeholders who, with the Countryside Agency, lay down the guidelines for implementation (2007). They have promoted landscape strategy based on new relations with: strategic tools for governing landscape and spatial planning, to define land use which is compatible with the requirements of enhancement, and on which to base policies for an inclusive approach of social stakeholders. These actions aim to:

— Coordinate the implementation of the ELC on a national scale;

— Promote the public distribution of information and best practices;

— Integrate landscape in planning, the SEA and the local projects.

In the Netherlands two ministries have traditionally competence over landscape action: the Netherlands' Ministry of Housing, Physical Planning and Environment (VROM) – responsible for guaranteeing the integration of landscape strategies in physical planning at all governmental levels (national, provincial and local) – and the Ministry of Agriculture, management of nature and fisheries (LNV) – which controls the effects on landscape of rural development actions, biodiversity and planning open spaces. The Ministry VROM was merged with the Ministry of Transport, Public Works and Water Management into the new Ministry of Infrastructure and the Environment (MIE) on 14 October 2010, integrating much more urban and infrastructure policy and quality living actions. In fact, starting to the National Spatial Strategy 2011 the spatial policy tries to balance urban, rural and water management, environmental and safety actions, defining basic quality standards for landscape, water areas, buffer zones and green spaces in and around urban areas. The Ministry LNV was merged with the Dutch Ministry of Economic Affairs to form the new Ministry of Economic Affairs, Agriculture and Innovation (MEL&I) on 14 October 2010, contributing to reinforce the integration among economic, social and development of the quality of open territory and landscape.

The ministries worked in close collaboration and, since the 90's, have been the co-authors of national strategies for quality (such as the Landschap Agenda, 2008), the result of a process based on the assessment of social landscape perception.

In Germany and Austria, in the federal regulatory framework, the Lander are responsible for legislative, programmatic and operative landscape matters. These are characterised by a consolidated tradition in landscape planning and management, dating back to the common law of 1935 (Reichsnaturschutzgesetz, 1935), which laid foundations for the protection of nature and landscape in the post-war period (Ferry, 1994), although today this is no longer the case. In Austria, federal law requires that landscape plans and territorial government must correspond to various administrative levels, with subsequent national laws making the two tools independent. The landscape plan is a tool of protection, for the

functional and managerial organization of protected landscape-environmental areas and/or areas subject to considerable anthropic pressure, but it is an independent tool of territorial government and does not include urban areas.

In Germany however, since the 1970's the national Bundesnaturschutzgesetz (1976 and subsequent amendments) defines a common policy for the eco-compatible transformation and use of the territory. It lays the foundations for: going beyond the dichotomous vision of anthropic and natural environment, which characterized the origins of measures for protection; an evolution after establishing protected parts of landscape with significant value, to the definition of a specific discipline on use and transformation; establishing plans of action for landscapes. For this purpose, a system of landscape plans are envisaged – integrated at all levels of territorial government (federal, state, local) with territorial planning – and projects for including and/or limiting impact.

France and Italy are characterized by the separation of the protection of excellent landscape assets and the enhancement of the same.

In France – the paysage law of 08/01/1993 and decree no. 94.283-11/04/1994 directives de protection et de mise en valeur des paysages – gives the state the task of passing directives for the protection and enhancement of landscapes (excellent landscapes, art. 1), while local bodies draw up guidelines for the daily management – in the planning and project.

In addition to applying the Cultural Heritage and Landscape Code (2004 and subsequent amendments), the state in Italy protects the assets and values of the territory using Regional Superintendencies (Soprintendenze Regionali, responsible for the conservation of heritage and landscape), while the regional authorities implement policies for the enhancement and orientation of the transformation processes with the landscape plan. The Code introduces the action of protection with the creation of new values, disregarding the role of landscape in favour of economic development. There is the possibility that the regional landscape plan may be more effective on ordinary processes of territorial transformation (Peano, 2009b), in cases where the Code envisages the following contents of the plan: the limitation of land consumption, establishing guidelines for urban development, focus on rural landscapes and Unesco sites, the possibility of establishing guidelines and incentives for the project.

In Spain the competence, the approaches to landscape and the methods with which funds are made available vary notably from one comunidad autonoma (region) to another. The establishment of Landscape Observatories on a regional scale (such as in Andalusia, Cataluña, etc.) to promote awareness provides guidelines for implementation and integrates development and landscape policies, is an experiment worthy of note. The case of Cataluña is particularly interesting which, through the Observatory, set up in accordance with law 8 - 2005 (Ley de protecció, gestió the ordenació del paisatge), draws up a "catalogue" of

landscapes and develops a method of assessment for the integration of landscape goals in territorial strategies with the participation of social stakeholders.

4.2.3. Regulations

One of the main problems with the implementation of the ELC is the need to extend the action of landscape policies to include the entire territory. This requirement has obliged some countries – such as Italy – to reform the legislatory framework and the characteristics of governmental tools; in fact the approval of the Cultural Heritage and Landscape Code (2004 and subsequent amendments), extends the planning action to the entire territory including excellent, ordinary and degraded landscapes.

The new season of planning is very much focused on landscape (innovation in Sardinia, Piedmont, Veneto, Liguria, Tuscany, Umbria, Abruzzo, Molise, Apulia). In fact in the regions, starting with "the analysis of landscape characteristics, dictated by nature, history and the interrelations of the same" (art.143a) the positive and negative values of landscape are represented to provide guidelines for protection, planning and management.

Landscape planning, for the protection and enhancement of landscape assets, is organized in descriptive, constructive and prescriptive terms (art. 143); the historical, natural and aesthetic values of landscapes and their interrelations are established through knowledge of the same, to: identify the "ambits" (135, 2) and draw up regulations for landscape use and quality goals. The Code – interpreted in different ways by the various regional authorities – is subject to discussion and experimentation to: define State-regional agreements and establish new relations between the regional authorities and the Superintendencies for the relevant competence in the construction of the plan and procedures for authorization; the form of the plan and its relationship with territorial and local planning, responsibility for interventions; the form and contents of the regulatory framework of landscape plans.

Great Britain, the Netherlands, Spain and Denmark have failed to approve a specific law for governing landscape, with reference to various legislative documents and for the orientation of policies for the protection of nature, monuments and territorial governance. In 1993 France passed a landscape law (Law of 08/01/1993 for the protection and enhancement of landscapes, the so-called Loi Paysage), integrated by Decree no. 2006-1643 – 20/12/2006. The law of 2006, while partly implementing the ELC, makes a distinction between territory and landscape. Territory is "an administrative entity, and dealt with as such", to be managed and organized along common lines, although for individuals and the society living in the territory however "a landscape can be, and will be perceived subjectively, by an individual or social category". In comparison with the law of 1993, which made no clear distinction between territory and landscape, the new law provides an aesthetic-perceptive view of landscape. Furthermore, it

requires that the SCOT (regional plans) and PLU (local plans) must be compatible with the "directives for the protection and enhancement of landscapes", establishing indications for excellent landscapes. The most important part of the law concerns the management of rural environments and gives prefects extensive decision-making powers.

These innovations give institutional bodies more powers (top-down) in Central-Mediterranean countries, partly contradicting the spirit of the ELC, which promotes the involvement of the populations.

4.2.4. **Historical roots**

Landscape is in continuous transformation; it is a "metamorphic entity" (Pesci, 2004, page 13), which lets us interpret the culture of places or non-places and the historical evolution of the same. By interpreting the function and role of landscape, we can see the change in cultures and their ethical and social structures in the 20th century.

The origin of landscape theory, as well as regulatory and planning action, is the way in which a society has learned to acknowledge and reinvent lost "wilderness" (Zanzi, 2004, page 24). The origin of social sensitivity for landscape for the most part dates back to the middle of the 19th-century, as a reaction to major changes associated with processes of industrialization and urbanization as a consequence of poetry, literature and paintings created thanks to new possibilities for travelling (Bonesio, 2007, page 101). This sensitivity, then as now, has manifested itself in various forms in different countries.

In many cultures (such as in the Germanic-Anglo-Saxon world – the Netherlands, Great Britain, Germany and Austria) landscape policies aimed at promoting productivity and preserving diversity and quality stem from the conservation and management of agricultural land. In rural management – which can be found also in the terminological root of landscape – there is specific focus on protection and planning through a multi-scale project (on a vast and local scale). This project has influenced territorial government, generating regulations, plans and implementory tools (financial and managerial) with strategies for the organization and management of rural landscape. The rural root of the policies refers to a distinctly operational approach; the original operativeness can be seen in integrated policies for protection, planning and management, and in the complementary actions of the project (the creation of databases, guidelines, and in the study of economic resources).

From this common root- which developed by a different cultural, political-institutional, and procedural history- emerged the environmental issue, which gave birth to the search for interaction between the safeguarding natural and cultural contexts and the transformation of territory adapted to economic development. Territory and environment in the political-cultural and regulatory

histories are closely linked. This link is evident in the ecological-functional analysis of: the environment as a place from which man extracts the fundamental resources necessary for his own survival (Scazzosi, 1999, p. 18); nature and landscape as social and economic resources. These concepts explain the interrelation between territorial use and natural processes in sustainability policies. The integration between socio-economic and territorial development and the safeguarding of natural and landscape contexts is therefore the characterizing element of the Germanic-Anglo-Saxon tradition.

In Central-Mediterranean culture, the terminological root of paese (a land or town considered as a built-up area) corresponds in Italy and France to an action on the landscape to protect historical-cultural assets, and in Spain to conserve the physical, natural and "material" resources, necessary for the survival of man (see cultural movement of regeracionismo; Gòmez Mendoza, Ortega Cantero, 1999, p. 137). The principle of stock-taking assets, including new categories in time (from monuments to principal ecological-environmental values and systems), is still a characterizing element of the protective action, for which today landscape is a parallel/superimposed element of functional, perceptive and symbolic integration between the "systems of assets and values" in the/of the territory.

In Central-Mediterranean countries the cultural approach, created through the development of their legislative framework, a separation between the management of land uses for settlements and the conservation of the territories of exceptional ecologic, aesthetic, and historical-cultural value. In fact, even if by means of different cultural and technical paths, this separation has produced distinct and non-interrelated management tools: territorial planning and safeguard restrictions. However, in both cases, limitations characterized the conservation efforts that found, until recent years, some interaction with territorial planning, aimed essentially at the transformation of territory for socio-economic development.

4.2.5. Identification and assessment

The first result in the implementation of the ELC is the processes for the identification and assessment of landscape (art. 6c). In fact "landscape, in other words the relation in terms of aesthetic sense and investment, does not exist unless the relation with natural space is perceived, interpreted and produced by a specific culture, which in turn is the recipient of an image" (Bonesio, 2007, page 24). Interpretation and assessment of landscape are the first operations in the selection process to define landscape guidelines and projects. Landscape assessment goes in this essential direction, and must be an argumentative process for the identification of positive and negative values for planning policies, to be created thanks to dialogue with the stakeholders and populations concerned (Brunetta and Voghera, 2008). The shared perception and representation of a landscape, through the social legitimation of values and criticalities, can only be guaranteed through a process of assessment. Despite the diffusion of good practices to identify landscapes (such as the International ECOVAST), a clear

methodology is required to define a structured program of actions for sustainability – starting from the legitimation of "values".

The assessment of landscapes must become the tool on which decisions are made and for communicating quality goals of landscape and territorial planning (CoE, 2008, Recommendation for the implementation of the ELC). In this direction, the most consolidated experiences are represented by Landscape Atlases (Peano, 2009a) or Landscape inventories set up years ago in many national contexts to identify landscapes on a vast scale (national or regional), through landscape units as in France, the Netherlands, Slovenia, France, Great Britain, Denmark and Germany. These methods of analysis attempt to integrate the objective and subjective descriptions associated with collective imagination and sensitivity for the places in question.

Jacobs (2002) on this subject mentions that there are two main approaches to research for the interpretation of landscape: "the descriptions in and of the landscape" (Tress B., Tress G., Fry, 2006, page 15). The first approach hails to the methods established by natural sciences from Descartes on, and makes a distinction between the subjective and objective dimension, separating the populations from the landscape as the context in which they live their daily life. The second "constructivist" approach is related to social sciences and acknowledges that landscape is constructed through daily interaction with society; this second approach puts greater focus on the values associated with the sphere of subjectivity such as sustainability, livability, beauty, utilization value and the potential value connected with possible future transformations.

The descriptive experiences, developed in European countries, are based too often on the first approach. In fact, we are still far from a real and effective involvement of the local social and economic stakeholders.

Furthermore, while these experiences appear to be effective in describing landscapes, they do not however represent the dynamics and trends associated with socioeconomic and territorial processes and are therefore all but ineffective for outlining prospects for action.

The most interesting methods have been developed in north European countries with a more consolidated landscape tradition. In Norway, Denmark, England and Wales there is widespread use of fact-finding GIS database systems to describe and distribute information on landscape as a "cultural environment", which constitutes a spatially delimited area the characteristics of which depend on the society that created and continues to use and transform the same (Etting and Møller, 1997). These methods have a similar approach as they develop a repeatable system of analysis, consistent in the quantity of data and qualitative type assessments, characterized by the focus on the relations between the historical-cultural characters of the places and landscape from an ecological-environmental point of view (Møller, Stenak, 2006). There is need for greater

integration with the planning tools used for the territory and landscape, and with those used to support the assessment processes (in particular the EIA).

Germany, Austria, Great Britain and the Netherlands base action for landscape on description and assessment. Guidelines and projects, coherent with the expectations for development of the socioeconomic stakeholders, are based on knowledge of the landscape. The result is landscape planning used as a concerted tool for the quality of landscapes. In these countries, the process of assessment is based on techniques that attribute judgments and degrees of value to the landscape units or ambits and – through the association of qualitative criteria and quantitative parameters – define strategies and interventions (Landscape and Historic Character Assessment in Great Britain, assessments on a Land scale for German landscape plans, Wardewolle Cultuurlandschap or the monitoring of perception and landscape appreciation in the Netherlands). Landscape guidelines are a strategic tool for the orientation of policies and projects in Great Britain, and are the source of the process of negotiations between public and private stakeholders to define common actions (such as the Village Design Statement).

There are also interesting attempts at innovation in France. The Atlases and the Charte Paysagère interpret current landscapes characters, the dynamics of socio-economic and territorial transformation, the pressures to define operational indications, based on paysage directives (for the transformation of excellent landscapes) and the territory plans of government.

In Germany however, the contents of landscape planning, coordinated on all administrative levels with territorial programs and plans, are defined by a complex mechanism of inter-institutional cooperation and, on the local scale, with social participation. Landscape assessment at every level of planning develops in the following phases (Brunetta and Voghera, 2008): description of the characters and state of use; qualitative and quantitative definition of goals for protection and enhancement; assessment of the state of use in relation to the goals; establishing criteria for action.

From the construction of analytical and interpretative landscape tools, landscape planning provides a framework of planning, economic-managerial lines and indications for the enhancement of landscapes, which involve local subjects in actions of sustainability, defining a territory and landscape project for biodiversity, the use and mitigation of anthropic pressures.

In Spain there has also been some experience in the assessment of landscapes with reference to the National landscape atlas Atlas de los paisajes de España (2002) and the Plan nacional por los paisajes culturales (Salamanca2002), for the long-term transformation and enhancement of cultural landscapes, through measures for the management of natural, rural and urban territories.

The Atlas divides the territory into characterizing landscape units, landscape types and associations starting with the interpretation of land use, dynamics, values and

perception. Furthermore, to support landscape planning, the Spanish Ministerio de Medio Ambiente has drawn up a Guide for the assessment of natural, ecological-perceptive characters and land use of the territorial landscapes; the assessment methodology interprets the value of landscape using qualitative and quantitative type indicators. Some significant components of the landscape such as the ecological fragility and visual quality are evaluated, integrating the vision of the experts with that of the population in different phases. The intention is to describe the landscapes using the more qualitatively interesting and integral values and aspects to the best effect in the construction of policies for protection and/or enhancement.

4.2.6. Integration and participation

Landscape studies are based on three major systems (Jacobs, 2006, page 11): Matterscape, Powerscape and Mindscape. Initially based on a reworking of the theory of Habermas (1984), the focus in each case is on:

— The real or objective world (Matterscape);

— The regulatory sphere (Powerscape), which depends on the indications, regulations and policies as a whole;

— The system of perception and thought, which derives from the expectations and emotions of the populations living in and visiting a certain landscape (Mindscape).

The ELC on the other hand indicates that the landscape derives from:

— Its objective characters, the ecological-environmental, historical-cultural and settlement aspects, land and economic use;

– The regulatory and political processes as a whole, which contribute to its continuous re-construction;

— The social perception of positive and negative values and policies.

Landscape studies and policies must both integrate these systems. It is only through integration on all levels of territorial government between materiality, rules and perception of the landscape that we can draw up plans and projects to establish shared visions for the daily management of landscapes.

Nevertheless, the landscape object is all too often interpreted as the passive effect of policies and processes based on plans and strategies that do not give due consideration to the populations. An important step in this direction can be the assessment for the explicit definition of values and criteria for selection, to identify quality goals for planning and management (Brunetta and Voghera, 2008). Participation plays a central role in the process of assessment because it is

a tool of communication and support to integrate decisions and policies, as well as acknowledge shared values and identify possible planning scenarios.

The integration of policies and the participation of populations (CoE, 2006) are in fact key aspects in the implementation of the ELC. The integration of policies must be interpreted as: integration of European recommendations in national strategies, inclusion of landscape in sector planning and policies (art. 5d).

Integration must envisage the construction of strategies and actions, which are coherent on various levels and allow for different landscape and territorial contexts, as well as also economic goals and resources, and the processes regulated by the plans. This integration requires also a different model for the construction of decisions, through extensive social participation.

In this sense the Dutch model is in line with the idea of the integration of policies indicated by the ELC. In fact, in the Netherlands the latest landscape policies are drawn up with a significant amount of information gathered on the social perception and appreciation of landscapes. To assess the social perception and appreciation of landscapes, a GIS model was developed to combine the data on the physical-morphological characteristics, land use, and historical-cultural information with data on appreciation of the aesthetic qualities obtained in interviews carried out in 2006 on a sample of 4,500 people (Farjon, 2007). This method made it possible to test the effective representation of landscapes with a national value, subject to actions of enhancement, to define shared strategies as in the Agenda Landschap (2008); this is a strategy for the enhancement of landscape, structured on the basis of types of action (rural environments, urban landscapes, green and protected areas, etc.), based on a programmatic-operational model which associates economic resources and responsibilities for implementation on the various scales of government with the actions - in accordance with the budget-programming system (Faludi, 1994). Landscape policies are therefore the result of a shared process, starting on a local scale, and implemented in the project.

In Germany, integration between landscape choices is guaranteed by construction in mutual coherence of strategies and goals for landscape and territory plans, from the national to the local scale. The planning and management of the English landscape is also characterized by a system of coherent strategies at various administrative levels; through the assessment, methodologically consolidated and based on participation, shared guidelines are defined, to be implemented in plans and projects.

Also in Denmark there is an interesting example of participative approach for defining landscape visions; the study combined scenario technique, photorealistic visualisation and stakeholder participation to identify the interests of stakeholders in the future countryside (Tress & Tress, 2003). Scenario visualisation by photorealistic design techniques proved to be a helpful tool for researchers in communicating the proposed landscape changes to stakeholders.

While research into the integration of policies for landscapes and for the development of the territory is a common element of Germanic-Anglo-Saxon tradition, there are significant differences in terms of social participation.

The Aarhus Convention (UNECE, 1998) identifies three occasions in which participation is necessary for:

— Decisions concerning specific activities,

— The construction of plans, programs and policies,

— The preparation of laws and regulations.

It indicates that the "public" must be informed effectively and in good time, to be able to analyse the proposals and express an opinion in verbal and/or written form, and exercise their own influence; it is only through a process such as this, with interesting applications in Great Britain, that the decisions taken can be considered the result of a process of public participation.

There are different forms of participation for making shared choices (CoE, 2006):

— Public discussions to assess studies on landscape impact (as in Belgium);

— Public communication of the results of the studies on impact or on scenarios of transformation (as in France);

— Written public observations on plans or scenarios for the transformation of landscape (as in Spain, Italy, Austria, ...);

— Discussions with the population for the construction of landscape scenarios (The Netherlands, Germany, Great Britain);

— The organization of a public referendum on landscape choices (in Turkey and France).

Great Britain, the Netherlands and Germany have consolidated experience in the promotion of awareness and the education of economic operators and the population, more frequently involved in maintenance and management (especially farmers). It is only in the Netherlands that landscape strategies, implemented in physical planning, are based on the negotiated construction of decisions taken with institutions, economic and social stakeholders from the phase for the identification of the values of landscape identity and appreciation, to the operational phase. However there is greater focus in both the Netherlands and Great Britain on the "strategic" dimension in the vast area of landscape policies, from which also actions on a local scale derive. On a local scale, actions for protection, enhancement and planning concern the ecological, aesthetic-perceptive and physical quality of small town centres or rural territories (UK Village Design Statement), where it is easier to involve the populations. The town and its private

and public spaces are in fact too marginally involved in landscape enhancement and innovation processes.

5. The Dutch and United Kingdom study case

5.1. Policies for landscape and the Agenda Landschap

Without a national physical planning document until after the Second World War, strategies for rural development were used to define action to be taken for landscape. Because measures for protection and fruition of the territory are intimately related to the agricultural-productive exploitation of the territory, the Law for development of agricultural territory (1924, revised in 1938) promoted largely innovative improvement programs and land reorganization.

Conservation of the historic-cultural character of agricultural landscapes by including production has become the central aim of agricultural economic diversification projects that play an important role in the ecology and identity of the territory. Local landscape plans (Advieslandschapsbouw) for rural landscapes have been experimented with and are co-ordinated by provincial Structural Plans for Landscape (Landschapsstruktuurplannen). Both of these instruments are "voluntary" and are used to solve specific problems (ecological, aesthetic, fruition, production) and are activated through local urban plans (bestemmingsplans).

During the 1970s the policy for landscape quality became an integral part of the all-inclusive territorial and environmental valorisation strategy and were included in physical planning at the various levels of territorial government. In fact, the policies are applied in:

— Ministry of Economic Affairs, Agriculture and Innovation (MEL&I) (MEL&I) strategies to rationalise agriculture;

— Ministry of Infrastructure and the Environment (MIE) action on the government of the territory;

— Specific measures to protect historic-cultural monuments by the Ministry of Education, Culture, and Science;

— Valorisation and transformation projects defined by physical planning (national, provincial, and local).

Each ministry published its own policies through "memorandum documents" for decades. Each document defined partially co-ordinated strategies identifying their own management and protection categories.

Moreover, an ad hoc law for the landscape has never been passed while theoretical references and objectives for its valorisation are found in the

Conservation of Nature Act, the Land Redevelopment Act, and in the Physical Planning laws (1965, 1985, revised 2008).

Landscape objectives are expressed in various documents, programs, and economic resources contributing to:

— The construction and development of landscape including through reclamation in order to satisfy demand for land for residential and economic-productive uses.

— Maintaining and valorising existing landscapes from the ecological-environmental and historical-cultural points of view.

These needs are reflected in the physical planning (at local and provincial levels), responsible for co-ordinating the landscape policies. The rules, planning choices, financial conditions, and the responsibilities for putting the policies into practice are defined in the physical planning.

The Agenda Landschap (2008) is an innovative national strategy promoting policies and transformations to protect, plan, and manage both excellent and ordinary rural and urban landscapes, starting from the study of social appreciation of the landscape (see section 1.2). This document follows the ratification of the European Landscape Convention (2002), and integrates the sectorial landscape policies and identifies financial resources, instruments, and responsibilities in order to guarantee their implementation. In applying the Agenda Landschap, The Netherlands reinforces the interesting experimentation with policies and operating methods (such as the Dutch Landscape Funding Task Force) initiated in part in the 1990s.

5.1.2. From the Appreciation index to a landscape strategy

Evaluation of the social appreciation of landscapes forms an essential preliminary study used by the Agenda Landschap. A GIS model that combines data for the physical-morphological features with data for appreciation of the aesthetic quality was used to evaluate perception and social appreciation of landscapes. Perception of the physical features was evaluated by interviews carried out in 2006 on a sample of 4500 people (representative by age, income, education, interests, etc. who had already replied to the SPEL questionnaire for social evaluation of landscape answered every twenty years; Coeterier, 2001). The study sample was invited to vote for the landscape in 300 areas identified in 15 photographs, selected because they represent the physical aspects that condition social perception.

Since appreciation decreases the further away from home the landscape is, the study shows the degree to which Dutch society appreciates the landscape of their place of residence. Furthermore, the high-income earners sampled evaluate the landscape of their residence positively: the naturalness, rurality, peace and quiet, and visual coherence of flat landscapes.

Social factors influencing perception are: age, income, and origin. The elderly appreciate the landscape quality more while natives attribute greater value to the landscape of residence with which they have a fruitful relationship every day, frequenting it for recreational purposes too. In addition, the promotion of the landscapes in the media influences appreciation, especially the rural and natural ones.

The relationship between physical features in the landscape and attractions was studied using a GIS system according to the following formula (Farjon, 2007):

ATTRACTION = 1.129 + 0.4 (quantity of natural areas) + 0.09 ("spontaneity" of nature) + 0.11 (historic identity) + 0.06 (height of the relief) + 0.07 (quantity of water) + 0.17 (unity)

The calculation shows that the physical factors influencing landscape appreciation are: naturalness, unity, historic identity (recognized by protective measures), and absence of urbanisation or rurality correlated with naturalness. These indicators have made it possible to map the influence of physical factors on landscape perception nationally.

This analysis is useful also to read the role of changes in landscape (such as fragmentation, urbanization increment, pressures in rural areas, changes in farming). In fact they are affecting people that derive a large part of their identity from the landscape in which they grew up, but numerous developments have steadily weakened their ties with that landscape.

From the appreciation index the government knows that the state of the landscape quality has a score of 7.3 in a 10 scale. The Government's aim with the Landscape Agenda (2008) is to raise that score to 8.0 by 2020. The objective is to achieve an attractive and varied landscape in which people are able to carry out their living activities was at the same time enjoying the landscape. The following three tasks are intended to give direction to this goal:

-"Careful use of space", in order to consider the scarcity of space in decision-making, in spatial planning and in building activities. The accessibility of and a recreational opportunities offered by the landscape need to be increased to develop green spaces for people and preventing and remedying the cluttering of the landscape. Also a set of clear rules to transform landscape is needed (such as innovative solutions in the landscape),

- "A landscape of and for everyone" that has a role to play in thinking about the landscape, taking action for the landscape, and paying for the landscape. Particularly the business community that can also do a great deal about the landscape, reducing the distance with/to citizens, investing in the (green) living environment and ensuring it is well maintained and managed will make it more attractive for everyone.

- "Sustainable funding of the landscape", integrating private donations, gifts and contributions. However, the government funds far and away the largest part of the expenditure on landscape consolidation and management. New ways of funding at regional level are being explored in four pilot areas and at national level, the government has installed a Task Force which has issued recommendations on the sustainable funding of landscape consolidation and management.

This strategy could innovate the landscape policy, responding to the actual landscape problems and weaknesses in ELC policy implementation.

OBJECTIVE	TASK	ACTION	When	By whom *
Careful use of space	Clear rules for maintaining city/countryside balance	Start pilots detailing core qualities at area level	2009	MIE/ MEL&I , provinces and municipalities
		Symposium on building in National Landscapes	2009	MIE
		Restoration management by Staatsbosbeheer in National Landscapes	2009-2013	Staatsbosbeheer/ MEL&I
		Complete the study of simplification of area categories.	2010	MIE, provinces and municipalities
		A spatial framework for areas with a green recreational function	2009	MIE/ MEL&I
		Integral policy evaluation for National Landscapes	2010	MEL&I /MIE
	More green space for people	Decision to expand National Buffer Zones and initiate public-private implementation partnership	2008	MIE/ MEL&I, provinces, business community
		Exploration of green key projects	2009	MIE
		Include connecting nature with landscape in the brief for *IBO on nature	2009	MEL&I
	Promote innovation, design and quality	Subsidise innovation and specific projects to improve green space near the cities via the Attractive Netherlands innovation programme	2009-2012	MIE
		Introduce landscape protocols	2010	MEL&I /OCW
		Last use of LOP by municipalities.	March 2009	Municipalities
		New landscape quality incentive scheme for municipalities, focused more on implementation and integration	2010	MEL&I, municipalities

Table 2. Actions from the Agenda Landschap (2008), updated and integrated by the author.

5.1.3. Implementation of the landscape policies

The Dutch experience is distinguished by the defining of action programs for landscapes in line with the strengthened.

Convention in which social, economic, ecological, and aesthetic aims converge. This integration is mainly the result of participation of social, economic, and institutional actors in defining the programs and projects for developing new landscape values that correspond to a precise subdivision of responsibility between the actors involved in their activation and management:

— Institutional actors, especially the provinces, who co-ordinate the negotiated development of valorization policy and provide up to 75% of the finance required, with the balance being made up by central government;

— The economic operators who must invest in the landscape and co-finance projects as environmental compensation;

— The social actors prepared to pay local and national taxes (Landschap Taxxes of 2% of the local tax and 0.2% of the national tax are set aside for landscape projects, 60 Euro per person, 2008) that are used to valorise landscapes, factors of identity, and quality of life.

Social participation is essential in the Agenda Landschap in order to initiate landscape action not only through the campaign to evaluate social appreciation and sensitisation, but also in the methods used to define plans and projects.

This approach is strictly related to the Dutch planning culture. Innes and Booher (1997, page 7) talk of "a process of constructing a consensus is required in order to allow the society and national policies to adapt and respond effectively to transformation of collective needs". An efficient participative process must construct networks and a feedback system that makes it possible to understand the landscape and environmental changes. The failure arises out of agreements between local actors based on inadequate discussion or consideration of the relationships and values on which the collective identity or processes in which the participants use their dominant position to divide the parties affected and maximize their own benefits. Unfortunately, this is also what has happened in the Netherlands in recent years, as social participation in construction of policies and projects has too often been a formal requirement but not a substantive part of the process. The provinces and the economic actors (large companies) have operated independently, guiding the negotiation process and controlling the choice of local actors (local authority and people) with evident effects on the effectiveness of landscape policies.

In spite of the strategies for improving its quality, landscape is becoming increasingly fragmented (Landscape Cluttering) as the pressure from suburbs and motorways has increased in recent years in the form of separate projects (individual transformations or groups of microurban transformations) according to an apparently casual model. Landscape Cluttering is the unintentional result of the objectives of various uncoordinated bestemmingsplan (local plans) in addition to expansion of the suburbs and poor integration of rural development programmes and landscape planning (Landscape Development plans). These have produced new building, greenhouses, windmills, motocross sites, camping sites, plant nurseries, and fish-breeding ponds causing the traditional open landscape to disappear and compromise the historic landscape of polders, protected by The Belvedere Memorandum.

The Landscape Perception Monitoring Program has also studied this phenomenon and has identified the areas affected, which are largely composed of the northern part of the province of Noord-Holland, Noord-Brabant, and Limberg in Randstad Holland in addition to the provinces of Overijssel and Gelderland (characterised by protected historic landscapes). In fact, between 1990 and 2000, 31,000 hectares of open space were swallowed up by urban development and periurbanisation in rural areas relating to the new composition of the family (singles, the elderly) and the growing demand for housing in open spaces.

Today climate change has resulted in the need to rethink methods and techniques of water drainage, dyking, and flood protection and this provides new opportunities to make the landscape "more attractive" but this needs the co-ordination of protection and creation of landscapes provided for in the physical plan to be strengthened. The current reform of the Physical Planning Act (2008) follows in this direction by assigning specific jobs in checking the landscape quality at provincial level, for example, co-ordination and checking of the sustainability of local plans and projects. In fact, notwithstanding that the

bestemmingsplan refer to national and provincial directions in valorisation, it is at the local level of the bestemmingsplan, responsible for controlling the landscape project, that the greatest criticalities are found, which have initiated territorial transformations including some near "protected landscapes" and above all in the fringes bordering the Randstad and Green Heart that lack landscape placement and preliminary evaluation of their sustainability.

Agenda for a living contryside (2006) also follows in this direction. This is promoted by the ex Ministry of Agriculture, Nature, and Food Quality (LNV) to help Provinces activate landscape policies. In particular, the government has decided to allocate 3.2 million Euros to strengthen the structure of the landscape and in particular to guide landscape placement of motorways (Motorway route design programme) as well as transformations of the Green Heart and protected national landscapes. The document dwells on protecting the view along the motorway in suburban areas between city and countryside (involving the ex VROM, Ministry of Transport, Ministry of Public Works and Water Management, Ministry of Economic Affairs, and the Ministry of Education, Culture and Science). The Provinces are responsible for protecting the views and are behind in reviewing and revising their plans and in controlling local planning (Netherland Environmental Assessment Agency, Nature Balance, 2007). In fact, the Provinces should have proceeded with the redefinition of the boundaries of protected landscapes identified at national level from the The Belvedere and the V Note (2001) so that urban areas are excluded from prevalently rural tracts of territory susceptible to future expansion (20 landscapes selected). This choice arose out of two interrelated questions: the aim of keeping the structural features, the integrity of the values, and the views present in the protected landscapes; negotiating "neutral borders" with the Provinces, that is, flexible areas shared by the Local Authorities to be developed in the provincial plans by planning at local level in order to guarantee "sustainable" management. However, this aspect is now strongly criticised, because in the absence of appropriate recognizable development and appropriate information and advice for planning and managing this landscape at the provincial level, the local authorities have been and are promoting transformation projects in border areas of many of the National Landscapes due to the natural growth of the population and commercial enterprises with a resulting impact on the value and openness of the views "from ordinary territory".

Tribunal has suspended some bestemmingsplan for the absence of criteria to guide the projects of new buildings in the boundary areas and for the lack of local and regional planning regulations (Sources: Provinces of Utrecht, Zuid-Holland, Zeeland, and Noord-Brabant, 2007; Statistics The Netherlands, 2003).

From this point of view improved integration between physical planning and government of the landscape is required, especially at provincial level. As seen in several case studies, the provincial governments play a crucial role in integrating and co-ordinating policies.

In fact, poor integration of development and protection of the landscapes is seen in the National Landscape of Arkemheen-Eemland where new residential developments have been provided for to balance a fall in the number of dwellings and lack of financing by getting other public organisations on board through negotiation between national and provincial governments. The only effect has been the decision to keep expansion outside the boundaries of the national landscape, but this has allowed radical transformation of the views and quality features in this "extremely open" territory. Not only has planning information of large areas not been activated in Arkemheen-Eemland but conflicts have also arisen between the decision-making processes with inevitableconsequences on the planning of the objectives and resources (case programmes, National Landscape, disposal of materials).

Planning paying attention to landscape can be seen in the integrated plan for the regions of Ijssel and Veluwe, Gelderland for which the Provincial Government studied options for the transfer of companies in the recreation-tourist sectors that affect the wild fauna in less sensitive areas.

The public and private actors in both the IJssel delta and Veluwe, involved in the process of defining the local plan, have initiated experiments to improve the integration of territorial and sectorial planning. The integrated planning of the territory (functions and uses) has brought about a coherent plan with individual elements/values. On the one hand, the territorial and landscape restraints and on the other the construction of significant infrastructure (such as Hanzelijn, a new motorway and railway connection) have proved to be important incentives in adopting an integrated approach. Furthermore, the "protected River space" provided for by V Note prohibits building in the IJssel delta and Nature 2000 also limited expansion of recreational activities in the Veluwe region.

The development of a general strategy at provincial level co-ordinating local choices has made it possible to activate national directions to the benefit of the landscape.

Although an integrated approach is able to provide added value, this occurs at the expense of sectorial objectives. The cases demonstrate the strategic role of the provincial governments in evaluating the conflict between the planned objectives of valorisation of the landscape quality and the uses of the territory provided for in the local plans.

The new Territorial Planning law being developed strengthens the role of the central and provincial government in landscape policy. The conditions for expansion of settlement in National Landscapes and in their border areas need to be attached to the plans, compensation provided, and the building of new housing and commercial sites limited. The initiative strengthens the provincial level by obliging the local authorities to take the preparation of local plans into consideration.

The Beautiful Netherlands2 project is also one of the current priority policies of the ex VROM Ministry (2008).

It promotes actions to oppose landscape fragmentation. Landscape fragmentation can be opposed through specific actions but above all by using knowledge of the value and disvalue of landscapes. The Ministry intends to use the project to stimulate public debate on this topic and involve the population in perceiving the landscape, as required by the ELC, and in creating new landscape values (dissemination of information, identification of possible scenarios involving local actors). By using the shared knowledge of the values diffused among the population, the ex VROM Ministry feels it can activate local control of landscape transformations and stimulate opposition to local plans and actions that may cause irreversible damage to the landscape.

5.2. Evaluation to participative planning in Great Britain

5.2.1. Historical roots of landscape protection

Landscape protection in England originated in the first half of the 19th century in policies for the countryside that aimed at promoting interaction between technical-agricultural development and protection of the natural and historic-cultural environment. This interaction permeates the national history of the protection movement that, influenced by romantic ideas, addresses the planning of new urban settlements in equilibrium with the countryside that finds reference in the garden-city projects of Howard and in the protection and management of public use of historic rural landscapes. In fact, the movement to protect rural landscape developed under the guidance of Ruskin who tried to find an appropriate equilibrium between economic needs, modernisation of production techniques, and the safeguarding and management of the ecological-landscape integrity of the countryside in order to promote its public enjoyment. At the same time the most significant experiments, integrating urban settlement and the simultaneous protection of nature and the agrarian landscape, lie in the garden city projects of Howard. In fact, the garden-city concept is connected with the need to plan new urban nuclei – to control the disorderly growth of the industrial city and to guarantee better living conditions for the workers – defending green spaces and peri-urban agriculture (Howard, 1898). The conservation of rural and natural landscape is strictly integrated with the design of the built city while simultaneously meeting the need to contain urban development, self-sufficiency in food production in the city, and improve the quality of the environment and life.

The integration of technical-agricultural use and enjoyment compatible with the ecological and aesthetic equilibrium of the natural, rural, and urban environment has therefore been the most important characteristic in the English tradition from the very beginning.

Conservation is always included in the landscape valorisation project.

This cultural tradition found its first institutional regulation in the Town and Country Planning Act (1947), in the Scott Report of the Committee on Land Utilisation in Rural Areas (1942), and in the National Park and Access to the Countryside Act (1949) that were the first legislative framework to protect nature. These laws activated experiments with innovative national programs that assigned the local development plans with the job of guaranteeing compatibility between initiatives to protect and manage protected areas and conservation policies of agricultural land use and the system of farms, essential for the care of the landscape and local economic development.

With the setting up of the Department of Environment (DoE) (1970), now replaced by the Department of the Environment, Food, and Rural Affairs (Defra), and by the Countryside Commission, the need to strengthen interaction between economic growth and attractivity in the local rural context by protecting the landscape became priority, which has favored diversification, combating the growing phenomenon of depopulation and an aging population. Policies provided with economic resources have been closely co-ordinated: helping the local community to provide services for public enjoyment and reorganise accessibility to protected rural landscapes (Countryside Act, 1968); setting up experiments of agricultural practice compatible with the ecological equilibrium of the fragile natural environments; and projects to diversify the companies in the hospitality sector (New Agricultural Landscape, 1977). This is the context in which strategic planning in the landscape sector was conceived in order to orient transformation projects eco-compatible with landscapes and to diversify the economy of rural territories: the landscape guidelines, developed by processing identification and evaluation of landscape (landscape assessments; Countryside Commission, 1987).

The guidelines are based on the dynamic dimension of landscapes that accompany the evolution of rural landscape in social, economic, and environmental transformations.

5.2.2. Evaluation and planning

In anticipation of the ELC, strategic planning in the landscape sector has extended protection to the entire territory and makes it an integral part of the complex project of managing sustainable use of environmental resources.

In fact, sustainable use of environmental resources and of the landscape in the countryside has been at the centre of national policy for territorial protection and development since the end of the 1980s. Indeed, it is the central government, co-ordinated by the British Government Panel on Sustainable Development and by the UK Round Table on Sustainable Development that provides the impulse to produce strategies and directions for sustainable development in the territory and landscape. Since 1997 the National Planning Policy Guidance (PPGs) notes, recently replaced by the National Planning Policy Statement and the Regional Spatial Strategies (Planning and Compulsory Purchase Act of 2004), has through a process of participation of institutional actors defined environmental, landscape,

and life quality strategies by valorising nature and landscape as a condition for regional development.

These strategies are the outcome of consultation with institutional actors and associations with responsibility for government of the territory and have been strengthened – by approval of the Planning White Paper (2007), the programs being defined more clearly, more effectively, and able to operate at local (Local Development Frameworks) and regional level (Regional Spatial Strategy).

The definition of the Planning Policy Statement (from 2007; for example in 2007 especially action strategy no.7 – Sustainable Development in Rural Areas) has oriented valorization of the landscape in this direction by basing it on national evaluation of the landscape (Landscape Character Assessment, LCA) that is characterised by an ample process of social participation, co-ordinated by the English Countryside Agency and by Scottish Natural Heritage. Today this activity is the first effect resulting from activating the ELC. Through knowledge of the features and values of the landscape, directions for planning the development and managing the use of the territory are defined, which help strengthen the quality and features in the landscape. The strategies now required are the substitution of the institutional procedures of new protected areas with criteria for the protection, use, and valorisation of the landscape founded on identification of its value and features using the LCA.

5.2.3 Instruments and methods

The evaluation and resulting strategies for the landscape are considered to be the most effective method of conservation and valorisation of the territory. In fact, in measuring landscape capacity and sensitivity, the aim of LCA Guidance (Swanwick, 2002) is to contribute to finding solutions to organising the territory not only compatible with the ability to support the various types of transformation but also capable of creating a new identity.

The evaluation provides the knowledge required to identify and define measures to evaluate the landscape at different territorial levels (local/district, regional, and national). On the large scale the geographical and morphological structure of the territory can be catalogued while on the local scale transformation measures and plans can be defined. The common goal at each territorial level is to define landscape protection and management policies in order to promote ecological and aesthetic quality. In fact, the evaluation subdivides the national territory into patterns (landscape units), recognisable and distinct in the colors and progressive numeration used. The patterns are then subject to further examination in the process of analysis (classification) at smaller scale (county or district) with character types being identified by combining the morphological, natural, and historic-settlement aspects. Initial indication emerge from the evaluation of very large areas for the succeeding process of qualification and legitimation of the values and development of guidelines that are put into practice in the local plans, in the transformations contained in the Village Design Statements, in the Countryside Character Programs, and in the projects.

The method used refers to national criteria: an initial phase of knowledge gathering and classification of the landscape unit known as landscape description, followed by a second phase of evaluation of the condition of the landscape and environmental structure known as landscape evaluation, and thirdly the knowledge acquired is used to define measures to safeguard, manage, and plan projects for the landscape known as landscape guidelines. The Landscape guidelines refer to planning at different scales and are a strategic instrument orienting the landscape transformations (Swanwick, 2002):

— Conservation of areas of particular historic, landscape, or ecological importance in what is known as conservancy strategy;

— Valorisation of degraded or abandoned landscapes in what is called enhancement strategy using restoration, reconstruction, and creation projects for new landscape forms that respond to functional and aesthetic needs.

The approach to landscape evaluation is based on conservation and strengthening of historic, ecological, perceptive, and economic values of various types and areas of landscape, through direct survey and written description. The current state of the landscape is examined (condition and integrity of the elements) and the processes, dynamics, trends, and potential pressures caused by development scenarios are evaluated.

This process passes from the determination of ability to support and respond to transformation in the long term (Landscape Capacity – LC) for each type of landscape by improving the ecological and visual quality and the economic use of landscape resources. Landscape capacity is the ability of every landscape type or area to support the pressure associated with processes of territorial transformation (such as development of settlements and infrastructure, changes in land use, introduction of new ecological elements such as areas designated for planting, rows of crops and trees, etc.).

An aspect correlated with the process of landscape evaluation is landscape sensitivity, stability of the landscape values and features, and ability to recover from any losses and/or damage. High sensitivity values, which if compromised are difficult to recover, correspond to the need for a specific policy.

This indicator is used in the Landscape and Visual Impact Assessment (LVIA), an essential component of Environmental Impact Assessment, useful in checking, evaluating, mitigating, and/or compensating the impacts on the landscape produced by the transformations. Evaluation of the sensitivity involves various methodological considerations:

— Some values have greater weight in certain types of landscape that must be expressed in the process of evaluation and identification (landscape characterisation);

— Some features and elements are more vulnerable than other;

— The ability to support the anthropic pressure and/or react/recover from notably varied stimuli and demands in each type of landscape.

Sensitivity makes it possible to evaluate the relationship between pressure generated by the policies of transformation and development, and various features of the landscape such as: the significance, vulnerability, substitutability, stability, and resilience of the landscape compared to the planning choices (Swanwick, 2002). The techniques used for the evaluation must of necessity be in proportion to the scale and type of planning (strategic, landscape, land use) with which the landscape is evaluated.

From this point of view three methodologies are used to evaluate landscape and orient decision-making in governing the territory:

— Determination of the overall landscape sensitivity, which is a function of the characteristic sensitivity of each individual landscape resource and the visual ones independent of the type of transformation planned. It is usually used to prepare strategies for large regional or sub-regional territorial areas or for LVIA;

— Identification of the sensitivity to a specific type of development or transformation. This is given by the interaction of the landscape, its values and features, and the way in which the population perceives the proposed transformations;

— Measurement of the Landscape Capacity (LC), ability to respond to different processes of territorial government. LC depends on the sensitivity to visual, general, and specific transformation of the individual elements in the landscape. The LC is used to evaluate the effects of relevant anthropic transformation policies in the territory such as introducing wind farms, infrastructure, and development of settlements (such as the building of at least 1000 new dwellings).

5.2.4. Instruments used to activate the Convention

Great Britain led the process of preparing for the ELC through Michael Dower, Director General of the Countryside Commission (1992-1996). Since its reception in Great Britain in March 2007, the ELC has caused serious reflection on the policies and methods in protecting, planning, and managing the landscape in order to adopt the new ideas, strengthen the subsidiarity of the landscape choices and develop methodologies to interpret the “subjective” component of the perception of the population. Characterized by a very decentralised territorial planning and management system, Great Britain based the activation of the Convention on the interaction of DEFRA, English Heritage (EH), and Natural England (NE) in the framework provided by the England Project Group (EPG) who drew up a

document: European Landscape Convention – A Framework for Implementation (2007, 2009).

The document responds to the need to conserve the value of landscape in its current condition, especially rural ones (91% of the sample interviewed by the Countryside Agency) by applying planning actions by 2020 (Countryside Agency, Scottish Natural Heritage, Landscape character Assessment guidance for England and Scotland). These actions are the result of work by the commission composed of DEFRA, NE, and EH, and define possible scenarios for the activation of ELC through gradual progressive innovations such as: the strengthening of current landscape policies oriented by Action Plans, improved knowledge of the features, dynamics, and both historic and current processes affecting the landscape in order to develop plans and projects shared by the population.

5.2.5. Participative Planning and the Landscape

Of great interest among the instruments used to activate the ELC is the Village Design Statement (VDS) introduced by the Countryside Commission in 1996 as a local planning landscape instrument to oppose the process of standardisation towards urban territorial models in rural areas. Focusing on ideas of regional diversity, local identity, harmony between settlements, individual buildings, open countryside, and introducing a new method for understanding and directing landscape projects in rural centres and small urban settlements, the VDS was put forward by the Countryside Commission in 1996 (Village Design –

Making local character count in new development) as an experimental project piloted in four areas, namely, Cottenham (South Cambridgeshire District Council), Cartmel (South Lakeland District Council), Elstead (Waverley Borough Council), and Down Ampney (Cotswold District Council) – for the purpose of making the urbanism and development plans compatible with the values and identity of the local territory. In doing this, the VDS is an instrument that influences the methodology used in territorial planning at the local level by approving Supplementary Planning Guidance, an instrument to govern socio-economic and territorial transformations, beneficial to the landscape, environment, and territory (Moseley, 2000).

The VDS is a process of direct involvement of the population in identifying and defining shared landscape policies (Nadin, 2007). This participation makes it possible to recognize the social perception and appreciation of places, effect a campaign of sensitisation to the importance of and role played by landscape in addition to using shared strategies to recognise and strengthen the "unique and subjective" value of landscape in terms of "materials, scale, form, and dimension" (Countryside Commission, 1996).

It is an instrument of social and community interpretation of the landscape that makes it possible to perceive the local and collective importance of places, spaces,

and symbols on which uniqueness and identity are based, resulting in the past and current processes being interpreted through collective perception of the territory in order to guide sustainable transformation.

In finding a balance between memory and development, between a feeling of belonging and innovation, landscape strategies to be incorporated into the instruments of local landscape governance can be defined.

For the participative landscape project, the VDS:

— Describes the identity of the rural centre and its contextual landscape;

— Interprets the landscape features and values through "the eyes" of the population by identifying three levels: the rural landscape, the form of settlement, and the type and character of the buildings; — develop planning principles based on local identity, allowing the population to "feel part of the planning and decision making process" (Countryside Commission, 1996, page 8);

— Work in partnership with other government actors in the landscape and in the territory in order to interpret the present and develop evolutionary scenarios.

Therefore, it is a local consultative and voluntary planning instrument directed at the ELC distinguished by its great flexibility and adaptability in its contextual form and objectives, and in the expectations of the population (Countryside Commission, 1996) that support the policy and institutional choices and decisions.

After approval by the County Council following a request from the Local Authority, the VDS is applied in the Local Development Framework as a Supplementary Planning Document, providing a shared transformation scenario, based on planning principles and directions for sustainable local development that is initiated by evaluating social perception of the landscape.

6. Conclusion

The implementation of the ELC helps creating interest in landscape, in its ecological-environmental, historical-cultural, perceptive, economic dimension and in the physical characterization of spaces, throughout territorial government – on the basis of various interpretations. In fact the ELC defines a common approach

and establishes programmatic indications to meet the growing demand to acknowledge landscape as one of the foundations of identity and the basis of territorial roots that let “man to renew his bond with the earth” and/or territory of the past, present and future “that modern times have dissolved” (Berque, 1995).

The need for landscape quality in European society therefore corresponds to the process of re-appropriation by the populations of the living environment, so the local community can structure elements and symbols that characterise landscape for common development.

Landscape is therefore the common representation of a territory (Raffestin, 2005) to be governed with shared policies and projects for sustainability.

Today, landscape and sustainability are two closely related requirements, referred to the ELC, which requires to review policies at European and at the state level for protection starting from the acknowledge of the landscape essence, inherent in local territories, and to the landscape enhancement with actions for the protection, management and planning of the same.

In this view a first key aspect to stress is the need of a joint pan-European landscape policy (Wascher, 2000) in order to integrate and coordinate EU sectorial policies and to control their effects on landscape, but also for stimulating directly the 23 EU member countries that had ratified the ELC in order to implement its innovative issues on their territories. A European landscape specific policy is necessary because:

— Many landscapes of European importance are the offshoot of natural and cultural processes that require transnational strategies;

— In recent years, many transformations in uses of the territory and of the landscape have been triggered by Community strategies;

— Landscape policies may play a strategic role in the sustainable future of Europe.

In this light, the EU must undertake to promote a framework of action for the landscape, starting from ratification of the ELC, in order to improve the quality of the territory through:

— Wide-scale coordinated actions for the landscape defined at Community level with reference to the national and trans-border dimension;

— “Special” actions intended to address and finance protection, planning and management actions of sensitive, unstable and downgraded environments of the regions of Europe;

— The development of new synergies between Community planning of policies, territorial strategies and the project of the regions and territorial communities who identify themselves in the same landscape values (bottom-up approach);

— Urban policies able to exert a strong influence on the aesthetic-perceptive and physical qualities of public and private spaces, and EU programs for urban regeneration that take social and economic effects in consideration have in fact made a very limited contribution to landscape valorisation in the urban environment.

Therefore the European states are taking actions, differently within the landscape cultures, on various timescales and with varying effects to study new forms of sustainable landscape development, with reference to (ELC, 2000, art. 6):

- Establishing landscape as one of the foundations of identity;

- Indicating landscape quality as the goal of planning actions on all governmental levels;

- The acknowledgement that the enhancement and creation of landscapes is based on institutional and social planning;

- The conviction that the quality of the landscape is based on a project of physical, economic and social spaces;

- The awareness of the institutional and socio-economic stakeholders and training specialists in the sector of landscape information and intervention;

- The landscapes identification and assessment to analyse the characteristics and define landscape quality goals.

Nevertheless, while each countries is establishing landscape goals in territorial and sectorial policies, the implementation of landscape policies is not so simple.

The result in landscape policies and ELC implementation is different in countries. Using the interpretative metaphors, the Germanic-Anglo-Saxon root (Voghera, 2004, 2006) corresponds to an integrated approach between actions for the protection and development of territory and landscape that guarantees the operational implementation of policies and projects. In the Netherlands, landscape action is dictated by a programmatic-operational approach closely related to planning the actions for the project and establishing responsibilities and economic resources. In Great Britain, common strategies and scenarios for the enhancement of landscape on a local scale are defined through shared assessment, an important legitimisation of policies and project for implementation.

In Germany the full-scale integration between plans for territory and landscape helps reinforce the operational character of policies and projects.

In Austria and Denmark the analytical approach, based on methods of interpretation and the legitimation of landscape values, makes it possible to draw up policies and projects. In these countries the central-national institutional role is strategic to define coordinated landscape policies, to individuate actions and economic resources to implement the landscape interventions. These policies find also references in plans at regional and local level.

Instead the Central-Mediterranean root (Voghera, 2004, 2006) corresponds to a more conservative approach for landscape values, although recently there has been an experimental and fragmentary attempt to integrate actions for protection and development. The role of Regions in Italy and Spain contributes also to make many diverse approaches and results in the ELC territorial implementation.

The countries are also trying to experiment participatory landscape plans and projects. People's participation has a key role for the identification of values through the comparison and contrasts that they make among the many potential meanings, interests, and expectations (as the UK and Dutch experiences demonstrate). In fact, participation promotes, supports, and directs a great number of actions that—because they are not produced by the institutions alone—generate a substantial reinforcement of the results of the strategies, communicating and legitimizing shared decisions and values that could reinforce human, social, and landscape capital (Brunetta and Voghera, 2008) and guarantee implementation.

In the diverse cultures and planning practices, the key features of ELC implementation are:

- The definition of protection measures aimed at conservation of the excellent landscape and collective identity values;

− The construction of new management methods, declined in relation to the institutional and social actor responsibilities;

− The definition of strategies, criteria, rules and economic resources, in order to implement the actions.

In this direction the countries are developing a landscape planning as follow:

- Strategies and vaste scale policies for the transformation of the landscapes, legitimized through social evaluation processes and aimed at development of landscape and life quality (Landschap Agenda, Landscape guidelines in Great Britain,…);

- Strategies and sectorial plans - like those for the development of agriculture, of mobility, for the energetic grids or those for water management, etc. - in which the landscape is an objective for the sustainability

- Strategies and sectorial plans - like those for the development of agriculture, of mobility, for the energetic grids or those for water management,… - in which the landscape is an objective for the sustainability.

They are trying to develop plans, policies and project for the landscape aimed at sustainability, integrating actions at different levels and linking territorial and landscape aims.

The innovative influence of the ELC has not been able to fully "transform" the territory and landscape project to date. While this is partly a reality on a territorial scale, it is to a lesser extent for the local urban dimension. Experimentation refers to the dimension of the territorial project (in a vast national and regional area), acting on a local level, with shared actions that mainly concern projects for small villages and rural centres, often popular with tourists. There is still no real and effective consideration of the urban dimension of the project. In fact, the many experiences in urban regeneration, supported also by EEC policies and programs, have contributed to socio-economic recovery and the integration of resources, but with scarce consideration of the physical and aesthetic dimension of the landscape (the form, structure and organization of common and relational spaces). This is one of the dimensions of the landscape project, which should be relaunched by the ELC.

Abstract

Keywords: *Light, Perception, Humanization, Color, "Troisieme-paysage"*

This intervention is a "light" redevelopment, made for the public administration of Terni (Italy), to valorise, in a "low cost" way, a series of public "junk-spaces" (Koolhaas, 2008). It's a series of painted walls realized from 2008 to 2011 and a project of a square, not yet realized (construction starts from October 2012 and will finish in June 2013).
Public commitment requirements:
This kind of urban public spaces (like green areas in between roads and railway lines, residual spaces of public infrastructures, etc...) are, generally, not important for public Administrators, because their marginal position (in respect, also, to the perception of these places) maintains the requirements of their re-qualification in a secondary point in all the electoral campaigns.
Anyway, they decide to redevelop these places in a very "low cost" way!
A "low cost" strategy is not only a "cheap" strategy (in the sense of money), but also in Social Terms: generally rapid changes of an urban area are not ever take in good consideration from the citizens because they don't feel a part of these interventions and they don't feel any civic sense for that.
Concept:
"Pink Landscape" is a project that qualified the perception of these "junk-spaces", with a low cost impact in economical and social terms: a series of wall painted in pink shocking colour forms a path of artificial landscape that the citizens can personalize with their overwriting.
In-fact, in these walls, you can overwrite your feelings, your thinking and also other information for the other citizens in a sort of "Memory Theatre" (Delminio, 1563) that contribute to humanize our public spaces.
This is a change of our vision (and perception) of these "public junk-space": a sort of artificial cave that we must humanize again, for a social sustainable living, giving to that a new civic approach, a new sense of appropriation of the public "things".
In these walls you can find your memories and your old feelings to learn, from your past and from the other people's pasts, the way of living, in peace and respect for all the different point of view.
Sustainability:
An important aspect of this project is to give attention to these places maintaining the characteristics of the "3rd landscape" (Clement, 2010): the biological diversity is a peculiarity of these new-natural spaces; we have to maintain that, giving their right to the lightness of this interventions.
Another important sustainable aspect is the Social Sustainability (the most important): the particular way of creation can satisfies all request about the customization and humanization of the public spaces, increasing the civic sense of appurtenance to their places in a long "heritage path" that speaks about our new Urban Culture!

1. Introduction

From the period of the *International Style,* where the discussion about architecture became a discussion about volume, regularity and abolition of decoration (Hitchcock,H.R., Johnson,P., 1932) , the core problem of architecture design has begun to move towards a 'generic box'.
Consequently the aim of the design (that has to maintain the maximum volume of construction) focused his attention in the surfaces of these boxes: these frames has the function to separate and communicate with 'the exterior'.
With the *Post-modern* movement, these boxes were made on decorated and communicating shed. For Robert Venturi (Venturi, Scott Brown, Izenour, 1972) there is two ways for communicate: with their form (the famous *Duck*) or with the decoration of the exterior surfaces (the *decorated shed*).
After Venturi, Rem Koolhaas, evolves this principle: the box, became a wrap for a functional program in a 'quantitative' sense. 'Qualitative' aspects became something of independent from the exterior (Koolhaas, 2004). In this kind of box we can change the interior functions without changing the outer appearance (or vice versa changing the external appearance without changing any function).
The most important part of our attention is concentrated on the technological systems integrated in the skin of the building, but we must not lose the side of the communicative aspect because this is also one of the key factors that determine the social sustainability of the intervention. Participation in the creation of our city is an important thing: *the image of* [our] *city* (Lynch, 1960) can be participated by our cityzens for to create a unique collective environment.

2. Analysis

This is, in the fact, an intervention of a “light” redevelopment made with acrylic paint, for the public administration of Terni (Italy). The idea is to exploit in a 'low cost' way, a series of public *junk-spaces* where the people can add other signs to participate, with their creativity, in the aesthetical creation of their city.
A “low cost” strategy is not only a “cheap” strategy (in the sense of money), but also in Social Terms: generally rapid changes of an urban area are not ever take in good consideration from the citizens because they don't feel a part of these interventions and they don't feel any civic sense for that. So, in this sense, *'Pink Landscape'* is a project that qualified the perception of these 'junk-spaces', in a low cost impact: a series of wall painted in pink shocking colour forms a path of artificial landscape that the citizens can personalize with their overwriting.
If you can overwrite your feelings and your thinking, you are creating, in fact, a sort of “Memory Theatre” (Delminio, 1563) that contribute to humanize our public spaces.
This is a change of our vision (and perception) of these “public junk-space”: a sort of artificial cave that we must humanize again, for a social sustainable living, giving to that a new civic approach, a new sense of appropriation of the public “things”. Like a new soviet *proun* we can participate all together to the aesthetic of our cities.

2.1 Analysis of perception

Another problem emerge from this point: how people can see these 'new places'? there is a 'speed reading' of these interventions? Certainly the answer is 'yes'!
These interventions are subdivided in three sections depending on the observation speed reading: *fast*, *slow* and *participated.*
Fast: these places are positioned in highway ramps (or similar) and the observer has only few seconds to read the interventions (generally from 4 to 8 seconds);
Slow: these places are positioned in the streets or in places where the observer can use more seconds to see well, generally there is a sidewalk or other facilities that permit another kind of observation;
Participated: these places are so quite and accessible from other people that can accommodate other overwriting, creating a wall customized by people.

3. Results

An important aspect of this project is to give attention to these places maintaining the characteristics of the “3rd landscape” (Clement, 2010): the spontaneous biological diversity is a peculiarity of these new-natural spaces.
After these experimental interventions, we can maintain that: the particular lightness of these changes (only in the aesthetics aspect) can show these places like a restyled places without feel the need of another modification.
Another important sustainable result is about the Social Sustainability (the most important): the particular way of creation satisfied (not in all cases) all request about the customization and humanization of the public spaces, increasing the civic sense of appurtenance.
In the following images, there is the picture of these walls and a table with an index.

4. Conclusions

A new way of thinking the surfaces of the public spaces it's possible: from the skin of the buildings to the walls of the infrastructures the participation of our citizens with their artistical contribution, can be another value to add to our cities and not another problem to solve again!

THE PLAN REVIEW
A NEW APPROACH TO URBAN PROJECT ASSESSMENT

David Hamers [1], Like Bijlsma [2] and Anton van Hoorn [3]

Abstract

Decision-makers experience problems with assessing urban investment plans. Because of the increasing complexity of our contemporary cities and the growing number of stakeholders involved in the planning process, a large variety of aspects of new plans have to be taken into account. This paper introduces a new instrument that can help stakeholders take stock of the most important spatial aspects of urban projects and improve and assess plans in a systematic and transparent way. We call this instrument the Plan Review.

In planning research as well as in actual practice, cost–benefit analysis (CBA) has been promoted as an instrument that makes project assessment more transparent and increases objectivity and accountability in decision-making. For a number of reasons, in the Netherlands (as well as abroad) CBA is currently heavily debated in (policy) research and spatial planning practice. If national public funding is involved, CBA is a mandatory component of the Dutch decision-making process with regard to large-scale spatial investments. However, the current CBA approach does not fit well with the ambiguous and multi-level policy goals that are common practice in our contemporary urbanised regions. Stakeholders have expressed a need for an assessment instrument that is better able to cope with these aspects of urban planning.

This paper introduces such an instrument: the Plan Review. It turns away from the dominant economic logic of CBA and puts the knowledge developed by spatial disciplines such as geography, urban planning and urban design at centre stage. The Plan Review takes the form of a matrix that helps reviewers to structure key spatial qualities of a project and acts as a checklist for stakeholder discourse. The matrix has two entrances: the scale of the plan (from urban region to project) and the nature of the available information (from generic to specific). Depending on the spatial scale of the plan and the available information about various plan characteristics, different matrix cells can be considered in the Plan Review.

Contrary to CBA, the Plan Review does not focus on the ultimate effects and efficiency of urban projects. Instead, it enables planners and reviewers to first take a

[3] PBL Netherlands Environmental Assessment Agency, The Hague, the Netherlands

step back. The Plan Review matrix brings together a variety of spatial conditions (16 in total) that must be met for a plan to effectively contribute to the achievement of policy goals. Think of accessibility by different modes of transport, and a local

public space design that fits with higher level project objectives. By opening the black box of relevant spatial conditions and explicitly addressing the line of reasoning in a project plan, the Plan Review matrix helps stakeholders discuss possible plan improvements (early in the planning process) and assess the project (in a later phase).

1. Introduction

1.1 Motivation and objective: improvement of spatial assessment of urban development plans

The decision-making process around spatial investment projects is faced with a number of problems related to the assessment of urban development plans. For example, there are misunderstandings between administrators and assessors about the relationship between policy targets and development plans. In addition, there is little unity amongst the various disciplines involved in such assessments; economists have an entirely different view on cities than urban planners and designers. This paper is intended to clarify the communication on urban projects, in order to contribute to the improvement of the process around urban investment planning and decision-making . It presents an analysis and assessment instrument that may be used by urban planners and administrators, to give them more insight into the main spatial characteristics of urban projects. In this way, they may be able to assess such projects more effectively, while taking into account certain policy objectives. We have called this instrument the Plan Review and have shaped it to the benefit of the dialogue between assessors and stakeholders. In actual practice, this involves assembling a list of themes (so-called spatial conditions) in aid of objectifying the analysis of the plan and structuring the dialogue with stakeholders. The Plan Review is intended for the improvement of urban development plans, or parts thereof, and to contribute to their spatial assessment.

1.2 Demarcation and set up

Although urban projects may serve a variety of purposes, this paper centres around physical spatial projects. The following section provides a brief description of the current debate on the assessment of such projects in the Netherlands, followed by the Plan Review instrument which was developed in response to the issues involved in this debate. A series of relevant spatial conditions is introduced in a matrix, each of these conditions is explained, and one of them has been further elaborated as an example. The paper closes with a synthesis and a brief discussion of the steps that could be undertaken to further develop the Plan Review, so that this instrument can be applied in actual practice.

2. Three issues around current planning assessment

In the Netherlands, the debate on planning assessment, to date, has been focused on the role of cost-benefit analyses (CBAs) in the decision-making process. In planning

research and practice, CBA has been promoted as an instrument that makes project assessment more transparent and increases objectivity and accountability in decision-making. In fact, in the Netherlands, CBA is a mandatory component of the decision-making process of large-scale spatial investments, whenever national public funding is involved. However, academics and practitioners across a wide range of disciplines have criticised these claims (e.g. Bebbington *et al*., 2007; Tribe, 1972); for instance, with regard to efficiency as the basic criterion of acceptability and the over-reliance on monetisation.

In addition, various parties in the processes around planning and decision-making have pointed to problems related to the way CBAs fit in with the planning of spatial projects in contemporary urban regions (e.g. Municipality of Almere and the Ministry of Infrastructure and the Environment, 2011; Renes *et al*., 2011). This paper considers three of these problems as main issues, in this regard.

The first issue relates to the multivalency of objectives of urban projects. These projects often have to contribute to very diverse objectives, such as in economic and environmental areas, as well as those relating to culture and landscape. In order to create a support base for such combined policy objectives, often, in the political arena more general terms are used that could be interpreted in multiple ways. Examples of such terms are 'attractive cities' and 'international business environment'. The aspects that make these expressions attractive for administrators to use, are the same aspects that create difficulties in the planning assessment that precedes decision-making, as objectives that are described with these expressions are difficult to operationalise. The translation of such expressions for the purpose of a CBA leads to a 'confusion of tongues' between the various parties involved in the planning and decision-making process.[4]

The second issue is one that is related to the various spatial scales on which contemporary urbanisation occurs, and the governance processes involved. Over the past decades, urbanisation – in the Netherlands as well as globally – has increasingly become a regional affair, in a morphological, functional and governance sense. This has led to the formation of urban agglomerations and daily urban systems, and has brought urban planning to the level of the metropolitan region. Moreover, central government also looks to urban regions in realisation of their objectives. The large Dutch cities, thus, are considered to be drivers of the economy; the current Cabinet considers a good international business environment a matter of national interest. Policy objectives of various administrative divisions may be in line, but may just as easily have opposing interests. This causes problems in the assessment of urban projects. After all, an assessment of a plan from a national perspective may look entirely different from one that is based on regional or local objectives. CBAs, in the Netherlands, only apply to the national scale, causing objectives on smaller scales to

[4] This problem is even increased by the large uncertainties that have characterised the planning practice over the last years. Plans that present a concrete ultimate goal, more and more, are being replaced by plans based on much more general guidelines and a phased realisation. This also poses problems for the traditional assessment of plans that precedes decision-making.

be ignored in planning assessments. Therefore, various parties have asked for additional assessment methods.

The third issue around the assessment of urban projects concerns the different types of knowledge required in competent decision-making. Because of the complexity of urban projects, knowledge is needed in various fields, such as traffic, economy, planning, geography and urban design. These fields of knowledge are sometimes difficult to unite. There may be differences of opinion, for instance, on the relationship between contributions of 'scientific' knowledge and those of 'crafts'[5], and misunderstandings caused by the use of different definitions could easily occur. Currently, the terminology of welfare economics as used in CBAs is leading. Several parties, however, have indicated that they require additions to this vocabulary from various spatial disciplines.

This paper introduces an instrument of analysis and assessment that would address the issues as described above. This instrument is the Plan Review; it does not follow the dominant logic of CBAs, but places the knowledge developed within spatial disciplines, such as geography, urban planning, and urban design, at centre stage.

3. Foundations of the Plan Review instrument

3.1 Plan Review positioning in relation to CBA

The Plan Review instrument has a different function than the CBA in the process around planning and decision-making. CBA primarily focuses on the effects and efficiency of a project. However, before a project has any effect, it must comply with several spatial conditions. Does it work? Does the project produce the spatial conditions under which it may have the desired effect, thus contributing to the aspired policy objectives.

In its current form, the CBA is not very well-suited to portray these conditions. This may lead to situations whereby the effectiveness of a project cannot be assessed properly. Moreover, in earlier phases of the decision-making process, options for stakeholders to improve on the project are sometimes overlooked. The Plan Review is intended to improve on the flow of information in the decision-making process in both areas (plan optimisation and assessment). In doing so, the Plan Review, unlike the CBA, does not focus on the effectiveness and efficiency of urban projects, but analyses the spatial conditions that projects must comply with in order to even achieve the desired effects.

A number of questions related to these issues are paramount: What are the spatial conditions that a project must comply with in order to realise the desired objectives? Which developments may facilitate a project and which would not do so; for example, compared to other, related projects? Which unwanted effects may present

[5] Sennett (2008) speaks of 'the craft of experience'.

themselves? And finally: Which conditions could be improved on, in order to achieve the objectives?

3.2 Connecting to available and desired information in the planning and decision-making process

The objective of the Plan Review is to improve on the decision-making process around urban projects. Therefore, the foundations for the instrument are to fit in with and connect as closely as possible to the informational requirements of policymakers and government administrators at various phases of the planning and decision-making process. In the Dutch situation, very many different plans are being assessed, and the relationship between policy objectives and the desired effects of urban projects differs from case to case. In certain cases, administrators have rather generally formulated ambitions that are difficult to translate to concrete, operationalised objectives and assessment criteria. This applies, for example, to the early stages of projects (ones that have not been worked out in great detail). Other projects, mostly those in later stages of decision-making, already have a much more concrete form.

Furthermore, projects also differ in size. From large-scale urbanisation projects with infrastructural improvements on a regional scale, to inner city projects with issues and opportunities centred on a smaller scale, such as a train station or part of the city centre. Often, several scales play a role, simultaneously, and the coherency between them calls for specific attention.

The Plan Review is intended to be applicable in all these cases. This implies that it must provide spatial information on scale (large to small) and measure of detail (generic to specific), befitting the nature of the project and the phase of planning and decision-making. These principles together form the entry points of the Plan Review matrix (Figure 1).

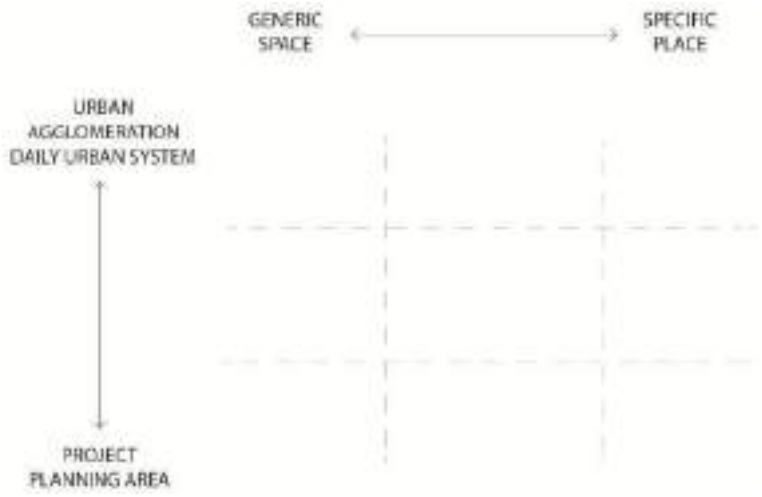

Figure 1. The rows and columns of the Plan Review matrix.

The rows of the matrix distinguish between the scales involved in urban projects; from regional to the planning area of an individual project. These scales relate to the policy objectives that the project is to contribute to – objectives that, mostly simultaneously, are set at various levels of governance. The matrix columns distinguish between the available or required types of information or knowledge, from generic to specific.[6] The types of knowledge depend on the particular phase of the planning and decision-making process, varying from the earliest to the latest stages.

A number of spatial conditions can be spread over the matrix. These are elaborated in the following section. To present the conditions in an orderly manner, the matrix has been divided into nine cells (three rows, three columns). The conditions have been distributed over the cells.[7] In this way, depending on the plan to be assessed, the dialogue between the parties involved can be focused on the relevant conditions. For example, a discussion on a regional project that is still in an early stage of planning is likely to be focused on the cells in the left-hand top corner of the matrix. In cases of much smaller scale projects and for which more details already have been established, the cells in the right-hand bottom corner would feature more predominantly.

In addition, if necessary, conditions in cells spread over the entire matrix can be discussed; for instance, in cases of urban projects that involve various scales (e.g. local business locations near national motorway slip roads). Talks between stakeholders and plan assessors may follow a certain 'route' over the matrix.

4. The Plan Review matrix

4.1 The cells: diverging spatial conditions

On the basis of literature research (e.g. on urban development, architecture, planning, geography, urban sociology and spatial economy), planning and map analyses, field studies and expert interviews, we assembled a series of 16 conditions that regularly feature in spatial research and design.[8]

The matrix needs to contain various conditions, as objectives of urban projects also differ, and because projects are realised within cities that differ in characteristics as well as for different target groups (context sensitivity). This must involve both

[6] In geographic terms, this would be space and place. Experience has shown that more abstract knowledge often is of a quantitative nature, whereas concrete knowledge can be labelled as qualitative. However, the reverse may also be true.

[7] The division in rows and columns is heuristic, for the purpose of easy applicability in assessments. Because the two axes of the matrix both represent a continuum, this division in rows and columns may seem somewhat contrived. Conditions cannot always be easily allocated to any particular cell. Therefore, cell boundaries are represented by dotted lines.

[8] There may be considerable differences between traditions directly related to various types of knowledge and know-how. For research that is based more on the classic (beta) science, the emphasis is on legalities and constants, whereas design research focuses more on options and possibilities within specific contexts. In addition to theory, also practical experience may form a valuable source of knowledge. Although some scientific researchers are less inclined to award appropriate value to such physical rather than scientific knowledge, the necessity of 'thinking through making', 'knowing-in-action' and 'reflection-in-action' have a solid basis in scientific theory (e.g. see Schön, 1984, 1987; Sennett, 2008).

physical and functional aspects of the urban environment, as well as the manner in which city dwellers experience their surroundings. These separate elements are important in isolation, but also their interconnection is significant; together, they determine how cities are used and experienced.

In addition to these dimensions of use and experience, also the time dimension is of great importance in project analysis. After all, analyses of urban investments do not represent one moment in time, but need to consider long-term developments. They must assess the degree to which these projects may adapt to changes, both expected and unforeseen.[9] Furthermore, also the short term is of interest, in relation to a project's planning and execution. This includes the circumstances under which a project can be realised and how the speed with which this happens could be increased (e.g. catalysed).

In order to address these issues in a planning assessment, we included a number of variables related to the planning process in the matrix. However, these process variables (e.g. flexibility, resilience, catalysts, phasing) have not been separately entered into the matrix, but may be addressed in all cells.

The chosen series of conditions is not exhaustive. It was constructed to fit a broad range of projects, while being sufficiently ordered and accessible to function as a checklist in actual practice. Figure 2 shows this series of conditions, as they are distributed over the matrix.

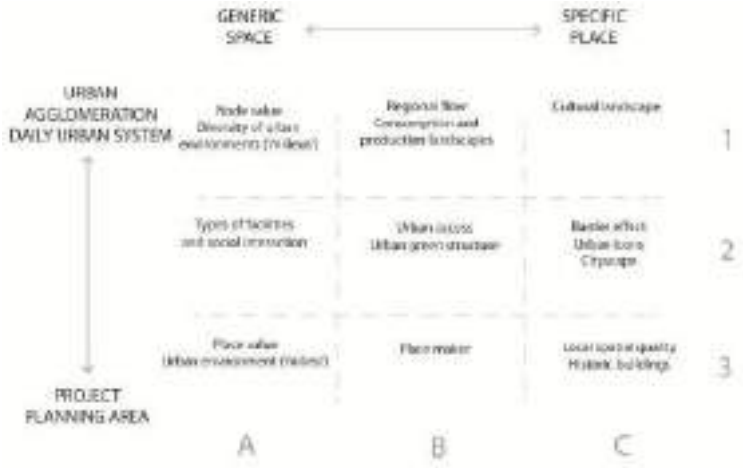

Figure 2. The Plan Review matrix

The following section provides a characterisation of all conditions, centred around certain questions that are subsequently elaborated on. Section 5 describes one of the conditions in greater detail, to provide an example of how conditions may be used in

[9] Flexibility and resilience are very important in Dutch contemporary planning practice, as urban development currently is struggling with large financial difficulties (short term) and sizeable uncertainties (long term) about, for example, economic and demographic developments.

discussions during the planning and decision-making process, to objectify the planning analysis and to structure the communication with stakeholders. In addition, attention is given to certain theoretical backgrounds and methods that enable the use of the Plan Review in the planning and decision-making process.

4.2 Node and place values (1A and 3A)

Are node value and place value sufficiently balanced? The node and place value concept (Bertolini, 1999) offers starting points for the analysis of development options for mobility in connection with those for the functions of an infrastructural node, related to visiting and accommodation. Certain questions are important, such as whether the transport capacity of a node is being used fully, in view of its position within the network, and whether this node value is balanced with the place value – the facilities in the direct vicinity of the node, such as numbers of shops, offices and/or residential homes.

4.3 Diversity of urban environments ('milieus') (1A)

What would the project contribute to the existing variety of environments within an urban region? In order to meet the needs of a variety of users (dwellers, workers, visitors), urban regions must contain various types of places and functions, together described as 'urban environments' (or 'urban milieus') (for elaboration of this concept, see Ritsema van Eck *et al*., 2009; PBL, 2010; Hamers, 2011). By considering the regional-urban diversity of environments, arguments can be found for possible changes (additions, restructuring, transformations) required in the light of the particular objectives. Here, regional coherence is especially important. Consideration of a project on that scale may indicate the relationship between both competitive and complementary environments (within as well as outside the municipality where the project is being realised).

4.4 Regional flow (1B)

Would the infrastructure on a regional scale be sufficiently robust and/or resilient to manage passenger and freight traffic in the long term, and would it be able to adapt to possible changes in traffic flows, such as increasing cross-traffic in a polycentric region, or decreases due to regional population decline? This includes parallel infrastructure on connecting routes, connections between suburban centres and choice options for either public transport or passenger vehicles. Another issue is whether measures that could be implemented in the short term to create flexibility (e.g. changes in timetables or by the construction of rush-hour lanes) would offer the required solutions.

4.5 Consumption and production landscapes (1B)

How does regional urbanisation relate to landscapes and nature (biodiversity, ecological passages)? Does the landscape in the urban region offer any possibilities

for water storage, in view of climate change? And is it able to meet urban demands related to regional and local food and energy supply, as well as recreation? In addition to existing and inherent natural qualities, this also relates to planned and still to be designed conditions in the consumption and production landscape.

4.6 Cultural landscape (1C)

To which extent have possible particular and unique area characteristics been taken into account? Does the project protect such characteristics or even use them by awarding them a visible position within the project? Depending on the situation, both conservation and development may offer possibilities. If the cultural landscape stretches over a large area, harmonisation between project plans on a regional scale may offer opportunities for making complementary choices in various different locations within the region. For example, if historic patterns at a certain location become unrecognisable due to the realisation of a plan, their conservation elsewhere could be guaranteed.

4.7 Types of facilities and social interaction (2A)

Do cities and neighbourhoods have appropriate facilities, and are these sufficiently accessible? Facilities, including social facilities, together with the public space, form the social-spatial infrastructure of a city. This may connect people. Also, people may feel at home in an environment if they feel connected to it. This may cause them to feel more responsible for maintaining the environmental qualities of the public space. Facilities do need to be easily accessible and fit with the environmental identity (visibility, fitting atmosphere), in order for people to feel involved (see Bromm et al., 2011).

4.8 Urban access (2B)

Are entry and exit roads and light rail or rail connections, on an urban scale, sufficiently robust and/or resilient to continue to process passenger and freight traffic, in the long term, and to adapt to possible changes in traffic flows? Are there any options for separating through traffic from local traffic on urban ring roads (see also 1B)? And will there be sufficient flexibility in the short term? These questions play a role, specifically, for plans relating to housing and business development within the existing city and along the urban fringe. Further urbanisation within existing urban areas mostly makes demands on infrastructure that are different from those of new housing in expansion areas.

4.9 Urban green structure (2B)

How do built-up areas relate to green areas in and around the city? How easy is it for city dwellers to reach these areas of urban green? These questions have different answers in different urban environments (see 3A). Various types of urban dwellers have varying preferences with respect to functionalities and types of greenery (e.g.

recreation, urban agriculture) . The ratio between ‘red’ and ‘green’ also not only refers to magnitude, but also to characteristics. The size of a park, for example, is not automatically an indication of its quality.

4.10 Barrier effect (2C)

What are the options for clearing spatial (and functional, socio-economic and mental) obstacles within a plan? Barriers come is all shapes and sizes; for example, in the form of an infrastructural bundle that separates city areas, or a long and closed front of buildings that forces pedestrians to take a detour. This may cause locations that are physically very close to appear very far away, both in travel time and in perception. Such characteristics can have a large effect on the particular meaning of a place, and, thus, on its value. Clearing such barriers can be a project’s main objective, but it may also be a side effect of developments that primarily serve a different purpose.

4.11 Urban icons (2C)

What could an icon contribute, in comparison to a plan with a fairly plain character? Although icons, by nature, possess a certain uniqueness, there are ways to analyse them. For example, they are rarely realised within a vacuum, but rather are adapted to their existing surroundings, in which often additional investments take place. This connection offers starting points for an analysis of the planned icon, and concerns the convincing logic of the plan as a whole. In addition to its functional value, especially its perceptional value needs to be substantiated. For example, will the icon evoke feelings of pride or identification, or will it mark the entrance of a certain area or connect two areas?

4.12 Cityscape (2C)

To which degree does the plan take into account the presence of a possible historic cityscape? Does the project protect such characteristics or even use them by awarding them a recognisable position within the project? Local historic characteristics of a city district or neighbourhood may offer starting points for creating a visible identity in a plan. This may enhance a project’s attractiveness to residents, businesses and visitors (depending on the planned programme) and offers possibilities for branding.

4.13 Urban environment (‘milieu’) (3A)

Which spatial and functional conditions are offered by the planned environment (‘urban milieu’) in order to achieve the related policy objectives? When changes to the range of environments within an urban region would contribute to achieving a certain policy objective (see 1A), the focus can be turned to the type of environment that would be needed to realise this change. The main question, here, would be that of which conditions are offered within the planned environment for realising the policy objective, taking into account possible tensions between objectives in different

fields of policy, of different municipalities in the region, and of different layers of governance. This also applies to options for urban milieu development contributing to a mutual enhancement of policy objectives.

4.14 Place maker (3B)

How can the transformation of a space into a place in locations with multiple problems be encouraged? We distinguish between three options. Firstly, the so-called 'golden key': could the plan be altered in such a way that qualities that are difficult to unify can be developed with a certain connection? Changes may affect both the programme and the spatial design. In some cases, a breakthrough in routine thinking can create space for new solutions with a broad support base. In these cases, puzzles are not pieced together again, but the puzzle itself is altered. Secondly, could pioneers give an extra impulse to the (re)development of an area? Plans may become stalled for various reasons in certain parts of a city, causing some areas to remain undeveloped for long periods of time, and resulting in the postponement of desired changes. Quite often, these 'interim' periods last for many years. Pre-investments in programmes and buildings (e.g. events, studios and workshops, and meeting places), as well as temporary permissions for unconventional use of space (e.g. urban agriculture) or unconventional urban development (e.g. experimental, organic architecture) may be catalysts for change or accelerate changes. Thirdly, could the project be carried out in phases (in consecutive steps)? In the current Dutch debate on uncertainties around projects, phasing is considered as a way of reducing financial risks. However, projects cannot simply be cut into several pieces. It is vital that an estimation be carried out first, concerning the practicality and relevance of such a part-project in the eventuality that the rest of the project is abandoned. In other words, would the first phase of the project have an independent functional-spatial logic, on the basis of which it would contribute to the city?

4.15 Local spatial quality (3C)

Does the plan's organisation of public space match the planned urban environment (see 3A) and the target audience? Local spatial quality – for lack of a better term – cannot be described in general terms but must be related to, for instance, location, existing functions, density and building heights. For a square, for example, sun and lighting would be important, in addition to shelter from the wind and a certain degree of enclosure. Furthermore, also information on the main users would be important; after all, they would make different demands on the location. For example, visitors to a certain place would look for entertainment, while residents may seek rest and quiet at the same location. In addition to a pleasant outside space, also local conditions for traffic circulation, as well as social safety and road safety may play a role.

4.16 Historic buildings (3C)

How does the plan deal with cultural heritage, on building level? Are choices being made solely with respect to preservation of protected historic monuments, or do such

historically valuable and characteristic buildings offer starting points for new development? Could they provide a project with some *coleur locale*, or even serve as centrepieces for the development of a recognisable, local identity for the surrounding areas (see also 2C)?

4.17 Various functions of the matrix in the dialogue with stakeholders

This list, as indicated above, may be used as a checklist in the dialogue with stakeholders. Depending on the phase of the planning en decision-making process, this checklist could have various functions. Planners could use the list throughout the development of a project, and subsequently it could also be used in discussions about possible improvement options. Towards the end of the planning and decision-making process, the checklist could become part of the assessment process, as a prelude to the assessment of expected effects and project efficiency, for example (as is current Dutch practice) in the form of a CBA.

The brief explanation of the conditions, as provided above, places the emphasis on the desired spatial development within a project. However, in addition, possible unwanted effects must also be considered. For example, the construction of a new exit/entry road may unwittingly create a barrier between two, previously well-connected areas, within or outside the planning area. Because such effects may create conditions that could hamper the achievement of policy objectives, they must be brought to light early enough to be considered when improvement options are discussed.

5. An example: local spatial quality (3C)

This paper only provides one example: local spatial quality (3C), seeing the limitations to the length of the paper. We provide a concise example of the application of the Plan Review instrument with regard to this particular spatial condition and briefly refer to the theoretic and methodological background. In order to provide a certain context, we have related the spatial quality condition to a current example from Dutch planning practice: the knowledge campus. In the example, a 'route' over the matrix is followed, as could be done in the discussions during such a project; from discussing the range of urban environments (1A), via the chosen environment (the campus) (3A), to a discussion on the fitting local spatial quality (3C) (see Figure 3).[10]

[10] The first two steps have not been described here. They are merely mentioned to present the workings of an analysis of the coherency between various conditions.

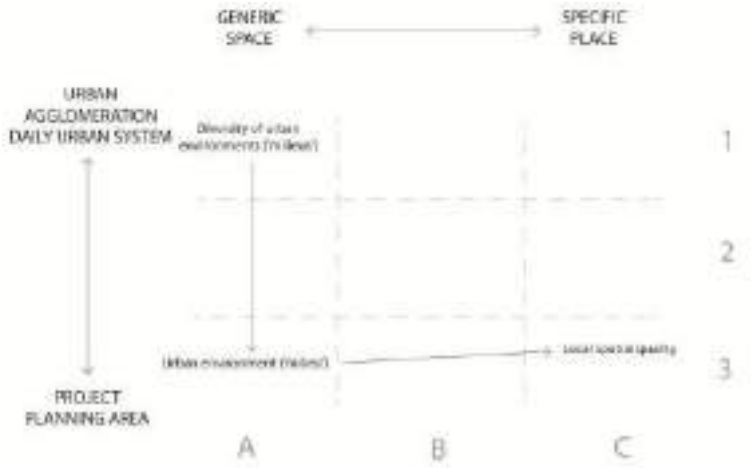

Figure 3. 'Route' over the Plan Review matrix

5.1 High Tech Campus Eindhoven

Imagine an urban region that wishes to develop an internationally competitive business climate, as well as realise knowledge development (e.g. by so-called knowledge spillovers). In addition, imagine that this region could demonstrate that a knowledge campus would be a suitable urban environment to achieve such policy objectives (3A). Now assume that this region could prove that such a campus would be a valuable addition to the existing range of urban milieus and that there will be no inefficient competition with other such milieus in the region (1A). This then leads to the relevant question of which type of local spatial quality would be required for the realisation of the desired knowledge development (3C).

The Dutch city of Eindhoven, the centre of the so-called Brainport region of the Netherlands, is home to the High Tech Campus. This campus houses dozens of knowledge-intensive businesses. This concentration of such businesses fits with the strong tradition in R&D in the Eindhoven region, and with regional and national ambitions in the field of knowledge development.

The campus set up gives shape to the chosen principle of 'open innovation', which centres around cooperation. Businesses on the campus all focus on their particular specialism, but they are expected to inspire each other by sharing knowledge and experience and by making use of the same facilities. The underlying thought is that, in this way, innovation not only occurs at a faster and cheaper rate, but also will be of better quality (www.hightechcampus.nl).

5.2 Shared facilities

The main question in relation to the local spatial quality on campus could be whether the public space is organised in such a way that it meets the needs of the knowledge workers (the campus target group) and achieves the objective of stimulating the

exchange of knowledge. One of the principles of the campus is that knowledge workers must be able meet in a casual manner and in a comfortable environment. To facilitate this principle, the campus has a centrally located, shared boulevard, along which a number of bars and restaurants are situated, as well as a conference centre, a wellness centre and some shops ('The Strip', see Figure 4). Although this boulevard with its facilities is no guarantee that people will meet, it does provide the conditions that encourage such encounters. In order to achieve these, facilities need to be inviting, which may be achieved by the shop windows' seductive and transparent exterior, and by the clever positioning of entrances in relation to the public space and passage ways.

Figure 4. High Tech Campus Eindhoven: shared facilities and lounge chairs on The Strip

5.3 Organisation and materialisation of public space

Public space design (spatial organisation and materialisation) also contributes to the conditions that encourage encounters. This includes benches, lighting and other street furnishings, pavement types and the presence of grass and trees. Local spatial quality must correspond with the needs of the main user groups. The High Tech Campus knows only one type of user: knowledge workers, national and international, with a technical background. They visit The Strip during their lunch breaks or for meetings, and particularly seek out environments that differ from their workplace. In the designing of the public space, the fact that these researchers usually like greenery and comfort was taken into account. Therefore, The Strip was not shaped to reflect a

historic European inner-city style, but rather accentuates the natural aspects of the surroundings. The pond takes up a central position in the design and offers a broad view from the lounge chairs placed around it. There are also wooden jetties, benches and bridges, creating a variety of places to sit and wander around (see Figure 5).

Figure 5. High Tech Campus Eindhoven: The Strip and walking route around the pond

In addition to a pleasant public space (due to walking routes, greenery and meeting places), the security of campus laboratories is, of course, also important. This requires a focus on the effects from the various design elements on their surroundings. For example, a high steel fence would have a very different effect on passers-by than would a glass door that is electronically secured.

5.4 Traffic access

Finally, there are local conditions which are important for traffic circulation.[11] The park-like campus contains many paths for walking or cycling. All around campus, bicycles have been placed for people to travel quickly from building to building. Moreover, this system of paths is connected to bicycle paths that lead to green areas outside the campus, and motorised traffic is efficiently routed to and from a separate motorway slip road towards the ring road along the outside boundary of the campus. All car parks are located directly off this ring road.

5.5 Guidelines and reference projects

Theoretical and empirical knowledge about the spatial quality of public spaces has been documented in handbooks. A number of urban designers and sociologists have

[11] In addition, also traffic safety and social safety could be named. In this example, these aspects have been ignored..

studied a variety of squares, parks and streets, and documented their main aspects (e.g. see Cullen, 1961; Gehl, 2001; Jacobs, 1961; Jacobs, 1993; Lynch, 1960, 1988). Notable fact is that these studies name best practices but do not formulate rules for constructing what could be seen as 'good' public spaces. This may be explained by the fact that each location, function and user target group is different; every situation requires its own approach.

However, this does not mean that projects cannot be compared. Although the appropriate spatial quality of a certain area cannot be determined using a general formula, this could be determined from reference projects; a comparison between the planned project and related, already finished projects elsewhere. Questions related to which actions were successful and which were not (ex-post analysis) are important to ask, as well as making certain that the reference projects match the planned project in type of urban milieu, magnitude and situation within the urban region.

Another notable fact is that a large part of available knowledge on attractive public spaces is related to a specific type of urban environment: the pedestrian areas in typical European cities. Examples are the historic Parisian boulevards, Italian renaissance cities and contemporary gentrified neighbourhoods, such as the London mews. Diversity and being small-scaled are important characteristics of these prototypes of urban environments. To date, is has been difficult to find handbooks that offer an alternative for these singular (cliché-like) references of spatial quality and urban identity. Complementary documentation of innovative examples of the spatial quality of other types of environments would contribute to the improvement of analyses and assessments of urban projects.

6. Synthesis

By introducing the Plan Review instrument, the communication on urban projects could be made more transparent, and thus contribute to improvements in planning and decision-making processes around urban investments.

Insight into the specific environment of a project location is vital to the assessment of urban plans (context sensitivity). In addition, there is a need for a system of analysis that would be widely applicable (scope, repeatability), and uses clear considerations (transparency) that are comprehensible to the wide variety of stakeholders (communication beyond the boundaries of individual disciplines).

The Plan Review meets the combined needs for context-specific knowledge and a system. It features a series of 16 spatial conditions that a project has to meet in order to achieve policy objectives (possibly at various governance levels and in different fields). This series is presented in a matrix, from which relevant conditions can be chosen, per case. This matrix may help to structure the dialogue with stakeholders, and maximise the objectification of plan analysis. Depending on the phase of the planning and decision-making process, the Plan Review may improve urban planning

and contribute to the related spatial assessment, in light of the particular policy objectives.

7. Discussion

The Plan Review has been developed on the basis of knowledge and know-how from various spatial disciplines. It deviates from the welfare economics approach of CBA – the instrument most used in the Dutch assessment process. The Plan Review is not intended as an alternative to CBA, but rather as a complementary instrument. Because of its deviating theoretic and methodical basis, a successful application of the Plan Review would require a team with a different composition of disciplines than present in the teams that currently mostly assess project plans. The application of this instrument requires a multidisciplinary team that represents both knowledge and experience in spatial research and design.

This new instrument as presented in this introduction, probably has not yet reached its definite form. In the coming period, practical application will test its usefulness, and further discussions with a wide variety of users may help to fine-tune the instrument. Initially, attention should be paid to the relationship between plan optimisation and plan assessment; looking at which aspects are focused on in which phase of the planning and decision-making process. Another area of attention should be the relationship between the Plan Review and the CBA. Because of the CBA's focus on effectiveness and efficiency of a project, and the Plan Review's focus on the conditions under which a plan could be most effective, we recommend that application of the Plan Review would precede the CBA. Actual practice will show whether this approach indeed delivers positive results. A third aspect that deserves particular attention is the weighing of the conditions as entered into the matrix. In its current form, the matrix does not provide any ranking. The parties involved choose the most relevant conditions, depending on the nature of the project. Further research as well as practical experience could indicate whether the possible incommensurability of various conditions would stand in the way of clear decision-making, and if there is a risk of cherry picking.

Multistakeholder Networking towards Circular Flow Land Use Management

Dagmar Petríková[1]

Abstract

This paper will address multistakeholder networking as an innovative approach in regional development. Networking will be organised as a platform collecting the land management data needed for innovations and development, bringing knowledge on the future trends affecting the region in order to take care of the shared strategic processes, cooperation and leadership. Municipalities in the microregion of Trnava have successfully started networking in order to prevent the use of greenfields for attracting new development projects, when brownfields are available in other parts of the micro-region and ready for redevelopment. The issue of brownfield redevelopment is pressing in central European countries. Shared understanding and joint vision and multistakeholder microregional cooperation contributes to the development of local industry and to cooperation and competitiveness within the micro-region, following the objective of sustainable spatial development.

Circular flow land use management is a concept applicable at regional and municipal levels, supported by networking to help the sharing of joined development and the decision-making in large municipal and regional networks. In the on-going study, the concept of networking is applied in a network structure, consisting of 12 small municipalities around the regional city of Trnava in western Slovakia, EU. The municipalities created a micro-regional platform in order to network and manage efficiently land use and other essential functions for better spatial and temporal qualities of the micro-region. Involvement of the Slovak University of Technology in the issues of brownfield redevelopment is bringing know-how to the strategy of redevelopment based on joint participation in the ERDF project, operational programme Central Europe "Circular Flow Land Use Management" No. 2CE174P4. The project started in Feb 2010 and will end in Feb 2013 and the first results of cooperation in the frame of networking are presented at the AESOP 2012 Congress.

1. Introduction

Circular flow land use management is a vital concept applicable at regional and municipal levels, supported by networking to help the sharing of joined development

[1] Slovak University of Technology in Bratislava, Vazovova 5, 812 43 Bratislava, Slovak Republic - dagmar_petrikova@stuba.sk

and the decision-making in large municipal and regional networks. Circular land use and management represents an integrative policy and governance approach that presupposes a changed land use philosophy with regard to land utilization. Such modified land use philosophy can be expressed with the slogan “avoid – recycle – compensate”.

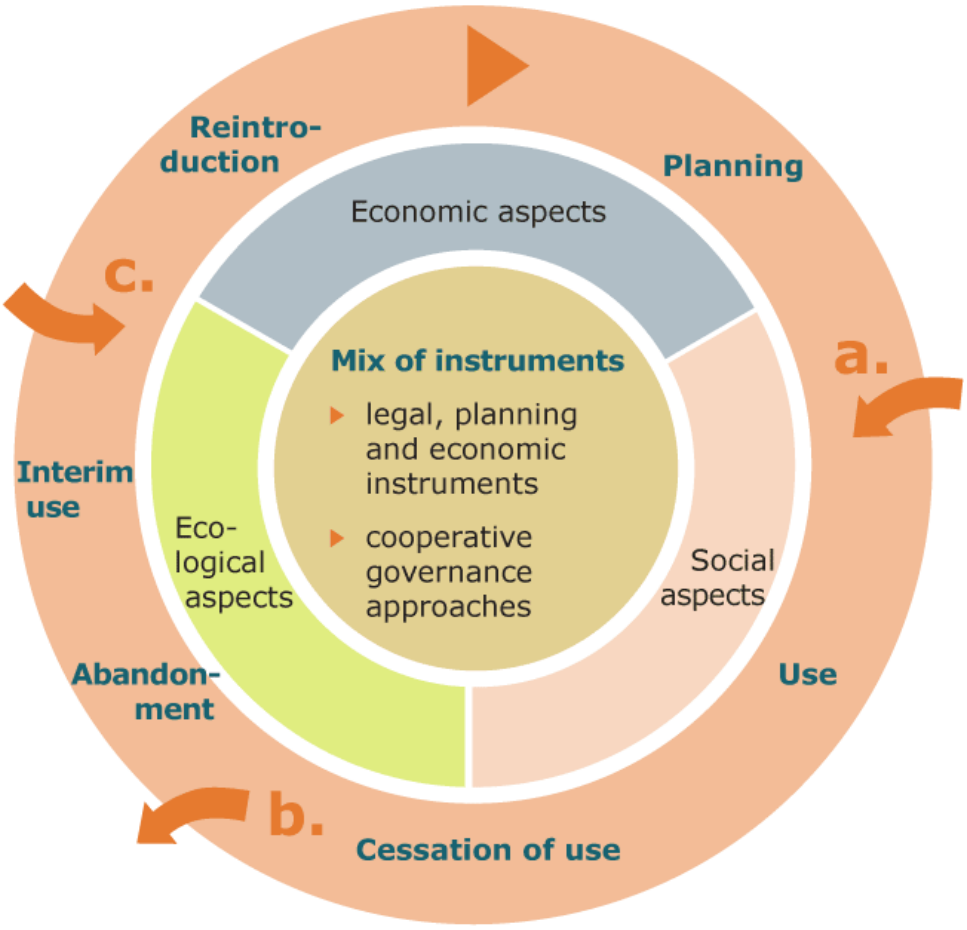
Similarly to the recycling-based principles, which have become commonplace in recent years in areas such as waste and water management, the concept “circular land use management” should become an established policy in sustainable land utilization. Materials cycles can serve as a model for circular land use management

The project CircUse “Circular Flow Land Use Management” No. 2CE174P4 is running under the ERDF operational programme Central Europe, where 12 partners are preparing the concept of Circular Land Management in 6 countries (PL, SK, CZ, DE, AT, I) under the leadership of the Institute for Ecology of Industrial Areas in Katowice, Poland. Involvement of the Slovak University of Technology is bringing know-how to the strategy of redevelopment based on participation in previous projects dealing with the issues of brownfield redevelopment. The project started in February 2010 and will end in February 2013 and the first results of cooperation in the frame of networking are presented.

Limitation of land consumption has become one of major spatial development policy tasks in across all EU member states. One of possible answers to the question how to minimise the land consumption and at the same time not to limit social and economic development is the reutilization of brownfields sites as crucial element of sustainable spatial development management.

Multistakeholder networking is an innovative approach in regional development. Networking is organised as a platform collecting the land management data needed for innovations and development, bringing knowledge on the future trends affecting the region in order to take care of the shared strategic processes, cooperation and leadership in order to avoid urban sprawl. Shared understanding of joint vision and multistakeholder micro-regional cooperation contribute to the development of local industry and to cooperation and competitiveness within the region, following the objective of sustainable spatial development.

Figure 1. Circular land use management (DIFU Berlin, 2008)



The philosophy visualised in the above figure shows the phases of land use resulting in a cycle. At the end respectively at the beginning of certain phases – see a, b and c – decisions concerning the further utilisation of land have to be made.

a. Zoning new “green belt” land for development
b. Rejection of land not suitable for subsequent use
c. Activating land potentials
- brownfields (industrial, commercial, military),
- gaps between buildings in internal areas,
- urban renewal sites,
- sites undergoing planning.

The end and the beginning of each phase are crucial decision points.

2. Analysis

In the Slovak Republic the Trnava microregion, located in west Slovakia, has been chosen as the case study in the CircUse project. Municipalities in the microregion of Trnava have successfully started networking in order to prevent the use of greenfields for attracting new development projects, when brownfields are available in other parts of the micro-region and ready for redevelopment. The issue of brownfield redevelopment is pressing in all central European countries and in the Trnava microregion in particular. The vision is the development of functioning, efficient and flexible cooperation structure and interlinks between different aspects of micro-regional development, different actors and interests in one interlinked strategy as a reaction to existing problems with brownfields areas, abandoned buildings and growing requirements concerning new capacities of public services and land for private investments.

Microregion of Trnava consists of 12 municipalities that create a microregion as a platform for cooperation and networking that will lead to new innovations in the development strategy of microregion. The aim is to integrate multi-task actions to re-use derelict areas in the city and municipalities in its suburban area, involving various stakeholders into the planning, decision making and implementation of joint strategy as a new chance to improve the quality of life in Trnava and other municipalities in the microregion.

This network platform is an organizational concept that helps the sharing of joined understanding and the decision making in large network structures by:

- Inviting the major actors of local development together around the table to discuss on land uses in the networking area of the microregion,
- Creating and sharing joint vision of the development and division of functions of the municipalities in this development,
- Promoting common values in the area of the microregion and developing trust and cooperation in reaching the targets,
- Preparing the joint development agenda,
- Developing the common innovation environment,
- Monitoring the implementation of the targets,
- Evaluating the results.

In terms of sustainable development it is necessary to create networks, alliances, elaborate joint strategies for several municipalities, which allow the division of labour, and make use of common potential. Each community has unique potential, each has different resources available. Cooperation and networking to achieve synergies and increase their attractiveness for investors to bring jobs, development and tax incentives, but also for people, which will be in the context of demographic change much more important. The cooperation of municipalities in the micro-region supports the diversification of the economic base of rural settlements, intensive use of specific human potential, innovation and local potentials.

Innovativeness of local development micro-region is based on:

- Increasing knowledge and skills about possible solutions and functions in the territory of the micro-region,
- Development of cooperation and networking relationships built on trust,
- Development of an innovative environment that allows an increase in the local economy,
- Development of ability for regeneration of microregion territory,
- Increasing the competitiveness of micro-region at regional and national scale,
- Using of marketing tools for creating a common brand (branding) of the territory, which re-uses the old areas (brownfields).

For the development of other economic activities and community facilities in the microregion the key role is played by the inclusion of the communities among the cohesion growth poles in the interest area of innovative growth pole of the city of Trnava. Municipalities also lie in the core belt of settlement zone first level. A major impetus for the development of micro-region was the establishment of the automotive group PSA Peugeot Citroen in the municipality of Zavar (2/3 of the factory area) and in the city of Trnava (1/3 of the factory area) in 2003.

An important factor for the development of transport infrastructure is the immediate proximity of the D1 motorway, linking the cities of Bratislava and Trnava. The advantage of geographical proximity of the villages of microregion is the exit from the motorway D1. The motorway passes through the village Zeleneč, at which it was built a new motorway feeder "Voderady" built, in connection with the construction of industrial premises Samsung. This goes directly to the village of Hrnčiarovce Parnou, which thus provides an excellent transport accessibility, but also serves to the surrounding villages of the microregion.

Also railway No.120 Zilina-Bratislava, which has undergone renovation in recent years. These two important transport elements become not only a significant positive solution to the territory, but somehow at the same time are also limits to the territory of the micro-region. In connection with the construction of the company Samsung that has taken place in the municipality of Voderady, the construction of a new motorway junction was finished, which significantly changed traffic conditions, eg. in the cadastral territory of Hrnčiarovce nad Parnou.

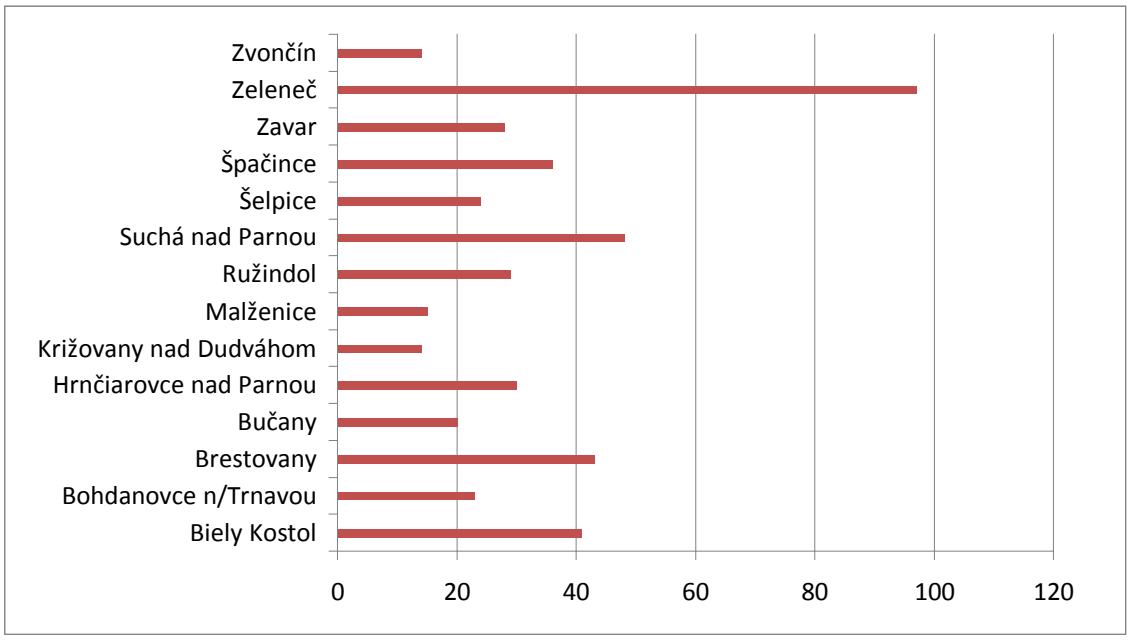
City of Trnava in Slovakia is among the cities hit by the suburbanisation tendencies. While even the late 90's, over 70-thousand people lived in Trnava, after 2000 the demographic characteristics of the city begins to fall. Causes of population decline not only in Trnava, but this process is taking place in almost all major cities not only in Slovakia but also in Europe. This is very similar: decrease in fertility, fewer children on average per family but especially moving into the new satellites in the countryside and villages near cities, that means suburbanisation.

Interesting is also the view of decades back: the greatest increase in population experienced Trnava in the seventies and eighties. The average annual increase amounted between 1970- 1980 enormous increase of 1529 people, in the years 1981 to 1991 the increase in Trnava per year on average was about 800 new residents. In the first half of the 90's, the annual growth fell to less than 300 in the second half of the 90's even dropped below a hundred.

The overall decline in population of Trnava is the independence of the municipality of Biely Kostol and Hrnčiarovce nad Parnou in 1993 and 1994. In recent years, the population decline has not stopped, on the contrary, continues. In 2001, in Trnava lived 69 563 inhabitants, a year later, 69 868 inhabitants, in 2003 68 588 inhabitants, in 2004 68 500 inhabitants. Five years ago there was still in Trnava 68 292 inhabitants, in 2006 67 878 inhabitants and at the end of 2010 only 67 368 inhabitants.

Number of emigrants from Trnava to various neighbouring municipalities for the period 1/2011-12/2011, according to the data by the Local Government of Trnava is directed largely to the municipalities of the territory of the reference micro-region (to 9 villages out of the 13 municipalities of the micro-region).

Table 1. Number of residents moved from Trnava to neighbouring municipalities in 2011



3. Results

In all municipalities a pilot survey of the area and communities was carried out, following the issues:

- Topography and landscape characteristics of the municipality
- Settlement structure, housing
- Population and social climate
- Transport, social and technical infrastructure
- Green areas / Settlement Greenery
- Public spaces
- Underused areas

The results are presented in the SWOT analysis:

Strong aspects of Trnava microregion development:

- infrastructure - proximity to the superior technical infrastructure,
- availability of superior amenities (retail and services) accessible in the regional and superior regional centres,
- investor interest for the development of housing construction and by microregion development induced demand for housing,
- good access centres to microregion and region (Trnava), followed by a multi-modal transportation centre of Bratislava - Vienna
- the availability of jobs,
- the dynamics of economic growth
- relatively good business environment,
- the development of demand-induced population growth,
- demographic increase.

Weak aspects of Trnava microregion development:

- lack of vacant land owned by municipalities,
- in many villages a little outdated building stock of individual housing,
- missing local streets and paths in many villages,
- the lack of barrier-free access solution,
- existing wild dumping sites,
- poor quality of public recreational areas, playgrounds,
- low quality of public transport,
- in many villages no parking and garaging facilities of cars,
- in many villages dust due to transport, lack of windbreaks and soil erosion,
- in many villages the poor state of historic buildings and a problem of their recovery realistic strategies and funding sources,
- in some villages lack local of social infrastructure (education, health, culture, sport),
- connotations associated with the existence of complex nuclear power plants.

Opportunities of Trnava microregion development:

- the use of PPP and structural funds to complete the reconstruction of technical, transport and social infrastructure,
- development of micro-regional cooperation involving common infrastructure building, cycling paths, building micro-regional collection yards,
- regional programmes and land consolidation implementation in order to access land to create building sites for various types of housing areas and infrastructure,
- use of the Environmental Fund and other EU funds for planting greenery outside built-up areas of municipalities,
- microregional cooperation intended to regulate the migration trends and investors in the most suitable locations in terms of sustainable development,
- microregional cooperation for more efficient and better public transport,
- cooperation with the universities close centres to support the micro-regional development.

Threats of Trnava microregion development:

- increase of unemployment,
- decrease in real estate prices,
- increase of the cost of living (energy, food, services),
- reduction in the level of employment in agriculture,
- nuclear safety and threat to environmental components,
- reduction in quality of life by the existence of nuclear facilities and radio waste,
- emergence of industrial and logistics parks,
- population migration,
- coming of problem causing population groups,
- an increase of the temporary present and temporary resident population,
- lack of interest to cooperate.

4. Conclusions

As it is clear from the summary of the outcomes of the SWOT analysis, the Trnava microregion is a typical representative of a core of urban metropolitan region. Good transport accessibility and availability of facilities makes it attractive for investors in the industry segment as well as in housing, services and benefiting from social infrastructure and the cumulative advantages of the core city - Trnava. The dynamic development of economy of the region induces demographic growth influenced by migration and the demand for quality forms of housing and services both for the production services as well as for the services to the population.

Despite the core common competitive advantages which include location, area availability, accessibility, infrastructure and transport facilities, each community due

to its location, the specific natural conditions and existing development have different potential for participation in the development of the region. A key factor in the competitiveness of microregion as a whole and the individual municipalities, including the core centre appears to be the exploitation of these specific potentials. This is only possible in a coordinated development strategy and cooperation enabling more efficient use of specific potential and division of labour. Microregion therefore has a unique potential to gain a competitive advantage from the development of inter-communal cooperation. By developing the intercommunal cooperation it is possible to respond to the need to optimize the structure and location of facilities covering the internally derived demand - it is primarily about leisure time activities, recreation and relax, and specific forms of housing and services, and in the external investment demand - it is especially locating the business of manufacturing services, small production , logistics services and transport. By optimizing the localization from the miroregional perspective it could both maximize use of existing potential of individual communities, as well as to minimize the take of un-built territory reflecting thus the limiting factor for extensive development throughout the region TSK – high quality of agricultural land and environmental protection. Optimising the location of functions on microregional level could also make the movement of population within the microregion more efficient and it could be effective also for the operation of services, with particular emphasis on services provided by public sector and thus contribute to saving municipal finances. Given the considerable similarity of the range of problems perceived by population (lack of green spaces, low services by public transport, incomplete services, long-term unemployment) it opens the possibility for using the cooperation within the Trnava microregion also for the associated projects financed by EU structural funds.

Between Energy of People and Vacuum of Institutions! Grassroots Planning in Albania: The case of Co-PLAN Institute for Habitat Development in the Informal Settlements of Tirana!

Dr. Besnik Aliaj[1]
POLIS University
International School of Architecture and Urban Development Policies
Tirana Albania

Abstract

This article addresses to professionals involved in community-based urban planning and development processes and particularly those working in the non-governmental sector. Those working in the local governments and who are engaged in dialogue and programs with community actors will find the experiences described in this study useful. The main objective of the study is to map institution-building processes, as well as to disclose the various actors and motivations during the way collaboration was established for policy reforms and institutional changes in a country in transition towards market economy as Albania. Until 1990 Albania experienced one of the most severe and orthodox communist system in the entire Eastern European bloc. Indeed, Albanians suffered for more than 40 years negation of the freedom of speech. Consequently, the citizens were not invited in no case to influence decision making, which was very centralized. It can be said that there was no tradition in the participation of community, also because the system abused with the "collective" approach. In the 1990 Albania too was influenced by the political, social and economic changes that brought down the iron curtain in Eastern Europe. Thus, Albania started on the difficult and new road of transition, but rather in a very chaotic manner and even with severe setbacks such as the 1997 social unrest caused by the collapse of the fraudulent pyramid schemes, or consequences of 1999 of the war in Kosovo and refugee crisis. Interestingly enough, a local NGO initiative called Co-PLAN, Institute for habitat development, started its activity as a professional organization in the difficult year of 1997. Formerly a Dutch social program in one of the most irregularly developed areas in the outskirts of the capital city of Tirana; Co-PLAN would be soon distinguished as one a pioneering organization committed to contribute in the difficult transition process. The first steps that were taken in the muddy and poor areas of the periphery aimed to organize the community in addressing problems like public spaces, social disarray and health education. It was very unusual in the Albanian context to approach the community, even more so in the irregular settlements. All too often, there has been an opposition from small

[1] *The article recognizes the contributions of the colleagues of Co-PLAN Institute for habitat development, Tirana Albania, and concretely the contribution of D.Shutina, S.Dhamo, F.Kuci and C.Acioly, Jr, etc.*

groups from these communities thus forming a strong and very conservative stream, backed up by the government and the "old-fashioned" professionals. In several cases as well as in the back stage, Co-PLAN was accused as "the protectors of the illegality".

Albania in Transition of 90-s: Co-PLAN, Institute for Habitat Development

In fact Co-PLAN stayed firm on its views of advocacy for the groups in need, vulnerable groups, the part of the community that would never get access and had no chances to influence decision making, even those decisions directly affecting them. Yet Co-PLAN has never acted as "charitable" organization. This in fact made the work in field more difficult. "Due to the persistent crisis often organizations, usually known as "shadow" organizations with their own "hidden" agendas, started to emerge in these areas with a philosophy of emergency in the background." In the beginning, it was nearly impossible to negotiate with the newcomers to give up their own land for the broader interest of public use, due to the fact that land often entailed a hard-earned asset for them. Even more difficult it became when residents were used with organizations distributing food without claiming any contribution from them for a public cause. In this transition period, also peoples' attitude shifted rapidly from "collective" into a highly "individual" oriented. The change in mentality has proven to be difficult and usually takes time. But it is probably due to this fact that it became a challenge that "co-planners" liked to embrace. However, the toughest battle was to be fought in a different environment; at the "sophisticated" level of professionals and authorities. Advocating for the formalization of "informal" was considered a heresy. Co-PLAN's important objective of bringing together the community (not necessarily those of the illegal settlements) with policy makers called for another level, which is professionalism. Therefore, Co-PLAN undertook several initiatives to establish networks and most importantly forums where different actors and stakeholders could forward, defend and confront different views and interests. On the other hand, in several cases Co-PLAN shifted to the role of intermediary between communities and authorities (local and central), by introducing comprehensive tools to cope with the challenges of the new urban dynamics of the transitional period. This required a comprehensive level of capacities as well as strong willingness to be a driver force in the entire process. Co-PLAN had to face new challenges. This shift to professionalism necessitated the broader view of neighborhood-to-city scale.

Kamza: From Informality to Municipal Autonomy

1. “The Municipality of Kamza was formed only in 1996 out of the need to cope with new unprecedented growing developments in the area. Kamza inherited a strong agricultural background and in the past fifteen years or so, the population has seen at least twenty-fold increase of 7,000 to 140,000 inhabitants, and losing almost all the agricultural potential as result of the conversion of land from agricultural-rural to urban” (Aliaj, B.,1995). It is not hard to imagine the burden and scale of problems this municipality is confronted with in coping with an alarming rate of 90% illegal constructions, while it totally lacks any institutional memory or capacity. This has all happened while support from central government was missing or inexistent, since the area was not in its own agenda of priorities, and is regarded as a “dirty dish”. “One should also take in consideration the country’s context of decentralization where transference of problems rather than powers to the local administration prevails. What’s more, political elections continue to cause waves of unjustified layoffs to the local administration staff. In the election of 2001, or 2004 in the Municipality of Kamza, with political changes 95% of the municipal staff was fired, creating a complete blackout in the local administration and transfer of knowledge” (Aliaj, B., 1996). On the other hand, Co-PLAN tried to emphasize the big potential lying in these areas.” In several surveys of the time, Co-PLAN estimated an incredibly large amount of 110,000,000 USD investment in housing made by residents (by contrast, the most successful privatization case in Albania at that time reached the amount of 80,000,000 USD), whereas the municipal budget spent for public investment reached the ridiculous amount of 100,000 USD in the best year.” (Co-PLAN, 2003)
Unfortunately, in several cases this potential has resulted in violent conflicts with government representatives. In 1995, the government tried to relocate by force the settlers, which braced themselves for an open confrontation that resulted in ferocious conflict between people and police. In fact this was not the only case. The government lacked for a decade the vision for coping with the situation and that has resulted in a misuse of the area for political purposes, making such unrealistic promises during electoral campaigns as legalization of settlements (an option that was never elaborated professionally by the government up to 2005) and hence never took off at that time. This caused other revolts since government has not been capable of finding the proper way of how to handle the situation, so long as bridges of communication between government and community had still a long way to go.

Building Invisible Bridges and Mutual Trust: Disclosing Actors and their Motivations

Co-PLAN has taken several initiatives with the financial support by foreign donors like CORDAID Holland (formerly known as Bilance, Mensen in Nood) and latter by NOVIB, or other Dutch governmental sources, trying to establish communication between government and communities that would eventually serve to address the issues, but also to identify the potentials of joining forces to overcome the problems. In the very beginning, Co-PLAN worked at a neighborhood scale in two very specific areas: i) Breglumasi, an illegally developed area with more than 250 families; and ii) Bathore, which has seen a very rapid expansion from 13-200 hectares, also illegally developed (part of the Municipality of Kamza) with more than 4,000 households; iii) a third case is in Keneta neighborhood in the main port city of

Albania Durres. "The newcomers in these areas originally come from the remote and mountainous areas of the country, where, especially after the 1990s, chances for a decent life were practically zero. Many people became unemployed after the collapse of the heavy industry that was the main source of employment for these areas." (Co-PLAN, 2004)

Working in these areas it was very important to look at the stages of the process, which the residents go through in order to gain access in the neighborhood:

2. *Step 1*: **Decision to migrate** - In the places of origin, life is still organized around the clan, which is usually an extended family. Basically this means that to a certain extent the family economy is common, therefore decisions are taken jointly in a group. Take a family of 4-5 brothers (usually these families have a high average number per households) that after it realizes that life in their village is becoming almost impossible, makes the decision to move to urban areas with greater chances for a better life. "*In the past ten years, the central part of Albania has attracted newcomers from all over the country, especially those from the northern parts of the country, which remain the most backward one*" (Aliaj, B., Lulo, K., Myftiu, G., 2003) There are few implications to this decision. In order to afford such an important and financially costly decision, the clan decides about the "sharing of responsibilities" among brothers. One of them (usually the youngest and possibly the single one) gets the mandate of clan to search for the most appropriate and affordable location for the entire clan, while one or two others are responsible for securing the financial means to afford the move and shelter. In many cases this implies that someone has even to emigrate and work abroad. There is always usually the oldest brother, or the grandfather, who remains and looks after the remainder of the family.

Step 2. **Identifying location** - This step is taken in a very discreet way. The basic criteria are the vicinity with the urban area, affordability, but also the land and property titles. This is a very delicate process. The newcomers are well informed about the tenure of the location they identify as appropriate. This means that if government is the owner of the parcel, the chances are to meet less difficulty for settling in there. Such an attitude stems from the peoples' belief that "collective property is nobody's property". Nevertheless, there is a "fee" to enter the area. It happened that the first newcomers in the area became also "middlemen" (not necessarily the real owners) subdividing the land and selling it out to other new comers. Needless to say the transactions are informal. In reality the new residents know that they do not actually buy the land, indeed they gain the "right" to settle in the neighborhood. This is reflected in the verbal agreement according to which "the deal would be invalid if the government or the real owners would step in the process".

Step 3. **Testing the firmness of the government** - The "purchase" of the plot is not immediately followed by the building of the house. In the very beginning, the residents build a shack or they just put building materials on the site as a sign for

later construction. This step is taken for two reasons. In so doing, they can test the reaction of authorities toward the area while at the same time it sends a signal to the neighbors to prevent the land from any sudden invasion from other newcomers. Sometimes, it happened that they had to deal with police as the latter tried to relocate them. This is probably also one of the reasons why in the beginning only one of the family members is dealing with the first stage.

Step 4. **Starting the investment** - Having gained a little security the investment on housing starts. What is interesting about this step is that the phases of investment follow the cycles of a financial flow. This means that the progress of the investment is very much relying on the income generated mainly from either emigration, or selling out old properties, or generating income from working in the urban area. Residents appear to be very creative in decreasing the costs of building. The tools used range from using cheap materials to decreasing labor costs by involving relatives in the house-building process. As the household economy grows one can realize how this effects the investment. Better materials are used and roofs replace terraces.

Step 5. **Moving in** - Usually the family moves into the house when the investment is complete. What is interesting in this step is that the family still lives around a common economy. They keep this system until housing for each family is secured. This is a solidarity system that stimulates the assistance among clan members.

Step 6. **Improve the surroundings** - Noticeably, until this stage infrastructure provision was not a priority. In fact once the plot is bought the buyer is supposed to have the right of access, but this is not always the case, and it becomes sometimes a source of conflict. The reason is that there is no layout whatsoever of the area to guide the land occupation process. But interestingly enough, there still is a natural order in the way the residents build. At this point, the process meets with the difficult task of mobilizing joint efforts and contributions for building and financing of the infrastructure.

Community as an Asset of Planning and Development:

The main focus of the work in these areas was to mobilize community efforts to identify and secure public space indispensable for the urban development of the area. It takes a lot of efforts to convince people who work hard to take out a living to buy the plot of land on which they sit, and who struggled with the police to live where they do, to push back fences and to allow some space for the public purpose and planning sake. However enthusiastic a small group of young professionals could be, it could not be much more done without having first established human relationships with the residents. It is understood that trust building is a lengthy process. It takes time and efforts. It cannot be achieved without trying to understand the real human side that exists behind the entire process. The gravel, for example, offered in return to square meters of public space, was just an instrument of bargaining and building trust with the community. The idea was to start a “snowballing” process, meaning that at a certain point in time someone had to break the ice, and as this process went

on, to have more and more people on the side of the development process. This also means that we wanted the process to take place and more people to accept it through a "social community pressure". In practice there were the community residents, which had to convince their fellows and neighbors to embrace the rules of the process. A very meaningful indicator is the fact that in three years a network of 6km public space was secured and modestly improved without the involvement of the police or other government authorities. Since the beginning therefore it was very important to identify the so-called "key persons", which are people that have a good reputation in the area and can be representatives of the community interests. Getting the community organized implied also to have an institutional representation of the area. Since the beginning, special regard was paid to the process of creating a community organization (CBO) named "Rilindja" (Revival). In the beginning, the challenge was to have people grasp such an idea. But soon, as the influence of the organization extended in the area, the challenge shifted to securing the wide representation of the organization. The only way to secure this was through fair, open and democratic elections. One can imagine that Albania did not inherit a strong democratic tradition; hence the task was tough.

Building Partnerships for Development:

After Dutch/foreign aid and development organizations also the World Bank joined the process later thanks to the "Urban Land Management Project" inspired by Co-PLAN work. In fact the World Bank and the Albanian Government financially supported the project jointly, but at that point the Albanian authorities could not yet grasp the importance and the philosophy of the project. With time the project was given the Albanian ownership and supported the upgrading process as first step towards a formalization reform. An important stage of the process was the negotiation between the community and the authorities for the details of the project. Co-PLAN had a key role in intermediating between the community represented by "Rilindja" and the authorities of local and central government. All kinds of issues, ranging from the cost sharing rates to steps of the process and technicalities of the project, were to be discussed and negotiated. After several months of meetings, discussions and negotiations, the process resulted in an official and institutional agreement between the community represented by "Rilindja" and the County officials as representative of the Local Government at the time. However, the Partnership Agreement was covering only a small part in the wide range of the problems the area faces. Co-PLAN remained concerned with the democratic and full-wide representation of the community interests. One of the election periods of the council of the CBO coincided with the local elections of "aldermen" (formerly official representatives of the neighborhoods). It was impressive to see how the "informal" elections of the association of the residents were given even more importance than the local elections and they had a high turnout. Thus, the transparency increased the residents' trust in the association. Indeed, "Rilindja" was taking on a big and important responsibility, that is, an honest and fair representation of the interests of community on the one hand, and to convey the philosophy of cooperation and collaboration in the urban development process in favor of the public interests most important issue and probably the most difficult one; change the

mentality from “expect the state do...” to “let’s get together take some action and after seek for some support”.

Prioritizing Developments and Consolidating Community via Gender Balance:
Nevertheless, easier said than done, the main difficulty to get the process going were money, though implicitly accepted. That is why Co-PLAN undertook a very interesting consultative process with the community. The approach used was ‘Participatory Analysis for Community Action’. The aim was to get the residents thinking about their own responsibilities and taking the respective actions overcoming the belief that nothing can be done without first having the money. The process resulted in an increasing interaction between residents or group of residents trying to come up with common and acceptable solutions. The questions put forward by the organizers were simple. Say, the question was to identify an appropriate and sizable plot to build a school assuming that the funding of this initiative was in place. In first place, the question was simple to be dealt with. In reality, the process was tough and residents found that it was not easy at all to conclude in a commonly agreed solution. Thus, after difficult negotiations amongst the different groups of residents, an appropriate plot for a health care center was identified and given as community contribution to the initiative of improving the access to health care. As a result, at least 300 families were reached. The entire process was very interesting to the team. Co-PLAN had a fantastic chance to observe from inside the decision making process. In first place, one can get the idea that the pattern of decision-making process is very gender imbalanced. Unfortunately, this is matter-of-factly true. The husband (man) is in charge to generate the income therefore is supposed to have a stronger say on the household expenditures. After a more accurate analysis, Co-PLAN found out that when facing issues like infrastructure the decision would eventually shift towards *water supply* or *sewerage* rather than say *roads*. This probably to banks or projects, focused only on disbursing money, means nothing but Co-PLAN tried to look deeper into that. The implicit assumption was that women were mainly dealing with housing maintenance (*although according to surveys conducted by Co-PLAN a lot of women were also involved in income generation activities by, for instance, assembling shoes at home for an underpaid salary* - Vejsiu, Y., and Misja, V., 1996), while men are more interested in mobility. This argument could be supported by the observed fact in the area that mainly women carry the arduous task of fetching water from often far away distances, by manual labor. Therefore, women mainly influenced the choice of water, while men mainly supported the choice for road network. In fact the women did influence decisions as far as they have probably the bigger stake in family responsibilities. However, the man remains, by an archaic tradition, the one and only articulator of the decisions. A similar effect could be observed in the case of the health care center. At first place, men, who at the time were main counterpart contacts, were not very enthusiastic about the idea. But when the issue was broadly discussed the situation changed. It is understandable; for the women accessing primary health care in the area was incomparably more efficient than say driving more then 10 km (*the distance to the nearest hospital*) to get a simple assistance. The close consultative process with the

community, in fact, later appeared to be crucial especially compared with another initiative of an organization oriented toward “cost-disbursement approach”, which failed to meet the need, and was illegally occupied without serving a single day to its purpose of health care. The accurate observation on the real influence of women in decision-making encouraged Co-PLAN to establish a better contact with the female part of the population. The process gained increasing importance as the involvement of women turned out to be very much relevant to the entire urban development of the area. A women organization was established and probably the most essential social activities were carried out in close collaboration with this group. They succeeded in carrying out the most interesting, traditional and inspiring aspect of the community living in the area, through fairs, social gathering, and other social activities.

Building a Future by Investing of Children and Youth:

In the frequent surveys conducted in the area by Co-PLAN, it was easy to understand that the majority of the population was very young. This has always been regarded as strength for the area, showing the vitality of this population. However, in the threat of sometime cruel reality of the pupils dropping the schools in order to generate income through selling cigarettes on the streets, this obviously becomes an issue of concern. Therefore, Co-PLAN put even more efforts in establishing youth groups that would undertake social as well as education activities (such *as language courses, sports etc*.). Even more specific became the objective of relating a sustainable future with the youth, the future of the population. Several initiatives were taken in having youths planting trees and taking care of them. The limitation of these initiatives was that community does not yet see public green spaces as a priority for the area. Of course the team met all kinds of difficulties. None of the initiatives was easy. In fact some of them were very difficult, while some others even failed. This was for instance the case of a program of waste collection, where a system of collection was introduced and residents were asked to contribute in order to carry on the process. Due to the efforts and energy of the social workers, this system kept running, and even well for some time. However, it could rely neither on the unlimited assistance of Co-PLAN, nor on the self co-ordination of the residents. The project failed to transfer the system to the local administration. Though it was a failure, this case was very interesting to draw some valuable lessons. Of course Co-PLAN neither aimed nor was able to individually focus in all aspects. Having identified several other NGOs operating in the area in different fields, Co-PLAN in collaboration with the Municipality of Kamza initiated the set up of a network of NGOs that would eventually exchange information, co-ordinate and also enter in joint initiatives to sharing the responsibilities. Definitely, the democratization issue of the area through information remained the top priority for Co-PLAN. We could not expect people to influence the governance without sharing information. Amongst the successful attempts in this direction was definitely the publication of the Newsletter of Bathore. This was a good chance for all residents to share their concerns and views on urban development, social, health and education issues.

Replicating Neighborhood Development Agenda at City Scale:

"When discussing about bridges, it would be simplistic to narrow down the issue to the neighborhood level. A constant concern of Co-PLAN was building bridges between community and authorities, between different levels of public administration, between different actors that have a stake in the urban development process including the professionals and more importantly building the main bridge toward the public opinion."(Co-PLAN & ENHR 2003) Such an important yet difficult process would have little or no effect without a series of Urban Forums or TV programs and debates, where Co-PLAN found itself not just as a participant but on most occasions as organizer and facilitator too. Indeed the Open Public Debate "*Managing Tirana's rapid growth*" in 1998 was the yearly event that still continues nowadays via so called Open Forum. Until then, the open debate in professional circles about problems to meet the real priorities of people was inexistent in the Albanian society. The echo of this event lasted for a long period of time. The event has come to be a good tradition with Urban Forum organized annually. This is a good chance for professionals, authorities, NGOs, CBOs and communities to join in and exchange views and ideas on urban development and related issues. Co-PLAN succeeded to make the issue a concern also at regional level, which have now carried on Urban Forum in several other cities, and have even established a regional network of professionals (in the Balkans) to address issues of similar content. An important milestone in the process was the ENHR International Conference *Making Cities Work* held in Tirana 2003, and AESOP Heads of School Meeting in Tirana 2011. The Albanian case in these conferences has been very relevant. Publications have also been supportive tools to bring together the professionals and students. "*City Made by People"* initially and Forum A+P nowadays are already a tradition. The aim of this book is to bring the most relevant experiences on urban development contributing in this way to create institutional bridges in the debate amongst professionals.

Building Capacities of Local Authorities towards Good Governance:

For several years, Co-PLAN was a chief advocate of formulating in a participatory way a model that would cater for the reality in the irregularly developed areas. Considerable efforts were put in preparing the community to take actions to improve the social and physical conditions. However, the authorities were far from being responsive to the initiatives of the community. Often this slowed down the process of integration of these communities with the rest of the city. On the other hand, Co-PLAN always tried to position itself as an organization that facilitates the communication between community and government rather than taking over the government duties. This differed quite a lot from what most organizations were doing. Building infrastructure, schools or other facilities were none of Co-PLAN's business, which was rather trying to bring together different actors to find the appropriate means and suitable solutions through multi-lateral contributions.

However, as Co-PLAN and "Rilindja" gained the trust and the mandate of community to spell out their needs, the government was still lagging behind. This was a crucial moment to realize that there was no longer a need to work closer with the local government in order to make them understand the real issues, and also to

increase the trust of the residents on local authorities as well as their capacities to deal with the situation. It was upon this basis that a new initiative named "Empowering the local government and community based initiatives in the Municipality of Kamza" would take off. The initiative was a joint effort between the Municipality of Kamza, Co-PLAN Institute for Habitat Development and IHS Institute for Housing and Urban Development Studies, Rotterdam Holland. In order to cater better for the needs of the local government, a priority needs assessment was undertaken. For this reason, a joint group of municipal representatives and professionals of Co-PLAN organized a workshop which concluded in an operational plan. "The main approach used was the Objective Oriented Participatory Planning. In fact, no one anticipated that the project was about to be strongly shaken by the local elections of that year. The sudden layoffs of 95% of the staff was a big lesson for the young team, which had to get used with the up and downs of the political climate of the Albanian reality. The only thing left when almost everything you built is ruined is to start anew. Hence, the immediate action was to re-establish contacts with the new political representatives of the Municipality of Kamza. At the end of the day, professionals must face reality, and the reality is that for good or bad the new administration represented the people of the municipality." (Aliaj, B., Dhamo, S., Shutina, D., 2009)

The Process of Making a Strategic Urban Development Plan:

A new process of carrying out the priorities of the local administration started. After a difficult consultative process the priorities were identified. However, it was difficult for some time for the project team to come to a full understanding with the municipal staff on the as often what they meant was different from what they said. For instance, they were wondering if something could be done about the "chaos". To our understanding (which latter proved to be right) the chaos was standing for the irregular urban development process. It is clear that the question whether something could be done about the urban chaos was a much talked-about issue. The "what" did take time and efforts to identify. In fact, the "what" was followed by the "how" and so on… During the process almost all these issues had to be reviewed according to the dynamics. What was important to be maintained was the close contact with the ground and community, which helped the team in not losing the realistic view on what we were doing. The project finally could identify: (i) urban development; (ii) infrastructure; (iii) economic development which indeed meant to them employment, as the priorities of the local administration of the Municipality of Kamza to cope with the very difficult reality. On the other hand, the project team had its limitations in terms of finance as well as knowledge and experience.

However, the experience accumulated through years of working with the grassroots level appeared later to be crucial for the success of the entire process. In order to respond to these needs we formulated the following objectives: (i) a vision for urban development; (ii) building capacities; and (iii) investment in public service. "Why a plan?" or "another plan" was the first question to come up and which needed an immediate answer. In the transitional period there were other planning initiatives that failed to meet the real needs of peoples. The traditional planning methodology in

Albania was a narrow physical one, without considering the involvement of different actors. To the project team it was clear that the process was going to make the difference. Another factor that would eventually make the difference was the fact that in the view of the project, the plan was never seen as an end, but rather a means in the hands of the local administration to foster the development of the area. Being a pioneer organization, Co-PLAN aimed to introduce comprehensive methods of urban planning and urban management. Hence, the assistance of IHS Rotterdam was estimated to be crucial especially in this process. "Capacity building" was a crucial component. One could not expect any comprehensive strategy to translate into actions by people that lacked first hand experience in dealing with urban management issues. Besides, the level of education of the local administration was low (this is common in such level of municipalities across the country and we had to deal with this sad reality). For this reason, the aim was limited to on-the-job assistance. "Investments" is the last but not least component. Given the project's financial constraints, the investments were not meant to meet the huge needs for infrastructure of the municipality. In addition, since they were limited this necessitated that choice to be well thought to addressing specific issues and models. In the end, Co-PLAN wanted to use these investments to assist the municipality rather than taking over its duties to meet the needs for public infrastructure and services. During the process, all the three-abovementioned components were combined together to complement each other and above all to serve the purpose of the process of empowering the local government.

Citizen Participation: tools, methods and results!

At the start of the project, the notion of citizen participation all but known and accepted. The notion was even strongly rejected by a considerable number of professionals. To a certain extent, the notion is not so welcome nowadays either. Such opposite views by them can be justified on the grounds of their former education in a society where the basic elements of democracy were lacking. Hence, the very first challenge was to build and support a cogent argument on why the citizen participation was important. Co-PLAN team came from a very interesting experience of work with the grassroots level, which in fact focused on organizing the community for joint actions. The terms of discussion and negotiations were simple and clear. You were dealing with sharing contributions to improve infrastructure, the steps, and stages of betterment of the area. All these topics were perfectly understood by residents. The move to a higher scale along with the shift from an action- oriented experience to policy formulation implied that also the terms of discussion with the residents needed to change. In the beginning this created few difficulties, as far as nobody was expected to address to the community issues like "How do you expect the improvement of urban management in Municipality of Kamza (MoK)?", or "Could you feedback on the vision formulation of the MoK?" Therefore, the team understood that he document that was going to be prepared should be easily translatable into actions, and phases expressed in operational terms. The same problem the team encountered with the municipal staff too. In different meetings with the municipal administration, we realized that the amount of feedback on the expectations of the plan was very low. This was only showing the scale of difficulty

that awaited us in the long process of formulating the strategy. The implication was that more efforts had to be put in conceiving a plan that would cater for the people's real needs. Moreover, this was a tough task especially when references to similar experiences in Albania were missing. It took several months (December 2000 – July 2001) of discussions and negotiations, brainstorming amongst the team members of the project as well as with the IHS Rotterdam consultants to come up with the an elaborated idea of how the plan was to look like. Building the argument of "why participatory approach" was only a small part of the picture. In order to ensure participation the team had to think about the tools and the infrastructure of participation. The same question Co-PLAN staff was making at time was: How citizens can reach us?

In order to expect any kind of feedback, the community ought to be informed about the process and about the expected product. The project team therefore launched a campaign of information about the project and the preparation process of the urban development plan. The campaign involved several ways of communication. Some of the most important national and local newspapers were involved in the coverage of the plan. In addition, in collaboration with the main national private radio in Albania the project team experimented a creative way of information. In the morning program (which has the biggest audience, due to the singular way of involving music, humor, phone calls and discussions on the real daily problems) the experience of the Municipality of Kamza, which to many in the capital was unknown, was brought in. Thus, the information was conveyed to both sides: the citizens of Tirana heard the new and peculiar situation in Kamza, while the residents of the newly created municipality of Kamza received the views and opinions of the city where they want to integrate to. Other means of information were used, including banners on the main road of the Municipality to announce the plan preparation, and give clues about contacts (the project office in the municipality was the point of contact). In addition, an announcement board served to communicate the progress of the process. However, this was only part of the communication process, to get the message through. The objective of the participatory process was not only to inform the community on the proposal of the draft strategy but also to receive feedback from the residents. Therefore, other means were employed to serve this purpose. A questionnaire was distributed to 10,000 households. The questionnaire contained an explanatory notes on the plan as well several questions to receive their feedback on the strategy. The return of the questionnaires was not optional, but special personnel were devoted to collect the questionnaires door to door, few days after they were distributed. Thus the residents were given enough time to for the answers. Time and efforts were devoted to the elaboration of the entire amount of questionnaires. The results of the questionnaires are included in the urban development strategy. Furthermore, in order to increase the transparency of the process, the result of the survey were attached to the strategic document. In the process of community participation in policy formulation, it is very important to look at the events and results from different angles. For instance, the process of questionnaires was very important. However, Co-PLAN staff was aware of the fact that in the questionnaires were received feedbacks at an individual or family level. But what about the

feedback at a higher community level? A series of meetings with the community were organized. What is interesting about these meetings is that regardless of what "conventional architects" might expect, residents are very sensitive in the proposals put forward. The secret of the process is to translate 'complicated topics" in simpler language so that the ordinary people can understand and react. For instance, instead of addressing broad issues on urban management theory, we simply aimed to collect feedback on the proposal of cost-sharing approach to build infrastructure. During these meetings, we also tried to bring other issues like education, health and economic development, to residents' attention and not to limit their thinking only about infrastructure. In fact, these meetings served to make a step forward in the process of changing the community attitude, from a passive and complaining (claiming state support) to a more proactive (initiative to take actions).

The Role of Media for Participatory Planning:

However the wishes of the community have to be confronted with the possibility of the government as well as with the wishes of the rest of the public opinion. Therefore going upper in the levels of participation was very important. To that end, Co-PLAN prepared other TV programs, with the aim to involve the general opinion in the difficult discussion of facing up such phenomenon like irregular land development. In addition, the Mayor of Kamza was present on TV answering to the online questions of the residents, as well as other representatives from the central government that took part in the online debate. The TV program appeared to be e very efficient mean to target greater audiences. In the way long of the process, the involvement of actors in a continuous debate on the strategic urban development plan became very important. A series of urban forums, specifically devoted to the discussion on the urban development strategy, was prepared. In the early stages of the project, the first forum aimed to set up, with different actors involved, a calendar of activities for the preparation, discussion, and approval of the urban development strategy. What makes the case different was is that the strategic thinking in the Albanian urban management methodology is almost inexistent. Hence, a common understanding on the stages of the process ought to be agreed upon. Once a certain progress was achieved with the design of the plan, such consultations and discussions were came be held on a regular basis. One of the most significant forums was organized when the first integrated draft of the plan was designed. In order to facilitate a sound and productive discussion, the draft was given beforehand to all actors involved, to give them the necessary time for reflection. It is worth mentioning the tough debate that discussions in those forums generated. In addition, the case in Albania is such that not all actors are interested in a sound development of the urban management system. "The central government is not willing to give its powers to local government or other sectors. In addition, several public/state intuitions would prefer to retain their exclusive powers, although this does not go in line with efficiency and development issues. The strategic plan, therefore, along with the entire process, had to cope with such diverse and sometimes odd interests and positions." (Aliaj, B., 2008) To create conditions that are more conducive for the different actors to receive comments and feedback, also other means were employed. All actors were expected to submit comments in a written form. However, the lack of

culture in writing reports was somehow an obstacle to the process. Instead, bilateral meeting resulted to be even more interesting for the actors to submit comments. Even more so to ensure the involvement of actors who are still reluctant to accept comprehensive approaches of urban planning, for them special activities were organized. They were even invited in workshops that included site visits in order to bring them closer to the reality. As mentioned above, there was a cycle of forums organized at different stages of the process. The strategic urban development plan draft reflected the comments made by different actors in the forums. Forums were open to the participation of whoever had the interest to join in. However, Co-PLAN took the responsibility of guaranteeing the presence of key institutions, government representatives, professionals, and NGOs/CBOs. In order to maintain the open-forum idea and bring the topics to the attention of the public, some of the forums were even broadcasted on television. *"It is interesting to look at a very simple fact; the distribution of the draft plan to different actors. Co-PLAN considered a success the fact that more and more actors were aware about the content of the strategic urban development plan. Grotesquely enough, the attitude of the public institutions differs very much in this respect. Still official regulatory plans are kept in shelves like they were classified."* (LMTF 1995)

Formulating new Urban Development Strategies:

In the process of formulating the urban development strategy, the involvement the donors' community is considered to be very important. The interaction with such community appeared to be very relevant to the process. Despite how it might look in first place, the relation with the donor was not focusing on possibilities of funding. This was only one of the issues. The donor community was present in Albania to assist the Albanian society in coping with the social, political and economic changes in the transition period. The technical expertise they provided has been very relevant to the Municipality of Kamza. The interaction appeared to result in a productive exchange of views on the urbanization process and ways and means to cope with it. In order to fully understand the process a look into the Albanian institutional set up is needed. In this way comparisons with other different cases might be a little simpler.

Different schemes have been designed in Kamza case to support the explanation:

(i) The governance scheme; aims to illustrate the governance set up. The governance in Albania is organized in two levels; local and central. Local government in urban areas is organized in *municipalities*, while in rural areas is organized in *communes*. The local government also is structured in two levels. Different municipalities and communes are joined together to establish the *second* level of the local government; the *county*. The system was introduced only recently, and to a certain degree has worked. However, the central government has its own system extended also locally; the *prefecture*. Municipalities and communes are elected in local elections. The county is established through indirect elections, while prefecture is an entity that is appointed. The prefectures are still used as instruments of central government to "control" the local government.

(ii) The decision making process on urban management aims to pave the way for the process of approving urban plans. The system reflects somehow the poor level of decentralization at that time in Albanian experience. In principle, the final approval/rejection of urban plans is always done by the central government! Oddly enough, the central government does not see itself committed in the urban development process through planning initiatives or policy formulating. This only reflects that; in the policymaking level a *controlling* attitude rather than *leading* still dominates. Moreover the Albanian concoction of Committees for Territorial Adjustment (read Development) only deteriorated the decision making process in that it does not ensure the necessary transparency and representation of the public opinion.

Some Findings and Conclusions:

The practice of Co-PLAN shows the actors involved in the process, aims to explain the extended environment the project team targeted in order to design the strategic document. Albanian society has progressed in the process of getting organized. However, the transition period is very short to result in having all groups of interest organized. Especially in the reality of Kamza, a recently created urban area, it was nearly impossible to have different groups represented. The process met such a difficulty while trying to contact and properly involve the private sector, which appears to be disorganized and scattered. Therefore the project could not but contact on an individual basis the members of this community. A special questionnaire was prepared for the private sector in order to attract its feedback on the urban development strategy. Many efforts were put in communicating with community, public opinion, professionals, and authorities. Since the early stages of the project, the team came to realize that the situation within the municipality needed to be carefully analyzed. At a certain point, Co-PLAN realized that the information flow within the municipality did not ensure the involvement of all necessary departments of the municipality. In the Albanian context, this was the praxis. Usually, what happens is that the levels of the municipality, especially the higher ones, prefer not to share the information. The challenge is how to improve the hierarchic interaction without a *telling* and imposing attitude. Therefore the project team suggested the expansion of the group and the creation of (municipal and Co-PLAN) Task Force. The idea was to allow the Municipality to have a greater say on the process and product, and at the same time to guarantee a better flow of information through removing the “monopoly” situation in information at the authorities’ level. The set up of the task force resulted in a better orientation of the rest of the activities of the project.

For instance, the Task Force found very useful the building of a geographic information system. Indeed, the municipal staff lacked the basic working tools. Because Kamza was a municipality without an institutional memory, the administration lacked basic geographic information. The training and workshops tried also to reflect the needs of the Task Force. Several trainings were done, ranging form Institutional Development and Organizational Strengthening, to information systems for Tax collection. The trainings never were an objective per se. “The

preparation process of the Strategic Urban Development Plan (SUD) served as a good chance for the on-the-job training. The approach resulted to be more efficient due to two factors: (i) municipal staff could not devote much time to conventional training; (ii) the topics were oriented towards the needs of the members of the Task Force. Each chapter of the SUD was discussed and commented in the weekly meetings of the Task Force." (Driscoll, J., 1995)

Co-PLAN has since then the strong conviction that participation should be included not only to influence the decision-making but also to share and take responsibilities. In fact, participation was a crucial argument behind different initiatives at the neighborhood scale. Participation was also when residents gave land in favor of public space, financial contribution to build public infrastructure as well as taking collective actions to improve the future education of the children. In addition, the investment component of the project served as a good chance to ensure participation of the municipality in different actions. Each initiative had its own specific purpose. The very first one was the initiative to improve the only public space in the center of the municipality. For several years, it was prone to illegal kiosks and gambling activities. Also an informal marketplace was using the green space. The demolition of the illegal kiosks was a clear message of the willingness of the Municipality of Kamza to improve the image of the city. In contrast with what happened in other cities, where the debris from the demolition of illegal buildings took some time to clear, the Municipality of Kamza and the project were looking forward to restore the public space and make it attractive for residents. After the space was renewed, we realized that the quality of the leisure time of the residents of the neighborhood was higher. The second initiative started in a different perspective. There is a considerable distance from the neighborhood of Bathore and the Town Hall, which implies that residents had to walk a long distance for the various stamp duties such as birth certificates, social assistance, etc. The local authorities agreed to join Co-PLAN' and donors' initiative to build a new complex building with municipal offices for that particular neighborhood. This proved to be a very suitable solution for the residents as well as for the administration. The project also offered possibilities for a kindergarten, which was missing in the area. From case to case, also the idea of participation and cost sharing developed ever further. Co-PLAN succeeded in implementing initiatives by sharing costs either with the municipality or with the community. In the last experiences also the attempt to bring together local government and community-based initiatives, was successful. In a package of intervention, the local administration entered in joint actions with the community by offering basic materials for the sewerage network, whereas the community offered its free labor force. In three years the management of the investment changed. In the beginning, Co-PLAN was leading the process and ensuring a safe implementation of the investment, while in the second part of the project the municipality took even more responsibilities in implementing the investments under pre-defined monitoring rules.

The performance of the Municipality of Kamza evolved in several aspects. In the process of preparation and defense the SUD in front of authorities, Co-PLAN put

even more efforts and energy, particularly in the first part of the project. The local administration was more reluctant to face a political and professional discussion with the central government on the urban development strategy for the region. However, as they got more involved in the process, they became more confident in the approval process. The Mayor of Kamza also presented and defended the SUD Plan in front of the highest national authority. Although Co-PLAN is a modest pioneering organization, the experience accumulated in different project has been meaningful to all members of the organization, but what is more important to the public opinion, professionals and authorities. Constantly Co-PLAN has been willing to share its experience with professionals, university, and civil servants especially through a series of public lectures. The most important lesson learnt from the experience in different projects and initiatives is that the process makes the difference. Indeed there have been different planning initiatives that from the technical point of view met high standards. However, these initiatives lacked a very important element, communication. Despite the fact that this is only the beginning in the field of urban planning in Albania, however, the experience of these years during two decades is a valuable lesson for the future of Urban Management in Albania. Co-PLAN has always stressed the motto of learning by doing, while government authorities and organizations are not in the same position to afford. Therefore, they can easily learn from others' experiences, so that the same mistakes are not repeated again. As far as participation is concerned, identifying the right actors and stakeholders for the process has been yet another task which required some degree of thinking. As a matter of fact, the Task Force set out to possibly reach all those interested in and relevant to the process. This was however something dependent also on the degree of organization of the actors themselves. Admittedly, the Task Force could reach even a greater number of participants, if better organization were possible.

The experience of Co-PLAN during 90-s and early 2000-s has been crucial for the platform this organization submitted to Albanian Parliament in 2004 for better handling territorial planning, environmental issues, and formalization of informal economy. As result of that since 2005 considerable changes happened in the mentality of urban governance in Albania, including new law of territorial planning and legalization of informal settlements. In addition Co-PLAN established POLIS University as an instrument of developing a critical mass of expertise that would hopefully provoke further reforming of planning in Albania.

USER PERCEPTION OF SOUNDSCAPES OF URBAN PARKS IN ANKARA

Işıl Çakcı Kaymaz[1], Nevin Akpınar[2], Nur Belkayalı[3]

Abstract

The concept of soundscape has recently gained attention of planning and design disciplines where focus is generally on the visual, rather than the acoustic, aspect. On the other hand, sound is an important element of a place which affects individual's perception and understanding of an environment. Urban acoustic environments are complex and involve a broad diversity of sound resources. Evaluation of urban soundscapes is crucial not only for noise mitigation but also to assess acoustic comfort which is integral to overall environmental quality.

This study presents user-perceived acoustic comfort and characteristics of urban parks in Ankara, Turkey. The research was carried out through face-to-face questionnaire surveys and sound level measurements in five urban parks (Altinpark, Botanik Park, Gençlik Park, Güvenpark and Segmenler Park) of Ankara between June and September 2011. The parks were chosen to represent different physical attributes and users with varying socioeconomic backgrounds. The questionnaire form consisted of 24 questions relating to demographic characteristics, park use, sound perception and sound preferences. A total of 200 users participated in the survey. Data were analyzed using SPSS version 15.0. Sound level measurements were conducted during questionnaire surveys for 1 minute. For further assessment another series of sound level measurements were conducted at 27 locations in five parks twice for a week (one weekday and one day on the weekend and twice between 09:00-12:00 and 17:00-20:00).

No statistical significance was found between acoustic comfort evaluations and gender, age and educational background. Natural sounds were found to be preferred to artificial sounds. Furthermore, user identifications of general soundscapes of the urban parks seem to have a strong relationship to physical attributes of the parks and visitor expectations. The results of this study are expected to raise awareness on the role of soundscape in context of urban environmental quality amongst planners and designers and assist them in soundscape planning and design.

1. Introduction

[1] Ankara University, Ankara, Turkey-cakci@agri.ankara.edu.tr
[2] Ankara University, Ankara, Turkey- akpinar@ankara.edu.tr
[3] Kastamonu University, Kastamonu, Turkey- nbelkayali@kastamonu.edu.tr

Noise pollution is a growing environmental problem, especially in urban environments, which might cause serious health effects on living organisms. Governments and global institutions have been developing measures to prevent noise pollution and to reduce noise levels. However, reducing noise levels does not always lead to more pleasant environments (Zhang and Kang, 2007; Cain et al., 2011) or increase life quality. In his book "Tuning of the World" (1977, p.4), Schafer points out that noise abatement is a negative approach and we need to seek positive ways to study environmental acoustics in order to understand which sounds must be eliminated from our surroundings. In fact, it is now well known that sound quality cannot be determined by evaluating sound merely in physical terms and ignoring psychological dimension (Raimbault and Dubois, 2005). On the other hand, in soundscape studies both physiological and psychological dimensions are taken into account and they aim to understand the relationship between people and their acoustic environment by joining together physical and psychological aspects.

Salvador (2010) defines a soundscape as "*a temporal and typological organization of sound objects, related to a certain geo-cultural context, in relation to which a listener can apply a spatial and semiotic transformation*". Since the concept of soundscape was first introduced by R.Murray Schafer in late 1960s, it has become a research area for many disciplines, acoustics in particular. However, it is very recent that it has gained attention by planning and design disciplines. Generally planning and design goals do not involve acoustic dimension of the environment, except noise control. This is mainly because sound is generally perceived and considered as a negative element within an environment and often misused as a synonym for "noise".

There are many inputs and outputs in urban environments due to the high variety of human activity. As a result, designing and management of urban environments are considerably complex in many aspects. These environments are constantly moulded by the spatial, and both social and cultural characteristics of the community. Consequently, the soundscape of an urban environment becomes fairly complex as well, due to physical, psychological and social factors (Cain et al., 2011). But how are people and their quality of life affected by the acoustic environment of an urban surrounding? In order to integrate sound as a resource for urban design and planning, first we need to understand how people perceive their sonic environments and how they react to them. There is a perceptual dimension of a soundscape which is influenced by both explicit attributes of the physical place and implicit attributes of social and cultural factors (Yu and Kang, 2010). Perception is an active process where perceiver selects information from its environment through senses; then organizes and interprets it. Although vision is the dominant sense for human's perception of his environment, sound –as second most dominant sense- also plays an important role in sensing and understanding our environments. Preference studies are common in environmental psychology to evaluate people's perception of their surroundings. Hence, evaluating sound preference is very important in order to determine the quality of soundscape in a specific space (Yu and Kang, 2010).

Urban open spaces contribute to overall quality of an urban environment in many aspects (aesthetics, ecology, leisure and recreation etc.). They are comprised of natural and cultural features which provide urban citizens with opportunities to refresh and enjoy themselves within the fast paced urban life. Although most soundscape studies focus on relatively large rural and urban areas, there is a limited number of research on urban open public spaces (Kang and Zhang, 2010; Yu and Kang, 2010). Similar to other design and planning disciplines, landscape design and planning have traditionally focused on mitigation of unwanted noise and its effects so far. McHarg (1969) defined landscape planning process as the overlay and synthesis of land data in his famous work "Design with Nature". He also included sound data as a resource for noise. However, sound is more than an element that generates noise but also a potential resource for the designer and planner. On the other hand, while digital visualizing tools allow us to see how a proposed project might actually look like, it is much more difficult to contemplate or visualize possible outcome in terms of acoustic environment. Hence, there is a certain need for theoretical background and research methodologies for evaluating sound in landscape design and planning (Hedfords, 2003).

The concept of "soundscape" (*işitsel peyzaj* in Turkish) is very little known in Turkey. The first soundscape research has been conducted by Özçevik (ongoing PhD dissertation) on soundscape in covered spaces (Özçevik and Can, 2011). However, there wasn't any soundscape research in urban open spaces; furthermore researchers were unfamiliar with the concept and its context. In 2010, our proposed research project titled "Evaluation of Soundscape Perception and User Preferences in Urban Parks in Frame of Life Quality: Case Study Ankara – Turkey**"** was accepted by TÜBİTAK (The Scientific and Technological research Council of Turkey) within the COST (European Cooperation in Science and Technology) Action "Soundscape of European Cities and Landscapes" (TD0804). In this paper, preliminary results of the project are presented. The research project aims to:

- integrate soundscape concept with urban parks,
- provide data on subjective sound perception and soundscape overall using qualitative and quantitative measurement and assessment techniques, and
- interpret urban parks' soundscape, acoustic comfort and life quality in the context of perception and preferences.

2. Materials and Methodology

2.1. Spatial Data

In this study, 5 urban parks (namely Altınpark, Botanik Park, Gençlik Park, Güvenpark and Seğmenler Park) which are located on the north-south axis of Ankara city have been selected (Figure 1). The selection criteria are; (i) parks that represent different types of parks in the city, (ii) parks that are preferred by users, (iii) high diversity of activities, and (iv) high diversity of different sound resources. The characteristic features of the selected parks are shown in Table 1.

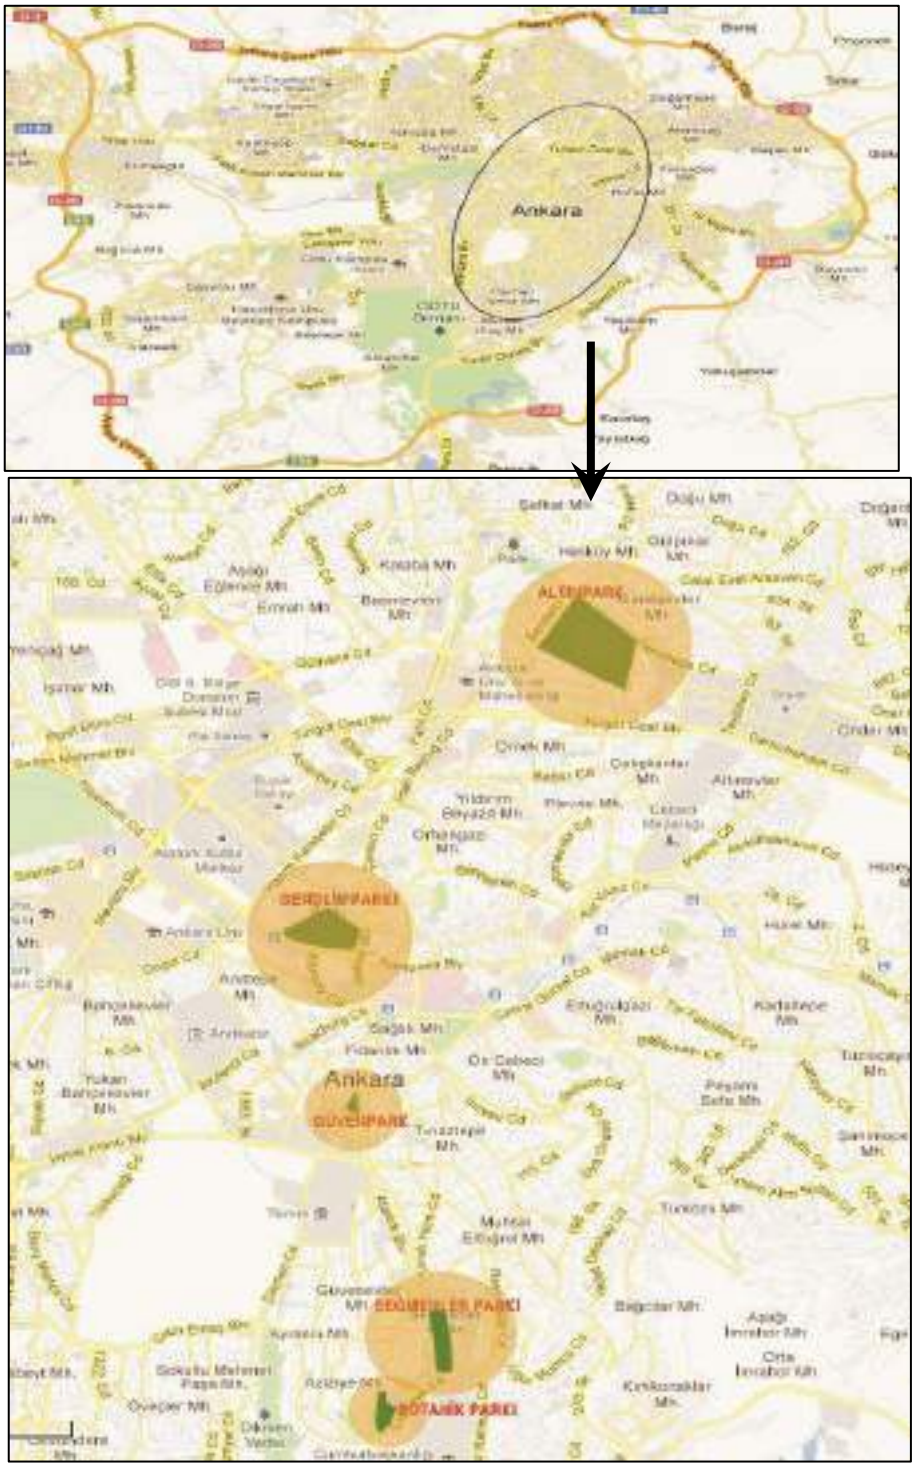

Figure 1. Selected Parks for The Research

Table 1. Characteristics of The Selected Parks

PARK	**Size (m^2)**	**Main Features and Facilities**	**Established**
Altınpark (Google Maps, 2012)	640.000	Green areas Water surfaces Exhibition hall Amphitheatre Playgrounds Cafés Restaurants Rollerblade and skate ring	1993
Botanik Parkı(Google Maps, 2012)	63.085	Green areas Water surfaces Playground	1970
Gençlik Park (Google Maps, 2012)	275.000	Green areas Water surfaces Cafés Fairground Playground Theatre complex Parking lots	1940 (Reopened in 2009 after revision of the master plan.)
Güvenpark (Google Maps, 2012)	22.000	Green areas Water surfaces Playground Famous for Güven Monument	1936

Seğmenler (Google Maps, 2012)	67.200	Green areas Water surfaces Amphitheatre Playground Café	1983

2.2 Questionnaire Surveys

A questionnaire survey consisting of 24 questions has been prepared to investigate the user perception of soundscapes in urban parks. The questionnaire items are a mixture of open-ended, multiple choice and Likert type questions. The questionnaire forms have been divided into four sections: (i) demographic characteristics, (ii) park use pattern, (iii) satisfaction level of physical environment and (iv) sound perception and preferences. Between June and September 2011, questionnaires were administered to randomly selected 200 park users (40 at each park) face to face. The data have been evaluated using frequency analysis, factor analysis and chi-square test in SPSS version 15.0. One minute sound pressure level (SPL) measurements were also made during the interviews.

2.3 Field surveys

For further assessment of soundscape perception and preferences of users, another series of sound level measurements were conducted at 27 locations in five parks twice for a week (one weekday and one day on the weekend and twice between 09:00-12:00 and 17:00-20:00). SPL for each location was measured for 15 minutes in terms of L_{eq} values, with a sound level meter. The locations where the measurements took place have been selected to represent various user activities such as playgrounds, open air cafes, surrounding roads etc. Finally, the data have been transferred to the SoundPLAN® software in order to generate sound maps of the parks.

3. Results

Of 200 participants 62% were male and 38% female. Other personal and demographic characteristics of the participants are shown in Table 2. Most of the participants (80%) live in apartment buildings.

The results show that visiting parks on a daily basis is not common among the users. Most participants (25%) visit parks for a few times a week. They mostly (28%) spend 2 hours at most in a park. The parks are least used between hours 12 and 14. This might be due to the fact that the questionnaire surveys were conducted during

summer time when the temperature can be quite high during the day in Ankara. The highest temperature recorded during the questionnaire surveys was 37°C on 1st of August, 2011.

The participants were asked to identify the aspects of the parks which they were most and least satisfied with. The results for each park were shown in Table 3. General appearance and air quality are two significant aspects which the users are most satisfied with. On the other hand, most participants complained about the inadequate site furnishing and lack of variety of activities in the parks. None of the participants mentioned about acoustic environment quality within the parks. However, 31% of the participants stated that "silence and tranquility" was the first reason for their preference of visiting a park. The other significant motives include "to have contact with nature" (35%) and "transport accessibility" (20%).

Table 2. User Characteristics

User characteristics	**Percent (%)**
Age	
15-20	25
21-30	24
31-40	16
41-50	14
51-60	6
>60	15
Level of education	
Elementary	11
Secondary	13
High school	38
Higher education	36
Other	2
Employment	
Working	41
Student	25
Unemployed	6
Retired	18
No answer	10

Table 3. Users Satisfaction with The Parks

Park	**Most satisfied with**	**Least satisfied with**
Altınpark	General appearance (aesthetics)	Site furnishing
Botanik Park	Air quality	Children playgrounds
Gençlik Park	General appearance (aesthetics)	Function of activities
Güvenpark	Accesibility	Walking paths

Seğmenler Park	Air quality	Site furnishing

Only 7% of the participants indicated that they were hard of hearing. On the other hand, 31% of the participants stated that they had sensitive hearing. Except Botanik Park and Seğmenler Park, participants defined the general sound level of the environment as "moderate" (Table 4). Although Güvenpark is located in the "core" of the city centre where vehicle traffic and pedestrian density are quite high, only 22% of users defined the sound level as high and 5% as very high. On the other hand Botanik Park and Seğmenler Park are located in a valley which provides a significant reduction in vehicle traffic noise from the main roads which surround both parks. Furthermore these parks have a dense vegetation cover, mainly a mixture of both deciduous and evergreen trees.

Table 4. Users' Evaluation of Sound Levels of The Parks (%)

Park	**Very low**	**Low**	**Moderate**	**High**	**Very high**
Altınpark	10	31	**54**	5	-
Botanik Park	3	**57**	37	3	-
Gençlik Park	-	12	**65**	20	3
Güvenpark	2	5	**66**	22	5
Seğmenler Park	5	**47**	**47**	-	1

Acoustic comfort of the parks was evaluated as the satisfaction with perceived sound levels of the acoustic environment. In general, most of the participants (75%) were pleased about the sound level of the parks. However, while only 51% were pleased with Güvenpark's ambient sound level, Botanik Park's ambient sound level was found to be pleasant by 89% of its users. These results have been expected by the researchers because of the explanations given in the previous paragraph. Similarly, while Gençlik Park, where hard surface is dominant within the park's landscape, was found pleasant by 67% of its users, more users in Altınpark (85%) and Seğmenler Park (82%), where vegetation cover is more dense, defined ambient sound level as pleasant. The sound level measurements during the questionnaire survey show that SPL varies between 48 dBA and 75 dBA for the interviewees who were pleased with the ambient sound levels. Therefore, it is not possible to draw a conclusion on the relationship between measured sound levels and satisfaction of ambient sound level.

The participants were then asked to identify which sounds they hear at that moment. The responses were a mixture of both natural and cultural sound types which were shown in Table 5. Although different activities in the parks generate different types of sound, the participants in all parks identified similar sound types.

Tablo 5. Sound Types Heard in The Parks

Altınpark	**Botanik Park**	**Gençlik Park**	**Güvenpark**	**Seğmenler Park**

Bird Water People Plane Vehicle traffic Children Music Plants Other animals Wind Phaeton	Bird Water People Plane Vehicle traffic Children Plants Other animals Wind Construction	Bird Water People Vehicle traffic Children Music Wind Construction Screaming	Bird Water People Vehicle traffic Children Music Plants Screaming Adhan	Bird Water People Plane Vehicle traffic Children Plants Other animals Wind Construction

In all parks bird and water sounds were defined as pleasant. The participants stated that the most annoying sound types were screaming, vehicle traffic and people talking on mobile phones. Furthermore, the participants perceived the vehicle traffic noise as the most dominant sound type in the parks except in Gençlik Park. In Gençlik Park screaming was the perceived most dominant sound type. This might be as a result of the fairground which is located within the park. However, it is no surprise that people preferred natural sound types over artificial sounds. Various research also showed that people tend to prefer natural sounds more (Carles, Barrio and de Lucio, 1999; Reiter, 2004; Kang and Zhang, 2010).

In the final part of the questionnaire, participants were given 17 bipolar adjective scales and asked to define how they felt about the acoustic environment. The adjective list was given in Table 6.

Table 6. Adjective List for Acoustic Environment Evaluation

Acoustic aspects	**Adjectives**
Sound power	Quiet-loud
Spatial organization	Organized-disorganized
Clarity	Clear-unclear
Diversity	Similar-diverse
Activity	Calm-lively Slow-fast Monotonous-varied
Rhythm	Orderly-disorderly
Tone	Soft-hard
Sound assessment	Interesting-uninteresting Pleasant-unpleasant Meaningful-meaningless Relaxing- annoying

	Happy-sad
	Emotional-apathetic

Factor analysis was made for all the data using varimax rotated principal component analysis. Four factors (with Eigenvalue > 1) were determined and the cumulative variance was 59%. Kang and Zhang (2010) found a similar value (53%) in their research and suggested that such low values might be due to the significant variations in number and type of the sound sources in urban public spaces. Factor 1 (%32) was found to be associated with power, activity and tone of sound, as well as with pleasantness, interestingness, and relaxation. Sound power was also found to be a significant factor in satisfaction of ambient sound levels ($p<0.05$). Participants who were "very pleased" and "pleased" about the acoustic environment also evaluated the ambient as "quiet". Likewise, participants who found ambient sound level as "annoying", defined the acoustic environment as "very noisy". Factor 2 (10%) was related to sound activity and Factor 3 (10%) to spatial organization of the sound. Finally Factor 4 (7%) was associated with sound diversity.

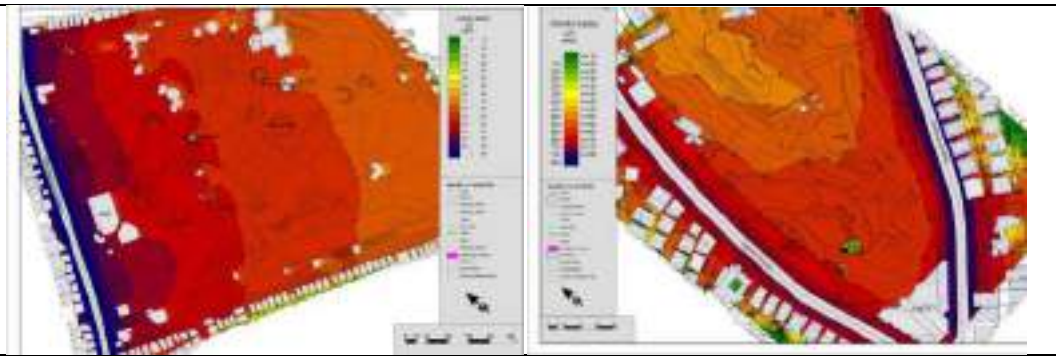
The participants were unfamiliar with the concept of soundscape and they had difficulties in understanding the last question and expressing their perception of the acoustic environment. However, in the reliability analysis Cronbach's alpha was found higher than the expected; 0.7 for Botanik Park and Gençlik Park, and 0.8 for other parks. The significant characteristics of the soundscapes perceived by the participants for each park are presented in Table 7.

Table7. User Perception of The Soundscapes

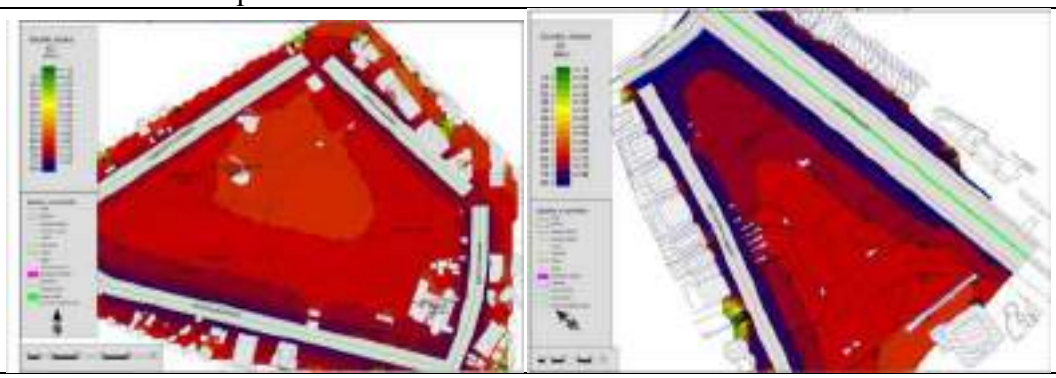
Park	**Characteristics of the soundscape**
Altınpark	Diverse
	Neither quiet nor loud
	Neither happy nor sad
	Neither emotional nor apathetic
Botanik Park	Quiet
	Calm
	Diverse
	Soft
	Neither happy nor sad
	Neither emotional nor apathetic
Gençlik Park	Neither happy nor sad
	Neither emotional nor apathetic
Güvenpark	Very diverse
	Neither happy nor sad
	Neither emotional nor apathetic
Seğmenler park	Neither emotional nor apathetic
	Quiet
	Calm
	Neither happy nor sad
	Soft

There was no correlation found between demographic characteristics (gender, age, and level of education) and sound level evaluations or satisfaction with ambient sound levels. Similarly, there was no statistical significance found ($p>0.05$) between participants with sensitive hearing and others in ambient sound level satisfaction or sound level evaluations. However, preference for different types of sounds was found to be related to age. While younger participants tend to prefer rather cultural sounds such as music, middle aged and elder participants preferred natural sounds such as bird and water.

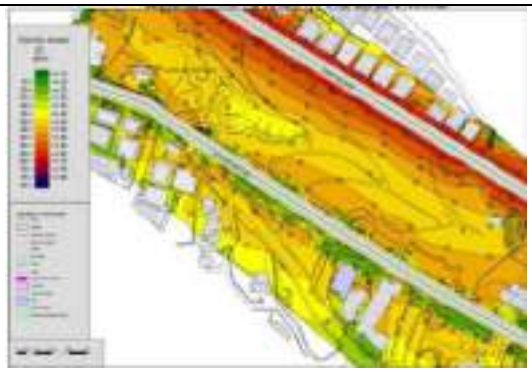
The sound maps of the parks which were created by using sound level measurements show that there is an obvious influence of vehicle traffic noise nearby (Figure 2). The SPL decreases as the distance from roads increases. Although a majority of participants in Altınpark, Gençlik Park and Güvenpark evaluated the ambient sound level as "moderate", it can be seen that actual sound levels show difference from one park to another. Especially SPL is quite higher in Güvenpark than the other parks. Hence we can assume that visitor expectations from the environment can also affect user judgments. As mentioned before, Güvenpark is located in an area where vehicle and pedestrian traffic is heaviest. Therefore, people might already expect higher ambient sound level and perceive it as "moderate".



Altınpark Botanik Park



Gençlik Park Güvenpark



Seğmenler Park

Figure 2. Sound Maps (Highest sound levels are shown in navy while lowest shown in green)

Furthermore, the ambient sound level of Seğmenler Park defined as “moderate” and “low” by the same percent of users. Yet, sound maps show that the SPL is much lower in Seğmenler Park compared to other parks. Besides, despite the fact that factor analysis revealed that sound power is an influencing factor; quietness is not always associated with high levels of user satisfaction. Although Seğmenler Park has the lowest SPL, it was ranked third in terms of satisfaction from the ambient sound levels. It can also be suggested that overall satisfaction from urban parks has an influence on ambient sound level satisfaction. Research data show that as the satisfaction level with the physical environment increases, users tend to perceive soundscapes in the parks more pleasant.

It is also observed that physical characteristics of the parks play a significant role in user evaluations of soundscapes. In this study, topography and vegetation cover are found to be the two main factors that affect user perceptions and actual sound levels. Ambient sound levels of the parks with most vegetation cover (Botanik Park, Altınpark and Seğmenler Park) were most pleasant for their visitors. Topography also helps with reducing sound levels, especially in Seğmenler Park and Botanik Park which are located within the valleys. However, it should be noted that this paper only presents the analysis of the data which was obtained in summer time. Since climatic conditions were quite steady during the field work and questionnaire surveys, it is not possible to interpret the role of climatic variables.

4. Conclusions

In this paper, preliminary results of research on user soundscape perception of Ankara’s urban parks have been presented. Physical environment characteristics and user expectations have been found to be influencing on the visitor perception of urban parks’ soundscapes in terms of acoustic comfort evaluation. People tend to tolerate higher levels of sound if they are content with their physical surrounding or if they already expect an environment to be noisy. Furthermore the quietest environment is not necessarily the most preferred.

People visit urban green spaces mainly for having contact with nature. It is also a well known fact that people prefer environments with natural contents such as all forms of vegetation and water. This study has concluded that they also tend to prefer natural sounds over artificial sounds. Hence, creating places with natural elements in urban open spaces might help to mitigate uncomfortable effects of unwanted or least preferred sounds in an urban environment such as traffic sound. The data has shown that there are a wide range of sound types perceived by users in an urban park. Designers should realize that diversity of activities in urban open space is directly linked to the diversity of the soundscape. On the other hand, existence of unpleasant sound types does not necessarily have adverse effect on overall satisfaction with the soundscape. Meanwhile it should also be noted that silence and tranquility are amongst the driving motives for people visiting urban parks where sound levels are relatively lower than other urban areas.

In an era of increased environmental awareness, open and green public spaces play a significant role in developing sustainable societies. Urban parks are important assets that contribute to the quality of life in many aspects. They provide community and urban environment with ecological, psychological, sociological and various health benefits. As planners and designers, we should more focus on how people perceive and what they expect from their physical surroundings. Furthermore, the European Landscape Convention emphasizes the concept of "landscape quality" and acknowledges that "*landscape is a key element of individual and social well-being*" (Council of Europe, 2000). Sound, in this sense, is an important resource in planning and design which has been neglected so far. Hopefully, more research on urban open space soundscapes will help professionals and authorities to include sound as a key element in their projects and understand sound can be a vital and guiding resource in open and green space design. We expect the outcomes of this project to contribute to the field of urban design when the research is completed.

Acknowledgements

The authors would like to thank TÜBİTAK, fellow researchers and the postgraduate students in the project team for their contributions.

THE COMPACT CITY: PLANNING STRATEGIES, RECENT DEVELOPMENTS AND FUTURE PROSPECTS IN THE NETHERLANDS

Kersten Nabielek[1]

ABSTRACT: The concept of the compact city is a key strategy to limit suburban sprawl and to obtain a more sustainable urban development. In the Netherlands, concepts for compact forms of urbanization have played a major role since more than half a century.

In various Dutch national spatial policy documents different concepts for urban compaction and urban densification have taken a prominent position. The Second and Third National Policy Document on Spatial Planning (1966 and 1973) introduced the concept of 'clustered dispersal' and 'growth centres', whereas the Forth National Policy Document on Spatial Planning (1988) was based on the concept of the 'compact city'. More recently, the National Spatial Strategy (2004) set specific goals for so-called 'concentration areas' around greater urban conurbations and 'urban densification' in existing built-up areas.

However, recently ambitions concerning spatial planning and urban compaction have been decentralized to the regional and municipal level and national funds supporting urban regeneration projects are about to face substantial cuts. Moreover, a number of recent studies and publications claim that urban densification is reaching its limits in several Dutch cities because of complex constellations of ownership, increasing costs and complicated legal procedures.

This paper gives insight into recent developments of dwellings, inhabitants and jobs in Dutch cities and their surroundings. It raises the question if the recent developments can be described as compact urban developments. Furthermore, future possibilities for compact urban developments in the Netherlands are discussed.

KEYWORDS: compact city, urban densification, urban compaction, sustainable urban development, density, spatial quality, spatial planning

1. Introduction

Since more than half a century concepts for compact forms of urbanization have played a major role in the Netherlands. In various Dutch national spatial policy documents different concepts for urban compaction and urban densification, strategies to achieve compact urban developments, have taken a prominent position. The Second and Third National Policy Document on Spatial Planning (1966 and 1973) introduced the concept of 'clustered dispersal' and 'growth centres', whereas the Forth National Policy Document on Spatial Planning (1988) was based on the concept of the 'compact city'. More recently, the National Spatial Strategy (2004) set specific goals for so-called 'compaction areas' around greater urban conurbations and 'urban densification' in existing urban areas. Although each time in a different form, all of these concepts for compaction and densification were guided by the same aims: the protection of the surrounding landscape, the limitation of private car use and the ambition to sustain vital urban facilities and public transport. In order to achieve these aims and to promote urban densification in Dutch cities, urban regeneration projects have been supported by national funds throughout the past decennia.

However, a number of recent studies and publications (i.e. Ecorys, 2005) claim that urban densification is reaching its limits in several Dutch cities because of complex constellations of ownership, increasing costs and complicated legal procedures. Moreover, national funds supporting urban regeneration projects are about to face substantial cuts. Furthermore, recent publications question how the ambitions for urban densification match with the prevailing preferences for suburban living environments in the Netherlands. After all, the population within the existing urban areas of most Dutch cities continues to decline as affluent households and households with children keep moving to suburban areas.

1.1 International debate on the compact city and sustainability

The objectives of the Dutch national spatial policy documents are strongly related to the concept of the compact city and the general aim to create sustainable urban areas. In international research, the concern with sustainable urban development has grown enormously in the past 25 years. Following the publication *Our Common Future* (WCED, 1987), which introduced the idea of sustainable development, a great number of publications have been dedicated to the environmental impacts of urban developments and the improvement of life in the city. A couple of years later, the *Green Paper* of the Commission of the European Communities (CEC, 1990) and the United Nations *Earth Summit Agenda 21* (United Nations 1993) emphasized the role of compact forms of urbanization as a basis for a more sustainable urban development. More recently, the *Charter of Leipzig* (European Urban Knowledge Network, 2007) and the publication *Cities of Tomorrow* (European Commission, 2011) emphasize the importance of compact urban developments as an important sustainable strategy for the future development of European cities.

Since the publication of the CEC's *Green Paper*, a central debate focuses around the

Compact City idea. Many researchers and planners argue that a contained, well-connected city is the most sustainable form. They suggest that a compact city reduces energy, makes investments in public infrastructure more viable, reduces land usage thereby preserving agricultural land and natural areas, and is positively associated with social diversity and with cultural and economic development. The main supporters of the concept of the compact city include the CEC (1990), Jacobs (1961), Newman and Kenworthy (1989) and Elkin *et al.* (1991).

However, there is also a considerable group of researchers who argue that the case of the compact city is not proven and that there is evidence which suggests that the claims of the supporters do not reflect the hard reality of economic demands, environmental sustainability and social expectations. Some of the main arguments opposed to the compact city are that the concept contradicts the profound fondness of suburban living (Breheny, 1992), that the concept of the green city (also promoted by the CEC, 1990) is in contradiction to that of the compact city and that the compact city would cause congestion, with increased pollution, on the local scale (Knights, 1996). The relationship between transport, urban form and energy consumption has been investigated in several international research projects, but unfortunately the results are inconclusive. There is evidence that fuel consumption per capita is highest in more rural areas, but there are indications that the largest cities (e.g. London) are likely to be less efficient than medium-sized and smaller towns (Bannister, 1992).

The different arguments supporting and opposing the concept of the compact city show the complexity of the discussion. Unfortunately for the proponents of the compact city model, in-depth research has shown that simply employing policies to stimulate compact city style development will not necessarily always lead to sustainability of the urban environment. However, in general there seems to be an agreement that the compact city model is necessary, but not sufficient for sustainable urban development.

1.2 Recent research related to compact urban development

In recent years the PBL Netherlands Environmental Assessment Agency has conducted several research projects related to urbanisation, densification and the effects of urban density. A study on the changes of the urban area 2000-2006 has shown that the density of dwellings, shops and jobs has significantly increased around InterCity-train stations (Ritsema van Eck *et al.*, 2009). Furthermore, the areas around motorway exits are characterized by a relatively low overall density, but that that density has strongly increased over the last years. Also in general, the density has increased stronger in areas outside of the city centre, i.e. in subcentres and peripheral commercial zones. A research project on mobility has shown that work-related car-use around InterCity-train stations is more than half compared to car-use in areas around motorway exits. Moreover, a study on housing and segregation has concluded that urban renewal contributes to a reduction ethnic and socio-economic segregation, whereas suburban developments lead to higher segregation in most cases (van Dam *et al.*, 2010). Finally, a study on economic development in the Netherlands concludes

that a higher degree of urbanisation leads to higher economic productivity and a stronger growth in jobs (Raspe *et al.*, 2010). Although the researched topics show a high degree of complexity and results are not always conclusive, the general outcome of the mentioned studies supports the concept of the compact city. However, it can be argued if the recent urbanisation in the Netherlands actually can be called compact. In the period 2002-2008 most urban development took place in suburban areas adjacent to the existing urban areas. More than 60 per cent of the new dwellings and about 75 per cent of the new jobs were created outside the existing urban areas (Ritsema van Eck en Farjon, 2008). In comparison with other European countries, the suburban developments are rather compact and concentrated in surrounding of existing urban agglomerations. However, they still are suburban developments and have led to a significant growth of urbanized area.

2. Empirical research on urban densification 1996-2008

To get a more detailed insight into developments within the existing urban areas, the PBL Netherlands Environmental Assessment Agency has recently conducted a study on urban densification analysing developments of dwellings, inhabitants and jobs in the period from 1996 to 2008 (Nabielek *et al.*, 2012). Furthermore, this period is subdivided, the first period covering 1996-2002 and the second period covering 2002-2008. The study focuses on the developments within the boundaries of the existing urban areas. Moreover, the study consists of quantitative and qualitative analyses. The quantitative part of the study analyses how much densification (of dwellings, inhabitants and jobs) has taken place in the Netherlands. On the local scale, the development of density has been analysed within postcode 6 areas[2]. The qualitative part of the research describes at which locations densification has taken place within the urban area, looking at a selection of Dutch cities.

2.1 Quantitative analysis: developments within the urban area 1996-2008

From quantitative analysis of the study the following developments are notable:

- Within the urban area of the Netherlands the number of added new dwellings has decreased in the second period (2002-2008). The densification of dwellings has slowed down (see Fig. 1). Moreover, the total number of inhabitants within the existing urban area has decreased in the second period leading to a lower density of inhabitants (see Fig. 2). Furthermore, the number of added jobs is much lower than in the first period (see Fig. 3).
- Divergent developments can be observed comparing different cities. In all of the four biggest cities (Amsterdam, The Hague, Utrecht and Rotterdam) the net-production of dwellings within the existing urban area has declined significantly in the second period. In The Hague and Rotterdam the figures even show a loss of dwellings due to demolishment of houses. Looking at the development of inhabitants, Amsterdam and Utrecht show an increase, whereas the number of inhabitants is decreasing in The Hague and Rotterdam.

[2] A postcode 6 area is an administrative classification representing the scale of an urban block.

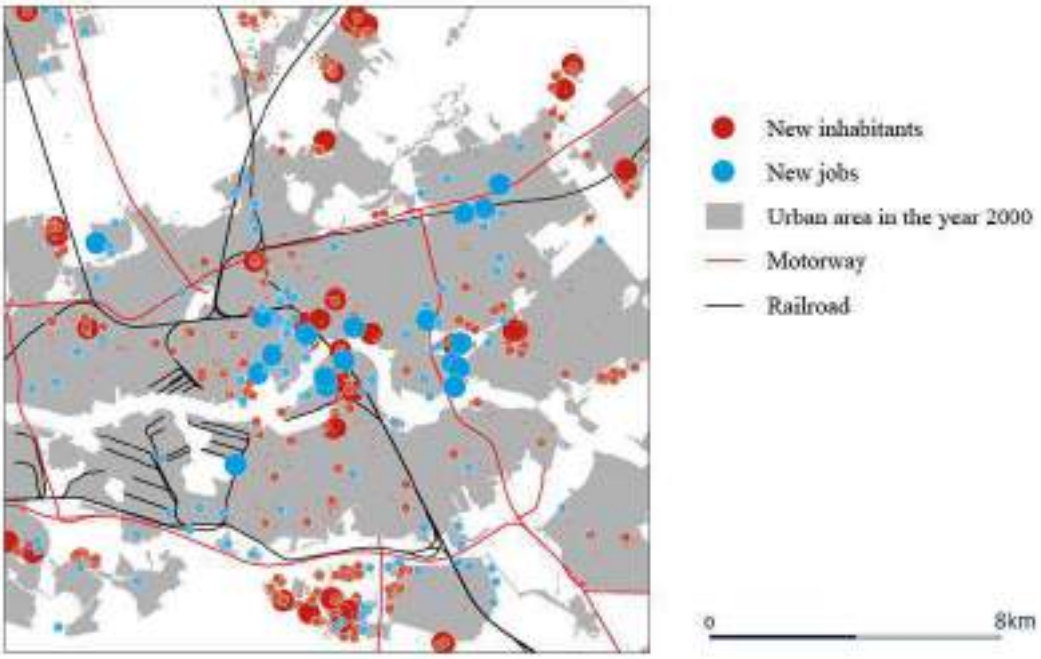

Figure 6 Densification areas in Rotterdam 1996-2008 (PBL)

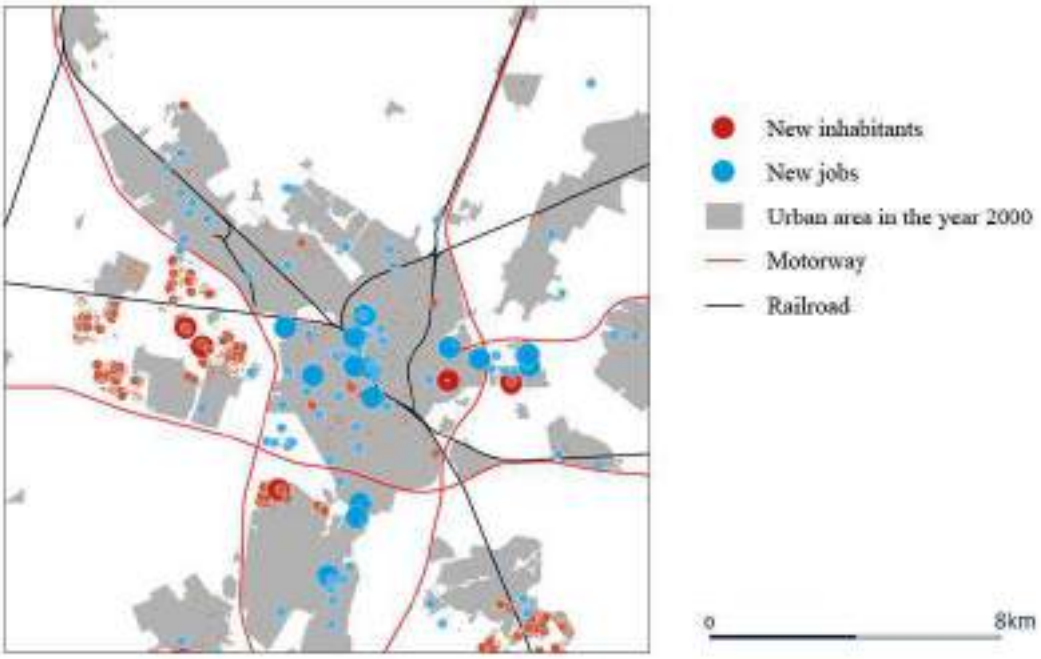

Figure 7 Densification areas in Utrecht 1996-2008 (PBL)

2.2 Qualitative analysis: spatial patterns of densification areas in Dutch cities

The maps of densification areas in different Dutch cities show different spatial patterns for the densification of inhabitants and jobs (see Figures 4-7). In this paragraph the main developments in Amsterdam, The Hague, Utrecht and Rotterdam are described.

In Amsterdam (see Fig. 4) major densification areas of inhabitants can be found in the former harbour areas in the vicinity of the central city area. Moreover, densification areas of inhabitants are located in peripheral areas where urban renewal has taken place. Development areas of jobs can be found in the central city area and along the motorway ring. There is little overlap between the densification areas of inhabitants and jobs.

In The Hague (see Fig. 5) the developments take place in a ring around the central city area, nearby the two central railway stations. Densification areas of jobs are mainly located north of the city centre and densification areas of inhabitants to the south of the city centre. Large developments can be seen outside of the existing urban area, in the urban fringe.

In Rotterdam (see Fig. 6) the development areas of inhabitants and jobs are less separated than in the three described cities and can be found in the central city area. This can be explained by the lack of an historic centre and the location of urban renewal areas in the city centre of Rotterdam. As in Amsterdam, a number of large development areas of jobs are situated along the motorway ring.

The map of Utrecht (see Fig. 7) shows predominantly densification areas of jobs within the city boundaries. In existing urban area the densification areas of inhabitants are very small. As in The Hague, major developments can be found in the urban fringe.

Looking at the maps of the four described cities, it can be concluded that every city shows a different spatial pattern of densification areas. Generally, we can observe that densification areas of inhabitants can be found at the edge of the city centre, around train stations and in urban regeneration areas, whereas densification areas of jobs predominantly are located in central city areas and at more peripheral sites along motorways. With the exception of Rotterdam, the maps show a clear functional separation between development areas for inhabitants and development areas for jobs.

2.3 Results

The study on densification has shown that the density of dwellings and jobs has increased in the period 1996-2008 but that the growth has slowed down between 2002-2008. At the same time, a strong shift towards suburban areas can be noted in recent years and the density of inhabitants within the existing urban areas has decreased in de period 2002-2008. In this period more than 60 per cent of the new dwellings and about 75 per cent of the new jobs were created outside the existing urban areas. Therefore, it can be argued if the national policy of the compact city has

been successful or not. The answer to this question obviously depends on the definition of the compact urbanisation and densification. However, it can be assumed that without a national policy the urban development would have been even more dispersed than it is now. Furthermore, the quality of the urban areas has improved strongly in the past decennia. Urban renewal, transformation of industrial sites and improvement of public and green spaces has had a positive effect on the quality of living in the Dutch cities.

3. Conclusions

Strategies for compact urban structures and urban densification face many challenges on the local scale, such as complex ownership, functional transformation and environmental regulations. Furthermore, factors as built-in parking facilities, the development of public space and ambitions to realize social housing make inner city projects expensive. However, it has to be noted that suburban locations also are costly. Especially, if long term maintenance, infrastructural and environmental costs are taken into account. Furthermore, the international debate on the compact city model has brought forth significant arguments questioning the concept of compact urbanisation, such as preferences for suburban living and possible social, economic and environmental disadvantages of compact cities. However, recent research of the PBL Netherlands Environmental Assessment Agency has shown that a higher degree of densification supports the development of economic productivity and the emergence of new jobs on a regional scale. Moreover, the concentration of functions around multi-modal infrastructural nodes reduces car-use significantly and can help to limit the growth of mobility. Additionally, PBL research has underpinned that inner city developments help to reduce ethnical and social-economic segregation, leading to a more mixed city. The results of these studies support the concept of the compact city.

The results of the empirical analysis of developments within the existing urban area 1996-2008 show that there has been a significant decline in densification of dwellings, inhabitants and jobs within the urban areas in the period 2002-2008 compared to the period 1996-2002. This decline can be explained by the substantial production of suburban areas around the existing urban cores and an increase of the amount of demolished houses within the existing urban areas in this period. However, there will be no alternative other than to focus on the possibilities of urban densification in Dutch cities since there are no plans for large suburban developments in the near future. Important points of attention for future urban densification are to differentiate ambitions according regional development prospects (with different strategies for shrinking and growing regions) and to focus on urban developments around existing multi-modal infrastructural nodes on the regional level. It should be noted that potential development areas around infrastructural nodes are not only located in central but also in peripheral urban areas, i.e. in the vicinity of smaller train stations. Furthermore, it will be important to improve the development of multi-functional areas with high quality public spaces on the local level. Medium and high density developments will have to be combined with sufficient open and green spaces to create attractive and sustainable urban environments. Moreover, it will be vital that housing

types match the preferences of (future) inhabitants and are flexible enough to be adjusted for prospective demands. On basis of the conducted research we can conclude that urban densification will stay a necessary tool to sustain and develop urban areas in the Netherlands regarding environmental challenges, economic viability and the quality of urban life.

The future success of compact urban developments will strongly depend on decisions of local and regional authorities since the national government has recently decided not to continue with the ambitions for compact urbanisation and has given more responsibilities to municipalities and provinces. At the moment the economic crises has led to a slowing down of urban developments inside and in the surrounding cities and there are no new plans for large suburban residential areas. However, municipalities have more possibilities to allow small scale developments outside the existing urban areas. Depending on local decisions, this could lead to a more dispersed and less sustainable urban structure in the future.

Improving Adaptation of Coastal Communities through Self Initiated Bottom-Up Approaches: A Case Study of the Cardwell Community, Australia

Serrao-Neumann[1], S., Crick[1], F. and Low Choy[1], D.

Abstract

During the 20th century there has been a dramatic development of the coastline leading to substantial population growth in coastal areas worldwide. Given that this trend is expected to continue in the future it raises critical challenges as climate change is likely to exacerbate the exposure of coastal populations to extreme weather events. While the severity of extreme events affecting those areas may lead to widespread damage and disasters, they might generate opportunities for change to occur in their socioeconomic, political and organisational systems improving their adaptation to climate change. For example, opportunities might be created to review how those areas are planned and managed as well as to gather lessons from past extreme events.

This paper investigates how those opportunities emerge and are optimised by focusing on the Cardwell community in Far North Queensland, Australia. Like many other coastal locations worldwide, Cardwell is particularly vulnerable to sea level rise and tropical cyclones leading to severe storm surges and intense rainfall events. Cardwell's vulnerability to extreme weather events was confirmed in February 2011 when category five tropical cyclone Yasi affected the town causing widespread damage to its coastal community. Nonetheless, this community has begun a distinctive recovery phase by initiating the preparation of a long term strategy for its future independent of official planning processes of State and local governments.

The paper focuses on this distinctive recovery phase in which the Cardwell community took the initiative of developing a long term strategy to maximise the opportunities presented in the post Yasi reconstruction phase and beyond. The paper describes the collaborative process involved in developing this strategic planning initiative which culminated in the proposition of a long term vision as well as a set of priority actions to improve adaptation of the Cardwell community. We also discuss how this bottom-up, community initiated and led, visioning and strategic planning initiative, may contribute to inform the planning process for climate change adaptation in urbanised coastal areas.

Key words: adaptation, community recovery, strategic planning, coastal settlements

[1] Griffith University, Brisbane, Australia – s.serrao-neumann@griffith.edu.au

1. Introduction

Urbanisation of coastal areas has increased significantly during the last century (Nicholls et al, 2007). As a result, coastal areas host significant populations and provide important socio-economic activities for regions worldwide (Birkmann et al, 2010). For example, it is estimated that they are now home for 10% of the world's population (McGranahan et al, 2007) and have an average population density 3 times higher than the global average (Small and Nicholls, 2003). The combination of increased population growth in coastal areas and forecasted climate change impacts is likely to exacerbated the vulnerability of many coastal communities (Nicholls et al, 2007). In the face of climate change urbanised coastal areas are likely to be vulnerable to coastal and riverine flooding, sea level rise and storm surge (Brooks et al, 2006; Nicholls et al, 2007; Solomon et al, 2007; Hunt and Watkiss, 2011).

The fact that climate change impacts are expected to be spatially non-uniform across the world (Füssel, 2007) indicates that cities and regions will need to adapt to climate change in different ways. While there is strong evidence that climate change is already happening (Solomon et al, 2007), many communities worldwide have experience in dealing with extreme weather events such as tropical cyclones and therefore provide important knowledge based on experience that can inform future climate adaptation. Consequently, it is important to capture the idiosyncrasies of different communities across the world in their efforts to adapt to extreme weather events. This paper focuses on the example provided by the town of Cardwell, Queensland, Australia, where category five Tropical Cyclone Yasi made landfall in February 2011 causing widespread damage to this coastal community.

Coastal areas in Australia followed the worldwide trend of coastal urbanisation and about half of the current country's population lives along the coast (Chen and McAneney, 2006). For example, the east coast of Australia hosts major urban centres and many smaller townships such as Cardwell that will need to adapt to climate change. Specifically, the north east coast of Australia is particularly vulnerable to tropical cyclones and associated impacts. While climate change is likely to decrease the frequency of tropical cyclones affecting this area of Australia, the intensity of such storms is likely to increase (Suppiah et al, 2010). Coastal communities such as Cardwell, because of the uncertainty related to global environmental change, increased population growth and trend in development are likely to have increased exposure to extreme weather events in the future (Nicholls et al, 2007).

Further, economic damages associated with extreme weather events have increased through time due to both social vulnerabilities and change to physical hazards (Adger et al, 2005). For example, the economic impact associated with cyclone Yasi in terms of damage costs is estimated to be three times higher than previous category four

cyclone Larry's half billion dollars (O'Brien and Howells, 2011; Australian Bureau of Meteorology, 2007). While natural hazards are an ongoing part of human history, a changing climate coupled with coastal development and population growth may exacerbate the exposure of coastal communities to their impacts (Nicholls et al, 2007) and continue to challenge their ability to respond appropriately as well as their economic recovery (Gunderson, 2010). Extreme weather events resulting in disasters also lead to a range of intangible social costs such as trauma which is likely to affect 95% of people in the early aftermath of the disaster and continue to affect 10-25% of people after the immediate recovery period (Gordon, 2007). Consequently, there is an urgent need to build resilience of coastal communities given their vulnerability to extreme weather events and future climate change impacts (Adger et al. 2005).

It is argued that planning plays an important role in safeguarding communities against future climate change impacts, particularly through adaptation (Bulkeley, 2006). Adapting to climate change thus is challenging and demands a rethink in the way in which our cities and towns are planned and built (Leitch et al, 2010). Such rethink will need to take place in partnership with those communities which are vulnerable to extreme weather events as they are at the forefront of impacts when those events occur. Coupled events such as sea level rise and tropical cyclones leading to severe storm surges and intense rainfall events will posit significant challenges to how coastal areas are managed as well as testing the strength of the communities inhabiting those areas. While the severity of extreme weather events affecting those areas may lead to widespread damage and disasters, they might also generate opportunities for change to occur in their socioeconomic, political and organisational systems (Pelling and Manuel-Navarrete, 2011). This paper explores how those opportunities emerge and are optimised by focusing on the recovery process of the Cardwell community which initiated a process to develop a long term strategy for its future independent of official planning processes of state and local governments.

To this end, the paper is structured in three parts following this brief introduction. In the first part, we present the research approach which includes elements of participatory intervention research. In the second part, we describe the collaborative process involved in developing this strategic planning initiative which culminated in the proposition of a long term vision as well as a set of priority actions to improve adaptation of the Cardwell community. Last, we discuss how this bottom-up, community initiated and led, visioning and strategic planning initiative, may contribute to inform the planning process for climate change adaptation in urbanised coastal areas.

2. Research Approach

This study adopted a research-intervention methodology (Hatchuel, 2001). This type of research methodology, also called participatory intervention research (Daniel et al, 2011), has gained momentum over the last decades amongst sciences which deal

with collective action processes (Hatchuel, 2001). It is an approach that builds on elements of action research (Hatchuel, 2001) first developed by Kurt Lewis in the 1940s (*cf.* Halkup et al, 2004). Widely used in the fields of human health where it is referred to as community-base participatory research (Halkup et al, 2004; Wallerstein and Duran, 2011) and management research (Hatchuel, 2009), it comprises a type of research which allows collaboration/interaction between actors and researchers to generate the means for collective action (Daniel et al, 2011). Midgley (2008) defines intervention related to research methodology as a "purposeful action by an agent to create change" (pp. 56).

Advantages of adopting this type of research methodology include its contribution to aid decision-making processes as well as the fact that researchers play a dual role of investigators and stakeholders in the process which can increase its path to impact (Daniel et al, 2011). Furthermore, intervention-research is conducive to bring about positive change (Midgley, 2008).

In adopting research-intervention as our methodology we created a broader scope for the collaborative component of the study. Advantages of establishing collaborative approaches in the planning context are well discussed in the literature and extensively represented by the work of Patsy Healey (2006, 2008). Specifically, collaborative planning provides opportunities for the argumentation and debate of critical issues in the policy-making practices (Healey, 2008, pp. 285). In this collaborative process, negotiations between stakeholders assist in defining which focal issues are included or discarded as well as responsibilities and accountabilities further down the track when implementation takes place (Daniel et al, 2011).

In our context, the research comprises a partnership between the Cardwell community and the research team established to conceptualise and develop a long term strategy for the community's future. The research was complemented by a three-pronged approach related to data collection which involved:

a) Literature review and background research ;
b) Semi-structured interviews (Hay, 2005) with community members focused on disaster preparation, response and recovery; and
c) Participant observation (Hammersley and Atkinson, 1983; Tedlock, 1991) during workshops with the community.

The literature review and background research involved assembling and analysing background planning data and documents and climate change data; confirming key existing and potential planning initiatives for ongoing engagement by the Cardwell community (including planning process opportunities and initiatives); and identifying potential natural and socio-economic triggers for the area.

The semi-structured interviews and participant observation during the workshops and strategic action planning process enabled the investigation of the critical community attributes, community networks and essential steps of successful community bottom-

up approaches that may lead to improved community resilience and adaptation to natural hazards and climate change, particularly in coastal areas.

3. The Collaborative Process

Located in Far North Queensland, Australia, the broader Cardwell has a population of approximately 9,500 (Australian Bureau of Statistics, 2006). The township itself is located more than 1,500km from the State capital Brisbane and halfway between two regional centres, Townsville and Cairns (see Figure 1). The area is known to be vulnerable to extreme weather events such as cyclones (see Figure 2) which often cause widespread floods and wind destruction (Australian Bureau of Meteorology, 2011).

Figure 1. Location map for Cardwell, Australia (source: Google Earth)

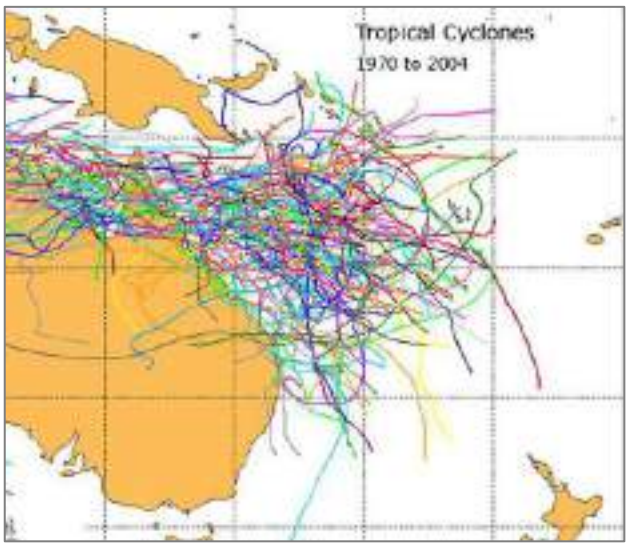

Figure 2. Tropical cyclones affecting the Australian East Coast (source: BOM)

The collaborative process of developing a long-term strategy for the Cardwell community was initiated by the Cardwell Chamber of Commerce in the aftermath of cyclone Yasi in March 2011. A partnership was then established between the

Cardwell community (facilitated by the Cardwell Chamber of Commerce) and the research team.

The research to date has involved the conduct of five community workshops which included community members representing 24 community groups (see Figure 3 for

Workshop 1- a preliminary scoping workshop with the Chamber of Commerce (CCoC) to define a Cardwell 'Community of Interest'; and develop a long term vision for Cardwell.

Workshop 2 - a community workshop with a broad representation from the Cardwell community to confirm the Cardwell Community of Interest; identify community networks; confirm the long term Vision for Cardwell; completed a SWOT analysis to identify the strengths, weaknesses, opportunities and threats that may influence post-Yasi Cardwell development; define community priorities; and scope options for community responses to future natural hazards and disasters. As an outcome of this workshop, a number of factsheets was produced that summarised information on a range of relevant topics to further enhance an understanding of the key issues involved.

Workshop 3 - a community workshop to identify the key drivers of change influencing the community of Cardwell over the next 25 years; identify key strategic initiatives and proposals; and identify preliminary strategic actions (responsibilities/timings/priorities/resources etc.).

Workshop 4 - a community workshop to develop and assess a set of initial 'Future Options' for consideration in the Cardwell small Strategic Action Plan.

Workshop 5 - a community workshop to assess and confirm preliminary Future Options to be included in the small Strategic Action Plan.

Figure 3. Outline of workshops

an outline of each workshop). As a result of these workshops, the Cardwell community in partnership with the research team has developed and confirmed a vision for the future of the community (see Figure 4); identified a series of future options for the community; and composed a draft action plan which contains a series of prioritised actions that will have to be implemented over the life of the action plan in order to achieve its vision and strategic intents.

Vision Statement

Cardwell – *a future community of eco-living* will be noted for its embrace of a high standard of ecologically sustainable living, energy efficient buildings and its town location and design that provides maximum safety and security from natural hazards.

With its permanent population capped at sustainable levels of 3000-4000 persons, its urban centre will comprise three low rise nodes, each with a distinctive core function. The polycentric urban centre will focus on and support five core regional businesses, namely: agriculture, aquaculture, eco-tourism, aged-care, and services.

The community will maximise its diverse tourist opportunities afforded by its location in proximity to World Heritage areas and national parks.

Figure 4. Community vision

The remaining step in the process is to disseminate the action plan to the wider community as well as authorities from both local and state governments. Ultimately, it is expected that the proposed future options put forward by the Cardwell community will be integrated and incorporated as part of the review of official plans and strategies that have direct implications for Cardwell.

The compilation of future options for the community involved an iterative process in which community members were given the opportunity to submit a selection of options to be assessed by the whole group during the workshops. These future options were accompanied by the following descriptors: the source of the idea; the relevant area or location for its applicability; main mechanisms for its implementation; identified responsibility for its implementation; identified anticipated benefits; identified undesirable or unintended impacts; and priority relative to other options.

Initially, a total of 25 preliminary future options were proposed to be included in the action plan. These options were tested against a set of five 'What If' questions during workshop 4 which sought to evaluate:

i. the extent to which the option would enable the community to deal with future major natural hazards;
ii. the extent to which the option would enable the community deal with future shocks and surprises (e.g. economic downturn, collapse of the international and national tourism industry, dramatic changes to oil availability);
iii. the extent to which the option would represent the best use of public money;
iv. the extent to which the option would have a negative impact on the community; and
v. the extent to which the option assisted in achieving the proposed vision for the future of the community.

Future options were then reviewed by the research team and re-confirmed by community members before being reassessed during workshop 5.

The major themes under which those future options were grouped include: planned retreat (with provision of cyclone shelter); economic development (by fostering and enhancing existing industries); sustained population growth; town development and promotion; improved infrastructure provision; opportunities for youth development; strengthening its cultural policy; supporting its Indigenous community; and improved skills base.

4. A Way Forward

Understanding how communities function to recover in the long term from the impacts of natural hazards and what are the necessary attributes that can lead to resilient communities is of critical importance, especially to government agencies from all levels, as they seek to support and meet the needs of these communities. The research sought to improve this understanding by relying on primary data obtained through both workshops and interviews.

Drawing on workshop outputs, two characteristics were identified in the Cardwell community that are understood in the literature to be important elements that assist the community recovery process after disasters (Airriess et al, 2008; Colton and Samper, 2008). These include place attachment and strong social networks. These two characteristics became evident during workshop 2, when participants undertook a SWOT analysis to identify the community's strengths, weakness, opportunities and threats. In doing so, participants were able to indirectly reflect on the actual impact of Tropical Cyclone Yasi upon their community and identify key characteristics of their community that enabled them to overcome/deal with such impact. Specifically, a strong sense of belonging and identity was identified to be one of the key strengths of their community. This was exemplified by the high valorisation of their lifestyle which is enabled by the attributes of the surrounding landscape, e.g. located between the boundaries of two World Heritage areas and micro climate; and by the high level of voluntary participation and involvement of community members in the town and district's affairs through multiple memberships across community groups.

Interviews also confirmed the strong place attachment and strength of social networks that characterise this community. In particular, they highlighted the strong commitment and involvement community members have in doing voluntary work across a range of fields, including amongst others charity work, sport and cultural activities, training and advice, assistance to elderly people and voluntary rescue services. Additionally, they demonstrated the level of social networks in place exemplified by the mutual assistance that was provided during cyclone Yasi. A few qualitative explanations of these characteristics are provided on Table 1.

With regard to the collaborative process described in section 3, the community was able to identify and deliberate on focal issues perceived to affect their community and therefore requiring attention by relevant government bodies. Specifically, there was a clear call for increasing the involvement of the community in the decision-making process concerning their area. Specific issues included the lack of political support and weak political representation of the community's interests and needs and overregulation. The need to rehabilitate communication channels between the community and local authorities was also noted and articulated. These issues are particularly relevant to the planning process currently in place in the area as they indicate fractures in current community engagement initiatives.

While, one of the key challenges related to establishing effective public engagement initiatives relates to the difficulties to involve and motivate the community to participate (Head, 2007), the circumstances exemplified by the Cardwell community

also indicate that in some cases the community is willing to participate but appropriate channels are not provided by authorities to do so. Scholars have pointed out that there are limitations associated with establishing community engagement initiatives at larger scales in terms of the number and representativeness of social

Table 1. Evidence from interviews supporting key community characteristics

Key characteristic	Qualitative explanation
	"*I would say I volunteer three to probably about four to five hours a week."* (Full-time employed female community member) "*I volunteer one day a week at our* (organisation 1*) *I'm also the secretary of* (organisation 2), *which is pretty involved because you do have a lot of paperwork; you have to deal with that and you actually have to run the whole thing. So that would take up, I don't know, probably a day a week. I'm on the committee,* (organisation 3), *I was the secretary. I just got rid of that job and so I do a bit of work for the* (organisation 4) *and the* (organisation 5)." (Retired female community member)
Place attachment and Social networks	(on cyclone Yasi) "*We also had some local people who were being told to leave their home, and we just took as many people that wanted to come and stay. We basically all sat in the dining room so that we had a couple of walls between us, and I also had my two kids here. So, you know, there was probably about 10 or 12 of us here or something that night*" (Full-time employed female community member) (on cyclone Yasi) "*We had people ringing up saying, "Can we come out?" And that was the same with our neighbours. Everyone knows ... Road is well above sea level and we had nine in our house. The neighbours had, I think they had, they'd left but they let people use their house. I think there was about eight people in that house. There was about 30 something in – 20 something in the house two up from us. 30 something in the house above that. We didn't know this until the next morning, but that many people."* (Full-time employed male community member)

* Names were omitted for privacy reasons

groups that can be involved, specially the hard to reach groups (Few et al, 2007; Wiseman et al, 2010). Another potential reason for this lack of involvement of the Cardwell community in official decision-making process could be related to episodic/tokenistic approaches in public engagement initiatives (Head, 2007). Both barriers certainly need to be further investigated to determine the extent to which

they are engrained in the planning practices and hindering the establishment of broader community engagement initiatives in the Cardwell area.

Furthermore, complex and highly contested issues such as climate change demand the adoption of better collaborative approaches in planning practices to aid decision-making (Head & Ryan, 2003; Innes & Booher, 2004; Horlick-Jones et al, 2006). The collaborative process, the subject of this study, demonstrates that there are critical issues that the community would like to see discussed/incorporated in future official plans concerning their local area. These were identified through the iterative process of developing and assessing future options for their community which ultimately would enable the Cardwell community to deal with future extreme weather events. The extent to which these issues will be incorporated in future official plans is yet to be determined however efforts are already in place to improve the communication channels between the community and government authorities. These efforts can be mostly attributed to the Cardwell community itself further demonstrating the strength and will of its members to bring about positive changes.

Lastly, there are two key aspects of the partnership established between the Cardwell community and the research team that enabled the success of this collaborative process thus far. These are related to the reputation of the research team in undertaking collaborative research elsewhere in partnership with other stakeholders and the existence of community champions. Both aspects are understood to be critical for the success of intervention-research as indicated by Daniel et al (2011). According to the authors, on the one hand, reputation of the participants in this type of research model is seen as a crucial because it brings trust to the process. On the other hand, while involving community champions requires clear protocols to avoid the dominance of individual interests in the outputs of process, it is an essential aspect to ensure ongoing participation of other community members throughout the process.

Nevertheless, collaborative process through intervention-research such as the one outlined in this study need to be continuously evaluated to ensure its legitimacy and robustness. These would involve some key criteria such as the ones proposed Holkup et al (2004), including: credibility, transferability, fairness, level of participant involvement, community voice, acceptable problem solution and feasibility of project sustainability.

5. Conclusion

Intervention-research is perceived to be a useful research model to generate the means for collective action. This study confirms its usefulness as it generates important information related to the community's values and interests that should be discussed and potentially incorporated in future plans for their area. Additionally, the collaborative process between the community and research team, implemented through this intervention-research, is fostering the re-establishment of communication channels between the community and government authorities.

However, the real effectiveness of this collaborative process will continue to be tested in the years to come as the action plan is widely disseminated to both the broader community and government officials.

Acknowledgments
This research was kindly supported by the Griffith Climate Change Research Program and the Cardwell Chamber of Commerce. We would like to thank the Cardwell community for their time, efforts and enthusiasm to participate in this research. We also would like to thank Greg Laves for his work on the study. The content of this paper are the solely responsibility of the authors.

THE RECURRENCE OF HEALTH IN URBAN PLANNING: TOWARDS AN INTEGRATION OF ENVIRONMENTAL HEALTH ASPECTS

Thomas Verbeek[1], Georges Allaert[2]

Abstract

While urban planning and health were initially interlinked, in the twentieth century planning practice slowly moved away from its public health origins. In recent years however there is a growing interest in the health effects of our spatial organization. Although the direct impact of the physical environment on health has decreased – due to better standards of living, sanitary developments, improved housing – environmental quality still deserves our attention. First, the focus has shifted from life expectancy to health expectancy and quality of life. Public health impact no longer predominantly involves clear mortality risks, but rather comprises aspects of human well-being in a broad sense. Several direct impacts, like noise or air pollution, do not immediately kill people, but cause physical or mental disorders on the long term or severely reduce the quality of life of people. Second, the physical environment has many indirect effects on lifestyle and health, for example a reduced physical activity caused by a lack of walkable neighborhoods. A final important reason to justify this research is the aspect of environmental justice. The spatial characteristics responsible for direct and indirect health effects are spatially heterogeneously distributed, causing important differences in health status and healthy life expectancy between various residential neighborhoods.

Today a lot of research exists on different health impacts caused by aspects of the physical environment. Most of this research focuses on one single impact (e.g. noise) or one spatial aspect (e.g. a road). An integrated approach, in which all the impacts and aspects are combined, seems to be lacking. However, there is a giant need for a better understanding of this issue, to inform community leaders and spatial planners about which community design and land-use choices are most effective in improving the physical, mental and social well-being of people.

In this paper an attempt is made to give an overview of the main environmental characteristics with an effect on people's health and well-being. The aim is to evaluate the evidence of the existing research output and to explore the relevance for spatial planning.

Finally the results are discussed and recommendations for urban planning policy are formulated. Here the aspect of environmental justice comes into view, the right on a healthy living environment for every citizen regardless of social and economic status.

1. Introduction

Health and urban planning are historical allies. In the mid-19th century a tremendous population drift from the countryside to larger industrial cities took place, causing overpopulation in cities with an underdeveloped public hygiene. Modern planning originated expressly in order to combat these unsanitary, overcrowded and inhumane urban conditions. Endemic problems of poor water supply, sanitation, light and air triggered a response in terms of not only infrastructure engineering but also urban design (de Hollander and Staatsen, 2003; Galea and Vlahov, 2005; Barton, 2010).
In the mid-to-late 20th century planning practice moved away from its public health origins. Original objectives of clean air and water are still deeply entrenched in planning and building control systems, but contemporary diseases have been ignored in many ways. Planning policies have facilitated if not actually fostered the powerful trend towards car-dependent, sedentary and privatized lifestyles, with their negative effects on health and well-being. We have been literally building unhealthy conditions into our local human habitat (Barton and Grant, 2006; Barton et al., 2009).
At the beginning of the 21st century a resurgence of interest in the relationship between 'place' and 'health and well-being' can be noted. Recent concerns about levels of physical activity, asthma, sleep disturbance, stress and increasing environmental inequality have put the aspect of health back on the spatial planning agenda. We now realize that how we design the built environment may hold tremendous potential for addressing many of the greatest current public health concerns (Jackson, 2003a; Barton and Grant, 2006).

The development and significance of environmental health can be analyzed using a conceptual model (Ruwaard and Kramers, 1998). This model (figure 1) shows that health status can be regarded as a function of a variety of determinants. Up until the 20th century the physical environment was the largest source of avoidable disease burden in the Western world, with an attributable fraction of 70-80% (de Hollander and Staatsen, 2003). Since the public health revolution from the 19th and 20th century, this factor is only directly responsible for minor health loss, while life-style is responsible for the bulk of the current avoidable disease burden (de Hollander et al., 1999; Smith et al., 1999; Melse and de Hollander, 2001). Especially among young people and lower socio-economic classes trends in unhealthy behavior are alarming (smoking, dietary habits, sedentary life-styles) (van Oers, 2003).

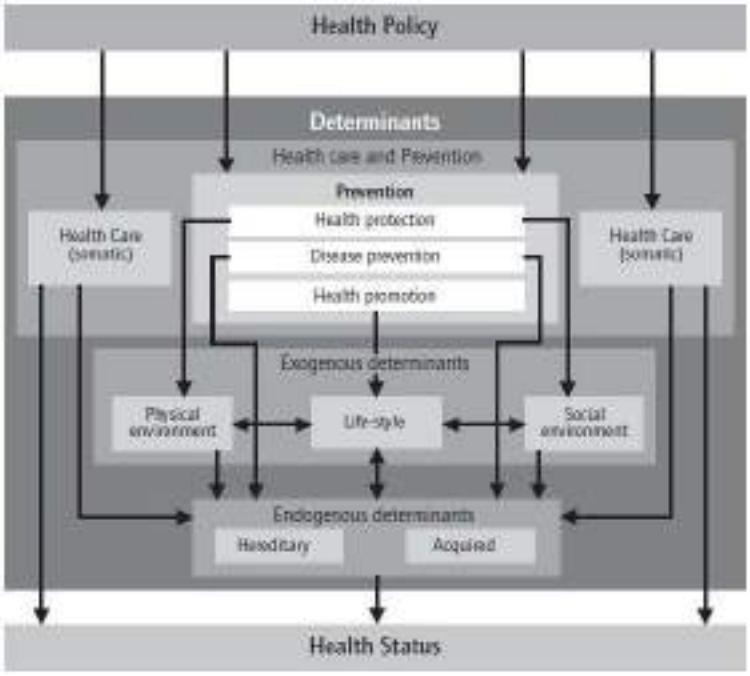

Figure 1. Conceptual model - determinants of public health status (Ruwaard and Kramers, 1998)

The increasing importance of life-style in the public health status of Western countries is a consequence of the growing control over other determinants. In fact, modern post-industrial people have become very healthy people, thanks to public hygiene, vaccination programs, antibiotics, a general improvement in standards of living and a comprehensive system of health protection (de Hollander and Staatsen, 2003). Today, the health loss due to exposure from the physical environment is much higher in low-income countries compared with Western countries (lack of access to clean water, inappropriate housing, infectious diseases, indoor air pollution, malnutrition …). Further, the health risks associated with industrialization, such as large scale air (and noise) pollution generated by transport and energy production, do now receive a lot of attention, but in fact these problems did make many more victims in the past (Lomborg, 2001). Many of the impacts of environmental factors have been annihilated or reduced to be 1/10 or 1/20 of their original impact (de Hollander and Bol, 2004).
Because of this conclusion, one can wonder whether the physical environment still deserves our attention when it comes to public health. Three reasons can be given why this focus is still useful.

From quantity of life to quality of life
The main reason why environmental quality is still a valuable research theme is the shift from quantity of life to quality of life. Public health impact no longer predominantly involves clear mortality risks or loss of life expectancy, but rather comprises aspects of well-being and quality of life in a broad sense (de Hollander and Staatsen, 2003; de Hollander and Bol, 2004). Firstly, this includes the

aggravation of pre-existing disease symptoms, e.g. asthma, chronic bronchitis, cardiovascular disorder. Secondly severe annoyance, like sleep disturbance or a reduced ability to concentrate and communicate, is comprised. A third category consists of feelings of insecurity or alienation, unfavorable health perception and stress in relation to poor environmental quality. Environmental annoyances, like noise pollution, do not lead to many supplementary deaths, but do affect the quality of life of people and cause stress and concentration and communication problems.
The World Health Organization (WHO) already adopted this broad definition in 1946, stating that health is "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" (WHO, 1946). Also in research the concept of health has expanded beyond a mere absence of illness and objective indicators of health, to address well-being and quality of life (O'Neill and Simard, 2006).

Indirect effects of the physical environment on lifestyles and health
The physical environment also has important indirect (and complex) effects on health, through impacting life-styles (Barton and Grant, 2006). This can easily be illustrated by Barton's settlement health map, depicting the ecosystem of a human settlement (figure 2). Each outer sphere (natural environment, built environment, activities) affects the health and well-being of people, represented by the inmost sphere, directly or through an effect on local economy, community or lifestyle – the intermediate spheres. The built environment can for example provide attractive walkable neighborhoods with mixed land use, thus stimulating a physically more active lifestyle and consequently a better health status.
Because of these clear links between environmental quality and life-style (see also Pickett and Pearl, 2001; Roux et al., 2001), a study remains useful, but one has to be aware of selection processes that can have more impact than actual causal relationships.

Environmental justice
The spatial characteristics responsible for direct and indirect health effects are spatially heterogeneously distributed, causing problems of environmental inequality. It has been recognized that environmental hazards in urban areas disproportionately affect low-income people and members of minority groups (Brulle and Pellow, 2006). This is due to a social polarization of opportunity, which ties some people to locality, making them increasingly vulnerable (Barton et al., 2009). These people often cannot afford to live in relatively healthier neighborhoods and bear a greater burden of risk (Dannenberg et al., 2003; Moudon, 2009).
There exists empirical evidence that low income is associated with higher noise exposures (e.g. Seto et al., 2007) and higher air pollution exposures (e.g. Laurent et al., 2007). Moreover, members of minority groups are relatively more exposed to air pollutants than whites, independent of income and urbanization (e.g. Perlin et al., 1999). Kohlhuber et al. (2006) add that not only the perceived exposure differs but also the generation of environmental problems may be distributed unequally. Poor people are less likely to own a car than wealthier people, they contribute less to environmental pollution but suffer disproportionately more often from it.

These three arguments show that the relation between urban planning and health or well-being still deserves our attention. The main line of thought is that every citizen has the right on a living environment that stimulates health and well-being, regardless of his or her social and economic status. This basic principle of the right on well-being and environmental quality connects an ecocentric with an anthropocentric view, clearly illustrated by Barton's settlement health map (Barton, 2005, 2009) (figure 2). On the one hand this diagram expresses an ecocentric view on human settlements, by depicting an ecosystem with different spheres, that are interconnected in different ways and have to be in a good balance to ensure healthy settlements. On the other hand people are placed at the heart of the map, reflecting the anthropocentric definition of sustainable development, aimed at improving the livability and the quality of life (e.g. IUCN, 1980; Newman, 1999).

Figure 2. Human ecology model of a settlement (Barton and Grant, 2006)

To include the health aspect in spatial planning and design, a good scientific basis is needed. We need to know which impacts are important, what health effects they bring about, and how these impacts can be spatially influenced (Jackson, 2003b).
Today a lot of research exists on different health impacts caused by aspects of the physical environment. Most of this research however focuses on one single impact (e.g. noise) or one spatial aspect (e.g. a road), and results are typically not widely shared across disciplines (Dannenberg et al., 2003).
The spatial planning discipline should strive to this integration of the different associations between aspects of the built environment and impacts on health and well-being. Starting from this concern for an integrative approach, a PhD research project has been started up focusing on the combination of impacts and the modeling

of environmental health. The remaining part of this paper presents the results of an exploratory literature study, carried out to discern the main environmental impacts, originating in aspects of the built environment, and relevant for spatial planning and design decisions.

2. Framework

To guide the literature study, two important choices were made, concerning the range of impacts included and the spatial scale of the effects. To discern the environmental characteristics that are relevant for spatial planning, the analysis was focused on impacts caused by the physical environment, and not the social environment, and on impacts that generate differences at a local neighborhood level, and not the building or regional level (for an analysis of impacts on other scales, see Jackson, 2003a).

As a framework for the assessment of the different impacts, a scheme was used that consists of three parts (figure 3): 1) spatial conditions, 2) impacts and 3) effects on health and well-being.

Figure 3. Framework

A simple example is the spatial configuration of a highway (1), generating traffic noise (2) with an effect on sleep quality of neighbors (3).
The aim was to characterize the different impacts following this scheme. The linking parts, the ‘impacts’, will be considered as the steppingstones of the research project. This is partly due to the aim of the further research steps, modeling the environmental quality based on a combination of the most relevant impacts.

The literature study was carried out on an exploratory basis. It was not the aim to be exhaustive and complete, nor to give the most recent insights in the domain. The purpose was to get a broad view of the different impacts, their importance, the scope of their effects and the value of the existing empirical evidence. Nevertheless it was attempted to select primarily those sources that are cited regularly and that incorporate possible confounding variables. One of the main lacunas is the primary reliance on cross-sectional studies, because of the limited availability of longitudinal studies.
Notwithstanding several shortcomings, the literature review should give a broad view on the relation between the built environment and health or well-being and set the scene for further research. Based on this analysis it should be possible to select the most important impacts for further modeling.

3. Impacts

Based on the literature review, four important impacts could be discerned, with sufficient scientific evidence. These are: air pollution, noise, the absence of green space as a restorative environment and the lack of physical activity.
For other impacts the effects on health and well-being have limited evidence, the spatial component is less pronounced or the spatial differentiation at a neighborhood scale is unsure. Among these non-included impacts are the lack of social interaction (e.g. Leyden, 2003), soil pollution (e.g. Vrijheid, 2000), electromagnetic fields (e.g. Röösli, 2008), the urban heat island effect (e.g. Tan et al., 2010) and unhealthy food environments (e.g. Rose and Richards, 2004).

3.1. Air pollution

Figure 4. Environmental impact scheme: air pollution

Air pollution is definitely one of the most important environmental impacts at a local scale. The local differentiation is mainly due to the spatial organization of roads and the accompanying traffic. Also industry can contribute to local air pollution but few research focuses on this aspect.

The relation between air pollution levels and roads has been investigated extensively. A lot of studies show that traffic intensity and/or distance to major streets or highways are important predictors of differences in measured pollutant concentrations, for NO_2 (Roorda-Knape et al., 1998), $PM_{2.5}$[3] (Fischer et al., 2000; Janssen et al., 2001), (ultra)fine particles (Hitchins et al., 2000; Zhu et al., 2002), elemental carbon or 'soot' (Roorda-Knape et al., 1998; Kinney et al., 2000), CO (Zhu et al., 2002), benzene (Fischer et al., 2000) and ozone (Kuhler et al., 1994). These relations indicate that the measured pollutants are related to vehicle exhaust emissions.
For most traffic volumes and pollutants, the major decrease in traffic-based pollutants occurs in the first 100 meters and then levels off somewhat after 150 meters (Zhu et al., 2002). However, until 1000 m of a highway a contribution of the road to local air pollution can be measured (Fischer et al., 2007).

[3] Particulate Matter (PM) with a diameter of 2.5 micrometers or less.

Today there is sufficient scientific evidence to conclude that living alongside busy roads is less healthy than situations with a bigger distance between the home and major roads.
The most important and most described health effects are in the field of the respiratory system, with increased *respiratory symptoms, lung growth deficits* and *allergy development* in children.
Many studies show an association between high vehicle traffic and chronic respiratory symptoms like cough and wheeze in children (e.g. Wjst et al., 1993; Oosterlee et al., 1996; Van Vliet et al., 1997; Hirsch et al., 1999; Venn et al., 2001; Nicolai et al., 2003; Shima et al., 2003; Andersen et al., 2008), or asthmatic symptoms and/or asthma hospitalizations (e.g. English et al., 1999; Lin et al., 2002; Brauer et al., 2007; Morgenstern et al., 2008; Nordling et al., 2008). A recent research by Gehring et al. (2010) provides further evidence that traffic-related air pollution exposure may contribute to the development of asthma in children, and not only aggravates existing symptoms.
Some cross-sectional studies in Europe have shown that deficits in lung function growth in children – associated with morbidity and mortality in adulthood (e.g. Knuiman et al., 1999) – are related to residential exposure to high (truck) traffic (Brunekreef et al., 1997; Sugiri et al., 2006). A highly cited research of Gauderman et al. (2007) showed that pronounced deficits in attained lung function at age 18 years were recorded for those living within 500 m of a freeway, for both asthmatic and non-asthmatic children, thus giving evidence for adverse effects of traffic exposure on otherwise healthy children.
Associations between distance to the nearest main road and the risk of allergy development and exacerbation of allergic reactions have also been demonstrated (e.g. Krämer et al., 2000; Brauer et al., 2007; Morgenstern et al., 2008; Nordling et al., 2008).

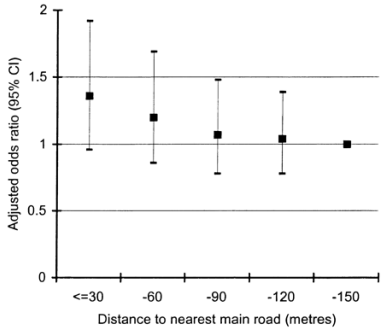

Figure 5. Exposure-response relationship between distance of the home from nearest main road and parent-reported wheeze in primary schoolchildren (Venn et al., 2001)

Further, chronic exposure to air pollution from traffic is associated with *increased mortality risks*. Several studies show that individuals who live close to major roads have an increased risk of mortality, although relative risks are generally small (e.g. Roemer and van Wijnen, 2001; Hoek et al., 2002; Finkelstein et al., 2004; Gehring et al., 2006; Beelen et al., 2008).

The assumption that increased mortality is primarily associated with a higher prevalence of *atherosclerosis* (the hardening of arteries) and *coronary disease* is supported by the research of Hoffman et al. (2007), who found that long-term residential exposure to high traffic is associated with the degree of coronary atherosclerosis, and Gan et al. (2011), who observed an association between exposure to road traffic and adverse cardiovascular outcomes.

In terms of proximity, most studies use distances of 50 to 300 meters to indicate exposure to traffic-related air pollution, but adverse effects on health have been observed in people living up to 1000 m from a busy road.
It is clear that the closer to a road people live, the higher the increase in adverse health effects, but there are no studies available that give evidence about an acceptable distance or a mathematical relationship. Each choice for an 'acceptable' distance between residential location and major roads or highways is not based on thresholds of health, but on the societal acceptability (Fischer et al., 2007).

3.2. Noise

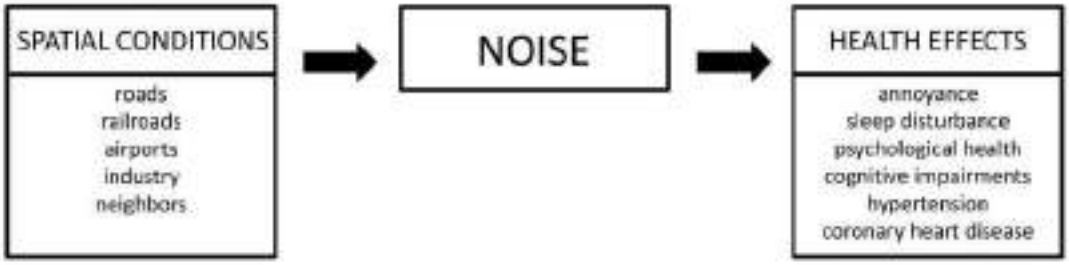

Figure 6. Environmental impact scheme: noise

Noise, defined as 'unwanted sound', is perceived as an environmental stressor and nuisance. It is an increasingly prominent feature of the urban environment and is being seen as an important environmental public health issue (Clark and Stansfeld, 2007). Noise is a phenomenon that is sensed and evaluated by everybody, and this is why noise exposure is one of the most frequent complaints of populations living in large cities (Muzet, 2007).

The direct auditory effects of noise on humans – like hearing loss – are well established. The corresponding sound levels and effects however do not occur in normal urban settings. Non-auditory effects, on the other hand, cannot be explained as a consequence of sound energy, but are the result of noise as a general stressor (Clark and Stansfeld, 2007).
Annoyance is the most reported problem caused by noise exposure and is often the primary outcome used to evaluate the effect of noise on communities (Ouis, 2001). Noise annoyance is a feeling of resentment, displeasure, discomfort, dissatisfaction, or offense when noise interferes with someone's thoughts, feelings or actual activities (Passchier-Vermeer and Passchier, 2000). Of all health effects associated

with noise, the dose-response relationship between community noise and annoyance is the most developed (Seto et al., 2007).
Associated with annoyance, there is both objective and subjective evidence for *sleep disturbance* by noise. Exposure to night-time noise can potentially interfere with the ability to fall asleep, shorten sleep duration, cause awakenings and reduce quality of sleep (Michaud et al., 2007). Sleep disturbance can have an important impact on well-being, causing after-effects during the day: annoyance, irritation, low mood, fatigue, low vigilance and impaired task performance (Stansfeld and Matheson, 2003; Muzet, 2007). Community studies of traffic noise exposure have found consistent evidence for a direct effect on sleep disturbance (e.g. Öhrström, 2002; Miedema and Vos, 2007).
Given the effect of chronic noise exposure on annoyance responses, it has been hypothesized that also *psychological health* might be affected. Studies of adults have confirmed that noise exposure relates to an increase in the number of reported psychological symptoms, such as anxiety and depression, higher levels of psychological distress and a higher prevalence of hyperactivity (e.g. Jones et al., 1981; Stansfeld et al., 1993; Haines et al., 2001a).
Further, strong evidence is available for a direct effect of noise on the *cognitive development of children*. Several studies have established that children exposed to noise experience some cognitive impairments – especially impaired reading comprehension and sustained attention – with the suggestion that the children's further cognitive development may be affected (e.g. Haines et al., 2001a; Haines et al., 2001b; Stansfeld et al., 2005). A highly cited field study was the naturally occurring longitudinal quasi-experiment reported by Evans and colleagues, examining the effect of the relocation of Munich airport on children's health and cognition (Evans et al., 1998; Hygge et al., 2002), demonstrating a causal link between noise exposure and cognitive effects.

There is also consistent and strengthening evidence for a small but significant effect of transport noise on *hypertension and coronary heart disease* (Babisch, 2006; Clark et al., 2007). One of the most striking results comes from Jarup et al. (2008), who found an increased risk of hypertension related to long-term aircraft and road traffic noise exposure. Other studies demonstrated an effect of transport noise exposure on the use of anti-hypertensive drugs (Greiser et al., 2007), self-reported hypertension (Rosenlund et al., 2001; Bluhm et al., 2007), heart attack (Babisch et al., 2005; Selander et al., 2009) and heart disease (Babisch et al., 2003; Babisch, 2006). Recently, findings of Gan et al. (2012) made clear that there are independent effects of traffic-related noise and air pollution on cardiovascular disease and mortality.

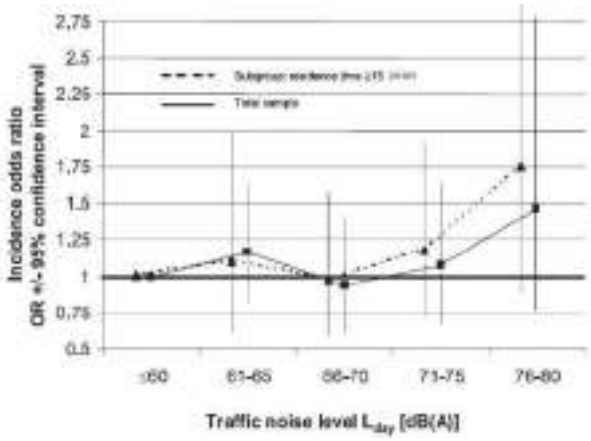

Figure 7. Association between road traffic noise level and incidence of heart attack (total sample vs. subgroup with minimum 15 years of residence time) (Babisch et al., 2005)

This overview shows that effects of noise are strongest for those outcomes – like annoyance and sleep disturbance – that can be classified under 'quality of life' rather than illness (Stansfeld and Matheson, 2003). What these effects lack in severity is made up for in numbers of people affected, as these responses are very widespread, and the chronic nature of exposure.

3.3. Absence of green space as a restorative environment

Figure 8. Environmental impact scheme: absence of a restorative environment

Since the beginning of the 21st century, a new research field has been set up, concerning the relation between the availability of green space in a neighborhood, associations with several health outcomes and the restorative effect as the mechanism behind. In this point of view, green space has to been seen as "open, undeveloped land with natural vegetation", including parks, forests, playing fields, and river corridors (Mitchell and Popham, 2008).

Today, evidence has been found for a positive relation between the amount of green space in the neighborhood and *self-perceived health* (de Vries et al., 2003; Maas et al., 2006; Mitchell and Popham, 2007; Sugiyama et al., 2008), a measure that

coincides very good with actual health and well-being (Jylhä, 2009). In these studies the relations are usually stronger for people with a lower social-economic status, and for youth and elderly. Further these studies suggest that quality of green spaces also plays an important role (Mitchell and Popham, 2007).
A recent study of Maas et al. (2009) showed that 15 of 24 assessed types of disease were less prevalent in living environments with more green space in a 1 km radius. The found relation between green space and physician-assessed morbidity was comparable with the relation between age and morbidity. The strongest association was found for *anxiety disorder and depression*, suggesting that mental health in particular might be affected by the amount of local green space. Also Nielsen and Hansen (2007) found a relation between access to green space around the dwelling and prevalence of *stress*.

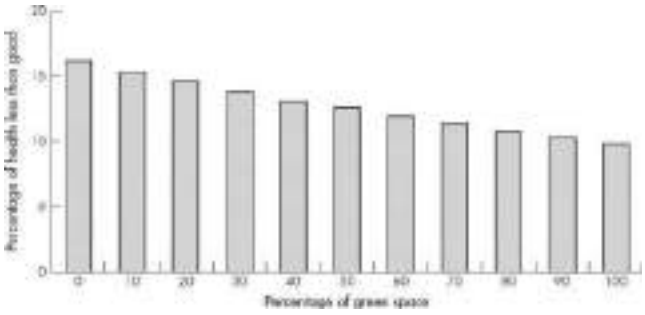

Figure 9. Relation between amount of green space (in a 3 km radius) and self-perceived health (Maas et al., 2006)

Further, the availability of green space seems to have a *moderating effect*. It was demonstrated that inequality in all-cause and circulatory mortality related to income deprivation is lower in populations who live in the greenest areas than in those who have less exposure to green space (Mitchell and Popham, 2008) and that the relationships of stressful life events with the number of health complaints, were significantly moderated by the amount of green space in the neighborhood (Wells and Evans, 2003; van den Berg et al., 2010). Other studies found a moderating effect of availability of green space on stress-related psychosocial symptoms from noise exposure (Gidlöf-Gunnarsson and Öhrström, 2007) and on the damage of traffic stress on individual's well-being (Song et al., 2007). These results support the notion that green space can provide a buffer against the negative health impacts of a lower social economic status, stressful life events or environmental stress factors.

Despite the growing amount of empirical evidence on the relation between availability of green space and human (mental) health, the way in which green space exerts a beneficial effect on health is uncertain. However, strong scientific evidence has been found for the positive effects of nature on recovery from stress and attention fatigue, the so-called Attention Restoration Theory (Kaplan and Kaplan, 1989; Verheij et al., 2008). Most of the evidence for the restorative effect comes from laboratory experiments that exposed participants to photographic simulations of various types of natural environments (van den Berg et al., 2003; van den Berg et al.,

2007), or controlled field studies that compared residents with natural elements in their view from the window to residents without such view (Kaplan, 2001). Several experimental studies have suggested that exposure to green spaces (either physical or visual) can also reduce blood pressure (Hartig et al., 2003; Pretty et al., 2005).

It can be concluded that the absence of green space in residential neighborhoods can have serious impacts on the health and especially the well-being of people. Probably the restorative quality of these small nature areas is the most important mechanism for this effect. Policy makers however tend to view green space more as a luxury good than as a basic necessity, and appear to overlook its potentially important effects on health and well-being (Groenewegen et al., 2006).

3.4. Lack of physical activity

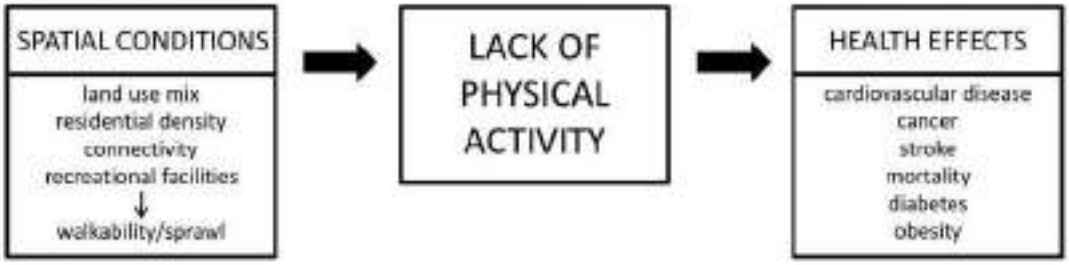

Figure 10. Environmental impact scheme: lack of physical activity

In recent years the relation between the built environment and physical activity has gained a lot of research interest. The idea is that low residential density, single-use zoning and low connectivity are associated with less walking and cycling (Frank, 2000; Frumkin, 2002).

Low levels of physical activity threaten health both directly and indirectly. The direct effects of a sedentary lifestyle consist of a higher risk on cardiovascular disease, stroke and all-cause mortality (e.g. Wannamethee et al., 1998; Sesso et al., 1999; Wannamethee and Shaper, 1999; Wei et al., 1999; Lee et al., 2000; Lee et al., 2003) and some cancers (e.g. Oliveria and Christos, 1997; Lee et al., 1999). Today, it is the second leading modifiable risk factor for chronic disease after smoking and it contributes significantly to total mortality in Western countries (Mathers et al., 2000).
In addition, lack of physical activity contributes significantly to the risk of being overweight, which in itself is a well-established risk factor for a number of diseases: heart disease, hypertension, stroke, osteoarthritis, gall bladder disease, some cancers and diabetes (e.g. Must et al., 1999; Mokdad et al., 2000). Also mortality is associated with obesity (e.g. Adams et al., 2006).
Obesity prevalence has risen steadily over the past decades. It is recognized as a major threat to public health, accounting for substantial disability and costs (e.g. Flegal et al., 2005; Olshansky et al., 2005; Caballero, 2007). Research has recently

expanded from a focus on individual determinants of obesity to investigating upstream influences in a social ecological model, including how the environment in which people live influences their lifestyle and weight. Of course, urban design does not fully account for increasingly sedentary lives, and physical inactivity does not tell the entire story of the epidemic of being overweight, but today there is a growing consensus on the environmental contribution to obesity (e.g. Hill et al., 2000; Frumkin, 2002).

Empirical research into the effects of the built environment on physical activity and obesity has increased dramatically in recent years (Day and Cardinal, 2007). Several recent review papers discuss the evidence to date (Saelens et al., 2003a; Booth et al., 2005; Duncan et al., 2005; Davison and Lawson, 2006; Kaczynski and Henderson, 2007; Papas et al., 2007; Wendel-Vos et al., 2007; Black and Macinko, 2008; Lee and Moudon, 2008; Feng et al., 2010; Renalds et al., 2010; Durand et al., 2011; Ding and Gebel, 2012). The concluding part of this subsection will go more deeply into the different measures that have been shown to be related to physical activity and obesity. The focus is on spatial characteristics that can be modified through urban policies and planning initiatives, not on simple design interventions.

Many reviews approve the relation between physical activity and the concept of *walkability* of a neighborhood, a measure mostly based on a combination of at least residential density, street connectivity and land use mix (Saelens et al., 2003b; Frank et al., 2007). A large amount of studies show that adults who live in walkable neighborhoods walk and cycle more for transportation and are more physically active (e.g. Takano et al., 2002; Berke et al., 2007; Frank et al., 2007; Handy et al., 2008; Lee and Moudon, 2008). Also the county *sprawl* index of Ewing et al. (2003), based on measures of low residential density and poor street accessibility, is related to physical activity, with residents of sprawling counties walking significantly less.
The variables used to form these two measures are also individually associated with physical activity levels. *Land use mix*, notably mixed commercial-residential land use, is associated with higher levels of physical (walking) activity (e.g. Doyle et al., 2006; Frank et al., 2006; Li et al., 2008). Also the related characteristic of proximity to retail stores and commercial establishments appears to increase physical activity levels (e.g. Berke et al., 2007; Nagel et al., 2008). Some studies confirm the association of *residential density* with physical activity, for example using measures based on population density (Frank et al., 2005) or compactness of urban settings (Frank et al., 2006). Also *connectivity* of the local transport network is associated with physical activity levels, with positive relations found for bike lane connectivity (Titze et al., 2008), intersection density (Frank et al., 2006) or size of neighborhood blocks (Wood et al., 2008).
Finally there is substantial evidence that proximity to a *variety of accessible recreational facilities* (such as parks, playgrounds, sports grounds, recreation areas) is associated with higher physical activity levels. The relation has been found for all ages (e.g. Giles-Corti and Donovan, 2002; Wendel-Vos et al., 2004) as well as for specific target groups like children (Roemmich et al., 2006), adolescents (Babey et al., 2008), and elderly (Kemperman and Timmerman, 2009).

Concerning obesity, in general the available reviews conclude that there is a lot of evidence available about a relation with the built environment, but much uncertainty about the specific associations. Given the large-range factors which affect weight status and potential time-lags between exposure and change in bodyweight, the lack of a strong association with weight outcomes found in cross-sectional studies is however unsurprising (Durand et al., 2011).
Based on the selected reviews obesity or increased body mass index can be linked to *walkability* (e.g. Frank et al., 2004; Frank et al., 2007; Rundle et al., 2008), *sprawl* (e.g. Kelly-Schwartz et al., 2004; Ewing et al., 2006; Joshu et al., 2008), *mixed land use* (e.g. Frank et al., 2004; Mobley et al., 2006; Bodea et al., 2008; Rundle et al., 2008), *population density* (e.g. Lopez-Zetina et al., 2006; Rundle et al., 2007; Stafford et al., 2007) and *access to recreational facilities* (e.g. Giles-Corti et al., 2003; Burdette and Whitaker, 2004).

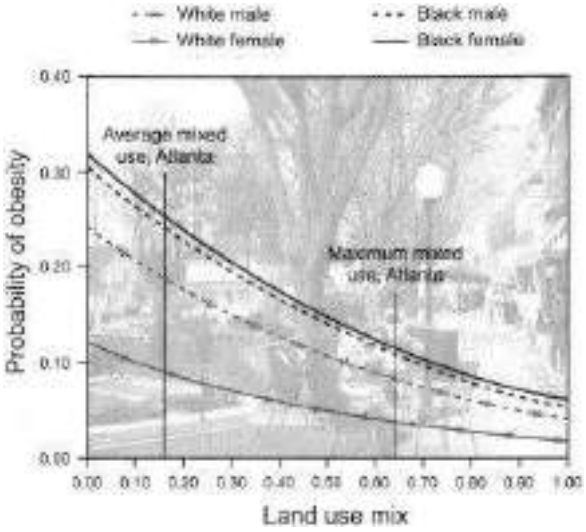

Figure 11. Probability of obesity in relation to land use mix, for different gender and race (Frank et al., 2004)

Although the importance of several urban design measures is evident, there is no agreement about which factors would be the most effective or efficient targets for intervention. It is however clear that (a combination) of the discussed measures can be used to support urban design choices and to evaluate neighborhood suitability for physical activity.

4. Discussion

Without having the ambition to give a complete overview of the state of the art knowledge, the exploratory literature study in this paper shows that the relation between urban planning and health definitely needs our attention. The health relevance of the four described impacts is founded by a considerable amount of empirical evidence, of which only a part is mentioned in this paper. Although no firm

conclusions can be provided on the quantification of these impacts, it is very likely that for each impact a comparable impact-effect relation exists, with higher negative impacts leading to more serious health and well-being consequences.
These four impacts are of high relevance for urban planning, because they can be acted on by urban planners and designers. The location of infrastructures like roads and railroads and the traffic intensity can have an effect on air pollution and noise, the planning of green space in cities can create restorative environments and increase the mental health and well-being of nearby residents, the residential density and mixed land use of neighborhoods can contribute to higher levels of physical activity. These examples show that it is important that the results from environmental research are incorporated in spatial planning policy and design. Despite planning concern for the 'quality of life', a conspicuous lack of integration of disciplines in relation to settlement planning remains (Barton, 2005). There is definitely a need for more collaboration between environmental scientists and urban planners and designers, in order to know more about which community design and land-use choices are most effective in improving the physical, mental and social well-being of people (Dannenberg et al., 2003).

The four discussed impacts create differences in health and well-being at a neighborhood scale and thus contribute greatly to environmental inequality. This supports the idea of implementing environmental justice as a generic rule in urban planning, based on the idea of well-being and living quality as a universal right for every citizen. In realizing this objective, interventions at the neighborhood level are needed, to come to equity at a city level. These spatial planning interventions can be very diverse. To influence the impacts of air pollution and noise, both measures to limit the emissions as measures to limit the exposure are possible. An example of the former is an urban transport policy aimed at lowering private car use in the city. An example of the latter is the avoidance of construction of certain buildings (schools, hospitals, houses) within a certain distance from major roads, by setting out setbacks (Hitchins et al., 2000). Some legislations (e.g. British Columbia Ministry of Environment, 2006) already implement such distance measures. To influence the impacts of absence of green space and absence of environments stimulating physical activity, interventions apply most to the urban design process. For example, urban designers can take care of the availability of green and the realization of a mixed residential and commercial land use in urban renewal processes.
It is however impossible to create a perfect living environment with the ideal conditions for human health. On the one hand, the spatial conditions of the four concerned impacts are often interfering with each other. For example, the higher the population density and mixed residential and commercial land use in a neighborhood, the more physically active people will be, but also the more people will complain about neighbor and activity noise, and vice versa (see Gauderman et al., 2007; Moudon, 2009). On the other hand, the financial means of cities and planning departments are usually restricted, making it necessary to make choices.

To support a health promoting planning policy, insight is needed in the effects of a combination of different impacts and in the amount of people that are positively or

negatively affected in their health and well-being by planning decisions. To the best of our knowledge, today no studies can be found where the combined effect of different impacts is assessed. Thus there is definitely need for a more integrative approach, in which different health impacts are combined into one framework, to make an integral assessment of environmental quality (The Health Council of the Netherlands, 2008).
The research project at hand, in which this paper forms a first step, can substantially contribute to this aim. The project wants to create a spatial geographical model (with GIS software) in which the different impacts with an effect on health and well-being can be presented layer by layer, and be combined in a final 'environmental health map' of an urban region. This model would start from the discerned impacts in this literature study and available quantification methods. If the modeling is successful, a tool will be available that can be used by spatial planners to evaluate the combined environmental quality of a spatial location. This tool would make it easier to understand spatial variations in environmental impacts and health effects and city planners may use it to better balance the health effects of spatial interventions. Also, this tool would make it possible to track the health of a community as it develops, and to suggest spatial interventions where the most people would benefit. In this way the tool can help urban planning in the pursuit of fulfilling the universal right of well-being and living quality for every citizen.

Housing Rights of Women in Former Socialist Countries in Eastern Europe.

An Analysis of Human Rights Discourses under ICESCR and CEDAW.

The well known metaphor "My home is my castle" describes with very simple words multifaceted humane needs associated with a home. A home keeps us grounded, gives us a place to live, allows us to feel safe and protected, embeds us in social networks and influences living conditions by empowerment and participation in political, economic, social, and cultural spheres of life. But what happens to a home in a country where housing reforms change the whole housing sector? The transformation of the socialist systems in the early 1990s has caused enormous impacts on national housing policies and housing rights as many research studies about the effects of transition show (for example in Struyk; Telgarsky 1991; Kingsley, Struyk 1992; Clapham et al. 1996; Weesep 1997).

The ten Eastern European States Bulgaria, Czech Republic, Hungary, Republic of Moldova, Poland, Romania, Russian Federation, Belarus, Slovakia, and Ukraine[1] have ratified human rights instruments providing the right to housing and commit themselves to report about the provision and fulfillment of housing periodically. The documents, called States Parties Reports, refer to the availability of housing, its quality and the accessibility to housing. The States Parties give an overview about the housing situation of their citizens, their housing policies and developments influencing housing in their countries like the economic and social changes in the 1990s.

Taken the findings from the former Special Rapporteur on Adequate Housing who is a key figure in the universal housing discourse, women still constitute one of the most disadvantaged subgroup of all vulnerable persons faced with the violation of their housing rights in many aspects (Kothari 2003, 2005 and 2006; see also UN Habitat 1999). In order to deal with restrictions and limitations of women's housing rights, he advertises to reflect the invisibility of specific constraints and vulnerabilities of women in relation to the right to housing and the access to housing (Kothari 2003: para. 21)[2], because "gender-neutral laws were interpreted and implemented in ways that discriminate and disadvantage women" by de facto discrimination (Kothari 2006: para. 9; see also Zetu 2010: p. 26). He also points out that the States Parties should provide access to housing for women in need as well as access to housing benefits in order to provide adequate housing (Kothari 2003: para 39-41). Further he is of the opinion that inadequate housing (conditions) like a lack of sanitation, water, electricity and inadequate building materials "affect women in particular", because they do mainly the reproduction work and spend more time at home than men (Kothari 2003: para. 25). From his studies he found that changes in the political, social, or economic system like the transformation and privatization in Eastern Europe has influence on women's housing situation:

"… privatization on women's access to housing and essential civic services such as water and sanitation, domestic violence, forced eviction, affirmative action and special measures for women." (Kothari 2003: para. 61).

Against this background it is not surprising that women's housing rights are an elementary part of the global housing discourse and have been on the agenda of the Commission on Human Rights as a key topic since 1997[3].

[1] The classification of those countries belonging to Eastern Europe is based on the classification of the UN region system.
[2] See also Moller Okin 1998 who argues about considering the needs and vulnerabilities of women in the human rights in general (Moller Okin 1998: 313-321).
[3] Recent relevant resolutions include 2000/13, 2001/34 and 2002/49 of the Commission on Human Rights; 1997/19, 1998/15 and 1999/15 of the Sub-Commission on the Promotion and Protection of Human Rights; and 42/1 of the Commission on the Status of Women

The existence of those States Parties Reports makes thus the analysis of those self-descriptions very attractive in order to reconstruct the position of women in the global housing discourse in these countries and helps – of course just to certain extend - to fill the blind spot of research analysis on women's housing rights in Eastern European Countries especially in the context of the transformation processes in the early 1990s.

Before presenting the results, I will explain why spatial planners are vicarious agents in the realization of human rights on the one hand and what is regarded as adequate housing on the global level on the other hand. Linking planners to human rights helps to understand why analyzing self-descriptions of those ten countries from a discourse analytical perspective is important for planners, too.

1. Housing Rights and Spatial Planners

Basic living conditions like housing, food, and water provide a minimum of livelihood and are elements of global human rights discourses as well as of local planning discourses. Planners as well as stakeholders in human rights discourses are engaged in developing policies and measures to provide housing. It is thus not surprising that spatial planners can be titled as vicarious agents in realizing human rights, although it can be assumed that they would not associate human rights with their work directly when for instance, they develop a legally binding land-use plan.

In order to find out if, and to what extend spatial planning with a focus on land policy plays a role in the human rights in general, the research project "*Socio-ecological Land Policy*" (principal investigator: Professor Dr. Benjamin Davy; TU Dortmund), funded by the DFG[4], was developed. It analyzes land policies, land as common and private property as well as the "spatiality of poverty and wealth" in the human rights in order to find out if a global understanding of a minimal access to land can be identified (Davy 2009, 2012: p. 170). Although the distribution of human rights is not equal to all humans and specific groups experience higher human rights' violations than others, the project does not focus on persons with special needs and interests. For that reason I will add this aspect by writing my doctoral thesis. The project of Professor Benjamin Day is part of FLOOR (Financial Assistance, Land Policy, and Global Social Rights), an interdisciplinary research group that examines social security as a human right from a spatial, legal and sociological perspective (principal investigators: Benjamin Davy, Ulrike Davy, Lutz Leisering; www.floorgroup.de).

[4] German Research Council (Deutsche Forschungsgemeinschaft)

2. Adequate Housing in ICESCR and CEDAW

In the universal human rights system two treaty bodies have been established which focus among other human rights specifically on the right to housing as being part of the adequate standard of living and adequate living conditions (Davy 2012). Whereas ICESCR[5] guarantees the right to housing, CEDAW[6] monitors the living conditions of women and promote women's rights like "... housing ..." (Art. 14 para. 2 [e], CEDAW). Both base on the UDHR[7] upon which the current system of human rights has been built.

The right to housing is not only related to the home as a building. Neither the language of ICESCR nor of CEDAW defines the meaning of "*adequate*" as a form of a consensus. For that reason the Committee on Economic, Social and Cultural Rights points out in its General Comment No. 4 that "adequate is partly determined by social, economic, cultural, climatic, ecological and other factors" which should be reflected as a complex construct in the descriptions of the national situation of housing and property rights in a member state (Committee on Economic, Social and Cultural Rights 1991: para. 8).

Housing rights as the committee argues imply some key issues which can be identified as minimal criteria or benchmarks for monitoring the adequacy of housing:

- a legal security of tenure,
- availability of services, materials, facilities and infrastructure,
- affordability of housing
- habitability
- accessibility
- location[8] and the
- cultural adequacy of homes

  (Committee on Economic, Social and Cultural Rights 1991: para. 8 [a-e]).

In addition to the General Comment, the States Parties should orientate their contents towards the reporting guidelines. These guidelines include specifications about housing related topics that should be integrated into the reports like (inter)national legal housing instruments and political measures to fully realization of housing rights. Knowing that external and/or internal factors have a positive or negative impact on

[5] International Covenant on Economic, Social and Cultural Rights, adopted on 16.12.1966 by General Assembly Resolution 2200 (XXI), 21st Session.
[6] Convention on the Elimination of All Forms of Discrimination Against Women, adopted on 18.12.1979 by General Assembly Resolution 34/180, 34th Session.
[7] Universal Declaration of Human Rights, adopted on 10.12.1948 by General Assembly Resolution 217 A (III), UN GAOR, 3rd Session.
[8] Location includes the distance to social infrastructure like schools, jobs, medical care or the provision of public transportation for example (Zetu 2010: p. 11-19).

housing rights and its effects on "disadvantaged and marginalized individuals and families" as the actual guidelines from 2009 postulate (Committee on Economic, Social and Cultural Rights 2009: para. 51 [b]), the States Parties also take such factors into account.

3. Women's Housing Situation in Former Socialist Countries – Selected Research Results

After explaining the relationship between spatial planners and human rights and the understanding of adequate housing, the following chapter provides information about women's housing rights described by former Socialist European Countries in the human rights instruments ICESCR and CEDAW. The data source consists of the States Parties Reports and Concluding Observations of the member States Bulgaria, Czech Republic, Hungary, Republic of Moldova, Poland, Romania, Russian Federation, Belarus, Slovakia, and Ukraine[9]. The States Parties Reports and the Concluding Observations (ICESCR) were collected and prepared by Professor Ulrike Davy and her team from the Chair of Constitutional and Comparative Law (University Bielefeld) in the context of FLOOR[10]. The data material of CEDAW was collected and prepared by Professor Benjamin Davy and his team from the Chair of Land Policy, Land Management, Municipal Geoinformation (TU Dortmund University). Following a discourse analytical approach of Reiner Keller (2008, 2011a, 2011b), this paper includes the self-descriptions of the member States of ICESCR and CEDAW and the reactions on those reports of the associated Committees. This leads to an analysis which topics are discussed and not on the global level. It reflects a need for further discussion and action, because the States Parties do not refer to all specific parameters of the guidelines and requirements for adequate housing. Referring to the statements of Kothari in the first section, I am analyzing the following selected aspects from a gender perspective in the context of the transformation processes in the 1990s[11]:

1. Legal equality of housing rights

[9] In the following passages of the article acronyms for the country names are used to facilitate the readability of the text: Bulgaria (BGR), Czech Republic (CZE), Hungary (HUN), Republic of Republic of Moldova (MVA), Poland (POL), Romania (ROU) Russian Federation (RUS), Belarus (BLR), Slovakia (SVK) and Ukraine (UKR). Although some States like RUS etc. had other country names before 1990, the actual ones that are used in the UN reporting system are applied instead of the old country names. In order to differ between reports from CEDAW or ICESCR, the reports under CEDAW get an asterisk behind the country name (for example HUN*2006 is the sixth periodic States Party Report submitted by Hungary under CEDAW).

[10] Thank you for sharing! Special thanks go to Luise Buschmann.

[11] The effects of Chernobyl and wars have not been considered, although both events have had enormous impacts on housing till today. Thus the article includes only selected aspects of the housing discourse in the context of human rights.

2. Women in selected national housing measures
3. Adequate housing

3.1. Legal Equality of Housing Rights

This section deals with housing related topics from a legal perspective found in the States Parties Reports and the Concluding Observations. From the analysis of the human rights' documents the following aspects play a role for the States Parties and both Committees referring to legal law:

- Provision of the right to housing
- Free choice of the residence
- Access and availability of housing benefits, bank loans, mortgages and other forms of financial credit

ICESCR provides the **right to housing** (Art.11.1, ICESCR); in contrary to the covenant, the States Parties under CEDAW argue describe potential discrimination in joy of this right under Article 14.2. All States promise to realize this goal for their citizens in general in both reporting systems (see table 1). Seven CEDAW member States[12] and four ICESCR member States[13] mention equal access to the right to housing especially for women in their reports (see table 1).

Table 1: States Parties Reports under ICESCR and CEDAW mention the right to housing

Topic	Right to housing (in general)		Right to housing (for women)

POL	X	X	X	X
ROU	X	X		
RUS	X	X		X
SVK	X	X		X
UKR	X	X		X

Source: States Parties Reports under ICESCR and CEDAW, author's analysis

[12] BLR*, CZE*, HUN*, POL*, RUS*, SVK*, UKR*
[13] CZE, HUN, POL, MVA

Following the self-descriptions legal law does not include restrictions for women (constitution, civil code, family code) or the language of national housing instruments implemented after 1990 like the cadastral register (BGR 1996: para. 7 [d]), housing programs like "Your own home" (RUS 2001: para. 293), or National Housing Funds (POL 1996: para. 426), and land/agrarian reforms (for example BGR* 1994: para.12 [e]; RUS* 1991: para 275 [g]; BGR 1996: para. 3; RUS 1995, para. 213). Although housing laws have been renewed or implemented like State Privatization Acts for example in the Ukraine since 1990, detailed information about the effects of those rights on the housing situation does not exist in general, as well as there is a lack of specific information on women's housing situation as the Committee on Economic, Social and Cultural Rights criticizes (UKR 1995 CO, para. 27)[14]. Only Russia explains in its fourth States Party Report under ICESCR that "violations of the housing laws have multiplied" since 1990 (RUS 2001: para. 43), without naming affected groups of persons. But it documents restrictions for their citizens in the housing sector as an effect of the transition:

> "A large proportion of cases concern the issuance of unlawful legal documents imposing restrictions on people's rights to receive housing or housing subsidies, housing privatization, and the housing of minors and of citizens unable to look after themselves." (RUS 2001: para. 43)

All member states of CEDAW admit women **to choose the residence and domicile** as Article 15.4 CEDAW demands. On the contrary, the language of ICESCR as well as the guidelines do not include such a request with the result that the States do not take the stand if women are allowed to decide where they want to live in the reporting system under ICESCR. If cultural norms or traditions exists that deprive women from their freedom of choice as the Special Rapporteur on Adequate Housing Kothari highlights (2006: para. 37f.) is not documented either in the reports of the convention or the covenant, nor being requested from by both committees.

The language of the Covenant on Economic, Social and Cultural Rights as well as the guidelines do not include a request to describe the **availability and accessibility of housing benefits, bank loans, mortgages and other forms of financial credit** as the Article 13 (a) and (b), CEDAW, does. For this reason only the States Parties Reports in the CEDAW reporting system can be consulted. Here, all ten countries agree in the equality approach of CEDAW that there are no gender based causes why women should be limited or restricted in getting financial support in order to realize their right to housing. If access to housing benefits is limited for women in reality

[14] The Concluding Observations are published by the Committees under CEDAW and ICESCR. In order to show to which States Party Report a Concluding Observations belongs, the Concluding Observations are titled as follows: UKR 1995 CO. This means the Concluding Observations belong to Ukraine and was published in 1995.After the country name of Concluding Observations published by the Committee on the Elimination of Discrimination against Women an asterisk is attached to differ between the Concluding Observations of both Committees.

cannot be inferred from the self-descriptions of the States, although the Committee complains 2010 about limited access to social benefits of housing for Roma women in the Ukraine (UKR* 2010 CO: para. 29).

The findings collected from the descriptions of the States and the Committees imply that women are not categorized as disadvantaged or discriminated by legal law. But that does not indicate that women are not faced with discrimination in the housing context from a legal perspective, because the Committees ask for more details in the descriptions of the States and further research on housing rights of women in order to assess the effects of gender neutral law. The existence of a lack of information about the effects of law on women's housing rights can be derived from the Concluding Observations of both Committees. General housing statistics are requested from five member States of ICESCR in order to get a better overview about the housing situation without a gender perspective[15]. Seven States should provide specific information about women's housing situation in the CEDAW reporting system[16]. The Committee on the Elimination of All Forms of Discrimination against Women advises to collect statistical data for specific situations which affect housing rights of women directly like general multiple forms of discrimination (BLR* 2011 CO: para. 41). It has also comments in its Concluding Observations to the Czech Republic that "domestic violence deprives from safe accommodation" and demanded thus the Czech Republic, but also the Russian Federation to provide measures against violence as well as statistics (CZE* 2002 CO: para 81; RUS* 2010 CO: para. 48). Although "serious changes in the national housing policies have occurred since 1990" as Bulgaria summarizes the transition effects (BGR 1996, para. 222), the States do not inform about restrictions or limitations on women based on the legal texts on the one hand. They also do not describe if they have taken specific needs and vulnerabilities of women in law into account.

3.2. Women in Selected National's Housing Measures

In order to realize adequate housing, living space must be available and accessible and should be provided for women, because on the global level it is common sense that women face discrimination in practice, even national legal frameworks provide equal access and availability to housing (Kothari 2003: para. 42-49). Thus this section deals with following housing aspects:

- Improvement of housing
- Housing construction
- Housing benefits

[15] HUN CO, POL CO, ROU CO, SVK CO and UKR CO
[16] BLR* CO, BGR* CO, CZE*CO, HUN* CO, MVA* CO, RUS* CO, UKR* CO

One aspect of the improvement of living conditions is the **improvement of housing** in general as six CEDAW member States[17] and nine ICESCR member States postulate[18]. For the States, this task is "one of the basic targets of economic and social policy" as Poland already explains in the 1980s for the other countries representatively (POL 1980: p. 18). Only few reasons for the improvement differ before and after the 1990s. Inadequate housing conditions play a role since the first reports in the late 1970s (see 3.3). Housing needs of young married couples or families (for example HUN 1985: para. 7; POL 1980: p. 19; ROU 1979: para. 20-21; UKR 1985: para. 17), housing needs of low-income families (POL 1986: para. 19 [a]; RUS 1980: p. 15), and unsatisfied housing demands (HUN 1985: para. 47) are listed before 1990. As a consequence of the changes in the housing sector since 1990, the States argue with ineffective housing distribution (BGR 1996: para. 216) and deteriorated basic structure of buildings (MDA 2003: para. 492) in order to legitimate the improvement of housing.

Seven member States of CEDAW[19] and four member States of ICESCR[20] point out housing improvement especially for women in their reports. Reasons are focused on women in need in cases of domestic violence (POL*2004: para. 104) or "for basic target groups like […], pregnant women, women with underage children…." (RUS* 2009: para. 16). Unemployment or lower wages are not listed as reasons for targeted housing improvement, although the States Parties describe in their reports under CEDAW[21] that the transformation processes cause instability and job problems especially for women like Moldova:

"The unstable social-economic situation in the country and the increase in unemployment and in the number of persons socially vulnerable affects the micro-climate of the family and women." (MDA* 1998: para. 63)

In the ICESCR reporting system only the Ukraine reveals the connection between the transformation process and the lack of women's jobs (UKR* 1991: para. 7). Neither under the covenant nor the convention, the member States do not connect negative effects in the economic sphere as well as the failing living conditions resulting from the reforms in the 1990s to the housing situation of women.

The **construction of housing**[22] is provided firstly in form of nationalized social housing or private housing offerings; secondly, citizens can receive financial subsi-

Housing construction for women has been established in Poland for women affected by domestic violence (POL* 2004: para. 104) as well as for "incomplete families" in Belarus (BLR* 2002: p. 56). The Czech Republic also organizes homes for mothers with children (CZE 1980: p. 10). Bulgaria and Ukraine provide shelters or housing help for victims of trafficking (BGR* 2011: para. 57; UKR* 2008: p. 37). For invalids like the "Heroine Mothers" in Belarus and women with children who do not overcome life damages housing is also provided (BLR* 1987: p. 21; CZE 2000: para. 423-424). Female refugees in Russia were resettled (RUS* 2009: para. 88). Hungary and Poland report about the provision of shelters for homeless women with children, housing help, mother-child homes, crisis homes and women's houses (HUN* 1995: para. 128; POL 1996: para. 286 (v); POL 2001: para. 259; POL 2007: para. 574-582), although most of the shelters in Poland were run by nongovernmental organizations (POL* 2004: para. 109). Housing construction was reduced in some countries before the collapse of the socialist system as Hungary 1985 explains. There, the

"…volume of state-financed housing constructed diminished and priority was given to the construction of dwellings in housing property held by citizens" (HUN 1985: para. 48).

Although privatization had existed before the transformation processes, it was seen as an option to improve the offering of living space after 1990. In how far this approach combined with political activities has helped to increase private housing property has been successful or implies housing problems, has been documented by the Republic of Moldova just picking up one example. It says that:

"…the home construction sector reached its highest point, but beginning in 1991 it has seen a continuous decline both in the public and private sectors. Construction decreased from 20,200 units in 1990 to 2,900 in 1999; many dwellings were left unfinished." (MVA 2003: para. 486)

For housing consumption – irrespective of being used for ownership or rent – **housing subsidies** are offered for different target groups with different needs in order to guarantee them economic access to housing for rent or ownership. Credits and housing benefits as well as long-term loans are granted by States for housing consumption especially to young married couples or families as target groups as seven States document in their ICESCR reports[25] (see table 3). Since the fundamental changes of the former socialist systems, credits for residence or mortgage credits have been developed as Russia 2009 for example informs (RUS* 2009: para. 19, 33). In how far similar credits, tax benefits or adequate benefits for rent for women have been introduced or further developed for other target groups rather families, are documented only in a few countries. The Russian Federation informs in its actual CEDAW report that single mothers are also allowed to get financial support (RUS* 2009: para. 404). In addition, in its combined sixth and seventh States Party Report submitted to CEDAW, the State bring up the extension of housing benefits for single parents in general (RUS* 2009: para. 89). In order to monitor this development, the Committee on the Elimination of Discrimination against Women asks for further information (RUS* 2010 CO: para. 42).

[25] BGR, CZE, HUN, POL, ROU, RUS and SVK

If the provision of housing benefits in general or housing benefits for women have been influenced by the transformation processes is only described by Bulgaria. Under the covenant it points out 1996, that a

- "discontinuation of States subsidies for housing",
- "a reduced solvency of the greater part of the population and a sharp rise in prices" as well as a
- "high interest rate on house loans" lead to great problems for its citizens."
  (BGR 1996: para. 222)

The existence of problems to get access to housing as a consequence of the transition can be assumed from the following statements, because the Committee on Economic, Social and Cultural Rights is

"**...** deeply concerned about the acute shortage of housing and the privatization of some public housing stocks which have resulted in a sharp rise in rents, forced evictions and homelessness." (CZE 2002 CO: para.19)

It also criticizes the Republic of Moldova because "… rising real estate prices have negatively affected the accessibility and affordability of housing …" (MVA 2003 CO: para. 23)

3.3. Adequate Housing

The Committee on Economic, Social and Cultural Rights published their global understanding of adequate housing in 1991. In this context three questions arise that should be embedded in the changes of the economic and social systems: First, which countries report about the lack of adequate housing; secondly which reasons are listed and third are women affected by that.

Only Poland uses the term of inadequate housing in its fourth periodic States Party Report from (POL 2001: para. 238); other terms are a substandard housing (POL 2001: para. 238) or inappropriate housing (CZE 2000: para. 419). But most of the States do not evaluate housing as inadequate, although the criteria for adequate housing are not fulfilled as the following example of the Russian Federation shows:

"Owing to the shortage of good-quality drinking water, the majority of rural areas are at risk of an epidemic. Many rural inhabitants use water from wells, rivers and natural reservoirs for cooking and other domestic purposes. Only 28 per cent of rural settlements have running water." (RUS 2001: para. 286)

Eight States under ICESCR[26] describe that shortcomings with the provision of adequate housing are mainly based on a lack of infrastructure (water supplies and sani-

[26] BLR, BGR, CZE, HUN, POL, MVA, RUS, UKR

tary conditions[27], electricity[28]). Other reasons are: illegal or inhabitable housing (HUN 2005: para. 416; MVA 2008: para. 624), and overcrowding (BGR 1999 CO: para. 18). Under the covenant, the States Parties do not explain if and how inadequate housing conditions influence women particularly. In contrast to ICESCR, all member States of CEDAW document a reduced adequacy of housing in general (see table 4). In those reports, too, infrastructural problems are identified as the primary cause for substandard housing. With the exception of Roma women in Hungary and the Czech Republic, women are not mentioned or specified as vulnerable or limited in the context of inadequate housing conditions. Hungary names unhygienic standards as a result of bad housing in this context (HUN* 2000: p. 10); both States correlate the appearance of diseases with bad housing (HUN* 2006: p.40; CZE* 2004: para. 258).

Source: States Parties Reports under ICESCR and CEDAW, author's analysis

The essence of the reports shows that problems referred to inadequate housing have been existing for a long period of time or are elements of the actual housing problems of the citizens in Eastern European Countries, although the States invest in collective water and utility and sanitation like Hungary after the reforms of 1990 (HUN 2005: para. 374).

In both reporting systems the States Parties do not express in how far the radical change of laws, privatization and changes of the economic system influence the pro-

[27] for example CZE 1980: p. 30; CZE 2000: para. 523; HUN 1984: para. 129; HUN 2005: para. 348; POL 1996: para. 402; RUS 2001: para. 277

[28] MVA 2008: para. 669; RUS 2001: para. 277

vision of adequate housing positively or negatively in their reports. But after those changes, the States Parties focus more on the seven criteria of the Committee on Economic, Social and Cultural Rights linked with adequate housing.

4. Conclusion

The analysis of the States Parties Reports with regard to women's housing rights expose two results. Firstly: the analysis of the self-descriptions of the States shows a lack of detailed information about women's housing rights in both human rights treaties, although the former Special Rapporteur on Adequate Housing highlights that women are faced with multiple discrimination in their housing rights and the guidelines recommend the States Parties to document the influence of housing measures and policies on their citizens as well as discrimination should be described under CEDAW. Secondly the analysis makes clear that the blind spot in scientific research referring to women's housing rights in the context of the collapse of the socialist system cannot be filled, but is a first step to illustrate the need for further analysis. Following Tsenkova and French, "gender inequalities in housing in Europe […] may not be as problematic compared to other regions of the world" (2011: p. 55), the reports and the Concluding Observations include some hints that the housing situation of women is influenced negatively by the radical changes in the 1990s.

All States document that housing laws and policies are gender-neutral and that women are not excluded from enjoying a free choice of residence or housing benefits, and other forms of financial measures to guarantee adequate housing. This neutrality, seen as progressive policy, in connection with a reappraisal of old gender stereotypes and the primary view on women as the Committee on the Elimination of Discrimination against Women have observed (RUS* 1995 CO: para. 530; BLR* 2000 CO: para. 361; POL* 1991 CO: para. 170), are potential causes for de facto discrimination and disadvantage following the argumentation of Kothari (2003, 2005, 2006). Gender-neutral law or gender-neutral housing policies do not prevent women from traditional or customary practices that restrict housing rights or the access to financial support of women (Kothari 2003: para. 21). Although this knowledge is part of the global housing discourse, the States did not seize the chance to take women's interests and vulnerabilities into account in the renewing of housing laws in order to harmonize national law and the global housing approaches.

Worldwide observations of Kothari also show that few women are able "to pursue claims for their rights against male relatives" in cases of divorce, inheritance or domestic violence (Kothari 2003: para. 44-45). Violence and unsafe accommodation plays a role in both reporting systems, because it can lead to eviction, homelessness and other forms of discrimination. Some States document that they improve housing

for women in need (see 3.2), but they do not describe whether the transformation processes have had influences on those offerings as well as they do not describe whether women are affected by eviction and thus unsafe or uninhabitable housing (Kothari 2006: para. 66-70). In how far housing help is implemented in national housing policies to abolish an existing lack of awareness of legal rights has not been reported. This is in the context of legal security of tenure important, because low income groups or persons "who are not able to buy or rent a formal house" are affected by that particularly (Zetu 2010: p.17).

The elaboration of gender-sensitive housing policies as Kothari 2006 requested has been established by providing housing for women in need (see 3.2), but not for women in unstable economic situations. Through the economic changes in those countries, especially women have been affected by unemployment, lower wages, and failing living conditions (see 3.2). This facts together with increasing rents, housing shortage, eviction, and homelessness as a consequence of the transition (see 3.2) implies that women's housing rights are affected by that, too. This is in so far speculative, because only few States Parties refer to negative effects like restrictions to the access to housing, housing subsidies, or housing privatization and do not name affected groups. In order to monitor this adoption, statistics and information are needed especially referring to the economic situation of women and access to housing.

A lack of information can also be identified in the descriptions of adequate housing. Only few criteria are mentioned like technical infrastructure and the affordability of housing. With exception of Roma women, effects of substandard living conditions on women or other groups are not mentioned, although most States inform about problems with inadequate housing. From the actuality of the findings can be concluded that it is still part of ongoing housing policies in those ten States. The connection between the transformation processes (including privatization) and its consequences for adequate housing-related aspects like the availability and accessibility of safe water, energy, sanitation etc. have had not been liaised from the States. Privatization and liberalization of those services lead to increased costs, bureaucratic barriers and finally to access limitations (Kothari 2005: p. 2). Thus detailed data should be collected in order to find out whether this global observation from Kothari can be transferred on the housing situation of women in these Eastern European Countries, too.

Till now many questions have not been answered yet; for instance the availability and accessibility of housing in the context of privatization, the development of a housing market, and not least the effects on property under a gender-sensitive perspective. Therefore we as spatial planners, as experts for adequate housing conditions, can resume the discussion of what is not mentioned in the reports and where

our experts’ opinion and survey is requested in order to focus more on people rather than places.

FROM RAPID URBANISATION TO RAPID VERTICAL GROWTH: PLANNING POLICIES IN LIMA, PERU

Ana María Fernández-Maldonado[1]

Abstract

Lima, the capital of Peru, is a city of more than 8 million residents which has the typical urban issues associated to rapid urbanisation: large areas of informal developments, and a clear socio-spatial divide between the 'formal' and 'informal' parts of the city. Planning has been unable to tackle the troubles of rural-urban migration. Recently, new housing policies have produced a housing boom and the densification of central (formal) areas. What has been the role of planning in these processes? Focusing on the link between local political processes, planning policies and their spatial implications in the city of Lima during the periods of rapid urbanisation and political-economic change, this study provides a first scan to spatial planning trends in the fifth largest Latin American metropolis.

1. Introduction

Planning and policies to tackle the effects of rapid urbanisation in cities of Latin America have been in many cases characterised by laissez-faire attitudes. Growth management issues have been generally neglected, in front of the urgent problems brought about by rapid urbanisation, such as housing and employment for thousands of newcomers to the city. This is also the case in Lima, the capital of Peru. The city expanded swiftly during a period of high demographic growth and industrial expansion (mid-1950s - late 1970s), in a process which transformed the country from an eminently rural into an eminently urban country in few decades. These processes gradually modified the city's structure into one characterized by a centre-periphery pattern, which at the same time represents a clear socio-spatial divide between the 'formal' and 'informal' parts of the city.

In the frame of large neo-liberal political and economic transformations, new housing policies have begun to deliver affordable new homes to middle and low-middle income groups since 2002. This process has worked as an economic catalyser and produced a remarkable construction boom in Lima and other large Peruvian cities. This, in combination with a huge housing demand and the lack of appropriate land for new expansions have led to a process of rapid vertical growth in central districts of Lima, in what may be seen as a process of 'return to the centre'.

What has been the role of planning in the above-mentioned processes? The objective of this paper is to explore the spatial implications of (national and local) planning policies in the city of Lima during the periods of rapid urbanisation and political-economic change. The main question refer to the roles of metropolitan development planning and of national housing policies on urban growth and sustainable

[1] Delft University of Technology, The Netherlands; a.m.fernandezmaldonado@tudelft.nl

development. To answer the question the study uses evidence from analysis of data gathered through local and international literature, legal document and regulations, internal reports, websites, articles in the media and qualitative interviews with local researchers.

To understand the main features of the planning context the following section positions Lima within the planning circumstances of Latin American cities. Section 3 pays attention to the role of growth management in metropolitan planning in Lima. Housing policies and their effects on city growth are the focus of section 4. The last section discusses the results and presents some preliminary conclusions.

2. Planning policies and horizontal expansion in Latin America

In 1900 Latin America one out of four inhabitants lived in urban centres of more than 2000 people, while at the end of the century three out of four were living in cities. This has made Latin America the most urbanised region of the developing world and the second highest after North America. In front of such an explosive rate of urbanisation, governments have been unable to regulate and guide land development, or to provide housing, employment, urban infrastructures and services for the huge amount of rural migrants settling in the cities. Migrants eventually managed to get land, housing and employment in informal ways, generally invading peripheral or unsuitable land and building vast squatter settlements. The results have been massive informal urban sprawl, together with growing urban poverty and informality. Spatially, the result was a "clear-cut spatial differentiation between the rich (city centre) and poor (urban periphery)" (Verkoren a al., 2009), in what has been called the polarized city (Borsdorf and Hidalgo, 2010). A great proportion of the self-built neighbourhoods that settles in the 1960s and 1970s – the period of faster expansion – has consolidated and has been provided of urban services and property titles, but the "informal city" continues growing in many cases.

During the 1990s, a new wave of horizontal expansion was observed (De Mattos, 2002). This time the spatial transformations have not been driven by demographic processes, but linked to the economic and cultural pressures coming from globalizing processes. The construction and improvement of motorways and rings in the periphery have greatly contributed to the expansion of the cities. The peripheries, which before were the exclusive domain of informal neighbourhoods, had a huge transformation due to the emergence of gated communities, and the construction of housing projects for the middle classes and social-housing projects for lower-income groups. Furthermore, a significant proportion of jobs and service activities also moved outwards, and shopping malls were built for different sectors of the population at the intersections of transport networks. New industrial areas also appeared in the periphery, some of them in the form of formal clusters, but also as informal production clusters (Verkoren et al., 2009). Figure 1 illustrates the schemes of the evolution of the Latin American city from the compact colonial city until the current fragmented agglomeration.

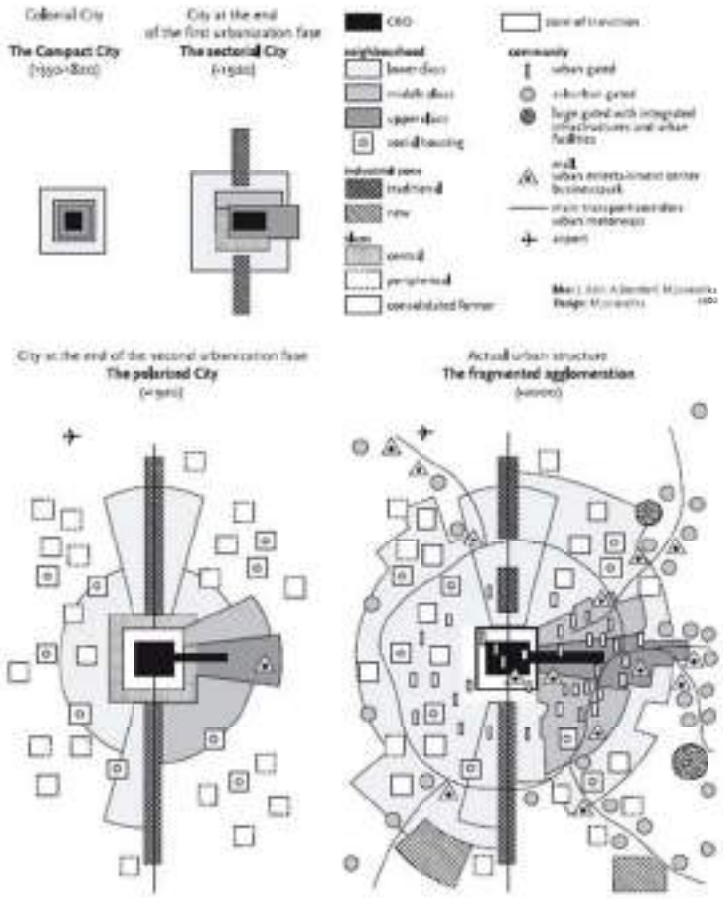

Figure 1. Evolution of the urban structure of the Latin American city (Source: Borsdorf and Hidalgo, 2010)

The last two waves of growth have meant a substantial horizontal expansion in the form of urban sprawl, which is basically the result of weak planning and development control rather than a deliberate strategy. This horizontal growth has brought about serious environmental and management problems: "the way that cities have grown by swallowing up neighbouring towns outside their jurisdiction has created difficulties in making decisions on investment and regulation. It has also caused tensions between mayors and governors who frequently compete with each other using tax incentives and other regulatory tools to shift business from one town to another. This destabilizes the long-term financial stability and governance of these large cities." (Cadena et al., 2011, p. 30).

In spite of the slower rates of growth, the fate of the Latin American cities far from easy. Latin American large cities are world known by their pressing problems: traffic congestion, housing shortages, air pollution, The lack of urban planning or deficient planning is frequently mentioned as one of their main problems. De Mattos (1987) mentions three issues of Latin American urban planning in the 1980s: economic reductionism, formalism and "utopian voluntarism", by which planners tended to set their own ideology above the one of the decision-makers. This resulted in an ineffective planning system, centralised in planning agencies isolated from

other public offices and agencies, and with a clear separation between plan elaboration and implementation. The state had the leading role formulating and implementing development plans. This traditional conception of planning was spread by the UN's Economic Commission for Latin America and the Caribbean (ECLAC) since the 1960s, which sent planning consultants to different countries of Latin America and run several schools and courses to educate planners.

Despite the lack of effectiveness, these traditional planning systems were perpetuated by local bureaucracies and educational and job training institutions. "The rational, technocratic planning model, master or comprehensive planning and zoning have been common approaches to planning in LAC that have not been adjusted much in decades, except for exceptional cases." (Irazábal, 2009: p. 52). Unsurprisingly, during the rapid urbanisation process of the second half of the 20th century, planners were unable to face the urban challenges, which eventually led to housing shortages, congestion, pollution, insecurity and socio-spatial segregation in the largest cities. "Urban planning in LAC has often been thwarted by changes in governing bodies, lack of constituency involvement, financial constraints, natural disasters and other challenges, resulting in failed implementation of plans." (Irazábal, 2009: p. 22).

Despite their reputation, Latin American cities have produced significant urban innovations that have been exported to other cities in the region but also to developed economies. Santiago's policy of housing through subsidies to the demand, Porto Alegre's participative budgeting, Bogota's process of civic renaissance and Curitiba's transit oriented development have proved to work successfully in other realities too.

To compare the overall planning performance of the eight largest Latin American cities against the McKinsey Institute elaborated a benchmark study – using a benchmark defined as the average of Helsinki, New York, Singapore, and Toronto – with four criteria: (1) economic performance; (2) social conditions; (3) sustainable resource use; and (4) finance and governance (Cadena et al., 2011). The report concludes that Latin American cities perform poorly against international benchmarks and that despite a reasonable economic performance, "… their institutional, social and environmental support structures have not kept up with their expanding populations." (see Figure 2). Lima is the worst-off of the eight cities evaluated in terms of overall planning performance, and the only one which is below the regional average in all four benchmark criteria.

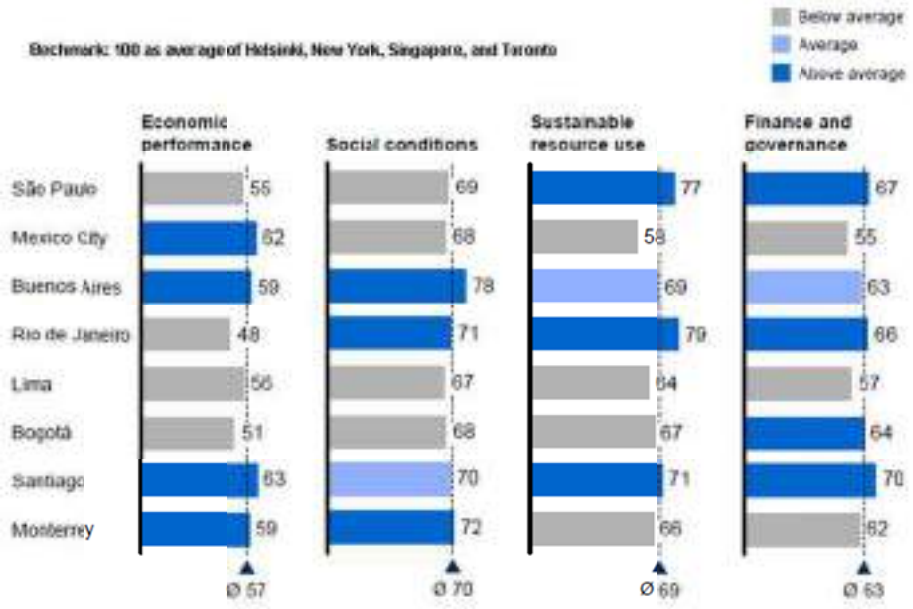

Figure 2. Performance of the eight top Latin American cities (Source: Cadena et al., 2011).

3. Metropolitan planning and urban expansion in Lima

Lima ranks well below the average of large Latin American cities in criteria related to land use, a conclusion that has been drawn after examining its below-average population density, its extremely low number square metres of green spaces per person, its severe housing shortage and the lack of land use policies for curtailing the environmental impacts of urban development (The Economist Intelligence Unit, 2010). This evaluation coincides with the empirical evidence gathered in Lima: the city does not have a well-established land use policy, and sectoral housing policies are not coordinated with the local government at both metropolitan and district level.

The most frequently mentioned metropolitan planning challenge in Lima is the huge fragmentation in terms of political decision-making, which leads to a management conundrum. Lima and its port, Callao are two different (provincial) municipalities conforming a vast conurbation, which in spite of their common problems have not managed to coordinate plans for the development of their shared metropolitan area. Lima has 42 district administrations, plus one for the province, while Callao has 8 more districts and one provincial administration which in total make up for 51 government bodies. "… the (district) government is quite absurd: 42 pieces of a puzzle that no one knows how to assemble and that do not mean much. Districts mean very little, no one knows what the members of the council do, they do not represent tangible territories, and their competences and responsibilities are completely lost in space." (Interview to Augusto Ortiz de Zevallos in Paredes, 2006, p. 64).

Besides, there is a prevalent confusion in the identification of the competences at every level of government (national, regional and local), evident in important urban sectors as transport and housing (García, 2009), whose policies and regulations have

a great impact in the spatial expansion and functioning of the city. What finally occurs is that the national level takes the lead and implements sectoral policies and programmes without consulting the lower government levels. For example, "the Ministry of Housing has exercised pressure on local governments to allow many building permits for projects subsidised by the Mivivienda Fund, without the existence of previous studies or even against the same municipality's urban plans." (Riofrío, 2010a, p.76).

Riofrío (2010a) comments that there is a tradition of presidents that act as mayors of Lima that dates back to the 19th century and is explained by the Peruvian centralism. But the imposition of national decision-making over city plans worsened since 1990. "In Lima, for instance, it can be argued that the city's fate has been primarily led by national policies, following the alienation of the municipal districts' autonomy by the Fujimori administration in 1990. While the districts regained their autonomy after Alejandro Toledo's election in 2001, the ten previous years of uncoordinated spatial policies and nonexistent metropolitan agenda have frustrated urban planning and become engraved onto the city's territorial organization." (Crot, 2006, p.244).

As in many other Latin American cities, the Peruvian planning system is very formalistic and normative, and exhibits high implementation problems. Local governments pass many legal norms, ordinances and strict building codes, but there is very little concrete results of the achievement of the proposed aims and objectives (García, 2009). City authorities do not have enough capacity to control the observance of the local regulations. Ploger (2010) provides an example of this, describing the case of ordinance 690, passed by the metropolitan council in 2004 to respond to the Peruvian ombudsman's requests regarding the spread of gates and barriers obstructing the free access to public streets in Lima, that emerged during the 1990s. "The ordinance has however been implemented very slowly by the district authorities. Only a few consolidated districts have made serious efforts to enforce the legal guidelines, while the informal status quo persists elsewhere."(Ploger, 2010, p.42).

These problems are associated to the institutional weakness and the features of planning in the Peruvian context. The former has been abundantly debated at local level and is widely considered as the product of an incomplete process of nation building. A World Bank report (2001) that deals with the institutional roots of poor governance in Peru mentions, among other issues, the institutional disorder created by a confusing administrative structure that weakens transparency and accountability, incoherent policy-making, weak checks and balances on the central government, and even weaker checks and balances on the local government. These processes were deepened by "the progressive decomposition of Peruvian democratic institutions (occurred) between the presidential inauguration of Alberto Fujimori in July 1990 and the announcement of his leave on 16 September 2000." (Crot, 2002).

Admittedly, there have been great improvements in terms of institutional capacity since 2001, but many of these problems are still part of the local culture and as such are difficult to eradicate. The weaknesses and low legitimacy of Peruvian institutions help to explain important urban issues, such as the widespread process of informal

appropriation of peripheral land by lower-income groups, as well as the negligible influence of planning on guiding and regulating urban growth (Ploger, 2010).

The particularities of the local spatial planning culture is, as in most other Hispanic American countries, highly related to the Spanish tradition of spatial planning (the so-called Urbanism tradition). This has been characterised as having "a narrow scope in terms of methods of intervention through zoning instruments, design codes, building control and development projects… Private actions tend to dominate. There is recognition of the relationship between physical environmental change and wider societal objectives. The model has a strong bias to design and professional solutions with only limited mechanisms for citizen involvement and managing conflicts." (Duhr et al., 2010, p. 182). Because of this difference between aim and outcomes, it is considered an immature kind of spatial planning.

Another important challenge of planning Lima's future refers to the limitations of its public finances. Metropolitan Lima's annual metropolitan budget was about US$ 100 per inhabitant (in 2010), an amount which included with the budgets of the metropolitan and all local (district) governments. As a comparison, Medellin has five times and Bogotá ten times that amount per inhabitant. While in the two latter more than 80% of the budget is addressed to investments, in Lima, due to the huge administrative personnel of so many districts, the investment budget is only 30% of the total budget (Fernández-Dávila, 2010). Despite the reduced budget, mayors have been generally almost exclusively concerned with the realization of public works. The disregard of long term planning in favour of short term interventions is evidently linked to political opportunism, because mayors have generally tried to use the mayor's post as a trampoline to the presidency of the country. Concerns for strategies for future growth have been neglected, as many other important urban issues that do not clearly belong to the realm of the four year period of the mayor.

With these serious limitations, it becomes clear that the problems of spatial planning in Lima are not so much of a technical but of a political-administrative nature (Fernández-Dávila, 2010). A report assessing the economic losses due to the lack of urban planning in Peru (Sociedad de Urbanistas del Perú, 2011) states that only 3% of municipalities in Peru has a valid Urban Development Plan, and 30% of them have never elaborated one, even if it is mandated by law. "The few existing Urban Plans are not used by city authorities due to their excessive technicalities, or the weak appropriation of the plans by the local civil society" (Sociedad de Urbanistas del Perú, 2011, p. 3).

Even in the capital city there is no valid Metropolitan Plan for its development. The previous plan – the so-called PLAN MET – was elaborated at the end of the 1980s and was valid up to 2010. PLAN MET ended during the last mayor administration without minimally achieving its goals (García, 2009). Former mayor Luis Castaneda (2006-2011) focused his government almost exclusively on the construction of roads and transport works, some of which improved traffic flow, but since they were built in an uncoordinated with other sectors and local governments, they also produced many urban conflicts. His administration was hardly interested in local economic development or human development issues, up to the extent that knowing that the

Metropolitan Plan would expire in 2010, it made no provision to update it (DESCO, 2012).

This verifies that "The state – central government and municipalities alike – has in practice abandoned its role of planning and guiding urban expansion." (Ramírez Corzo and Riofrío, 2006, p.54). The absence of a sound regulatory framework for land use planning is more a rule than an exception in Latin American cities, as the examples of Buenos Aires (Crot, 2006) or Mexican cities (Azuela, 2002) have shown. What is singular in Lima, however, is the negligence of (former) city authorities toward metropolitan planning, as suggested by the absence of metropolitan planning to guide the overall urban development.

In November 2011, however, the new major has appointed a commission chaired by an expert in governance with the mission to elaborate a Participative Regional Development Plan for 2012-2025, which is expected to be ready in October 2012. It is being elaborated in consultation with different organisations of the civil society, which gather around topics in each of the main zones of Lima: Lima Centro, Lima Norte, Lima Sur, Lima Este and Callao. The consultations have already began. One of the ten thematic groups discusses Urban Growth, Housing and Urban Services. This group will work during six months to identify a shared and strategic vision for urban growth, housing and services by means of 56 Dialogue Meetings (Mesas de Diálogo) in districts, four inter-district events, surveys and focus groups (Municipalidad de Lima, 2012).

4. Housing policies and urban expansion in Lima

The expedition of the Peruvian Law of Marginal Settlements and Popular Neighbourhoods in February 1961 marked the beginning of the official housing policy to tackle the effects of rapid urbanisation in Peruvian cities. Recognizing the legal status of the expanding informal neighbourhoods at the periphery, it aimed at integrating them to the city by coupling physical upgrading and legal regularization processes. But the planned social housing projects were never implemented and the land reserved for them was delivered without basic services producing a massive horizontal and informal expansion of the city. The housing policy developed into a land delivery policy, which was carried out for 30 years until the available land was exhausted. In such way, informal land occupation became institutionalized as housing for the poor (Fernández-Maldonado, 2007).

This has produced an enormous strain in the internal structure and urban functioning of the city, in which socio-spatial segregation has become a typical feature. It has also produced a city of low density that is difficult to manage and extremely expensive to provide with adequate services. Currently, Lima has an estimated 300 inhab./ha^2, which is a low density compared with the average of 450 inhab./ha^2 of the 18 largest cities in Latin America (The Economist Intelligence Unit, 2010). Lima's huge horizontal expansion is illustrated in Figure 3 in the 1910-2000 period.

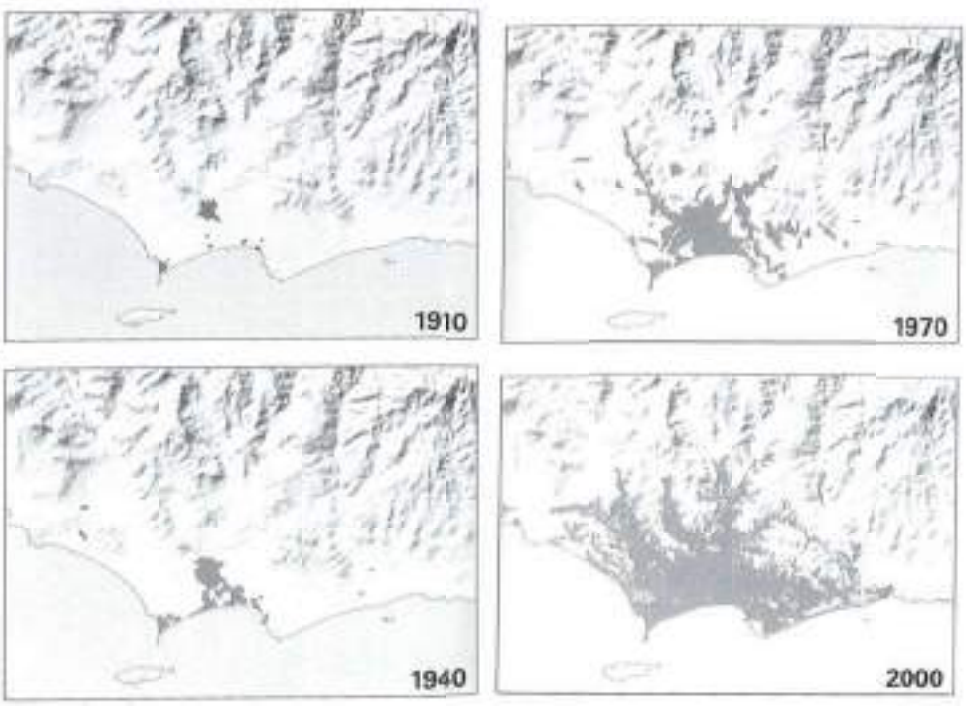

Figure 3. Evolution of Lima during the 20th century (Source: Hays-Mitchell and Godfrey, 2005)

As in other large Latin American cities, Lima's rate of growth diminished greatly after the 1970s, although in a lesser extent than in other countries. However, demographic processes have also led to a very high demand of housing, since there is a vast number of young people at the age of forming new households. This, mainly unsatisfied demand, has resulted in the continuous occupation of land in the outskirts.

The Peruvian housing sector was profoundly reformed in the 1990s in the frame of national political and economic transformations. The constitution of 1993 annulled the right to housing, while the government neglected planning and the housing sector and closed the Ministry of Housing, the National Planning Institute, the Central Mortgage Bank, the Housing Bank, and housing cooperatives. All this produced the stagnation of formal housing construction and the city continued growing only by the way of informal settlements.

After many years of crisis and recession, Peru's economy began to grow rapidly after 2001 and its average rate of growth (as percentage of the GDP) has been more than 4%, and since 2005, 2% more than the average of Latin American countries. Poverty rates began to decline moderately, and somewhat more rapidly during Garcia administration (2006-2011).

The housing sector underwent significant changes after 2002. Following recommendations of international agencies, new housing policies that began to be implemented during the Toledo administration (2001-2006). Housing programmes were initiated promoting housing through subsidies and easier access to credit. To implement the policies the government launched a National Housing Plan (PNV) for

2003-2007, establishing different programmes to promote the construction of affordable new homes for different socio-economic sectors. Direct housing subsidies were created – the Bono Familiar Habitacional (Housing Family Subsidy) – to support the demand of lower-income groups (Fernández-Maldonado & Bredenoord, 2010).

These processes – economic growth, clear housing policies and programmes, increased availability of credits, and available funds for subsidies – gave an unquestionable impulse to the housing construction activities, in the context of the contained demand. In turn, this contributed to the dynamism of the whole construction sector. The construction sector is now one of the pillars of the economy, whose growth increased the availability of public and private resources. A virtuous economic circle was created through the housing policies.

The number of new homes built through these policies is still low in relation to the huge housing deficit, and has mainly targeted middle-income groups (Fernández-Maldonado & Bredenoord, 2010). However, the process has produced a "rebound effect'' and become a catalyser of overall building activities, pushing downward the property prices and allowing the redirection of private construction capital to income segments previously considered unprofitable. Calderón (2009) mentions as main effects of these policies: (a) an increased housing supply; (b) the reduction of property prices; (c) the growth of mortgage market; and (d) the 'repopulation' of central Lima as an additional residential space of the middle class.

The housing construction boom has led to the densification of Lima's central areas, in view of the increasing scarcity of accessible urban land (see section 6). The subsidised housing projects were initially located in the traditional middle-class districts in central Lima. Later, the locations changed towards more peripheral areas or working-class central districts due to the higher costs of land. In front of the new housing possibilities, the traditional middle class has kept its preference for central areas while the emerging middle class stays in the periphery or ventures into older central areas, working class districts or even old industrial areas and military terrains (Fernández-Maldonado and Bredenoord, 2010). In a city with a horizontal pattern of urban growth – by the way of one-family houses in an own piece of land – these trends toward densification seem very auspicious. Instead of suburban homes, 98 per cent of new homes are apartments in central areas (Vera, 2009) and the need to lower the housing costs has made land consumption moderate. This change of preference towards multi-family housing is a step in the right direction for sustainability.

However, there are also heavy local criticisms to this housing policy. Some authors argue that this new housing policy was not designed to meet lower-income groups housing needs, but had a broader economic logic, as the core of an economic programme addressed to support the financial and construction sectors, which were still suffering from the 1998 economic crisis. Supporting the construction industry was considered a tool to reduce unemployment and to reactivate the local economy. The fact that the policy was designed in close consultation with the CONFIEP (Peruvian Federation of Entrepreneurs) and CAPECO (Peruvian Chamber of Construction), who represent the large construction firms, and not with the

metropolitan and local authorities, who have jurisdiction over the territory and have to deal with building and land use permits, gives a strong suggestion that it is indeed more and economic than a housing policy.

Through CONFIEP and CAPECO, the private sector made several demands to guarantee enough profitability for the construction sector, and lesser risks for the financial sector. In the need to activate the whole economy, many of these demands were met and building standards were relaxed to allow a reduction in the production costs of the new homes (Calderón, 2009) in 'acceptable' (central) areas of the city. The government also waived the payment of the General Sales Tax (VAT) for homes of up to US$ 30,000 (at the time around 18 percent) in 2001.

Data from the last two population censuses (2005 and 2007) confirm that the new social housing programmes have promoted the re-population of central areas, especially those of the traditional middle-class. In 2005, 15 of the 21 central districts of Lima had lost population, while the whole central area lost population in absolute terms. But in 2007 there was a recovery of the population loss in 13 districts. Thanks to the new projects, central districts of Modern Lima recovered 84% of its population. In contrast, working-class central districts had only recovered 22.5% of the previous losses (Calderón, 2009).

Local empirical studies of informal urban growth show that the trends have drastically changed in the last decades. Trends toward densification have also been observed in informal areas, and are the reason why local researchers highlight that Lima currently grows on the space that it already occupies (Riofrío, 2010b). The locations of recently-formed informal neighbourhoods are not any more flat lands or with a soft slope, but steep hills and dangerous places which will be almost impossible or too expensive to provide with urban services (Ramírez-Corzo and Riofrío, 2006).

The localisation of these recently-built areas can be seen in Figure 4, which illustrates Lima's growth evolution. The areas occupied by recent developments (2004-2010) are showed in dark red, and their location confirm what is argued in the empirical studies. Except from (formal) developments at the north part of Lima, most of them constitute piecemeal developments located uphill from the existing hills occupied by informal neighbourhoods. This shows that the recent trends toward densification of formal areas have not greatly modified the usual pattern of land consumption in Lima: the city keeps on expanding without control.

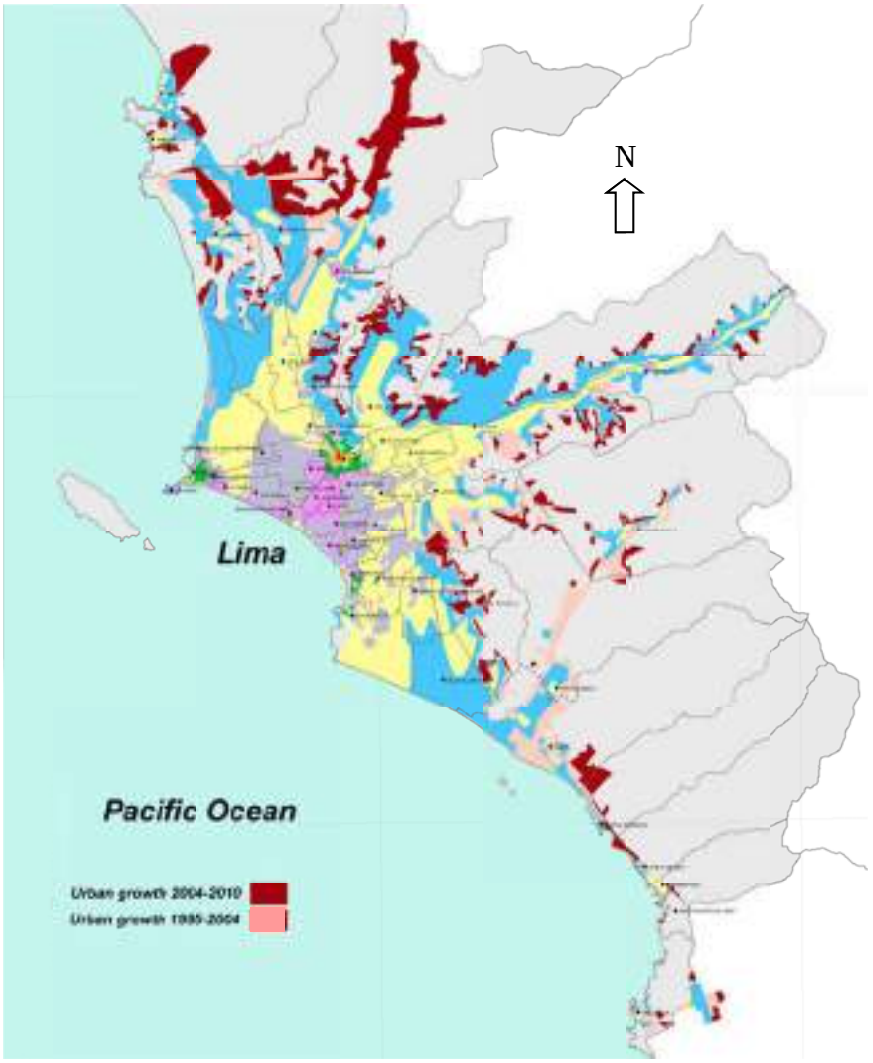

Figure 4. Urban evolution of Lima 1995-2010 (Source: Municipalidad de Lima, 2011)

The unplanned vertical expansion has produced an evident deficit of public spaces, which acquires a higher importance due to the higher densities and the smaller areas of the new homes (Riofrío, 2010a). Representatives of the professional association of architects have argued that, under the justification of supporting local investors, the state's approach to urban growth has been the deregulation of urban practices, instead of regulating and organising the densification process (Sota, 2011). Riofrío (2010a) comments that the housing policy constitutes a simple housing delivery scheme without attention to the surrounding urban space, without creating a city. Indeed, the exclusively commercial character and lack of urbanity of the new projects is widely discussed in the media by architects and urban professionals.

Since the densification of central areas has occurred without enough control from the local authorities, it is increasingly producing conflicts among the residents. Zoning and building codes are not always followed or are later arranged through fines or 'administrative silence', and developers build 12 storey building where there should

be 8, or plan less parking places than the norm (Sota, 2011), what increases congestion at street level. Better-off districts have been more efficient in controlling the densification process, modifying their regulations to demand stricter measures in criteria such as the number of parking places and square metres per apartment. But in general, the densification of central areas has developed according to the rules of a completely free market: the higher profits possible for the developers, without attention to issues of general welfare.

The housing boom resulting from the housing policies has produced a strong intensification of land use in central areas, but this process is not sustainable since 'the business of densification' is ending in central districts and the large construction firms have not found a way to extend it to low-income areas (Riofrío, 2010a), which are the ones who are more in need of affordable housing. Without solving this issue, there is no possibility of sustainable growth.

5. Results and Conclusion

The previous sections have examined how, as a result of the several limitations of the Peruvian planning system, the laissez-faire political attitudes toward urban growth seem to remain. The absence of regulatory framework for land use planning has produced a city that keeps on growing without control by means of informal land occupation. There has been a neglect of metropolitan planning since 1990, which has produced the absence of a long-term vision for the development of the metropolis and a clientelistic attitude to carry out opportunistic short-term projects to get fast political dividends.

The metropolitan government installed in 2011 seems eager to correct many of these serious troubles, but to reverse 20 years of nonexisting spatial planning seems an immense task. The participative character of the regional development plan in the making is an auspicious development and a step in the right direction, but it still has to pass the test of implementation.

In the absence of metropolitan growth policies, national housing policies have been traditionally the drivers of urban growth in Lima. Since 2003, Lima has experienced an acute intensification of real-estate led urban development that has rapidly densified its central districts. Remarkably, this process of 'return to the centre' has been the result of a sectoral policy without any links with the planning of the development of the whole city.

The unplanned horizontal growth has given way to unplanned vertical growth. The unregulated character of the densification process is bringing about serious conflicts and problems of urban space. The trends of social housing delivery – attending mainly the demand of middle income groups – suggest that it is, as local researchers claim, more an economic than a housing policy.

Lima has serious internal problems that demand proper attention: high housing demand, huge congestion and chaos in the roads, high levels of air pollution, lack of green areas, socio-spatial segregation, etc. But these problems should not be the reason to neglect growth management and other long-term issues. Lima is far behind

in terms of urban planning performance compared to other Latin American cities and has to do its homework to catch-up with them.

This first approach to the topic of spatial planning in Metropolitan Lima has found good ideas and stakeholders willing to improve Lima's urban situation. The fact that most stakeholders are demanding a more important role for spatial planning in Metropolitan Lima is a good step forward but, on the other hand, the fact that there is such a small body of research on the topic indicates a serious neglect to the subject for a long time. The good intentions will have to show an extraordinary ability to harmonise the different economic, environmental and socio-cultural assets of all important stakeholders involved in urban development for the sake of a more sustainable and inclusive city.

Making Sustainability Operational;

Coping with Contextual Circumstances

Umaporn Pupphachai, MSc.[1], Dr. Christian Zuidema[2]

Abstract

Sustainability became popular through Brundtland Commission's report published in 1987 and has subsequently been introduced as a key planning guideline in urban governance. To make the abstract and fuzzy notion of sustainability palpable, various governments are using a list of Sustainability Indicators (SIs). Common sets of Sis, for example those form the UN, help compare the sustainability of urban areas all over the world, whilst they inspire the development of national and local initiatives to measure and monitor sustainable performance. Using SIs should, however, not be isolated from the different geographical, socio-economic, political and institutional circumstances that exist in various towns and cities. Instead, in this paper we argue that for SIs to be well integrated in the local policy process, SIs should be adapted to different contextual circumstances. We discuss this argument based on a desk study of key policy documents and research reports on cases in four clearly different regions: the UK (London), China (Hong Kong), South Africa (Johannesburg) and Singapore. One the one hand, we will explain that sustainability is indeed defined differently in different contexts and, also, that it makes sense to do so as priorities and contextual circumstances do matter for integrating Sis in local governance. Hence, indicators should also be tailored to the existing policies and local policy priorities so as to function as a bridge between various disciplines both within urban governments and between governments and non-governmental stakeholders. Secondly though, we will also explain that improving the fit between SIs and existing policies and local policy priorities does not discard the importance of a common set of SIs. To avoid skewing definitions of sustainability to whatever 'fits' in a local context, we will argue that a common set of SIs can function as a benchmark for reflecting on existing sustainability plans and policies and, as such, inspire innovation. We will thus conclude that making sustainability operational is a two way process of using a common set of generic principles and of adapting them to local circumstances, which should be reflected in the design and use of SIs.

---

1. Introduction

At the beginning of the 21st century the world is faced with the tremendous challenge to pursue a transition towards sustainable development. It is a challenge that was brought to the forefront of the political and social debates by the 1987 Brundtland Commission. During the 1990s many governments on all levels of authority responded by starting to experiment with new policies and instruments to translate sustainable development ambitions into practical plans and programmes (e.g. Miller & De Roo 2000, O'Riordan & Voisey 1998, Selman 1996). Also at the local level, sustainable development gradually got cited as an ultimate urban planning tool (Briassoulis 1999). Nowadays, sustainable development is a common part of the policies and plans in towns and cities throughout the world. Nevertheless, sustainable development lacks a clear definition and no universal consensus has yet emerged upon how best to make sustainable development operational. Implementing sustainable development and translating it into policies that make a real impact on the ground is therefore still one of the main challenges of our time, also when it comes to urban planning.

One of the prime means used to both operationalize and measure sustainable development is the use of sustainability indicators (SIs). The importance of SIs for advancing sustainable development was already highlighted by the United Nations Conference on Environment and Development in 1992. Various governments all over the world subsequently started using SIs, showing that SIs could be very useful for quantifying change, for identifying problems and also, for providing governments with a framework for setting targets and monitoring performance. Many governments were inspired by the pioneering work of the United Nations. In 1995 the United Nations Commission on Sustainable Development presented a first draft framework of 134 common SIs, which after testing was eventually adopted in 2001 (UN 2001). Although the common set of indicators issued by the UN created awareness of the value and importance of SIs, it was also noted that we should not expect the emergence of a universal set of indicators that is equally applicable to all localities (e.g. Dhakal & Imura, 2003). Rather, the relevance of different SIs depends on the contextual circumstances, such as socio-economic, geographical, cultural and political circumstances and priorities. This is especially prompt when it comes to the use of SIs in a local realm, where unique local circumstances often have a major impact on both the causes and effects of the problems to address and on the policy objectives that are prioritized.

In this paper we address the role of SIs in assisting local governance for sustainable development. We begin by explaining why sustainable development is so hard to make operational and address how SIs might be of assistance in doing so. On the one hand, we will argue that SIs need to be well integrated in the local policy process and should be adapted to different contextual circumstances. On the other hand, we will also argue that improving the fit between SIs and existing policies and local policy priorities does not discard the importance of a common set of SIs. To avoid skewing definitions of sustainability to whatever 'fits' in a local context, we will argue that such a common set can function as a benchmark for reflecting on existing

sustainability plans and policies and, as such, inspire innovation. To support our argument, we conducted a research on the use of SIs in cases in four clearly different regions: the UK (London), China (Hong Kong), South Africa (Johannesburg) and Singapore. In this paper we report on the first phase of our research, which was largely explorative so as to assess whether cities indeed use SIs in accordance with our idea of a 'two way process', or, whether this might add value to the use of SIs in these cities. Hence, our study is mainly meant to be illustrative and to indicate whether subsequent research is needed to further substantiate our argument. We will report on the results in sections four and five, where we discuss whether and how SIs can help make sustainable development operational without causing undesired biases. The conclusions of our research are presented in section six, where we also explain how these conclusions can be used for improving the role of SIs as an appropriate tool for local authorities.

2. Delivering Sustainable Development

Sustainable development is a fairly recent concept that evolved during the past four to five decades. It largely emerged out of an ecological sustainability concern during the 1960s and 1970s (e.g. Baker 1997), such as revealed in the report 'Limits to Growth' by the 'Club of Rome' (Meadows et al. 1972). Gradually, this idea of ecological sustainability was confronted with ideas that some degree of economic growth and especially, social development is needed next to sound ecological and environmental management (e.g. Beder 2006). Eventually, sustainable development emerged as a compromise that seeks to combine three key objectives; i.e. economic growth, social welfare and environmental quality (also see Connely 2007, Jordan 2008).

Commitment to sustainable development gained momentum after the publication of the 1987 report 'Our Common Future' (Brundtland 1987), which defined sustainable development as "development, which meets the needs of the present without compromising the ability of future generations to meet their own needs" (1987; p. 43). Its rhetoric power became visible in the widespread use of sustainable development in policy documents on all levels of authority and in all regions of the world. Nevertheless, more than two decades since its rise as a general policy guideline, our current world society is arguably still far removed from a condition of sustainability. Rather, we face ongoing unsustainable trends in relation to for example climate change and energy use, environmental threats to public health, poverty and social exclusion, poor management of natural resources, biodiversity loss, etc. (for discussions see Global Footprint Network 2010). It is illustrative of the difficulties of putting sustainable development into practice. Indeed, popular initiatives such as Local Agenda 21 and the EU Sustainable Cities Campaign often only met limited successes (e.g. CEC 2004, EEB 2006).

Disappointing results in practice have led to criticism on sustainable development and, especially, its rather vague and abstract nature. In being a compromise,

sustainable development remains a fairly abstract concept. This abstract nature does make sustainable development an attractive concept as it is hard to 'oppose' to it. After all, in remaining rather abstract and vague, conflicts are avoided regarding the exact choices between economic, social and environmental interests and objectives (e.g. De Roo & Porter 2007, Mitlin & Satterthwaite 1996). Remaining abstract and vague can, however, also be regarded a drawback, which Richardson makes clear when he considers sustainable development "a political fudge: a convenient form of words, promoted, though not invented, by the Brundtland Commission, which is sufficiently vague to allow conflicting parties, factions and interests to adhere to it without losing credibility" (1997; 43). The abstract notion of sustainable development only covers a basic and mutually accepted 'core of understanding' (also Creedy & Zuidema 2012). Once this core gets taken apart, a whole array of different interests and interpretations gets uncovered (e.g. Campbell 1996, Connelly 2004, Richardson 1997, Rydin 1997). The result is that struggles emerge between parties concerning what sustainable development actually means..

2.1 Sensitivity to local conditions

Over the years, none of the many hundreds of attempts to redefine sustainable development have resulted in more operational clarity regarding how to put sustainable development to practice. Instead of searching for better or more detailed definitions, many authors nowadays suggest that sustainable development can best be given meaning in direct relation to its specific context (i.e. social, political, environmental etc.) in which the concept is discussed (also see Baker et al. 1997, Connely 2007). After all, as Selman explains, "the local 'patch' is the crucial arena in which progress towards sustainability must be made. It is where conflicts arise, attitudes are changed and actions are instigated" (Selman 1996; p.3). Consequently, Kemp et al. (2005; p.15) conclude that "what is most needed, appropriate and workable always depends heavily on the context. One could say that sustainability is about locally suited options that are globally sustainable. But it is also about local awareness and behavior that shares the larger agenda".

In response, Rydin explains that "the notion of top-down implementation of a sustainable development strategy at the urban level is inappropriate" (1997; 153). Instead she calls for debate on a local scale where interactive processes based on (following Lindblom) 'mutual adjustment' can result in linking sustainability to the "distinctive characteristics of the local area, (…) [and] the ambiguities of local policy to sustainable development" (1997; p.154). So instead of making sustainability more concrete through a more detailed definition (i.e. uncovering a 'second layer' of conflicting interpretations and interests), the concept gets more substance through connecting its abstract claims to the specific context (also see Healey 2007). It is based on the idea that "the social, economic and political contexts are very much local in nature" (Dhakal & Imura 2003; p.116). Clearly, then, this context is not just made up of specific spatial or environmental circumstances. It involves the local policy network, society and related objectives and interest as well. Discussing

sustainability in its local context therefore also involves the integration of different interests and objectives. Within government this can result in cooperation between different policy fields. This can, however, also involve deliberative processes in which both governmental and non-governmental bring their specific interests, knowledge and means to the table. As both these processes involve the typical local policy networks, the outcomes will ideally constitute solutions to local issues as well. In this they can be considered typically area-specific solutions to local problems.

2.2 Can indicators help?

While struggling to implement sustainable development, many academics and practitioners have put their hopes in the development of SIs to make sustainable development more tangible. The 1992 United Nations Conference on Environment and Development in Rio de Janeiro was the start of a worldwide effort to promote the use of SIs. In 1995, the Commission on Sustainable Development (CSD) was established, which meant to make SIs more accessible to decision-makers. This was further emphasized during the 2002 World Summit on Sustainable Development in Johannesburg, which showed that SIs had become key instruments for measuring and inspiring sustainable development policies at all levels of government from the international down to the local (The Pastille Consortium 2002)

As Rydin et al. (2003) also note, the early days of developing SIs was largely a 'technical' endeavour, focused on measuring aspects and degrees of sustainability. To some degree, it resembled efforts to (re)define sustainable development by identifying a set of criteria to be measured. As Rydin et al. (2003) discuss, this work largely failed to assess links between SIs and the actual process of planning and policy making. In response, later academic and practical work in SIs was more focused on integrating SIs with planning and policy making processes (also see Dhakal and Imura 2003, The Pastille Consortium 2002, and Shen et al. 2011). Often, SIs are meant to play a role in all stages of policy cycle, which include policy making, implementation, evaluation, learning and policy adjustment. SIs are then not meant to be a stand-alone policy effort, but instead, should be well connected to local policies. Indeed, the final report of the Pastille Consortium (2002) also indicates that "creating successful indicators relies far more on focusing on how they are integrated into the processes of urban governance and far less of devising, designing, and tuning particular indicator sets".

Integrating SIs with planning and policy making processes does have some important consequences. Rydin et al. (2003) identify three interrelated consequences of doing so that we will also address here. The first follows the idea that implementing sustainable development should be sensitive to local contextual circumstances. As Dhakal and Imura (2003) also show, SIs should therefore be related to their local contexts where they can developed and combined given the relevant local priorities and circumstances. Recent literature on SIs also clearly embraced the idea that SIs should be tailor-made to local contextual circumstances. Consequently, it is now

increasingly accepted that “there is no universal set of indicators equally applicable to all those places. Economic, social, natural and political situations, and the priorities/values based on these situations vary considerably from place to place, which would mean a common set of indicators would have difficulty in addressing the sustainability issues without many compromises in each place” (Dhakal and Imura 2003; 116). In response, indicators at local level have in more recent years also been designed to show the result of local action on sustainability issues (The Pastille Consortium, 2002). Increasingly, then, the local is the level where the application of sustainability indicators can be best appreciated and compared (Shen et al. 2011). After all, as Salvaris notes, “community indicators and benchmarks are necessarily context-specific” and hence, “need to derive their own indicators of progress to assist local decision-making” (2000; 7, also see Rogers and Ryan 2001).

The second consequence Rydin et al. (2003) identify is that integrating SIs with processes of planning and policy making, highlights the role of SIs in communication. If well designed, SIs has the potential to bridge gaps between laymen and experts, between community representatives and policy officers, between policy practitioner and technician, and between consultant and academic. Consequently, SIs becomes the instrument that can help to bring multiple actors and perspectives together. This cannot only expand the local capacity to govern, but it also shows how SIs can help to develop and adjust existing policies in a more collaborative process. This also directly brings us to the third consequence.

The third consequence that Rydin et al. (2003) identify is closely related to the first two. It follows the idea that an indicator is more than just measuring tool of sustainability. Instead, the process of devising and using indicators fuels and is based on debates and conflicts over what constitutes sustainable development. In other words, developing locally relevant SIs is a means to allow stakeholders with conflicting interpretations and interests to mutually ‘make sense’ of what they consider as sustainable development in their localities. In other words, developing SIs forces local actors to translate the abstract notion of sustainable development into locally meaningful indicators by respecting local issues and priorities and are influenced by multiple actors with their own interests and resources.

2.3 A two way process?

Linking SIs to the local process of policy making and planning highlights the importance of making SIs tailor made to local circumstances, including local stakeholders, their interests and perceptions and locally relevant issues and priorities. While this has important benefits for making sustainable development meaningful in different local contexts, it also holds a risk. After all, as Shen et al. (2011) show, each local practice has its own drivers and goals for developing indicators. Consequently, different local practices focus to a different degree on the dimensions they connect to sustainable development: environmental, economic, social and governance. It follows the idea that each town and city is different in terms of the

economic situation, geography, culture, social values, influencing its specific local policy priorities. The study of Dhakal and Imura (2003), for example, shows that developed countries tend to be more interested in the notion of the eco-city, a recycling based society, the reduction of consumption and the changing of life styles, while developing countries are still struggling with basic sanitary needs and public health issues. When taken into its extremes, biases in policies can be such that cities no longer focus on a balanced effort to promote economic development, social welfare and environmental quality, but instead, focus rather solely on only one or two of these. When adjusting SIs to local circumstances, there is thus a risk that they will merely reflect these different biases in monitoring performance and inspiring policy development and hence, reinforce the status quo.

We argue that SIs should be designed in such a way that they can help to reflect on existing local policies and prevent a strong bias to only one or two dimensions of sustainable development. To do so, we argue for a combination of using a set of common or generic SIs, often inspired top-down by for example the UN or national governments, and adjusting these to the local specific circumstances. It indeed allows for a process of 'mutual adjustment' between common or generic SIs and local circumstances. Ideally, this will be an ongoing and iterative process of constantly improving and expanding existing policies, inspired by a common set of indicators. SIs can now function as a benchmark for reflecting on existing sustainability plans and policies and, as such, inspire innovation and avoid the skewing of definitions of sustainability to whatever 'fits' in a local context.

In the next section we will continue by reflecting on four cases where SIs have been developed and used in the past decades. Our ambition is to first address the contents of the SIs used and to assess the kind of bias that exists in relation to different local circumstances. We will subsequently reflect on how SIs are integrated into policy process and will critically assess missing gaps in SIs and sustainable development policies in these localities. In doing so, we will explain how SIs are used to inspire improvements in sustainable development policies and, possibly, to highlight missing gaps in these policies.

3. Four cases

In selecting cities we looked at both cities that currently work with extensive SD plans and SIs, which are written and presented in English and have clearly different problems, priority issues and policy objectives. We therefore chose to select cities in different regions with quite serious differences in their geographical, political, social and economic backgrounds.

The first city is London, which is world-leading financial centre with the largest GDP in Europe. Key issues are social in nature. A rising number of high-income residents are contrasted by an also large group of low-income groups and unemployed residents (GLA, 2011). As a result, the incidence of poverty has increased and the polarization is associated with a range of social problems such

as ill health, substance abuse and crime. In addition, almost 30 percent of London's population belongs to a black, Asian or minority ethnic (BAME) groups that are typically among the least prosperous.

The next two cities are the Asian city-states of Hong Kong and Singapore. The problems that these cities have in common are an escalating overcrowding, scarcity of land, an intensification of land-use activities and the absence of raw materials and natural resources. Hong Kong was developed as a British colony and became a Special Administrative Region of the People's Republic of China (PRC) in 1997. Over 150 years of colonial rule caused a westernized society and a unique social-economic structure. The population in Hong Kong is mainly of Chinese origin, but their manners, behaviour, mentality, and even work attitude are different from the Mainlanders. Hong Kong balances a modernized way of life with traditional Chinese practices. In terms of economics, Hong Kong is one of the key financial centres of Asia, which is also associated with its rather open market and western-style society (HKPDR, 2007). Singapore has many similarities in also being highly urbanized and a key economic hub in Asia. Unlike Hong Kong that sets its goal to be an Asia's world city with good quality of life and wealthy economy, Singapore pays much attention to reserve environmental resources and calls their plan the 'Green Plan' (MEWR, 2006).

The last city is Johannesburg, a capital of South Africa where the low level of education and income inequality are major concerns. Johannesburg is one of the most progressive commercial cities on the African continent and attracts many migrants seeking economic opportunities, access to services, political safety and shelter (COJ, 2011). The city subsequently has becomes a multi-cultural city, with a rich diversity as the migration brings cultural, political and social plurality, both creating opportunities and challenges to an already-stretched resource pool.

Table 1: Key policy documents and their focus in the cities studied

	London (UK)	**Hong Kong (China)**	**Singapore**	**Johannesburg (South Africa)**
Area (sq.km.)	1,572	1,095	710	1,644
Population	7,825,200	6,900,000	5,183,700	3,888,180
Density per sq.km.	4,978	6,301	7,315	2,400
Program name	London Plan 2011; Spatial Development Strategy for Greater London, 2011	Hong Kong 2030; (HK2030 study)	Singapore Sustainable Blueprint (SSB)	Joburg(GDS) 2040; (Joburg 2040); The Johannesburg's Growth and Development Strategy 2040
Main actor	Greater London Authority GLA	Hong Kong Government	Inter-Ministerial Committee on Sustainable Development IMCSD	City of Johannesburg

Start Planning	1999	Start in 1997	Start in 2008 (Supersede the SGP2012 started in 1992)	2000
Launched Plan	1st edition in 2004 2nd edition in 2008 3rd edition in 2011	1st edition in 2005 2nd edition in 2007	1st edition in 2009	1st edition in 2006 2nd edition in 2011
Duration	20 years (2030)	30 years (2030)	20 years (2030)	30 years (2040)
Update monitoring	Annual	Annual	Annual	Annual
Vision	Making London the best big city in the world *from Mayor of London, Boris Johnson	Asia's world city	To make Singapore a livable and lively city state, one that Singaporeans love and are proud to call home	A World Class African City
Focus Area / Objectives	-Meets the challenges of economic and population growth -An internationally competitive and successful city -A city of diverse, strong, secure and accessible neighborhoods -A city that delights the senses -A city that becomes a world leader in improving the environment -A city where it is easy, safe and convenient for everyone to access jobs, opportunities and facilities	-The desired living environment -The national dimension -The changing economy -Population dynamics	-Improve resource efficiency in water, waste and energy, -Maintain a clean environment with good air quality, green and blue spaces -Effective public transport	-Eradicating poverty -Building and growing and inclusive economy -Building sustainable human settlements -Ensuring resource security and environmental sustainability -Achieving social inclusion through support and enablement -Promoting good governance

As our ambition was to address our cases so as to assess whether cities indeed use SIs in accordance with our idea of a 'two way process', or, whether this might add value to the use of SIs in these cities. Our study was therefore largely explorative and based on an extensive desk-study of key policy documents. It was focused on the use of strategic policy documents, documents conveying the choice of indicators and the ambition levels connected to them and, finally, the links between these (also see Table 1). In addition, our desk-study was supported by several academic studies closely linked to our interests (Dhakal and Imura 2003, Hezri 2004 and Shen et al. 2011). Our first question was to assess how these circumstances affected the use and development of SIs, which we will report on in section 4. Our second question was to assess whether SIs, possibly based on

existing common sets of SIs, function as a benchmark for reflecting on existing sustainability plans and policies and, while doing so, also stimulate policy innovation. We will address this question in section 5, where we thus reflect on the use of SIs in addressing missing gaps, both regarding the contents of the indicators and the existing governance capacity and instruments.

4. Local circumstances and the tailor-made Sis

4.1 Priorities and indicators

Differences in local circumstances are first of all reflected in different priority issues that cities identify. These priority issues have also influenced the choice and use of SIs, most notably in several specifically designed indicators that cities use. Examples can be found in all the cities studied. To begin with, the Greater London Authority uses two SIs that directly follow from the high degree of social inequality between different social groups in London. The first indicator refers to inequalities related to health and measures the inequalities in life expectancy between those living in the most and least deprived areas of London. The second indicator addresses whether London is successful in reducing the employment rate gap between both BAME groups and the white population. As such, it measures whether there are increased employment opportunities for those who are suffering from disadvantages in the employment market. A final example from London is the choice to measure 'fuel poverty', which is related to increase travelling by car from house to work and (LSDC, 2009).

Hong Kong is a good example of a city facing rather specific problems, fuelled by its physical geography, climate and extreme (population) density. The SARS epidemic in 2003 was the motive for Hong Kong to pay more attention to health-conscious living environment. This is reflected in indicators that measure the effects of development layout and building design on air circulation and pollutant dissipation. In addition, it specifically measures issues such as public satisfaction of the cleanliness, the living space per person. In the meantime, both Hong Kong and Singapore face a strong scarcity of land and the absence of raw materials and natural resources. This is also reflected in the cities policies and choice of SIs. Singapore designed policies to make optimum use of the available land and, more specifically, to increase green space per habitant and to increase greenery in high-rise building. It also focuses specifically on an intelligent use of energy and water. Each of these topics is directly reflected in its key indicators as these issues are given a high degree of priority. In Hong Kong, similar policies exist. It therefore also specifically measures the consumption of energy per unit of output and the percentage of population living in districts with a shortfall of open space and/or recreation facilities.

Policies in Johannesburg specifically focus on issues related to migration into the city, poverty, access to food and jobs and poor levels of public health and low life expectancy. Hence, their indicators indeed focus specifically on the existing poverty rate, HIV prevalence, social cohesion, levels of literacy and a food security and public safety index. Related to issues such as poverty and an increased population size, Johannesburg also prioritises economic growth. Currently, though, Johannesburg does face a strong, but also unequal economic growth. It therefore aims for a more resilient economy, which is reflected in specifically created indicators measuring whether the city has a job-intensive economic growth, sees a growth of the desired small businesses and an the increased competitiveness of its economy.

4.2 Bias or balance?

Differences in local circumstances are also reflected in the degree in which cities focus on the three main dimensions of sustainable development (economy, social, and environment). On the one hand, this can be seen when assessing the number of indicators that cities use on each of these dimensions. London clearly has a focus on social issues and environmental sustainability. Out of its 24 key performance indicators, only 3 address economic growth and development. Social issues are better represented, with 8 indicators, while most indicators (13) are focussed on environmental issues. In Hong Kong and Singapore a similar situation can be witnessed, as they focus mainly on environmental issues. Hong Kong has 21 out of 27 while Singapore has 41 from 46 environmental indicators and the rest of the indicators are on social issues. Johannesburg is clearly different; the three dimensions are almost equally taken into account. Out of 24 indicators, there are 5 in social, 6 economic, 9 environmental. Interestingly, the remaining 4 indicators are directly linked to measure the quality of its governance capacity.

On the other hand, the number of indicators on the three dimensions need not say much. It is also important to look at the ambitions levels reflected in these indicators; i.e. what is measured? In doing so, some important differences can again be witnessed. Good examples can be found when addressing environmental issues. London for example aims at encouraging the use of public transport and a decreased use of the private car. Johannesburg is not that far yet. It does aim for developing a mass transit system. In the meantime, it however also aims for eco-mobility (non-motorized transport such as walking, cycling and light electric vehicles), which is also directly measured. In term of natural resources, Singapore and Hong Kong concentrate on resource efficiency. Especially for Singapore, a lack of water resources is a main issues, reflected in indicators that show whether Singapore can ensure adequate water supply for future generations; e.g. by reducing water consumption. Additionally, Hong Kong focuses strongly on issues related to health and hygiene, while London tries to take things a few steps further by focusing on reducing its ecological footprint. When it comes to social issues,

the contrast between Johannesburg and London is again a striking example. Johannesburg focuses on issues such as food supply, literacy, HIV and on lifelong learning and increasing practical skills of its citizens. In London the focus is on increasing equality regarding health and job accessibility and on issues such as increasing new affordable homes.

5. Linking Sis to policy innovation

5.1 SIs in the local policy process

A strong integration of SIs into the local policy process has important benefits for both developing new policies and improving the existing set of SIs. First of all, it allows for improving existing policies or the development of new policies based on measuring degrees of success or failure by using SIs. Secondly, results from monitoring and measuring can also help to continuously update the set of SIs. They can be (re)calibrated to become more effective or efficient in measuring those aspects considered most relevant, while new indicators can be developed to measure the effects of new policies. Ideally, then, a progressive learning process can be created where SIs are constantly improved and help to fuel the development of new or more effective policies.

Our case studies indeed show how SIs are well linked to existing policies and, in doing so, help to fuel policy innovation. They are most telling in the cases of Hong Kong and London. In Hong Kong SIs are indeed explicitly designed to serve as a support-tool in the policy-making process. In the HK2030 study, Hong Kong used a so called sustainability assessment (SA), which is built upon eight guiding principles and a total of 42 indicators that align with the principles. It is supported by a computer-aided sustainability evaluation tool (CASET) that guides users to complete the SA process through a structured and step-by-step framework. The system comprises a set of baseline data for the indicators and supporting maps to assist users in the assessment process (SDU, 2006). The SDU is committed to keep the SA system and the CASET effective and up-to-date. For instance, the data updating in July 2005, they have taken the opportunity to add a new indicator on landscape value as recommended in Planning Department's consultancy study on 'Landscape Value Mapping of Hong Kong'. The indicators are now used to revise the existing policy and adjust the future one.

In London we also find examples where indicators are altered based on progressive learning. The London Annual Monitoring Report (AMR) shows several changes in the key performance indicators (KPIs) used in 2010 and 2011. The KPIs that are considered ineffective were ejected and a new set was developed. The link of the KPIs to the policy process is also made explicit, by the so-called London Development Database (LDD). It is a live system monitoring

planning permission and completion, which provides good quality and comprehensive data. It allows both the development and implementation of London's plans and policies in accordance to the KPIs.

5.2 Identifying gaps

Integrating SIs into the local policy process runs the risk of updating and improving policies and indictors in a process of mutual adjustment that further increases a bias into one or two of the dimensions of sustainable development. To prevent such a bias, we have argued for a mutual adjustment to occur also between local SIs and common sustainable development principles and indicators. Our study revealed that most cities gave no explicit means to do so, although especially Singapore and Hong Kong have implicitly done so.

To begin with, the Singapore Green Plan (SGP) was inspired by the result of a preliminary study commissioned by the World Economic Forum (WEF) in late 2000, which rated Singapore among the worst 10 in a ranking of the environmental sustainability of 122 countries. Its poor ranking on the World Economic Forum inspired the 2002 SGP to promote their vision on 'green and clean'. Consequently, the targets indicators in the SGP were mostly linked to the urban environment dimension, with some on social welfare and none on economic development. Links between these three main dimensions of sustainable development were therefore largely missing. More recently, Singapore has updated its plans and has issued Singapore Sustainable Blueprint (SSB). The SSB does try to link economic growth with pursuing a good living environment. Following the SBB, new indicators have been developed and also reflect the need to combine environmental quality with economic issues. For example, one of the key priorities is to improve resource efficiency, so the cost is reduced, helping economic growth in the long run.

Another good example is Hong Kong; the guiding principles of SUSDEV21 were based on its use of Local Agenda 21 policies. The Local Agenda 21 process was conducted in Hong Kong and highlighted that 13 of the 27 guiding principles were of high relevance for Hong Kong to address: i.e. economy, health and hygiene, natural resources, social, biodiversity, cultural vibrancy, environmental quality and mobility. These key principles have subsequently been translated into a set of performance indicators, taking the local contexts into account. In the meantime, the latest Hong Kong plan, the HK2030, has taken the recommendations of the Commission on Strategic Development into account, which was re-affirmed by the community through public consultations. It allowed for the development of the new future road map, focussed on three broad and interlocking planning directions: providing a quality of living environment, enhancing economic competitiveness and strengthening links with the mainland (HKPDR, 2007).

Finally, the example of Johannesburg also shows evidence of altering policies so as to prevent biases. The first GDS plan (Joburg 2030) was developed to stimulate economic growth and competitiveness. The main purpose was to compensate economic growth imperatives with a focus on pro-poor interventions, to reduce poverty. In the new Joburg 2040 plan, the main intention has been somewhat changed and now also focuses on the context of climate change and natural resources scarcity, which are also reflected in its use of SIs. Importantly, though, it seems that this innovation is less based on the existing set of SIs, but more on reflecting city policies by following the international sustainable development discourse.

6. Conclusion

In this paper we argued that SIs need to be well integrated in the local policy process and should be adapted to different contextual circumstances. In doing so, however, we also warned against creating a strong bias to only one or two dimensions of sustainable development. Our proposal was using a set of common or generic Sis and adjusting these to the local specific circumstances. It would then allow for a two way process of mutual adjustment between common or generic SIs and local circumstances. Ideally, SIs would inspire policy innovation and help to avoid the skewing of definitions of sustainability to whatever 'fits' in a local context. In this paper we reported on the first explorative phase of our research. It meant to assess whether cities use SIs in accordance with our idea of a 'two way process'.

Our first conclusion is that, in the cities studied, SIs are rather well integrated into the local policy process. They indeed help to inspire adjustments to existing policies and the development of new policies. In the meantime, SIs are also improved based upon newly emerging policy themes, changing local conditions and learning regarding how best to measure aspects considered relevant. Secondly, by well integrating them into local policy processes, SIs are indeed used to translate the 'fuzzy' and abstract notion of sustainable development into locally relevant policies.

Thirdly, however, evidence is less convincing is indicating that common sets of SIs can help to avoid a biased focus on sustainable development that simply 'fits' the local context. Our findings do show that policies are gradually adjusted so as to better reflect a balanced pursuit of economic, social and environmental objectives. Also, our findings suggest that SIs help to do so. Cities such as Singapore and Hong Kong have used common sets of SIs to inspire their own sets of indicators. Our findings are, however, not suggesting that such common sets of SIs function as a benchmark to continuously inspire policy development in accordance with the desired balanced pursuit. A real 'two way process' of combining common sustainable development principles and SIs with local developments of SIs to inspire new policy development was not found explicitly. Importantly, reflection of a city's SIs to common sets of SIs might also occur in a more informal way. This can for

example be done while developing or renewing existing sets of SIs, or by embedding this process of (re)development in the wider global sustainable development discourse. It is a question that would require further research, which explicitly addresses the process of developing and renewing SIs. It is indeed the focus of a second, and more elaborate, study into the role of SIs in urban governance we aim to conduct.

Concluding then, our findings suggest that SIs help to translate the 'fuzzy' and abstract notion of sustainable development into locally relevant policies. How such a process of translation might be improved by also reflecting back to common sets of sustainable development principles and of SIs is, however, a question we aim to pursue in more detail in the next phases of our research.

Paper for the 26th Annual AESOP Congress

Ankara, Turkey
July 11-15, 2012

Draft paper: not for citation or quotation without the permission of the author

Abstract

The activity and process of conservation-planning occurs at multiple spatial and governance scales. In the English context there is, on the one hand, the obligation to respond to an international infrastructure around the inscription and management of world heritage sites and, on the other, a deeply embedded sense of the passionate protection of local neighbourhoods by their communities.

This paper will seek to unpack the multi-scalar levels of English conservation-planning practice with reference to the theoretical formulation of "Authorised Heritage Discourse" (Smith, 2006). It will examine the various scales of practice and governance from the international (through the World Heritage Convention), through the national system of legislation, policy and regulation, the local state and the very local as represented by non-state civic action. The paper will start with a brief analysis of the historical evolution of conservation-planning practice and the important legacies this has for perceptions of the role of governance levels today. So for example, the development of national laws and policy, and the willingness of government to use them to override the local state, are often considered a pivotal part of the success of conservation-planning in becoming a central and important planning policy.

It will then focus on the contemporary planning context. British planning is currently dominated by an agenda of localism, introduced by the coalition Government through the Localism Act. This legislation ostensibly aims to shift power from central and local government to local communities. The planning provisions include, for example, various provisions on community-generated neighbourhood planning. When draft legislation was introduced the overall goals of the legislation were warmly welcomed by much of the heritage sector, but tempered by reference to the enduring importance of national systems of regulation. This new context will give a new dimension to the contestations and multi-scalar perspectives that frequently exist with urban conservation

The paper will explore these issues through two case studies. First, it will look at the fierce contestation that has occurred in recent years over development proposals in world heritage sites and the complex multi-scalar politics this has involved, with, for example, very local bodies seeking to mobilise international organisations due to their lack of faith in the local and national state. Second, it will look at the emerging localism agenda and the role conservation-planning is playing in some of the pilot areas for neighbourhood plans. How much weight is heritage given when plans are formulated in this way? Is there a danger heritage will be deprioritised in favour of economic development goals?

> ‘The locality where we belong…is the centre of reassurance (identifiable) more by the tenacity of its users than by its architecture: it may even be ugly, will generally be shabby, will invariably be overcrowded. British planners call it the “historic core”, note its tiny extent in relation to the built-up area as a whole, mark it a Conservation Area and hope for the best. Civic societies passionately defend its every cobblestone’ (Brett 1970: 142)
>
> ‘The Heritage Alliance welcomes the Coalition Government’s intention to shift the balance of policy-making more towards the communities who care about them…..
>
> We welcome the Coalition Government’s intention that there should be no lessening in the level of protection for national heritage assets….
>
> Although local interests are important and we do not underestimate the quality of expertise available in many communities, there is also significant knowledge and expert advice in our national civil society, outside central and local government (extracts from The Heritage Alliance consultation response to Localism Bill, 2010).

Introduction

British planning is currently dominated by an agenda of localism, introduced by the coalition Government through the Localism Act, 2011. This legislation ostensibly aims to shift power from central to local government and from local government to local communities. The planning provisions include, for example, various provisions on community-generated neighbourhood planning. At first sight this has strong positive resonations with the heritage sector. As the first quote above by Lionel Brett (Lord Esher) illustrates; deep within the identity of the heritage movement is a sense of heritage as something to be fought over and protected by local groups and local people in opposition to external forces, whether the state or capital. Surely the Localism Act, therefore, is to be warmly embraced; devolving powers and giving control to local people to define what is important about their place and ensure that those qualities are sustained.

However, as the second quote illustrates, it is not quite that simple. Here, *The Heritage Alliance*, an umbrella body for national extra-state heritage organisations, is reminding government that heritage is not just a local concern. National laws and national bodies are important too. In practice the British heritage protection system, and its administration, that has developed over the last century or more, and that in recent years has been so successful in limiting the destruction of protected heritage (Pendlebury, 2009), is in practice a complex “assemblage” (Pendlebury, 2012) that includes actants within and outside the state, at international, national, local and very local levels, underpinned by laws, regulations and policies, which again operate at a variety of spatial scales.

This paper will seek to unpack the multi-scalar levels of English conservation-planning practice. It will examine the various scales of practice and governance from the international (through the World Heritage Convention), through the national system of legislation, policy and regulation, the local state and the very local as represented by non-state civic action. The paper will start with a brief analysis of the historical evolution of conservation-planning practice and the important legacies this has had for perceptions of the role of governance levels today.

It will then focus on the contemporary planning context. The paper will explore this through two case studies. First, it will look at the fierce contestation that has occurred in recent years over development proposals in world heritage sites and the complex multi-scalar politics this has involved, with, for example, very local bodies seeking to mobilise international organisations due to their lack of faith in the local and national state. Second, it will look at the emerging localism agenda and the role conservation-planning is playing in one of the pilot areas for neighbourhood plans.

The evolution of conservation-planning

An important part of the identity of the British heritage movement is its evolution outside the state, as part of wider civil society, responding to, and opposing, changes to buildings and places. This history is generally traced to the nineteenth century. The seminal national figures are John Ruskin and William Morris, famous in particular for opposing the treatment ('restoration') of medieval churches and cathedrals and, in the case of Morris, for the formation of the first national amenity society for historic buildings, the Society for the Protection of Ancient Buildings in 1877, a body that is still very much with us today. In the same period local bodies were being formed that were the antecedents of the local civic movement, which perhaps reached its height in the 1970s, but again remains of huge significance today. So, what was arguably the first such local body was formed in Sidmouth in 1846 and then definite civic groups were formed in 1897 in the rather different and contrasting locales of the leafy and wealthy Surrey town of Guildford and the big industrial city of Glasgow.

The key part of conservation history I wish to briefly focus on in this paper, however, is the late 1960s and early 1970s. Throughout the course of the twentieth century the focus of conservationists had often been focused on achieving conservation goals through the development of a comprehensive planning system and securing conservation objectives as part of this. In principle this had been achieved with the post-war planning acts culminating in the 1947 Town and Country Planning Act., which contained provision for the "listing" of buildings. In practice, however, the conservation provisions were weak and tended to be marginal in the implementation of the system. As the post-war economy finally began to accelerate in the 1960s, and the amount of redevelopment grew apace, the consequences of this became very evident as even the relatively small numbers of buildings listed were being rapidly

lost. Opposition to such redevelopment grew. Ultimately one outcome of this was a significantly enhanced legislative framework for heritage protection, developed in the period 1967-1974 (and spanning two changes of government). The 1967 Amenities Act introduced conservation areas and the 1968 Town and Country Planning Act introduced systematic controls on listed buildings and legal rights of consultation on applications to demolish list buildings for a group of national amenity societies. Other legislation in the early 1970s stiffened the system further with, for example, the 1974 Town and Country Amenities Act extending demolition control to all conservation areas. Legislative change was accompanied by a welter of government guidance with, for example, Circular 61/68 introducing a presumption in favour of retaining listed buildings. This circular also introduced Conservation Area Advisory Committees - recognition of the lack of conservation expertise within local authorities and designed to connect to local amenity movements and give public voice into conservation-planning decision-making.

Thus one of the most important outcomes (perhaps ultimately the most important) of the mobilisation of opposition to redevelopment in the 1960s and 1970s was a much more robust system for protecting historic buildings, a new system for protecting historic areas and an acknowledgement of the importance and legitimacy of voices in decision-making, beyond the professionals (typically in local planning authorities) usually charged with such matters. Having achieved these goals, an important way to fight local development struggles was to use this legislative framework. Perhaps the emblematic case of this in the early 1970s was the Covent Garden area in central London. The possibilities for major development in the area became apparent with the decision in the mid-1960s to relocate the fruit and vegetable market, eventually executed in 1974. From its creation in 1965 the Greater London Council (GLC) formulated ambitious proposals for comprehensive redevelopment, involving demolition of two-thirds of the buildings in the area. In the early 1970s the heterogeneous communities of residents, small traders and so on in the area mobilised to oppose the GLC plan. What ultimately killed the GLC plan was the decision by central government to list 245 buildings in the area. Subsequently the Covent Garden Conservation Area was designated in 1972 and extended in 1974; the Seven Dials Conservation Area immediately to the north was also designated. The Action Plan of 1978 (GLC 1978) was of a very different character, encompassing a much more sensitive attitude to both place and process. The GLC had not been removed as planning authority, but was forced by a combination of local opposition and central government intervention (through use of heritage protection powers) to take a very different planning approach to the area.

Using Covent Garden as an example, we can begin to see the importance of scale in British conservation practice. Redevelopment was resisted by the very local groups of residents and businesses mobilising against the local state and succeeding in their aims by persuading the central government Minister to use his powers set out in national legislation. In terms of the evolving planning framework for Covent Garden, once the approach to its planning was reversed the local state (the GLC) became important is developing a new strategic future for the area through first using its

powers to designate conservation areas and with its subsequent Action Plan for the area.

Conservation-planning today: Urban World Heritage Sites

The 1972 World Heritage Convention introduced a further, international, scale to conservation-planning, most specifically in relation to World Heritage sites. This is particularly so with those WHS that are not *sites* as such; but are urban WHS that effectively cover significant parts of cities. The UK ratified the World Heritage Convention in 1984 and between 1986 and 1988 the first eleven cultural sites within the UK were inscribed. By 2011 there were twenty-three cultural or mixed WHS in the UK with a significant number of these being located within cities or are themselves a significant part of a city.

All WHS have a particularly complex set of governance arrangements and in the case of urban WHS this complexity is magnified. This has been evident in urban WHS such as Bath, Edinburgh and Liverpool. Until relatively recently, the booming economy and rising property market brought intense development pressures to each of these cities. Whilst different development cultures exist in the three cities – for example, between economically deprived Liverpool desperate for development, more affluent and conservative Bath and the political and financial capital Edinburgh - in each place there have been strong voices arguing for vigorous modernisation. In each of the three cities this has led to development schemes and proposals that have concerned UNESCO sufficiently to send missions to inspect on the ground.

In the case of Liverpool it was apparent at the time of the nomination in 2004 that extensive development was both anticipated and seen as desirable by the various UK authorities - within the site, its buffer zone and its wider setting. Concerned about the impact of this intended development, UNESCO imposed conditions relating to the height of new construction and expressed anxiety about development proposals at the symbolic heart of the site at Pier Head. The inscription of the WHS attracted the general support of the many agencies and government bodies involved in regenerating Liverpool, yet there has been concern within the business community that the tightly drawn boundaries are stifling investment. Conversely, some conservation bodies have been intensely critical with what they perceive as a poor track-record on maintaining historic buildings and a laissez-faire approach to development within the city (e.g. see Merseyside Civic Society website, http://www.liv.ac.uk/mcs/mcshome.html, Hradsky, 2009); a critique that has been mirrored in the local and national press (e.g. Hunt, 2008).

It is in this context that, following the World Heritage Committee's main annual meeting in 2006, a reactive monitoring mission was dispatched to the city in the October of that year. Reporting to the World Heritage Committee in mid-2007 the mission team indicated that they did not consider the integrity of the site to be under imminent danger but foresaw potential threats to the future functional and integrity

of the site (UNESCO-ICOMOS, 2007). They expressed concerns over developments on the waterfront and were also concerned that the 'world heritage perspective' has not been effectively communicated and 'sold' to local stakeholders. However, perhaps their most powerful conclusion was over the inadequacy of the planning framework for appraising development proposals. This led in due course to a new Supplementary Planning Document for the WHS (Liverpool City Council 2009).

More recently there was another reactive monitoring mission in November 2011. The desirability of this mission was noted at the World Heritage Committee in Paris earlier in 2011, followed by, as protocol requires, a letter of invitation from the UK government. The mission looked at the overall state of conservation of the site and was generally positive in its conclusions. However, the particular prompt for this mission was an enormous development proposal known as 'Liverpool Waters'. The Liverpool Waters scheme is a massive proposed development by the private UK developer, Peel Holdings. The mixed-use scheme (of offices, residential units and port infrastructure) comprises a redevelopment of the historic docklands north of the city centre, with significant consequences for altering the skyline and profile of the World Heritage site. Not surprisingly the proposal has been hugely contentious within the city and beyond. Separate heritage impact appraisals have been undertaken by Peel Holdings, Liverpool City Council and English Heritage (the statutory advisors to government on heritage matters). All reached a different conclusion. Perhaps not surprisingly the study by Peel concluding the scheme would not be detrimental to the 'outstanding universal value (OUV) of the site', whereas English Heritage have concluded that there would be a very serious impact on OUV. Liverpool City Council have been broadly supportive of the scheme and granted outline planning consent. The relevant central government department, the Department for Communities and Local Government are, at the time of writing, deciding whether to let that decision stand or to 'call-in' the application for determination at a public inquiry chaired by a central government-appointed planning inspector. The UNESCO mission concluded that the proposed Liverpool Waters scheme would irreversibly damage the WHS (UNESCO-ICOMOS, 2011)..

In reading the appendix to the monitoring mission report, the diversity of stakeholders who were involved in the visit is notable, with the three-person mission meeting with some 55 people in Liverpool. This included representatives from the national Department of Media, Culture and Sport and English Heritage, politicians and officers from the local authorities, developers and industry representatives (not just Peel Holdings), other bodies linked to the local state, such as the economic development-company Liverpool Vision and amenity bodies such as the Merseyside Civic Society.

This example gives some sense of the governance complexity in managing an urban WHS such as Liverpool. There is clear potential for conflict between the international regulatory bodies and local decision-makers. An added layer to this, demonstrated by the situation in the UK, is the role of national government. As the state party, the UK government is responsible not only for nominating sites but for

implementing the convention and reporting back to UNESCO. It has had to become, as a result, far more involved than is usual in local decision-making about particular development as a result of intense interest and pressure from UNESCO and ICOMOS and has therefore had to mediate between competing, and often hostile, interests. The level of complexity and difficulty in making meaningful decisions about conservation, management and development within this context results in friction between different scales of governance. In the UK this tends to mean powerful local interests pursuing pro-development strategies within the context of an often relatively weak regulatory regime. Weaker local conservation interests resist perceived threats to the integrity and authenticity of place, calling in UNESCO as an ally with their infrequently used, but politically powerfully, potential sanction to classify a site as 'in danger' or, in extremis, to remove sites from the list.

Conservation-planning today: Neighbourhood planning

The 2011 Localism Act in England is ostensibly intended to shift power in various spheres of activity "downwards", from the centre to a more local level. It is, in the words of the Government,

> "the Government's revolution to hand power back to local communities… Local people, businesses and councils are at the heart of communities and the Government is determined to put them back in control with the choices and chances to shape the future of their local area… wiping away unpopular bureaucratic interferences and cutting red tape that locked out communities, slowed progress and stifled innovation" (http://www.communities.gov.uk/news/corporate/2126182).

The Localism Act is not exclusively concerned with the planning system, but planning is a major focus in the legislation. Focus on the local has been accompanied by the stripping out of other layers of planning strategy, such as the abolition of regional planning policy. Amongst the various planning provisions the most eye-catching has been the provision for Neighbourhood Development Plans. These provisions effectively enable local neighbourhoods to assume the responsibility for statutory plan-making. The development of these powers raised many contentious issues. So, for example, and immediate question is who has the right to propose and prepare a plan? – an issue that cuts right to the heart of the difficulties of how we think about the nature of communities. Historically most rural areas are divided into "parishes" with parish councils, relating to the territory under the care of a particular church, but most urban areas do not have an equivalent and a variety of new groups will need to be evolved to undertake this work. It is also clear that, despite the localist rhetoric from the Government, there is a firm view that the purpose of neighbourhood planning should be to enable development, not to prevent it. This is not supposed to be a "NIMBY charter"; yet history suggests community mobilisation most frequently occurs in affluent areas seeking to safeguard the existing qualities of place. Linking these issues of representation and strategy together, one of the most

contentious elements of the Neighbourhood Development Plan provisions is the possibility this has created for plan-production to be a business-led process.

During the period that the legislation was being drafted and subject to consultation there was much anxiety in the conservation-planning sector about proposed clauses that would have allowed Neighbourhood Plans to effectively ignore some of national statutes on conservation; the quotes at the beginning of this paper from *The Heritage Alliance* were addressed to these concerns. The legislation that was ultimately introduced responded to these issues and Neighbourhood Plans are now expected to be in general conformity with a range of other plans and planning policy, including the recently introduced National Planning Policy Framework. Nevertheless, there is much interest in what Neighbourhood Plans will comprise of in practice and what the process will be to get there and, in relation to this paper, what implications this might have for the definition of, protection and management of the historic environment.

As a prelude to the introduction of the legislation the Government committed a modest amount of resource to supporting a number of pilot or "frontrunner" Neighbourhood Plans. There have been several waves of frontrunners and, at the time of writing, there is significantly in excess of 100 plans under development. One of the very first wave of 17 frontrunner plans was North Shield Fish Quay, an historic but somewhat run-down area close to the mouth of the River Tyne, with a mix of commercial and residential land-uses. Like many of the front runner proposals, the impetus for a community planning process did not arise out of a vacuum. A variety of community planning processes have in recent years preceded the rather more formal provisions of Neighbourhood Plans; such as, parish plans, village appraisals, Placecheck, Planning for Real and so on. Community planning processes started up in Fish Quay in 2002, linked to the evolution of conservation and regeneration plans for the area. Previous outcomes have included a community-generated conservation area character appraisal and a community design project. Thus when frontrunner projects were being sought, the combination of an active community engaged in processes of planning and regeneration and a market interest from developers made it an obvious candidate for frontrunner status. Fish Quay was proposed as a bid for frontrunner status by the local Mayor and this was met with cautious enthusiasm by the existing community partnership in the area and less reservedly by development interests.

Having been successful in the bidding process, the first difficult stage was the need to create a group with the locus to produce the Plan. As a non-parished area there is no Parish Council and the existing FISH community group was not considered to be constituted correctly to take on this role. The creation of a new group, the Fish Quay Heritage Partnership, was a difficult and contentious process and there has been a change in the dynamic of community representation in the area. So there is now, for example, a more overt business representation and a number of people from outside the area are an active part of the process – something allowed for under the legislation.

At the time of the writing the plan is around half-way through an 18 month plan production process, which will lead in due course to a local referendum on the plan proposals, and it is too early to be clear what the outcomes will be. However, discussions with the independent planning facilitator reveal some interesting trends in the way the plan is evolving. There seems to be significantly less focus on traditional conceptions of heritage and conservation-planning goals in developing the plan than in previous planning initiatives. Instead there is an increased emphasis on other concepts, such as amenity. So, for example, there is a site in the area currently empty of buildings but that has been up to now earmarked for development. Analysis of the historic morphology and the townscape has supported this as the "correct" approach. However, as part of the neighbourhood planning process different perspectives have arisen and greater stress placed upon the amenity of residents in a nearby building. This has led to this site being proposed as a "village green" and left as an open space in the area. Thus, whilst it is too early to come to clear conclusions about how the plan for Fish Quay may evolve, it seems as though the new neighbourhood planning process has created a different dynamic and interaction of interests in the area. One outcome of this might be a modified conception of place with different values given emphasis in its future management.

Discussion and Conclusion

The activity and process of conservation-planning occurs at multiple spatial and governance scales. In the English context there is, on the one hand, the obligation to respond to an international infrastructure around the inscription and management of world heritage sites and, on the other, a deeply embedded sense of the passionate protection of local neighbourhoods by their communities. One of the principal theoretical contributions to the study of heritage studies in recent years has been Laurajane Smith's concept of the Authorised Heritage Discourse (AHD) (Smith, 2006).

The AHD is considered a self-referential discourse that 'privileges monumentality and grand scale, innate artefact/ site significance tied to time depth, scientific/aesthetic expert judgement, social consensus and nation building' (p 11). The AHD can seek to control fundamental questions about why material objects from the past should be considered valuable and extend this to what in practice should be protected and to how that protection should take place, what constitutes acceptable conservation practice. Furthermore, critical to Smith's concept are the power relations it embodies, and the way that the AHD is used to close-down other possible heritages, or subaltern heritages and as such is seen as a regressive process, a point that subsequent writings by Smith (e.g. 2010) and others (e.g. Waterton, 2010, 2011) reinforce.

A simplistic reading of AHD might see the extension of planning powers to neighbourhoods through the Localism Act as a straightforwardly positive development. Such a reading would see the possibility of the wresting of the

hegemonic control over heritage definition and management away from the centre, away from experts, away from the state towards the local, and towards community and civil society. As such it would open up more inclusive, more diverse, more democratic readings of heritage and how these might be planned for. The neighbourhood plans could, from a heritage perspective, develop more holistic conceptions of place and place-value, with less emphasis placed upon locally applied expert-led judgements of national criteria. And indeed, this may be one outcome of the localism legislation.

Yet the examples in this paper illustrate some of the complexities and problems from taking such a straightforward interpretation. Specifically, we can see this around issues of scale. So, for example, the binaries of expert vs. community or state vs. civil society do not map easily on to issues of scale. Deep within the history of British conservation-planning are conflicts between national civil groups vs. the local state. National and local amenity bodies have consistently seen, and used, national legislation as a key element in achieving their aims. In the conflicts over World Heritage Sites we can see local amenity groups appealing to the expertise and authority of international expert organisations in their conflicts over their local place that is also freighted with WHS status.

I have previously written about how remarkably successful conservationists have been in moving conservation from the margins of planning objective. Conservation goals have been successfully positioned such that they have become a central and rarely challenged objective of modern British planning practice (Pendlebury, 2009). This achievement has been the result of a complex multi-scalar interaction encompassing local amenity groups, local authorities, national amenity bodies, national conservation agencies and governments of different political persuasions. Indeed, one of the mechanisms that has been important in creating and sustaining this position has been the creation of a powerful AHD, existing in competition not only with subaltern discourses of heritage but equally if not more so with other elite discourses over the future of place and specifically processes of capital accumulation.

It is too early to say how the Localism Act and Neighbourhood Development Plans impact upon this position. However, in bringing new “voices” to the process of place and heritage management new and unintended consequences may arise. We might see new, subaltern and more holistic conceptions of place and heritage structuring the discourse of planning, albeit in tension with conceptions of the historic environment held within the AHD across all spatial scales from the international to the very local. We might see subversions of the process; the status of locally valued places put under challenge by commercial or other interests directly through the plan-making process. Indeed, we may see both.

MEGACITIES AT NATURAL DISASTER RISK FOCUSING ON TRANSPORTATION ON LONDON AND ISTANBUL CASES

Funda Atun [1]

Abstract

The city is a composite of interrelated systems; each performing its own functions and each of them is strongly connected to one another. Therefore, the city can be defined as a complex system or a network in which human activities emerge from the interaction among multiple spatial, temporal, economic, social and organizational levels. When such a complex system is struck by a natural hazard, it turns into a disaster that creates serious human causality, economic and moral lost due to damages and discontinuity of functions. In this paper, London and Istanbul Megacities are introduced to reveal the advantages of complex systems and to solve the problems that lead to damage. The data gathered from various institutions, organizations and individuals are analysed to give a general framework about the situation in the case study areas in terms of identification of possible structural, functional and organizational failures.

This paper covers "disaster risk management", "complexity science" and "transportation system" research areas within a theoretical framework that enables the researcher to adopt a methodology to solve the critical problems of the transportation system in case of a natural disaster. Transportation system has been chosen as the core subject of this paper, because it is one of the sub-systems in a city, and it is broadly interdependent to other subsystems, such as water, gas, sewage, electricity, telecommunication, fuel supply, fire fighting. Moreover, transportation infrastructure often requires long repair times than other lifeline systems and having failures in the system could serve to stress pre-existing conditions of the entire city's vulnerability. Besides, it has long-term economic impacts because of long restoration times in comparison with the other lifelines. The hypothesis of this paper is that with an understanding of the complex nature of transportation system and interdependent character to its own components and to other subsystems a strong and sustainable transportation system could contribute the resilience of a city.

In particular this paper provides a way forward to handle the complex problems in a city system by focusing on transportation system on the one hand, and decisions and solutions taken by decision makers on the other hand. Thus, for engineers and urban planners the question is "what should be the methodology to solve the problems in the transportation system due to being hit by a disaster before its occurrence?" On the other hand, for decision makers, or governmental authorities, the questions of

[1] Politecnico di Milano, Milan, Italy – funda.atun@mail.polimi.it

"how to use the expert knowledge and implement it?" can be answered more easily by identifying the hidden connections in the system between vulnerable parts that affect the entire system.

Keywords: Disaster Risk Management, Transportation System, Flood Hazard, Earthquake Hazard

1. Introduction

Cities are not separated from their environment and having a problem in one of them could rapidly affect the other. Regarding to two specific examples London and Istanbul, these two cities are interconnected globally and an unexpected event in these cities could create a shock effect on the global financial market. However, their consequences could be different, as they are interconnected at different levels. For example, London is the main financial centre with Tokyo and New York. Having these three cities in three different time zones keeps financial market working 24 hours without stopping. An unexpected flooding in London could have global effects and aid could come from the all connections of London to recover the city and to keep it functioning. Besides, the economy of London is growing and they have enough resources to be used during emergency. As Istanbul is not interconnected as much as London, the aid would be less than the one offering to London, and due to competitiveness, if the recovery process takes long time, the city can be easily replaced with another developing city in the global arena. In the case of London, complex nature of the city could be an opportunity to recover immediately after a disaster, whereas in the Istanbul case complexity could lead to long term economic, structural, organizational and functional failures. So, the situation in these two cities clearly states that being complex could be either a problem or an advantage.

2. Problem definition

First of all, in case of a disaster cities stop operating as in normal conditions due to altering elements and interrupted connections among the layers, such as infrastructures and artefacts. Vulnerability analysis could help to indicate which elements are vulnerable to disasters and how they can be affected by hazards; however, how interaction affects the number of variables and consequently the number of dimensions cannot be foreseen clearly before its occurrence.

Chang and Nojima (2001) state that while much attention has been paid to understanding and predicting the performance of individual bridge structures under seismic loading, only recently researchers have begun to evaluate performance of the transportation system as a whole. There are studies focusing on the bridge damage modelling (Rojahn et al. 1997; Werner et al. 1997), the cost associated with travel times (Werner et al. 1997), network traffic flows (Werner et al. 1997; Nojima, 1997), transport cost and regional production losses (Shinozuka et al. 1998). However, the problem is that none of these studies deal with the disaster problem by considering

the relation of individual transportation problems (mainly structural) with regard to function and organization of the entire transportation system.
Secondly, one cannot be sure the reaction of humans, whether they follow orders and/or join the evacuation process properly. There are many examples to human failures. For instance, after occurrence of a hazard not shutting down the main gas valves by the operator immediately, and waiting for a while just to be sure, could lead to a big fire which would increase the death toll of the event. Moreover, not having an evacuation plan which responds to people's needs can be ended up with many failures. Furthermore, not forecasting the hazard in time could lead to un-sufficient warning lead-time, and this would be ended up with a huge traffic jam as it is seen in the Rita Hurricane.

3. Transportation system as the core subject

Transportation system has been chosen as the core subject of this paper. The reasons are:
• Transportation infrastructure often requires long repair times than other lifeline systems and having failures in the system could serve to stress pre-existing conditions of the entire city's vulnerability.
• It is one of the sub-systems of a city, and it is broadly interdependent to other subsystems, such as water, gas, sewerage, electricity, telecommunication, fuel supply, fire fighting, structurally and/or functionally (Figure 1).
• During an emergency the transportation system is one of the most important systems to keep the city system functioning and respond rapidly to emergencies. Any mistakes done on the transportation system or any other mistakes done on another subs-system affect the functions of the transportation system, and consequently could lead to increase the death toll.

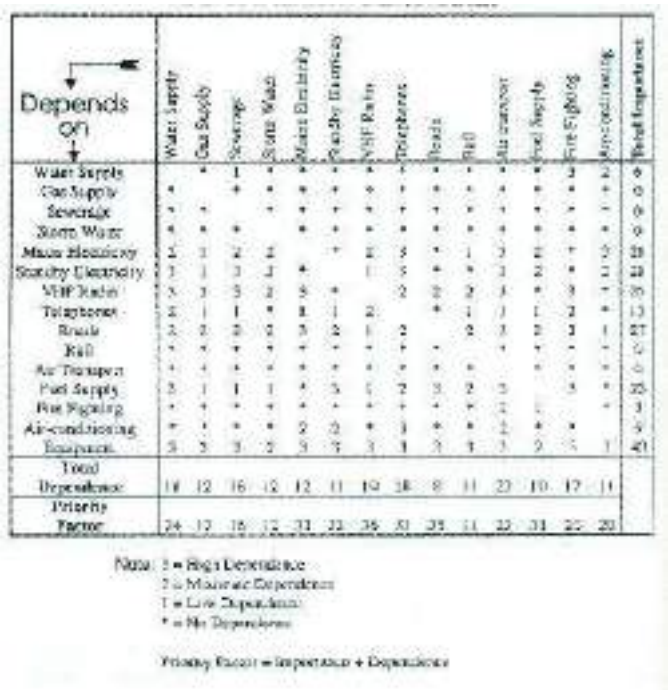

Figure 1. Interdependence matrix. Source: Paton and Johnston, 2006, p.62.

The transportation system is represented as a network of routes, railways linked by cars, trains etc. To connect the idea of networks with a study related with transportation system that is prone to natural hazards, the first step could be characterizing the structure of the transportation system, and understanding how it is spread. To be short how the transportation network works in its local and regional environment, responds to failures, and evolves depending on the needs should be understood clearly to find the short paths while improving it against natural disasters.

Last but not least, when humans are considered as one of the component, and may be the most leading one (Geoffrey West, talk in ECCS'11, 12-16 September, 2011), of a complex city system. Consequently, preparing "what if scenarios" could be the best way to deal with uncertain behaviour of human beings to simulate the actions and interactions of autonomous individual and collective entities.

4. Aim and objectives

The aim of this paper is to focus on the structural, functional and organizational connections among the elements as well as the elements itself. By achieving the defined aim this paper intends

- to consider transportation system as a whole within the entire city system by indicating nodes and edges
- to consider possible human behaviours

To have better understanding how a complex city system work and how agents react during an emergency and evacuation of people in case of an emergency, a "what if

scenario" is given as an example at the end of the paper by taking into account mega-cities, such as London and Istanbul.

5. London

Today London is ranked 28th in size by the year 2006 in the world's cities ranking. Although it is consisting of around 7.6 million population, it is not the world's largest city anymore. However, with its 300.000 employees inside the borders of the Greater London Authority, and 800.000 employees across these borders, London is one of the global centres for international banking and financial services by leading in foreign exchange turnover, trading of international bonds, trading overseas equities and fixing the gold prices. London precedes the other cities in all areas of competitiveness, and it is closely followed by New York and Tokyo in the world and by Paris, Frankfurt and Zurich in Europe (The Global Financial Centre Index, March 2009, p.7). By being one of the global centres, having an unexpected disaster could affect not only the city itself but also others that are strongly connected to London. On the other hand, increasing economy of London could help to recover and reconstruct the city in a short period. Rapid population growth, major economic transformation and rapidly changing urban environment are the three leading topics considered in mega cities.

Rapid Population Growth

After 80s by the changing economic policy, London attracted millions of population ones more in its history. As it's seen in Figure 2, London's population is increasing steadily since the late 80s and it is projected that the population increase would continue. As the industrialization has changed its shape and financial sector had gained importance more than manufacturing, the industrial and dock areas became vacant. The new coming population have settled in these old industrial new residential locations especially in the London Boroughs of Newham, Tower Hamlet, Lewisham and Southwark. For example, the population of Tower Hamlet was 140,000 in 1981, and this number has increased to 234,828 people in 2009. "The resident population of Greater London at mid-year 2009 was projected to be 7.75 million, an increase of 85,000 or 1.1% from 7.67 million in 2008. Between 2001 and 2009 London's population increased by 5.9% or more than 430,000 people" (Tfl, 2011, p.15).

Figure 2. Greater London Population, millions. Source: Tfl, 2011, p.127

Major Economic Transformation

Moreover, economic activities has transformed from manufacturing to business and financial services, construction, retail, tourism and leisure activities (Figure 3). The areas of the economic transformation overlap with the areas, which experienced the rapid population growth.

Rapidly changing urban environments

In a place where it has experienced population growth and changes on the major economic activity, it is inevitable to have major changes on the urban environment. Old docks transformed into residential buildings, commercial areas, governmental buildings and the City Airport.

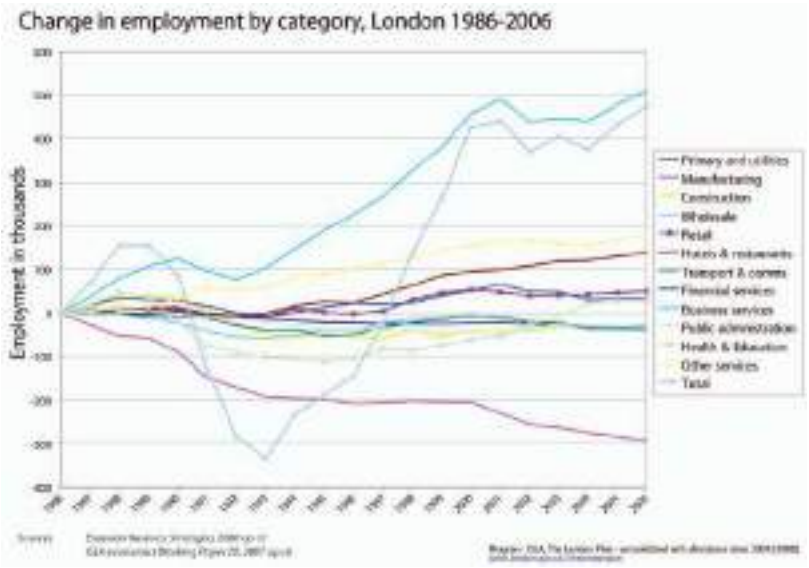

Figure 3. Change in employment by category

Source: GLA, 2007, cited in the London Plan, 2008, p.29

5.1 Changing flood hazard risk concept

Although flood hazard probability is changing due to climate change and sea level rise, the main reason of increasing flood risk in London is the *post-defence development* (Parker 1995, p.341) and increased ownership of goods and property in the floodplain (Parker et al. 1897; Green and Penning-Rowsell, 1989, cited in Parker 1995, p. 342). Consequently, the post-defence development after the construction of the Thames Barrier in the 80s, such as increasing number of population, buildings, companies and firms, and extended infrastructure in the floodplain, led to increase exposure to hazards. This means that there are more people living in the floodplain. Moreover, more businesses has been established and more infrastructure has been constructed in the area. However, not only direct damages but also indirect damages have increased due to increasing number of businesses, infrastructure and demand on traffic in the area (Parker, 1995, p.342). Having a low probability hazard could affect the area tremendously and lead to high consequences in terms of human causality and economic lost. As London is the heart of the finance and business in the UK, the effect of the economic lost in the area could be also financial.

The photo in Figure 4 was taken at the Thames Barrier. A part of the barrier is seen on the left side of the photo. On the right, there are the areas, which were developed by the construction of the barrier. The photo clearly shows the changing urban geography of London by the construction of the barrier.

Figure 4. Thames Barrier and Canary Wharf, Source: Author, August 2011

5.2 Existing risk of flooding in London

Approximately 15% of all the properties in London are in the floodplain – that is just over half a million properties, and around one million people. Approximately, 70% of them are at risk of tidal flooding, 29% of them are at risk of fluvial flooding, and 1% of them is at risk of both of them (Source: Environment Agency). As the tides in the Thames Estuary raise 60cm every hundred year, the risk of flooding in London is

increasing. There are number of reasons defined by the Environment agency to explain this fact. These are:

- *"The weather becoming stormier*
- *The south eastern corner of the British Isles tilting downwards*
- *Sea level rise*
- *London settling into its clay bed*" (EA)

The worst scenario would be a high surge that occurs at the same time with "spring" tides, which occur twice a month. Surge tides occur when low pressure comes towards British Isles by increasing the sea and creating "hump" of water, which moves the low pressure. Dangerous conditions could occur if this low depression goes through Scotland into the North Sea. Besides, strong northerly winds could increase the severity of the situation (EA).

Consequently, a severe flooding could affect first the transportation system. Underground system would stop functioning in the central London and this would affect the whole city. Moreover, a severe event could cause damage to all (sub)systems, such as water, sewer systems, electricity, gas, telephone etc. One million people can be affected directly in case of a severe flooding event in the central London. Additionally, millions of people can be affected indirectly, due to not functioning businesses, factories, and supply and chain network. The financial cost could be tremendous. Environment agency stated that it could take months to get London functioning as in normal conditions again (EA).

5.3 Tools to response to flooding

There are two types of tools to respond to flooding in London: structural and non-structural. Structural tools are the walls and embankments along the Thames and the other rivers, and indeed, the Thames Barrier and the Barking Barrier. The non-structural tools are the Flood forecasting, warning and response systems, flood plain development, insurances and the emergency management system, which is highly developed and hierarchical.

5.4 Transportation system in London

According to the report of Tfl published in 2011, the demand for travel has increased 8% more in 2009/10 than in 2000/01, as a result of 7.1% population and 5.5% occupation increase. Moreover, mode of transportation in London has shifted from car to sustainable public transport, such as walking and cycling (*5% points at the trip level*), which makes about 1 million trips. Furthermore, bus kilometres have increased with 32% and unground kilometres with 9% more in 2009/10 than in 2000/01, because of development in the docklands and DLR (Tfl, 2011, p.1). Regarding to road traffic volumes (Table 1), there were 6% fewer vehicle kilometres in London in 2009 than in 2000. Volumes of road traffic in London decreased by 3% between 2008 and 2009, having reduced by 2% between 2007 and 2008 and by 1.4%

between 2000 and 2007 (Table 1). The main reason of the steady decrease between 2008 and 2009 was economic recession in 2008. Consequently, there was an increasing shift towards public transportation modes, especially within central and inner London (Tfl, 2011, pp.2-8).

Table 1. Index of London road traffic in central, Inner and Outer London: major and minor roads, all motor vehicles. Index: year 2000=100, Source: Tfl, 2011, p.52

Year	Central London	Inner London	Outer London	Greater London - major roads	Greater London - minor roads	Greater London - all roads	Great Britain
2000	100.0	100.0	100.0	100.0	100.0	100.0	100.0
2001	101.7	101.2	99.8	100.7	99.5	100.3	101.6
2002	98.2	99.0	100.5	100.3	99.5	100.0	104.2
2003	90.0	98.3	101.3	100.3	99.4	100.0	105.0
2004	88.8	94.6	100.6	99.4	96.8	98.5	106.7
2005	87.0	94.3	98.4	96.0	98.2	96.8	106.9

5.5 Transportation system prone to flooding

The map of transportation system merged with 1 in 1000-year flood hazard map prepared by the Environment Agency[2]. In the Figure 5, only the flood hazard maps of London Borough of Newham and London Borough of Tower Hamlet have been merged with that part of the transportation network. In this limited area 28 tube and DLR stations, 4 railway stations, an airport and two hospitals have the risk of flooding. Having flooded stations in the tube network could affect not only that part of the city, but also all the other connected tube networks. Merging the transportation network and flood hazard map indicate the areas which has to be given the priority, such as providing evacuation plans to the hospitals that are in the middle of the floodplain. Besides, this way of combining diverse maps could also help to improve tube network and see the vulnerable parts of the network and act accordingly.

[2] http://www.environment-agency.gov.uk/

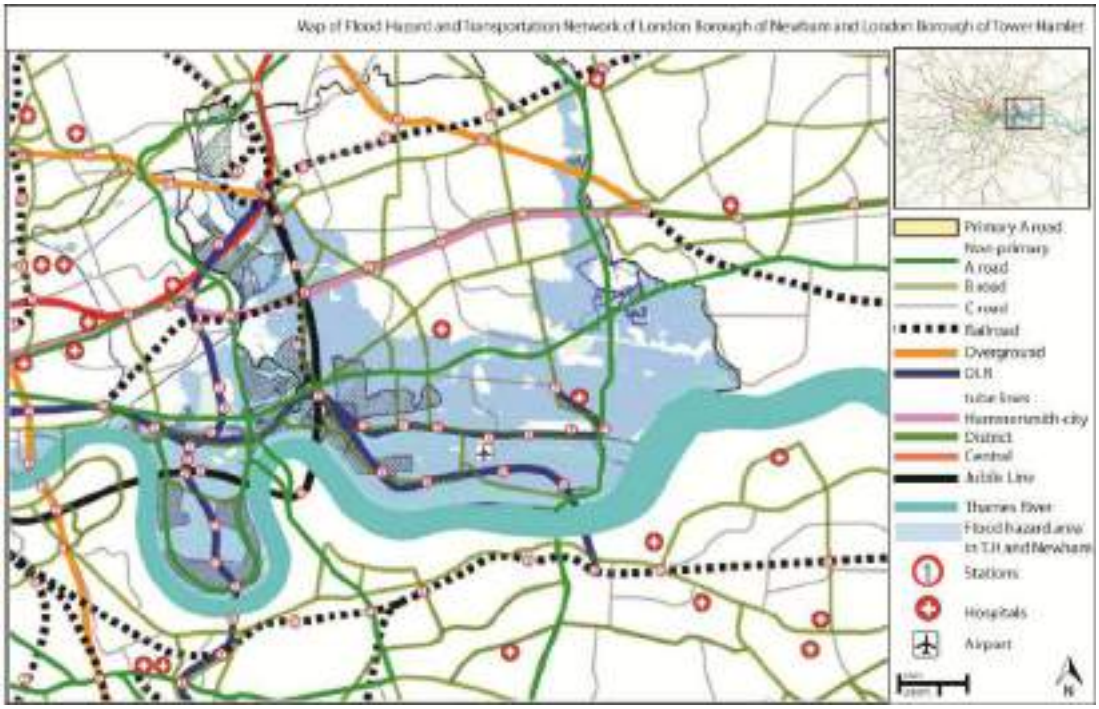

Figure 5. London borough of Newham and London Borough of Tower Hamlet: Map of flood hazard, transportation network and hospitals, Source: Author

5.6 Survey to public

Public survey carried out on the both sides of the Thames River in Lewisham and in Canary Wharf by aiming to have representative sample of people from different classes, ages, genders and backgrounds. In total carried out 61 valid questionnaires. Albeit the number of the questionnaires is not sufficient to represent the entire population in these two boroughs, the result of the questionnaires provided significant insights into the understanding of the present conditions in terms of perception and awareness of public on risk and existing information, and consequently social vulnerability. The questionnaire is made up of six parts. First there is the introduction part for understanding the respondents' profile and consists of 8 questions. The following five parts have 21 questions in total and these parts are:

- Part 1: Perception and awareness of risk condition
- Part 2: Awareness of the flood warning
- Part 3: Awareness of the access of information
- Part 4: Awareness of the information programmes
- Part 5: Population's individual preparation

During the questionnaire flood warning signs (Figure 6), which one can find in the environment agency's website, had been showed to the respondents and asked them whether they have seen them before or not. Correspondingly, 82% of the respondents said no and they do not know the meanings of the signs, and 18% answered yes. They have seen them mainly in the driving exam. Moreover, one person said that he

had seen it while driving on the county, and another one said that he had seen them abroad.

Figure 6. Flood warning signs (Source: Environment Agency)

Furthermore, the respondents had been asked whether they know what to do during an emergency, and if do they have a plan. The vast majority of the respondents (%87) said that they do not know what to do during an emergency. The other 13% said that they would call emergency line to learn what to do and to get some help. Besides, 59 respondents (97%) said that they have never informed about any evacuation plan by the authorities, 2 people (3%) said that they had informed by their workplaces (Figure 7).

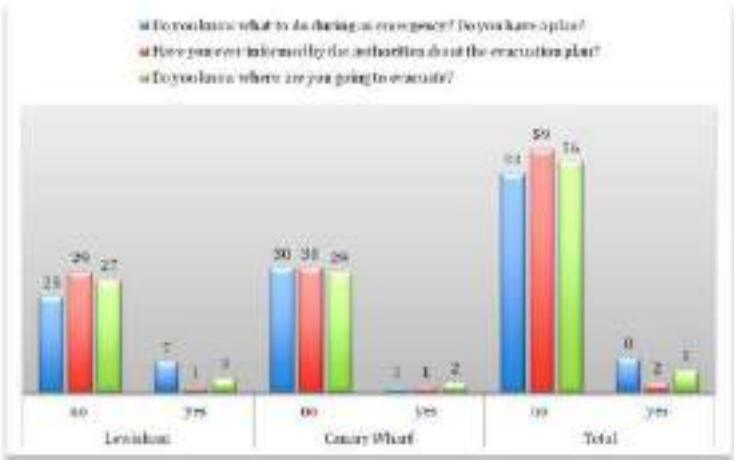

Figure 7. Preparedness to emergencies (Source: Author)

Another result of the survey is that people do not know where to go if they need to evacuate. The vast majority of responses (92%) were negative and they said that they do not know where to evacuate if they need to do so. Others who are in the 8% said that they would go to the Borough's main building to ask help, some of them said that they would go to other family members' homes that are living outside London. Regarding to the evacuation vehicle, the answers can be grouped into four: their own car, neighbour's/friend's car, public bus/train/boat, and a vehicle provided by the government. Mainly the respondents (46%) chose their own car for evacuation. Moreover, 29% said that they would use public bus/train/boat. This is followed by the vehicle provided by the government (15%) (Figure 8).

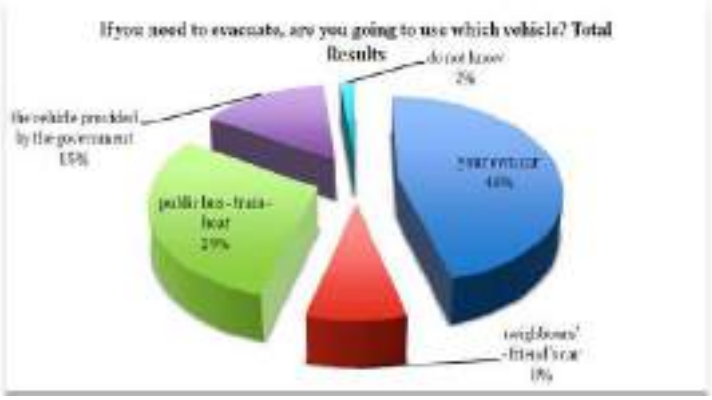

Figure 8. Modes of transportation for evacuation (Source: Author)

According to the insights coming from this survey, although there is information available online about emergency responses and flood warnings, it is not reasonable to expect all people know what to do during an emergency and follow those websites to gather information. Not sharing the information face to face with people especially make elder people more vulnerable, as most of them do not know how to use internet and most dramatically not able to read messages coming to their mobile phones. So, all possible reactions coming from public shall be considered in every phase of disaster management.

6. Istanbul

By the foundation of the Turkish Republic in 1923, during the 30s and the 40s, the city had been enlarged beyond the former districts to provide room for the growing population. The most rapid and recognizable population growth is seen in the 50s with a high migration rate from rural to urban. Today Istanbul is the primary city of Turkey by covering 5 512 km and by having 13% of Turkey's population (12 573 836) and 23% GDP of Turkey (IMM, 2008[3]). In 1945 the population of Istanbul was 1 078 000, due to the given dominant economic role to Istanbul this number had reached to 1 533 000 during the 50s. According to the census in 2000, the population of the city has reached more than 10 million and today it is 12 573 836 (SIS, 2008).

6.1 Changing vulnerabilities

Vulnerability is a dynamic concept that can be formed by policies and trends over time and across spatial scales (Menoni et al. 2012). The changes on the vulnerability due to dynamic structure of cities are seen clearly both in London and Istanbul megacities. Like London, Istanbul has also experienced the global trends in urban vulnerabilities, such as rapid population growth, rapid urbanization, major economic transformation, and increasing gap between socio-economic classes. Additionally,

[3] http://www.ibb.gov.tr/en-US/Pages/Home_Page.aspx

Istanbul has experienced also increased illegal housing supply starting by the 50s. After the 50s central government had left the regional policies and focused on the economic improvement of the Istanbul region. As a result, the city itself and the Marmara region had developed rapidly. Furthermore, by aiming to modernize the city, Henry Prost has prepared a plan for Istanbul between 1936 and 1950. By this plan, a part of the existing housing stock had demolished by aiming to open new roads, and industrial facilities located in the centre of the city.

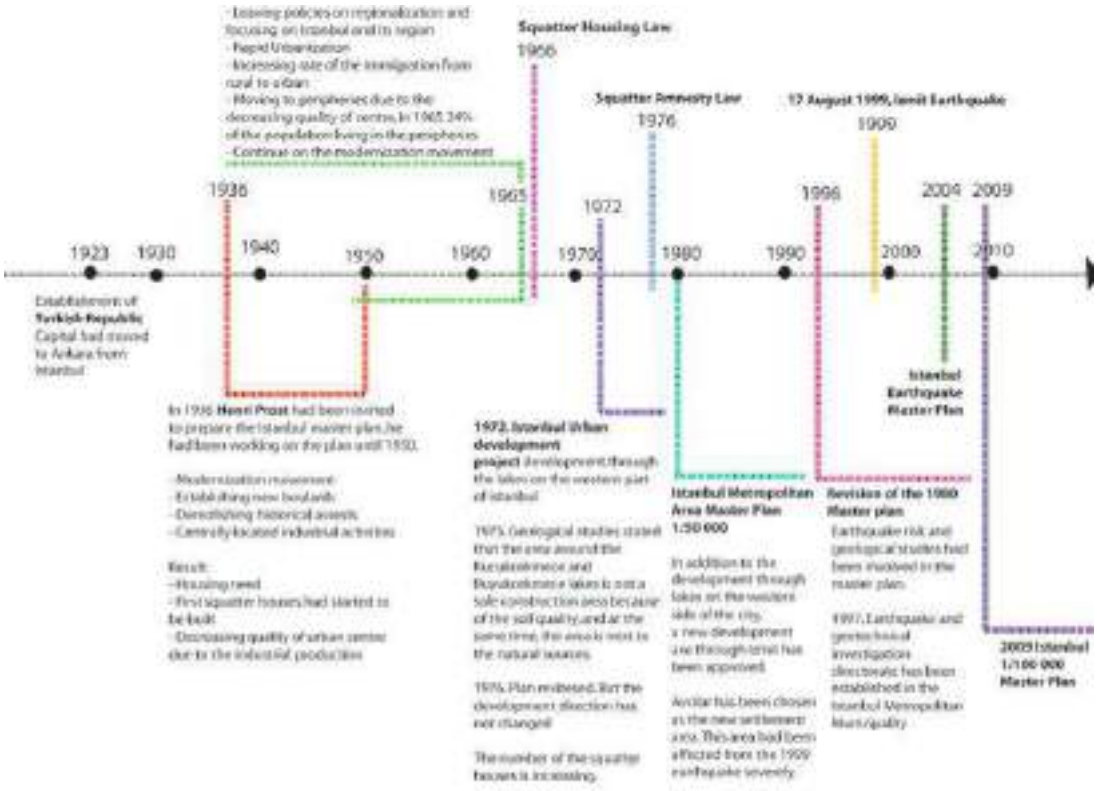

Figure 9. Retrospective view of changing vulnerability of Istanbul (Sources: Compiled from data in Tekeli, 1994; Keskinok, 2001; Şengezer, 1993; Türksoy, 1993; Görgülü et al. 1993; Angel, 1993; Gencer, 2007; Gedikli, 2001)

By the 50s, the city started attracting population from the entire country. Existing residents of Istanbul moved to the peripheries of the city, as the housing stock in the city centre were deteriorated. Moreover, new immigrated population moved in the emptied old urban fabric that is located in the hearth of the city. Besides, some of them built their own houses illegally and mostly situated on risky zones, because central and local governments were unable to fulfil the residential needs of large number of immigrants. By the 80s, by the new regionalization policies, industry started to move to Kocaeli and Adapazarı in the eastern part and to Küçükçekmece in the western part of the region, which are the areas prone to earthquake hazard more than the other parts of the city. As a result of these trends, the city become more vulnerable to hazards, because of the low quality dwellings, increased density and the industrial production in between residential areas. To have more detailed information on retrospective view of changing vulnerabilities please see Figure 9.

6.2 Changing hazard concept

Before the 1999 Marmara Earthquake, Istanbul was accepted as the second priority earthquake hazard zone. After the event it has became the first priority earthquake zone, because now it is expected another major event with the probability of 62% within the next 30 years in the Marmara Region, as a result of the tension created by this earthquake on the fault line (Figure 10).

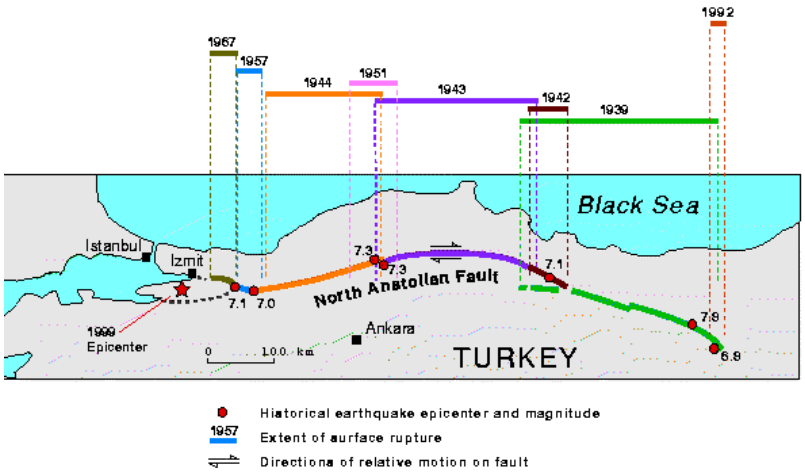

Figure 10. Historic progression of earthquakes on North Anatolian Fault line, Source: http://neic.usgs.gov/neis/eq_depot/1999/eq_990817/T990817000138.html

6.3 Existing risk of earthquake

In the IMM and JICA research (JICA and IBB, 2002), four earthquake scenarios were prepared, and they were compared to estimate the damage due to their distribution of peak ground acceleration (PGA), the damage distribution pattern and damage amount.

Building damage

Building hazard estimation was calculated for every type of the building included in the building census year 2000 by the JICA and IMM team (JICA and IBB, 2002). Building damaged is examined into three main topics; heavily, moderately, partly and four models (A, B, C and D) had prepared. According to model A, the total number of the damaged buildings is 252.000, which makes 35% of the total building stock. In addition, 1.116.000 households would be affected by the event. In the model C, the damage distribution is almost the same as that of model A. The total number of the damaged buildings is 300.000, 38% of the building stock and affected number of households is 1.300.000. In the models, southern west coast of the Istanbul is the most affected area due to the location of the epicentre. The less affected areas are located along the Bosporus and northern part of the Istanbul.

Human casualties

Human casualties are defined considering with collapsed buildings and have been done according to the night-time. These scenarios just give a framework to understand the growth of the event. Model A is estimated 73.000 deaths and 120.000 severely injured. According to model C the number of deaths is 87.000 and the number of severely injured is 135.000. In both of the models islands have the biggest ratio of death, which is 8.4% according to model A and 9.3%.according to model C.

6.4 Earthquake risk and transportation system

To have better understanding on the existing situation Figure 11 is prepared by combining 4 different maps: the map of existing road network, vulnerable buildings, vulnerable infrastructure and medical capacity. When these maps merged in one map, south-western part is indicated as the most vulnerable part of the city, because of having narrow roads, the vulnerable and aged infrastructure, and vulnerable housing supply.

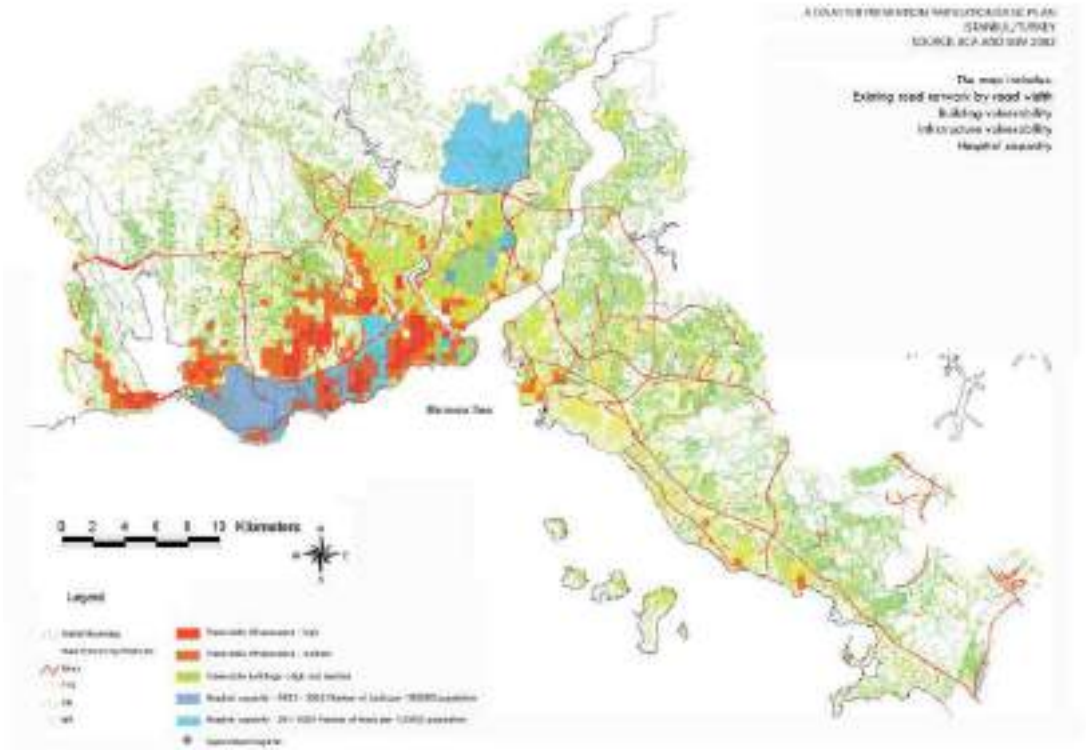

Figure 11. Vulnerability of infrastructure, buildings and medical facilities, (Produced by the author by combining the maps in the JICA and IBB, 2002 report)

As the main hospitals are located in this part of the city, it would be needed to reach that part from the other parts. However, due to vulnerability of the infrastructure and artefacts, it could be difficult to reach there during an emergency. Moreover, medical supply in the other part of the city would not be sufficient for the entire city.

7. “What if Scenario” – Evacuation

A “What if Scenario” can be defined as a simulation which aims to investigate the possible behaviour of a complex system (Golfarelli and Rizzi, 2008, p.1). Experiences, such as 2005 Katrina and Rita Hurricanes and most recently 2011 Tohoku earthquake and Tsunami, show that there are domains of people acting differently especially during evacuation phases. The unforeseen behaviour of people affects the emergency procedure negatively. In the first part of this paper, not being able to forecast human behaviour was indicated as one of the problems. Preparing a “what if scenario” provides a simplified representation to understand the way that people react and their effect on the transportation system. An evacuation starts by giving the decision of evacuation and ends when all these people turned back to their families and homes. In the scenario (Figure 12), it is expected that not all the people follow the evacuation order properly, the reasons and possible human reactions schematized by asking some questions whether they have received the evacuation warning, and whether they follow the rules etc.

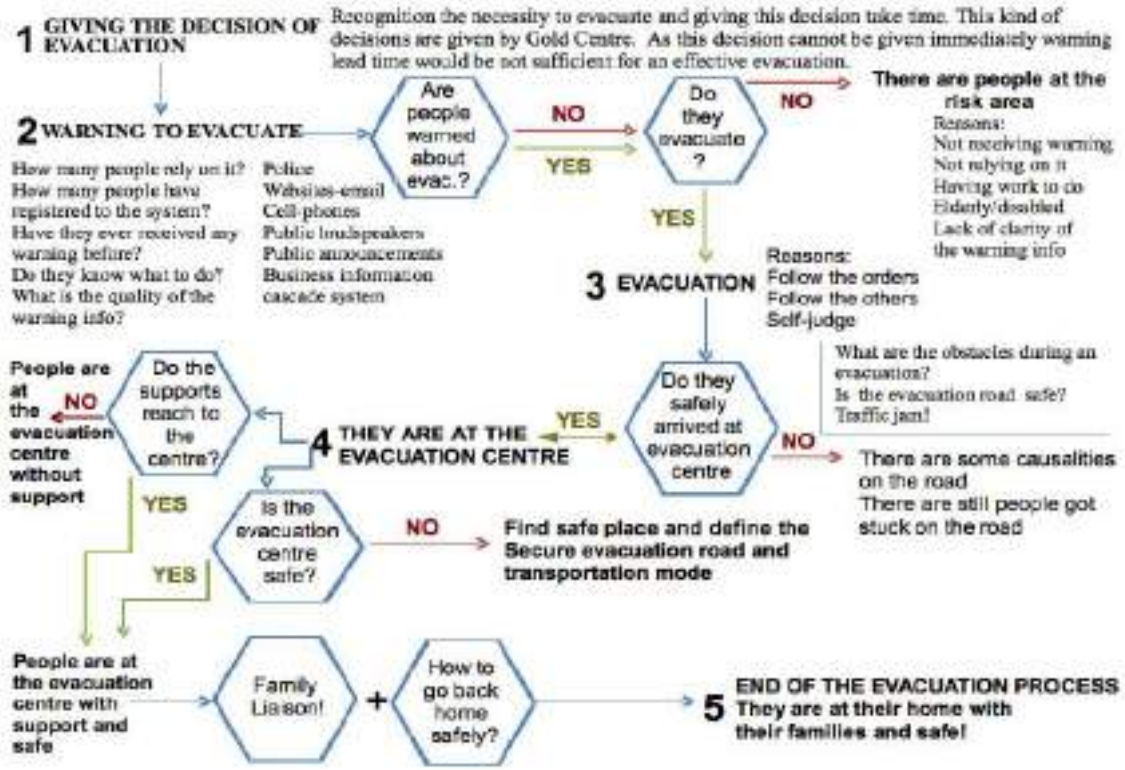

Figure 12. A scenario for evacuation, Source: Author

8. Conclusion

In the beginning of the paper two problems have been identified, the first problem was not considering the entire city while providing policies or tools for solving the existing problem. For this reason, both for London and Istanbul different maps have merged to identify the most vulnerable part of the city in case of a disaster. The

second problem was being unable to forecast the human behaviour. To have more simplified picture on this issue, a survey has been conducted in London to gather some insights and several real cases (such as Rita and Katrina Hurricanes in 2005, Northridge Earthquake in 1994 and Tohoku Earthquake and Tsunami in 2011) have studied to achieve a scenario on evacuation and possible behavioural domains of people.

The methodology to solve the problems in transportation system in case of a disaster should consider hidden connections between elements of the city. The relation between vulnerable buildings and vulnerable parts of the roads has to be studied before concentrating on a single part of the transportation system. The fact that reaction of people could contribute into the resilience of a structural system either negatively or positively should also be considered in all kind of emergency plan. Moreover, having information on hazard and emergencies in the online platform does not mean that people know about the existence of this information, or even if they know that it exists, they might be not interested in acquiring this information. There is a need to have face-to-face interaction with public to provide them the information on hazard and emergency. On the other hand, if decision makers, or governmental authorities, have the simplified and completed picture of the situation in case of a disaster, it can be more effective for them to use the expert knowledge and implement it. The reaction of a complex city system to a disaster depends on the initial conditions. The initial condition includes both vulnerabilities and strengths of a city. Having small changes in the initial conditions would affect the results tremendously.

Acknowledgements The author acknowledges and thanks with gratitude to the members of the Flood Hazard Research Centre at Middlesex University for their excellent help and support during the author's research period in London. Moreover, the author is grateful to Prof. Scira Menoni for her support in all the time of the research.

Establishing Mixed Method Research Design Guidelines in Health Impact Assessment (HIA) Investigations

John Gaber and Tammy Overaker[1]

Introduction

In the last decade planers have become more aware of the possible health impacts of existing and proposed plans and projects. The most common strategy planners use to assess the health impacts of their planning decisions is through a Health Impact Assessment (HIAs) strategy. HIAs are founded on "the ethical use of evidence, emphasizing the use of quantitative and qualitative evidence … to get as comprehensive assessment as possible of the expected impacts" (European Centere for Health Policy, 1999, p.4). As much as HIAs are based on a mixed method research design strategy (quantitative and qualitative data sets combined in one research project), the HIA literature since the Gothenberg Consensus Papers in 1999 has yet to provide any guidelines on how planers should conduct a mixed method HIA research project. Research methodology has become the Achilles heal of HIAs, in turn, limiting their planning and policy impact.

In this paper we conducted a content analysis of 149 HIAs conducted around the world starting from 1999 to 2011 and analyzed their research methodologies. Observations generated from the analyzed HIAs are used to establish a series of mixed method design guidelines to help planners improve the analytical capabilities in future HIA investigations.

The paper is organized into four sections. The paper begins with a simple overview about HIAs. Here, we discuss it's assumptions and the different approaches they are applied. This is followed with a brief discussion about mixed method research design. In our discussion about mixed method design, we identify the most common applications ("reasons") when planners typical use a mixed method research design. The third section is a discussion of our HIA data. This session concludes with an analysis of the mixed method HIAs to develop a working "HIA model for mixed method research design." The paper concludes with a discussion on next-steps planners can take to be improve their future HIA investigations via a mixed method research design approach.

The World of HIAs

Health Impact Assessments (HIAs) are assessment strategies used by planners that combine community input with a series of data sets to evaluate the health impact of proposed and existing projects. In 1999, the World Health Organization European Regional Office in collaboration with the European Health Policy Centre developed the "Gothenberg Consensus Papers" that established an international framework by which planners and policy makers can operate from a common understanding in the application of HIAs.

An HIA is a community-based approach to addressing local health issues. It:

- provides a broad definition of health that includes economic, environmental, social and psychological factors
- particularly concerned with disadvantaged populations
- takes a multi-disciplinary approach to "evidence" that includes quantitative and qualitative data slices to inform decision-making

The act of conducting an HIA is very much like going through the rational planning process. It is in part the similarity between the HIA process and the plan making process that draws planners to HIAs. The HIA process is divided into five sequential steps. They are:

1.) Screening -- The selection process that determines whether a particular policy, plan, or project has a potential health impact. Is an HIA needed?

2.) Scoping -- If the screening has determined that an HIA is to be carried out, this is the process that identifies the steering group and establishes a work plan for the HIA.

3.) Assessment (research) is -- The "engine" of the HIA where impacts are considered, evidenced gathered, and recommendations are framed.

4.) Report -- Formal identification of recommendations and production of the final report.

5.) Monitoring -- relevance of Assessment of the HIA process: 1.) impact of the process, and 2.) research.

Before any research is conducted in an HIA, an extensive screening process takes place to determine if an HIA is needed. (See Figure 1 below.)

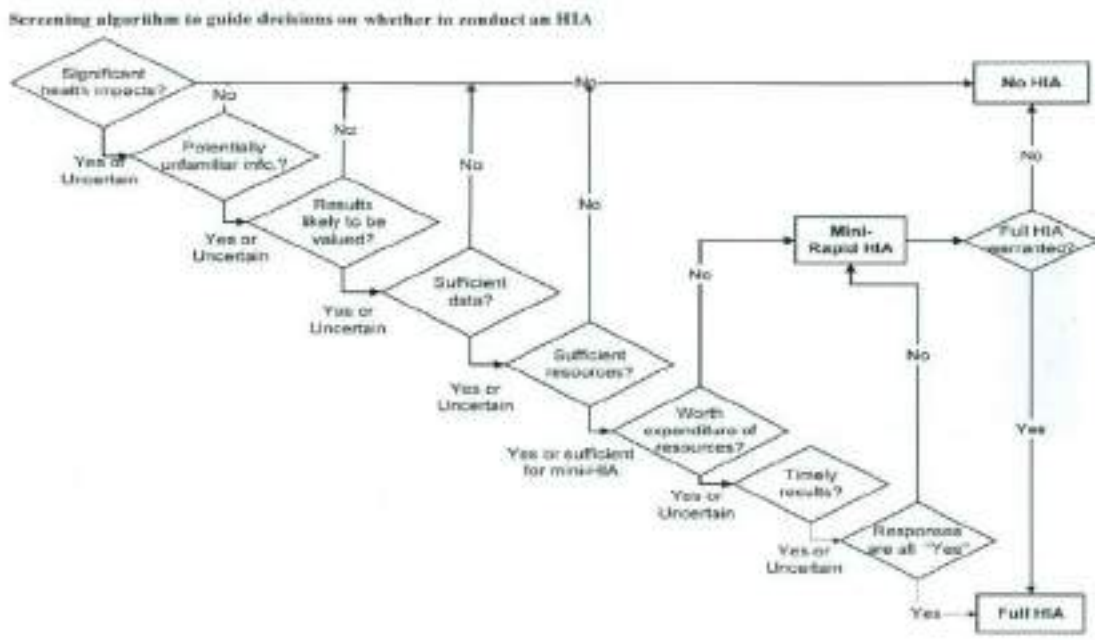

Figure 1. Source, UCLA, (2004) Health Impact Assessment, p.4.

There are three types of HIAs depending on the amount of time needed to execute the process: *rapid* (also called "tabletop") --the shortest study (one to two days), *intermediate* – a more detailed investigation (several weeks), and *comprehensive* -- an intensive investigation (several months up to a year).

Mixed Method Research Design

Mixed method research designs help planners better understand the complexities of life. In most situations, there is not one singular perspective. There are multiple perspectives. In working in a mixed method investigation, the planner is required to combine more than one research method to generate multiple data slices that are organized into a single research project. Mixed method research projects involve the integration of quantitative methods (the collection of numbers) and qualitative methods (the collection of words and images). An example would be the combination of census data with participant observation field research data to learn more about a particular community.

Mixed method research design is further broken down into two kinds of strategies: *within-method* and *between-method* triangulation. In a within-method investigation, the planner takes one method and use different strategies within it, such as using a survey that asks closed-ended questions for quantitative data and open-ended questions for qualitative data. Between-method

investigation combines dissimilar methods to examine a particular situation, such as using census data research and a focus group investigation to figure out the best location for a new neighborhood park. Between-method designs are the most common mixed method approach used with HIAs.

The mixed method literature five identifies "purposes" (more easily understood as *reasons* why researchers use this technique) for a planner to employ a mixed method research design. They are: convergence (triangulation), development, complementarity, expansion, and initiation. *Convergence*, also known in the literature as triangulation, is the most sought after process in mixed method research. The goal is to use several different methods to analyze a single phenomenon in order to increase the validity and credibility of the results (Cook 1985, p. 46, Bryman 1992, p. 131).

Mixed method research strategies can be classified as simultaneous or parallel/sequential Greswell, 1994, p. 182). A simultaneous mixed method investigation uses multiple research methods at the same time. In sequential mixed method research, the results of one method are essential for developing the next. Mixing methods for the purpose of *development* involves the sequential use of quantitative and qualitative strategies where results from the first method are used to inform the second method. The goal of development is to increase the strength and sensitivity of additional research methods.

Complementarity combines methods to measure overlapping, as well as different aspects of a situation, in order to get an enriched enhancement of that situation. The goal of complementarity differs from the goal of convergence in that the focus of convergence requires that different methods assess the same conceptual phenomenon, while the methods used in complementarity address *different* phenomena (Greene, et. al. 1989, p. 258).

Expansion combines the processes of complementarity and development to extend the range of understanding about a situation by using different methods targeting different components of the situation (Greene, et. al. 1989, p. 259). Expansion has two goals. First, similar to the development process, expansion focuses on applying research methods particularly strong in analyzing specific situations. Information generated from one method is not used to help another method in its assigned tasks. The second goal is similar to the complementarity process—the planner applies the images of reality generated by one method to help analyze other sets of images generated by different research methods.

Initiation is at the opposite end of the mixed method spectrum from convergence. It looks for situations where research findings do *not* converge. The goal of initiation is "to initiate new interpretations, suggest areas for further exploration, or recast the entire research question" (Rossman and Wilson, 1985, p. 635, Jick, 1983, p. 149).

HIA Investigation

We conducted a fairly exhaustive internet investigation of all published HIAs (in English) from 1999 to 2011. A total of 149 HIAs were obtained and analyzed. The countries represented in the HIA sample include: Australia, Canada, Germany, India, Italy, Netherlands, New Zealand, Russia, Slovenia, Sweden, UK (England, Ireland, Scotland, Wales), and the US. The HIAs were first found through international collecting HIA websites (e.g. "The HIA Gateway," maintained by the West Midlands Public Health Observatory). After exhausting these collecting HIA websites, we then looked at specific agencies / organizations that have published HIAs found in the collecting HIA websites to see if they have any more HIAs in their archives. Two examples of this secondary search would be our looking at the US HIA organization "Health Impact Partners (HIP)" and the UK HIA Organization "Impact" at the University of Liverpool to see if they had any additional HIAs.

The HIAs were catalogued and analyzed first by latent content analysis and afterwards by a manifest analysis (Gaber and Gaber, 2007, pp.103-134). The HIAs were read twice through a latent content analysis to obtain comparable bits of information. In the first reading of the HIAs, we collected information on the following variables: date, author, topic (e.g. land use or social services), type of HIA conducted (Rapid, Intermediate, or Comprehensive), location in the planning process (Prospective, Retrospective, or Concurrent), type of research design. In the second reading, we focused on only the research design section of the HIA to determine what type of research design was used (mono method vs. mixed method), and if a mixed method research strategy was used, what type of mixed method research design was carried out. Once all of the comparable data was collected, they were in dropped into a spread sheet, the HIAs were then analyzed via a manifest content analysis to determine thematic trends.

Mixed Method HIA Investigation

The most surprising observation among the analyzed HIAs was that only 68% of them used mixed method research strategies. As outlined in the *EPHIA HIA Methods Guide (A Guide)*, mixed method research is the foundational research design for all HIAs , so this number should be closer to 100%. A little over quarter of the reviewed HIAs (26%) used a single method investigation. 5% of the HIAs did not even have a methodology. Lastly, less than 1% (0.6%) of the HIAs recognized that they conducted a mixed method investigation. From this overall assessment of the HIAs methodologies, it is very clear that much more work is needed in bolstering the rigor and improving the explanatory capacity in HIAs mixed method research projects.

By looking more closely at the HIAs that actually completed a mixed method research design, we can discover where best to apply mixed method guidelines that generates the easiest and

quickest results for future HIAs. The HIA cohort that clearly executed a mixed method research project are for all extensive purposes are representative to the total population of surveyed HIAs.[i]

Within the mixed method HIAs themselves, they are fairly evenly distributed in terms of the level of detail in their investigations. The largest third (36%) of the HIAs are Rapid investigations, with the middle third (33%) being for Intermediate projects, and the smallest third (31%) are Comprehensive HIAs (Table 1). In an earlier study (Gaber and Overacker, 2011), it appears there is a trend away from more time consuming and expensive comprehensive HIAs and a move to shorter and more affordable HIAs.

Table 1. HIA's by Level

Level	Mixed Method HIA Population
Rapid	36%
Intermediate	33%
Comprehensive	31%
Not Identified	
Total	100%

What dramatically stands out about the mixed method HIA population was the Type of HIA that was conducted (Table 2). More than 60% of the mixed method HIAs were conducted within a Prospective planning calendar. This highlights that mixed method research strategies are actively

used in the HIA process as a way to get as much diverse bits of information as possible to access "possible" health impacts. A little over a third (33%) of the mixed method HIAs focused on Concurrent HIA research.

Table 2. HIAs by Type

Type	Mixed Method HIA Population
Prospective	61%
Concurrent	33%
Retrospective	6%
Total	100%

As seen in Table 3, it is very clear that Mixed Method HIAs are more focused on Human Services and Land Use topics. Topically, the mixed method HIAs were fairly evenly split between Human Services assessments at 48% and Land Use assessments at 44%.

Table 3. HIA's by Topic

Topic	Mixed Method Population
Human Services	48%
Land Use	44%
Environmental	8%
Total	100%

The authors to the Mixed Method HIA cohort are fairly representative of all the organizations that would normally be interested in assessing the health impact of identified projects. None of the authors are from the private sector. Over half of the authored mixed method HIAs are from the public sector with 33% of them being written by government agencies and 30% by university organizations (all are public universities), or some combination of government, university, or non-government agency at 19%. (See Table 4.) The remaining 18% of the HIAs were conducted by non government agencies.

Table 4. HIA's by Author

Author	Mixed Method Population
Government	33%
University	30%
Non-Govt. Org. (NGO)	18%
Combination	19%
Total	100%

In looking more closely at how the HIAs conducted their investigations, a very clear image of the HIA model to mixed method research design becomes very distinct. Let us go into more detail on what we discovered in this profile of HIA mixed method design. Straight of out of the gates, the way HIAs approach mixed method research design is very different from what is considered "common" mixed method investigation. Two (out of three) defining aspects to the HIA's model to mixed method research are shown in Table Y1. First, HIA mixed method research strategies significantly lean to the "expansion" purpose of mixed method investigations. Expansion mixed method investigations are when the researcher uses different research methods to obtain different data sets. This makes sense since HIA investigation are required to obtain very disparate data slices (e.g. health, demographic, traffic, economics) in a single HIA study. What is particular interesting with the HIA model is that an overwhelming majority of them using Expansion mixed method investigation, while in the mixed method literature Triangulation is the

most common use of mixed method investigation. (Source this) As discussed earlier, the primary reason and benefit to a triangulation mixed method design is the added confirmation in internal validity with different research projects converging on the same observation. Only 2% of the reviewed HIA's utilized a mixed method investigation for triangulation. It is very clear among HIA researchers that they are more concerned with the breadth of research observations (the main reason to expansion mixed method projects) than in shoring-up depth in confidence of their research observations with a strong argument for internal validity.

Table 5. Strategy Mixed Method Type and HIA Type

	Prospective	Concurrent	Retrospective
Expansion	69% (42)	88% (29)	50% (3)
Complementarity	5% (3)	0	0
Triangulation	3% (2)	0	17% (1)
Initiation	2 (2)	0	0
Development	0	0	0
Hybrid	20% (12)	12% (4)	33% (2)
Total	100% (61)	100% (33)	100% (6)

The second distinct characteristics to the HIA model to mixed method research is also the second most popular purpose in why HIA researchers used mixed method investigations: Hybrid. The Hybrid purpose for mixed method investigations is when a researcher uses two or more investigative techniques (e.g. survey and focus group investigations) for more than one of the 5 major purposes for mixed method investigations. The Hybrid mixed method approach is the most complicated mixed method purpose because it requires the investigator to be acutely aware of the different purposes for mixed method investigations and that they are combining two (or more) purposes to either achieve a more detailed analysis or greater depth of confidence. In this case of HIA investigations, a more accurate explanation is that the HIA formula to research requires a multi-purpose for their mixed method investigations and that they are executing a Hybrid mixed method study more out of functionality of the investigation than out of other understandings about the basic application of mixed method investigations. Properly grounded in mixed method research strategies, HIA investigators will be better able to take on more Hybrid mixed method projects and be able to expand on the explanatory value of their hybrid mixed method investigations.

As shown in Table 6, Hybrid mixed methods are gaining popularity in the last ten years. 67% of all the Hybrid HIAs were conducted between 2007 and 2011.

Table 6. HIA Mixed Method Research Strategy from 1999 to 2011

	'99	'00	'01	'02	'03	'04	'05	'06	'07	'08	'09	'10	'11
Expansion	1	3	5	7	3	2	3	11	11	12	8	5	3
Complementarity	0	0	0	0	0	1	0	1	0	0	0	1	0
Triangulation	0	0	0	0	0	1	1	0	0	1	0	0	0
Initiation	0	0	0	0	0	0	0	1	0	0	1	0	0
Development	0	0	0	0	0	0	0	0	0	0	0	0	0
Hybrid	0	0	2	0	0	4	0	0	2	4	2	4	0
Total	1	3	7	7	3	8	4	13	13	17	11	10	3

In looking at the type of mixed method research study was applied in relation to the size of the HIA study, the third characteristic of HIAs becomes apparent. (See Table 7.) While Rapid and Intermediate HIAs mostly focus on the Expansion mixed method approach (80%), Comprehensive HIAs are more evenly split between Expansion (46%) and Hybrid (32%) mixed method approaches. Stated differently, more than half (55%) of all Hybrid mixed method HIA studies are conducted within the Comprehensive HIA format. A partial explanation for this can be that the Hybrid mixed method project are particular adept at analyzing complex problems which is the focus of Comprehensive HIAs. In addition, Hybrid mixed method research projects, with their added layer of complexity, tend to require added attention which is made possible through the long-term Comprehensive HIA process.

Table 7. HIA Mixed Method Research Strategy and HIA Level

	Rapid	Intermediate	Comprehensive
Expansion	81% (29)	85% (28)	55% (17)
Complementarity	0	0	10% (3)
Triangulation	5% (2)	3% (1)	0
Initiation	3% (1)	0	3% (1)
Development	0	0	0
Hybrid	11% (4)	12% (4)	32% (10)
Total	100% (36)	100% (33)	100% (31)

At first sight it appears three are very little differentiation in the type of mixed method research used in the substantive topics of the HIAs (Human Services, Land Use, Environmental). (See Table 8.) All three of the substantive HIAs use Expansion mixed method research approach at least 70% of the time (77%, Land Use, 75%, Environmental, and 71%, Human Services). What is important to point out here is that 67% of the Hybrid HIAs (Table Y4) have focused on Human Service issues.

Table 8. HIA Mixed Method Research Strategy and HIA Topic:

	Human Services	Land Use	Environmental
Expansion	71% (34)	78% (34)	75% (6)
Complementarity	0	7% (3)	0
Triangulation	4% (2)	2% (1)	0
Initiation	0	4% (2)	0
Development	0	0	0
Hybrid	25% (12)	9% (4)	25% (2)
Total	100% (48)	100% (44)	100% (8)

When breaking down the mixed method HIAs by author, it is very clear that Expansion investigations are heavily used by government, university, and NGOs. (See Table 9.) Interestingly, although university authored HIAs primary focus are in Expansion mixed method strategies, they did have the second largest number of Hybrid HIAs after Combination authored HIAs. It is not surprisingly that the combination of University and Combined authored HIAs account for 72% of the Hybrid HIAs. In fact, within the Combined authored Hybrid HIAs, University co-authored 100% of the Hybrid authorships. It is fairly safe to assume that more complex and integrated mixed method HIA projects are conducted by or with university researchers.

Table 9. HIA Mixed Method Research Strategy by HIA Author

	Government	University	NGO	Combination
Expansion	79% (26)	77% (23)	83% (15)	53% (10)
Complementarity	6% (2)	3% (1)	0	0
Triangulation	6% (2)	0	0	5% (1)
Initiation	3% (1)	0	0	5% (1)
Development	0	0	0	0
Hybrid	6% (2)	20% (6)	17% (3)	37% (7)
Total	100% (33)	100% (30)	100% (18)	100% (19)

In looking more closer at the Hybrid HIAs (Table 10), it becomes very clear that Universities play a significant role in authoring this type of mixed method investigation. As a single author, University accounts only for 31% of all of the Hybrid HIAs. However, when the single University authorship is combined with joint authorship with other organizations (Government, NGOs, and Government/NGOs), over 70% of the Hybrid HIAs are authored by University.

Table 10. Hybrid Mixed Method by HIA Author

Author	Hybrid Mixed Method HIA

University		31% (6)
Government		12% (2)
NGO		17% (3)
Combination		40% (7)
University/Government	17% (3)	
University/NGO	17% (3)	
University/Government/NGO	6% (1)	
Total		100% (18)

The Hybrid HIAs focus primarily on two very different mixed method combinations. (See Table 11.) The largest combination at 39% of the mixed method Hybrid HIAs used the Complimentarity/ Expansion Hybrid model. This makes sense that given that Complimentarity and Expansion are very much sister mixed method research strategies and combine different investigations in a very similar fashion. The way the authors apply this particular HIA mixed method approach is that they first start out the investigation according to an Expansion strategy and use the different methods to access different data sets. Once all the data is collected, the authors then jump over to the Complementarity investigation and use the data obtained from one method to then analyze the data generated by a different method. For example, in the "29th Street San Pedro Street Health Impact Assessment" conducted by Human Impact Partners (2009), they used "(d)ata from specific survey questions … alongside census and other data sources to provide additional information about existing health conditions in the community" (HIP, 2009, p. Intro. 5).

Table 11. Most Common Hybrid Mixed Method Combination

Type of Mixed Method Combination	Total
Complimentarity / Expansion	39% (7)
Expansion / Initiation	31% (6)
Expansion / Triangulation	12% (2)
Development /	12% (2)

Expansion		
Complimentarity / Initiation	6%	(1)
	100%	(18)

The second popular Hybrid mixed method approach strategy was in the mixture of Expansion/ Initiation. This is somewhat unique in that Expansion mixed method investigations are not closely aligned with Initiation as would it would be with Expansion to Triangulation where different methods generate observations that can share on a shared observation. In the Expansion / Initiation Hybird mixed method investigations, the researchers start off the study in an Expansion strategy and are using different methods to obtain and analyze very different data sets. Once a set of observations are generated from the first round of data gathering work, the authors then analyze the data and discover new realities and take these discoveries and take to a new research project (Initiation) to explore this new empirical path. An example of this Hybrid approach is the "Stopping the Out Case Study," HIA investigation project conducted by the University of Liverpool in their study of vulnerable young women in South Sefton. In this study, one researcher conducted two additional focus group investigations with "other key informants and stakeholders who are not directly associated with the project as either employees or users" to get a sense of what "people outside of the organization" thinks (University of Liverpool, 2001, p. 18).

Piecing Together the HIA Mixed Method Profile

Through the piecing together of the more dramatic characteristics among the mixed method HIAs, a "HIA Mixed Method Model" can be delineated that stands out from the typical HIA population. Our analysis is able identify four very clear mixed method HIA characteristics. First, mixed method HIAs are much more likely to be for a Prospective application (61%) than either Concurrent (33%) or Retrospective (6%) . Second, mixed method HIAs are less focused on Environmental topics than Human Services and Land Use topics. Methodologically, mixed method HIAs are more commonly based on an Expansion mixed method design. Expansion HIA investigations are more commonly applied in Rapid and Intermediate investigations than in Comprehensive projects. Lastly, and very unanticipated, mixed method HIAs are actively using Hybrid mixed method strategies. Interestingly, the inverse is true with Hybrid mixed method HIAs that are more commonly found in Comprehensive HIA projects than in Rapid and Intermediate studies. Hybrid mixed method HIAs are more likely to be authored or co-authored

by a university and tend to be evenly split between an Expansion / Complimentarity approach or an Expansion / Initiation approach.

Next-steps in HIA Mixed Method Research Strategies and Planning

I will finish this last paragraph by the end of the month. Thank you, John Gaber

PLANNING FOR A RESILIENT OPEN SPACE. A COMPARATIVE STUDY ON THE DRIVING FORCES AND SPATIAL EFFECTS OF URBANIZATION IN FLANDERS

Barbara Tempels[1], Thomas Verbeek[1], Ann Pisman[1], Georges Allaert[1]

Keywords

open space, urbanization, spatial transformations, regional differences, driving forces

Abstract

Open space is scarce and under pressure in the highly urbanized region of Flanders, the northern part of Belgium. Due to urbanization and fragmentation, the former countryside has disintegrated into a complex spatial structure of open space fragments with different densities and functions, such as housing, work and recreation. The built-up density of the open space – defined as all space outside of residential areas, such as village and city centers – is increasing, while the predominance of agriculture as the traditional manager of open space is decreasing.

The question arises to what extent open space is resilient to urbanization and at what point the morphological transformations and new functions exceed the carrying capacity of open space. This is especially relevant since there is little coherent and effective spatial policy for some of these functions. Therefore, this research aims to gain insight into the current state and structure of open space in Flanders through a spatially coherent analysis based on a system approach.

The article focuses on four uses of open space, which are largely responsible for its increasing building density and changing morphology. These are (a) the residential use, with a growing household density, (b) the diverse economic use, altering the formerly agricultural rural economy, (c) the private use for gardens and hobby farming as an extension of the home environment, and (d) the use for public recreational purposes. The first two are 'hard' functions, taking place in buildings, whereas the other two are 'soft' activities, oriented towards the unbuilt space. While hard functions seem to be a threat to open space, soft functions are potential managers of open space, keeping the open space open. These new functions are mapped and analyzed through a comparative study in nine case municipalities with different spatial characteristics. In the paper, their region-specific or spatially heterogeneous patterns are examined. Since understanding the drivers that push open

[1] Center for Mobility and Spatial Planning, Ghent University, Belgium - barbara.tempels@ugent.be, thomas.verbeek@ugent.be, ann.pisman@ugent.be, georges.allaert@ugent.be

space into a new regime is key to resilience management, these are also analyzed through literature review.

The study shows that within Flanders, some open space areas are more resistent to urbanization than others. In more peripheral parts, production agriculture is strong enough and urbanization is only possible when space is available. In suburban parts, the open space serves urban needs and is highly fragmented by roads and buildings. These areas have passed a certain threshold and moved on to a different regime. The drivers for this process are very diverse, both in scale and type. Generally, we can conclude that the importance of these new users is substantial for the resilience of open space.

The insights presented in this article can contribute to a policy that is better adapted to the regional differences and current dynamics in open space. Since open space is a product of activities and lifestyles, reflecting a society that is subject to change, these transformations cannot be reversed, but can be steered towards a desired regime.

1. Introduction

Under the influence of urbanization, the open space in Western Europe is undergoing a number of fundamental changes. In this study, ‘open space’ is defined as all areas outside of cities or town centres. This was archetypically an open, monofunctional area used for production agriculture, forests and nature. Due to an external urbanization pressure, in combination with internal changes, the agricultural front seems to be losing power in the political struggle for land (Kühn, 2003; Busck et al., 2008). This allows urban centres to expand into open space and urban fragments to be scattered across the open space, systematically decreasing open space and fundamentally changing the structure of the remaining open space. This creates a complex, fragmented structure with besides the traditional open space users, several non-archetypical functions (such as housing, work and recreation).

Antrop (2004: 10) defines urbanization as a ‘complex process of change of rural lifestyles into urban ones’. Also Madsen et al. (2010: 48) indicate that ‘urbanization is not only a matter of land use change, but also a matter of functional and lifestyle changes, which may or may not manifest themselves as physical changes in built-up areas and land use.’ These definitions indicate that research on urbanization should not merely focus on spatial patterns, but also on functional changes - the driving forces behind morphological transformations -, which are fundamental to the analysis and the understanding of the urbanization process.

The condition of the Flemish countryside has been discussed a lot in recent years, in particular concerning the disappearing contrast between city and countryside. Many authors agree that ‘city’ and ‘countryside’ are archetypes that no longer exist in Flanders (De Meulder et al., 1999; Xaveer De Geyter Architecten, 2002; Van Eetvelde en Antrop, 2005; Thomas et al., 2008). Elements of these two archetypes can be found scattered and fragmented across the Flemish landscape.

The article addresses four functional transformations in Flanders' open space: (a) the increasing residential use, (b) the economic diversification, (c) the increasing private use, and (d) the increasing recreational (shared) use. These functional transformations introduce new, non-archetypical functions in open space, reflecting its urbanization. Most of these transformations are widely recognized and have (recently) been studied individually and independently (Leinfelder, 2007; Bomans et al., 2009; Verbeek et al., 2011; Dewaelheyns et al, 2008; Verhoeve et al , 2012). However, a spatially integrated approach, that considers not just one individual phenomenon, but focuses on open space as a whole, is missing. Given the scarcity of open space in Flanders, its limited carrying capacity and the high pressure on open space for further urbanization, insights into the current state of open space as a whole are nevertheless relevant.

In order to assess at what point this carrying capacity is exceeded, it is important to have an insight into the different aspects of the combined impact of these transformations on open space. This is especially relevant in the context of a policy oriented toward preserving and protecting the remaining open space. This article argues that the non-archetypical uses of open space have a fundamental impact on the morphology, the use and the meaning of open space. Their strongly individual, demand-oriented and autonomous character strengthens their spatial impact. In most cases, these new functions mark the transition of the archetype of open space to a new kind of (urbanized) open space.

The article first places the four selected transformations in their socio-cultural context, followed by a mapping of the new land uses via a terrain study in 27 case areas across nine municipalities with different characteristics, which allows an estimation of how much open space they take up. Through the terrain study results and map analysis, complemented by literature review, the impact of these new land uses on open space is assessed. More specifically, the effects on the morphology (physical), the dynamics (functional) and the symbolical meaning (the cultural values) of open space are considered. These form the core of the transition open space is undergoing due to urbanization. Finally, some reflections are made on the state and future of open space in an urbanized context.

2. Analysis

2.1 Study area Flanders

Flanders, the northern administrative region of federal Belgium and a small part of polycentric North-West Europe, is one of the larger urban regions in Western Europe with the most visible impact of urban sprawl[2] (Albrechts and Lievois, 2004; EEA,

[2] The other urbanized regions are London (United Kingdom), Paris (France), Milan (Italy), Rhine-Mainz and Rhine-Ruhr (Germany), and Randstad (the Netherlands).

2006). With a population density of 447 inhabitants per km² in 2007, it is one of the most densely built and inhabited, and economically active regions in Europe.

Within Flanders, the traditional boundaries between city center and suburbs, city and countryside, and residential and rural areas have faded. Only 10% of Flanders is defined as rural according to the OECD criterion (150 inhabitants per km² at basis district level (municipalities)). Kesteloot (2003) has determined that approximately 70% of the Flemish population resides in an 'urban complex' - an area characterized by suburbanization and by inhabitants commuting to and from urban agglomerations. In contrast, only 10% of the Flemish population lives in truly urban centers. Although the majority resides in a suburban environment, Cabus (2001) estimates that 76% of Flanders still remains open.

2.2 Literature review

Based on a literature review of current dynamics in Flanders' open space and reoccurring themes in research, in combination with previous research experiences, four functional transformations are selected, defined and placed in their sociocultural context. This analysis of driving forces contributes to a better insight into the current dynamics in Flanders' open space.

2.3 Case study, terrain mapping and impact analysis

For the majority of the selected phenomena, reliable and directly usable data on a Flemish scale are lacking. Dewaelheyns et al. (2008), Bomans et al. (2010) and Verhoeve et al. (2012) also emphasize this lack of data. This makes it impossible to study these phenomena on a generalized Flemish scale or to map evolutions over time. Therefore, it is chosen to detect these phenomena through an empirical terrain study in 27 study areas, across nine municipalities.

2.3.1 Open space

As mentioned before, open space is defined on a macro scale as all areas outside of cities or town centers. According to the definition by the National Institute for Statistics[3], 25.5% of Flanders consists of residential centers and 74.5% is open space, while according to TeleAtlas' definition of the built-up centres[4], 84.5% of Flanders can be considered open space.

2.3.2 Case study area

Nine municipalities, spatially distributed over Flanders, were examined. These were selected based on an earlier research project on mixed land use in Flanders,

[3] The statistical sectors are the base unit for the compilation and distribution of statistics. Their delineation is based on social, economic, urbanistic or morphological structural characteristics.
[4] TeleAtlas is a private digital mapping and navigation company. Their definition of the built-up centres is based on aerial photography.

distinguishing different spatial typologies (Leinfelder and Pisman, 2008). Eight of the selected municipalities form pairs with similar open space and urbanization characteristics. A ninth, little urbanized municipality was added as a reference[5].

Figure 1 shows their location on a building density map of Flanders.

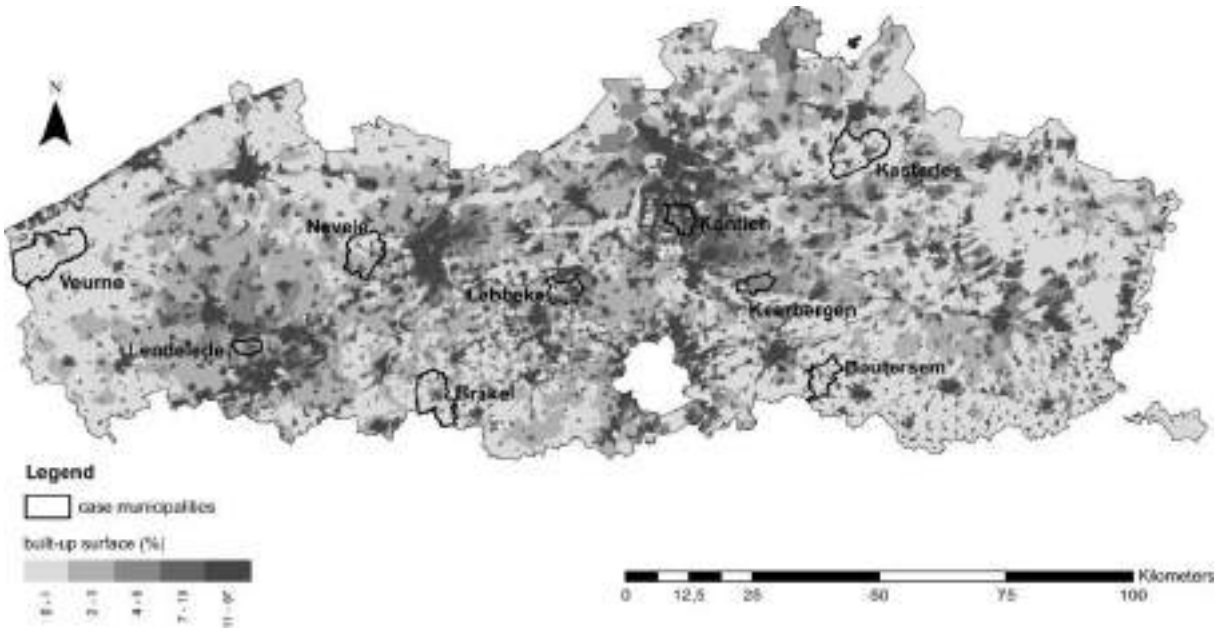

Figure 1. Location case municipalities on a building density map of Flanders (data: cadastral plan (CADMAP), 2009)

Per municipality three strongly different study areas were selected, to make the diversity of phenomena as big as possible:

- an area with a (possible) privatization pressure,
- an area with a (possible) recreation pressure, and
- a reference area, where production agriculture is still dominant.

Their selection was based - as far as possible - on the information in the respective municipal spatial structure plan.

The precise demarcation of the study areas was made by infrastructure lines, mostly roads and railways, to enable a clear parcel wise registration of the phenomena. The assumed size of a study area is approximately 200 ha, so that on average 600 ha is studied in each municipality. In smaller, highly urbanized municipalities the selected micro study areas are smaller (approx. 150 ha).

[5] The nine selected municipalities are (1) Veurne (low-dynamic open space under specific coastal recreational pressure); (2) Boutersem and (3) Nevele (low-dynamic open space under commuting pressure); (4) Brakel and (5) Kasterlee (dynamic open space under recreational pressure); (6) Keerbergen and (7) Lebbeke (dynamic open space in a suburban field); and (8) Kontich and (9) Lendelede (high-dynamic open space in an urban network).

2.3.3 Mapping methodology: terrain registrations

In these study areas terrain registrations were executed in the period 2008-2011. These consisted in the onsite registration of the selected phenomena, as far as possible at parcel level. For residential use (housing), non-agrarian economic activities and private use, the individual phenomena could be registered directly at parcel level. Recreational use on the other hand is mostly a form of shared use of space and volatile in nature, making it impossible to register the recreational use itself. Therefore, this phenomenon was operationalized by mapping recreational infrastructure elements as indications of recreational use. This resulted in the following categories and subdivisions of non-archetypical open space users which were mapped in the terrain study (see also Table 1):

- non-agrarian buildings: all buildings that have no link with productive agriculture and are thus 'new' users of open space, including their plot (buildings that are part of recreational attraction poles (such as restaurants and cafeterias and changing rooms of sports facilities) are not included here):
    - houses (a);
    - non-agrarian businesses (including associated housing facilities) (b): small and large scale commercial and manufacturing companies;
    - other (x): e.g. schools, public community centers, care homes, …
- non-archetypically used unbuilt space
    - privately used land (unbuilt) (c):
        - hobby pastures: all pastures that are used for hobby farming (mostly horses);
        - other privately used land: all other phenomena of private land use, like private woods, fishponds and scattered vegetable gardens;
    - indications of recreational use (d):
        - signposts: all forms of recreational signposting, generally linked to recreational networks;
        - recreational tracks: line-shaped structures that are clearly set up for or adapted to the needs of recreational users, like mountain bike and horse riding trails;
        - recreational attraction poles: all kinds of establishments that have a crowd pulling, recreational character, like restaurants, sports fields and riding schools;
        - public small-scale infrastructural elements: e.g. benches, information panels, bins.
    - other (x): e.g. utilities, …

If there was no clear indication of a certain activity, these activities were not registered, simply because these activities were 'invisible'. Therefore, the terrain registrations are an underestimation of reality. The invisibility of some activities (e.g. empty hobby pastures) may be related to the limiations of a one-time registration. In other cases (e.g. small businesses without signes), the activities taking place are

latent. In the context of a study on the spatial extent and impact however, these latent activities are less relevant, because they don't have a (significant) impact (yet). Nevertheless, they can grow out to be manifest activities, with a visible spatial impact.

Table 1. Overview of the elements that were registered in the terrain mapping

FUNCTION	REGISTERED ELEMENTS
(a) residential use	houses (+ parcel)
(b) non-agrarian businesses	non-agrarian businesses (+ parcel)
(c) private use	hobby pastures other privately used land
(d) recreational use	signposts recreational tracks recreational attraction poles public small-scale infrastructure elements
(x) other	other non-agrarian buildings other non-archetypical use (unbuilt)

Figure 2. Example of a digitalized terrain mapping in Brakel

Further processing of the terrain mappings took place in a GIS environment, making further analysis and calculations possible, as well as a convenient cartographic representation. For the digitalization of the terrain registration in GIS, digital aerial views[6] and cadastral plans[7] were used. This facilitated a detailed digitalization and made it possible to add some cases that were not visible on the terrain.

[6] OC_Gis Vlaanderen, 2003 and Google Maps, 2009
[7] Kadvec, 2005 and CADMAP, 2009

2.3.4 Extent and impact analysis

The different new uses were analyzed both quantitatively and qualitatively. Based on the terrain study mappings in GIS, a quantitative assessment of the spatial extent of the four new land uses was made. The qualitative evaluation of the spatial impact[8] was based on the fieldwork, map analysis and literature study.

3. Results

3.1 Four functional transformations in Flanders' open space

The increase in built-up density is generally seen as the core of the urbanization process and the main indicator for urbanization. However, literature review has indicated that there are also a number of transformations which are related to a different use of the existing structure, both built and unbuilt. These do not cause an increase in built-up density, but are nevertheless an expression of an urban lifestyle.

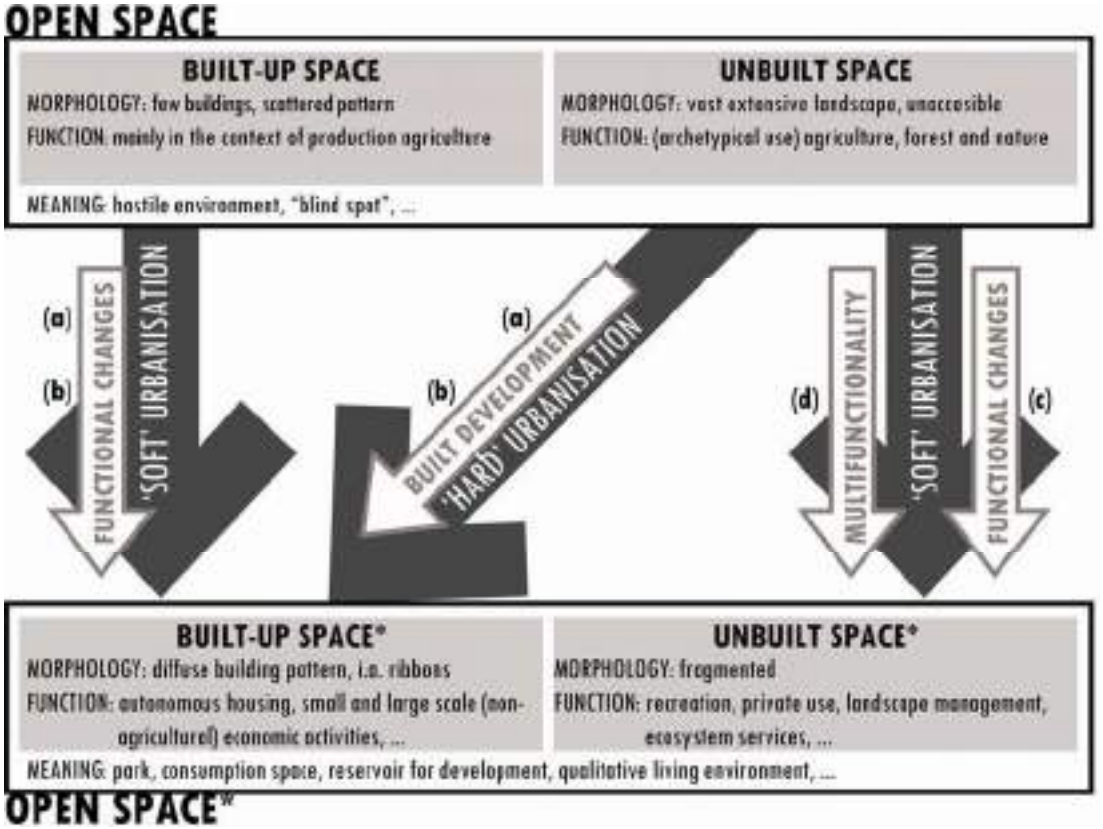

Figure 3. Schematic representation of the spatial transition open space is undergoing due to urbanization, with the indication of (a) residential use, (b) non-agrarian businesses, (c) private use and (d) recreational use

[8] Undoubtedly, these phenomena also have a certain ecological, economic, ... impact. However, these aspects are beyond the scope of this study.

Therefore, two types of spatial transformations can be distinguished within the urbanization process (Figure 3): hard urbanization, increasing the built-up density, and soft urbanization, functionally changing the existing built-up and unbuilt space from within. These are characteristic to the spatial transition that open space is undergoing due to urbanization.

3.1.1 Increasing residential use

One of the most important functional shifts in open space is the increasing use for housing. Flanders has a fragmented settlement pattern, with a lot of small housing concentrations spread out in its open space. Due to demographic growth, but also the shrinking size of families, the demand for housing is still high. Also the individual living space has grown dramatically as a result of increasing prosperity. Due to the creation of free time and the trend toward individualization, people spend more time in their home environment and more money on its design.

Figure 4. Examples of living in open space

On the other hand, there is a general preference for rural residential areas in Flanders (Verhetsel et al., 2003; Vanneste et al., 2007). This is linked to the rural idyll, the positive image of the countryside that urbanites have (Cloke and Milbourne, 1992). Also, higher travel speeds and lower travel costs have made living in open space technically and organizationally easier. Therefore, living on the countryside has evolved from a necessity to a choice.

Under the influence of a housing policy that is (historically) focused on dispersion and individual, detached housing, and a tolerant spatial policy, one tenth of the new households ends up in open space. Nevertheless, the household density in (residential) centers still increases relatively faster than in open space[9].

3.1.2 Economic diversification

As a part of the urbanization process, the agricultural production area has transformed into a diffuse field of different types of economic activities. Because of the decrease of the economic importance of production agriculture throughout the

[9] 6.8% increase of the household density in open space versus 9.1% in residential centers (period 1997-2007, based on the definition of residential centers by the Directorate General Statistics and Economic Information).

last century, space was created for other types of activities (Van den Bout and Ziegler, 2003; van der Wouden en van Dam, 2006). On the other hand, companies are becoming more and more footloose due to tertiarization and the knowledge economy, in combination with an increasing mobility, telecommunication and virtualization, also known as the emergence of the network society (Boudry et al., 2003). Furthermore, an integrated spatial policy for (small) economic activities is lacking, allowing these activities to settle in open space.

Figure 5. Examples of economic diversification in open space

This diversification of economic activities in rural areas is an irreversible dynamic with strong spatial and economic consequences (Verhoeve et al., 2012). Research has shown that most of these non-agrarian companies are active in the tertiary sector (mainly professions and other services) and are relatively young, indicating that this is a very recent dynamic. However, there is little known about the spatial reality of this economic diversification, both scientifically and politically.

3.1.3 Increasing private use

As a consequence of residential development, the surrounding (unbuilt) space is more and more incorporated in the private sphere, in the form of garden extensions, hobby pastures, weekend houses, private fishponds, private forests, etc. These types of land use are more private than the archetypical functions, such as agriculture and nature, in the sense that they no longer serve society, but an individual. They are also visually, physically and mentally linked with the private sphere because of their restricted accessibility and often strong enclosure. Because of this evolution, open space no longer has the character of a common place, but is becoming a patchwork of private enclaves.

Dewaelheyns et al. (2008) state that 8.2% of the Flemish territory consists of private gardens, and most of these gardens occupy former agricultural land. Bomans et al. (2009) conclude that 5.1% of Flanders, or 40% of all pastures, is occupied by horse pastures. These numbers illustrate the importance of this widespread phenomenon and the pressure it exerts on production agriculture.

These new land uses are part of the broad societal evolution towards individualization, which can be spatially translated into the concepts of privatization

and capsularization (De Cauter, 2005). Human activity moves from public to private space, which is isolated and directed inward. This use of open space is driven by lifestyle preferences instead of production needs, annexing open space as an extension of the living environment (Madsen et al., 2010).

Figure 6. Examples of private use in open space

3.1.4 Increasing recreational use

Opposed to the increasing private appropriation of open space, there are a number of processes that make the open space more accessible, introduce new meeting places and supply a multiple land use, mainly in the field of recreation (Leinfelder, 2007). In the past open space was situated only in cities and public space policy was mainly oriented towards central urban locations. Due to a scaling-up of urbanization processes, changes in leisure spending and fundamental transformations in the social-economic relations, public space is not exclusively an urban phenomenon anymore (Hemel and Van Uum, 1999) and the central public space loses its prominent role as meeting place and place of exchange (Sennet, 1997). A new (thinner) form of public life is emerging, giving public space a new meaning and making it appear at new places (Nio, 2001). Open space gradually fulfils a role as 'new' public space, an 'urban park'. It is more and more a shared space, consumed and experienced as a leisure space for urbanites (Van der Ploeg, 2001).

Figure 7. Examples of recreational (shared) use of open space

3.2 The extent of new uses of open space

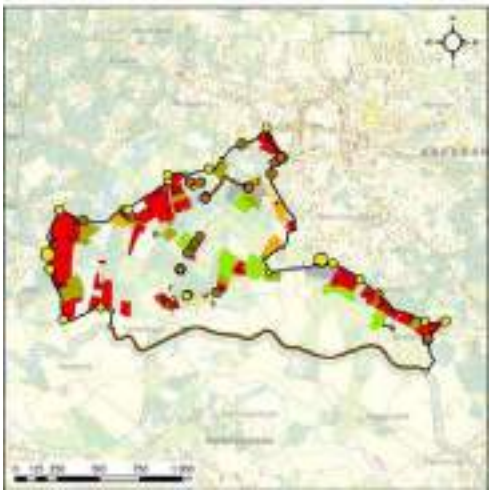
Table 2 gives an overview of the portions of the study areas used for the different non-archetypical land uses that were mapped in the terrain study. More than a fifth of

the whole study area is occupied by non-archetypical open space functions[10], of which the vast majority consists of the four selected functions. Of the total area of non-archetypical open space uses, about half consists of unbuilt parcels. Residential and private use are the most important non-archetypical open space uses in terms of surface, with each a surface of about 10% of the total study area. Non-agrarian businesses and recreational use each take up about 1% of the study area.

Table 2. Overview of the portion of the study area that is occupied by the different non-archetypical functions in open space for (a) the least urbanized study area (Veurne, Lovaart), (b) all 27 study areas, and (c) the most urbanized study area (Kontich, Broekbos)

SURFACE (%)	(A) LEAST URBANIZED	(B) ALL STUDY AREAS	(C) MOST URBANIZED
TOTAL	1,2%	22,4%	57,7%
built-up parcels	**0,7**	**11,3**	**24,5**
(a) residential use	0,5	10,3	21,5
(b) non-agrarian businesses	0,2	0,9	3,0
(x) other	0,0	0,1	0,0
unbuilt parcels	**0,5**	**11,1**	**33,2**
(c) private use	0,5	10,2	30,1
- hobby pastures	0,5	6,3	13,2
- other privately used parcels	0,0	3,8	16,9
(d) recreational use	0,0	0,7	3,1
(x) other	0,0	0,2	0,0

(a)



(b)

[10] For comparison, 10% of Flanders is taken up by forests (VBV, 2009), 2,5% by nature and forest reserves (INBO, 2007) and 46% by agriculture (AGIV, 2008). However, an overlap between these classes of archetypical land use and the non-archetypical land use classes of the case study is possible (e.g. a private forest).

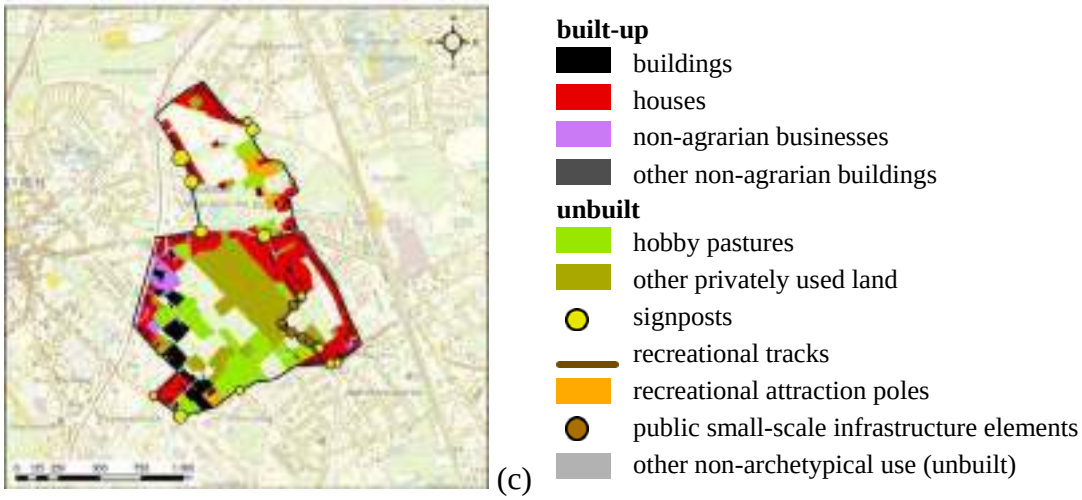


Figure 8. Terrain study results in three micro study areas: (a) the least urbanized study area (Veurne, Lovaart), (b) an average urbanized study area (Keerbergen, Broekelei), and (c) the most urbanized study area (Kontich, Broekbos)

The figures of the least and the most urbanized study area indicate that there are strong variations within Flanders regarding urbanization[11]. It is striking that almost all phenomena are found in each study area, even the least urbanized ones. This confirms that the new uses occur very widespread in the Flemish open space.

3.3 Spatial effects of new uses of open space

The discussed new land uses have an impact on the morphology, the function and the meaning of open space. In what follows, the combined impact of the four functional transformations is described.

3.3.1 Morphology

The physical-morphological impact of the new uses of open space covers many aspects. First of all, residential use and the non-agrarian businesses are the main driving factors for the increasing built-up density in open space, a classic indicator for urbanization. The growing claim of the various new functions of open space creates an expansion pressure, at the expense of archetypical open space uses. Moreover, the presence of buildings is a pull factor for new built development. This may lead to the conversion of open space into (residential) developments with a low density, and thus the loss of open space.

The urbanization process also has a morphological impact on the unbuilt space. This concerns not only gardens around houses or the space directly surrounding non-

[11] The spatial differentiation is - among other things - related to the spatial distribution of a number of factors of attraction. However, this is not addressed in this article. For this aspect we refer to the final report of the research (Tempels et al., 2012).

agrarian businesses, but also completely unbuilt parcels, such as garden extensions, vegetable gardens and hobby pastures. The morphological impact of this unbuilt urbanized space is limited, but not non-existent. Although no buildings are added, all other morphological aspects (parcel size, enclosure, vegetation, …) undergo major changes.

Figure 9. Built-up and unbuilt non-archetypical uses of open space: (a) non-agrarian business (metal trade) in Lendelede (Spoelewielen), (b) private use (isolated vegetable garden) in Kasterlee (Tielenbroek)

The diversity and the individual character of the new uses lead to changes in the open space design. Due to the lack of a (legal) framework, the urbanized open space follows its own logic, which is fundamentally different than that of agricultural land or nature areas. This logic is based on a unilateral (consumption) relationship, where the new users benefit from the qualities of a rural environment, but create little added value for that environment themselves. For example, many houses are private enclaves that are poorly integrated into the landscape, privately used parcels often have hard borders (both physically and visually) and non-agrarian companies sometimes pay little attention to the design of their plot. As a result, regional landscape characteristics are lost. It is however impossible to define a general rule. The visual impact is different for each individual case, ranging from virtually no to a very strong impact, both positive and negative.

Figure 10. Strongly individual and private character of the non-archetypical uses of open space: (a) private use (garden extension) in Boutersem (Kerkom), (b) residential use (houses and gardens) in Boutersem (Kerkom) and (c) private use (horse pasture) in Keerbergen (Heikant)

For soft urbanization, the morphological impact is rather limited, because no greenfields are developed. Recreation for example mainly uses existing infrastructure, with the addition of a number of small infrastructural elements, such as paths, benches and trash cans. Also for functional changes, such as the conversion of farms into housing or non-agrarian businesses, the intervention is limited to modifications to the building in the surrounding space, although the impact of these interventions can be important.

The increasing number of functions and uses requires an increasingly better physical accessibility of open space. The combination of a dense infrastructure network, a high building density and a small average parcel size with strongly defined and demarcated boundaries lead to a highly fragmented open space. From an ecological, economic and spatial perspective, this is often seen as a negative evolution.

Figure 11. Fragmentation due to ribbon development: (a) Lebbeke (Poelstraat), (b) Boutersem (Velperbos)

3.3.2 Function

This research focuses on four new, non-archetypical uses of open space. Obviously, the introduction of these functions themselves, and the dynamics they cause, are the most fundamental impact on the functioning of open space. These functions are in fact connected within a larger structure, each adding a new layer to open space in which goods and people move. For recreational use for example, this impact is much more important than the physical-morphological impact.

Figure 12. New layers of use in open space: (a) recreational shared use in Veurne (Lovaart), (b) non-agrarian business (insurance office) in Lendelede (Spoelewielen)

Also a number of secondary effects can be noticed, that originate from the relation between the transformations. Non-agrarian businesses, private use and

recreational use are inherently connected to the residential function, making living in open space an important catalyst for the whole urbanization process. Further, living, working and recreating in open space induce a diffuse movement pattern, which may lead to further spatial distribution of (urban) functions.

3.3.3 Meaning

As a result of the functional changes in open space, also its significance and meaning change. While the archetypical open space serves the common interest, these new functions each project their own individual desires on open space, nourishing the perception that open space is a reservoir of 'empty', developable space. Open space is seen as a qualitative living environment, as available space for (economic) development and production, as an attractive landscape for consumption, … Its significance is each time different, from an inaccessible, private space that can be individually appropriated, to a common place with a strong public character, from a series of private enclaves to a public attraction pole, and from a production space to a place for consumption. Because of these strong diversity of functions and meanings, open space is no longer complementary to the city, but rather a diluted version of the city.

Figure 13. Image of the (a) least urbanized study area (Veurne, Lovaart), and (b) the most urbanized study area (Kontich, Broekbos)

3.4 Typology of urbanized open space

The case study also shows that within the defined types of spatial transformations (hard and soft urbanization), the non-archetypical uses often occur together (Table 3). The economic diversification is strongly related to residential use, given that non-agrarian businesses often operate from the home environment. Although private and recreational (public) use appear to be contradictory, also a spatial relation can be noted. Where privatization uses whole parcels, closing them off, public use uses the (road) infrastructure between them. In this respect they are spatially complementary.

Table 3. Extent of the different non-archetypical functions[12] in open space for the different case municipalities.

	Veurne	Nevele	Brakel	Kaster-lee	Lende-lede	Bouter-sem	Keer-bergen	Lebbe-ke	Kon-tich
(a) residential used (%)	1,2% --	6,7% --	11,9% -	6,1% --	7,7% -	12,2% +	24,6% ++	14,6% ++	12,7% +
(b) non-agrarian businesses (number/km²)	0,5 --	1,3 --	2,2 -	1,2 --	8,0 ++	4,9 +	3,3 +	7,4 ++	2,7 -
(c) private use (%)	1,6% --	9,2% -	7,3% --	16,3% ++	7,3% --	8,3% -	14,1% +	10,3% +	21,1% ++
(d) recreational use (indicator)	11,5 --	18,3 --	40,4 ++	29,7 -	22,3 --	37,6 +	41,5 ++	33,9 +	25,6 -

The extent of the different non-archetypical uses of open space is determinant for the new regime open space is shifting into. Throughout the different case municipalities, it appears that there are four types of open space in respect to the urbanization phenomena. These originate from the varying relationship between hard and soft urbanization.

The two extremes are the highly urbanized regions (hard and soft urbanization; Keerbergen, Lebbeke, Kontich and Boutersem) and archetypical open space (little urbanization; Veurne and Nevele). In addition to these two obvious types, two different types in the middle spectrum can be distinguished: areas with only hard urbanization (Lendelede) and areas with only soft urbanization (Brakel and Kasterlee). In the areas with only hard urbanization, a high building density is combined with the use of the remaining open space for production agriculture. The open space with only soft urbanization on the other hand, is mainly used by visitors of urban space further away.

4. Conclusions

This paper has demonstrated the diversity and the great extent of urbanization in Flanders. The four selected non-archetypical uses of open space (residential use, non-agrarian businesses, private use and recreational use) take place in both the built and the unbuilt parts of open space and are all current and important phenomena in Flanders' open space. These phenomena take up more than a fifth of the case study area and even in the least urbanized areas, virtually all of these phenomena are present. These developments are on the edge or outside of the policy framework, causing them to be strongly autonomous. The fact that these phenomena are structured by supply (availability of open space, for example due to the decline of

[12] Since the recreational use could not fully be expressed by a surface, an indicator was used. This indicator represents the number of elements (signposts, recreational tracks, recreational attraction poles and public small-scale infrastructural elements), weighed in accordance to their importance (respectively the factors 1, 3, 3, 2) and divided by the surface of the study area (in km²).

agriculture) and demand (driving forces) contributes to their wide distribution and great extent.

The impact of the four new uses fundamentally affects all aspects of open space: its morphology, its functioning and its meaning. Although some new functions are less important in terms of land use, they can cause important dynamics. Therefore, these also have an impact on open space.

It is clear that attention is needed for these widespread but underrated new uses of open space, especially from a policy perspective. The transition described in this article proves that in large parts of Flanders archetypical open space no longer exists. In these areas, quality can only be generated if policy is no longer aimed at the protection and preservation of archetypical open space, but acknowledges this new context and responds to these new needs, new perceptions, …

Monitoring is in this respect an important first step. The lack of knowledge about these changes is an obstacle in the development of a vision on these changes. Monitoring however is not evident, since many of these changes are latent and are hard or impossible to map on a large scale. In addition, their impact on for example the functioning of open space is very difficult to capture (quantitatively).

Subsequently the question arises whether these changes are desirable. This is a difficult discussion and opinions will differ. The carrying capacity of open space cannot be defined universally, but depends on the capacities and characteristics of open space in relation to the specific functions it needs to fulfil. In order to estimate this carrying capacity, it must be determined what is expected of open space and according to which priorities.

Hereby a comparative assesment should be made of the individual demand (housing, gardens, ...) and the public interest (water management, nature preservation, ...). Most new developments in open space have a very strong individual and private character. Given the high pressure on open space, ways of combining these two seemingly opposite interests should be found. Due to the lack of embedding of for example the economic diversification, the open space often doesn’t benefit from the advantages and a certain potential remains untapped. This contributes to the conservative attitude toward these new developments.

Anyhow, these transformations reflect a societal change that is irreversible and seems unstoppable. Therefore, the question might not be whether these transformations are good or bad, but rather how they can be controlled and be integrated in open space in a suitable, judicious way. This assessment should deal positively and creatively with the urbanized context. Urbanization is often seen as a negative evolution, especially from the open space perspective. However, it should be taken into account that this evolution is the expression of a rapidly changing society. The type of open space that often spontaneously develops in Flanders - multifunctional, dynamic and versatile - resembles in some respects very much

visionary urban greenbelt models from the last century (in which this belt was sometimes even seen as a field). Consequently, the observed evolution can also be seen as a natural and necessary adaptation to a new context, since the archetypical open space cannot survive in an urbanized society.

Strategies are needed that start from the qualities and the potential of open space. In an urbanized context, where production agriculture stands little chance, private and recreational use can for example be used to protect open space for built development. Also the economic diversification brings about investment dynamics, of which open space does not (yet) benefit. From this perspective, the changes in open space are not seen as a threat, but rather as an opportunity. In this context the issues in open space are not so much related to the strong change per se, but rather the fact that it is happening unnoticed and strongly autonomous, causing opportunities to be missed.

5. Acknowledgements

The discussed methodology and results are part of a research carried out in the period 2007-2012 by the Center for Mobility and Spatial Planning of Ghent University, funded by the Flemish Policy Research Centre on Space and Housing.

CAPITALIZING ON SPACE PLACE AND LOCATION
THE CASE OF REGENERATING NUREMBERG WEST

Nadia Alaily-Mattar[1], Alain Thierstein[2], Agnes Förster[3]

Abstract

Numerous cities, in which industrialization had been the main stimulus for urban agglomeration, are experiencing urban decline. As the tide of industrial urbanization is ebbing, Nuremberg West (NW) is one such area in the State of Bavaria, Germany. Once the birthplace of Germany's first railroad between Nuremberg and Fürth, NW features today an oversupply of abandoned industrial space, which is coupled with low demand. The area features a disconnected and fractured urban fabric; it is a set aside and increasingly stigmatized area in transition. If the situation is kept unaddressed, the urban transformation process will likely bring redundancy and economic obsolescence to NW.

As public funds are diminishing, public authorities have an interest in sustaining the capital stock of cities. NW with its sunk-capital intensive infrastructure can surely be of added value if it is properly utilized than if it is left to decay. However, while the physical transformation is the most visual and, perhaps, apparently immediate task, the challenge for cities like Nuremberg is far greater than merely restoring the left behind debris of de-industrialization. Rather, the challenge is to find new rationale(s) for "being" and to set up mechanisms that work to replace the economic rationale that has been lost. This task is not simple, on the one hand, the success of cities today presumes connectivity to global networks of economic activities, in which bits and piece of goods and services are produced, assembled and consumed globally. On the other hand, cities continue to have a regional and everyday life dimension in which people are grounded as they socialize, study, and play, grow old, and get sick, etcetera. Area-based regeneration approaches often get lost within this two-tiered expectation, one emanating from local considerations and expectations and the other from considerations that are outside of the area proper. Frequently one expectation is addressed to the detriment of the other.

This paper presents the research methodology that the Chair for Spatial Development has devised to propose innovative, creative, politically unrestrained and impact oriented transformation possibilities for NW, set purposefully at the sufficient temporal distance of the year 2050.

We propose a framework for identifying way(s) forward in area-based-approaches. Our framework takes into consideration (1) the different scales at which NW contributes in terms of functions and in return is exposed to impacts in terms of trends, namely local, metropolitan, regional and global, and (2) different perceptions of NW, as an object of analysis, which is simultaneously a *place* with meaning and socio-cultural attributes, a *location* anchored in a particular geographic setting and part of *spaces* of flows that transcend its administrative and morphological boundaries. We elaborate on our notion of impact-oriented interventions. We argue that area-based interventions and their associated impact might not necessarily be congruent in time and scale.

1. Introduction

Numerous cities, in which industrialization had been the main stimulus for urban agglomeration, are experiencing urban decline. As the tide of industrial urbanization is ebbing, Nuremberg West (NW) is one such area in the State of Bavaria, Germany (Figure 1). Once the birthplace of Germany's first railroad between Nuremberg and Fürth, NW features today an oversupply of abandoned industrial space, which is coupled with low demand. The area features a disconnected and fractured urban fabric; it is a set aside and increasingly stigmatized area in transition. If the situation is kept unaddressed, the structural transformation process will likely bring redundancy and decay to NW, a situation in which the externalities of decay would have far reaching impacts on Nuremberg at large.

The Municipality of Nuremberg has acknowledged the precariousness of the situation and has commissioned a number of studies with the purpose of identifying intervention possibilities. In a parallel track, the municipality has commissioned the Centre for Energy Efficient and Sustainable Design and Building (ENPB) of TUM with a research project, titled, "Stadtlabor Nuernberger Weststadt", whose mission is to propose ideas for the transformation of NW under the guiding theme of sustainable urban development. The ENPB has assembled an interdisciplinary team at the TUM, to work on this task. Among the interdisciplinary team, is the Chair for Spatial Development, where the authors of this paper work.

Figure 1. Location of Nuremberg in Germany

This paper presents the research methodology that the Chair for Spatial Development has devised in order to address structural transformation of NW. We define structural transformation

as the visible, profound and severe change of the share of the different sectors in the economy;– As opposed to a smooth, continuous change, this type of change alters the structure of the economy, the locational behaviour of firms and the workforce, and has widespread effects on the structure of society. Structural transformation is propelled by technological development, increased global competition, financial deregulation and the growing deregulation of global labour markets. As foreign labour markets become more competitive, NW as a location for industries has lost competitive advantage. Industries located in NW have been either forced to close or to move elsewhere where the conditions for industrial production are more favorable.

Our methodology is based on the premise that as *spatial* transformation lags behind *structural* transformation, NW today captures a mismatch between, on the one hand, the spatial capacities of NW based on what NW once was and, on the other hand, the role that NW is playing today[i]. In the context of role vacuum and lack of alternative futures, this mismatch cements associations of loss and nostalgia. Such a context demands interventions of strategic nature that look forward towards the future rather than lament the past. Interventions that are not committed to steering change fall into the trap of becoming city beautification. Palliative interventions are assumed to be preparing NW to many potential futures while, indeed, these interventions are just stalling the process of structural change. Our methodology is based on the belief that while the future is uncertain, proactive steps can and must be taken to shape it. Hence, we argue that the goal of interventions is to steer *spatial* transformation rather than an all-sweep "cleaning up" of the area. Selectivity, prioritization and specificity of interventions are crucial in this regard. We define spatial transformation as one that goes beyond the physical/morphological transformation of space to encompass also aspects related to functions and processes. Indeed, spatial transformation is about the transformation of the intricate multi-scalar workings of morphologies, functions and processes. .

In what follows, we first discuss the different conceptions of NW as an object of analysis and intervention that is as an area *of* and *in* transformation. Second, we lay down the working definitions of key concepts of space, place and location. Third, we elaborate on the challenges of planning in the context of change and highlight the peculiarity of area-based regeneration. We then elaborate on the notion of impact-oriented interventions. We argue that area-based interventions and their associated impact might not necessarily be congruent in time and scale. Fourth, we propose our methodology for identifying way(s) forward in area-based-approaches. Identifying evidence-based future alternatives for NW based on SWOT analysis is the keystone of our methodology. Our SWOT analysis is disciplined by the different perspectives of NW and includes various scales. We show how OT's can be derived from the analysis of trends.

Finally, we conclude that in order to steer the transformation process, spatial interventions must surpass addressing the negative symptoms of structural transformation as manifested through fragmented urban fabrics and decayed architecture. Rather spatial interventions must be geared at addressing the *spatial* transformation of the area in question.

2. Conceptions of NW as an area *of* and *in* transformation

A newspaper headline in the local Nuremberger Abendzeitung (2012) titles "Deputy mayor for economic affairs dreams of Masdar city in Abu Dhabi as a role model for NW".[ii] The Masdar

city allegory is ill conceived for many reasons, disproportionality of financial capacities of the municipality, investors, intuitional context, social context etc…. However, this reference to Masdar city is an indication of the potential view at NW as an object that can emulate an *other* object, one that can be packaged for development, marketing, commodification and other purposes. This view is frequently the case, when an area is *declared*, usually by a plan-making agency, as fit for regeneration; the term area-based regeneration, carries such connotation. Indeed, the declaration of an area, such as NW, as a base for regeneration focuses the attention of analysis and restricts intervention.

The objectification of NW is a hypothetical exercise and useful only for the purposes of temporarily drawing attention to a certain area in the city. Indeed, NW, as an object, is only conceived as such within the confines of this study. NW is neither an administrative entity, nor is it perceived or lived as such- to use Lefebvre's well-known triad of lived, perceived and conceived space (Lefebvre, 1991). The acknowledgement that NW is a temporarily and artificially conceived object, one that is not congruent with a perceived and lived dimension, forms the basis of our methodology. In addition, we distinguish between two conceptions of NW, as a hypothetical object, namely, first as an object of analysis and second as an object/area of intervention (Figure 2).

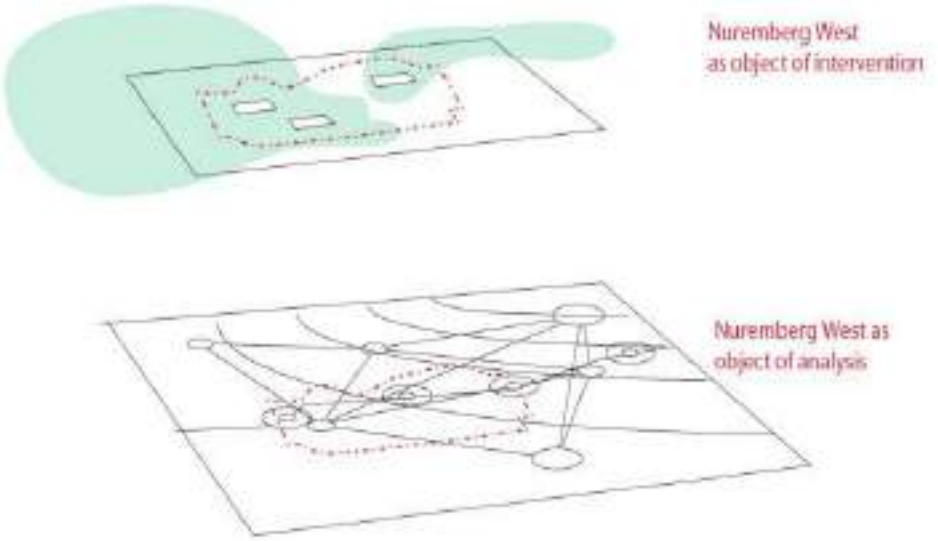

Figure 2. Nuremberg West as an object *of* and *in* transformation

First, as an object of analysis, NW is an area *of* structural transformation whose drivers emanate elsewhere. Globalization, ICT's, economic restructuring etc… are all factors onto which stakeholders of NW have no immediate agency. Nevertheless, as we analyze the problematics of NW it is precisely these outside factors that are identified as the root causes of structural transformation. Lest, the artificiality of conceived NW and the mismatch between its objectification and the lived and perceived reality haunts us we analyze NW by taking into consideration (1) its contribution and impact, at different scales, and (2) the different perceptions of NW, namely, as a *place* with meaning and socio-cultural attributes, a *location* anchored in a particular geographic setting and part of *spaces* of flows that transcend its administrative and morphological boundaries. The objective of analysis in classical spatial planning is to identify

change-induced spatial problems, in order to assess intervention requirements to alleviate spatial problems. The objective of our analysis is to identify the levers for steering change through spatial interventions. We hence shift focus from the spatial outcome of change associated with loss to the spatial prerequisite of change associated with the promise of gain.

Second, as an area of intervention, NW is an area *in* transformation. Spatial transformation lags behind structural transformation. Industrial production has ceased to exist in NW while the physical and functional spatial structure is still fit for such an activity. A mismatch exists between the capacity of NW as enabled by its physical spatial structure and the economic function of NW that is disabled by outside economic factors to which stakeholders of NW have no immediate agency. As intervention is restricted to the confines of NW, the objective of intervention is to push spatial transformation along a desired and possible direction. The possibility of this direction is confirmed through trend analysis. The intended effects of the interventions within NW radiate beyond its confines. Therefore a multi-scalar and systemic analytical understanding of NW is necessary (Thierstein et al., 2012). Hence, spatial transformation goes beyond addressing the left-behind debris of de-industrialization. Rather spatial transformation repositions NW within the metropolitan urban hierarchy in sync with the process of acquiring a new economic role.

3. Perspective and scale of spatial analysis: The concepts of space, place & location

A main argument that we make in this paper is that *spatial* transformation can be steered through strategic spatial interventions. We use the term *strategic* to describe interventions that are selective and specific; they are prioritized along an impact chain and sequenced along a time line.

Laying down what we mean with spatial transformation is a more complex affair and calls for a lengthier discussion linked to the complex definitions and concepts of space. Since it is beyond the scope of this paper to unflesh the broad spectrum of the definitions of space, we restrict ourselves to adapting the existent definition of Boesch and Weichhart (Boesch, 1989, Weichhart, 2008). In addition, we highlight the differences between the three seemingly similar terms, namely, space, place and location.

Boesch identifies three concepts of space, namely, Distance space (d-space), Function-space (f-space) and Process-space (p-space). Boesch explains the difference between these three different concepts as follows. D-space focuses on the physical and morphological aspect of space. Space here is conceived of as a container as a stage set. F-space focuses on the functionalities that space acquires. Space here is not just a container of activities, but has the props that enable actors to function in certain ways. P-space focuses on the processes that occur in space and on the interaction between the different actors. Actors on the stage set whose role-play is facilitated by stage props are the focus here. Boesch, however, does not make the important distinction between the static aspect of d-space and the dynamic nature of f-space and p-space. This is an important distinction. When we operationalize these three different concepts in the analysis, we discover that d-space can be bound geographically while f-space and p-space flow due to their dynamic and relational components. Last but not least, for analytic purposes it is convenient to

unbundle the different concepts of space, however, it is important to keep in mind that the intricate working of space is only understood as these different concepts are bundled back together again. Indeed, space that "works" is space in which the three concepts of d-, f-, and p-space "work" together, it is space in which actors, find the relevant props and relevant container to perform *their* act.

The notion of place is related to meaning, sense of belonging and collectivity emerging out of physical constellations that are geographically located, spatially related and lived in. To start with almost everybody has a *place* of birth that s/he relates to willingly or unwillingly. But place is more than that, place is what happens to a chunk of space when people inhabit it and acquire it as their own. Place evokes memories and emotions; stories get stuck in building facades, sidewalks and alleyways. Graffiti on walls make voices visible, however, the silent messages that place transmits are multifold. Place spawns collective action. People are brought together in place. The boundaries of place are flexible; a place can be a neighborhood a park, a street, a piazza, a playground or a building entrance. A place records histories, personal and collective ones. Places can therefore have symbolic significance. A place gets old and instigates good/old memories or ones that need to be forgotten. Place has also character, it can be boring or fun. Hence, place brings the emotional and social element of the physical to the foreground.

Location is related to geographical proximity vis-à-vis other areas. While the geographical location of a certain area cannot be altered, its connectivity and accessibility can. Distance is related to geographical distance measured metrically, and to travel distance measured in time. Cost of travel and environmental impact of travel are criteria that can also be considered to further sensitize this concept of location. Location is affected by political and psychologically constructed territorialities. NW is located adjacent to the town of Fürth; however, the psychological boundary between Fürth and Nuremberg expands this distance beyond the actual metric reality. Whether in NW such psychological boundaries are carried into the future through tradition and senses of belonging is questionable. Political and administrative boundaries such as those of NMR squeeze distances as the pressure to compact growth accentuates. Location is a given while accessibility of a location can be altered.

Space, place and location can be perceived at different scales. Analyzing NW at the scale of the city quarter scale along the different concepts of space, place and location, yields different findings than analyzing NW at the municipal or metropolitan scale. Hence it is important to superimpose also the notion of scale as an additional organizing structure of analysis (Figure 3).

Areas undergoing structural transformation exhibit an operational mismatch between the three different concepts of space. D-space and f-space are capable of operating but deficiencies in p-space inhibit the capacity to operate. To use the theater allegory, a functional stage and functional props are paired with actors of a different play. Areas undergoing structural transformation are prone to loose on the place dimension. The transformation process is accompanied by a high turnover of people. Decline or rapid increase of people translates in fewer or fewer proportion of people with claim to place. Dialectic develops between saving/keeping old places versus bulldozing the old to make room for inventing new places. Interestingly, it is only location that is a constant; therefore the locational aspects in terms of competitiveness and specificities of areas in transformation becomes one of the guiding factors that are taken into consideration in both analysis and intervention proposals.

Scale	Concept				
	Space			**Place**	**Location**
	D-	F-	P-

Figure 3. Matrix of the different perspectives and scales of spatial analysis

The above matrix is useful for organizing our analysis and focusing our investigation. However, it is important to keep in mind that the different concepts are not mutually exclusive but they overlap. Indeed it is the workings of these different concepts together and their overlaps that provide richness to analysis. Hence, in the matrix we isolate the various concepts only temporarily for the sake of clarity. Figure 4 visualizes these overlaps .The important role of visualization in capturing these complex overlaps on maps and diagrams is highlighted.

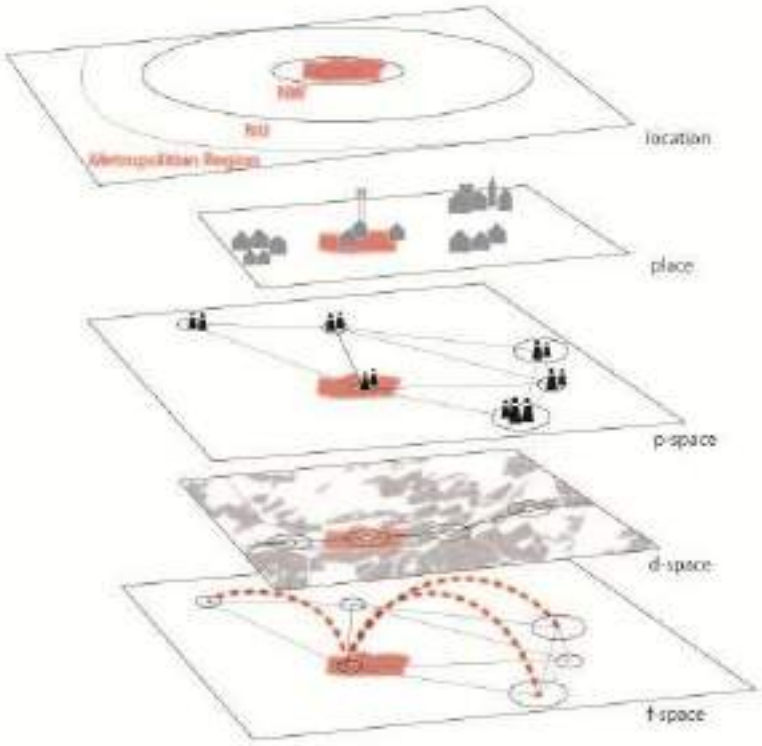

Figure 4. Visualization of the different perspectives and scales of spatial analysis

In the previous section we have highlighted the dual *conception* of NW as an object of analysis and as an object of intervention. In this section we have unbundled the different *perceptions* of these objects of analysis/intervention aided by the various concepts of space, place and location. In the next section we superimpose the different *perceptions* of NW - on top of the conception of NW as an object of intervention. This helps in organizing our understanding of the relationship

between intervention and associated impact. This is particularly important in contexts where change has a “hyper-dynamic” nature.

4. Planning in the context of “rapid change”: Formulating the problem is half the solution

Structural transformation is associated with change. Change can be related to growth, decline or stagnation. In addition change can be experienced at various speeds, intensities, scopes, scales and certainties. Growth can be fast paced but volatile, isolated, local and fluctuating. Decline can be slow, but widespread, global, intense and certain. In the case of NW, structural transformation is related to economic decline related to the loss of economic base. This decline has been intense, covering various sectors and certain.

Within the context of rapid change, political pressure builds up to devise equally rapid responses. In fast growing industries, such as China, we can identify a planning paradigm built around panicking; one that relents to the pressure of fast paced change and becomes enslaved to it. Pressured by the influx of population movements, demography, economic growth and the need to deliver, ad hoc spatial planning becomes the order of the day. However, matching the speed of response to the speed of change is not an appropriate approach. Institutional mechanisms within democratic regimes circumvent adhocracy by working their in-built valves that introduce patience into the system. Citizen consultation is one such example; constant negotiation within institutions is another.

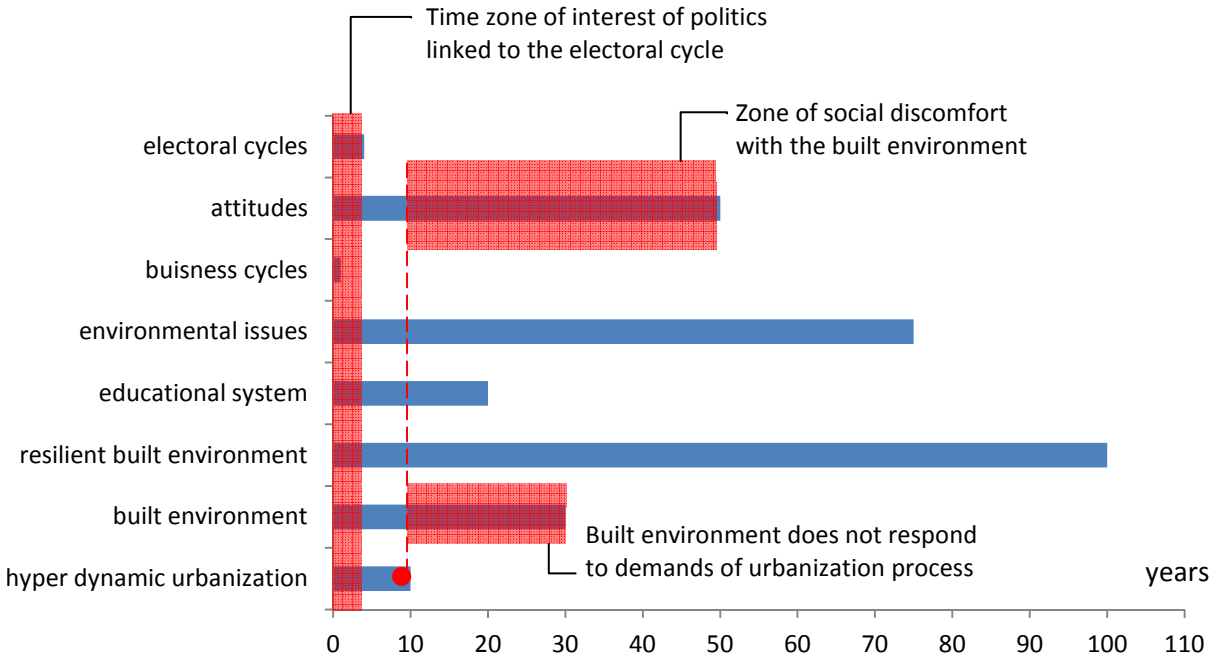

Figure 5. The speed of change of some driving factors of spatial transformation

However, the issue is not stalling response or buffering it. Rather, the issue is to analyze the various driving factors of change, relational and stock factors, in order to identify different rhythms of urgency and thus necessity to cater for in planning. Figure 5 illustrates how a hyper dynamic context of change within the urban environment, set at 10 years, supersedes changes in social attitudes, educational systems and even the life cycle of built environments. Hence, within hyper dynamic contexts of change, we frequently witness the bulldozing of functional buildings to give way to new ones; changes within social attitudes on average lag behind, frequently resulting in severe social problems as societies cannot cope fast enough along the speed of change. Figure 5 also illustrates how political actors have high stakes in changes occurring within their electoral cycles. This helps explain the disinterest among politicians in kick starting changes whose results are manifested way after their political cycles have been completed. As a result, it does not surprise that issues, such as environmental ones, which beg for a long-term approach are addressed within a short-term perspective for fast results.

However, if we consider change as an evolving process that occurs within cycles, it is possible to identify the intersections of cycles of change as windows of opportunity. For example, Figure 6 depicts a hypothetical situation in which the urban fabric has reached an end of a cycle, where refurbishment is necessary. This end of cycle coincides with the need to address pressing environmental concerns and the beginning of change in societal attitudes. To make things even more opportune all of this happens within an electoral cycle. Hence, in our figure all the factors of change have come happily together. We can also add the fact that the different cycles can support each other positively, for example, it is possible achieve faster cycles of environmental change if societal attitudes change in a way that support this. Hence, as we consider the intersection of different cycles of change and the possible mutual reinforcements, we become able to identify historic coincidences as such. As a result, it becomes possible to utilize all the available levers for steering change within a intended direction.

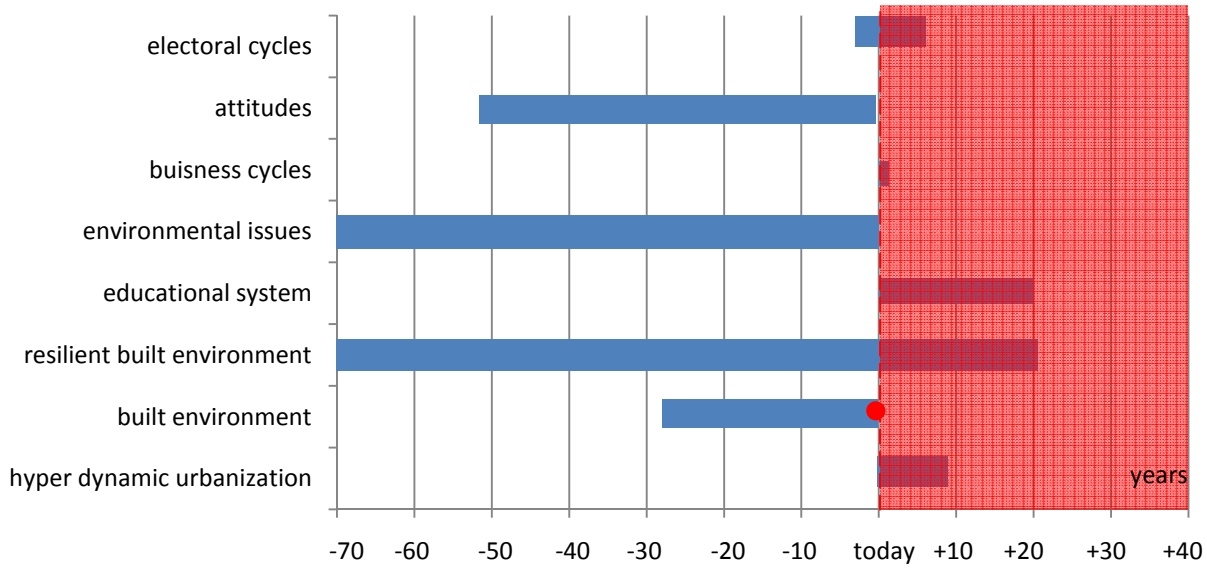

Figure 6. The intersection of cycles of change open windows of opportunity for spatial transformation

Formulating the problem in areas undergoing structural transformation around the element of change, the nature, scope, scale and speed of change and ways to deal with it, rather than restricting the view to spatial problems induced by change, is literally half the solution for tackling structural transformation in urban areas. In NW we have started from an area delineated as fit for regeneration by the municipality. However, NW is one site in Nuremberg in which the negative externalities of change are concentrated. To identify the opportunities presented by change it is vital to zoom out to larger scales in order to understand the capacities of the functional urban area to which NW geographically belongs.

As we take into consideration the temporal and multi-scalar aspects of the impact of spatial interventions, it becomes evident that area-based spatial interventions and their associated impact are not necessarily congruent in time, scale or scope (Figure 7). For example, proposed interventions might target the function space of NW. Such proposed interventions could result in an impact onto the function space of Nuremberg Metropolitan Region, but have only a minor impact on the physical space of NW. Also, intervention proposals can be bundled or unbundled. For example, in the NW project, intervention on all spatial levels can be proposed only within the confines of NW – the mandate of the project – hence, area-based. However, the associated impact of interventions spills over; some of this impact might not even happen or be felt in NW itself.

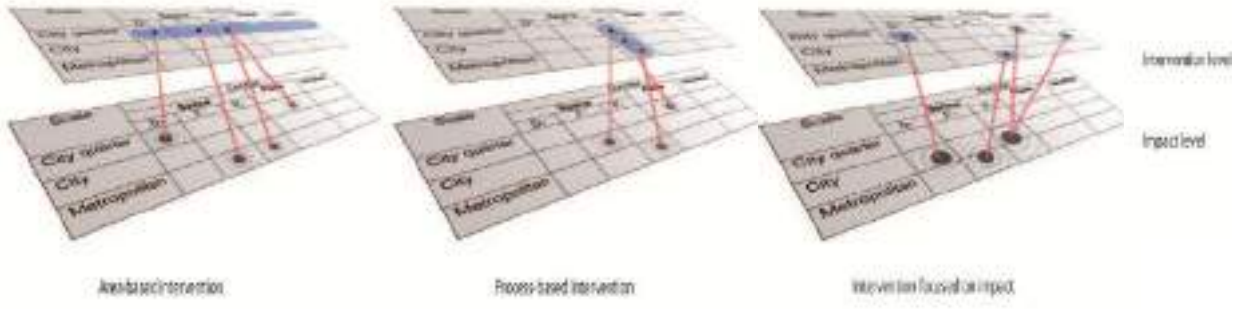

Figure 7. Interventions and associated impacts

Hence, spatial restriction of interventions by area-based mandates impedes the consideration of the full potential of space. Conversely if intervention can be proposed throughout the city, planners could start by deciding what kind of impact they want to achieve. Do they want to have an impact only on NW, if yes where should intervention occur? It can be the case that intervening in the process-space at the level of Nuremberg city can have a positive impact on the distance-space of NW.

This calls for putting the consideration of the impact of spatial interventions at the very forefront of any proposal for addressing structural transformation of areas in transition. Not doing so, risks moving problems from one part of the city to the other at best; at worst, the identification of good solutions to structural urban problems is severely restricted. For example, starting from the

consideration of the impact of spatial interventions, it is possible to conceive of a strategic concerted effort throughout the functional urban area of Nuremberg to address structural transformation in NW (Figure 7). It is equally possible to consider the impact of spatial interventions in NW on the town of Nuremberg.

Hence, we conclude, that if formulating the problem around the element of change is half of the solution, then the other half is formulating intervention proposals along the capacity to steer change at various scales, speeds and scopes rather than respond to it. Steering change through impact oriented spatial interventions is an approach that clearly diverges from approaches that put physical transformation at the fore.

5. A framework for Way(s) forward for NW: Methodology

Our previous discussion highlights that NW has a double handicap. Economic restructuring inhibits NW from assuming its old functions that its spatial structure enabled it to perform quite well in the past. Simultaneously, NW is inhibited from assuming new functions sustainably as its spatial structure has not yet adapted to new functions. This is precisely what characterizes areas in transition everywhere. The old [function] is dead while the new [structure to contain new functions] cannot be born yet. In the case of NW, structural transformation is associated with economic decline. In areas of transition experiencing rapid growth the new function is born while the old structure has not adapted yet. It is within this context that we propose our methodology for identifying way(s) forward for NW. The objective of our methodology is to enable the birth of the new. This we argue can be done by identifying possible future alternatives that become goals that selective impact-oriented interventions could aim to realize.

4.1 SWOT analysis

Our SWOT analysis of NW takes the different perspectives and scales of NW into consideration. By utilizing the conceptual structure of space, place and location, we organize analysis and discipline synthesis. As a result we identify the linkages between the different perceptions of NW. Since the scope of this paper does not allow a wide elaboration on our findings, we show the SWOT findings in an exemplary form to highlight our methodology.

To start with we analyzed the strengths and weaknesses (SW's) of NW. We focused on the functions of housing, economy and social cultural networks. The conceptual frame of space, place and location provided an organizing structure to our analysis. One of the key strengths identified for NW is its strategic location within the municipality of Nuremberg, that is, at close proximity to both, the centre and to transportation nodes that connect it to high-speed roads, high speed trains and to the airport. This strategic location is a strength that the future of NW can build on. In addition, the location of Nuremberg within Europe at close proximity to Eastern Europe is also a strength that NW can capitalize on. The Metropolitan Region of Nuremberg might well become the receiving end of waves of population migrations. Already today NW is home to a diverse population. The current social diversity means that NW is well experienced and trained in mediating between diverse socio-cultural groups. Hence, the current social diversity within NW is also a strength. Within another perspective of analysis, the rich history of

NW, its associated tradition linked to industrial pride – with brands like AEG, Triumph-Adler, Quelle – leaves places within NW laden with value, pride and meaning that radiate at the scale of Nuremberg at large. These places are distinctive of NW. They provide a strength that can be built upon. On the other hand, fragmentation, spatial discontinuity, noise, physical barriers and quality of the existing housing stock were identified as weaknesses of NW. Interestingly; most identified weaknesses are linked to the physical urban fabric of NW. These SW's were listed along a scalar hierarchy (Figure 8).

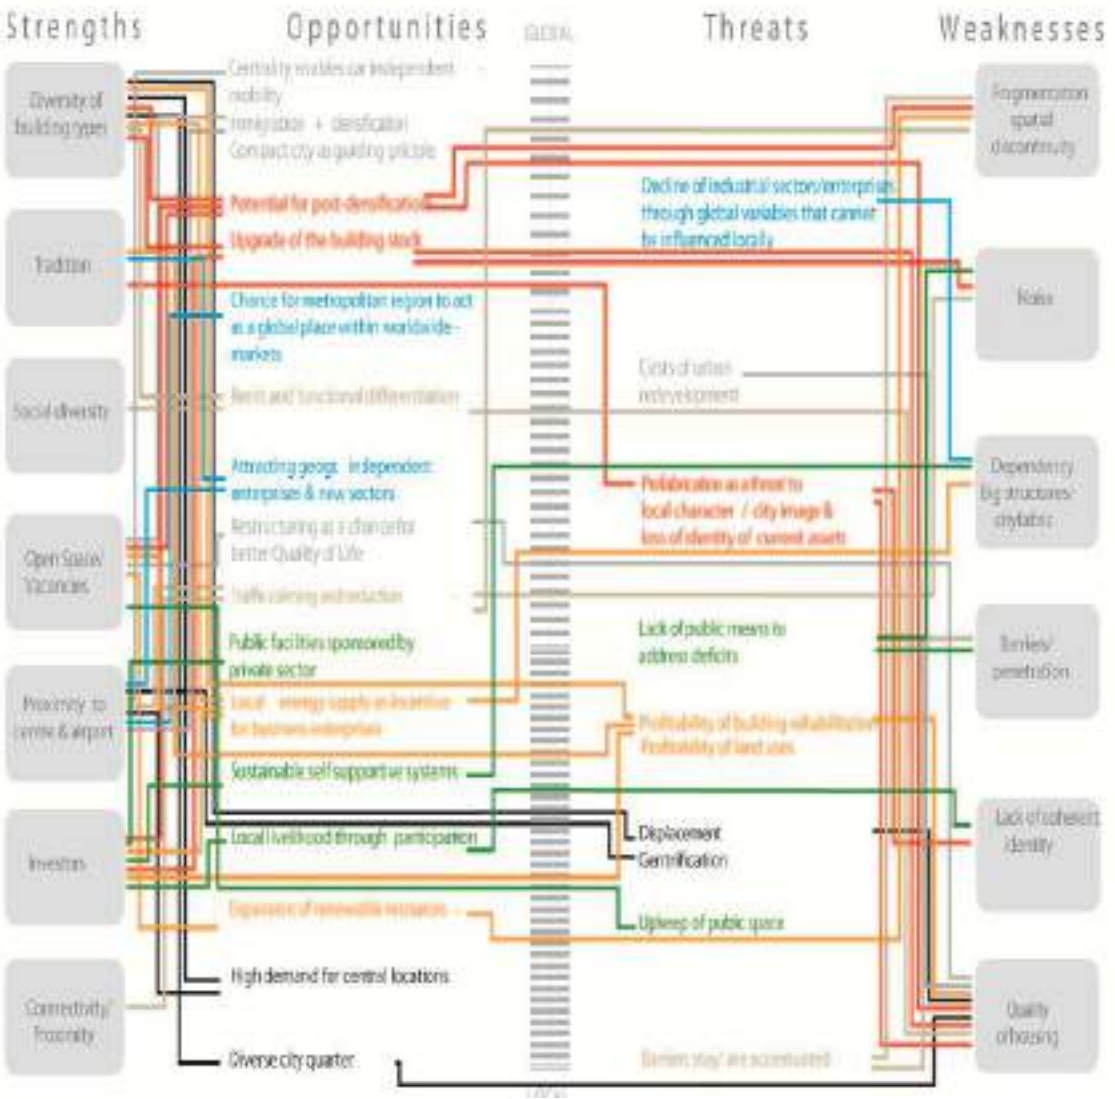

Figure 8. SWOT's of NW (Source: Student work)

In order to identify the opportunities and threats (OT's) we selected a number of trends from the trend document of the consultancy of Ernst Basler Partners Ltd (EBP, 2010). These selected trends were clustered thematically (Figure 9).

Figure 9. The clustering of trends

We applied these trend clusters onto NW with a view at the Strengths and Weaknesses of NW. The idea was to identify how Strengths and Weaknesses transform into Opportunities and Threats and how different trends reinforce each other (Figure 10). As the different OT's were identified they were listed again along a scalar hierarchy alongside the SW's (Figure 8).

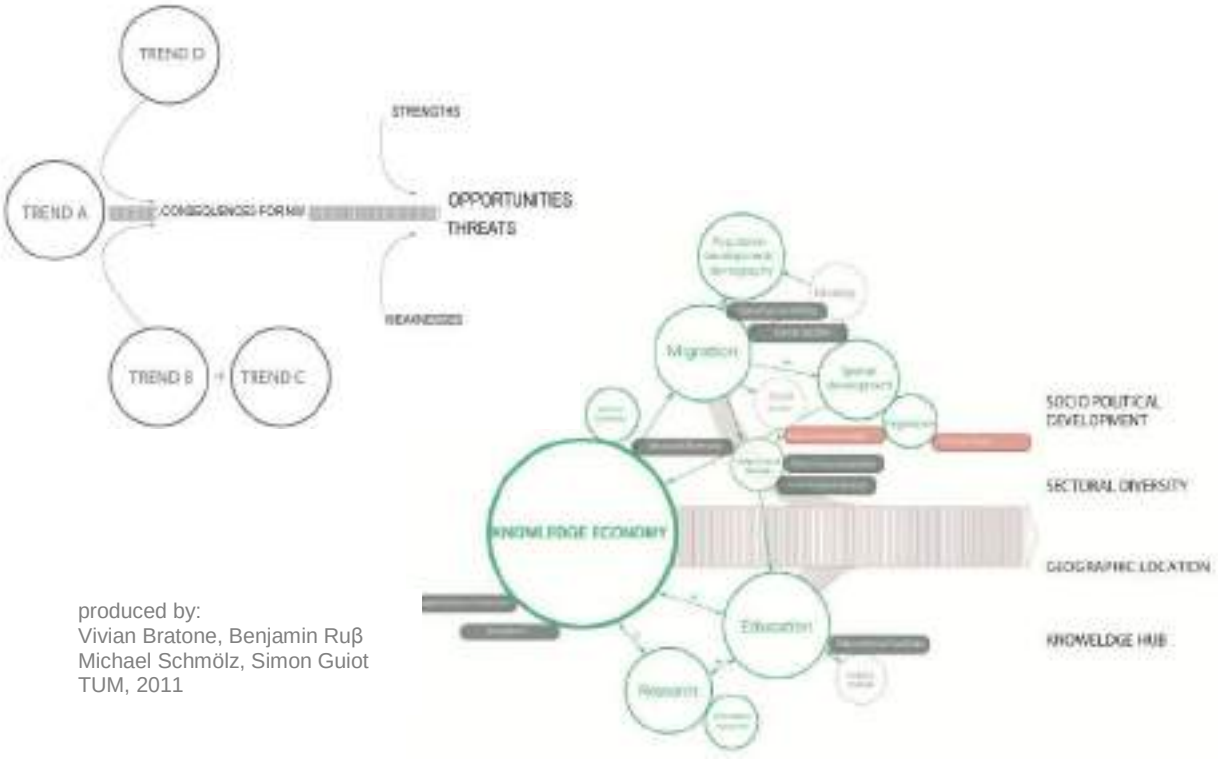

Figure 10. Applying the trends onto NW to identify OT's (Source: student work)

In addition, on hand of Frederic Vester's model of the paper computer, (Vester, 2002) we assessed these selected trends in terms of their role within the overall systemic context (Figure 11). The selected trends were listed on the horizontal and vertical axis of the paper computer. The effect of each trend listed on the horizontal axis on a trend that is listed on the vertical axis was assessed. This assessment was quantified at a value of 0 to 3, whereby 0 denotes no effect and 3 denotes a maximum effect. For example, does the trend of "changing lifestyles and values" have an effect on the trend of "mobility"? If yes, is this effect major or rather minor? As each trend is assessed against all others, the paper computer becomes complete. The values were then summed up for each trend on the horizontal axis and the vertical axis. The summations on the horizontal axis thus denote the active nature of a trend, summations on the vertical axis denote passivity.

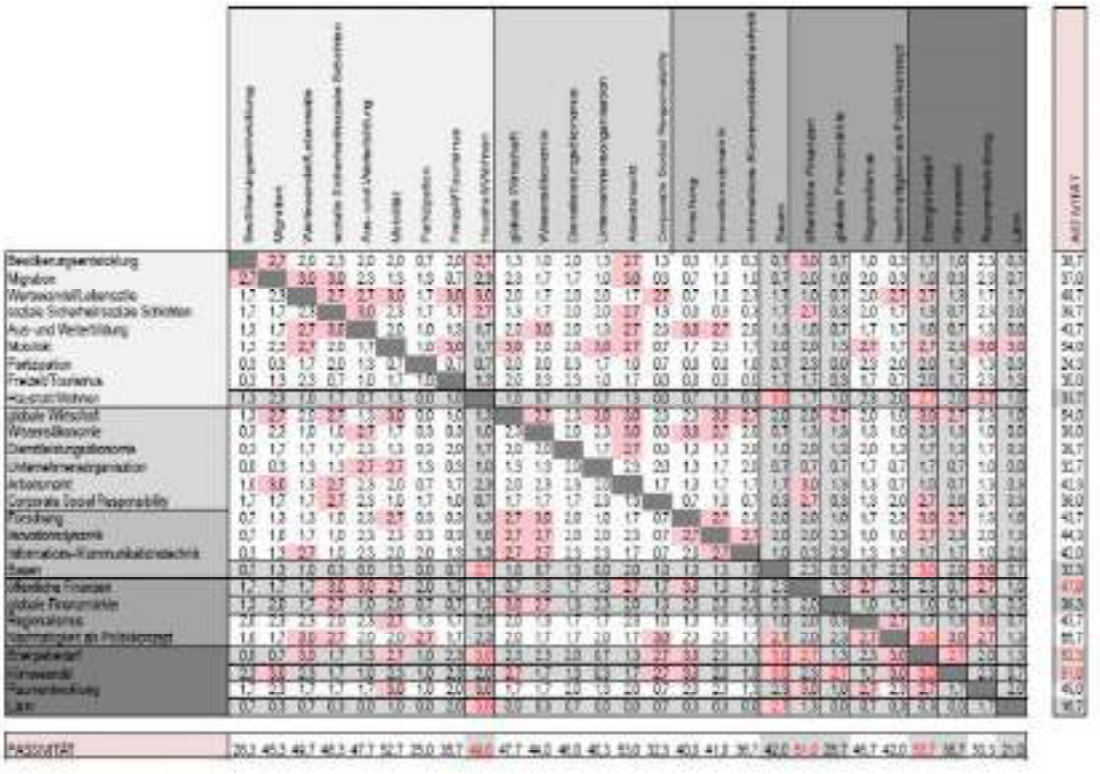

Figure 11. Paper computer

The idea of the paper computer is to identify reciprocal effects, levers of control and fields of action (Thierstein et al., 2008). Given the position of the different trends regarding their active or passive nature we classified their role in the overall system as active, critical, reactive or buffering. "Active trends have a strong influence of other trends and are influenced only minimally by the latter. Critical trends are heavily influenced by other trends and, in turn, exert an equally strong influence on the latter. Reactive elements are heavily influenced by other trends and only have a minimal influence on the latter. Buffering trends only exert a minimal influence on other trends and, in turn, are influenced only minimally by the latter. Reciprocal effects are significant with regard to political intervention. Without a sound knowledge of the

overall systemic context, isolated measures soon run “out of control” and have non-intended effects in other fields of policy ” (Thierstein et al., 2008).

The trend of global economy has transformed the process and function space of NW; as a result this has had an impact on d-space and NW as a place. NW is however still a well connected location. Is it possible to address such a trend and redirect its impact in NW? This is what we asked ourselves as we analyzed each trend. For example, identifying the physical fragmentation of the urban fabric of NW as a weakness impedes certain functionalities and processes to evolve. Hence, even if the municipality would intervene through, for example, tax incentives to encourage certain functionalities, deficiencies of d-space would still be a counter force.

Based on the SWOT analysis and our clustering of trends we were able to identify the possibility of three future alternative developments of NW.

4.2 Alternative futures

The keystone of our methodology is proposing evidence-based, possible future alternatives of NW based on a SWOT analysis that takes into consideration the various perspectives of NW. We propose innovative, creative, politically unrestrained and impact oriented transformation possibilities for NW, set purposefully at the sufficient temporal distance of the year 2050.

The year 2050 has been chosen, in order to break free from the short-run where almost all handles/levers to intervene are fixed and sticky. The temporal distance of a generation makes almost everything become fluid and flexible. At the same time 2050 is not too far in the distance. Trends of today can be used to help predict the shape of the future. Hence, the view to the next generation creates a condition, in which liberation from today’s constraints is experienced simultaneously to the engagement with today’s identified trends. This condition begs for an understanding of the inter-relatedness of factors and assessing of the relative speed of change in planning. As we elaborated previously, identifying the relative speed of change is the key for identifying windows of opportunity for planning.

These alternative futures are assumptions of the potentiality of a positive transformation of NW in 2050. Positive is judged by the fact that NW is *sustained* and recognizable as a *place* that contributes value to the city and region of Nuremberg. Our proposals of future alternatives are based on our belief that it is possible to negotiate in NW, future conditions proactively. As a result our proposals are (1) evidence-based, (2) positive, problem solving and impact oriented and (3) function oriented.

The future alternatives are evidence-based, because they emanate from the findings of the SWOT analysis. Future alternatives are not impulsive or spontaneous visions; they are systematic-conceptually drawn analysis (SW’s) of the current condition of NW and systematically developed-assessment (OT’s). Future alternatives are developed with a view at the opportunity presented by the municipality with regard to intervening in a proactive way today, in order, to address the threats posed by challenges and steer the transformation process in a way that conforms to current values (e.g. sustainability). Hence, future

alternatives are proposed based on the belief that a positive future for NW is possible and desired impacts are achievable.

These proposals for alternative futures of NW in 2050 provide the direction and incentive for "way(s) forward". They organize intervention proposals of various disciplines along aggregated desired impact. Hence, we do not propose one alternative future, but rather a number of ones. In the case of NW we propose three future alternatives. These future proposals have been useful in structuring the work within our multi-disciplinary team at the TUM (Figure 12). At the onset of this research project, the common ground in our inter disciplinary team was the aim to follow the guidelines of sustainability. However, sustainability as a value leaves out many grey areas. In addition, the pace and scope of sustainability transitions proposed by the various disciplines vary. The three alternative futures emerged as a good container to sort out various proposals of the different chairs involved in this project.

Alternative future 1	Economy	Housing	Social cultural	Open space	Transport	Energy	…
Role NW vis-à-vis NMR							
Functional Transformation							
Spatial Transformation							
Process of transformation							

Figure 12. Detailing of alternative futures

Proposing a number of future alternatives rather than just one can serve the political process as a platform for debate, as stakeholders ask themselves, where to, which way forward? As discussed in section 4 of this paper, in the context of hyper-dynamic change, it becomes difficult for public authorities to assess the impact of the decisions they take. In deed different decisions, which at first glance seem to be consistent, are frequently counter productive and end up pulling development in contradictory directions. Hence, proposals of alternative futures serve as goals, against which public authorities can continuously check the effectiveness of their decisions.

Of course, we are aware of the fact that the life cycles of cities transcend a future goal that is set today. The objective of setting a future goal is not actually reaching the goal but rather to sort out and organize interventions. In deed alternative futures are developed with the underlying idea of "Der Weg ist das Ziel".

As decision is taken for a direction and commitment is taken for one alternative future, strategic plans can be developed to get there. Committing to one future alternative demands a political process. Lack of commitment in the short run in order to leave out all options open stalls the process of achieving desired change. Such a reactive approach is likely to be adopted by risk avert municipalities. Future alternative proposals in this instance are not goals but rather are used as assessment tools for interventions.

4.3.Application on NW

We have identified three alternative futures as to the potential positive transformations of NW in 2050. Proposals identify the potential roles of NW within the metropolitan urban hierarchy and the associated functionality of the space of NW. We term the first proposal "NW sustains through managed care", the second, "NW transforms into a hub for the Knowledge Economy", the third, "NW transforms into the birthplace for the Subsistence Economy".

In the first proposal, NW sustains along a process of what we term "managed care". NW does not become a popular site for a particular sector of the economy nor does it assume a particular function within the metropolitan urban hierarchy. Rather NW sustains by responding to a plurality of demands that emanate from the Nuremberg Metropolitan Region (NMR). With NMR we are referring to the functional urban region of Nuremberg and not to the administrative metropolitan region. This proposal is one that acknowledges the "downgrading" of the role of NW, namely, from a site in which activities and production contributed to the economy of NMR, to a site of tertiary activities. Within this proposal the restructuring of space will play a crucial role. The configuration of space at present reflects the previous citywide role that NW has played. Its future "downgraded" role demands a reconfiguration of space that focuses on local connectivity in which housing and the local economy are important drivers of sustainability. It is within such a context that we talk of "managed care". The process of enabling a successful "downgrade" of the status of NW should be carefully managed to ensure that NW does not slip into decay and obsolescence but continues to provide value to Nuremberg albeit at a secondary level.

In the second proposal, NW is transformed as a hub for the Knowledge Economy (KE). The beginning of such a process is under way already; the objective of this proposal is to support this process. Within this proposal NW continues to have an active role at the citywide scale, although this role has transformed from activities linked to industrial production, to activities linked to the KE. Assuming a role at the city wide level means spatial connectivity and locational advantages must be bolstered. However, this is not enough. In deed, for NW to successfully acquire such a role, the local spatial fabric of NW has to respond to the changed clientele of people involved in the KE. The lifestyles of KE workers are different than that of people involved in industrial production. Different lifestyles are associated with changed demands on space. Hence, in this proposal, two important considerations are citywide spatial connectivity as well as the restructuring of the local spatial fabric to respond to new demands.

In the third proposal, NW is transformed into a hub for the Subsistence Economy (SE). NW becomes in 2050 what is envisaged in retrospect as the "birthplace" of the SE in Nuremberg. In

other words, the “sparks” for the evolution of SE in Nuremberg are set along a process starting in 2012 in NW. The acquisition of functions related to the operation, maintenance and management of a subsistence economy builds on the availability in NW of vacant land for development.

Each of the three future alternatives proposes a different pace and scope of “sustainability transition”. In “Managed care” transition would be slow; its scope narrow, especially in the short term. In “KE hub”, transition could be fast, but its scope not really dramatic. In “birthplace of SE”, sustainability transition would be slow but the scope vast.

5. Conclusion: Steering the transformation process through spatial interventions

In this paper we have elaborated on the role of space in addressing the challenges of structural transformation. We have provided a conceptual framework for both (a) analyzing areas in transition as hypothetically conceived objects of analysis and (b) for proposing impact-oriented spatial interventions that address change induced spatial problems.

Our conceptual framework helps shift the focus of planners from the spatial outcome of change associated with loss to the spatial prerequisite of change associated with the promise of gain. As we described the methodology that we have developed for addressing spatial transformation of areas undergoing structural transformation, we have focused on the importance of formulating proposals of future alternatives based on SWOT analyses. SWOT analyses take into consideration the different perspectives and scales of spatial analysis and development trends.

Anticipating the future and identifying how it can be shaped today in a proactive way is not a visionary exercise; it can be arrived at through systematic analysis of the current situation and the factors of change. Assessing the speed of change, considering the intersection of different cycles of change and possible mutual reinforcements, it becomes possible to identify windows of opportunity; those historic coincidences, which if seized become transformative. As a result, it becomes possible to utilize all the available levers for steering change within a desired direction. Based on this approach, we have argued for a spatial transformation that addresses structural transformation in a forward-looking rather than a submissive way. The objective of identifying future alternatives is to organize and assess spatial interventions along desired aggregated impact. Doing so helps planners to move away from proposing palliative interventions that seize the moment to searching for transformative spatial interventions that pave the way to the future.

While we have not in any way been dreaming of Masdar, which translates from the Arabic language into ‘source’, we conclude that space is the very source of sustainability transition. Spatial transformation is the purposeful transformation of space, one that takes into consideration the intricate working of space in all its aspects and scales of impact.

Wirtschaftsreferent Fraas traeumt von Abu Dhabi. Abendzeitung Nuernberg,) The newspaper article quotes deputy mayor for economic affairs, Fraas, for looking to Masdar city in Abu Dhabi for inspiration. Masdar city is an emerging urban development project designed to be built on a tabula rasa in the desert of the UAE. This planned city is currently being built by Abu Dhabi Future Energy Company, a subsidiary of Mubadala Development Company. Designed by the British architectural firm Foster and Partners, this city is planned to rely entirely on solar energy and other renewable energy sources (Source: http://www.masdarcity.ae/en).

Flexibility, Justification and Financial Results of Land Development Projects by Local Governments

Vitnarae Kang[1]

Abstract

Land development projects undertaken by local authorities in the Netherlands appear to be an exception to the general rule of cost-underestimation with benefit-overestimation frequently observed in large public projects (Flyvbjerg et al., 2002). In the case of the Netherlands, the profits from municipal land development are larger than the estimated (Korthals Altes, 2010). The exception deserves to be studied, as it may provide with explanations for the budget overruns of other kinds of large projects and inform about their solutions.

In this paper, land development projects are looked at from the perspective of 'flexibility, justification and financial results'. Though public land development projects are seemingly well managed in the Netherlands, local authorities are struggling to make their projects financially and qualitatively feasible, especially in changing market conditions; for example with reduced housing transaction and decreasing building land prices due to the 2007-2008 global financial crisis. In that sense, the following points are shed light on by a case analysis of 'Midden-Delfland's practices from 2008 to 2012; how to incorporate uncertainties and emerging information flexibly in the plan considering its financial implications, how decisions are justified in the process, and how all those points are influencing on the financial end (Faludi and Korthals Altes, 1994).

1. Introduction

Land development projects undertaken by local authorities in the Netherlands appear to be an exception to the general observation in the planning of large public projects that costs are underestimated while benefits are overestimated (Flyvbjerg et al., 2002). In the case of the Netherlands, incomes from municipal land development have been larger than the estimated (Korthals Altes, 2010). This happens in the planning environment where costs and benefits are generally underestimated, however, realized benefits are much higher than actually incurred costs (Korthals Altes, 2010). During the period of 1999 to 2007, the realized annual surplus from land development projects was minimum 1.22 and maximum 2.92 bigger than the budgeted (Korthals Altes, 2010). Besides, the income from land development projects is a relatively important revenue source for local governments in the Netherlands, which accounts for approximately 12% of the whole local government income (Korthals Altes 2008, Allers 2011). While more than 80% of local

[1] PhD candidate, Section Geo-Information and Land Development, OTB Research Institute for the Built Environment, Delft University of Technology, the Netherlands. v.kang@tudelft.nl

government income depends on grants from the national government (Needham 2007a), either general or earmarked (Figee et al. 2008), municipal land development gives a room for local governments to exercise their discretion in a way that tailor-made financing mechanisms are made possible in response to local needs.

The recent estimation by Deloitte (2011a), however, presents a different picture. An expected yield on the land development portfolio of all Dutch municipalities in total can be 2.9 billion euro less than what was estimated in the budget of 2010. This loss of 2.9 billion euro is composed of the direct loss of 1.8 billion euro from financially negative plans and the indirect loss of 1.1 billion euro from financially positive plans. This dramatic turn is attributable to the global credit crunch; reduced housing transaction, falling housing construction, decreasing housing prices and subsequently decreasing building land prices (Priemus 2010). Yet, Dutch municipalities are struggling to make their land development projects financially and qualitatively still feasible in the midst of changing market conditions by adopting various micro-adjustments in their project-management(Deloitte 2010). Policies such as the Decree on Budgeting and Financial Reporting (BBV) and Municipal Memorandum Land Policy also provide a municipality with frameworks to manage financial arrangements of land development projects. Those policy-guidelines were formulated before the credit crunch, not necessarily in the prediction of the credit crunch but still relevant to responding resiliently to changing conditions. Those policy-guidelines stand path-dependent on traditional Dutch land development practices.

The Dutch exception with respect to the relation between budgets and realized results of public land development projects deserves to be studied further; why, how and what kind of discrepancies between the budget and the result takes place, and how land development project is managed by the municipality. Since it may provide with explanations for the budget overruns of other kinds of public projects and inspirations for their solutions (Flyvbjerg et al. 2002). Furthermore, it would present more realistic lessons to look at the post-credit-crunch practices of municipal land development, as the post-credit-crunch practices are expected to partly be in the continuation with the ex-credit-crunch practices and partly be innovative. They would reveal more dynamics of changing conditions in which land development projects are operated and of decisions taken by municipalities.

In this paper, municipal land development projects are looked at from the perspective of flexibility, justification and financial results. First, I discuss the concepts of flexibility, justification and financial results used in this paper for analyzing municipal land development based on literature review. Factors that the municipality can influence regarding costs and incomes are briefly explained. Suggested explanations for why municipal land development projects in the Netherlands usually generate surplus over the estimated costs and benefits are also discussed with the introduction to the municipal planning and monitoring cycle of land development projects according to the task division within the municipality. Second, research questions are proposed based on the foresaid concepts with a purpose of a case-study method and an introduction to a selected case. Findings from the case-study are

presented according to the proposed research questions. Third, further discussion points and considerable lessons are suggested based on the case-study findings. What needs to be notified here is that the case-study in this paper is a pilot-study to explore possible research directions further based on collected data and to sharpen the asked research questions for subsequent study based on an identified gap between the questions and what collected data show.

2. Literature Review: Flexibility, Justification and Financial Results of Land Development Projects

2.1 Flexibility

The relation between plan and its implemented result has been an issue in planning studies for a long time (Alexander 1998, Faludi and Korthals Altes 1994, Faludi 1987, Thomas et al. 1983); how much the realized result deviates from the initial plan, what are the reasons for it and how positively or negatively the deviation can be interpreted. One of the main lessons from accumulated case studies is that the initial plan can better be situated in the process of plan implementation as a guideline for further improvements of the plan and its project itself in order to accommodate emerging information and changing conditions (Alexander 1998, Faludi and Korthals Altes 1994, Faludi 1987, Thomas et al. 1983). Thus, flexibility can be defined according to Faludi and Korthals Altes (1994, p.405) as allowing institutional room in the process of project implementation for a possibility of further learning and to reflect newly acquired information on the project, based on the view that 'the plan can be reconsidered'. Tasan-Kok (2008) distinguishes the use of the concept 'flexibility' in the planning literature into three categories; 'changing decision-making approaches and urban government system' with such keywords as complexity, multi-actor governance and non-linear decision-making, 'shifts in urban development traditions and attitude of planning practice' with such keywords as project-led development, incrementalism and opportunism, and 'the recognition of diversity, multiculturalism, and heterogeneity as positive aspects of urban society by the planning profession' with such keywords as diversity and sustainability. Muñoz-Gielen and Tasan-Kok (2010, p.1103) define 'flexibility' in their research on public value capturing in urban regeneration projects as a degree of certainty about future building possibilities i.e. what, where and how the landowner is allowed to build and about future contributions i.e. what and when the landowner has to give in kind or in the form of a financial contribution to the concerned planning authority. In this paper, it is meant by flexibility that an initial plan for land development projects can be changing till the completion of the projects. The questions related to flexibility here are why and how changes in the plan were brought about, how those changes in the plan actually improved the project in terms of spatial quality and financial feasibility and what are their consequences on incomes and costs of the projects.

2.2 Justification

The foresaid leads to the following keyword; justification. By justification it is meant what decision makers of public land development projects who bring and approve changes to the plan propose as arguments for such changes to a municipal council which takes ultimate responsibility for its constituency; why those changes are necessary and more beneficial for public interests than without them, as a way of guaranteeing accountability in public policy implementation. Arguments used for justifying decisions show how technical expertise within a project executive body contemplates market conditions, physical constraints or local sentiments. Justifying decisions involved in public land development projects is about choice made on the goal, the design, the contents, the phasing, and the spatial quality of the projects. It is about to find out a balance between the spatial quality to achieve via the project and the financial consequences through the process. Justifications for such decisions are presented in municipal budgets and financial reports which hold the decisions subject to the public debate.

2.3 Financial results

Flexibility is also strongly related to financial results. Needham (2007b) and Korthals Altes (2007, pp.1506) identified the most important financial variables influencing the financial end of a municipal land development project and the possible decision-making areas in the project. Main financial variables are (a) land acquisition costs, (b) costs of site-preparation, (c) interest charges and (d) incomes from land disposals.

Verhage and Needham (1997) identified the cost side and the income side from the point of view of the municipality in more details.
Costs: land acquisition; primary and secondary services; making and supervising the plan; interest costs; possible contribution towards other residential development (for a more extended list of costs, see Muñoz-Gielen, 2010, pp.229-230)
Incomes: revenues from selling serviced plots; possible subsidies from other governmental funds; possible contribution out of local taxes; and possible contribution out of surplus from other projects

Based on the identified financial variables, the scope of choice to the municipality is more elaborated hereunder.

Variable a: the municipality can choose an acquisition strategy;

- Using pre-emption right to acquire future development sites.
- Pursuing an amicable acquisition, using the possibility of compulsory purchase as a big stick (Buitelaar 2010).
- At what price level land acquisition cost would be determined, depending on land ownership situation in the concerned plan area and the bargaining power of the municipality: the price is usually set to be higher than existing use value but same with or less than double existing use value (Needham 1997). In the compulsory purchase law, compensation for expropriation ought to be according to the market price and the market price is likely to be double existing use value (Needham 1997).

- What kind of cooperation-form the municipality chooses with private developers.

Variable b: the municipality can choose the quality and the quantity of services and public facilities delivered within the plan area, and outside of the plan area in relation to needs created by development.
Variable c: the municipality can control or influence the speed and phases of development, determining when to make what kind of costs. The longer a project takes to finish, the more interests are incurred in general. Thus, inflow of incomes can better be expedited as possible and costs can better be incurred later, closer to inflow of incomes. For example, postponement of costs-incurring activities according to actual land disposal schedule can be one of the ways to improve the financial result when acquired land is not likely to be sold soon.
Variable d: the municipality can make a choice on the mix of land uses, cross-subsidizing unprofitable land uses from profitable ones within the plan area. 'More commercial houses' means more profits and 'more social houses' means less profits. By adjusting a development programme, such as types of houses and maximum density, the municipality can influence incomes from land disposal, even though it can hardly influence prices of end-products since the prices are highly determined in the real estate market.

Therefore, decisions made by the municipality influence the financial result of a land development project. How the municipality perceives risks involved in the project, how it interprets the financial status of the project and why and how it chooses to respond to recognized problems in such a way in the process of development; they are to be found in public justifications for such decisions by the municipality.

2.4 Institutional settings: municipal land policy in the Netherlands

There are some starting points to analyse the financial result of municipal land development when looking at it from the viewpoint of flexibility, justification and financial results. From discussion of the financial estimates and results of servicing land by Korthals Altes (2010), it is possible to extract the following explanations for why land development projects by local planning authorities in the Netherlands usually generate surplus over the estimated expenses and revenues.

1) Because of flexibility in planning, to adapt to changing conditions by realising the project incrementally in subdivided units and by accommodating emerging information to piecemeal decisions (Korthals Altes, 2010, pp.936 and pp.938).
2) Because of conservative accounting rules (BBV) that losses must be recorded in anticipation and profits may only be recorded after realisation so that the principle of prudence in business is encouraged while it is discouraged to justify a cost-overrunning project without making provision for expected losses (Korthals Altes, 2010, pp.934 and pp.938).
3) Because of no institutional inducement for land development agencies to show figures that are too positive; in other words, institutional incentives for those

agencies to budget conservatively in order to prevent local authorities from reducing their funding (Korthals Altes, 2010, pp.937-938).

4) Because of buoyant housing market which leads to the option value of future actions, which is especially relevant to the period before the credit crunch, and specific characteristics of local residential market (Korthals Altes, 2010, pp.937-938).

The first point is related to internal factor of the municipal management, namely flexibility in the decision-making process. Here, a budget based on land development plan functions as a financial framework for further manoeuvre in which the project may proceed, focusing on the final quality of the project and not merely on the costs or revenues of the project. Thus, decision-points in one project are not concentrated into a single moment but are spread over time (Korthals Altes, 2010, pp.931 and pp.939). In that way, political influence is to be constantly exercised by checks and balances in the decision-making cycle, rather than decisions are solidified after a certain moment out of the political reach.

The second and the third are related to the way the municipal cabinet presents the budget and the financial result of executed land development projects to the municipal council and the way the municipal council interprets and judges them in order to control and steer development. The fourth point is rather an external factor. The way the municipality is responding to such an external factor is yet determined largely by the first three points. Because the extent that municipalities are affected by the credit crunch may vary from a municipality to a municipality and local scarcity of houses is also different from location to location, it is worth looking at how the municipality perceives the impact of the credit crunch and the status of the local housing market, which would lead to specific adjustments in the project implementation.

Since the first three points are all related to task-division and communication between the municipal council and the municipal cabinet, and also to the administrative cycle of planning and control within the municipality, it is worth mentioning the Dualism in Local Government Act enforced in 2002 and the Decree on Budgeting and Financial reporting enforced in 2004.

The Dualism in Local Government Act gives municipalities a framework in which the distinction between the local council and the cabinet of mayor and aldermen is made clearer. The local council now plays a more independent role in checking and scrutinizing the policy implementation by the cabinet than before. The cabinet consists of mayor and aldermen. They become more professional in local policy formulation and execution because alderman who had formed a member of the local councilors before 2002 become separate from the council and they can now be recruited from outside the municipality according to required expertise in his/her policy field (Severijnen and Bovenkamp Ba 2007).

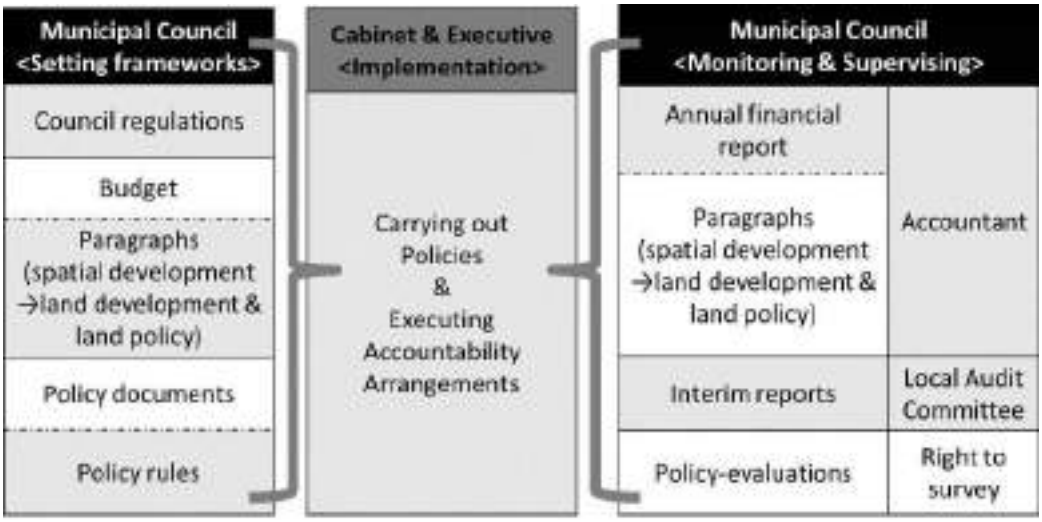

Figure 1: the municipal task division between the council and the cabinet (Deloitte, 2009, pp.10)

The council sets policy-frameworks and the cabinet carries out its policy within the designed frameworks (See figure 1). One of the examples of such policy-frameworks is a 'Memorandum Land policy' (Nota grondbeleid), which is tailor-made by each municipality. Main contents of the memorandum land policy are as follows; the aim of land policy, the forms of land policy pursued by the municipality, possible cooperation models for land development with other parties, land acquisition strategies, disposal methods of serviced land, use of reserves for covering possible losses and public procurement principles. The memorandum land policy works in combination with other municipal planning documents such as Strategic Vision (Structuurvisie) and Land Use Plan (Bestemmingplan)[2] which are mandatory for each municipality to produce, update and conform with, according to the revised Spatial Planning Act.

Based on those planning documents, the cabinet drafts the budget of municipal land development both at a project level and at a municipal level of all projects, carries out the municipal land policy and annually reports the result of its implementation. Annual budgets and annual financial reports drafted by the municipal cabinet are approved by the municipal council (See figure 2). Since 2004, the Decree on Budgeting and Financial Reporting have mandated municipalities to establish a programme-plan or justifiable grounds for the municipal land policy in both annual budgets and annual financial reports.

[2] Strategic Vision (Structuurvisie) is not legally binding but an indicative plan which globally guides future spatial development, translating other policies of a municipality into spatially-relevant arrangements. Contrary, land use plan is legally binding and contains more detail than the strategic vision.

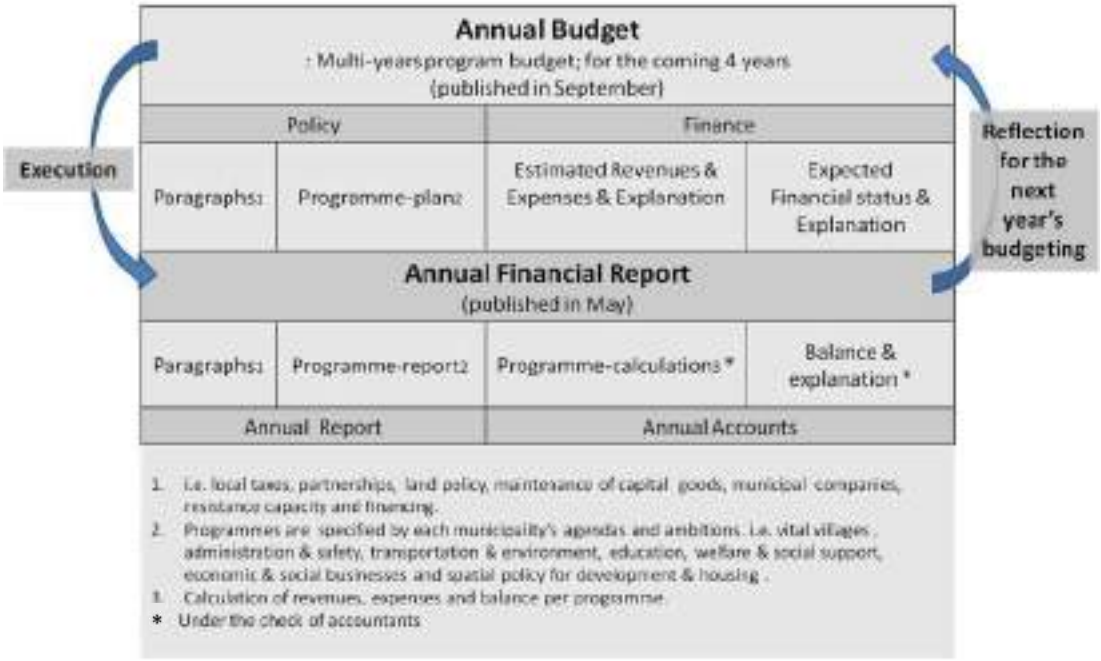

Figure 2: the cycle of planning, execution and monitoring of municipal land development projects and contents of municipal annual budget and financial report (Deloitte, 2009, pp.13)

In the annual budget, the cabinet should state what kind of land policy will be carried out in the next year in order to realize the spatial plan based on the Strategic Vision. Article 16 BBV requires the following items to be explicitly stated in the budget; an integrative vision of the land policy in relation to the realization of the objectives of the programmes which are recorded in the budget, an indication of the way the municipality implements its land policy (active land policy or facilitating land policy), an up-dated forecast of the financial results of the whole land development projects within the municipal boundary with each project's detailed programmes monitored, explanations for estimated incomes and policy principles to run a reserve fund for land development to save generated surplus or to cover possible losses in order to manage risks of land development. Besides, the reasons for a specific policy choice in a specific project should also be stated, since a suitable policy approach can vary from project to project due to each different ownership situation of area in question or available budget.

The annual financial report basically gives an account for the result of how the approved budget is actually spent on, as a reflection on the annual budget. As actual budget execution is carried out at the executive's daily management level, special attention from the council is called for to revisions of land development plans and substantial deviations from the plans. Not all the decisions proposed by the executive require the sanction of the councilors. Still, the councillors are reported of the progress of land development projects, not only by the annual financial report, but

also by the interim communications in a form of either formal or informal hearings and with confidential reports.

3. Case: Midden-Delfland

3.1 Research questions and method

A pilot case study is performed to test the possible research directions based on collected data and to sharpen the asked research questions based on an identified gap between the questions and what data show for subsequent study. Midden-Delfland was chosen for the convenience of access to information and for a relatively small municipal size with dynamic land development, which makes the pilot study possible for a given time; January, February and April 2012 .

Questions are asked as follows.
For the aspect of flexibility:
1) How are uncertainties with emerging information flexibly incorporated in the planning and realization process of land development projects within a municipality considering its financial implications?
For the aspect of justification:
2) How are decisions justified in the process and what are the justifications used?
For the aspect of financial results:
3) How do all the discussed points in the previous questions influence the financial end?

Annual municipal budget documents (Multiyear-programme budget; Meerjarig Programmabegroting in Dutch) published for the year 2009, 2010, 2011 and 2012 and annual municipal financial report documents (Annual report and annual accounts; Jaarverslag en Jaarrekening) published for the year 2008, 2009, 2010 were used to collect data. Except the specified years' documents, it was difficult to get other year's documents in the similar kind when contacting the communication department of the municipality. The contents of the mentioned documents were compared to each other with respect to land development projects and land policy in order to trace back the progress of land development projects and to identify the gradual tendency that the municipality responds to changing conditions such as the credit crunch if there is any mention. Other municipal planning documents such as the Memorandum Land Policy (Nota grondbeleid gemeente Midden-Delfland), Strategic Vision (Structuurvisie), Municipal Housing Policy (Woonvisie; Vitale Dorpen Midden-Delfland 2025), Analysis of the housing market in Midden-Delfland (Wonen in Midden-Delfland 2009-2025; Analyse van de woningmarkt) and interim reports on revisions of land development projects were also referred to. Besides, a semi-structured interview was carried out in February with a planning coordinator who is working for the land development department of the municipality.

3.2 General introduction to Midden-Delfland

Midden-Delfland (hereafter, MD) has a population of 18,225 residents in a relatively spacious area of approximately 50km^2. Being located next to Delft, and between Rotterdam and The Hague, MD strives to preserve its unique landscape of green pasture in the middle of highly urbanized region. There are three villages, 'Den Hoorn'(7,156 residents), 'Schipluiden'(4,534 residents) and 'Maasland'(6,535 residents), and two neighbourhoods, 'de Zweth' and ''t Woudt'. MD aims to provide recreational green space for people living in highly urbanized adjacent areas and to stay attractive for people who want to live there enjoying high quality of life (Gemeente Midden-Delfland 2009b, Gemeente Midden-Delfland 2011f). Faced development pressure in the highly urbanised region, MD has long been active in preserving green landscape by land banking and relocation of glasshouses (van Rij and Korthals Altes 2010, Gemeente Midden-Delfland 2011f). The municipality also tries to balance preservation and development by limiting housing development in the key villages (van Rij and Korthals Altes 2010). Such strategy is called as 'Preservation through development' and its image as 'Vision of Vital towns'. Comparing to other municipalities with a similar population, the municipality has a relatively big scale of land development in terms of a number of projects and capital investment involved.

3.3 Active land policy of MD

Active land policy, in which the municipality acquires land, services and subsequently sell to developers, is called for in order to induce the kind of spatial use desired by the municipality as stated above. The memorandum land policy states the objectives of municipal land policy as follows (Gemeente Midden-Delfland 2009b).
1) In order to influence the spatial use.
2) In order to influence the spatial quality.
3) In order to ensure legitimate distribution of costs and benefits involved in land development.

Those objectives leads to the adoption of active land policy in most projects for the reasons stated in the memorandum land policy as follows (Gemeente Midden-Delfland 2009b).
1) In order to ensure cost-recovery by charging costs of site-acquisition and preparation to land disposal prices.
2) In order to realise municipal land use plan in an optimized way by the municipality's legitimate rights over land which are derived from holding legal ownership of land.
3) In order to use discretionary power when servicing and disposing land to achieve public objectives that cannot be realised by mere application of statutory rules and regulations.

Besides the main use of active land policy, the municipality also uses various forms of cooperation with other private parties, namely, land owners or market developers. Among them are building claim, joint venture, concession, and private self-realisation. The degree of municipal direct influence in servicing land is the highest

in traditional active land policy entailing municipal land acquisition and disposal, and the lowest in private self-realisation. The rest can be classified in between as we see the municipal influence vary in degree.

3.4 Key projects in MD and their relevant features

In order to answer the research questions, relevant points in the course of key projects were reorganized based on the municipal documents of annual budget and financial report (see 3.1 Research questions and method). The following projects are identified as key projects due to their relatively big size or their recurrently emphasized meaning for the municipality. There are far more projects on a smaller scale to be found but the focus will be on the key projects in Den Hoorn and in Schipluiden.

Village Den Hoorn: Look-West, Lookwest-Noord and Kreekzone
Look-West, Lookwest-Noord and Kreekzone are large projects respectively for about 500 houses, 290 houses and an unknown number of houses in Kreekzone. Den Hoorn borders Delft. Thus, the location is regarded relatively more attractive due to the approximation to Delft. At the same time, it is regarded more sensitive to market-competition in the period of the economic crisis since development in the jurisdiction of Delft also generates housing supply.

Village Schipluiden: Keenenburg III and Keenenburg V
Keenenburg III is a project for a new municipality hall of Midden-Delfland and new houses around it. Keenenburg V is a project for development of the area where the current municipality hall is situated. Keenenburg III as mostly green field development and Keenenburg V as redevelopment are related to each other since the planning of Keenenburg V is to fit in with the relocation schedule of the municipality hall.

Table 1: summary of identified key land development projects in MD

	Changed conditions (Key-responding decisions)	Justification used for the key-decisions	Financial result
Look-West In Den Hoorn	a) Technical problems in site preparation (Separation of the problematic subunit) b) Presumably, due to low sales rate of housing in general influenced by the credit crunch (Delay of land disposal and building schedule) c) Extra revenues such as subsidy for public transport connection & tax reimbursement	a) To remove bottlenecks in proceeding the project b) (Description. No justification explicitly stated) c) (Description. No other specific justification)	Positive with an expected profit of approximately 2 million euro

Lookwest-Noord In Den Hoorn	a) One unyielding landowner against land acquisition (Application for an expropriation procedure and finally reaching an agreement) b) The economic crisis and bottlenecks in negotiations with developers on house-types and land disposal prices c) Less costs of site preparation	a) (Description. No other specific justification) b) (Description. No other specific justification) c) (Description. No other specific justification)	Negative with an expected loss of approximately 0.37 million euro
Kreekzone In Den Hoorn	a) Technical problems in site preparation (Separation of problematic subunits from Look-West and Lookwest-Noord and establishment of a separate project) b) Delay in servicing the site and diminished financial result (programme-adjustment from 60% social housing to 30%)	a) To remove bottlenecks in proceeding the projects b) To diminish an expected loss. Because the original plan of 60% social housing has not formally been approved (A strong financial justification. No other options suggested)	Negative with an expected loss of approximately 1.4 million euro
Keenenburg III In Schipluiden	a) Fragmented ownership among the municipality and a group of developers (adoption of building-claim model. Transfer of land from developers to the municipality) b) Technical problems related to peat dikes (re-planning of residential parts of the plan area) c) Extra needs for soil remediation and relocation of public utilities (extra budget-allocation and rescheduling of required work to later)	a) (Description. No other specific justification) b) (Description. Explanation for extra planning costs. No further specific justification) c) (Description. Explanation for extra site-preparation costs. No further specific justification)	Negative with an expected loss of approximately 1.5 million euro
Keenenburg V In Schipluiden	a) Municipal land become vacant and available (developing a residential area and acquisition of the adjacent parcels) b) Insufficient number of social housing in other projects (Increasing a number of social housing)	a) (Description and explanation) b) To compensate a lack of social housing in Keenenburg III	Positive with an expected profit of 0.1 million euro

Figure 3 (left): Look-West project and its sub-plan-units

Figure 4 (right): Subunit 1b, Plan Victoria (Gemeente Midden-Delfland 2011d)

3.4.1 Lookwest: Phasing and parcerlization

The project Look-West is physically close to Lookwest-Noord and related to the latter in terms of the development schedule. After the Look-West had entered into a significant progress, the development of Lookwest-Noord followed to start. Due to its big scale, the Look-West project is composed of several sub-plans. In 2008, a part of Look-west and a part of Lookwest-Noord were consolidated into a separate unit of project, called 'Kreekzone' due to technical problems for servicing the land (Gemeente Midden-Delfland 2008). By separating a difficult subpart of the plan, Kreekzone, it was possible to improve the net present value of the project in 2008 (Gemeente Midden-Delfland, 2008). However, delay in disposing land and subsequently in building from 2009 to 2010 incurred extra planning costs, which is not an insignificant amount contributing to less positive financial result. There was an external subsidy from a regional governmental body, 'Haaglanden', for connecting public transport and reimbursement of value added tax from the national government. The Look-West project is about to finish in a couple of years.

3.4.2 Lookwest-Noord: Difficulties in negotiations and influence of the economic crisis

At the beginning of 2007, a big part of the plan area in Lookwest-Noord was purchased by the municipality (Gemeente Midden-Delfland 2008). There was still one house remaining which needed to be acquired. However, the owner was not willing to sell it to the municipal (Gemeente Midden-Delfland 2008, Gemeente Midden-Delfland 2009c). As a result, the project was impeded. In the end, the expropriation procedure had begun in 2009 (Gemeente Midden-Delfland 2009c) and has not stopped until an amicable agreement was reached in 2010 (Gemeente

Midden-Delfland 2011b). Originally, Lookwest-Noord was expected to yield a positive result with the strategy to diversify house-types. However, negotiations with two project developers starting in 2009 were brought to a deadlock due to disagreement on house-types and land disposal prices. The difficulties are attributable to the impact of economic crisis (Gemeente Midden-Delfland 2009c). In 2010, the impasse in negotiations led to further reduction of the expected result. At the end of 2009, the expected shortage of approximately 0.5 million euro was charged to the reserve of land development (Gemeente Midden-Delfland 2011b, Gemeente Midden-Delfland 2010b) Then, the new calculation in 2011 became positive with 0.13 million euro (Gemeente Midden-Delfland 2011b). Costs of site preparation slightly went down in 2011 due to the more favourable results of public procurement than the estimated.

3.4.3 Kreekzone: Programme-adjustment and plan-optimization

Kreekzone is a deliberately separated unit of project from Look-West and Lookwest-Noord. It was created as a different unit of project, due to technical problems against site preparation found during the development of Look-West and Lookwest-Noord; especially the presence of a 150 kv high-voltage electricity connection (Gemeente Midden-Delfland 2008). It was decided to remove the connection, which would delay in servicing affected areas. In order to avoid the delay of those two projects, the problematic area only was cut from Look-West and Lookwest-Noord, letting the majority of those original plan-areas be steadily developed. Due to the expected negative result of approximately 3 million euro, the plan optimization was proposed in 2010 that the negative result could be reduced to approximately 1.4 million euro by decreasing the initial 60% social housing to 30% in the development programme. (Gemeente Midden-Delfland 2010a, Gemeente Midden-Delfland 2010b). The expected loss of 1.4 million euro was charged to the reserve of land development in 2010 (Gemeente Midden-Delfland 2009a, Gemeente Midden-Delfland 2010a).

3.4.4 Keenenburg III: Increasing losses due to technical problems and subsequent delays

The most of Keenenburg III was owned by the municipality and a group of developers in 2008. In 2008, it was decided to designate a part of the plan area for realizing a new municipality hall. In 2009, the group of developers transferred their land to the municipality and gained the rights to build houses on serviced land. Thus, Keenenburg III is developed in the building claim model (For the building claim model, refer to Needham 2007a, pp. 194). However, technical problems related to peat dikes discovered in the plan area caused substantial delay in further planning in 2008. As a result, parts for residential use had to be re-planned. Accordingly, the historical costs increased so that the project has been expected to yield a negative result since 2009. Extra required work such as soil remediation and relocation of public utilities also worsened the negative result. The expected shortage was charged to the reserve of land development in the annual financial report of 2009 and that of 2010 (Gemeente Midden-Delfland, 2010a, Gemeente Midden-Delfland 2010b). Even

though houses developed in Keenenburg III are targeted at a more expensive price range to increase incomes, the budget-neutral development is not possible.

3.4.5 Keenenburg V: Seizing the opportunity for compensating lacks from other plans

A part of the plan area is a municipal land. The site is currently used for the municipality hall. When it is relocated to the new building in Keenenburg III, the municipal site in Keenenburg V becomes vacant. The municipality is planning to develop the original municipality hall and the adjacent parcels for residential use. In 2010, the percentage of social housing increased compared to an earlier plan in order to compensate a lack of social housing in Keenenburg III (Gemeente Midden-Delfland 2010a, Gemeente Midden-Delfland 2010b). As a result, the expected financial result diminished but still shows a positive amount of 0.1 million euro. An agreement was reached in 2010 on the acquisition of a parcel from other governmental organisation, Service for Rural Areas (Dienst Landelijk Gebied) (Gemeente Midden-Delfland 2010b). Including this, all other planned acquisition has not actually taken place yet (Gemeente Midden-Delfland 2010b, Gemeente Midden-Delfland 2011e).

3.5 Findings

Based on the reorganized course of the key development projects and collected data from a semi-structured interview with a planning coordinator, answers to the research questions are as follows.

3.5.1 How are uncertainties with emerging information flexibly incorporated in the planning and realization process of land development projects within a municipality considering its financial implications?

In the key-projects, information emerged as the projects proceeded. One of the most frequently encountered problems was a technical impediment related to site-preparation which required extra planning and costs (in the cases of Look-West, Look-west Noord, Kreekzone and Keenenburg III). Bottlenecks encountered in negotiations with a landowner and developers and subsequent delays also incurred costs exceeding an initial financial budget (in the case of Lookwest-Noord). Those unexpected events which had negative implications on the financial results in general could not be tackled necessarily in advance but were translated into financial terms as soon as found in order to make fund available for covering any expected losses.

The financial estimation of extra expected costs is required by the Degree on Budgeting and Financial Reporting (BBV). According to the BBV, MD set the rule that an expected loss is charged to the reserve of land development as immediately as the loss is foreseen and that an expected profit can be taken from an original project to the reserve of land development when incomes are greater than remaining expenses to be paid and when it is highly certain to secure expected incomes. Thus,

the reserve of land development functions as a financial buffer for whole land development projects in the municipality in order to cross-subsidize unprofitable land development projects from profitable ones.

In this condition, an initial financial budget based on an initial concept plan functions as a framework for the further progress of the project. It does not necessarily prevent the project from being changed or tried in different directions in response to changed conditions. There is no specific rule to prevent a project from yielding a financially negative result. Aimed spatial quality is sometimes more important than financial result itself. More costs necessary for achieving desirable spatial quality are allowed. Thus, extra incurred costs are tolerated as long as the reserve of land development can cope with expected losses and as long as the municipal council politically declares that the project is necessary and meaningful for the municipality.

With respect to the economic crisis, its negative impact on financial results of land development projects was reflected in general by lowering the annual increase rate of land disposal prices from 3% to 2% for the coming years in the budget of 2012 (Gemeente Midden-Delfland 2011c). For the year of 2010, The annual increase rate of land disposal prices was even fixed as 0%.

3.5.2 How are decisions justified in the process and what are the justifications used?

There are two kinds of decisions in terms of justifications. One requires the sanction of the municipal council in advance. The other is taken by the municipal executive while the municipal council afterwards checks and approves the decisions made. It falls into the former category to establish a new land development project such as Kreekzone as a separate unit of project or to make a new land use plan. Changing details in the boundary of the already approved land use plan falls into the latter category. After the council gives the executive an approval for working on a project, annual plan revision of each land development project is presented to and approved by the council.

The degree of detail in the land use plan is not specified by law so that the land use plan processed in detail can be made and implemented by the executive without asking an approval of the municipal council as long as it fits the overall land use plan (Needham 2007a, p.132-133). Since the land use plan contains what are ‘spatially relevant’, the financial factors such as the type of houses in the plan and the composition of market and affordable houses in the plan are not necessarily specified in the land use plan. Thus, those financial factors can be adjusted in the process without making a new land use plan which requires the sanction of the municipal council (Needham 2007a, p.155). If the detailed land use plan has already been formally approved, any change of those details specified in the approved land use plan should be referred to the council again. It is one of the reasons why the executive are not likely to have financially-sensitive factors such as the composition of different house types already specified from an initial stage of a project. These

aspects can be found in the case of Kreekzone. As a justification for suggested programme adjustment from 60% social housing to 30%, the executive states as follows.

> "The plan optimization is still possible because an original plan of the 60% social housing has not been approved formally."(Gemeente Midden-Delfland 2010a, Gemeente Midden-Delfland 2011a).

For changes in expected costs and incomes which are highly subject to planning officials' discretion, the executive does not provide specific justification except illustration of kinds of costs and incomes. In general, there is no explanation for why certain costs amount to a specific sum and why certain arrangements of a project are formulated in such a way. For example, justifications for the use of building claim model in the case of Keenenburg III are not found. The arrangements of the building claim model are highly influential on the financial result of the project in general because the arrangements concern at what price range the developers transferred their land to the municipality, on what kind of conditions the developers would get back serviced land including the matter of land prices and allowed house types. They can be commercially sensitive information, of which public availability might damage the bargaining position of the municipality against initial land owners or developers so that the information can better be kept confidential. Yet, it can be questioned why any background information for the adoption of the building claim model are not told which is a crucial factor guiding the financial result of the project in the remaining phases, while other deviations from the previous budget are described in more detail of which the influence is relatively limited on the financial end.

In that vein, it can be questioned about not only what are told for justification, but also not told. For example, only one option was suggested by planning officials to the council, excluding other possible solutions, in the case of Kreekzone when justifying the reduction of social housing from 60% to 30%.

> "In this report, we assume that the land development plan will be established in 2010 and that the foreseen loss will be charged to the reserve of land development. Considering the expected loss and the fact that the plan has not been formally established, it was considered if a loss should already be taken in the annual settlement of 2009. For this, possible plan optimizations were sought for. Political and juridical considerations, wills and decision are not taken into consideration when looking for possible plan optimizations." (Gemeente Midden-Delfland, 2010a, pp.72, Gemeente Midden-Delfland, 2010b, pp.91).

Presentation of one option excluding other possibilities could form cognitive closure for municipal councillors who are supposed to compare possible options and make a political decision as politicians (Hanssen and Saglie, 2010).

The most noticeable justification for the suggested change is financial feasibility. Other solutions such as incorporating more social housing for sale than that for rent or affordable housing targeting at low-middle incomes are excluded here.

Background explanation for the initial scenario of 60% social housing is also missed; why 60% target was set and how it is now justifiable to change it. The original target of 60% social housing was perhaps for compensating a relatively small number of social housing in Look-West and Lookwest-Noord (Gemeente Midden-Delfland, 2009a, pp.90) and for satisfying 30% of social housing at the municipal level based on the municipal housing policy 'Woonvisie; Vitale Dorpen Midden-Delfland 2025' (2010). The municipal housing policy provides a testing framework for determining on house types and residential programmes but its scope is limited to what needs to be realised at a whole municipal level without specifications. Thus, the municipal housing policy states that it is possible to deviate from the criteria of 30% social housing at a project level depending on financial feasibility. That provides planning officials with flexible room to choose a different strategy from project to project. According to the interviewee, it is conventional for the executive to be allowed to deviate from the municipal housing policy if there is a financial reason, given that the council approved the plan.

As explained above, justifications for decisions in land development projects are not all stated in formal municipal documents such as annual budget and financial report. In that sense, the role of elected council members becomes important to ask the executive for accountability. Room for citizens to directly ask accountability or to involve in decisions is relatively limited in terms of access to information and available participation opportunities, except voting and submitting opinions (inspraak procedures). What are not told in formal municipal documents in open access are primarily discussed between the executive and the council. The department of spatial development in the executive takes care of all building projects in the municipality. They suggest or present development initiatives first to the cabinet, the head of the executive, then to the council. Ultimately, those initiatives lead to development programme. The planning officials in the department negotiate with market parties, process the land use plan and translate the plan into financial calculation which is brought to the council. The council confirms the financial and spatial framework of the development. Amendments of the confirmed framework should be referred to the council. Amendments within the confirmed framework can be decided by the cabinet itself. In the described process, the council and more specifically the land policy committee of the council hold several meetings with the executive. The planning officials from the spatial development department explain the progress of projects and answer to questions of the councillors. It is possible to trace back what kind of subjects in the development process they discussed via recorded agendas of the meetings but crucial numbers or detailed information are not usually available in public access.

3.5.3 How do all the discussed points in the previous questions influence the financial end?

Three of the five key projects currently present financially negative results. Delays caused by difficult negotiations with market parties or technical problems in site-preparation mostly resulted in worsened and even negative results than the expected.

However, it was justifiable at the whole municipal level due to the reserve of land development. As long as the reserve of land development could cover an expected loss, it was generously tolerated to exceed an initial budget if necessary. On the other hand, efforts were not necessarily spared to diminish the gap between expected costs and incomes as much as possible, seizing the opportunity to generate more incomes. Thus, dealing with an expected loss is not only depending on the reserve of land development. An internal plan optimization in terms of a balance between financial feasibility and aimed spatial quality should be sought for first. In the case of Keenenburg V, newly available municipal land becomes developed for residential use with the adjacent plots, resulting in a positive result. It is limited with an amount of 0.1 million euro but it is at least helpful to create an extra revenue which would compensate a shortage in its related project, Keenenburg III via the reserve of land development. In the case of Kreekzone, it is expected to diminish an expected loss by reducing a number of social houses.

Expected losses from projects can generously be accepted and allowed because of financial resilience created by the reserve of land development. Thus, available amount of fund from the reserve of land development should be in line with the actual status of land development projects, namely, the amount of losses required to be covered in order to keep the degree of financial resilience at an acceptable level. In the current status, the reserve of land development is decreasing in its size (See figure 5). At the same time, worsening of expected losses from several projects is often observed in the documents of annual budget and financial report, not alone from the identified key projects. If the reserve of land development is not sufficient to cover expected losses, it is possible to make a use of municipal ‘resistance fund’ (weerstandvermogen) as an exceptional case. The municipal resistance fund is for general use and not dedicated to land development projects. According to the interviewee, it is not expected yet that they have to cover losses from the municipal resistance fund. The currently available fund from the reserve of land development seems to be accumulated mostly before the economic crisis, when a considerable amount of serviced land in Look-West and other projects were sold (See figure 5). However, the historical evolution of the reserve volume and the relation between the reserve and the tendency to more generously accept financially negative projects cannot be analysed here due to limited data.

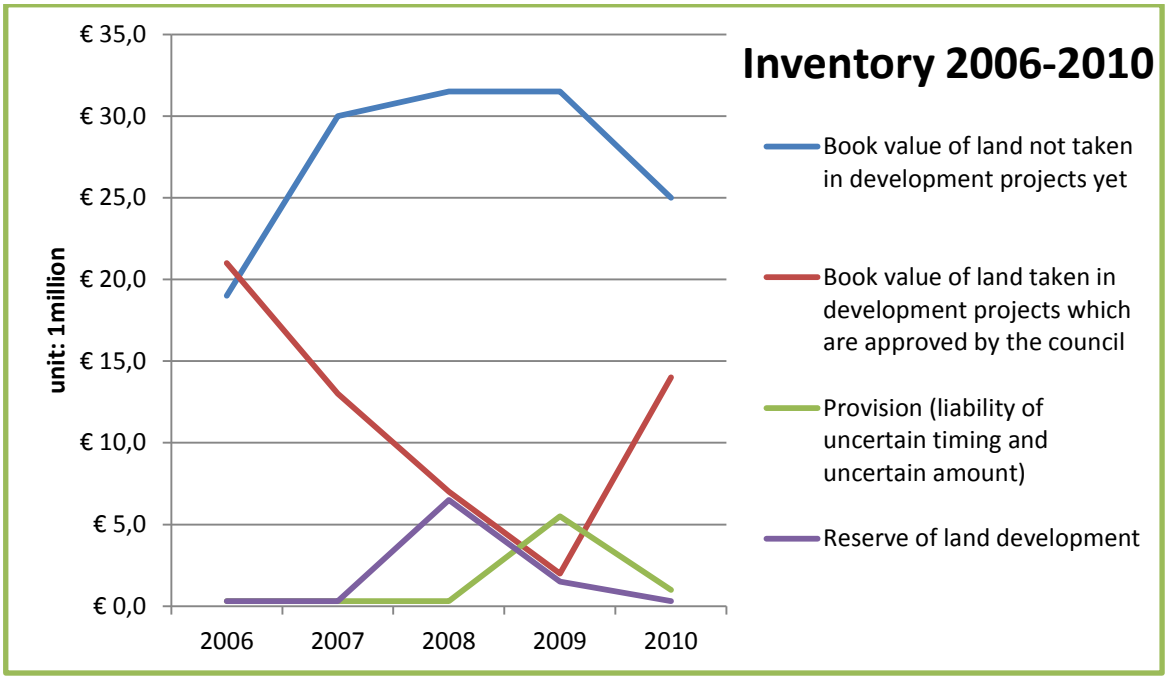

Figure 5: land development inventory 2006-2010 (Deloitte 2011b)

4. Further discussion

Since a pilot case study was intended to test the possible research directions and to sharpen the asked research questions based on the identified gap between the asked questions and what collected data show, some generalizable lessons and further discussion points are presented here based on the findings of the pilot case study.

Flexible decision making is institutionally made possible to improve a project in terms of spatial quality and its financial consequence because an initial plan functions as a framework for further guiding the project. It is made possible by a financial buffer created by the municipal reserve of land development. Even though efforts to improve the project are clearly observed in the identified key projects, those efforts do not necessarily result in a financially positive result but in a less negative result. Unavoidable losses which could not be prevented by plan-optimization are covered by the municipal reserve of land development. The use of the reserve gives the executive flexible room to manoeuvre the project within discretion and also the municipality as a whole to manage several projects related to each other simultaneously. In that sense, the use of the municipal reserve of land development needs to be given extra attention to better understand municipal management of land development projects. It requires more skills and data to analyse the evolution of the reserve of land development as a whole with the status of other projects. An analysis at an individual project level only is not sufficient to understand institutional settings relevant for explaining why certain costs-exceeding is so easily allowed. In order to accommodate emerging new information for adjusting an initial plan which has a financial consequence and to create a financial buffer, the municipal

reserve of land development can be recommended to be applied elsewhere. However, from the perspective of justification, there are some issues to be improved when operating the reserve of land development. No explicit framework for the allocation of fund from the reserve of land development could be observed in the case of MD. The municipal council can better set up principles to prioritize the allocation of the reserve of land development in order to clarify why more losses are allowed for certain projects than others and to set a limit of costs-exceeding so that the executive does not let costs just be accumulated without making possible efforts to tackle them.

The process of justifying decisions regarding land development projects is deeply embedded in ultimate responsibilities of the municipal council to hold the executive accountable. Ordinary citizens are not much involved in such process. In that sense, communication between the municipal executive and the municipal council on municipal land development projects, especially on risks of land development projects seems worth further studying. Even though the results of key negotiations are informed to the municipal council via confidential meetings and reports, a doubt arises whether a confidential form of reporting and communication would be a good way for the municipal council to hold the municipal executive accountable for the best possible performance in reaching their targets in negotiations. The contents of annual budget documents and financial report documents by themselves which are available to the public seem hard to provide enough insights on each land development project since each land development project are not described well as a story of a project from the beginning to the end but more as a collection of annual financial mutations in realizing the project. Then, original intentions to initiate a project and political justifications for such an initiation can easily be missed out from the public discussion on the project. Because each project is discussed annually based on financial mutations taking place in an relevant year, a judgement becomes difficult to be made on whether the project as a whole has been fully optimized or not, as long as there is no description of the full course of the development. If an estimated loss is once covered by the funding from the reserve of land development, the project becomes budget-neutral again in the case of MD. This is a specific way of making a provision for an expected loss among two ways to recognize losses (Commissie BBV, 2012, pp.22). In the case of MD, historical records of loss-covering or revenue-taking are not emphasized much when making a choice on future decisions as long as there is no deliberate reference to those historical records. Reporting is by its nature a retrospective way to ask public responsibilities afterwards. Those historical records are not necessarily to be repeated every time since what happened are not to be reversed anyway. However, it would still be important to trace back the financial records of a project, not only on an annual basis but also on a project basis with its full history in order to accumulate municipal knowledge and lessons for better project operations in the future. At the moment, those knowledge and lessons may be in hands of planning officials in the executive body, but seemingly not in the hands of the municipal council members.

FROM GOVERNMENT TO GOVERNANCE A NEW PARADIGM OF TERRITORIAL MANAGEMENT

Francisco Serdoura[1], Helena Almeida[2]

Abstract

Western world is changing to a new Era, where there is global accessibility to information which is permanently updated: the 'Feedback Society'. Now, people can work and live anywhere, so each city has to prove it's the ideal choice to live, visit, invest and work (Morgan, Pritchard & Pride, 2011; Ascher, 2010; Allan, 2007:3; Winfield-Pfefferkorn, 2005:11).

Also, social mobility increase is changing people's reality (Freire, 2005). In reaction to globalization and Information and Communication Technologies (ICT) evolution, there's no need to integrate a group anymore, leading to a sense of '*dislocation*' and '*unspontaneousness*' and, therefore, to a fragmented society. Today, democracy, government and decision making processes have to be reinvented, due to the disappearance of the common sense of public interest (Ascher, 2010).

Complementarily, people are getting more conscious on equity and political decisions, and consequently, theirs opinions are getting more consistent. As the society is fragmented, no longer homogeneous, decision-making processes need a real involvement of the largest possible number of representatives of society (van Gelder, 2008a).

Traditionally, decision-making was centered on public administration ('top-down' process). Ongoing changes have opposite values, empowering people on decision-making process and reducing hierarchic relations, but also sharing responsibilities with all agents ('bottom-up'). It is necessary to ensure a constant motivation from the agents and decision-making focusing on developing life quality and civic pride, but also place's position on global markets. The objective is to enhance democratic processes with impact on communities, to involve people with community's problems and other larger scope issues, as well as to engage them with public administration and all the head-agents (van Gelder, 2008a).

The study discusses some cases that have already begun the changing of the paradigm and discusses about experienced good practices and problems.

[2] Centro de Investigação em Arquitectura, Urbanismo Design – Faculty of Architecture, Technical University of Lisbon, Lisbon, Portugal - almhelena@gmail.com

The key-question is: how to manage territories and improve them towards a better productivity, success, attractiveness and equity in the third modernity context?

The aim is at contributing to the development of a theoretical and methodological framework to optimize democracy and trust relations between all agents of urban development, considering that the best way is to elaborate equitable, sustainable and inclusive socio-economic and urban solutions.

Keywords: Globalization, Governance, Democracy, Society, Territorial Management.

1. Introduction

Western world is changing to a place where information is permanently spread and updated and where global accessibility is increasingly easier. In consequence of globalization and ICT development, nowadays it's possible to work and live 500km away, which results in an increasing of competitiveness between cities.

People are now able to share, analyze and use information over time and space, which strongly influences performance and growth of economies. (Yigitcanlar, 2009:6). However, there is a common posture of not being part of a group anymore, which leads to a sense of '*dislocation*' and '*unspontaneousness*' and to the fragmentation of society. Nowadays, democracy, government and decision making processes have to be reinvented, as there is no more sense of common good, or public interest (Ascher, 2010).

In order to reflect the deepness of the changes society is facing, the concepts of 'public space', 'place' and 'common good' are now redefined, in line to what François Ascher calls the third modernity Era.

Cities are the incubators for technological innovation, as they have always attracted urban 'in-migrants', which caused an increased stress both on the urban labour and housing market and on the urban environment (Cohen, Geenhuizen & Nijkamp, 2001:1). 'Smart Cities' is a concept that emerged as an answer to problems of overpopulated places, meeting their challenges through the strategic application of ICTs to provide new services to citizens or to manage its existing infrastructure (The Climate Group, 2011:7). 'Smart Growth' is another concept which emerges with the aim at giving new uses to vacant and underutilized land left in older communities by decades of disinvestment and real estate speculation, therefore creating compact development patterns with efficient transportation links. More than anything else, smart growth is about a more deliberate and sensible allocation of land and development (Benfield, 2012).

Globalization and Governance concepts are then analyzed, as well as explained and illustrated with several ongoing examples. Next, a critical analysis is made about

ways of implementing and the probable consequences of it, as well as a discussion on how to avoid the negative ones.

2. The new Glocal Era

The use of ICT on spatial development is one the most responsible factors for the ongoing changing meaning of space, place, distance and time. Distance and time are no longer problems, since wireless communications allow connection independently of place and time. The so-called death of distance or end of space and virtualizing everything can be an opportunity to reorganise inhabited space for diverse human purposes, as the peculiar attributes of locations play an increasingly important role in choosing location for people and companies (Talvitie, 2003:8).

However, once it's not needed physical proximity to social and economic exchanges, society is heading to its fragmentation and individualism is quickly increasing. This process is turning society's perception as a whole or by their classic sectors more difficult, because it is building extremely complex and diverse aggregations, which are still impossible to categorize or simplify. Ascher (2010:47) calls this the 'hypertext', networked, society.

Freire (2005:352) states that increasing spatial, temporal and social mobility is directly related to the way people experience the world. Each place is a freely chosen destination, increasing competitiveness between places to afford the best life quality to their users (Almeida, 2012).

Development of ICT and transportation of people, information and goods eased acculturation between exotic societies. Its impact on world evolution of social values, production and diplomatic relations has been increasingly strong. Nowadays, it can be observed deep society mutations on ways of thinking and acting, as well as on sciences, technology, social relations, economy and, in consequence, on the forms of democracy (Serdoura & Almeida, 2012). Consequently, post-industrial societies learned to valorise knowledge and information development, instead of material goods production. It's a knowledge-based society. However, local identities positioning have been hampered, influencing democratic systems with the emergence of the new 'public space' and 'common good' definition (Innerarity, 2006:9).

The new knowledge-economy Era is based on production, appropriation, selling and using knowledge, information and processes. Western industry tends to a dependency on its capacity to understand markets using science, techniques; developing creative solutions and managing the immediate; and reacting instantaneously, in order to keep its attractiveness in a mutating world.

The growth of the open-data movement has taught general population they can enhance local government, identify and solve civic problems. Therefore, the relationship between city governments and residents has been shifting.

Social media, the internet, 'cloud' computing, sensors and mobile phones are creating an increasing powerful digital infrastructure, allowing people to do everything from communicating with one another, to solve problems collectively, to making electricity grids more efficient, or providing new options for services such as using video conference (The Climate Group, 2011:7).

The complexity of contemporary society is the responsible for the shift in relationships between people, society, knowledge and places. The MIT Media Lab elaborated a chart (see Fig. 1) to illustrate the relationship between information and organizations (Ito, 2012). The power of networks and permeable organizations is not only applied to innovation, but especially to promote collaboration on shared ideas generation, to communicate theories and strategies and to civilly debate with the public (Bernholz, 2012).

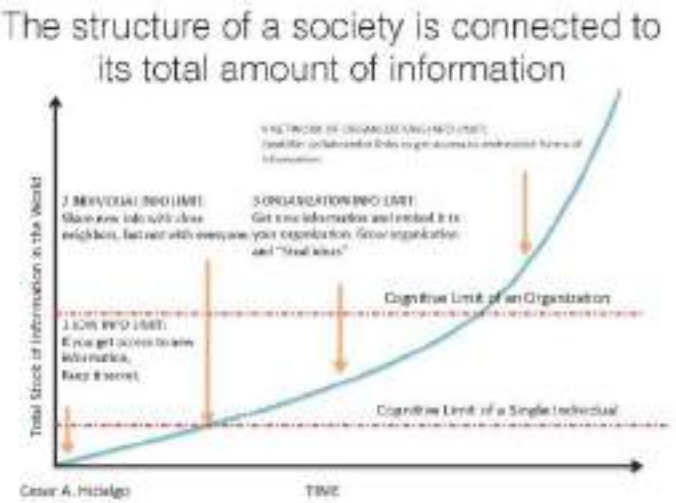

Fig. 1 – Analysis of the cognitive limits of individuals and organizations
Source: Ito, 2012

Cities shall now be able to access benefits from economies of scale, combining resources across projects, promoting their international competitiveness, improving existing services, mitigating risk through better planning and prediction, and engaging citizens in the process (The Climate Group, 2011:8). However, while there has been a tendency to cultural and social values homogenization, pressing places to enter the competition for economic and human capital (Morgan, Pritchard & Pride, 2011:7; Allan, 2007:3; Winfield-Pfefferkorn, 2005:11), competitiveness also led to a valorisation of affording the best life quality possible and of building a common civic culture (Innerarity, 2006:11-12), therefore seeking to recover local values against other society's domination, which is heading to an urban development based on the efficiency of decision-making systems.

On the other side of the globalization, acting as a reaction, information-intensive nature of technological activities leads, unexpectedly, to a need for face-to-face communication, favouring places that offer a high level of competence, many fields

of academic and cultural activity, excellent possibilities for communications, a widely shared perception among interest groups of particular, underused opportunities, and a general business environment facilitating a synergistic development. It is an emergent need for the materiality of relationships, at a local level. The condition for promising urban opportunities is life quality. In general, an attractive urban climate is a *sine qua non* factor for life quality (Cohen, Geenhuizen & Nijkamp, 2001:3) and locals are aiming at playing a fundamental role in their communities.

So, these times' phenomenon can be called 'Glocalization', as a seek for balance between a global economic society, making some pressure for social values acculturation, and a development of local identities, communities, revitalization of traditional activities and an increasing involvement of locals in decision making processes.

'Smart Cities', as an urban answer to the new Era, is an unfinished concept. It's about technologies to improve public services, but also civic empowerment enabling technologies when to new forms of digital intervention in the collective creation of the city. This vision is on street level, whether the first one sees the city from above as the generic idea, allowing to recognize some needs (energy distribution networks, traffic flows, etc.), but doesn't achieve real life and its citizens.

Life takes place on street scale, where we can understand what are the real needs to use more public transport, what real obstacles exist to creating viable business models for automated real-time parking information systems. The street is a dynamic space where we can find more justifications to use the full potential of the city in its interaction between the physical and the digital (Fernandez, 2012).

ICT and social positive evolutions promoted a more conscious and critic view of decision-making from the population. Better qualifications of middle class gave people a more realistic view of society's course. The new paradigm and its new concepts of 'reflexive society' and 'public space' have the aim at long term implementing an open policy culture, as well as a constant assessment and reviewing of the practices (Ascher, 2010:33), so that it can be built the new 'common good'. Today's governance and society complexity demand more stakeholders involvement in decision-making process; it is no longer possible to decide the future with only public realm and some private partners involved, but with representatives of all society (van Gelder, 2008b:3).

The counterpoint to place global positioning is local development through the promotion of active participation, thus increasing civic pride. These are the necessary tools to deal with an increasingly aggressive global competition and to create defensive plans to avoid annulation of the identity of people and places as an investment, residential and tourism destinations (Rainisto, 2003:234). On the other hand, digital revolution brought co-responsibility of decisions to local population, Public-Private Partnerships (PPP) and the municipality. Therefore, risks that

population used to delegate only to public administration and economic groups are now distributed by all sectors of society.

Humanity innovates and switches to new rule sets in times of transition, creatively finding new ways of being. Whichever they will be, Being requires always face to face contact, randomness, unplanned encounter, interaction of groups.

3. Governance

Cities have long since adopted the internet. However, the rise of the web 2.0 is again requiring updates. Today, there are two categories of web services public administration that can be used for local development: websites, which provide useful information for general population and visitants and customizable tools for collecting resident ideas and opinions. Both of them can be tremendously empowering, but can also complicate things, as the sense of easiness for self-expression can be distractive. City project websites have to take into account the ABCs: applicability, brevity, and clarity, to avoid that effort for transparency end up obscuring the process (Doyon, 2012a).

François Ascher's third modernity Era promoted a greater role for population in local communities and neighbourhoods for enhancing sustainable urban development, through public advisory boards, task forces and round tables, and implementing other forms of participatory democracy. Sustainable development can only be achieved through active partnership between all stakeholders and by capacitating communities to direct change. It's a process of managing change by making training and resources available to different communities. It involves developing and organizing local constituencies to take part in community involvement programmes. Local governments and a variety of volunteers can play key roles in supporting capacity building, driving communities to a more mature state by being able to establish commitments for the common good. These processes involve meeting community needs, merging natural resources, linking interest groups, creating investment opportunities and connecting social and economic priorities. The basic schema is presented in Fig. 2. The top three elements represent the main focus. Community-oriented planning projects are regarded as central to the planning process. The three rectangular boxes at the bottom represent key components of development plans (Yigitcanlar, 2009:8-9).

Figure 2. Community-oriented planning process
Source: King *et.al*., 2000 *in* Yigitlancar, 2009:9

Community-based territorial decision making is a holistic and collaborative approach that brings together public and private stakeholders to identify concerns, set priorities, and forge comprehensive solutions. This is a place-based ecosystem approach, where stakeholders consider environmental protection along with social needs, working towards achieving long term ecosystem health, economic prosperity and well being (Yigitcanlar, 2009:9).

4. Solutions to improve civic empowerment in a sustainable urban development framework

One example of Smart City project is the 'Connected Urban Development' (CUD). It will support the development of data, voice, video and mobile communication platforms to be used in local and national policy and other efforts to enable anywhere/anytime work. It will also be created an IP-enabled framework for commercial and business real estate and IP-enabled civil infrastructure that connects roads, railways, gas / electricity / water utility networks, and other city assets such as traffic lights (CUD, 2011). These technological improvements are believed to to promote innovative practices for an environmental improvement, such as:

- Developing broadband-based urban communication and services infrastructures;
- Making use of these infrastructures for congestion charging;
- Developing intelligent, IP-based solutions for dynamic traffic management and rerouting for private transport and highly responsive, on-demand public transport practices;

- New uses of public sector data, enabling more creative thinking and action by key players to survey staff and students (CUD, 2011).

In December 1999, North Denmark decided to become a national IT Lighthouse. The objective was to create the future networked society (Larsen, 2003:2). The project "The Digital Municipality" was a democracy project and educational/skill developing project. It focused on three goals:

- Involving citizens in democracy on a community level;
- Developing the IT skills of the citizens;
- Obtaining new knowledge of IT potentials and limitations in relation to democracy.

Several initiatives has been put into action in order to pursue these goals, like giving computers to the senior citizens followed up by courses in how to use the computers and construction of discussion forums on the internet. As a secondary objective a digital version of the local municipality plan was under development (2003), in order to obtain a higher level of information amongst the citizens and to support the discussions in cyberspace (Larsen, 2003:5).

An example more focused on governance and civic empowerment is Neighborland, a collective online urban planning platform. Neighborland allows the kind of organic conversations started by the stickers to happen online, where they can build group ideas and facilitate connections. Neighborland users post what they want for the city overall or for a specific neighbourhood, and others can click "me too" or comment. Ideas can be sorted by most recent or most popular. (Thompson, 2012).

In result, people are feeling their voices can be easily heard by public officials, because Neighborland shows what people want and their priorities. It provides a concrete, but continuously evolving, record of the needs and desires of the residents. Neighborland also recognizes public spaces are important venues for communication, especially for E-illiterate citizens. So, there were installed physical posters at New Orleans' streets, distributing stickers with the web address on the bottom (Thompson, 2012).

It is important to remember that there can be some practical and ethical problems associated this kind of civic empowerment webbased networks. Community life can be harmed if electronic communication replaces face to face contact and if difficulties on accessing ICT contribute to a different type of social segregation. Moreover, the conflict between privacy and data availability is concerned with public access without discrimination (Yigitcanlar, 2009:18). It is also important to realize that these platforms might confuse people about knowing the difference between collecting ideas and building consensus. Questions posed like ´What would you like to see?´, can lead people to naturally assume that anything is possible, allowing appealing but unrealistic ideas to rise to the top, subsequently disappointing people and leading to the judgement that "government isn't listening to the people".

Constructive ideas are those held to standards of viability, not wishful thinking (Doyon, 2012a).

Another example of the power of social media in community-based urban development is the creation of crowdfunding platforms like 'Kickstarter', 'Indiegogo', 'Ioby' or 'Brickstarter'. These are spaces created to let people expose what they want to make and how much money they need to implement their idea. The goal is to spread the word and be supported in several ways: voting "me too", which is a kind of "like" button of 'Facebook and expresses approval and shared purpose for the same space; commenting in the project page; collaborating and discussing constructive ideas to improve the project; and micro-funding it. The goal of micro-funding is to share responsibilities, risk and involvement on ideas' implementation. 'Kickstarter' and 'Indiegogo' are focused on several areas of innovation, but 'Brickstarter' has as its only focus the territory.

Crowdfunding has been so successful because it solves the problem of taking a big risk on investing on a project which it is not certain whether there is market demand for it. These platforms give a trustful and rapid answer, cheaply and quickly. The public enjoy it as well, as they know their money is going straight to the people who deserve it (Hon, 2012).

In the UK it's been suggested that they should even eliminate all public funding of TV, movies, arts, products, and services, and let the market sort it out. However, it is not going to happen, but a hybrid version of public/crowdfunding system, which means that, if organizations set aside, for example, 1 per cent of their budgets, to matched funding or prizes to qualifying crowdfunded projects in specific areas of interest this would combine the best of public funding and crowdfunding, distributing risk amongst more parties, providing more choice to the public, saving money from wrong investments. This could be a genuinely democratic boost for the new Era; and it would also be a very direct form of economic stimulus. Funding would go directly to the producers as decided by the market, bypassing middlemen, would allow to build a bridge between public and private worlds and to give the public a say in what they want for the future of society (Hon, 2012).

Also crowdfunding platforms have their limits and problems to solve, in spite its potential. As Lange (2012) notes, this is a great first step, but it may cause an illusionary sense that everything is possible to implement on public space, as long as its supported by an important part of the community. However, the bureaucracy involved in realizing such a dream usually becomes a nightmare, leading to frustration and difficulties on implementing supported ideas, which can run against public administration.

An example is the idea for the LowLine to take a 1.5 acre abandoned trolley terminal on the Lower East Side of New York and to turn it into what co-founders were initially calling a park. They raised those funds with a visually attractive idea, first shown in New York Magazine in September 2011. When the LowLine launched on

Kickstarter in February 2012, it proved to be unfeasible as their dream was years, thousands of dollars and bureaucracies away (Lange, 2012).

More recently, Seisdedos (2008:7) verified a new obstacle to sustainable urban development, emerged in 2007: the 'surprise' before the turbulence and subsequent accelerated changes that begun to happen, after the collapse of Lehman Brothers Inc. Suddenly, ongoing mega-plans to promote cities, trying to repeat the 'Bilbao Effect' gone (Rybczynski, 2002).

In consequence, population started to believe in less ambitious development models. Seisdedos (2008:10) states that, due to this sudden political, social and economic change, it is important to create a new development model which establishes how leaders will meet citizens' expectations. Municipal stakeholders have to promote a real and effective involvement with each citizen. The idea of an active and decisive public administration, serving passive and dependent citizens is already outdated, as society is even more made by unique citizens (Seisdedos, 2008:13).

Seisdedos (2008) identified five trends in spanish cities reactions to the ongoing paradigm changing:

- Assuming a radical change in citizens' needs;
- Establish a monitoring system to observe citizens' needs and compare their city with the other competing cities, in order to direct a territorial development and reputation management;
- Change policies towards the new paradigm, avoiding investments in heavy infrastructures, but implementing social and care policies, more focused on a professional recycle of citizens and on local jobs active policies, in order to attract specific clusters investments (Winfield-Pfefferkorn, 2005:14). To achieve success in these policies implementation, local organizations have to establish partnerships, and to avoid traditional territorial marketing, which is about generic and massive approaches, based on public diplomacy and on the creation and integration in strategic alliances networks;
- Combine ICT's utility to urban planning and management and digital marketing;
- Work on the necessary policies changes (Seisdedos, 2008:14-16).

Stakeholders and population knowledge fusion is the basis for developing a strategic plan, in order to better meet the needs set out by all the actors. Such a plan can lead to a place identity redirecting, justified by combining stakeholders and locals' development goals and, additionally, with international markets' objectives (Laurenson, 2002).

The model Seisdedos (2008) proposed is called 'Estrategia de Desarrollo Urbano' (EDU) and it is already considered a positive evolution of Territorial Management Instruments (TMI), because it converges a deep and objective urban analysis with the

recognized needs of general population, stakeholders and the markets, towards a serious commitment (see Fig. 3).

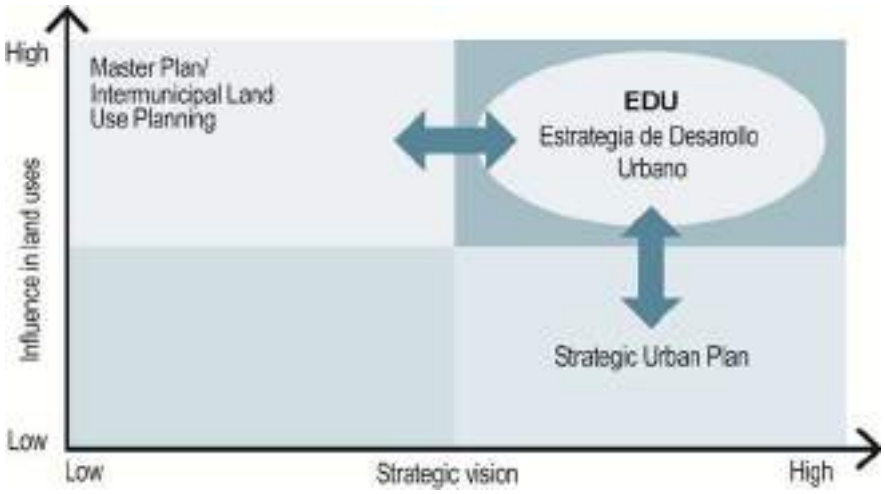

Fig. 3 – EDU tools and TMI convergence
Source – adapted from Seisdedos (2008:17)

Seisdedos (2008) states that the current separation of these two instruments (strategic plan *vs.* Master Plan is due to the inconsistency between urban strategy and land uses planning. A new instrument aiming at connecting both vision and action would redefine more properly the municipal strategic positioning and transform automatically strategic vision into concrete actions, objectively selected in order to achieve strategic success.

This model defends a holistic approach in order to widely meet the identified needs. Urban planning actions would lead to structuring projects, integrating both strategy and reality. Their effects should go beyond physical space. Therefore, EDU would be a main instrument for territorial management and municipal policies, providing the graphic and systemic structure for actions coordination from the most diverse fields, which would then be useful as a communication tool with citizens and investors Seisdedos (2008).

In a bottom-up development process, communities are questioned about their expectations and requests on defined spaces in order to propose solutions to decisions makers. 'Lively Cities' (2011-2014) is a European project which aims at turning misused, underused or unused public spaces into new destinations where people choose to spend their spare time. The project has three working steps, in order to achieve a successful bottom-up approach in improving public space quality:

- **Define** - partners observed, analysed the spaces and sensitised communities involved in the public space;
- **Test** - From all the observations, analyses & work with communities, partners have pointed out what to test on the public space. All the tests shall be evaluated about their users acceptance;

- **Implement** - Final actions of place making will be set up as well as long term structures to manage these new destinations on a daily basis (Bouakaz, 2012).

The practice of good urban governance calls for local authorities to direct their actions toward efficiency, effectiveness, accountability and fairness (Yaakup, Sulaiman & Bakar, 2006:3).

Nowadays, municipalities have the task of strengthening relationships with local population and users, in order to ease active sessions of civic participation in decision making processes and avoiding hostile postures from less happy social groups. So, Lindstedt (2011:42) establishes four (4) dimensions that municipalities should develop in order to approach locals and public administration towards better commitments, co-responsible decisions and better partnerships for effective implementation:

- Ability to manage place demand;
- Continuity 'related' to the place and 'congruent' with the place. This means that there is the need to maintain identitary references of local population, as well as to maintain generic physical characteristics of the place, which is recognized by locals as an integrant part of place's identity;
- Support in achieving the goals – by providing enough resources to achieve individual goals, people feel identified, supported and understood by the place, thus forming affective relationships with the place (Lindstedt, 2011:47);
- Distinction – sometimes people feel so identified to their places that use them to manifest belonging to a social group and to distinguish from other groups. In spite of the inherent segregation that subsists in this reaction, this is crucial as an element of human identity construction, as nobody feels identified with a place that reflects everyone /no one.

Some cities, like San Francisco, USA, are working on an urban model that identifies some areas of the city which welcome prototyping, ephemeral interventions and innovations. Like Apple's ready-made platform created to let anyone build an iPhone app, San Francisco is creating platforms of public space experimentation (Badger, 2012).

5. 5. Conclusion

ICT possess the potential to provide tremendous support to public by empowering them with information and web-based decision making environments can mould today's society, by providing efficient public access, supporting empowerment of the public's capacity to work with data and to participate in the discussion of community development initiatives, environmental problems and decision making. Developing virtual decision making tools may also encourage community involvement and provide focus for a community's discussion of diverse ideas as well as guiding them through the planning and design process (Yigitcanlar, 2009:18). In fact, ICT is

proved to be a powerful tool to improve democratic processes of decision making and civic empowerment; by elaborating technologically advanced solutions that can serve as a platform to lead society to a higher level. In another words, ICT are a mean, not an end, to develop a sustainable urban environment.

The first key-factor to complete the third modernity transformation is still underdeveloped, as population is only reactive to decisions come from the top decision-makers. The turning point will happen when all society representatives are truly involved, proactive and co-responsible for the decisions made together. (van Gelder, 2008b:4).

The second is related to globalization combined with deindustrialization, which transformed territory, life quality standards and economic fabric health, as they are dependent on a growing competition for human and economic resources, in order to provide any distinctive character to places and a relatively balanced location of production lines (van Gelder, 2008a:1). The co-responsibility of every sector of the society has an added onus of maintaining and growing the investment and economic activities on the respective place, in order to satisfy the life quality needs of the population and to avoid loss of competitiveness and consequent social and economic fabric exodus (van Gelder, 2008b:4).

The third factor is providing e-learning tools to share knowledge and information among collaborators and raise awareness in environmental problem solving process. This could enable effective web-based decision support systems through which individuals could express directly to the decision makers. It should provide equal access to data and information for all sectors of the community. A high degree of trust and transparency needs to be established and maintained within the public realm to give the process legitimacy and accountability (Yigitcanlar, 2009:19).

Government gives place to Governance, understanding it as a devices and methodologies system associated to civil society representatives, with the aim at implementing policies and public decisions, in order to strengthen representative democracy, through new consultation and decision-making processes (Ascher, 2010:94).

Social media is the attempt of public administration to engage with citizens in a new forum through which the public sector relationship with citizens can play out in plain sight. Then, if city leadership has built strong and trusting relationships with residents, social media can make them even stronger and help on the development of wider support. However, if the community has little or no trust in governance, then it can promote unhealthy and unbalanced discussions (Doyon, 2012b), as these platforms are also able to empower networks of discontent. It has also to be taken into account the limits of engagement systems like social media and crowdfunding platforms in particular, and try to find solutions to soften bureaucracies and effectively engage all the interested parts and authorities.

New decision-making processes needs to focus on the following objectives:

- Transparent policies, directly related to place values;
- True messages and promises;
- Creativity and innovative solutions;
- Accountability, in order to promote trust between all agents;
- Turning urban development and branding a sole strategic management, focused on enhancing governance and leadership (Anholt, 2009).

Municipalities have the role of strengthening relationships with local, by developing conditions to make better commitments, co-responsible decisions and better partnerships for effective implementation.

The objective of this new civil society is to discuss points of view, decisions, and share goals. To achieve this, it is required the constitution and skills of city management and civic representatives staffs, boards, and advisors, the way they provide access to their key decision makers, and the ways they engage with critics and supporters in the real context in which those things will happen (Bernholz, 2012).

Empowering local population by involving all sectors of the society in this plan construction and actions implementation has the aim at achieving more adequate strategies to the real needs of the population, leading on the other hand towards more cohesive and confident communities, increasing civic pride and therefore willing to contribute to place's good evolution (van Gelder, 2008b:5).

The current challenge for territorial management is how to deal with contradictory goals of such a diverse population, and how to manage the new people-led interventions in the city, in order to unlock bureaucratic barriers and boost co-responsible urban development and distribution of risks (Badger, 2012).

ECONOMIC GROWTH, URBAN DEVELOPMENT AND ENVIRONMENTAL SUSTAINABILITY

Petter Næss[1]

Abstract

The paper discusses the prospects of decoupling growth in the urban building stock and in the availability of options for jobs and service facilities from negative environmental consequences. Compact and dense urban development combined with improved public transport is often conceived as conducive to that end. Using the Norwegian capital of Oslo as an example, the paper shows some of the achievements but also limitations of this approach. Oslo has since the mid-1980s followed a clear urban containment policy. Still, growth in the building stock has only been partially decoupled from traffic growth and land consumption for urban development, and the densification has increased the number of people living in areas exposed to noise, air pollution and traffic accidents. Area reserves where densification can take place with small environmental effects will gradually be exhausted. Climate change adaptation may pose further limits to densification. Full decoupling between building stock growth and negative environmental impacts over a long period of time thus seems implausible. In a longer term, environmental sustainability might involve removal of the least environmentally friendly buildings, urban districts and infrastructure to compensate for new construction, and in some cities even shrinkage of the total building stock.

1. The urban decoupling agenda

Nearly 25 years have passed since the UN World Commission on Environment and Development put the issue of sustainable development on the international agenda as a common challenge for all nations. According to the Commission, the key tenet of a sustainable development is to meet basic human needs – especially the needs among the world's poor – in a way that sustains the possibilities for future generations to meet their own needs (WCED, 1987:43). Based on this understanding of the concept, important challenges of a sustainable urban development in wealthy nations are to mitigate climate change, limit energy consumption, reduce pollution, protect natural areas and arable land, and provide a safe and healthy environment for its citizens, in particular the most vulnerable groups. There is, however, a clear tension

[1] Aalborg University, Department of Development and Planning, Skibbrogade 5, DK-9000 Aalborg, Denmark. petter@plan.aau.dk

between these concerns and the widespread goals of city authorities of enhancing economic growth.

Cities – and the urban regions to which they belong – are large spatial concentrations of dwellings, other buildings, and infrastructure. Contemporary economic growth of cities is closely associated with growth in the volume of all these elements. The growth entails a process of urbanization (migration to major urban regions, where the most growth-generating businesses usually prefer to locate) as well as per capita growth in the size of the built environment. In the poor countries of the world, urban economic growth may still play such a progressive role (although the ways in which the benefits are distributed is often highly skewed). However, with increasing affluence levels, the costs of growth have become more and more evident, compared to its benefits (Mishan, 1967; Jackson, 2009). In the 1970s, the report Limits to Growth published by the Club of Rome (Meadows et al., 1972) triggered a wave of skepticism and criticism against growth.

In the 1980s, this growth criticism receded while a belief in green technological inventions as the key to sustainable economic growth won through, supported by the theory of ecological modernization (Huber, 1985; Mol & Spargaaren, 2000). In the dominating debates on sustainable development, decoupling economic growth from negative environmental impacts has thus been highlighted as a main avenue to achieve environmental sustainability. (OECD, 2002). For urban development, a main challenge of decoupling is to find ways of accommodating growth in the building stock and ensuring accessibility to facilities while reducing negative environmental impacts resulting from the construction and use of buildings and infrastructure.

In the recent few years, the assumptions of the ecological modernization paradigm have, however, been increasingly challenged by critics who from different perspectives argue that the quest for economic growth in affluent countries should be replaced by policies aiming at zero-growth or even de-growth (Jackson, 2009; Spangenberg, 2009; Martinez-Alier et al., 2010). This literature has, however, generally not paid much attention to the relationships between economic growth, urban development and environmental sustainability.

2. Densification as decoupling

According to the European Environmental Agency (2006), the urban population in Europe grew by 33% between the mid-1950s and 2000. During the same period, the area covered by European cities grew by 78%, corresponding to an increase in urbanized land per capita by 34% on average. In most cities the growth in the volume of the building stock has been higher than the growth in the area covered by the city. Higher buildings have replaced lower ones, and in-

fill development has taken place on vacant sites within existing urban area demarcations. However, in most cities, there has also been considerable outward urban expansion where previously undeveloped land in the surroundings of the city has been converted into sites for urban development.

The stronger growth in the volume of the urban building stock than in the number of inhabitants is partly due to a substantial reduction in the average household size. For example, in Denmark, the average number of household members was nearly 3.5 in the 1950s, dropping to 2.51 in 1981 and further down to 2.16 in 2009. Thus, today there are considerably more households – and hence also dwellings – per 1000 inhabitants than there used to be 'in the old days'. Instead of becoming on average smaller, as one might expect from the decreasing number of household members, the average dwelling size has grown. There has been a substantial increase in the per capita housing consumption, measured in floor area. This growth has to a very limited extent been problematized in the debates on sustainable consumption.

As can be seen in Figure 1, floor area per capita in Denmark and Norway has increased to nearly twice and a half times as much as in 1960 (second homes not included). The growth in the total building stock is even higher than the growth in residential floor area. A similar development has been seen in many other European countries.

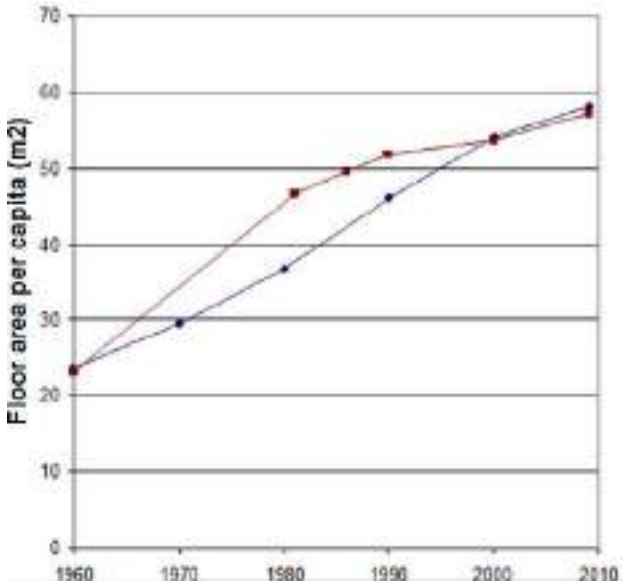

Figure 1: Changes in Residential Floor Area per Inhabitant Since 1960 in Denmark (red) and Norway (blue)[2]

[2] Sources: Røpke (2000), Statistics Denmark (2010) and Statistics Norway (2010a).

During the recent 15-20 years, urban sprawl has stagnated in many West European countries (Kasanko, 2006). Some North European countries, notably Norway and Sweden, have witnessed a clear change from urban sprawl to urban densification during the most recent decades (Statistics Norway, 2011a; Statistics Sweden, 2009). It should be noted that urban densities were at the outset not very high in these countries, so the physical opportunities for densification have therefore been larger than in the more compact south European cities.

A number of studies have shown that low-density suburban development increases the need for motorized travel (Newman & Kenworthy, 1999; Næss, 1993; Næss, Sandberg & Røe, 1996; Næss, 2006). It is difficult and expensive to provide high-class public transport services in low density urban districts. Combined with road construction in the advent of future demands for road capacity, urban sprawl has contributed to the creation of highly car-dependent cities.

Compared to urban sprawl, densification can bring important benefits in terms of the protection of natural landscapes, arable land and biodiversity, in particular if the densification can be channeled to 'brownfield' sites such as derelict or under-utilized industrial areas, obsolete harbor areas and parking space. Multifamily houses require less energy for space heating and cooling per square meter than detached single-family houses (Høyer & Holden, 2001; Mark & Wolfe, 2007), and less material for the construction of the buildings themselves, sewers, cables and access roads (Burchell et al., 1998). And not the least, compact urban development can provide accessibility to facilities through proximity instead of by means of high mobility, thus combining important environmental and social aspects of sustainability. In particular, densification in the inner and central parts of a city or metropolitan area is favorable, seen from the perspective of reducing energy use and emissions from transport (for an overview of evidence from Nordic urban contexts, see Næss, 2012). For the above reasons, densification is considered by many urban planners as a key strategy for decoupling and 'smart growth' (Commission of the European Communities, 1990, Smart Growth Network, 2012).

Some planners have believed that decentralization of jobs to the suburbs would reduce commuting distances, since suburbanites could then be employed at workplaces close to their residential neighborhood. However, in contemporary specialized and high-mobility societies, people do not choose jobs (or recruit workers) mainly from within their local district. For example, in a study in Oslo, employees at the most peripheral workplaces had the longest mean commuting distances among the whole sample. Together with the influence of workplace location on travel modes, energy consumption for journeys to work was therefore found to be on average three times as high among employees of the

most peripheral than among the most central workplaces (Næss & Sandberg, 1996).

3. Oslo as a case of ecological modernization

The urban development of the Norwegian capital Oslo may serve as an illustration of the possibilities and limitations of obtaining a decoupling between growth in the building stock and negative environmental consequences (Næss, Næss & Strand, 2011; Næss et al., 2011; Næss, 2011). Oslo received the European Sustainable City Award in 2003 and was ranked third among 30 cities evaluated for the European Green City Index in 2009. Oslo thus has a reputation for being among the forerunners on the path toward urban sustainability.

In Norway, the political attention to sustainable development has been strong since the late 1980s. Professionals and decision-makers at that time formed strong discourse coalitions promoting a more space-efficient and less transport-demanding urban development. A long-lasting period of spatial expansion in Norwegian cities came to a halt in the 1990s, particularly in the largest urban regions. In Oslo, the reurbanization trend began even earlier. As can be seen in Figure 2, the population density within the continuous urban area of Greater Oslo increased by as much as 27% over the period 1985-2011. During the latest half of this period, Greater Oslo increased its number of inhabitants within the continuous urban area from 755,000 in 1998 to 907,000 in 2011 (i.e. by 20 %), with an increase in urbanized land of only 7 %.

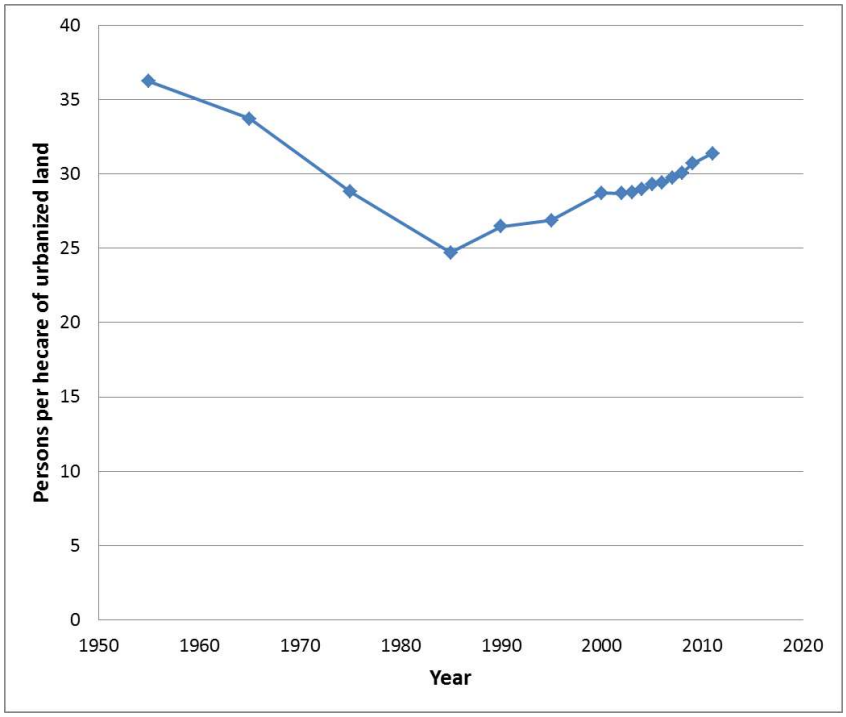

Figure 2: Changes in Population Density within the Continuous Urban Area of Oslo during the Period from 1955 to 2011.
Sources: Statistics Norway, 2011a and b; Riksrevisjonen, 2007.

Within the so-called Inner Zone of the municipality of Oslo, now comprising around 200,000 inhabitants, population density grew by 39% over these two decades. There has also been an overall population density increase for all urban settlements of Oslo Metropolitan Area seen together, although the peripheral settlements have combined densification with some development of dwellings and workplaces on previously undeveloped land. In spite of the latter, the number of inhabitants per hectare of urbanized land within the region as a whole (including 1.2 million urban inhabitants in 2011) grew by 7.5 % over the years 2000-2011. Figure 3 shows how the urban population density has developed within the inner zone of Oslo, the municipality of Oslo, the continuous urban area and within the entire Oslo region since 1999/2000.

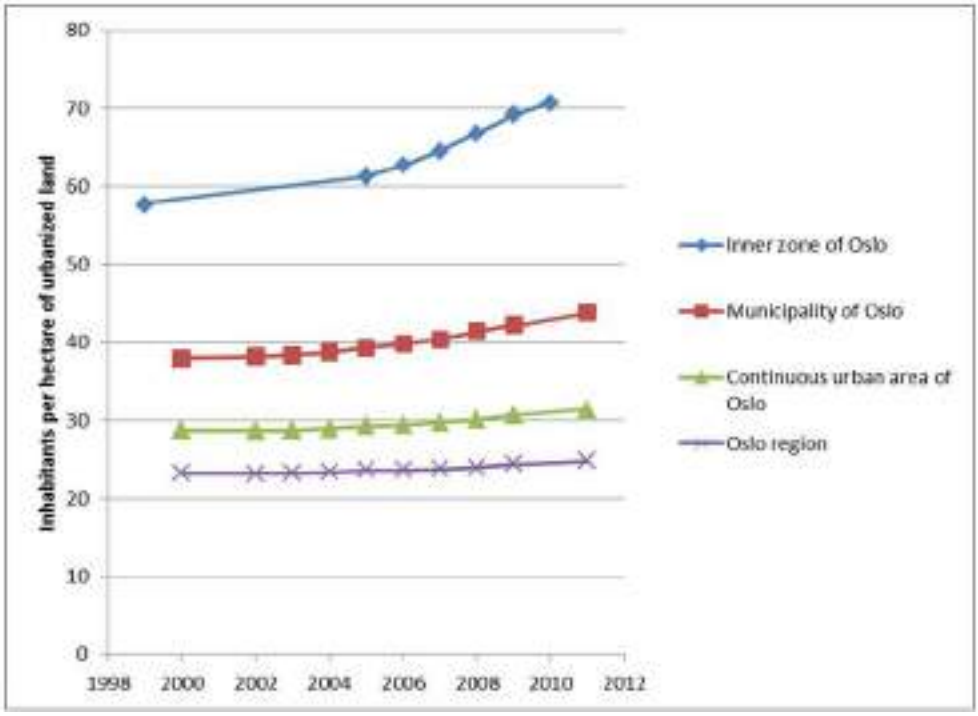

Figure 3: Changes in Population Density within the Inner Zone of Oslo, the Municipality of Oslo, the Continuous Urban Area and within the Entire Oslo Region since 1999/2000.
Sources: Statistics Norway, 2011a and Municipality of Oslo, 2010.

For Oslo Metropolitan Area as a whole, most of the employment growth during recent years has taken place in the counties outside the municipality of Oslo, usually close to main public transport lines. However, for jobs occupied by employees with university education of at least four years, 70% of the job growth since 2000 has occurred within the municipality of Oslo, especially in the inner districts. According to the Dutch "ABC-principle" for environmentally sound location of employment (Verroen et al., 1990), it is especially this type of jobs that should be located centrally in order to reduce car commuting.

4. A partial decoupling

Compared to current urban development in most European cities and to its own development in the postwar period until the mid-1980s, Oslo has managed to combine high growth in population and building stock and low encroachments on natural and cultivated areas. Traffic growth has also been moderate, especially since the turn of the century. During the twelve years from 1996 and 2008, road traffic within Oslo Metropolitan Area increased by 24.5%, with a growth of 11.5% in the period 1996-2002 and 8.5% from 2002 to 2008. These figures may not seem very impressive unless the rapid population growth is taken into consideration. Adjusted for population growth, traffic increased by

1.2% annually from 1996-2002, while there was a weak negative growth (-0.03% annually) over the years 2002-2008. (Statens vegvesen region øst, 2010.)

Figure 4 illustrates how regional GDP, traffic growth and the size of urbanized land in Oslo Metropolitan Area have developed since the mid-1990s (Riksrevisjonen, 2007; Statistics Norway, 2010b and c; Statens vegvesen region øst, 2010). The size of the urbanized area has increased at a considerably lower rate than the regional GDP, indicating a clear tendency of decoupling between economic growth and land consumption. Especially the extension of the continuous urban area has been decoupled from economic growth, but also land consumption measured at a metropolitan scale. Traffic has also increased more slowly than regional GDP during the whole period, and in particular since 2003 there is a clear gap in the growth rates of these two parameters.

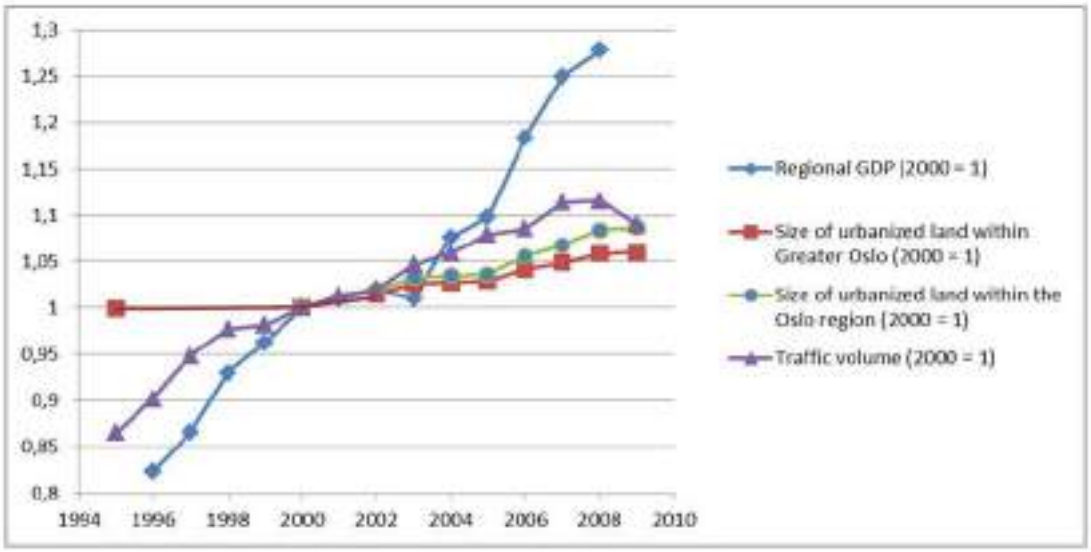

Figure 4: Changes in Regional GDP, Size of Urbanized Land and Traffic Volume since the Mid-1990s in the Oslo Metropolitan Area.

However, slowing down the growth in car traffic is not sufficient to bring about environmentally sustainable mobility. In Oslo, continual road capacity increase has worked against the fulfillment of the sustainability targets. While a new Metro ring has been opened, streetcar services have been improved and new express bus lines have been established, new multi-lane roads have also been constructed. Partly, road building has been motivated by a wish to lead traffic through tunnels away from city centers and housing. But most of the new tunnels have had more lanes than the surface roads they replaced. The purpose of this road capacity increase has been to combat congestion. Such 'predict and provide' infrastructure development will hardly contribute to reducing

greenhouse gas emissions and other negative impacts of urban road traffic (Strand et al., 2009).

5. Environmental justice dilemmas

While Oslo's urban densification has reduced the conversion of natural areas into building sites, it has reduced the intra-urban open-access areas within the continuous urban area of Greater Oslo. For example, there was a 5% reduction of such areas over the five-year period 1999 – 2004. Partly, this was a result of transport infrastructure construction, but green areas also had to yield to new kindergartens or schools in districts where densification caused population growth beyond the capacity of existing social infrastructure. Together with the rapid inner-city population growth, this has diminished the availability of open-access land per resident in these districts.

Moreover, inner-city residential densification will, other things being equal, increase the number of inhabitants exposed to the higher levels of noise and concentrations of air pollution typically found in the inner parts of metropolitan areas. In Oslo, levels of mortality and coronary infarcts are higher among inner-city dwellers than among suburbanites, and this difference is also present when controlling for age, income, education, and unemployment (Statistics Norway, 2005; Municipality of Oslo, 2009).

Regarding traffic accidents (Røe & Jones, 1997), noise (Kolbenstvedt & Hjorthol, 1987), as well as local pollution, the location of developmental areas has its impacts on the distribution of burdens and benefits between the city's own inhabitants. Metaphorically, as illustrated by Krier (1996), the suburbs are 'bombarding' the inner city with cars and their associated environmental problems. If the construction of new residences takes place in the outer parts of the urban area, those who move into the new suburban dwellings will benefit from a local neighborhood less polluted and less exposed to traffic accidents than the urban average, while themselves contributing to an increased overall amount of transport burdening residents living closer to the city center with more through traffic, noise, air pollution and a higher risk of accidents.

Low-density suburban development thus leads to increased polarization by aggravating the local environmental problems facing those inhabitants who are at the outset exposed to the least satisfactory local traffic situations, while providing a sheltered situation for those who move into the new suburban residences. Compared to a more dispersed urban structure, high urban density decreases the city's overall amount of traffic and its contribution to air pollution, and inner-city densification contributes to a less unequal distribution of traffic-related environmental nuisances, since the suburbs will then 'bombard' the city center with fewer cars. On the other hand, high density concentrates the (although reduced) traffic volume and its related local

environmental impacts. The concentration of local air pollution and noise in inner-city areas shows that there is a need for additional policy measures that can lower the amount of local traffic more radically than what is attainable solely through urban containment.

6. Limits to densification and building stock growth

As the densification process goes on in areas where the construction of new buildings can take place with small negative environmental impacts, such area reserves will gradually be exhausted. Subsequent growth in the building stock must then be located to areas where the construction requires the conversion of natural areas or agricultural land. Importantly, many of the sites where densification has taken place without encroachments on natural areas or farmland have become available because manufacturing industries have moved from Oslo (like most other cities in wealthy countries) to developing countries with lower labor costs and less restrictive environmental regulations. Global-scale relocation processes resulting in large encroachments on nature in newly industrialized developing countries have thus been a precondition for the partial decoupling between growth in the building stock and negative environmental impacts achieved in some European cities.

Densification on sites made vacant due to the moving of manufacturing industries to countries with lower wages is an example of picking the 'low-hanging fruits', where it is relatively easy to obtain a reduction of environmental impacts per unit produced (e.g., dwellings or office space). The (spatially delimited) decoupling resulting from such picking of 'low-hanging fruits' and export of polluting, energy-intensive and land-consuming industries to poor countries is, however, temporary. After some decades, no more polluting industries will be left to out-locate, and the technologically and socially easiest achievable efficiency gains will already have been made.

A high rate of growth in the building stock and technical infrastructure may also make it an even more challenging task to combine climate change mitigation and adaptation strategies in urban land use. Although it is possible to design adaptation measures as well as urban densification strategies in ways minimizing conflicts between mitigation and adaptation, the difficulty in setting aside sufficient intra-urban pervious surfaces while containing new construction of buildings within the existing urban area demarcations will of course be higher, the larger is the increase in the building stock.

Buildings are seldom, if ever, constructed with environmental protection as a main purpose. Instead, construction takes place to accommodate growth in the number of households, jobs etc. and in the floor space per resident or employee. As noted by Høyer & Holden (2001), larger dwellings are also associated with higher consumption of other items like furniture, electronic appliances etc.

Increase in the building stock can at best be made environmentally friendly in relative terms (by choosing resource-efficient solutions), not in absolute terms (Høyer & Næss, 2001). In order to make omelet, you have to crack eggs. As already mentioned, fewer environmental 'eggs' will normally be cracked by densification than by urban sprawl. Densification still has its negative environmental and health impacts.

According to the theory of ecological modernization, environmental problems can be solved within the context of existing political and economic institutions by decoupling economic growth from environmental degradation (Barry & Paterson, 2003). Oslo's densification and public transport improvements are examples of ecological modernization strategies within the field of urban development. However, the Oslo case shows that economic growth has only been partly decoupled from traffic growth and land take for urban development. If economic growth without negative environmental consequences were to be possible anywhere, this would most likely be in societies with a high level of prosperity, a high degree of economic freedom of action, as well as a high level of knowledge among the citizens. Oslo metropolitan area has a higher score than most other metropolitan areas worldwide on all these criteria. In this respect, Oslo might be considered a "critical case" where the thesis that a non-environmentally-harmful economic growth is feasible could be tested. So far, however, it looks as if no city region - neither in Scandinavia nor elsewhere in the world – wishes, or is able, to implement more than a partial decoupling between growth and negative environmental impacts.

In the Nordic as well as other European countries, studies have been conducted to investigate the potential for reducing the energy consumption and environmental load per unit produced by 'factor four', 'factor ten' and even 'factor twenty', i.e. down to 25%, 10% and 5%, respectively, of present levels. When the resource to be economized on is undeveloped land, such rates of reduction will only be possible if it is accepted that important characteristics of the 'products' are changed. Among other things, it would require a complete halt in the construction of detached single-family houses in urban areas. Replacing all development of new single-family home neighborhoods with the construction of apartment buildings in the inner cities would, however, be highly controversial. In the long run, it is also dubious whether this would be sufficient to make continual growth in the housing stock environmentally sustainable.

Similar lines of thought could be pursued regarding the construction of other elements of the physical urban development, such as the construction of transport infrastructure, energy supply systems, and sewage systems. Especially investments in transport infrastructure usually give large direct intrusions into the natural environment. Moreover, infrastructure can of course not be recycled in the same way as the products we throw away as consumers.

According to Høyer (1997), the decisive ecological limits for a further growth in the global mobility are therefore set by the tying-up of resources that must take place in the infrastructure.

This leads us to the question of whether it can at all be in accordance with an environmentally sustainable and globally just development to increase the building stock substantially beyond its present size in rich countries like the Scandinavian ones. Population growth, in-migration to the largest urban regions, and changes in the composition of households imply that there will still be a need to increase the number of dwellings. Moreover, despite the overall high Scandinavian housing standards, some people still live in substandard dwellings. Historically, the housing standard among low-income groups has been substantially elevated as part of a general increase in housing consumption, e.g. as a result of moderate-price dwellings becoming vacant when people who can afford it move into new high-standard dwellings. As evident from the preceding sections, such a continuous, general increase in consumption is problematic in an environmental and natural resources perspective. It is also an inefficient way of improving the residential standard among the population groups experiencing the poorest housing conditions (Bysveen & Knutsen, 1987). If we want to meet the need for improved housing standards among these groups while limiting the overall growth in housing consumption per capita, a policy of 'selective improvement' will instead have to be pursued.

As can be seen above, growth in the urban building stock inevitably tends to increase the environmental load, although the environmental pressure can be reduced significantly by means of environmentally friendly urban planning principles and building design. At the same time it is difficult to envisage a society where there is general economic growth but no growth in the building stock (Harvey, 2010). In Norway, the category 'dwellings, lightning and heating' accounted for 29% of household expenditures in 2007 (Statistics Norway, 2009). If we want general economic growth, non-growth within the building sector would require even higher growth within other sectors. Such a shift of growth from buildings to other sectors of society would, however, not necessarily lead to reduced environmental impacts (Xue, 2012). In many of the other sectors there are similar difficulties in decoupling growth from negative impacts as in the building sector. Not the least, this applies to the transportation sector, where CO2 emissions and other environmental impacts have increased steadily in all European countries, despite the fact that climate change mitigation has been high on the agenda (Tapio, 2005). .

7. A de-growth urban planning agenda

In the European environmental discourse, the perspective of de-growth has gained increasing attention during later years. According to this perspective, the

volume of consumption in the EU countries and other wealthy nations is already higher than what can be sustained in a long term if vital natural resources and environmental qualities are to be maintained and people in poorer countries are to be allowed to reach the same consumption level as in the wealthy North (Martinez-Alier, 2009; Spangenberg, 2010). In the Scandinavian countries, residential floor area per capita is currently nearly three times as high as it was sixty years ago, and there has also been a substantial growth in the stock of non-residential buildings. A long-term continuation of such growth in the building stock will put an increasing pressure on the natural environment. There has actually been a tendency of reduced growth rates in residential floor area per capita in Norway and Denmark (Figure 1). Partly, this reflects a strong increase in the cost of housing per m2 of floor area. In Oslo, housing costs per m2 increased threefold from 1993 to 2005, reflecting changes in the financing conditions and land values rather than technical standard improvement. But the declining tendency may also indicate that the consumption of floor area is approaching some saturation level. If so, further growth in households' purchasing power will be channeled to other items, for example holiday flights. Less money spent on housing will then not contribute to reduced environmental load, but rather increase it.

As long as the purchasing power grows, reduced growth in the consumption of one category (such as housing) tends to be compensated by increased growth in the consumption of other items. Such 'rebound effects' have a tendency of reducing or offsetting the environmental gains from energy- or material-saving technologies or reduced consumption of one particular type of commodity, since the money thus saved can be spent on other types of consumption that are not necessarily environmentally neutral (Nørgaard, 2009).

A number of environmental, social and distribution-ethical reasons indicate that the per capita size of the building stock and technical infrastructure in Scandinavian cities has reached a level of sufficiency. From a sustainability perspective, we should instead of quantitative growth give priority to qualitative improvements of the building stock, such as environmentally friendly building-technological solutions, area-effective and flexible layout of the rooms, and a high esthetic quality. Improved housing conditions for the small proportion of the population who still live in substandard dwellings should be realized through selective residential construction directed towards the housing needs among these groups. The rest of the population – the large majority of Scandinavians – would hardly suffer any hardship from continuing their present level of housing consumption. Measures to enhance a better utilization of the existing building stock in cities should also be high on the agenda, including policies to encourage a subdivision of the largest residences into more units, and facilitation of co-housing schemes (Lietart, 2010).

In a longer term, the question of reducing the volume of the building stock and the size of the urbanized land may enter the agenda in cities in affluent countries. In particular, this might be relevant in cities where the number of inhabitants is stable or declining. If the total building stock is not to increase, the construction of new and more environmentally friendly buildings through densification should be combined with the abolishment of some of the environmentally least favorable built environments, such as the most car-dependent single-family home areas and office parks. This could open up possibilities for nature regeneration projects and a larger coherence of the natural areas and landscapes surrounding the city. In a situation with a deliberate de-growth in the economy, a dismantling of several of the most resource-consuming and unfavorably located built structures might become relevant.

In a shrinking total economy, there is a risk that low-income people will be locked in continual or even worsened poverty. Redistribution of wealth from rich to poor population groups will be necessary, if degrowth shall be socially sustainable and gain public support (Martinez-Alier 2009; Spangenberg 2010). Needless to say, such a development would require radically changed political prioritizations and a much higher extent of political influence on societal development than under current, predominantly market-led conditions. It is difficult to imagine how such a societal development can at all be possible within the confines of an economic system driven by competition between individual actors aiming for capital accumulation (Harvey, 2010).

A decision to support de-growth strategies – a planned and voluntary reduction of consumption levels, working hours and the general busy-ness – is thus far beyond the agenda of the present society. However, if our cities are to become truly environmentally and socially sustainable, such a trajectory would arguably be necessary. The environmental load of the existing building stock, infrastructure and consumption in general exceeds the ecological footprint that would be ecologically sustainable and in accordance with a just distribution globally. Technological improvement can only to some extent reduce the negative environmental impacts. The efforts to develop more environment- and human-friendly cities should therefore not be limited to the creation of smarter building designs and urban planning solutions for a growing building stock. We must also dare to raise our view and ask which needs the construction of ever bigger dwellings, shops, offices, other buildings, and roads actually serve to meet – and which political-economic changes the prioritization of better built environments instead of bigger built environments would require.

SYSTEMATIC OVERESTIMATION OF BENEFITS IN APPRAISALS FOR ROAD CAPACITY EXPANSIONS

Petter Næss[1], Morten Skou Nicolaisen[2] and Arvid Strand[3]

Abstract

Although the phenomenon of induced traffic has been theorized for more than 60 years, the traffic-generating effects of road capacity expansion are still often neglected in transport modeling. Such omission can lead to serious bias in the assessments of environmental impacts as well as the economic viability of road projects in urban areas. This has been illustrated in the present paper by a comparison of environmental and economic appraisals for a proposed road project in Copenhagen with and without short-term induced traffic included in modeling. Even though only short-term effects were included, the comparison showed substantial differences in project feasibility. Induced demand resulted in lower travel time savings, more adverse environmental impacts and a considerably lower benefit-cost ratio when induced traffic is partly accounted for than when it is ignored. Omission of induced traffic can result in over-allocation of public money on road construction and correspondingly less focus on other ways of dealing with congestion and environmental problems in urban areas.

1. Introduction

The aim of the present paper is to illustrate how common appraisal techniques can be, and often are, depicting benefits and drawbacks of proposed transport infrastructure investments in a distorted way. Cost-benefit analysis (CBA) is typically the most common form of appraisal technique for such projects (Mackie 2010; Odgaard, Kelly, and Laird, 2005).

For road projects, the accuracy of traffic forecasts are crucial to the validity of subsequent impact assessments. These forecasts form the basis for estimates for a wide range of impact factors, including time savings, emissions, and noise. Since several studies have concluded that traffic demand for road projects are on average underestimated (Flyvbjerg, Bruzelius and Rothengatter, 2003; Holm 2000; Parthasarathi and Levinson, 2010; Welde and Odeck, 2011), one might assume that this would cause benefits to be underestimated as well. However, underestimating the demand for road traffic also means that the expected time

[1] Aalborg University, Aalborg, Denmark – petter@plan.aau.dk
[2] Aalborg University, Aalborg, Denmark – mortenn@plan.aau.dk
[3] Institute of Transport Economics, Oslo, Norway – arvid.strand@toi.no

saving benefits might not materialize due to additional traffic, since demand could become so high on the new infrastructure that congestion occurs. It is this latter effect that will be the focus of the present article (see Næss, Nicolaisen and Strand, 2012 for a more extensive discussion).

Model simulations of a road project in Copenhagen with and without inclusion of induced traffic is a main source of evidence. In addition, similar, but less in-depth simulations have been carried out for the network of major roads in Greater Oslo, as well as for a planned motorway in a less congested part of Copenhagen Metropolitan area. The empirical context of the paper is the Scandinavian countries, particularly Denmark, but we think the conclusion are relevant also in a wider international context insofar as induced traffic is not fully taken into account in transport modeling practice.

2. The effect of induced traffic

Omission of induced traffic could be a possible explanation why traffic demand for road projects appears to be systematically underestimated. Road improvement generally tends to increase overall traffic volumes due to lower cost of traffic in the form of less time spent to reach a given destination. The effect of induced traffic is now widely accepted among transport researchers (American Association of State Highway Officials, 1957; Downs, 1962; Goodwin, 1996; - Mogridge, 1990; Nicolaisen and Næss, 2011; Noland and Lem, 2002; Næss, Mogridge, and Sandberg, 2001; Overgaard, 1966; SACTRA, 1994; Thomson, 1977). In line with theories of transport economics and transport geography, and a number of empirical investigations in various countries, road development facilitating higher traffic speeds will result in generated and induced traffic by influencing the following six parameters:

1. Route choice
2. Peak hour traffic
3. Modal split
4. Overall transport volume
5. Land use (long-term)
6. Quality of public transport services (long-term)

Among these six effects, the four latter contribute to genuinely induced traffic (i.e. additional vehicle kilometres), whereas the two former contribute to relocation of existing traffic in time (e.g. between the rush-hour and other times of the day) and space (e.g. between different routes in the same transport corridor). To avoid confusion we do not refer to changes in the temporal or spatial distribution when using the term induced traffic, but are mainly concerned with the effects of parameters 3-6 in the case presented here. In the discussion in section 5 we shall, however, cover parameters 1 and 2 as well.

For road projects, the effect of induced traffic implies that traffic demand exceeds forecasts if these do not take this effect into account (or traffic is overestimated in the no-build alternative, see Næss (2011) for a discussion of this). One interpretation of this could be that more drivers benefit from the new capacity, and that the latent demand means the infrastructure investment has been more feasible than expected. However, more traffic also causes higher environmental stress in the affected area, and if the traffic volume becomes large enough to have a detrimental effect on flow, there is also a loss of time saving benefits. The short-term effect of this is problematic for the situation immediately after the new capacity is opened, but the long-term effect from changes in land use, car ownership, and commute patterns are even more severe. It is possible to include the short-term effect of induced traffic in models, but often this is not done (Johnston and Ceerla, 1996; MOTOS, 2007; Nielsen and Fosgerau, 2005; Næss, 2011). Long-term effects are even more problematic to include, due to the inherent uncertainty associated with estimation of parameters that are dependent on a wide range of unknown factors.

In Denmark, only very few transport models currently in use take induced traffic into consideration. According to Nielsen and Fosgerau (2005), induced traffic has usually been underestimated or totally ignored in the forecasts made as preparation for decisions about larger Danish road projects in the past decades. The only exception is the so-called Ørestadens Trafik Model (OTM), which was originally developed to assess the demand for the Copenhagen metro project, opened in 2002. For most of the modeling work undertaken in Denmark in this period, induced traffic has thus usually been disregarded. According to the responsible parties in the Danish Road Directorate, the regional transport models have during the most recent years been adapted to account for induced traffic (UNITE, 2011a).

However, these model features are not always used in practice. For example, in a recent analysis of the impacts of adding motorway capacity to an existing bridge, a model that did not account for induced traffic was preferred over one that did, in spite of the latter being available[4]. The argument for not doing so seems to be a feeling that induced traffic does not cause significant growth in traffic, and that the effect on the CBA would be negligible even if it was taken into account. In a recent report by a government appointed commission on the need for future development of transport infrastructure in Denmark, the effect of congestion as a deterrent against further traffic growth in a given road network was disregarded in the transport model calculations (Danish National Infrastructure Commission, 2008). Traffic was therefore assumed to grow at a fixed rate, even in situations where driving speeds were predicted to be significantly reduced due to congestion. The identical traffic growth forecasts with and without capacity increases result in exaggerated assessments of the

[4] (interview with HNJ, September 2010)

amount of congestion in the absence of new road construction. Since this document now serves as a reference for appraisal of transport infrastructure projects, such bias in the underlying assumptions distorts the entire appraisal system, and thus also the validity of any results it produces.
Neglect of induced traffic appears to be commonplace in other European countries too. According to the European MOTOS handbook on transport project evaluation, many transport models used in practice do not adequately account for induced traffic, and use of fixed matrices have traditionally been quite common (MOTOS 2007). This is also confirmed by preliminary results from a survey carried out as part of the same research project as the present paper. Among 48 respondents experienced with Swedish transport models, 67 % stated that they completely or partly agreed in the statement that transport models are poor at forecasting the effects of induced traffic. In Denmark and Norway, the corresponding shares were 52% and 48%, respectively (UNITE, 2011).

Figure 1 is adapted from Litman (2011), and illustrates how expected travel speeds are systematically overestimated when induced traffic is ignored. It is this effect that causes a distorted assessment of benefits in CBAs for road capacity expansion.

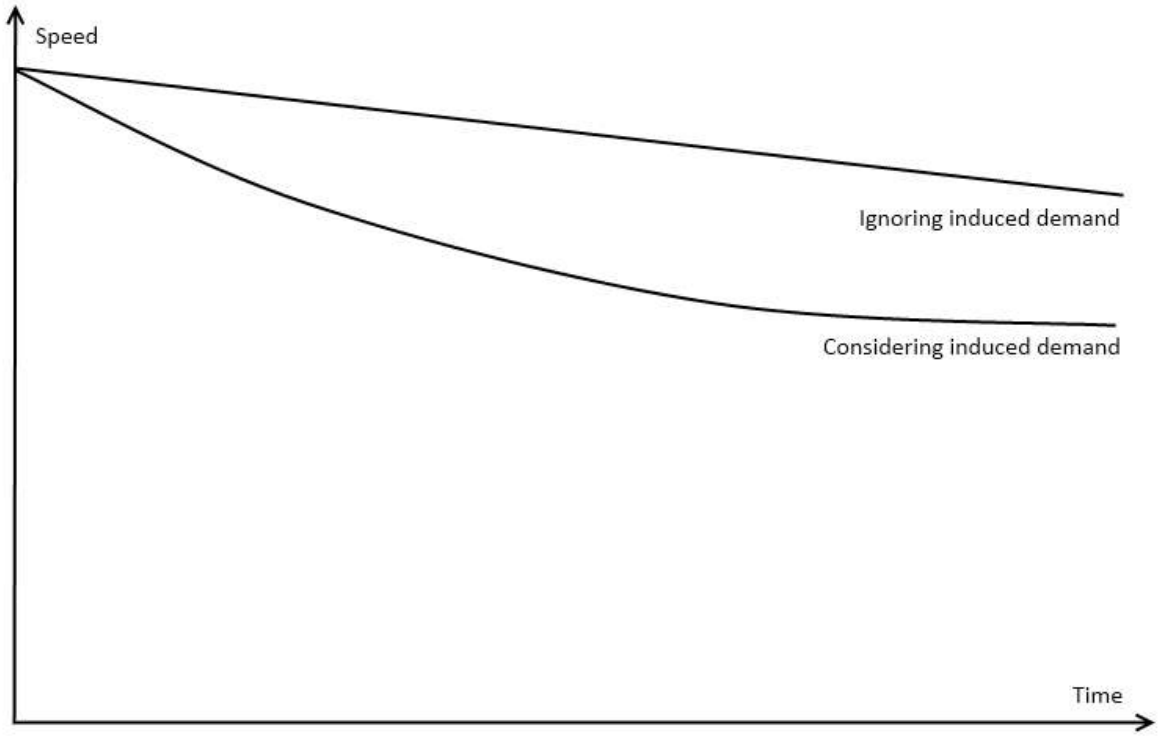

Figure 1. Projected Average Future Traffic Speeds, Depending on whether or not Induced Traffic has been Included in the Forecasting Model. Adapted from Litman (2011, p. 18).

The magnitude of induced traffic can be illustrated through the results of a model simulation for Greater Oslo in Norway. The transport model applied until recently for this region, FREDRIK, offered the opportunity of including induced traffic as well as omitting it. As part of a transport study for the Oslo Region, the need for additional road lanes resulting from a requirement for free-flowing traffic (i.e. no congestion) in a future 2030 situation was illustrated. A simulation specifically made as input for the present paper was made with and without induced traffic taken into consideration. As shown in Figure 2, the estimated need for additional lanes is considerably higher when induced traffic is taken into consideration than in the simulation where induced traffic is ignored. The difference between the simulations with and without induced traffic varies from none to six additional lanes, depending on the position of the road in the entire road network.

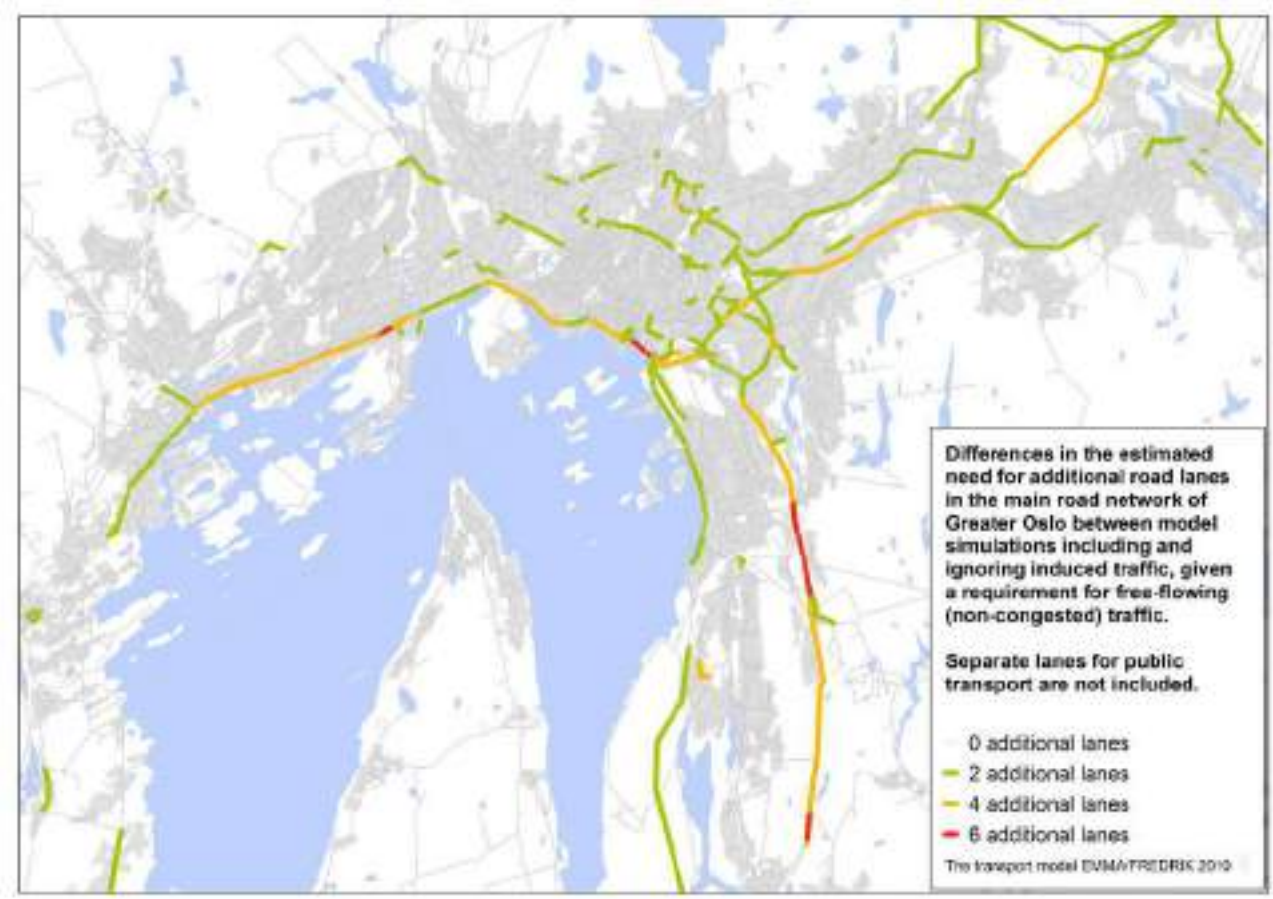

Figure 2. Differences in the Estimated Need for Additional Road Lanes in the Main Road Network of Greater Oslo between Model Simulations Including and Ignoring Induced Traffic, Given a Requirement for Free-Flowing (Non-Congested) Traffic. Source: Simulation made specifically for this article, carried out by Andersen (2011).

Nielsen and Fosgerau (2005) illustrate how the effect can be problematic for assessment of time saving benefits, especially in the form of CBAs. Figure 3 is adopted from their work, and illustrates the supply curves with and without new capacity (do nothing vs. do something). As new capacity is introduced on the network the cost (time) of traffic decreases, and the equilibrium moves from X to Y, which causes an increase in traffic volumes in the short term. An approximation of travel time savings would in this case be the total area A+B. However, if we do not take the effect of induced traffic into account we end up with the approximation A+C instead, clearly a much larger estimate.

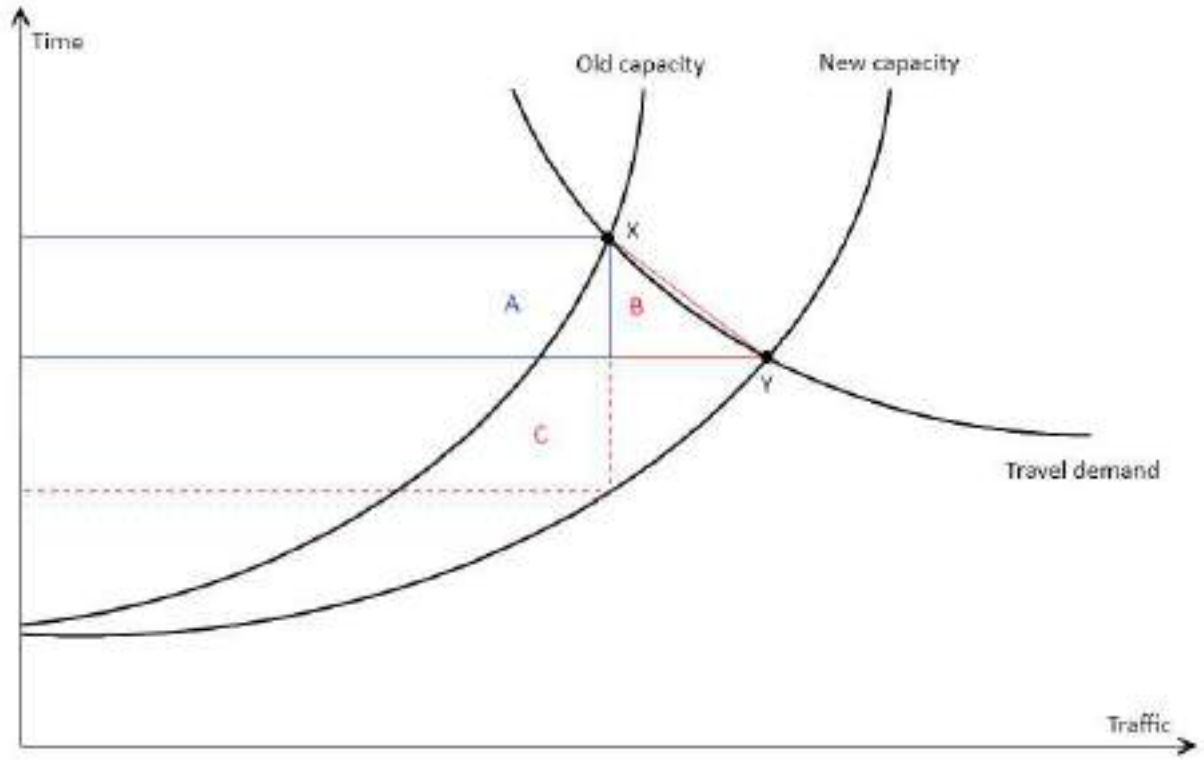

Figure 3. Example of Supply and Demand Curves and Time-Benefit Calculations for a Road Before and After Capacity Increase. Adapted from Nielsen and Fosgerau (2005, p. 10).

It is important to observe that if initial demand is low (i.e. no congestion at X) this effect likely underestimates benefits in the form of travel time savings, as additional drivers would enjoy the benefits without increasing the cost of traffic in any significant way. A Danish example of this could be the new motorways constructed in the northernmost part of Jutland in the years before and after 2000. In such cases the improved road standard usually does not release a large amount of latent demand, and the additional traffic induced by higher speed limits etc. will not be sufficiently great to raise the traffic volume to a level where congestion arises. There are, however, also situations where traffic volumes are high enough that new road capacity can release some demand, but not sufficient to cause immediate congestion problems on the new and

expanded road. In such situations, the time savings for new drivers may exceed the increased travel times among existing drivers caused by induced traffic. In addition to our main case example, we will briefly illustrate such a situation in Section 4, Results. Our main case will, however, be a new road constructed to improve traffic flows in a highly congested urban context. Since capacity expansion is often a measure employed to reduce congestion in areas where this is already a problem or expected to be so in the near future, we consider it highly relevant to illuminate such a situation.

3. The applied methods in the case example

In order to illustrate how neglect of induced traffic can lead to overestimation of benefits we have chosen to perform two appraisals for a selected Danish road project in a congested transport corridor; one which includes induced traffic (model A), and one which does not (model B). The results will then be compared to see whether inclusion of induced traffic in the transport model will result in a reduction of estimated benefits in a CBA. In order to make the results as representative of a typical appraisal as possible, we have chosen to use a recent road project proposal as our case.

All calculations were performed by the agency that typically handles these tasks in the case area, in order to ensure that the appraisals are as true to standard practice as possible. The consultancy firm Tetraplan was thus hired to do the appraisal. The proposed road link was evaluated using current standards for unit prices set by the Danish Ministry of transport. The appraisals with as well as without induced traffic include most of the impact factors included in a standard CBA. However, several effects that could influence the CBA results were excluded due to resource constraints, such as impacts on public transport services or disruptions during construction. However, as construction costs and travel time savings make up the vast majority of total costs and benefits in the CBA for a typical transport project, we doubt that the exclusion of some of the minor effects can have resulted in any substantial misrepresentation of the appraisals presented in the present article. The consequence in the present appraisal is a slight underestimation of costs, which is reflected in higher net present values for both models than would otherwise be the case.

In the chosen case the OTM model (version 5.2) has been used for this purpose, as it is the only model used in practice in Denmark that has the ability to model induced traffic to the extent necessary for this study. It is a state-of-the-art tour-based demand model at the tactical/operational level, and has several sub-models for predicting the traffic demand for different traffic modes based on different traffic purposes. It should be noted here that the OTM model only models the short-term effects of induced traffic, and the results should therefore be considered highly conservative estimates of the impact of including vs. ignoring induced traffic on appraisal results. The standard OTM model will

represent model A. A modified version, which performs like the simpler models typically used in practice, will represent model B. For details on the differences between the two models we refer to Tetraplan (2011a).

The selected case is Nordhavnsvej, which is a planned road project in the northern part of Copenhagen (see figure 4). The new road is intended as congestion relief for the dense residential streets in the nearby Østerbro area just south of the new route. This is argued to be a consequence of comprehensive plans for new urban development in the Nordhavn area just east of the new route, which is expected to house 80,000 new residents and jobs (Municipality of Copenhagen, 2009). These plans are of course expected to increase traffic demand significantly, and the case seems well suited to illustrate the effect of induced traffic on appraisal results for a capacity expansion on a congested network. The current plans for the road involve a new urban link of 1650 meters, with two lanes in each direction and a speed limit of 60 km/h. About 620 meters will be done as a cut-and-cover tunnel, with open ramps in each end. It is expected to reduce traffic in the Østerbro area with 15 % and is set to open in 2015.

Figure 4. The Proposed New Nordhavnsvej Link in Copenhagen. Legend: Black line: surface road; black dotted line: road tunnel; blue line: surface ramps. Source: Municipality of Copenhagen (2011).

In addition to the full case study we have, as mentioned earlier, also made simulation of a road project on a network with little congestion. The extent of this appraisal was more limited than for the full case study, as only first year benefits were calculated. The purpose of this additional study was mainly to confirm that the induced traffic effect is less important to the CBA results under conditions of low congestion, which also turned out to be the case. More information on this appraisal can be found in Tetraplan (2011b).

4. Results

The overall findings of the Nordhavnsvej case are summarized in Table 1. Although a considerably higher traffic volume could be expected in model A as a result of induced traffic, the difference is only around 5 % compared to model B.

Seen in the light of a range of international studies estimating a 10 % capacity increase to result in 3-5 % short-term increase in traffic volumes (Duranton and Turner, 2011; Hansen and Huang, 1997; Litman and Colman, 2001; Noland and Lem, 2002; Strand et al., 2009), the results of model A appear to be in the low range of potential short-term traffic growth. After all, the new link will tie together a four lane motorway with a large redeveloped urban area, where the existing network requires traffic between these destinations to go through dense residential areas. However, in the Nordhavnsvej case, the congestion level is at the outset so high (close to capacity limits) that even a moderate additional traffic can cause substantial reduction in travel speeds. In such a situation, the so-called Braess' paradox may occur, where road capacity increase contributes to reduce overall travel speeds in the network instead of increasing them (Nielsen and Landex, 2005). Since the induced traffic reduces the improvement in travel speeds on Nordhavnsvej considerably, the road's ability to attract additional traffic increase will be constrained. The magnitude of induced traffic will therefore be lower than in a situation where there is considerable congestion but where the capacity increase is large enough to allow for all latent demand to be met without reaching capacity limits.

Table 1. Estimated Main Traffic-Related Impacts of the Proposed Nordhavnsvej, Based on Transport Model Forecasts With Induced Traffic Included (Model A) and Ignored (Model B). Source: Tetraplan (2011a).

Impact factor	Model A	Model B
AADT on main link	22,820	21,740
Total travel time savings (mil. DKK)	2,749	4,589
Changes in fuel consumption (tons)	483	-284
Changes in CO2 emissions (tons)	1,525	-897
Changes in noise level (weighted score[5])	167	162
Changes in safety (accidents involving personal injury)	-0.3	-1.2
Net present value (mil. DKK)	403	2,157
Internal rate of return (%)	5.6	8.1
Benefit ratio per invested capital unit	0.2	1.1

The increased traffic volume in model A results in higher estimates for all environmental cost categories than in model B, although the differences are fairly small compared to the total impact of these factors. An interesting observation is that model B gives the impression that CO2 emission levels will drop as a result of increasing capacity. When the effects of induced traffic are taken into account however, the increased emission levels as a result of higher traffic volumes show up correctly in the appraisal, and model A gives a picture that fits much better with the impacts we would expect for this type of project. A

[5] The weighted score is expressed as SBT (støjbelastningstal), which is a standard unit in Danish noise evaluations. A higher score indicates a higher noise level, although in this case the difference is fairly insignificant.

similar issue can be observed for traffic accidents, where the benefits calculated in model B are four times larger than in model A. While the absolute figures might appear small, the unit values for accidents are quite high, and the monetized impacts over the lifespan of the project measure in hundreds of millions.

It should be noted that the non-monetized values are only for the opening year of 2015, and that long-term effects must be expected to widen this gap – at least if further capacity increases are made allowing traffic to grow beyond the capacity limits soon reached after the initial road construction. In the simulation, traffic is expected to increase by an additional 10 % towards 2030, but from this point on the traffic level is considered static. Both of these assumptions could be expected to underestimate future traffic levels (at least unless policies to limit traffic growth are introduced, including non-expansion of road capacity), and the results of the appraisal must therefore be considered conservative. This becomes especially important when evaluating the travel time savings calculated on the basis of these traffic volumes, as benefits for the entire 50 year period used in the CBA are likely to be overestimated as a result (even in model A).

Even with all these reservations in mind it should be clear from the results in Table 1 that there is a significant reduction in benefits when the effects of induced traffic are taken into account. The results in Table 2 give a better understanding of why we observe reduced travel time savings when including the effects of induced traffic. In line with the underlying economic theory presented in section **Hata! Başvuru kaynağı bulunamadı.**, we observe positive travel time savings from additional drivers benefiting from the new capacity when we include induced traffic. These benefits correspond to area B in Figure 3. However, it is clearly evident from Table 2 that the benefits from these additional drivers are far too small to offset the loss of benefits to existing drivers, which corresponds to area C in Figure 3.

The above-mentioned effects are the results of quite elementary relationships between supply and demand, but they are often ignored in performance evaluations of demand forecasts. For example, Flyvbjerg, Holm and Buhl (2005) observe that while rail demand is typically greatly overestimated, the trend for road demand seems to be a slight underestimation. They therefore conclude that the problems associated with forecasting benefits are much greater for rail projects than for road projects, which also seem plausible when you only look at the actual traffic volumes. However, as the results of the present study clearly show, even slight underestimations of traffic volumes on roads can lead to quite significant benefit shortfalls within the CBA framework. In the Nordhavnsvej case a 5 % increase in traffic results in a time-savings loss of 40 %. Since these effects usually make up 80 % or more of the total benefits, this implies that actual benefits are less than 70 % of those expected from the CBA.

Table 2: Estimated Travel Time Savings from the Proposed Nordhavnsvej, Based on Transport Model Forecasts with Induced Traffic Included (Model A) and Ignored (Model B). Source: Tetraplan (2011a).

Travel time savings (hours per weekday)	Model A	Model B	Change
Cars			
Existing drivers	834	1282	448
New drivers	37	0	-37
Trucks			
Existing drivers	207	284	77
New drivers	6	0	-6
Travel time savings in congestion (hours per weekday)			
Cars			
Existing drivers	435	874	439
New drivers	16	0	-16
Trucks			
Existing drivers	85	163	78
New drivers	1	0	-1

As mentioned earlier, we have also carried out a simulation for a planned motorway in a less congested part of Copenhagen Metropolitan Area. In this case (the so-called Frederikssund motorway leading from one of the outer-area towns to the outskirts of the continuous urban area of Copenhagen), the percentage of traffic growth resulting from induced traffic was higher (around 10-11 %) than in the Nordhavnsvej case (5%). However, due to the much lower congestion level at the outset, the traffic increase in the Frederikssund motorway due to induced traffic would not bring congestion up to a level resulting in significant difference in travel time savings between the models with and without inclusion of induced traffic. Travel time savings were estimated to be 2.7% lower in the simulation with induced traffic than in the model where such traffic growth is ignored, and the benefits due to accident reductions were assessed to be 19% lower. Total travelers' benefits were estimated to be 3.5% lower in the model including induced traffic than in the model omitting induced traffic. (Tetraplan, 2011b).

Although the analysis of the Frederikssund motorway did not show significant congestion arising as a result of induced travel, the 10-11% increase in traffic obviously implies that the time at which the general, 'background' traffic growth causes the traffic volume to approach capacity limits will be shorter than in the absence of induced traffic. As mentioned earlier, only first-year benefits were calculated for the Frederikssund motorway case. Within a longer time horizon, say 15 years, the induced traffic might make up the increment making the difference between severe congestion and high capacity utilization still below capacity limits. With such a time horizon, the difference between the two models in travel time savings would probably have been more similar to that of

the Nordhavnsvej case. Or conversely: additional lanes would have to be added several years earlier in order to maintain relatively free-flowing traffic than indicated by the model ignoring induced traffic (cf. also the Oslo example shown in Figure 2).

5. Discussion

The simulations for the Nordhavnsvej project illustrate the point made by Litman (2011) that a small amount of induced traffic can have a disproportionately large effect on the cost effectiveness of a road project. This is especially so in congested transport corridors, because of non-linear speed flow relationships and typically small net differences between large costs and large benefits. In such situations, underestimation of traffic demand resulting from failure to take induced traffic into account results in appraisals that, ceteris paribus, favor capacity expansion to a larger degree than if this effect is accounted for. The effect is especially crucial in the calculation of travel time savings, as the increased traffic volumes eat up much of the expected utility gains from capacity expansions. There might be a larger total number of drivers benefiting from the new capacity, but the benefit per driver is significantly reduced due to congestion forming much earlier than anticipated.
In the short term the extra traffic leads to benefit shortfalls in the form of longer travel times, which is problematic for the validity of appraisals (particularly CBAs). In the long term it leads to even further benefit shortfalls for time savings, but also severe underestimation of the adverse environmental effects of facilitating continued growth in urban vehicle traffic.
It is important to note that the issues raised in the present paper do not mean that there are no benefits to gain from expanding road capacity in congested urban areas, as more capacity will always offer some form of benefit for drivers. If nothing else, it creates the ability for more traffic to flow through the network. What we argue here is simply that the costs of providing this increased capacity are underestimated and the benefits exaggerated when traffic volumes are underestimated, by ignoring the loss of time savings and increased environmental costs.

Since future traffic volumes are usually estimated on the basis of trend extrapolation, the neglect of induced traffic might also cause an overestimation of demand in the case where no new capacity is added (Næss, 2011). The observed trends in traffic growth are themselves partly a result of prior capacity expansions, and a deliberate choice to abstain from this predict-and-provide approach is likely to result in lower traffic growth than in a business-as-usual scenario. By ignoring induced traffic the deterrent effects of congestion on future traffic growth for the zero-alternatives is thereby also ignored, and since these are the baseline with which different alternatives are compared, this causes further overestimation of benefits from capacity expansion.

6. Concluding remarks

The results presented show a significant overestimation of short-term benefits in appraisals that fail to account for induced demand. Long term effects must be expected to increase these errors exponentially. The faulty conclusions that decision-makers might derive from such appraisals can create a positive feedback loop of continued capacity expansions that do little to solve congestion in practice. Instead, such appraisals create an artificial demand for further capacity expansions, since the expansions themselves create much of the demand that is later extrapolated to reflect a 'natural' traffic growth for which capacity must be provided.

Although model-based forecasts, and the cost-benefit analyses in which they are used, do not influence decisions about project implementation in a one-to-one manner, a systematic overestimation of benefits and underestimation of adverse environmental effects generally tend to legitimize a high spending of society's resources on road construction. They also tend to delegitimize environmental opposition and disarm environmentalists of their arguments. Motorway construction can thus be supported by transport model forecasts by ignoring induced traffic, and it is sometimes portrayed as a suitable approach to reduce greenhouse gas emissions.

Due to the considerable difficulty in knowing beforehand how large the elasticity between road capacity increase and traffic growth will be in a particular transport corridor at a particular time, there is an inherent non-exactness of forecasts of differences between 'do something' and 'do nothing' (Næss and Strand, 2012). In cost-benefit analysis, uncertainty and controversy about how to assess the monetary value of travel time savings (Nicolaisen and Næss, 2011) as well as environmental impacts add to the overall uncertainty of the method. Cost-benefit analysis, which requires precise quantitative input, is therefore in our view not appropriate for assessing whether or not to build a proposed project of a particular category (e.g. a road project) in a specific geographic context. It may, however, be less inappropriate if the task is to compare different alternative ways of designing this project (e.g. layout A, layout B or layout C for a proposed new road). However, due to the uncertainty mentioned above, the CBA should then only be used to assess the marginal differences between different variants of the project, not its absolute economic value.

Given the problematic issues associated with current appraisal practice we argue that it would be more fruitful to pursue a more holistic appraisal approach with simpler, theory-informed models based on multiple scenarios for input variables and more comprehensive sensitivity analyses, rather than pretending to calculate the exact implications of projects.

Such a practice does not square well with the function of model-based traffic forecasts as quantified inputs to cost-benefit analyses in their current form, since this requires forecasts to be extremely accurate. But are forecasts really accurate enough to determine whether commuters will save e.g. 2.15 or 3.12 minutes on average from a new link? Many other public-sector branches use this evaluation method to a much lesser extent, based on the rationality that the effects cannot be quantified to a desirable degree. When cost-benefit methodology builds on such uncertain premises as displayed in the present article, decision-makers should at least take the results with a large grain of salt when considering conceptually different solutions (e.g. investing in road projects, public transport solutions, travel demand management initiatives, or doing nothing at all). If the decision relate to mere design choices of a project that is already decided, cost benefit analysis methodology is likely to be less problematic.

THE STORY OF A CHANGE IN VENUE: GAZIANTEP

Cigdem Buyrukcu[1], **Deniz Erdem**[2]

Abstract

Cities are born, growing, changing and living spaces. Within these development, change and transformation some cities can maintain their physical and social structure. On the other hand some of them may lose their identification, texture and characteristics in this period of change. Especially in developing countries like Turkey, this change emerges faster and multi-sided. This conversion sometimes comes up as replace of functions by itself to meet the increasing demand, but mostly citizens and especially administrators lead to this change and transformation in cities. As one of the most important cities in Turkey, Gaziantep has made a remarkable progress in the last decades and its proportion of national economy has increased rapidly. Having a historical foundation Gaziantep has experienced significant changes in its development process. Especially since 1980s, the city has become attraction center of major investors and this situation is the main leading factor of dramatic change. Depending on increasing industrial employment, rising population and housing pressure, some open areas had been fallen into ruin. Besides this, changing in location of traditional housing, industry and retail facilities has caused existing of lacking quality areas. However, investments for protection and renovation projects have prevented these areas from being without qualification. These investments and restoration projects has made a contribution for economical development with tourism sector. In this study, changes and transformations of Gaziantep in historical period are investigated with positive and negative effects within the frame of existing planning approaches at that time.

Keywords: “urban transformation”, “urban development”, “Gaziantep”

[2] Istanbul Technical University, Istanbul, Turkey – deniz.erdm@gmail.com

Cities are born, growing, changing and living spaces. The ongoing socio-economic behaviors are effective in the cities for their spatial variations rather than physical interventions. Physical changes and transformations are results of these behaviors and interventions. The disappearance of borders in concrete terms with the concept of globalization and continuation the system with relational networks has led to appear both countries' national, regional and urban policies and their impact on space in very different ways. It is possible to say that countries which are affected by global trends in the spatial are generally less developed and developing countries.

As a developing country, Turkey is in a process of change in social and spatial issues for years. Since the Ottoman Empire, this change which began with "westernization" movements, named as "modernization" with the Republican Era and "globalization" nowadays. This process Based on social and cultural change is reflected in the cities as spatial. The current phenomenon of globalization continues to influence and differentiate cities and communities in economic, social, cultural and physical sense. Turkey lives in a very fast and versatile urban change and transform with its problems and potentials.

After 1980, adopted liberal economic policies and the industrial perspective have changed in Turkey, and understanding of the importer has taken place of import-substitution manufacturing. Increasing interest in the production of manufacturing industry has made inadequate industrial cities, so the state had to determine the new focuses and to develop them in a short time. 12 provinces which identified as new industrial centers, recorded a significant growth in the industrial sector as soon as possible with the incentive policies applied. Afyon, Bilecik, Çorum, Denizli, Eskişehir, Gaziantep, Kayseri, Konya, Malatya, Kahramanmaraş, Uşak and Karaman are provinces defined as new industrial centers. Each one of the major provinces in its region, and they provide a significant contribution to national economy in terms of export volume. Study on the city of Gaziantep is the most important difference between the foci of other new industries is that the trade center with past and present (Dinler, 2008). This feature prepared the ground for subsequent years for the development of the city in the tourism sector. Nowadays, Gaziantep is recognized with not only industry but also its historical and cultural values, and its recognition is increasing every day. The problems resulting in some parts of the city because of migration and population pressure that comes with fast-growing industry began to eliminate with conservation and renovation projects which were developed with the vision of culture and tourism. In this study, changes and transformations of Gaziantep in historical period are investigated with positive and negative effects within the frame of existing planning approaches at that time.

Gaziantep is the biggest province in South Eastern Anatolian Region and the 6th biggest province in Turkey. It has significant social, cultural and economical potential as not only regional but also national scale. The history of the city reaches to 1300s and it is one of the first settlements in Anatolia. So it has a broad cultural range from the Hittites to Ottoman Empire. As the geographic location of the historic Silk Road route in each period, the city has continued to cultural and commercial center. However, from the beginning of 20th century, city has gained a new

dimension with pursued economic policies. Especially, after 1980 depending on liberalizing Turkey's economy with the globalization movement, new focal points have emerged in Anatolia, and the city has become an important attraction center for investors. While new industrial institutions had taken the workforce to the city with the industrialization movements, investments of tourism sector had prepared the ground for new development dynamics in city. With these improvements in Gaziantep, a rapid change in both economic and spatial sense, and began the process of transformation. The change process in the residential, commercial, industrial and recreational functions of city were reflected in both spatial and functional. While the rapid developing industrial restructuring leads to degradation of urban structure and emerging of lacking quality areas in many cities, Gaziantep has been able to maintained its original character with its urban vision. Administrators and citizens combined historical and cultural potential of the city with the vision of tourism. Also, they managed to make the city more livable by evaluating the new industrial investments in the sustainable growth and development perspective. In the comprehension of this paper, the change story of Gaziantep was discussed and investment decisions affecting the city of change and transformation projects evaluated in this framework.

One of the most important dynamics of the change process in Gaziantep is population. The city's population began to increase, especially after 1960, increased more rapidly after 1975. After these years, migrations from other provinces have begun to increasingly as well as natural population growth. Place of birth data shows that the number of people who was not born in Gaziantep is more than the number of natives since these years. Between 1940-2000 years, during 60 years, while the population of Turkey had increased to 4 doubles; Gaziantep province's population has increased by slightly more than 4 doubles. Furthermore, in this period, as the urban population of Turkey had risen to 13 doubles, the urban population of Gaziantep had grown to 10 doubles. While the city was 13th rank in 2000, it became 9th rank in 2011. According to the percentage of urban and rural population, urban population increased from 65% to 89%, on the other hand rural population had a remarkable decrease from %35 to %11 between 2000-2011 years. This situation proves that being high the speed of urbanization in Gaziantep province (Statistical Institution of Turkey-TUIK).

It is known that there are large industrial investments on the basis of rapid population increase especially since 1980s. Industrial investments creating employment has made the city an attraction center and resulted in rising of population with migration in a short time. There are many structuring refreshing not only regional but also national economy and they created remarkable employment opportunities in the region. Growing industrial sector, primarily led to the establishment of organized industrial zone in Gaziantep. The first organized industrial zone has installed in 1969 had comprised production fields for both region and nation. Therefore it contributed to recognition of the city in terms of economical potential. Depending on changing of economical structure after 1980s, production activities increased and local products began to be imported. Following these developments, the capacity of organized industrial zone remained insufficient and second, third and fourth organized

industrial zones established in 1986, 1994 and 1998 respectively. Thus, Gaziantep has become a major city with a big portion of employment in industry sector.

In addition to organized industrial zones, existing of free trade zone in Gaziantep is a notable component in the context of economical development aspect. There was an important growth in the volume of trade in the Gaziantep Free Zone. It went into action in 1999 and total trade volume increased by 89% from 2002 and to 2003 years. This rise implies that the increase in the share of imports in the region. Besides the macro scale industrial and commercial structures, small scale industries, small retailers and artisans activities contribute to urban economy in Gaziantep.

Population growth along with developments in industry and trade sectors impacts in different ways on the land use format of the city. Development trends of the Gaziantep began to be orientated as planned by a development plan from Professor H. Jansen in 1935. In this plan, Jansen approved that the city will improve in each direction of the settlement. So the planner led to the usages of southern slopes as residential and northern slopes as administration areas. Also, existing green spaces were retained and applications in new settlement areas planned suitable with features of the traditional urban configurations in this development plan. In 1950, a new development plan was prepared by Professor Kemal Ahmet Aru. Opening more lands for usage of urban facilities in development plan is an important indication of the growth rate of Gaziantep. This is also similar to the previous plan which was made by Professor H. Jansen in terms of preserving of traditional pattern of the city.

The first settlements has begun the around of historical castle in Gaziantep. Until 1950s the city did not show urban sprawl intensely and kept its borders generally. Population impression increasing with migration movements caused the insufficiency of city core in the aspect of housing and trade functions and new residential areas including public open spaces were planned on the north and south part of the conventional settlement. Since 1950s rapid population growth in the city was a reason for transformation of public spaces to housing areas and increasing urban density. Residential areas expanded towards new lands which were used for agricultural production before to satisfy housing needs of incoming people. Immigrants who have low income located in the new settlements which beginning from the southern part, while high income people preferred to settle in the west part of the city. Broadening of city center to south and west direction resulted in the segregation of main urban functions as spatial. In this process, to fulfill emerging needs of commercial area, a new central business district occurred between the residential and traditional commercial zone. The direction of new extension areas have shaped by the site selections of industry mainly in the period after 1970. Some mass housing areas were constituted close by new established industry sites to supply with housing need of workers.

Depending on development of industrial employment, unhealthy constructions appeared in some areas of the city, with increasing the pressure of population and housing. In addition, changing in selection of spatial location of

main functions such as traditional residential, commercial and industrial sites led to some worn areas in the city. About this deterioration of urban, the city's characteristics, social, cultural and economic indicators had been effective. However, investments in conservation and renovation partially prevented to become the depression area for those parts of the city. These investments and renovation projects have contributed to development of the city by uncovering the city's tourism potential.

Gaziantep Castle, the city's one of the most important assets, has a history of thousands of years, has hosted many civilizations. Its restoration project was the first step in tourism investments. The castle, the city bore the nature of a focal point of the development process; then it has indicated a landmark identity (Ugur, 2004). Beside this, with increasing about the awareness of preserving historical and cultural heritage for future generations, increased protection and restoration activities throughout the city accelerated the tourism investments. History of Copper Bazaar renovation Project is one of the major developments mentioned above. Under this project, eight streets and 300 shops were renewed, and Gaziantep province won the Grand Prize for Union of Historical Cities with this project in 2007. This award is increased the recognition of the region, especially in terms of cultural tourism. In addition to these restoration projects, the conversion and renovation activities were started in parts of the city had become depressed and giving trade and tourism function to these places allowed to increase in tourism activities. For instance, 120 houses were renovated in Bey District with conservation activities, and inclusion in the scope of renovation of the Atatürk House located in the region, was an important step in increasing recognition of the region. It is observed in the area, corrected the deficiencies in infrastructure and commercial activities caused an increase to boutique hotels, restaurants and entertainment spots (Strategic Plan of Gaziantep Metropolitan Municipality, 2007-2011). There are 974 archeological site and immovable cultural property including 113 monumental structures, 681 civil architectures, 180 archeological sites in the province. The ancient city of Zeugma, the ancient city of Dülük, Chain ruins, mound Tilmen, Sakçagözü (shepherd) mound, Cıncıklı ruins, tombs Dolman are among the important tourism potential. In addition to all of these, the cultural structures such as Archaeological Museum, Hasan Süzer Ethnography Museum reinforces the tourism potential in the city (Gaziantep Governorship).

To summarize the change of physical space in Gaziantep, it is said that the structure of traditional forms of restoration efforts largely preserved places in the city for the figure ground properties, connections, and preservation of the original structure. Furthermore, a growing number of recent protection projects have important contribution to local economic development.

In conclusion, before 1980s, Gaziantep was an agricultural city. Beginning from 1980s, it has a big development based on industrial growing. There are many reason of rapid growing of Gaziantep and some of these reasons are related with local projects such as conservation and renovation projects in historical city centre. Thanks

to encouragement of industry by the state, Gaziantep has a rapid development in a short time. To parallel with the provocation of state, possibility of investment increased in this region. Therefore, population increased depending on immigration and urbanization became too faster. From 1980s to nowadays Gaziantep has a big development with not only industrial growing but also conservation of physical, social and cultural structure. It can be said that easily this conservative approaches and economical movements made Gaziantep one of the most important cities in Southeast Anatolian Region and Turkey.

STRATEGIC-LOCAL TENSIONS UNDER THE ENGLISH PLANNING SYSTEM: RECONSIDERING THE ROLE OF VALUES IN SPATIAL PLANNING

Mandy Lau [1]

Abstract
Strategic-local tensions occur when there is conflict between the strategic objectives of central government, and the aspirations of local communities. Such tensions were common under the New Labour administration in England, when 'spatial planning' was promoted to deliver neoliberal supply-side solutions to housing needs. Interestingly, however, the Cambridge sub region experienced relatively limited tensions, despite having to deliver major housing growth. This paper argues that effective mediation of strategic-local tensions in the Cambridge sub region, can be attributed to a distinct set of values, in particular the concern for social equity on a sub-regional scale. However, it also demonstrates how these value choices were made within the context of central government's meta-governance framework, as well as local politicians' selective privileging of particular values. This affirms the need for developing 'situated' planning theory, which relates value choices to the contingent contexts in which spatial planning takes place.

Keywords: *Spatial planning; values; strategic-local tensions; England*

1. Introduction

More than two decades ago, Eric Reade (1987) observed that "[planners] devote much time and energy to urging 'co-ordination', and to discussing possible changes in administrative arrangements, at the cost of neglecting the analysis of *the purpose which planning is meant to achieve"* [author emphasis] (p. 157).

Arguably, the introduction of the 'spatial planning' approach in England during the early 2000s, also involved a similar preoccupation with coordination processes, at the expense of considering the normative purpose behind planning. 'Spatial planning' was constructed by the New Labour government as a more effective approach to planning, given its emphasis on stronger 'integration' through the creation of multi-stakeholder partnerships (Nadin 2007). Questions surrounding the purpose of planning were buried under a series of vague discourses, such as 'sustainable development' or 'sustainable communities'.

[1] University of Cambridge, UK – mhml3@cam.ac.uk

In reality, spatial planning in England could not escape the question of values, since all partnership decisions were inevitably guided by a set of normative values. It is not surprising, then, that towards the end of the New Labour administration, more critical commentaries on spatial planning emerged, which highlighted the role of spatial planning in perpetuating neoliberal values, through its emphasis on competitiveness and a supply-side agenda to meet housing and infrastructure needs in the south of England (Allmendinger & Haughton 2012).

What this paper sets out to do, is to bring values back into the analysis of spatial planning. This is not an easy endeavour, however, since there has long been a reluctance to engage with the question of values in planning theory. Part of this reluctance stems from recognition of the oppressive capacity of homogenising models, which assume that particular values can be generalised across different places (Campbell 2006, pp.99–100). Another cause of hesitation is the perception that normative planning theory is too generic, with little relevance to the context-dependent nature of practical planning decisions (Sanyal 2002).

Nevertheless, these concerns could possibly be addressed through development of what is known as 'situated' planning theory (Alexander 2003; Watson 2008). This suggests that it is possible to theorise the role of values in planning, through 'case-based' contributions to theory which relate value choices to the contingent contexts in which planning takes (Alexander 2003, p. 180).

This paper attempts to develop a case-based analysis of the role of values in spatial planning, by focusing on the Cambridge sub region in England. Under the New Labour era, many sub regions experienced tensions in delivering the objectives of spatial planning. In particular, there were tensions between the *strategic* housing development objectives of central government, and the aspirations of *local* communities, a problem which Gallent (2008) referred to as 'strategic-local tensions'. Interestingly, however, the Cambridge sub region experienced relatively limited tensions, despite having to deliver major housing growth.

As will be argued later, successful mediation of strategic-local tensions can be attributed to a distinct set of values, in particular the concern for social equity on a sub-regional scale. In other words, it reflects a concern for *spatial justice* (Upton 2002, p. 259). However, the study also illustrates how these value choices were made within the context of central government's *meta-governance* framework, as well local politicians' *selective* privileging of particular values.

Though focused on the New Labour era, the findings in this paper are relevant to current planning reforms in England. Given the rhetorical emphasis on 'localist' planning, and the simultaneous attempt of central government to retain influence through the National Planning Policy Framework, it is likely that strategic-local tensions are likely to intensify. Under these changing circumstances, which values are going to take precedence in the making of planning decisions? By bringing in the

concepts of central meta-governance and local selectivity, this paper provides insights into the interaction between national and local contexts in shaping value choices, and what this implies for the manifestation of strategic-local tensions in different places.

2. Key concepts

2.1 Spatial planning: it's all about integration

The notion of spatial planning has been around for a while – it became common currency across Europe in the 1990s, especially following the publication of the European Spatial Development Perspective (ESDP). However, there has been much confusion over what spatial planning actually means (Albrechts 2006; Faludi 2002; Nadin & Duhr 2007). In some EU member states, spatial planning has been used as a shorthand reference to the *system* in each state or region for managing land use (Dühr et al. 2010, p.26). In other member states, spatial planning has been used to refer to an emergent approach to *coordinate* the spatial impacts of sectoral policies across the European Union (ibid).

With respect to the English planning system, the emergence of a spatial planning approach has been distinguished by its central emphasis on *integration* (Nadin 2007; Tewdwr-Jones et al. 2010, p.247). This spatial planning approach was formally introduced by the New Labour government through a national planning policy statement, which suggested that spatial planning

> "goes beyond traditional land use planning to bring together and integrate policies for the use and development of land with other policies and programmes which influence the nature of places and how they function." (ODPM 2005, para.30)

The emphasis on integration was accompanied by a specific narrative on the mechanisms by which integration would be achieved, namely through partnerships, networks and 'joining up'. In other words, the New Labour government appealed to the notion of joined-up governance, as the solution to the perceived crisis of the bureaucratic state and the fragmentation problems under New Right marketisation (Bevir 2005).

More specifically, the New Labour government encouraged local authorities to deliver spatial planning objectives through the establishment of Local Delivery Vehicles (LDVs). These partnerships were seen as more flexible networks, involving coordination across administrative boundaries and policy sectors.

2.2 Spatial planning under New Labour: all about meta-governance?

However, the emergence of such partnership approaches to spatial planning was subject to a range of criticisms. In particular, Allmendinger and Haughton (2009) regarded spatial planning as a *political* project of New Labour, in the sense that it

was used to push forward major housing growth and infrastructure investment, in the high-growth areas in southern England. As the authors argued, this was achieved by linking spatial planning to the vague objective of 'sustainable development'. On the surface, this suggested that spatial planning was a neutral activity concerned with balancing between economic, environmental and social needs to achieve sustainable development. In reality, this masked the government's pro-growth ideology (Cowell & Owens 2006), in other words its normative bias towards economic growth.

Building on the above critique, spatial planning under New Labour has been labelled as a form of 'meta-governance' (Allmendinger 2011; Brownill & Carpenter 2009). The notion of meta-governance suggests that the central state is involved in steering the conditions for local governance (Jessop 2002). Meta-governance may involve utilising a range of strategies for steering networks, including linking financial incentives to political priorities of the state, or influencing the decisions of networks through political persuasion or network framing (Sørensen 2006; Sørensen & Torfing 2007; Stoker 2000).

What the notion of meta-governance suggests is that spatial planning under New Labour was not a value-free activity. Instead, the state attempted to retain control over the outcomes of local partnership working, through an institutionalised interpretation of sustainable development, which selectively privileged pro-growth interests. It is within this context that spatial planning in many places was fraught with strategic-local tensions.

However, strategic-local tensions were not manifested to the same extent in every area across England: in some areas like the Oxford sub region, there were intense conflicts between development and anti-development interests; whereas in other areas like the Cambridge sub region, there were relatively limited tensions. How can we explain the variation of experiences under the same meta-governance context?

2.3 Interplay between national meta-governance and local selectivity

In response to this question, a conceptual framework is proposed in this paper to link the concept of *local selectivity* with the concept of meta-governance to explain value choices in different areas.

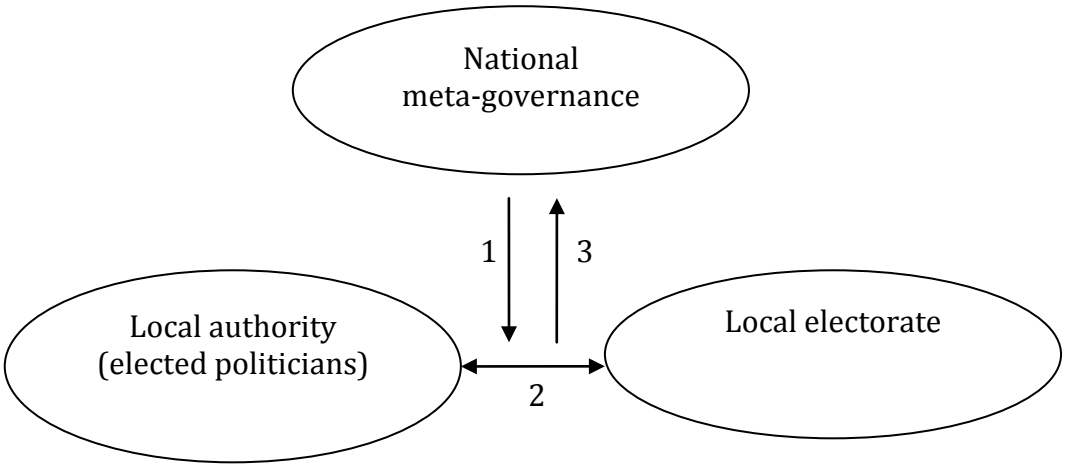
Significantly, the framework recognises that the selection of values is exercised not only at the national level through meta-governance, but also at the level of the local state. Local selectivity has been relatively under-researched (Jonas et al. 2004); likewise, there has been limited research on the role of local politicians as 'local metagovernors' (Sorensen, 2006).

What the framework suggests is that there is a two-way interaction between the values privileged by the national state, and the values privileged by elected politicians at the local level. Clearly, the value choices of local politicians are shaped by the opportunities and constraints inscribed in the national framework. However,

they are simultaneously shaped by the interaction between politicians and their electorate, where politicians need to appeal selectively to particular values to secure normative legitimisation from their electorate.

The conceptual framework is shown in Figure 1 below:

Figure 1: Interaction between national meta-governance and local selectivity



The framework suggests three pathways of interaction between national and local actors, including:

1: National state privileges particular values through establishing a meta-governance framework

2: Elected politicians appeal selectively to particular values to secure legitimacy from their electorate; local electorate respond according to their perceptions of the context

3: Local authorities (elected politicians) respond strategically to the meta-governance framework of the national state

This framework allows us to relate value choices made in a particular locality, with the strategic context which actors are embedded in. Additionally, what the framework suggests is that the extent to which strategic-local tensions are manifested, will depend very much on the specific interactions between pathways 1-3 in different places. This provides us with the conceptual tools to interpret how strategic-local tensions were mediated in the case of the Cambridge sub region, which is presented in the next section.

3. Methodology and case study

In this section, we set out to uncover how value choices have been made in relation to spatial planning in the Cambridge sub region. The Cambridge sub region is located in the East of England (see Figure 2), and the sub region is largely defined on the basis of five local authorities within Cambridgeshire County, including the historic City of Cambridge, surrounded completely by the rural district of South Cambridgeshire, as well as three rural districts adjacent to South Cambridgeshire (see Figure 3).

Figure 2: Location of the Cambridge sub region in England

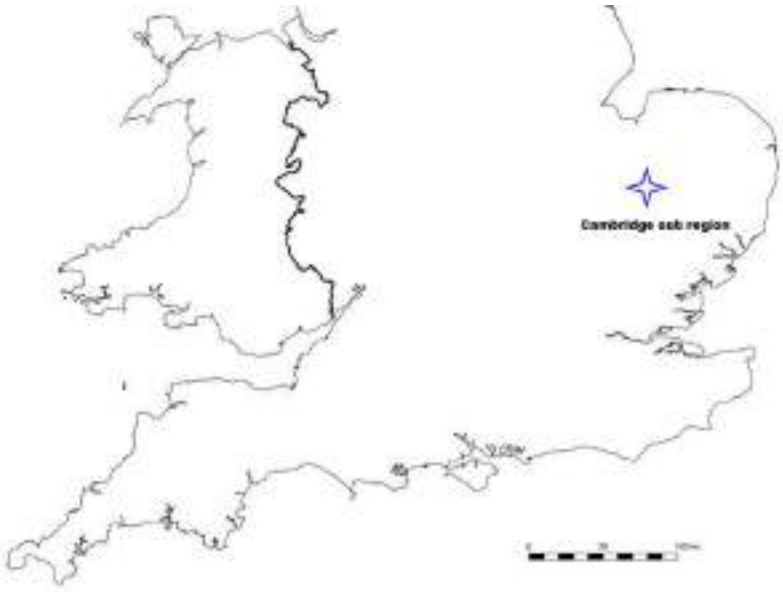


Figure 3: The five local authorities comprising the Cambridge sub region

1. Cambridge
2.South Cambridgeshire
3. Huntingdonshire
4. Fenland
5. East Cambridgeshire

The Cambridge sub region has been experiencing rapid household growth over the last decade, especially an influx of 'key workers' associated with research activities at the University of Cambridge and the high-technology businesses at the Cambridge Science Park. It is thus an interesting case to explore the values underpinning spatial planning, since it involves a strong entrepreneurial economy, co-existing with a historic environment which is sensitive to development pressures.

The empirical research in this case study is based on semi-structured interviews with planners, politicians and members of governance partnerships in the Cambridge sub region. It also draws on sub regional and local plans, planning studies and minutes of partnership meetings.

The case study spans a period of roughly ten years, starting from around 2001 when the spatial planning reforms were first initiated by the New Labour government, and ending in 2010, when the New Labour government was replaced by the Liberal-Conservative coalition government, thus bringing an end to the previous round of reforms.

3.1 Background: Inter-authority relations in the Cambridge sub region

Historically, the relations between Cambridge City and its immediate rural hinterland, South Cambridgeshire, has been uneasy. In the past, Conservative councillors in South Cambridgeshire District were often hostile to the pro-growth agenda of successive Labour and Liberal Democrat councillors in Cambridge City (While et al. 2004, p.289), which resulted in a series of high-profile conflicts over development proposals (Brindley et al. 1996).

However, there was a major reversal in the sub regional planning strategy upon the third review of the Cambridgeshire Structure Plan in the early 2000s. This strategy proposed major housing growth in and around Cambridge City, including three new urban extensions at the edge of the City, which would incur upon green belt land within South Cambridgeshire District, and a freestanding new town in South Cambridgeshire, which would be linked to the city by public transport.

Arguably, a range of values underpinned the change in the sub regional strategy. On one hand, change was driven by a 'competitiveness' logic, in other words a concern to meet the social reproduction needs of the labour force, through the provision of affordable housing and social infrastructure near to major employment sites. In turn, this concern was driven by a fear of losing out in the globally competitive economy. As a senior officer involved in strategic planning explained:

> "I think there was something along the lines that, well, we better all stick together guys, otherwise the growth will go away… so there was a bit of ganging together in adversity. There was a desire for all of the local authorities to say, right, we're pro-growth, it's hugely important to the economy, the quality of life in this area, therefore we want to plan together where that growth is going to go." (Interview, strategic planning officer)

On the other hand, the change in the growth strategy was also justified from the perspective of social equity:

> "We were realising that we were becoming a city for the rich, and for the very poor… you either had a council house, or you were rich. And that was it. Everybody else had to go way out somewhere, way outside the green belt, and we were becoming very, very frustrated and worried about this. We just realised we had to do a big green belt review and allocate some big sites." (Interview, Cambridge City councillor)

Thus the key principle underpinning the third Structure Plan adopted in 2003, was to improve the quality of life for all citizens in the sub region through a better balance between jobs and houses, in the form of major housing growth at the edge of Cambridge, close to major employment sites.

3.2 Changes to the national context for planning

Around the same time as the Cambridge sub region was reviewing its Structure Plan strategy, major changes were taking place in terms of the national context for planning. In 2003, the New Labour government published a national framework for planning in England, widely known as the 'Sustainable Communities Plan' (ODPM 2003). Though not a national spatial plan, the framework indicated the government's strategy for coordinating investment in targeted areas in the country. In particular, the Plan highlighted four major 'Growth Areas', one of which was the London-Stansted-Cambridge growth corridor.

Central government encouraged the establishment of Local Delivery Vehicles (LDVs) in the growth areas, which would provide the structures for coordinating delivery of housing and infrastructure, as well as coordinating bids to the new funding mechanism, which was initially known as the Growth Area Fund (GAF), and subsequently known as the Housing Growth Fund (HGF).

The introduction of this funding mechanism represented a major incentive for delivering new housing. A total of £164m was made available for he first round of GAF (2003-6); a total of £235m was made available in the second round (2006-8); and in the third and final round of funding (2008-2011), a total of £832m was available.

Significantly, these funds were earmarked for areas which were prepared to deliver major housing growth through a partnership approach. According to the guidance issued to all the Growth Area local authorities, the first and foremost criteria for appraising the bids to growth funds was the net addition to housing delivery (DCLG 2008) (criteria 1). In addition, the bids were assessed according to the robustness of local delivery mechanisms and partnership arrangements, meaning growth partnerships had to demonstrate high level of engagement and 'buy in' from major partners (criteria 2).

It is against this background of changes that we can understand the decision of partners in the Cambridge sub region to set up a joint delivery vehicle, known as Cambridgeshire Horizons. The process of setting up the partnership, however, was not short of tensions. Clearly, Cambridge City and South Cambridgeshire District could see the massive benefits of joining up to deliver the urban extensions and new town, since the government's growth funding represented a major stream of infrastructure investment which they had long been hoping for. Theoretically then, the local delivery vehicle could have been established based on partnership working between these two districts alone. And yet, when Cambridgeshire Horizons was created in 2004, the other three districts were also represented on the partnership.

What happened was that the 'outer' districts, in other words the three rural districts of East Cambridgeshire, Fenland and Huntingdonshire, lobbied hard for their representation on the partnership. They were concerned that a partnership based on the City and South Cambridgeshire alone, would suck up all the resources available from government, and leave the other districts struggling to deliver new development. These outer districts made their case by emphasising their interdependency with the urban core. They argued that their role as part of the travel-to-work area of the Cambridge economy, meant that many people who worked in the City were dependent on affordable housing in the market towns in the rural districts, and hence, it would only be fair for the outer districts to receive a share of growth funding to develop new homes and infrastructure.

Although initially reluctant, the 'inner' districts of Cambridge and South Cambridgeshire eventually agreed on the grounds of fairness:

> "It's important that we work with the market towns in other districts, and not only ourselves… it's absolutely right that places like St Neots and Huntingdon also get some money. The original concept was to spend the funds just for the major growth sites, but I think the others argued the case very well that we need to work together, that we need to look at the needs across the county." (Interview, Cambridge City councillor)

Thus, the final decision to establish the joint Delivery Vehicle based on all of the urban and rural districts in Cambridgeshire, was driven by a desire to address the needs across a wider geographical area. In other words, it was underpinned by a concern for spatial equity at the sub regional scale.

3.3 Implementation of the growth strategy

When it came to the actual implementation of the growth sites, a remarkable degree of unanimity was observed, both in terms of the relationship between the local authorities, and the relationship between developers and the local electorate. How do we explain the absence of political discord?

Again, it appears that values played an important role in the mediation of tensions at the implementation stage. First and foremost, the key decisions made at the implementation stage, including the prioritisation of housing growth funds, and the assessment of proposals submitted by developers, reflected the endurance of values and principles agreed at the plan-making stage.

When asked about the logic underpinning the spending programme for growth funds allocated to the sub region, interviewees repeatedly emphasised how the spatial strategy set out in the 2003 Structure Plan, was deeply embedded in the consciousness of all partners, such that everyone agreed that the use of growth funds was to be based on the vision set out in that strategy. The key principle, as we saw earlier, was to improve the quality of life in the sub region through a better balance between jobs and houses, to be achieved through major housing growth at the edge of Cambridge, adjacent to key employment sites. Thus, a major portion of growth funds were targeted at delivering the Cambridge urban extensions and new town in South Cambridgeshire.

At times, the outer districts wanted a greater share of the resources, but they also understood that they needed to respect the spatial strategy which had been agreed:

> "Looking back there was a remarkable degree of unanimity, which followed on from the Structure Plan strategy. We could hardly complain that a lot of money was going into developing Cambridge, because all of us had agreed that Cambridge needs to consume a bit more of its own smoke." (Interview, Huntingdonshire District planner)

The absence of tensions between the local authorities, however, is only one part of the story. The plan to deliver major housing growth on green belt land, with an impact on the historic character of the City, would certainly have been controversial in the eyes of the public. How can we explain then, that there was relatively limited opposition from the public, when major housing developments were actually proposed at the edge of Cambridge?

This draws our attention to how values played an important role in the interaction between local politicians and their electorate. The task of convincing the public about the need for housing growth was no easy one, since years of underinvestment in transport and social infrastructure meant that the public did not have a strong appetite for more houses to be built in and around Cambridge.

However, politicians framed the strategy for growth in a way that would be palatable to the electorate, by anchoring growth to local people's principal concern with housing affordability. In particular, politicians persuaded the public of the need for delivering the major growth sites, by suggesting that inaction would lead to difficulties for people's children to live in the same area in future, due to worsening housing affordability. Implicitly, these politicians appealed to the value of inter-generational equity The consequences of restricting housing supply were therefore relevant to the long-term well-being of families in the Cambridge area:

> "… if we didn't have growth, you wouldn't have a place for your daughter or son to live close to you… where is my family going to live? Have they got to live 40 miles away because there's no affordable housing? I think that was the point we pushed quite hard on… if you don't have growth that's what is going to happen to your family." (Interview, Cambridgeshire County councillor)

In addition, politicians managed to convince local people based on the promise that growth would be accompanied by investment in relevant infrastructure:

> "The public accepted that [growth] was the right way forward, provided that – and that was an important proviso – that there was infrastructure to support additional homes." (Interview, Cambridgeshire County councillor)

A similar view was articulated by developers, who believed that the promise of enhancing quality of life in the area was a key factor in achieving public consensus:

> "…..the public had enough confidence that elected politicians had the ability to ensure that better standards were enforced on these new developments" (Interview, urban extension developer)

Most importantly perhaps, these promises were not just empty promises, but they were actually deliverable given the substantial amount of growth funds which Cambridgeshire Horizons secured from central government. With these funds, not only were the local authorities able to deliver essential infrastructure *upfront*, including transport infrastructure, schools and community centres at the Cambridge Southern Fringe urban extension, they were also able to take a further step forward, through developing a framework for building sustainable communities, known as the Cambridghesire Quality Charter.

Although the Quality Charter is not a statutory document, it has been endorsed by both the local authorities and the developers for the major growth sites What the framework does is that it encourages partners to look beyond the planning system, by highlighting issues which can be addressed through the actions of partners across a range of sectors. For example, this Charter has encouraged the City, South Cambridgeshire District and Cambridgeshire County Council to create a joint Community Services and Infrastructure Group (CSIG), which coordinates the planning and delivery of *community* infrastructure and services across the growth sites. What this means is that growth is not just about delivering houses and physical infrastructure, but also about provision of a range of community services which are integral to the development of *sustainable communities*.

So it was the selective appeal to values by local politicians to secure legitimacy from their electorate, together with effective targeting of resources to deliver the promise of sustainable communities, which explain why political tensions were mediated during implementation of the major growth proposals.

Clearly, the values which politicians appealed to were not the only ones which mattered to local people. It would be fairly reasonable to suggest that some people also valued the principle of environmental sustainability, and hence would be opposed to creating urban extensions on green belt land. Nevertheless, local politicians attempted to legitimise their preferred growth strategy through a *selective* appeal to particular values, which resonated with the principal concerns of their electorate at that particular moment in time.

4. Concluding thoughts: the need for *situated* planning theory

This paper set out to demonstrate the role of values in spatial planning. The findings highlighted that the mediation of strategic-local tensions in the Cambridge sub region, was at least partly explained by the appeal to *relational* understandings of justice (Campbell 2006). This included appealing to the need for affordable housing, for people living across the wider sub region (spatial justice), and the need for affordable housing for the younger generation (inter-generational justice). These relational understandings of justice resonated with the concerns of the local electorate, which explains why resistance to major growth proposals was relatively limited in the case study area.

But the findings also illustrate how the national meta-governance *contex*t shapes the strategies adopted by local politicians. Given the privileging of high-growth economies through the spatial planning agenda of New Labour, the politicians in the Cambridge sub region were more capable of achieving success by positioning the sub region as a major contributor to competitiveness of the regional and national economy, to match the selectivities inscribed in the meta-governance context and thus tap into financial resources from the centre. Indeed, such strategic positioning enabled the Cambridge sub regional partnership to secure substantial resources for the actual delivery of affordable housing and community infrastructure. This, in turn, reinforced the confidence of the electorate of the possibility of delivering sustainable communities, and hence contributed to the relative absence of tensions.

Returning to the problem raised in the beginning of this paper, it is important for planning theory to engage with the question of values, in order to provide a satisfactory account of the complexities of spatial planning. This is not to suggest an abstracted theorisation of values. As Sanyal (2002) and Alexander (2003) have pointed out, normative theories of planning often suffer from the problem of not being able to take into account the role of context and how that leads to differentiation in practice. This paper echoes their view of the need for *situated* planning theory, which pays attention to normative issues, but which is also sensitive to the context in which such values are deployed. This paper has contributed by drawing on the concepts of meta-governance and selectivity, to illustrate how value choices in spatial planning processes are shaped by the national meta-governance context, as well as the selection of values within local political contexts.

The concepts of meta-governance and selectivity are indeed relevant to the current planning context in England, where the shift towards a more localist approach to planning has resulted in the creation of a new sub-local tier of neighbourhood planning. Within this changed context, local authorities are expected to play a role in overseeing the coordination of multiple neighbourhood plans, to ensure consistency with local plans. Simultaneously, local authorities are also expected to cooperate with their neighbours at the supra-local level, to ensure consistency with the objectives in the national planning policy framework.

This indicates the possibility of an emergent form of interaction between national meta-governance and local selectivity, where local politicians simultaneously engage with the selectivities in the national planning framework, while attempting to meta-govern sub-local neighbourhood governance processes.

Going back to the conceptual framework proposed in the beginning of this paper, we can see how an appreciation of the interaction between national meta-governance and local selectivity is crucial to our understanding of the tensions which emerge in particular places. Clearly, the three interactive pathways proposed in the framework are open to change: for example, the perceptions of the electorate may shift under changing socio-economic conditions. Similarly, values privileged by the national state will change under the election of a new government, while local selection of values will change when new politicians are elected into local government.

Whether strategic-local tensions are effectively mediated or not under the new planning context, will depend on how values are deployed by local politicians in their role as 'local meta-governors'. This suggests an interesting area for further research, to uncover how values are deployed under a changing socio-political context, to add to the development of situated planning theory.

The Study of China's central and western urbanization, risk and prevention during the Industrial transfer process

Wen Xiaoyi[1] Liu Tingting[2] Wu Juan[3]

Abstract

In the current economic globalization trend, industrial transfer has become a common economic phenomenon to promote macro-regional industrial restructuring, greater economic. Since reform and opening up policy, as the main field of international industry transfer, the regional economy of China's eastern coastal areas has been rapid development, while it plays a vital role to the regional urbanization. However, in the eastern region to achieve "economic miracle", the growing wealth gap between the eastern and western areas is increasing serious.

Following the implement of national regional development strategies, such as "Great Western Development Strategy", "Rise of Central China Strategy" , the central and western regions to undertake industrial transfer from the eastern region's economic development opportunities, and it will have a huge role in promoting the regional urbanization.

After experienced 1990s the government-led initiative to explore the market period, China's eastern industrial shift to the west China are under the guidance of the central macroeconomic policy, appearing initial extensive form breakthrough and market-oriented, showing the three major characteristics: Investment in expanding, large scale projects growing; Industrial projects with feature of large and high value investment; Industry has become a hot spot for investment. And it differences from the past eastern area undertake international industry transfer are: it undertakes from domestic; the industry is high consumption, high pollution and large scale; Industries to relocate to the city is eager to expand the city with the size of the industry concentration, enhance land value.

Based on the background of China's development background, analysis domestic and abroad relative research, the article makes a conclusion of China's industrial transfer characteristics of the various stages of development, power factor, etc. Comparing the

[3] Wu Juan, Urban Planning Master Degree, Tianjin Urban Planning & Design Institute, China

main cities' index feature of urban industry structure and urbanization indicators, to sum up different areas undertake industry transfer feature, analysis of deep-seated reasons and the effect to urbanization. Then the paper cites the specific urban cases of central and western regions, constructing the risk theory research framework. Through the process of risk recognize, risk assessment to analyze the characteristics of the central and western regions city to undertake the industry transfer. Finally, making the recommendations and suggestions related to prevention.

1 Globalization & Industrial transfer

Economic globalization is the world's economic activity beyond the borders, foreign trade, capital flows, technology transfer, provision of services, interdependent and interrelated organic economy as a global scale economic entirety. Since the 1990s, economic globalization has become the main theme of the world's economic development. In the trend of the globalization influence, the international industrial structure increasingly upgrade and optimization.

International industrial transfer is the industrial transfer between countries.In accordance with the principle of comparative advantage, some industries from one country or regiontransferred to another country or regionthrough international trade and investment.

In recent years, China's rapid economic development plays a very important role in the process of economic globalization. Meanwhile, international industrial transfer activities also generated a great deal of influenceon the Chinese economy.

2 History and the development trend of China's industrial transfer

China's industrial transfer process can be summarized as follows: First east part and west part, first international and regional. Firstly, the eastern coastal region mainly as a carrier taken international industry transfer; with the economic level of the eastern region increasing grow, some of the industry gradually transferred to the central and western regions.

In the influence of international industrial transfer activity, China has undertaken three times of international industrial transfer. The first time is in 1980's-1990's, textile products as the representative of labor-intensive industries transfer to developing countries, accelerating the pace of upgrading of China's textile industry. The second time is since the 1990s, with the international industrial structure adjustment and transfer, prompting China to become the main destinations of international industrial

transfer. And the industry transfer focus from the raw material industries to processing industries, from manufacturing to high value-added industries, from the traditional industries to emerging industries, from manufacturing to services. The third time was around 2000 due to WTO brings new opportunity, a new round of information industry, as a representative of the high-tech industry production manufacturing process mass to transfer to China. The Yangtze river delta and pearl river delta, ring bohai bay, the coastal areas of fujian initially formed unique information industry base. China has become the international "manufacturing center". Guangdong, fujian, Shanghai, zhejiang, jiangsu, shandong, as the eastern coastal province (city) has the dual task of industrial transfer and undertake industrial transfer .

The industry transfer from the east to the west has experienced the government leading market period of 1990's. The new wave of industrial transfer will influent central and western regions in economic development, industrial structure , ecological environment, urban construction, government management mode, urban image, wage level, traditional society and national culture, etc. Comparing with the eastern region undertake the world of industrial transfer, there are some differences: ① this industry shift's industry mainly comes from domestic; ② the transfer industry is always pollution, energy consumption and large land scale; ③ the city which undertaken industrial transfer is eager to expand urban scale to promote land value.

The directions of the industrial transfer from the east China, first is to the internal developing regions transfer; second is to central and western areas gradient transfer; third is transfer to neighboring countries such as Vietnam and India. With economic strength of the eastern, its radiation and influence rage expand increasingly, forming a certain gradient differences. Some traditional industry will transfer from the core area to surroundings, even to the central and western China by radiation and influence rage expanding.

3 The current industrial transfer characteristics of central and western regions

3.1 Industrial transfer and urbanization characteristics of western regions

In 1999, the state council put forward the western development strategy. In October 2000, the15th communist party of China the CPC central committee the fifth plenary session proposed "the national economy and social development made the tenth five-year plan proposal ", the implementation of the western development and promoting the regional harmonious development as a strategic task. The development of western China strategy including Gansu province, Shaanxi province, Qinghai

province, Ningxia Hui autonomous region, Xinjiang Uygur autonomous region, Sichuan province, Yunnan province, Guizhou province, Chongqing province, Tibet autonomous region, Inner Mongolia autonomous region, Guangxi Zhuang autonomous region , totally 12 provinces, autonomous regions, and municipalities directly under the central government, three minority autonomous prefecture, covering 685 square kilometers, accounting for 71.4% of the country's. By the end of 2002 population is 367 million, accounting for 28.8% of the China's.

Table1. GDP and per capita GDP of western provinces

Xinjiang	256.7	1378.48	1121.78	23.38%

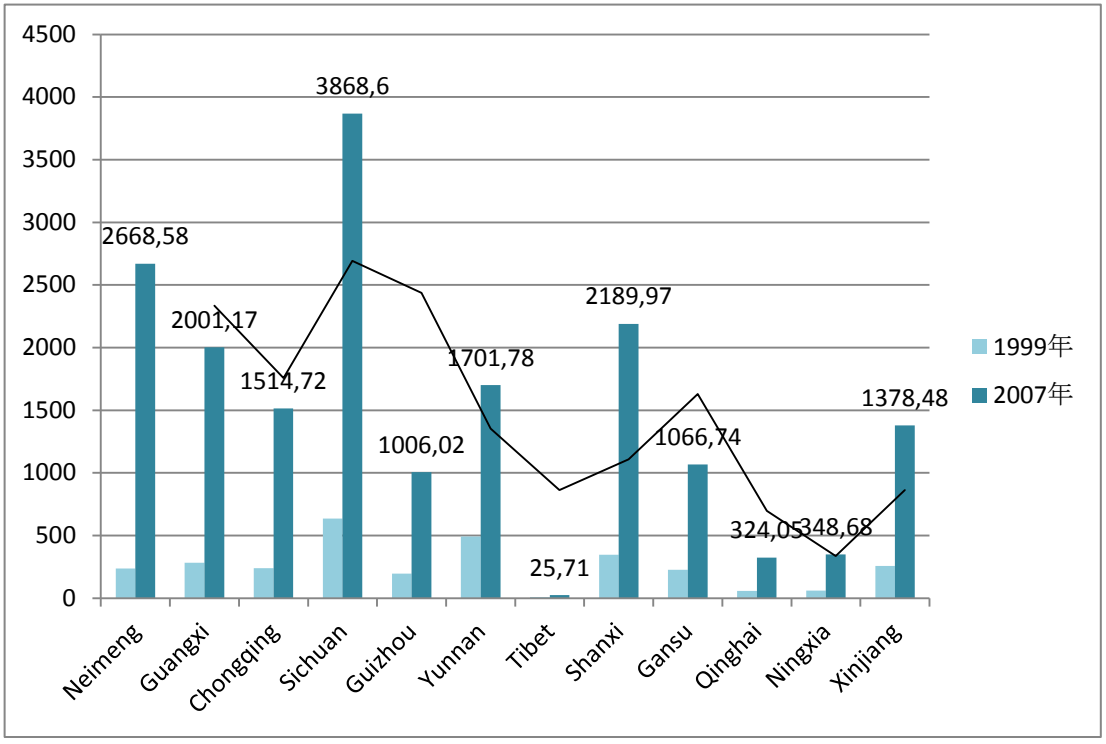

Figure1. Major economic index of western provinces

From the above data, after the implementation of the western development strategy, the western economy made great progress. And the development is uneven develop, Chongqing, Neimeng, Sichuan developed with the fastest speed. The industry also had a rapid development speed, making its share of the national economy proportion rise sharply. The industrial transfer from the eastern region to the western region promotes west China economic develop.

The central region including Shanxi ,Henan, Anhui, Hubei, Hunan, Jiangxi these six provinces, located in China's inland central part. Central China has 10.7% of the country land, the population is 28.1% of China, and the national GDP proportion is 19.5%. It is the population, economic hinterland region and the important market, which plays an important role of domestic regional division.

In March 2004, premier Wen in government work report, first put forward to promote the rise of the central region. “Central China's emerging strategy” meaning is far beyond the central region itself. The general strategy for regional development in China, the central province plays an important role of "as a bridge between the east and the west ".

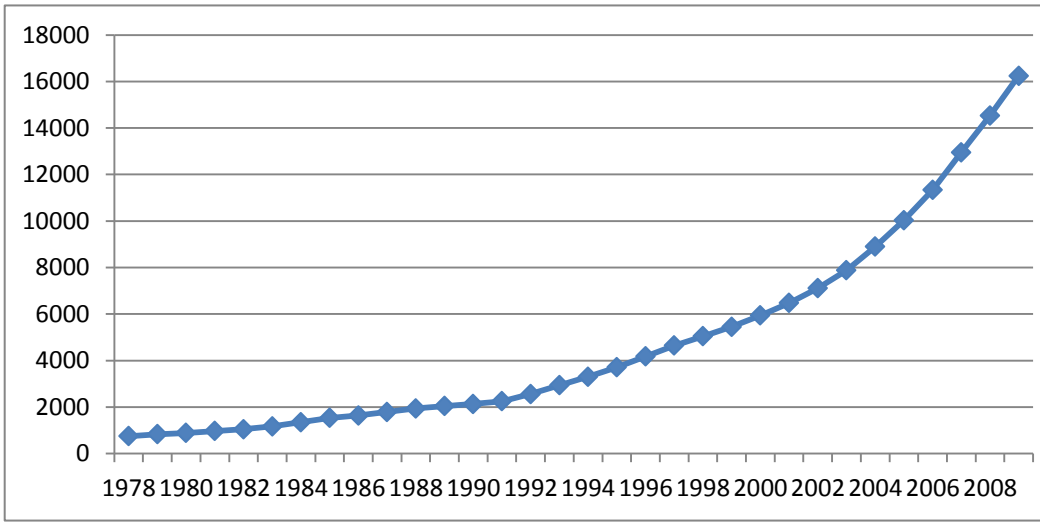

Figure2. GDP of Central China

Table3. Major economic index of Henan province

Year	GDP（hundred million yuan）	Per Capita GDP（ten-thousand yuan）	The three main industries the three main industries（hundred million yuan）		
			Primary industry	Secondary industry	tertiary-industry
1995	2988.4	0.32	763	1395	830
1996	3634.7	0.4	937.6	1677.6	1019.4

2002	6035.5	0.6	1288	2768	1978

2003	6867.7	0.7	1198	3310	2359
2004	8553.8	0.9	1649	4182	2722
2005	10587	1.1	1892	5514	3181
2006	12496	1.3	2050	6725	3721
2007	15012.5	1.6	2217	8282	4512

(1) Government-leading industry transfer from the east to the west

Since the 1990 s, in the central macro policy guidance, the local government in the Midwest as the main force of industry transfer has not changed. Since 2000, the eastern coastal area of the industrial transfer to the central and west scale is increasing, the key industry is manufacture, especially labor-intensive industry, resources or energy depending industry.

(2) The industry source opposite concentration

By 2010, only Guangdong, Shanghai, Zhejiang, Fujian these four provinces' and cities' industrial output which need to transfer to the central and western areas will reach 1.4 trillion yuan. For example, because Shanghai successfully held the World EXPO, there were thousands of companies moved away before 2010, and a group of traditional industries gradually out of Shanghai.

(3) The industry transfer has taken shape gradually

First is the industrial transfer level gradually improve, the industry focus from former labor-intensive products to the capital intensive industry and technology intensive industry. Second is the production capacity is no longer the individual enterprise of transfer isolated behavior, industrial transfer from the original single project, a single enterprise, or rather a single industry, change to the integrity industry.

(4) In the industrial transfer process, Zhejiang merchants, Redsun, Taiwanese, Hong Kong businessman' performance is more active

Zhejiang has become China's largest domestic (mainly private funds) output province, Zhejiang merchants also has become China's largest private economic investment venture subject. The capital flow of industry transfer direction is from the east to west, from the south to the north. The transfer industry mainly is labor-intensive industries. Zhejiang enterprise has become an important force in the western development.

With the industrial transfer process forward, based on current China's development situation and related policy guiding, it has the following developing trends: ① Industrial transfer will focus from the labor intensive gradually to the capital intensive and technology-intensive industries ;② Industrial transfer from the first single industry will transfer to the whole industry, and the industry field will be wider; ③ Industry transfer from a government's leading to the enterprise leading, enterprise's leading role is growing increasingly stronger; ④ Capital intensive industry, technology industry will pay more attention to the local technology, talent, research and development ability, and other comprehensive advantages, infrastructure and system conditions.

4 The risk analysis of industrial transfer

According to the characteristics of the industrial transfer, from the urban planning perspective, based on urban development research framework, the article made the risk identification research.

4.1 Urban planning risk

Planning development risk refers to the risk caused by the un-proper planning and design. Urban development projects not only are large scale, but also have great influence on the city development. In order to control planning and design, the government should focus on monitoring project planning and develop target.

Table4. Urban planning risk factors

NO.	Factors	Monitoring method	Monitor
A1	Development orientation	Subjective probability evaluation monitoring ， two-dimensional two-dimension risk matrix monitoring	The government planning departments 、The competent department of city development project
A2	Function layout		
A3	Space development intensity		
A4	Technology risk		
A5	Facilities risk		

Planning and design risk monitoring is in the planning decision stage, the government planning departments and urban development project departments are responsible for monitoring. Once the risk is too high, it shall be ordered to modify planning or direct negative its feasibility

4.2 Ecological environment risk

In China's current rapid urbanization and industrialization background, because the deviation of the development idea and dislocation, the manual intervention by urban development activities to ecological environment is becoming much stronger, and has become the main impact factor of urban ecological safety. So the ecological environment risk is an important urban development projects risk. Urban ecological environment development project risk is mainly in three aspects: First is ecological load, namely whether urban ecological environment can withstand the impact of the project; secondly is the human environment harmonious degree, refers to whether the environment can build project with human feelings in coordination; last is environment pollution.

Table5. Ecological environment risk factors

NO.	Style	Factors	Monitoring method	Monitor
B1	ecological load	Land resources richness	Per capita land area, such as land productivity index quantitatively estimates	The relevant government departments
		Water resources richness	Per capita water, water quality conditions in computer aided data monitoring	The relevant government departments
		Energy resources richness	Light index, energy supply and demand as indexes than quantitatively estimates	The relevant government departments
B2	human environment harmonious degree	Green Index	Building area, such as green area index quantitatively estimates	The relevant government departments, Project manager
		Landscape Diversity	Dominance index, evenness a d experts assess	The relevant government departments
B3	environment pollution.	Water pollution	Sewage treatment, wastewater index quantitatively estimates	The relevant government departments
		Air	S02, TSP emissions and	The relevant

		pollution	JingHuaLv index quantitatively estimates	government departments
		Noise pollution	Noise intensity, influence scope index quantitatively estimates	The relevant government departments
		Waste pollution	Solid waste emissions, cover an area of an area index quantitatively estimates	The relevant government departments

4.3 Social culture risk

The social culture risk mainly refers to the risk of social factors affect the project and project implementation process all kinds of external social effect brings the risk. For urban development projects, the government focused on the social culture risk can be used two monitoring indicators to reflect, namely, social and political stability and cultural risk.

Cultural risk can also let related experts according to the project of the influence of culture design a mass questionnaire, regularly collecting popular feeling, and the result will be transformed into index

The social and political stability risks and cultural risk monitoring is the project manager, but social cultural risk monitoring results and project management strategies and measures that coped with must be reported to the relevant government departments Urban development project social cultural risk often effect wide fields, improper management might cause serious social problem, so the government departments must supervise the social culture risk monitoring and response of project management.

Table6. Social culture risk factors

NO.	Factors	Monitoring method	Monitor
C1	The social and political stability	relocation, public security situation, social differentiation, social conflict, policies and regulations and improve the degree of stability to the public investigation or expert evaluation	Project manager

C2	Culture risk	The public questionnaire, expert evaluation	Project manager

4.4 Natural risk

It's inevitable for urban development project to face natural risk. Project management can regularly get natural risk the probability of information from relevant government department and research institutions and even the insurance company.

Table7. Natural risk factors

NO.	Factors	Monitoring method	Monitor
D1	Earthquake and its secondary disaster risk	Objective probability evaluation monitoring, computer aided data monitoring	The relevant government
D2	Other natural disasters and its secondary disaster risk	The typhoon, debris flow, lightning and other natural disasters and its secondary disaster risk, two-dimensional risk matrix monitoring, objective probability evaluation monitoring	Project manager

4.5 Economic risk

Economic risk of urban development project has four factors: macro-economic environment risk, regional competition risk and the regional cooperation risk, financing risk, debt service risk. Economic cycle, macroeconomic policy, fiscal revenues and expenditures, and other macroeconomic environment, as well as regional competition, the regional cooperation risk will inevitably influence on the project investment decision and operation of success or failure, in project decision-making stage project management should be on the basis of macro-economic environment risk, regional competition risk, the regional cooperation risk is the acceptable limits or whether there are effective strategies to decide whether or not to invest. In the project operation stage project management is still should be regularly monitoring macroeconomic environment risk, regional competition risk, the regional cooperation risk.

Table8. Economic risk factors

NO.	Factors	Monitoring method	Monitor
E1	Regional competition risk, the regional cooperation risk	risk assessment Experts assess	Project manager
E2	Macro-economic environment risk		
E3	Financing risk	Risk and control self assessment, (self assess possibility	
E4	Debt risk	Risk and control self assessment risk assessment	

4.6 Operation management risk

The operation of the urban development project management involves institutions-set, the structure organization and the daily operation management. Project organization setup has management committee, "company" or all kinds of mixed management mode. Considering the city development project public characteristics, in the project operation stage involved in providing service processes related risks but also through the mass questionnaire method regular monitoring.

Table9. Operation management risk factors

NO.	Factors	Monitoring method	Monitor
F1	Organization setup risk	The comparison inspection flow chart Risk and control self assessment	The relevant government; Project manager
F2	Operation management risk	The comparison inspection flow chart Risk and control self assessment Regular monitoring and inspection documents Mass questionnaire Key risk index monitoring	The relevant government; Project manager

4.7 Construction risk

City the large-scale development of the construction of the project need to monitor risk including project construction phase development progress can be expected to plan the project development of the risk and the progress of the project itself project risk, such as technology risk and construction risk, etc.

Table10. Construction risk factors

5 Planning response and risks prevention

5.1 Planning response strategy

In the industry of the transfer of the macro, pushed by the urbanization development bring mass construction planning, should give full consideration to the risk characteristics, in the development of management system and pattern, the innovation and perfection.

5.2 Risk prevention suggestions

（1） Set unified management institution

Urban development and management of the established separate institutions at home

and abroad in the practice of the urban construction is the common understanding. The different districts management committee may consider the film as a whole the development plan, can fully understand the basic situation of the city. At present, the city risk management methods have been widely recognized and popularity.

（2）Increase the risk management content

The risk for developing the city management work the centralized management, therefore, from duty scale, the ac requires a risk management function in the related department. Facing the complex urban development risk, city need to organize a high level of risk management team, team management ability will directly affect the city development process.

（3）Establish data information platform

In risk management, the information is vital, and how to get good information is the key to avoid the risk. Non-synchronous information cause people to the understanding of the risk degree have differences, also can't risk carries on the comprehensive analysis. Set up the development of electronic information about city data platform, we can ensure that the government, development, enterprise, residents sharing development material in the first time.

The subversion of democratic policy under a regime agenda: The urban governance of residential development in Melbourne

Matthew Ford
Faculty of Architecture, Building and Planning
The University of Melbourne

Abstract

Over the last twenty years in Melbourne, metropolitan spatial planning has increasingly sought to achieve urban sustainability and avoid continued low-density sprawl through policies encouraging consolidation. The important example of housing shows that development outcomes fall well short of policy objectives and that the city's spatial planning is widely perceived as ineffective. This failure is most easily seen in the large tracts of greenfield development far from the city centre, with no public transport, very limited employment opportunities, and only basic services. Yet development in these areas is expensive, with the city undergoing a crisis in housing affordability.

This paper reports on a case study of urban governance in Melbourne. The study is examining the hypothesis that residential development follows an agenda set by an informal urban regime comprised of state and market actors, rather than the metropolitan spatial planning policy generated by the formal planning system in Australia's representative democracy.

There is clear tension between the antagonistic objectives of communicative planning via network governance and urban regimes (working with reactive and discretionary regulatory planning systems), which enjoys widespread support in Australian urban planning practice, and the exercise of metropolitan spatial planning, which has a significant history under hierarchical government as a vehicle for urban vision and metropolitan spatial planning. Examining democratic concepts and the exercise of urban power, this paper argues that state policy (as expressed in metropolitan spatial plans) is superior to modes of network governance (such as urban regimes or communicative planning practice) for collective decision-making at the urban scale.

The superior democratic credentials of strategic spatial planning are also suggested by a consideration of democratic concepts. Whether in the guise of abstract philosophical concepts or as concrete systems of sociopolitical organisation, power and democracy have proven to be inexhaustible themes in the study of human society and are central concerns in any sophisticated understanding of the political economy of urban governance.

Similar challenges are common to many cities across our rapidly urbanizing globe. The political economy of planning is a crucial determinant of the mode of urban governance employed in any city, yet it is not frequently examined at a metropolitan scale. Rapid growth is expected to continue in Melbourne, which is consistently rated one of the world's most liveable cities, but the longer that spatial planning policy is left as political rhetoric rather than implemented across the urban area, the less likely that the city's future will offer the amenity enjoyed by today's residents as social, economic and environmental sustainability continues to decline.

1 The challenges of democratic urban governance in Melbourne

1.1 Growth, democratic policy and sustainable residential development

This paper is a progress report on a case study of Melbourne's urban governance. The study examines the challenges of democratic residential development in contemporary Melbourne and investigates the proposition that the city's spatial pattern of residential development reflects the operation of a metropolitan regime. Metropolitan strategy in the city has long promoted urban consolidation to improve sustainability while accommodating the city's rapid population growth, but a clear tension between modes of network governance and democratic spatial policy is evident in the contrast between the strategic vision for residential development and actual development outcomes in Melbourne.

The vision of a sustainable urban form is slipping beneath a banal reality of wasteful and unnecessary sprawl. The majority of residential development over the last two decades follows a pattern established in the 19th century of large, detached houses at the city's edge, seemingly oblivious to the needs of a 21st century city. These dwellings are far from high-capacity public transport, lacking in civic services, and remote from the urban environment that contributes to Melbourne's acknowledged amenity. The scarcity of inner urban dwellings relative to demand, limited development in many middle suburbs and the expense of new infrastructure and land banking strategies for fringe development have reduced housing affordability (Gurran et al., 2008, Federal Government, 2008). The average new dwelling has increased in size to be the largest in the world (Victorian Government, 2008, Moodie et al., 2008, James, 2009). This misalignment between supply and demand is a critical issue that threatens Melbourne's social cohesion, economic prosperity and environmental sustainability.

The case study posits that development outcomes have not met spatial planning objectives because in Melbourne's neoliberal political economy, an urban regime with a market-driven agenda effectively manages residential development. Melbourne's urban management has moved away from the mobilisation of a public sector led by representative government and towards governance networks that engage a plurality of actors with conflicting interests, goals and strategies (Albrechts, 2003a). The intersecting political and economic interests of an informal coalition of State Government and major developers appear to be most expediently satisfied by greenfield construction on the urban fringe.

The remainder of this introduction outlines the city's planning system and policy framework and defines urban regimes. With this context, the body of the paper examines the democratic credentials of two incongruent influences on urban governance – the approaches of network governance such as communicative planning and urban regimes, and the policy framework embedded in spatial planning.

1.2 Tensions in urban governance: Substantive or procedural guidance?

In Melbourne, the state is a gatekeeper to land development in an economy based on private property rights and operates a strategic planning system that focuses on determining broad categories of land use acceptable for a given place, controlling the form of development within certain parameters, and the timing of land release. Structural elements of urban governance include the legislative and regulatory environment, institutionalised organisational forms, and formally established relationships and decision-making practices.

Combined with residential development policy, this system ostensibly aims to resolve the inherent tensions between a market supply of dwellings unregulated by form, size, cost or tenure and only loosely regulated by location, and a reactive state-led planning context ostensibly focused on the social, economic and environmental dimensions of urban sustainability. Delivery of policy goals is left to a risk-averse market that matches and moulds its idea of consumer demand to a business model favouring supply of a limited range of products in locations relatively unconstrained by existing development, infrastructure or residents (Adams, 2011). The resulting spaces for informal decision-making ensure a major role for discretionary governance deliberations.

The case study suggests that a different influence on residential development is that exerted by an urban regime. As initially formulated by Elkin (1987) and Stone (1989a), urban regime theory is a well-established analytical approach to investigating the governance of urban change in neoliberal democracies (Imbroscio, 1998b, Davies, 2002, Lauria, 1997). Regimes are a mode of governance in which an informal coalition of state and market actors assembles the capacity to govern and deliver outcomes by cooperating across formal boundaries and institutions (Mossberger and Stoker, 2001, Irazabal, 2011, Stone, 1993). Regime analysis is steeped in the close and specific observation of networked urban governance and the structural dynamics of collective decision-making in a political economy (Mossberger and Stoker, 2001, Stone, 1993, Ward, 2001, Peck, 1995), where regimes may surround and complement the formal workings of government authority (Davies, 2003). Regime theory focuses specifically on urban development to ask 'how, and under what conditions, do different types of governing coalitions emerge, consolidate, and become hegemonic or devolve and transform' (Lauria, 1997). (Stoker, 1995, Stone, 1989b, Irazábal, 2009).

A lively academic debate emphasizes the conceptual value of urban regime theory in exploring complex urban issues while constructively criticizing its contextual and analytical limitations (Stoker, 1995, Mossberger, 2009, Davies, 2002, Imbroscio, 1998a). The regime approach seeks to understand *what is*, by revealing power relations and the consequences of power asymmetries, but its explanation of *why* a particular mode of urban governance eventuated and is maintained is left implicit, and the approach falls short of a normative vision of *what might be*, against which the quality of governance might be assessed (Gordon, 2005, Imbroscio, 1999, Davies, 2002, Stoker, 1995, Feldman, 1997). The critiques suggest that urban regime theory offers a realistic description of urban political economies but could improve its critical edge, normative perspective and explanatory ability (Stoker, 1994, Imbroscio, 1998a).

2 The democratic credentials of network governance and hierarchical government

2.1 Problematising network governance in a neoliberal political economy 368

There is clear tension between the antagonistic objectives of communicative planning via network governance (and its counterpart of reactive and discretionary regulatory systems), which enjoys widespread support in Australian urban planning practice, and the exercise of metropolitan spatial planning, which has a significant history under hierarchical government as a vehicle for urban vision and metropolitan spatial planning. Examining democratic concepts and the exercise of urban power, this paper argues that state policy (as expressed in metropolitan spatial plans) is superior to modes of network governance (such as urban regimes or communicative planning practice) for collective decision-making at the urban scale. Developed through representative democratic systems, state policy has a clear concern for the collective good and urban sustainability. It enjoys greater legitimacy, more logically delivers the collective will and better approximates the common good than collective decisions generated through the intrinsically compromised systems of network governance.

The significant discursive shift in recent decades that has favoured the adoption of postmodern network governance over modernist technocratic planning has been used in an attempt to invalidate spatial plans because they are perceived to pay insufficient attention to community input. Engaging with a deeper understanding of the concepts of power and democracy, rather than effectively dismissing these concepts through a superficial treatment bent to the demands of a particular discourse, develops a coherent logical framework for assessing the quality these competing modes of urban governance in Melbourne.

2.2 Networks in theory: The shift from hierarchical government to network governance

The argument begins by discussing an overarching contemporary influence on urban planning practice in neoliberal Western societies: the shift in emphasis in collective decision-making from formal hierarchical government to informal network governance. Neoliberalism has gradually encroached on pluralist Western democracies in recent decades to become hegemonic across social, political and economic life (Harvey, 2005). While a relatively authoritarian state once appeared to provide a clear framework for managing cities, the contemporary role of the state has been refigured from leader to facilitator (Deleon, 1998) and a wider range of actors are seen to have legitimate roles in collective decision-making. Erstwhile distinctions within and between the state, market and civil society have ceded to governance networks that, under varying degrees of state oversight, accept an open architecture of agent relationships and promote flexible political institutions.

Many urban planning academics tell us that planning practice has ‘moved on’ from modernist notions of technical expertise, state political control and substantive objectives (Hoch, 2007, Innes and Booher, 2003, Forester, 2009, Healey, 2006) in

favour of network consensus and process determinism. Proponents of network decision-making in urban planning such as Healy (1996, 2006) and Forester (1999) privilege interactive process over substantive problem solving as the rightful focus of the discipline. Descriptive paeans feature a rhetoric of privileging diversity and individual rights within notionally equitable frameworks, while discounting expert authority and ignoring the adversarial nature of interest group pluralism.

Led by an Anglocentric set of principles known as New Public Management (NPM), much contemporary theory in public administration positions governance networks as a benign corrective to the shortcomings of government by the state (Ansell and Gash, 2007, Gleeson et al., 2004, Leitner, 2002). Forming a shadow government, networks are claimed to deal more effectively with complex issues and appear to offer a new way of dealing with resource deficiency, bureaucratic rigidity and political obstacles (Agranoff, 2001). Networks are also suggested as crucial to knowledge development and the effective arrangement of human capital, making them vital to support innovation in social and economic production (Agranoff, 2001). The blithe support for networks prevailing in the Anglophone literature is often more concerned with the categorisation of an evolving neoliberal political economy rather than an attempt to understand, explain or assess it.

This merits of this shift, which has been concurrent with the spread of a neoliberal political economy, is challenged by academics in critical social theory who take a less sanguine view of the deployment of power and the concern for democratic process in the highly profitable realm of urban development (Harvey, 1989a, Harvey, 2006, Sandercock, 1998a). The call for network governance repackages the premise of neoclassical economic theory, that the state is operationally ineffective and public services should be outsourced, with an attendant disinterest in spatial, social or cultural insight (Dunn, 2007). In a constitutional representative democracy, where elected representatives remain accountable for outcomes and might be expected to have the upper hand in determining urban development, the legitimacy and transparency of governance networks are validly subject to critical assessment (Aarsæther et al., 2011). A limited consideration of structural drivers of network governance is sometimes ascribed to the notion that the knowledge base is still developing (Agranoff, 2001); but both the conceptual and pragmatic issues of governance are the subject of much attention in other disciplines. Academics such as Harvey (2005, 1985, 2008), Flyvberg (1998b) and Swyngedouw (2005, 2000) seek to make the internalised neoliberalism of network governance explicit by highlighting the logical and empirical links between networks and neoliberalism.

Assessed against its discursive claims, the pragmatic problems of network governance are myriad. The relatively fluid practices of network decision-making may not provide the clear objectives or coordinate the extensive resourcing required to manage the breadth and pace of change experienced in many cities (Klijn and Koppenjan, 2000). While the ideal network empowers a balanced representation of relevant stakeholders, including participants from the wider demos of indirectly affected citizens, and anchors processes in democratic norms, the entrepreneurial narratives common in many governance scenarios conspicuously threaten democratic process while diminishing

transparency, participation and inclusion (Aarsæther et al., 2011). The conceptual concerns are more subtle and, perhaps, invidious. With their bias toward idealistic description and lack of analytical structure, theorists supporting network governance unproblematically flout representative democracy and seek to supplant state power with market and civil society interests. The reasonable concern that the state is an imperfect repository of democratic intent is often taken to unreasonably justify greater empowerment of individuals in the market and civil society (Hajer and Wagenaar, 2003).

The concept of democracy is frequently intoned as a justification for the shift from representative systems toward network governance, but the democratic anchorage of networks is an empirical question (Aarsæther et al., 2011, Edelenbos et al., 2010, Klijn and Koppenjan, 2000). The forms of democracy that are claimed to deliver equitable collective decisions in networks hark back to the Greek polis of communal debate (Dahl, 1989), but contemporary cities are radically different in scale and complexity to the Greek city-states and the concept of democracy that was founded by the Aegean has similarly, and necessarily, evolved. Because greater participation does not mean better democratic process (Dahl, 2000), systems that favour deliberative and discretionary decision-making over the application of clear rules and enforceable rights are problematic, and strong controls are required to prevent network delegation from alienating democratic objectives (Dahl, 1994).

2.3 Networks in practice: The idealism of communicative planning and the realpolitik of urban regimes

Communicative (or collaborative) planning is a normative style network governance ascendant within urban planning. Based on Habermas' abstract concept of rational discourse, where some "better argument" prevails to engender an inclusive consensus between actors, communicative planning has been a major theme in planning theory for the last two decades and is seen by some as a paradigm for contemporary practice (Forester, 1999, Healey, 1996, Innes, 1996, Innes and Booher, 2003, Forester, 1993). Habermas' ideal of a communicative rationality sets a moral standard for 'good' communication, which fetishizes ideal speech situations where comprehensive and comprehensible statements are made with legitimacy, integrity and truth.

With its lynchpin of inclusive consensus, the ideal of communicative planning has certainly brought benefits to practice. The approach celebrates the interaction of diverse actors in a pluralist society, engaged in complex collective decision-making, seemingly liberated from the constraints of institutional structure, historical context and expert guidance. Heeding Habermas' call for a "transformation of the public sphere" (Habermas, 1989), freed from state and economic power relations, communicative planners identify distorted communication in planning practice as a precursor to transforming the culture and processes of urban governance (Healey, 1999).

However, at the metropolitan scale of urban governance relevant to this research, a communicative rationality raises considerable concerns for democratic decision-making (Albrechts, 2003a, Huxley, 2000, Hillier, 2003, Flyvbjerg, 1998a, Tewdwr-Jones and

Allmendinger, 1998, Flyvbjerg, 1998b). Following the concerns raised for network governance, there is a series of disjoints between the rhetorical promise of a communicative rationality and its use in practice that reflect the central paradox of the inconsistency between the modernist foundations of communicative planning and its postmodern expression (Sandercock, 1998b, Albrechts, 2003a).

Conceptually, the perspectives of a range of major philosophers suggest that the notion of inclusive consensus and appeal to objectivity that is central to Habermas' diktat is problematic, questioning the value of communicative planning as a normative ideal. In the intensely political practice of collective decision-making for urban development, two issues stand out:

- The first issue is Habermas' extreme level of abstraction. Nietzsche warns that highly abstract constructs of language and reason create a distorted view of reality (Nietzsche, 1888) while a Foucauldian understanding of all modalities of interaction as historically contingent reveals communicative rationality as an improbable idealization that assumes benign human nature and remains ignorant of relations of power (Foucault, 1991, Flyvbjerg, 1998a).

- Second, Lacan's distinction between reality and the Real demonstrates that no discourse can be fully inclusive, as it requires an "other" of excluded parties (Hillier, 2003) that falsifies any claim to consensus. Attempts to realize consensus may mask the imposition of an ideal as a totalising instrument of discipline (Baudrillard, 1988, Huxley, 2000). Even interchanges based on shared meaning and a commitment to understanding need not have any potential for consensus (Alexander, 2001, Fischler, 2000), while the conditions of inequality endemic to collective urban concerns may warrant conflict via strategic action as a productive force for change (Huxley, 2000). Theories of agonism develop this concept convincingly (Pløger, 2004, Mouffe, 2005).

There is little empirical evidence that the discursive claims can be realised. Research grounded in the specific analysis of urban conditions rarely observes the desirable performance characteristics ascribed to networks (Leitner, 2002). Actually existing networks depart substantially from their discursive representation to exhibit tendencies toward hierarchy, inequality and exclusion. Descriptions of the context and form of collaboration that are put forward as communicative planning in practice are often narrowly inferential interpretations of specific projects that admit of few other contributing factors and are conscribed by time, captured at a favourable point that may not be stable or representative (Fagotto and Fung, 2006, Dean, 2009). The circumstances under which powerful actors might relinquish the dominant positions that secure their aims in favour of ceding to consensus remain deeply opaque, and the notion that actors will be persuaded by an undefined and relativistic "better argument" seems untenable in a society where the use of strategic and instrumental rationalities are central forms of action (Pusey, Huxley, 2000, Alexander, 2001, Phelps and Tewdwr-Jones, 2000).

The allure of network governance and communicative planning is compromised. Although modes of network governance have sought to appropriate the concept of deliberative democracy, contrary to the central positioning of democratic practice in the rhetoric of a neoliberal political economy, governance appears relatively undemocratic (Cohen, 2002, Melo and Baiocchi, 2006). Networks provide a forum for resourceful market and civil society actors to question the validity of state input into collective decisions, offering conditions of reduced transparency and accountability where they can direct their skills and knowledge to advance private interests (Fagotto and Fung, 2006). This subverts representative democracy (Fischler, 2000) and can entrench socioeconomic inequality as political inequality because it makes public involvement more dependent on knowledge, skills and resources (Albrechts, 2003b).

Neoliberalism uses governance networks to direct social action toward the realisation of a market-driven agenda (Scott, 2000, Gleeson and Low, 2000). Whether co-opted as naive idealists unversed in realpolitik or active handmaidens of neoliberalism, proponents of network governance paradoxically expand the potential for non-communicative rationalities to flourish. A less sanguine analysis of collective urban decision-making would seek to identify structural forces driving development outcomes, perhaps the internal strength of powerful actors in the political economy, or the external influence of globalisation on any given city (Peck and Tickell, 2002). The expression of a hegemonic political economy in communicative planning suggests a normative planning practice that welcomes and enables community engagement, yet the accommodating milieu of networked governance support a laissez-faire process that rejects representative authority in favour of a false inclusiveness, bolstered by a shallow appeal to democratic values. This perversely conceals support for a neoliberal ideology amidst a rhetoric of civil society inclusion, allowing networks to function as a Trojan horse from which market and civil society elites can better assert their interests.

At the metropolitan scale which is the focus of this research, urban regimes more closely resemble actually existing networks than the idealistic networks promoted by proponents of communicative planning. The realpolitik of urban regimes is far more evident than the chimera of communicative planning in the closed, opaque structure of many observed networks: dominated by unelected officials, professionals and market interests, with limited input from civil society or even the local state. While the democratic credentials observed within actually existing forums of collective decision-making such as regimes may be little different from communicative planning, the form of manipulation is merely hidden rather than brazenly flaunted.

2.4 Democracy, power and the pursuit of the ‘good city’

The superior democratic credentials of strategic spatial planning are also suggested by a consideration of democratic concepts. Whether in the guise of abstract philosophical concepts or as concrete systems of sociopolitical organisation, power and democracy have proven to be inexhaustible themes in the study of human society and are central concerns in any sophisticated understanding of the political economy of urban governance.

Dahl (2000) suggests that the desirability of legitimate, accountable and transparent collective decision-making is unquestioned in pluralist democracies in the postmodern era. These democratic states recognize that citizens have the right to influence matters affecting their interests and use various systems of democracy in an attempt to rearrange the distribution and exercise of power. An ideal democratic system is too demanding for full realization, but all democratic systems include enforceable rights and the choice (but not the obligation) to participate in political life (Dahl, 2000).

The gap between rhetorical (communicative planning) and observed (urban regimes) forms of democracy under network governance shows a struggle to achieve inclusiveness and effective representation in their procedures, transparency in government interactions, argued deliberation of issues and options in collective decision-making and accountability of the state and its agents (Albrechts, 2003a, Dahl, 1982). The popular concept of democracy is at best amorphous (Dahl, 2000), so powerful actors can appropriate the concept of democracy and strip it of concrete meaning to create a cipher that they can load with rhetorical appeal: the promise of personal empowerment within a redemptive wrapping of collective concern.

The democratic flaws of urban-scale network governance are reinforced through an examination of power relationships in collective decision-making. The form of democracy is influenced by the distribution and exercise of power in the political economy. Power variously structures actor participation, drives a public agenda and determines processes of deliberation within the apparatus of governance, potentially leading to a significant divergence from democratic ideals. Power is a complex and concrete set of relations both set within and reinforcing the unequal social, cultural, economic and political reality of collective action (Albrechts, 2003a). Planning theory and practice demonstrate that the social distribution of power drives collective decision-making in an institutional context (Forester, 1989, Flyvbjerg, 1998b).

The study of power is often grounded in intense observation of specific spatiotemporal contexts, where its varied mechanisms are manifested through institutional and agency relationships. Appreciating the form of power is essential to investigating its use, but the face of power in networks is not always visible (Foucault, 1991, Stone, 1980, Alexander, 2001). Network governance advertises a social production model of power, or "power to", but many forms of indirect power forgo the coercive power of hierarchical government. The partnerships formed in regimes and other forms of network governance typically recreate existing relations of power by constituting and legitimating participants as powerful, perpetuating the position of the disempowered. A subtle, pre-emptive form of power allows networks to occupy a strategic position that can alter the terms of interaction to achieve 'non-decisions' (Agranoff, 2001, Stone, 2006, Flyvbjerg, 1998b, Stone, 1988). This indirect power can provide sustained support for preferred issues on the public agenda (Stone, 1988). Similarly, situational power reinforces and perpetuates existing advantaged positions (Stone, 1980) by controlling who has access to decision-making, which options are considered and how they are promoted (Stone, 1980).

The power arrangements in representative democracy may be more transparent and direct. The original form of democracy engaged all adult male citizens directly in the affairs of state, but since direct democracy palpably cannot be scaled to large populations and territories for the everyday workings of government, forms of indirect democracy developed and one such form, representative democracy, has become the norm in pluralist liberal societies. States operating as representative democracies are typically divided into spatially nested territories, within each of which individuals elect representatives who they believe best reflect their values and interests and have the appropriate skills to responsibly make collective decisions.

2.5 The improved democratic credentials of metropolitan spatial policy

Having identified the democratic shortcomings of both communicative planning and urban regime forms of urban governance, discussion returns to re-examine the credentials of contemporary metropolitan spatial planning. The pre-eminent guide to the pursuit of the 'good city' in pluralist societies remains metropolitan-scale spatial planning (CEMAT, 1983), although a common contemporary view of spatial metropolitan planning sees it as an undemocratic relic of modernist technocratic government. This section reviews the democratic legitimacy of spatial planning policy to show that the substantive visions of spatial plans do actually express democratically sourced collective decisions to guide urban development.

The evolution of metropolitan plans from their modernist origins shows the positive influence of communicative planning. Plans have progressed beyond a narrow technical determinism to become documents of broad social vision that understand urban areas as integrated systems and promote urban sustainability via consolidation (Gleeson, 2011). Cities are now commonly understood as part of the socio-economic fabric, and metropolitan spatial plans that recognise the causes of the urban problem are a necessary intervention and an active force in enabling change to resolve significant urban problems (Hastings, 2000, Albrechts, 1992, Healey, 1997).

The formulation of metropolitan plans now typically incorporates substantial consultation that recognizes and attempts to accommodate the interests and values of diverse individuals and communities (Owens, 1997). These improved processes and holistic strategies seem poorly recognized by many of the diverse market and civil society voices prominent in network governance. No matter the provenance or quality of a plan, some academics appear to hold an ideological antipathy toward them, variously dismissing them as malign, authoritarian, or relics of a command and control state (Healey, 1999). Healey claims society "should be trying to escape" modernist conceptions of planning, but assessment of the utility and legitimacy of a planning strategy should not hinge on whether it displays fashionable sensibilities in its formulation. Other voices raise concerns about the lack of clarity, level of input and poor implementation support (Moodie et al., 2008). Even when these improvements are recognised, the wider field of concern, increased sophistication and breadth of input in contemporary metropolitan plans brings a focus on the collective good and raises two critical problems: it challenges the entrenched interests of many private actors and results in far greater political complexity (Adams, 2011).

While metropolitan plans have become a core vehicle for reflecting on what cities are and shaping what they could be (Healey, 1999), neoliberalism has sought to sideline their substantive vision from influencing urban decision-making and implementation, via its favoured approaches of communicative planning rhetoric and urban regime reality. For example, the uncritical valorization of multiple individual perspectives in network governance fosters a situation where the urban visions presented in metropolitan plans have become vague and generic. This may limit dissent at a conceptual level, but ambiguous visions suffer a variety of problems in attempts at operationalisation, not least of which is that the lack of certainty advantages powerful actors with the ability to influence decisions. Because the implementation of substantive urban objectives requires an apparatus of governance that embraces a legitimate process of public participation, enjoys political commitment from all levels of government and benefits from strong regulatory support (Moloney, 2004), even isolated dissent from vocal vested interests can be crippling.

A focus on the perceived failings of metropolitan blueprints rather than their strengths as legitimate policy documents undermines the concept of spatial planning. Instead of generating greater commitment to effective implementation processes, dissatisfaction with substantive visions becomes a *casus belli* for jettisoning state policy in favour of undirected, unrepresentative and unaccountable governance practices. Decision-making that sidelines spatial policy effectively cedes power to private interests and disenfranchises the majority represented by the state. These concerns are more a demonstration of the inadequacies of postmodern network governance than an issue with modernist comprehensive planning, for after all, in their new focus on vision, recognition of diverse interests, and lack of substantive stipulation, contemporary metropolitan plans simply reflect the communicative zeitgeist.

3 Conclusions

In pluralist societies, the search for the conundrum of the ‘good city’ is typically conducted through some form of democratic process that attempts to ameliorate unbalanced power relationships, leading to a continual struggle to achieve collective goals while respecting individual values. The shifting nature of the political economy has influenced the mode and quality of urban governance, slowly diminishing the relative power of the state *vis a vis* the market.

Following Harvey (2005, 1989b), this situation animates the idea of a hegemonic neoliberal political economy that exerts direct and indirect power over the apparatus and practice of urban governance to validate networked approaches. The distribution and deployment of power in the political economy promotes collective decision-making that is based on networking between coalitions to mobilise, build alliances and reach political consensus, rather than a deep understanding of the content, scope and impact of urban strategies from a planning perspective (Albrechts, 2003b).

Network modes of urban governance have two distinct strands: the discursive ideal of communicative planning, and the more easily observable urban regime. The turn to communicative planning in Melbourne has been detrimental to the delivery of democratic state policy at the urban scale. The disjoint between the discursive claims and practical observation of communicative planning is disconcerting, raising the possibility that it may simply be a Trojan horse for elite interests. While communicative planning is based on an idealistic perspective of collective decision-making, urban regime theory provides a realpolitik view of actually existing networks that recognises the turn to network governance but engages with rather than glosses over power imbalances in the lucrative business of urban development.

Network governance has inferior democratic credentials when compared to established approaches of metropolitan spatial planning. The neoliberal values that are institutionalised in the apparatus of urban governance in Melbourne are in clear tension with the values underpinning support for sustainability that feature in the city's metropolitan spatial planning. This assessment reveals a lack of coherence between the mode of urban governance and the democratic policies it ostensibly aims to deliver. Descriptive interpretations of perceived urban planning 'failure' often deterministically isolate the cause to particular imperfections, say, of rigid institutional structure or limited community engagement. Critical analysis of the structural drivers in the political economy that have promoted the validation of network governance during the era of neoliberal ascendancy invites the interpretation that such 'failure' is a desirable feature of urban planning carefully managed by architects of the system.

Rapid growth is expected to continue in Melbourne, which is consistently rated one of the world's most liveable cities, but the longer that spatial planning policy is left as political rhetoric rather than implemented across the urban area, the less likely that the city's future will offer the amenity enjoyed by today's residents as social, economic and environmental sustainability continues to decline.

RISK CULTURE REGARDING BUILT ENVIRONMENT IN LARGE-SCALE DEVELOPMENT: THE SHANGHAI CASE

Nankai XIA [1],Sijie LIU [2],Hailan ZHANG[3]

Abstract

The culture of built environment is gradually formed during the urban development. The most important part of the culture is cognitive and memories that people sense the city and that is the value of historic area and protection. However, China now is experiencing rapid development and changes since China's reform and opening up in 1978.With the speeding up of industrialization as well as rapid expansion of urban area, the built environment is totally different from the city used to be and all the cognitive and memories about the city are facing the danger of extinction. And what China is going through these years can reflect directly the contradiction of the protection and development. Therefore, shanghai is a good case to study a system of culture risk.

The report explains the culture risk from risk identification, assessment, warning, and the management. In addition, culture risk evaluation system with certain risk factors is established. And this system can assess the culture risk of the built environment from different angles and levels. Furthermore, management measures based on the evaluation before are also proposed and provide some reference for the decision makers.

There are five parts in the paper. The first part is to give the background and significance of the research, and define the major concepts. The second part focuses on culture risk identification, which includes figuring out potential risks and their characters and origins, and also predicting the possible consequence. The third part is culture risk assessment, which is the most important part of the paper. In it, several

[2] College of Architecture and Urban planningTongji University, Tongji University, Shanghai, PR China - 15000270765@163.com

[3] Tongji Urban Planning & Design Institute, Shanghai, PR China-zhhlxb@gmail.com

elements influencing culture of physical space are raised, each is divided into a couple of indicators; a system of multi-level assessment is built up. The fourth section is warning and management of culture risk. It will look into the subjects of management and suggest proper solutions. The last part is case study, in which Fuxing Wharf Area will be taken as the example to access culture risk.

Key words: culture risk; risk evaluation; risk management

1. Research Background and Significance

The urban culture of built environment is the accumulation of history. While it's not so simple to be equaled to history which can be recorded, it's a concept based on both time and space, which is changing all the time. The events happened earlier can be so vague for us because of our absence under that time and space. Luckily there is a path for us to get closer to the earlier culture and daily life—the physical space. In certain physical space, it's possible for us to sense how people behaved in it and how they looked upon the environment. Usually we get the information from the texture, color, and all the other the characters of the physical space.

Today's China has been experiencing rapid development and tremendous changes since the Reform and Opening-up in 1978. As one consequence, thousands of valuable historic buildings and blocks are destroyed. Together with the disappearance of the physical space which carries human memories, our city is losing their characters, and we are losing our culture. As we can see today, more and more cities in different continents are changing towards a certain standard city form which is occupied with high buildings.

1.1 Theory Introduction

In different kinds of research and reports, there are a lot of study about cultural conflicts and cultural alienation. While cultural risk, especially in urban development, is rarely mentioned.

As represented by Rush and Douglas, culture risk commentators propose The Cultural Theory of Risk. They hold the opinion that it is meaningless to merely focus on society structure of culture. There are various kinds of risk culture existing in society: political risk, economic risk and natural risk. It is those three kinds of risk culture that causes the disordered and unorganized society structure. However, the culture risk brought by large-scale development is not included in their theory.

In China, the study about culture risk in large-scale development is exactly being started recently. The studies mainly focus on the fields of enterprise culture risk and

transnational business culture risk. When referring to risk study in urban development, researches are mainly about economic risk and ecological risk. As culture risk study is barely started in China, it's necessary to learn from those mature theories and techniques.

1.2 Concept Definition

According to the work of Prof. Xia Nankai (2007), the large-scale urban development project is defined as the project that is led by government and constructed in a large and contiguous area, no matter located in new urban areas or old districts. Unlike projects led by economic benefits, large-scale urban development projects with various and complex functions play an important role in urban development strategy.

In this paper, the object faced with culture risk in large-scale urban development is limited to physical space, including space form, scale, texture, style and color etc.

1.3 Causes of Culture Risk

1.3.1 Economic Aspect

1) Economic Development

Economic development brings new culture and new lifestyle which risks former culture.

2) Function Promotion

When the function of the land is promoted or changed into a great extent, it is likely that the historical buildings are facing higher risk of being knocked down.

3) Infrastructure Construction

Infrastructure construction plays an important role in urban development. It is possible that a historical culture can be damaged by the constructing of a subway line or a street.

1.3.2 Political Aspect

To a certain extent, the culture risk is caused by the leaders' disregarding of the historical and cultural heritage conservation.

1.3.3 Technical Aspect

New architecture technology and materials:

The application of new architecture technology is the symbol of the new architecture culture, meeting the requirements of modern city. Historical and cultural heritage with traditional technology and material is impacted in the process of new architecture material's application.

1.3.4 Social Aspect

Culture is a concept which is changing and developing all the times. When certain form of culture fits in the development of modern society, it faces smaller risk of being destroyed relatively. On the contrary, the risk may be much higher.

2 Identification of Culture Risk

Risk identification is the first and the fundamental step of the progress of risk management. Risk managers can never handle the possible culture risk in project development without a correct identification of the risk. There are 3 aspects to identify.

2.1 Identify Potential Risk and Its Characteristics in a Project

In risk identification, figuring out what kinds of risks we are facing is the first step, and the analysis of their nature and influence follows. It is necessary to analyze the factors influence project development as completely as possible and make a list of these possible risks.

2.2 Identify Principal Risk Source

The origins of culture risks vary in different projects. They are relevant to the appearance and developing pattern of the risk. With the understanding of risk developing pattern, we are able to measure the possibility and influence of the risk. Furthermore, the handling and management of the problems can be easier.

2.3 Predict Possible Impacts of Culture Risk

The final purpose of risk identification is minimizing or even eliminating the adverse effects of project risk. After the identification of risks and their origins, predicting the possible adverse effects is necessary.

3 Evaluation of Culture Risk

3.1 Selection of Culture Risk Indicators

3.1.1 Single Indicator

Speaking of the culture risk in urban built environment, the index factors are closely associated with the impacts on physical space from the large-scale development. There are seven aspects which seem to be impacted most directly. They are city texture, city environment, city scale, architecture style, city color, landmark and city sculpture (Table 3-1-1).

Table 3-1-1 The Assessment of Culture Risk Indicators

Elements of assessment	Brief index factor of assessment	Specific index factor of assessment	Assessment method
City texture	The space pattern of buildings The gridding and framework of streets system The segmentation and demarcation of blocks	The building arrangement pattern (enclosed pattern, line-and-row pattern, free pattern) How the planned street network influence the characteristic of original street network How the planned street network connects the original street network Comparison of original street network density and project street network density The gridding and framework of the street system The patterns of streets The scale of block	Expert scoring method Fuzzy comprehensive evaluation method AHP method
City environment	Axis design Sight corridor Major building interface	Axis pattern in the region Sight corridor Changes of building interface	Questionnaire investigation method AHP method

	Skyline	Changes of skyline	
City scale	Building volume Building height Street scale Block scale	The volume of new built buildings and preserved architecture The volume of new built buildings and neighboring buildings W/H (width/height) of the street The height of new built buildings and the originals The impact of building height on the preserved architecture The scale of the block	Index factor assessment method Expert scoring method AHP method
Architecture style	Pattern of the architecture plan Pattern of the architecture façade Architecture material Architecture style Pattern composition	Pattern of the architecture plan Pattern of the architecture façade New material and the original The degree of style unification Architecture symbol Art and technic of architecture treatment	Index factor assessment method AHP method
Architecture color	Major color of block Color coordination Color unification	How the characteristic color of historic block is preserved Characteristic architecture color The unification degree of new built color and the original The degree of association between architecture color and local building material	Index factor assessment method Weighted method
Landmark	Characteristic	To what degree is the	Expert scoring

	architecture	characteristic architecture preserved and made use of New landmark's impact on original block	method AHP method
Sculpture	Characteristic sculpture	To what degree is the characteristic sculpture reserved Neighboring space design of the characteristic sculpture Changes of new sculpture style	Expert scoring method AHP method
…	…		

3.1.2 Comprehensive Indicator

In the process of culture risk assessment of urban built environment, a comprehensive indicator is required. The indicator is brought out in following three steps:

1) Choose the indicators which reflect the characteristic of the physical space in the region.

2) Give each indicator its value according to its weight in all the factors.

3) Analyze the risk of each indicator with mathematic method and add up all the risks

3.2 Assessment System

There are two main parts in this assessment system.

3.2.1 Identification of Regional Culture Valuation_

Identification of the regional culture value is the first step to do in the process of identifying the culture risk. Determine the level of culture value (Table 3-2-1). Large-scale development brings larger culture risk to the region which has higher culture value. The determination can be finished by expert scoring method, or the existing result brought out by statutory planning.

Table 3-2-1 Assessment of culture value in region

The description of culture value	The characteristic of culture value	the level of culture value (color block)	The numerical value of culture

degree			value
Extremely low	Almost no culture		[0，0.2)
low	With a small amount of culture resource		[0.2，0.8)
general	With noteworthy culture resource		[0.8，1.2)
high	With culture resource to be preserved		[1.2，1.6)
Extremely high	With extremely rare culture resource		[1.6，2.0]

3.2.2 Assessment of Culture Risk Indicator

1) Select Indicators

The culture of urban physical space is accumulated along with the history of the space. The selection of index factors varies according to different regions with different functions and characteristics. In order to reflect the culture risk directly, the selection focus on the connection between factors and physical space characteristic. The index factors which have more direct connections with space characteristic should be selected.

2) Evaluate Indicators

An indicator weighs differently in different regions. For a given region, the weights of every selected indicator should be determined. Experts are invited to compare the importance of two factors in each pair. The factors are selected from table 3-1-1. The weights of factors are calculated with AHP method. Use number 1-9 to mark different levels of importance beyond the other factor (Table 3-2-2).

Table 3-2-2 The degree of relative importance for certain two indicators in culture risk influence

The degree of relative importance A compared to B	1-9
Extremely important	9
Much important	7
Relatively important	5
Slightly important	3
As much important	1

3) Define Indicators

Considering the impact on each indicator from large-scale city development, we divide the risk into 5 levels. They are healthy, okay, alert, dangerous and extremely dangerous (Table 3-2-3). There is barely risk when the status is healthy. When it is okay, the risk appears, while still under control. Status “alert” means attention from planning and developing agent is needed. Something should be done to avoid the risk. In the next status “dangerous”, it is necessary to make a thorough strategy and handle the risks. When the top status “extremely dangerous” is reached, the culture risks are possible to lose control at any time, destroying culture resource of the region. Risk control is vital.

Table 3-2-3 Levels of culture risk

Description of risk	Status of risk	Level of risk (color block)	Numerical value of culture risk
healthy	Barely risk		[0，0.2)
okay	Risk within limits		[0.2，0.4)
alert	Risk noteworthy		[0.4，0.6)
dangerous	Serious risk		[0.6，0.9)
Extremely dangerous	Risk anytime to lose control		[0.9，1.0]

3.2.3 Comprehensive Risk Assessment

Analyze the relationship between different single risks, forming the comprehensive risk assessment. First, determine the numerical values of each risk indicator with the expert scoring method, AHP method and questionnaire investigation method. Considering different factors in different regions, calculate the weight of each factor. Combine both the numerical value and the weight to figure out the factor risk (Table 3-2-4). Secondly, perform matrix analysis with factor risk and culture value in certain region to finally get the comprehensive culture risk (Table 3-2-5).

Table 3-2-4 Matrix analysis of different risk factor weight

		The level of culture risk				
		Healthy [0，0.2)	Okay [0.2，0.8)	Alert [0.8，1.2)	Dangerous [1.2，1.6)	extremely dangerous [1.6，2.0]
The relative	As much important					
	Slightly					

importance of two factors	important					
	Relatively important					
	Much important					
	Extremely important					

Table 3-2-5 Matrix analysis of comprehensive risk assessment

		The level of culture risk				
		Healthy [0，0.2)	Okay [0.2，0.8)	Alert [0.8，1.2)	Dangerous [1.2，1.6)	Extremely dangerous [1.6，2.0]
Degree of culture value	Extremely low [0，0.2)					
	Low [0.2，0.8)					
	General [0.8，1.2)					
	High [1.2，1.6)					
	Extremely high [1.6，2.0]					

4 Warning and Management of Culture Risk

4.1 Warning System of Culture Risk

The warning system is to predict the culture risks possibly happen. The fundamental of prediction is information collecting and risk monitoring. We perform data analysis and carry out the risk identification, risk assessment. The goal of the system is to prevent the risk from eruption, to minimize the adverse effect on regional culture.

The base of culture risk warning is culture risk assessment, which can be used to develop the standard of warning. Divide the warning interval into 5 situations according to the index of culture risk. Each situation is represented by a single color. Blue represents healthy situation, not necessity for warning. Green represents okay, slight warning is needed. The third is alert situation represented by yellow. When the

culture risk is higher, orange warning is sent out to alert the subject of development. The most serious situation is red warning with extremely high risk of damaging and destroying culture resource. Warning should be send out immediately to avoid the adverse effects. The assessment table is listed below (Table 4-1-1).

Table 4-1-1 Matrix of comprehensive culture risk assessment

Warning intervals	Risk situation	Level of risk (color block)
blue	Culture environment is not disturbed or destroyed. Structure of the culture system is complete. System function of recovering and regeneration is powerful. There is hardly problem in culture resource.	
green	Culture environment is slightly damaged. Structure of the culture system is comparatively complete. System function of recovering and regeneration is good. There is hardly problem in culture resource.	
yellow	Culture environment is damaged to some extent. Structure of the culture system is influenced. System function of recovering and regeneration is weak. The culture problem appears.	
orange	Both culture environment and structure of the culture system are damaged. Function of the system is weaker, difficult to recover from outside interference.	

	Culture problem is serious.	
red	Both culture environment and structure of the culture system are destroyed. System function lost, much difficult to recover from outside interference. Culture problem is more serious.	

4.2 Management System of Culture Risk

4.2.1 Subject of Culture Risk Management

There are four management subjects divided according to the roles they play in the process of management: manager, developer, designer and implementer. Government is the most important and powerful subject.

The management organization is made up by the government and social agent. Government (especially department of cultural affairs and research center in university) has the responsibility of increasing culture risk awareness. On the other hand, social communities such as cultural city center are more flexible to fill in the gap in which government can't reach. They may perform well in the fields of risk identification, monitoring and warning.

4.2.2 Solutions of Culture Risk Management

Before the very beginning of the building, it's necessary to publicize the warning planning, supervise the illegal buildings, collect feedback from the public and evaluation from experts. When the development begins, introduce various solutions according to the situation and warning level of the culture risk (Table 4-2-1).

Table 4-2-1 Solutions suggested according to different risk levels

Warning level	No warning	Slight warning	Medium warning	Serious warning	Special warning
Warning color	blue	green	yellow	orange	red
Status of risk	healthy	okay	alert	dangerous	Extremely dangerous

Measures	Supervise the process of development.	Take measures to limit and avoid the risk	Avoid the risk and keep the risk from being more serious.	Figure out solutions together with relative department.	Organize urgent management group to preserve specifically on the physical space.

5 Case Study

Research on culture risk of a region includes risk identification, assessment, warning and management. Among all the aspects, assessment system is the core part, on which we will put especially emphasis in the case study.

5.1 Case Selection

5.1.1 Case Introduction

The case of Fuxing Wharf Area[4] is located in a community named Dongjiadu of Huangpu district, Shanghai. The area's boundaries are Baidu road to the north, Dongjiadu road to the south, south Zhongshan road to the west, while Huangpu River lies in the east of (Figure 5-1-1). The total land use area is 16.40ha, while the plus area of all the blocks is 12.89ha. Existing construction area is 199,100m^2. The length of the bund along Huangpu River is 950m.

[4] Shanghai Tongji Urban Planning & Design Institute received the invitation of Shanghai Huangpu River developing bureau in 2007 to finish 《 Conservation-oriented development planning of Fuxing Wharf Region》. The author investigated the developing progress on-site. He found the planning was carried out exactly as its original intention, only slowly in speed. The case is considered to be fit for the following risk assessment.

Figure 5-1-1 Location of Fuxing Wharf

5.1.2 Reasons for Choosing Fuxing Wharf

The area locates in the riverside area outside the old town of Shanghai. This area used to be a typical wharf area of Shanghai. The land use was a mixture of traditional Chinese business, trade, physical distribution and residence. The region was characterized by little-scale blocks and high building density. The unique culture of Fuxing Wharf area can be sensed when we get close to the old architecture and space, for example, Waima Road, Wharf Road, riverside warehouse, the Customs and so on.

5.2 Assessment of Culture Risk

5.2.1 Identification of Regional Culture Risk

The area of Fuxing Wharf saw the industrialization progress of Shanghai. The city prospered on the basis of river. The ethnic capitalists gathered here to take advantage of the convenient water transportation. The culture characteristic of the area lies in the following aspects.

1) The warehouse

Eight warehouses are the most featured buildings in the area. Five of them are located on the riverside (Figure 5-2-1), and the other three are separately for medicine, fruit and freezing. The total architecture area is 65,000 m^2.

Figure 5-2-1 The five warehouses along the river

2) The streets

"Competition for the wharf" reflects the importance of wharf in the time of water transportation. The streets lie perpendicular to the river densely (Figure 5-2-2). Streets are named after different industries, families and areas.

Figure 5-2-2 Main streets

3) The neighborhood

Each neighborhood is owned by a certain industry, gang or family. The average area of a neighborhood is less than 1ha. In the neighborhood, business and shops are outside, while residence is located inside. Storage, business dealers and accounts settlement are all carried out in the neighborhood.

In summary, as the most typical wharf site of Shanghai, Fuxing Wharf area has a collection of valuable historical buildings and spaces. We can divide them into 3 elements. First one is the shops which reflect the society network. Second one is the warehouse and yards symbolizing the prosperous water transportation. The third is the neighborhood filled with characterized residential buildings "Linong". With expert scoring method assess the culture value of Fuxing Wharf Area is as follows (Table 5-2-1).

Table 5-2-1 Culture valuation of Fuxing Wharf Area

The description of culture value degree	The characteristic of culture value	The level of culture value (color block)	The numerical value of culture value
high	With culture resource to be preserved		[1.2，1.6)

5.2.2 Assessment of Culture Risk Indicator

1) Select Indicators

Fuxing Wharf Area is multifunctional with shops, warehouses and yards for goods in majority. There is hardly featured color and sculpture. So we remove the color and sculpture elements from the assessment table (Table 5-2-2).

Table 5-2-2 The assessment of indicators of culture risk in Fuxing Wharf Area

Elements of assessment	Brief index factor of assessment	Specific index factor of assessment
City texture	The space pattern of buildings	The building arrangement pattern (enclosed pattern, line-and-row pattern, free pattern)
		How the planned street network influence the characteristic of existing street network
	The gridding and network of streets system	How the planned street network connects the existing street network
		Comparison of existing street network density and project street network density
	The segmentation and demarcation of blocks	The gridding and network of the street system
		The patterns of streets
		The scale of block
City environment	Axis design	Axis pattern in the region
	Sight corridor	Sight corridor
	Major building interface	Changes of building interface
	Skyline	Changes of skyline
City scale	Building volume	The volume of new built buildings and preserved architecture
	Building height	The volume of new built buildings and neighboring buildings
	Street scale	

	Block scale	W/H (width/height) of the street The height of new built buildings and the originals The impact of building height on the preserved architecture The scale of the block
Architecture style	Pattern of the architecture plan Pattern of the architecture façade Architecture material Architecture style Pattern composition	Pattern of the architecture plan Pattern of the architecture façade New material and the original The degree of style unification Architecture symbol Art and technic of architecture treatment
Landmark	Characteristic architecture	To what degree is the characteristic architecture preserved and made use of New landmark's impact on original block

2) Evaluate Indictors

The value of each indicators is different in culture issue. It's necessary to compare the factors and calculate their weights. The 3 valuable culture elements: warehouse, street and neighborhood fit in with the assessment elements of mark and city scale. While the architecture style and city environment are less characteristic. On this analysis, we figure out the weight of each element (Table 5-2-3).

Table 5-2-3 Weight of culture risk element in Fuxing Wharf Area

Index element	Weight
City texture	5
City environment	5
City scale	7
Architecture style	3
Landmark	9

3) Define Indicators

Urban Texture

Figure 5-2-3 original texture the site

Figure 5-2-4 planned texture of the site

Figure 5-2-3 and 5-2-4 show the original and planned texture. By analyizing the index factors of city texture with the methods of experts scoring and AHP , we can get the comprehensive assessment (Table 5-2-4).

The building arrangement pattern: there used to be two types of textures. One is stand-alone texture which is formed by warehouses along the Huangpu River. The other one is enclosed pattern texture formed by residential building, hotels, banks and pawnshops. During the development, we keep the stand-alone texture and reform the original enclosed texture. Regroup each neighborhood to strengthen the enclosed texture. Integrate all the neighborhoods to form an integrated area.

The gridding and network of streets system: keep the streets network with the trend of extending to the river.

The scale of block: keep the original scale of block, divide the block with street network.

Table 5-2-4 Culture risk assessment of city texture

Description of risk	Status of risk	Level of risk (color block)	Numerical value of culture risk
okay	Risk within limitation		[0.2，0.4)

Urban Environment

Consider skyline and major building interface to be the index factors of city environment. By analyzing the two factors with the methods of experts scoring and AHP, we can get the comprehensive assessment (Table 5-2-5).

Table 5-2-5 Culture risk assessment of city environment

Description of risk	Status of risk	Level of risk (color block)	Numerical value of culture risk
okay	Risk within limitation		[0.2，0.4)

Skyline

The original skyline is higher in the middle and lower on the two ends. There are some tall buildings inserted, creating a complex and charming skyline of the area (Figure 5-2-5). While in the planning, we keep the diversity of the skyline, raising the building height in the south. The skyline seems to be higher on the two ends, and lower in the middle (Figure 5-2-6).

Figure 5-2-5 original skyline

Figure 5-2-6 planned skyline

Major building interface

The building interfaces formed by warehouses are the major interfaces in riverside area (Figure 5-2-7). We keep the space pattern and culture elements of the original interfaces, and change the utilization of the warehouses (Figure 5-2-8).

Figure 5-2-7 original riverside interface

Figure 5-2-8 planned riverside interface

Urban Scale

Consider building volume and street scale to be the indicators of city scale. By analyzing the two factors with the methods of experts scoring and AHP , we can get the comprehensive assessment (Figure 5-2-6).

Building volume

Keep the volumes of original warehouses and continue volumes in new buildings.

Street scale

Make a comparison of South Zhongshan Road, Waima Road and Wharf Road. Analyze the value of W/H. For Waima Road and Wharf Road, W/H=1. For South Zhongshan Road, W/H=2. The scale sense of South Zhongshan Road is comparatively weak (Figure 5-2-9).

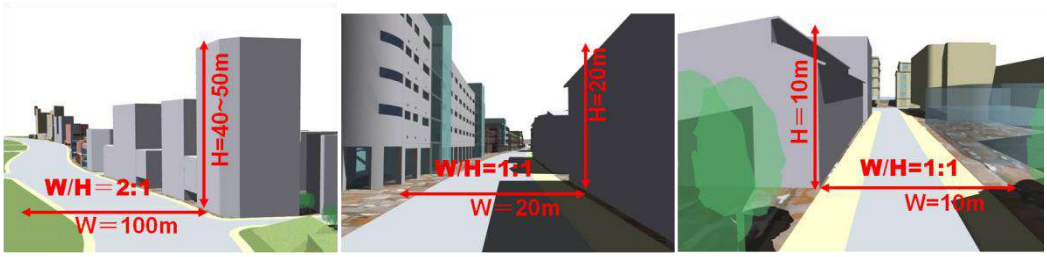

Figure 5-2-9 Street scale of South Zhongshan Road, Waima Road and Wharf Road

Table 5-2-6 Culture risk assessment of city scale

Description of risk	Status of risk	Level of risk (color block)	Numerical value of culture risk
alert	Risk noteworthy		[0.4，0.6)

Architectural Style

Keep original architecture style when renewing the warehouses. However, the modern style of new built hotels, office buildings and shopping malls is so incompatible with the original style (Table 5-2-7).

Table 5-2-7 culture risk assessment of architecture style

Description of risk	Status of risk	Level of risk (color block)	Numerical value of culture risk
alert	Risk noteworthy		[0.4，0.6)

Landmark

Consider characteristic architecture to be the indicator of landmark (Table 5-2-8). The New Wharf Square, the inner court of Jiqingli and a couple of warehouses are preserved. The original and planning are shown in Figure 5-2-10 to Figure 5-2-15.

Table 5-2-8 culture risk assessment of landmark

Description of risk	Status of risk	Level of risk (color block)	Numerical value of culture risk
healthy	Barely risk		[0，0.2)

Figure 5-2-10 Existing 4#5# warehouse and the transformation

Figure 5-2-11 Existing 1# warehouse and the transformation

Figure 5-2-12 Existing 2# warehouse and the transformation

Figure 5-2-13 Surrounding of 1# warehouse and the transformation

Figure 5-2-14 Inner court of Jiqingli and the transformation

Figure 5-2-15 Existing space between 3# and 4# warehouse and the transformation

4) Comprehensive Risk Assessment

Integrate the factor weight and level of culture risk to figure out the risk of each element with the method of expert scoring (Table 5-2-9).

Table 5-2-9 Culture risk level of each culture risk element

		The level of culture risk				
		Healthy [0，0.2)	Okay [0.2，0.8)	Alert [0.8 ，1.2)	Dangerous [1.2，1.6)	Extremely dangerous [1.6，2.0]
Index element	City texture					
	City environment					
	City scale					
	Architecture style					
	landmark					

Culture risk which the index elements are facing is low. Element levels are not necessary to be adjusted in the condition of high culture value. After integrating the risk level of 5 elements, we get the final comprehensive culture risk assessment. In a word, culture risk level of the case is okay.

6 Conclusions

As is known culture valuation of physical space is one of the most important parts of urban culture, since it carries all the memory and reflects culture context. This paper tries to construct a systematic analytical method applying to large-scale development of a city. This system is integrated by culture risk identification, assessment, warning and management, in which, culture risk assessment is mostly emphasized because of its key function in this system. With this analytical method we are able to minimize the risk with which we may face in the progress of city development. In this paper, management strategies are also recommended to provide a risk solution for the city planner.

THE ANALYSIS OF URBAN SPATIAL DEVELOPMENT UNDER THE INFLUENCE FROM LAND POLICY: SHANGHAI CASE

Nankai Xia[1] Jingying Chen[2] Hong Geng[3]

Abstract

China has started its reform of land market from planned distribution to market distribution by changing its land policy in 1988, at the time point of the first auction of usage right of one land in Shenzhen, in order to increase the efficiency of land distribution. In the early stage of economy development, land policy maximized the economic benefits and utilized the structure of urban space. However, with the speeding up of industrialization as well as rapid expansion of urban area, such reform led to the chaos on land market, which affected negatively on the efficiency of land distribution through market and utilization of functional planning on urban space.

The report aims to explain how the land policy influent the urban space by comparing difference between the policy and spatial development. And it also will explain the mechanism between the development of urban space structure and influence from the change of land policy, by studying the case of Shanghai, with applying the analytical methods from urban geography, urban economy and new institutional economy.

There are three main sections in this report. First section will apply the statistics method to analysis the influence of land policy on land market under different application subjects of land policy. Three aspects will be considered in this section: policy target, regulation subject, control measures. Furthermore, the second section will use the statistic method to analysis the quantitative change on the development of urban space structure of Shanghai with time series under the influence of land policy. The change of the urban space mainly reflects in urban form (increasing land for construction), land fragment and construction intensity (FAR). Finally, the third part will indicate applicable suggestion to the further land policy constitution based on previous analysis.

Key Words: Land Policy; Spatial Development; Reform

1. Introduction:

In the past 50 years, cities in China were going through a fierce transformation of land market system and reconstruction of urban space. Sticking to the state ownership of urban land and collective ownership of the rural land, land policy was experiencing a great turning in either acquisition way or basic rights. Especially after 1988 Shenzhen-a city in the south of China-succeed granting the land via auction way marked that the land granting mechanisms in China transiting from administrative distribution to market distribution. Therefore in a long term, the land supply of China is on the double track. One is administrative way to grant state-owned land to certain users, especially for the municipal infrastructure. And another is market way to grant land by bids, auction or listing.

In the early reform, the imperfection of land market system and localization of financial management leaded to a series of different kinds of violations such as keeping land unused, property hoarding, and price rigging. And it also results in chaos of the construction land expansion and irrational structure of land use. System of tax distribution in 1994 especially made more significant influence in land use. The total revenue of local finance decreased from 78% in 1993 to 47.7% while the income of the real estate and construction all belonged to the local government, which further promoted local government to increase their fiscal revenue via selling construction land (Jiang Xingsan, 2010). And all these behavior dramatically changed the urban spatial structure. Take Beijing-the capital of China-as an example. The urban land area was doubled during only 7 years (1985-1992). And so it was in Guangzhou-another city in China, which expanded from 182.3 km^2 in 1990 to 376 km^2 in 2002. Meanwhile real estate began to blossom in the late of 1990s. The aggregate area of commercial residential building was up to 1,200,000 m^2 in 1996 from the 500,000 m^2 in 1992 (Ding Chengri, 2006). That meant the average annual growth rate is 25%, which was a surprise speed to the world.

As the market being perfected by varieties of land policies, effective land protection policies began to play a more and more important role in controlling expansion and disorder of the urban space (Huang Jinxian, 2009). Land scale, development intensity and land fragment were all influenced and adjusted by these land policies. Especially after 2000 when primary and secondary land market were basically formed and land policies gradually became perfect, those policies promoted the spread of urban space as well as inhibit the de-normalize development of urban space.

This paper is based on the relevant land policy published by national government during 1980-2010 and micro data of Shanghai's land market during 1995-2010.

Statistical method is used to analysis the evolution of the land policy and its influences to the urban space (including construction quantity, development intensity and city fragmentation) and help people understand the interaction between policy and space.

2. Analysis of land policy

The reformation of the land policy was actually started from 1980s in China. The national government of China published 93 land policies from 1980 to 2010. In these policies, 69 policies are directly bound up with the urban land, Accounting for 74% of the total policies. The annual number of land policies published by government increased every year. View from the control objects, in 1980s, the land policy controlled the urban land use only via controlling the construction land itself. However, in 2000s the objects of the regulation are not only the construction area but also the non-constructive ones, which both influent the structure of urban space. As an important capital element, land gradually was becoming more and more vital in the urban development. The influences of land policy to the development were also increasingly obvious.

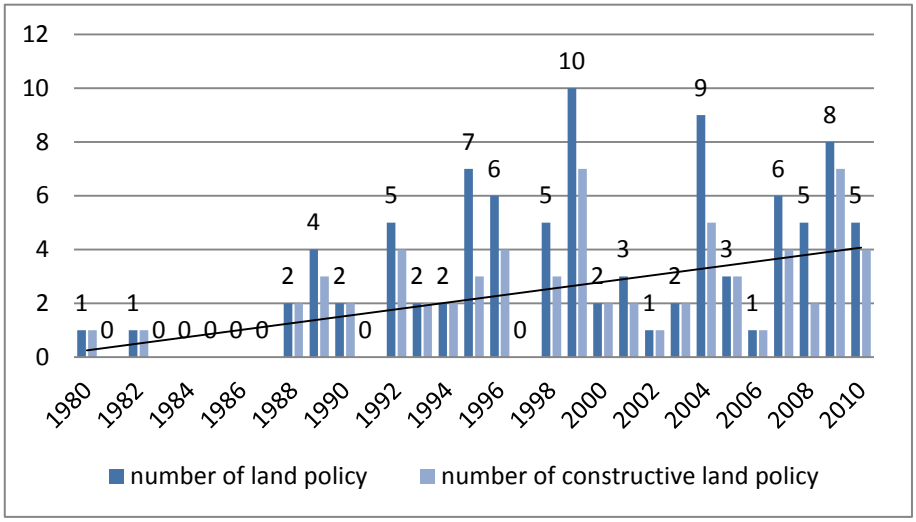

Figure 1. land policy distribution scheme (1980-2010)

According to the content of management, all the land policies can be decided into following types: planning policy, land use policy, price policy, land supply policy, cultivated land protection policy, tax policy, ownership policy, enforcement policy and cadastral management policy. In the early 1990s, tax policy and land supply policy are the main body of the published policies. And After entering the new century, companying with the maturity of the whole land market, the content of land policy became diversified. The regulation of Land use and minimum price policy, as

well as cultivated land protection were becoming an indispensable part of whole policy system, which help to regulate the land market and promote to form a rational land use structure.

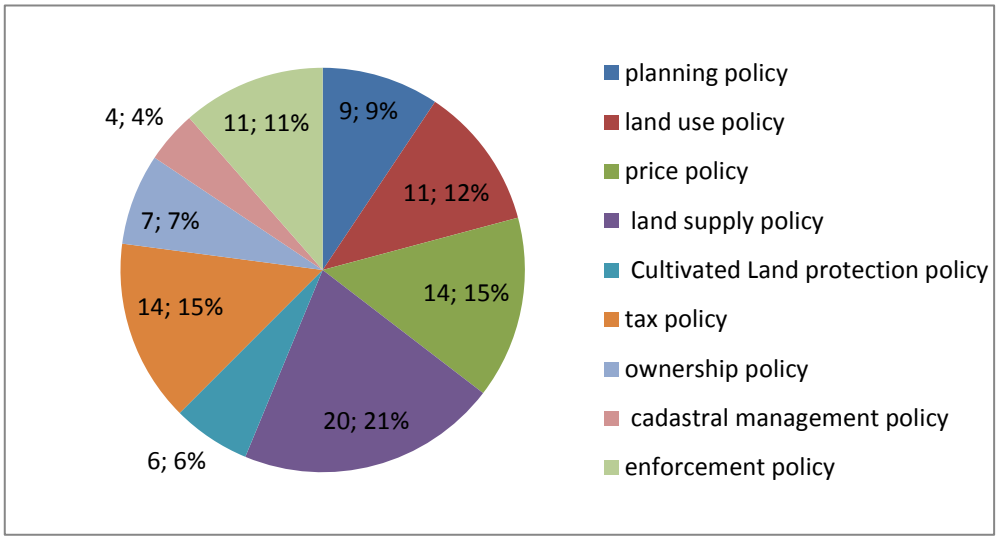

Figure 2.share of different manage content in the policy system(1980-2010)

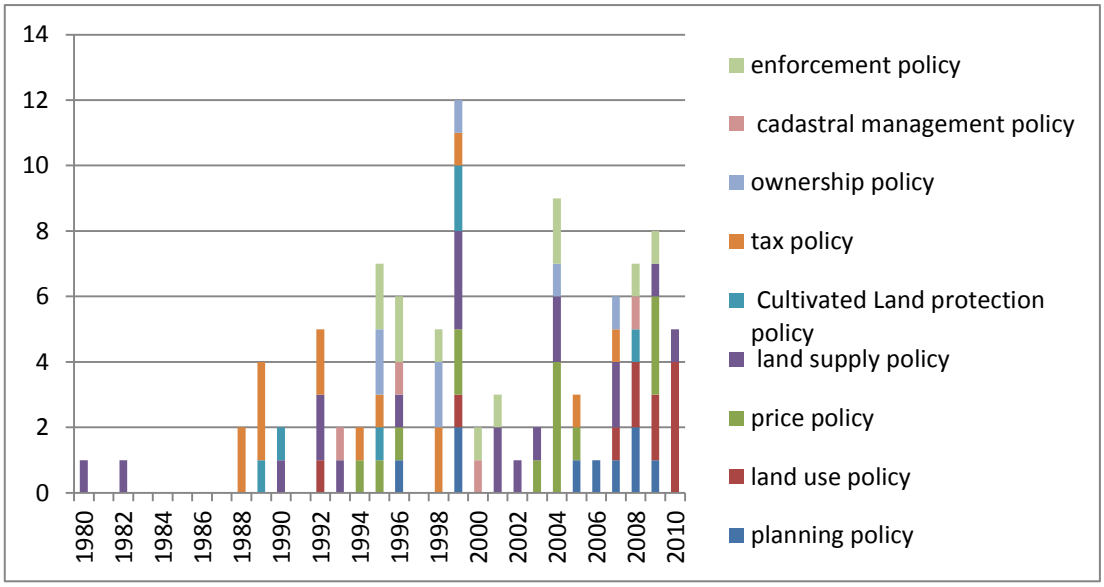

Figure 3. policy distribution scheme of different manage content each year(1980-2010)

According to the analysis of controlling object and management content ,the transiton period can be divided into three phases and they are as follows:

1)1980-1990: Transformation Period For Exploration

The transition of land policy from administrative distribution to the market

distribution in China began in 1980s. İn this period, land supply policy and tax policy were the main body of all the policies granted by national government. These policy framed the most basic of land market operation rules. At first, the land royalities were paid in the form of site fee which only collected from Foreign investors*(regulation of construction land to the foreign venture enterprise published by The state council* in1980). And till 1988, the government officially published *the land royalities regulation of people's republic of China* and other relevant policies such as *supplementary provisions of Some specific questions about land royalities* etc. Land royalities became a main way to exploring the land market distribution in China.

2) 1990-1999: The Land Market Formation Period

In 1990, the state council published *the interim regulations about Land use and transfer of People's Republic of China*. İt is the first comprehensive regulation about the state-owned land transfer method and essencially driving to the separation of the the land use right and ownership. Also in this period , right of transfer, lease, mortgage were clearly defined which meant the land market in China were truely formed. İn this period of time, the management content became to diversity and land supply policy and land price policy became the main policy at that time. And main points were as follows:

A. Futher clarify the ownership of the land, and refine some related rights, such as lease, grant and mortage etc.
B. carry out land registration system to Find out ownership of each land.
C. Evaluate land nationwide to form the basic price of the land market
D. Limited the administrative transfer way and define the lowest transfer price
E. Form the basic distribution mode of land revenue payments

After this period, land market were formed and standarded by all kinds of policies. Market distribution took place of the administrative one and became the main method to grand construction land and the basic price of land market were also formed at that time. The basic distribution mode of land revenue payments promoted local government pay more attention on the land value. Therefore, large scale of urban expansion was openning up.

3) 1999-2004: The Land Market Adjustment Period

İn the year of 1999, *land administration law of the People's Republic of China* and its relevant enforcement regulations were published by the state council. İn this regulation, land right were cleared, as well as the effect of land use planning. At the same time , policy pay more attention to the cultivated land protection and the use

control. İn this period, there were a great demand of urban land with the matureity of the land market, the speediness of urban construction and the tremendous inrush of population. The urban land became a scarce capital to the local government. Therefore land policy in this time began to focus on the rational and normative land structure instead of land itself. The structure of the urban land use and scale were taken seriously, which were so different with the policies in the earlier time. Strength the role of urban planning, reuse of the vacant land and attach more importance to protection of cultivated land and national resources. And main points were as follows:

A. Emphasize role of land use planing and urban planning, leading a rational and economic development.
B. Emphasize the graded examination system in order to control the scale of urban construction and construction quality.
C. Emphasize the regulation of disposing and reusing of vacant construction land, especially in downtown.
D. Relevant provisions about farmland, rural residence and scale of towns and villages. Meanwhile stipulate 15%of the land transferring fees should be used in protection of farmland.

4) 2005-2010: The Macro-Control Period

İn 2004, the Ministry of land and resources in China published a regulation which forbid all the business land be granted by administrative way from August 31 2004. This regulation meant that the market distribution, including auction, bidding and listing, became the only way to obtain the land-use right legally (except for military, affordable housing and infrastructure purpose, which can continue obtaining the land from government directly). In this period the national government limited the coverage of the administrative land and basically ended the double track of the land supply. Meanwhile, the ratio of land use policy increased sharply , strengthening control of land use as well as enforcement policy was published to deal with illegal behavior. Land, as a basic element of capital, began to take participation in national macro-control from this period. And main points were as follows:

A. Set up the relevant examination and approval system for land use control, including residential projects, key construction projects, land use scale, conversion, rural residence base, limited land examination and approval system.
B. Relevant regulation about transfer mode and minimum price of land grant fee.
C. Strengthen the role of the annual plan for the land use

3. Analysis of urban spatial development under the influence from land policy

3.1 Introduction of Shanghai Spatial Development

Shanghai, as one of China's most developed city, is bearing a lot of capital and population. the resident population of Shanghai has reached 23.02 million by the year 2010, 89.3% of which were urban population. İt is also the highest urbanization level in China. For Shanghai only has 6340 square kilometers of urban area, the population density has reached 3631 people each square kilometers by 2010. It is the most densely populated city in China. Especially during 1990s and 2000s ,with the tremendous inrush of capitial and population, the city was expanding quickly. Relatively limited urban area, makes Shanghai have sharp contradiction between human and construction land.

As the other metropolis in the world, Shanghai also made a lot of work to make land use economic and rational, and experienced from “single center” to “more centre”during 1990-2010. According to town system planning, urban master planning and land use planning, Shanghai local government put forward a plan called “one city and nine towns” in 1999, which means set up nine new satellite towns around the main city. With the launch of the plan, the government figured out “1966”urban system in 2005 based on the former one.(1966 urban system means one main city ,9 new satellite cities, 60 new towns and 600 villages.) considering on the great changes of the urban space, it is meanningful for us to take Shanghai as the example to analysis the influence between land policy and urban space.

3.2 The Evaluation Method of Land Policy Influences on Urban Space

This paper uses the macro data of land transfer in Shanghai during 1995-2010 to analysis the influences of land policy to urban space. Influences of the land policy are diversity and the effect on one certain aspect would be quantified in this paper. Three aspects of the urban space are considered in the research: scale of the urban expansion, development intensity and urban fragmentation. And the quantification didn’t represent the specific value but the trend of the influences. And the following characteristics of policies are considered in this process of quantification:

1) The effect of the policy is long-term and accumulating. The action spot of one policy is not one single point when the policy was published. Instead, the effect of one policy will last until it is abolished.

2) The effect of the policy will be explosive at first and then recess year by year. When the Policy (especially mandatory policy) appearing, it must play a larger role (either limitation or promotion) among the related department and aspect. As time pass away, the force gradually back to the balance point.

3) The effects of different policies are related. The regulation of one object may affect other aspects of the urban space indirectly. So policies have certain joint effect.

According to characteristics mentioned above, the index system of land policy quantification is set up as follows: (considering the first characteristic, the starting period should be earlier than the macro data of land transfer. Because of the small amount of land policy before 1990 in China, this paper chooses the land policy in1990-2010 for this analysis.)

Index A:
Performance evaluation index of a policy on certain aspect

$Y_{it}=\alpha_{it}*\beta_{it}*\gamma_{it}$

Y_{it}: performance evaluation index of a policy on certain aspect.

α_{it}: The importance of the policy i on aspect t (define comprehensive laws as the value of 3, Special regulations as the value of 2, Mandatory policy as the value of 1 and suggestion as the value of 0.5)

β_{it}: the relevancy of policy i on aspect t (define no-relationship as the value of 0, Indirectly relationship as the value of 0.25, partly relationship as the value of 0.5, directly relationship as the value of 0.75 and mandatory provisions as the value of 1.)

γ_{it}: the trend of the policy i on the aspect t (define promotions as the value of 1 and limitation as the value of -1)

Index B
Performance evaluation index of policies on certain aspect in one year

$Y_{nt}=Y_{(n-1)t}*\omega+\sum Y_{it}$

Y_{nt}: Performance evaluation index of policies on t aspect in n year.

ω: Attenuation coefficient of the policy each year, in this paper the value was defined as 0.9, which only represents the trend instead of the specific value.

$\sum Y_{it}$: Sum total of the performance evaluation index of each policy in one year.

Establish coordinates with Y_{nt} and the time. The trend of the land policy on certain aspects can be seen clearly.

3.3 Influences Analysis

3.3.1 The Influences of Land Policy on Urban Space Expansion

In 1980s and 1990s, the spatial evolution of shanghai was Significant with both outgoing expansion and internal reorganization. On one hand, urban land expanded outside and doubled in five years. On the other hand, the development intensity of city was still growing, especially in the downtown. After the year of 2000, the scale of shanghai became stability and internal reorganization became the main way for the changes.

Figure 3. The influences of land policy on urban space expansion (1990-2010)

Between 1995 and 2010, about 15963 pieces of land were transferred in market way, which covered about 60031.11million square meters in Shanghai. The trend was like a curve. At the same time, the influences of the land policy to the urban expansion were waning. Especially after a series of policies about intensive land use and macro control of the land market were published in 2004, the urban space influenced by policy was obviously. And three stages are included in the whole period:

1) 1995-1999: Slow Growth Stage

In this period construction land transferred about 1366.99 million m^2 every year, accounting for 11.38% in 1995-2010. And at that time, not all the business land was transferred by market way, so that the scale of new expansion may be a little greater

than the data above. Stable was the characteristic in this time both for the policy effect and land expansion. The regulation about land right and the processing of illegal cases push the whole market to a regularization, which gave a lot of confidence to both developer and government. Meanwhile, the distribution of the land grant fee system also made the local government start to pay more interest to the land transfer. As the spatial distribution, although *management method of nature reserve land (1995)* and *management method of construction land use (1996)* were published to control city expansion, for the small amount of land transfer, all these policies didn't really work. In this period, space expansion was optional and the amount of new construction area in the city was almost equal to it in the suburbs. Developing everywhere without a correct guiding and lacking the reorganization of internal vacant land were two big problem of this period.

2) 2000-2006:Fast Growth Stage

This period is the fastest expansion in the 15 years with the speed of 6062.06milion square meters per year, accounting for 70.68%of the total new area in these years. The land market is basically formed after the exploration for several years and the execution of *land management law of People's Republic of China* in 1999. The regularization of land market operation promoted the fast growth of land transfer. The regulation of land control were still strengthening in this period and more policies were published, including *agreement of granting state-owned land use right* (2003) and *announcement of continue to grant business land by bidding, auction and listing way* (2004) etc. This period is also a phase of world economic recovery; all the industries in the city were blooming this time. Local government took advantage of this opportunity to establish kinds of industrial parks to bring sustainable tax sources for the city. With the development of the industry, shanghai attract more population and services into it, which Speed up the city's expansion. Since late 2004, the national government realized the issue of land recourse limitation; policy became to transfer from encouraging to controlling, such as *The decision on strictly deepening the reform of land management by state council* (2004), *announcement About the protection of basic farmland* (2004) and *The notice of reinforcement of land control by state council* (2005) etc. Although those policies pushed the expansion control to a new high level, due to the boom of the development, the expansion continued until 2006.

3) 2007-2010: Macro-Control Period

In this period, the average annual land transfer decreased to 2690.44million square meters, comparing to the amount in 2000-2006. In this period, the national government continued to publish a series of policies about urban control, including *The measures of annual plan for the land use control* (2006), *notice on promoting the economical and intensive land use by The state council* (2008) and *announcement*

*about land use control and vacant land management by ministry of land and resources in Chin*a (2009) and other limitation policies about Industrial land and residential land. At the same time, the expansion in 2000-2006 took a lot of pressure for Shanghai. According to statistics, by the end of 2006, the construction land of Yangtze River region (with Shanghai as the center) had already reach 17.4% (without water), which is much higher than the percentage of it in USA. Policy guide, expansion pressure and world financial crisis made the amount of land transfer of shanghai in 2007 plunge suddenly, and maintained in the certain level till 2010.

3.3.2 The Influences of Land Policy on Urban Intensity:

National government didn't published relevant policy to directly control the intensity of the urban development. Intensity was more controlled by macro control of the supply amount, which changed the overall intensity (overall intensity= urban area/ building area) indirectly.

	1950	1960	1970	1980	1985	1990	1995	2000	2003
Urban area (km^2)	82.40	140.86	140.86	196.75	351.10	748.71	2057.01	3924.24	3924.24
Building area (million m^2)	4679	6140	7115	9134	12748	17256	22094	34206	51375
Overall Intensity	0.57	0.44	0.51	0.46	0.36	0.23	0.11	0.09	0.13

Table 1: table of comparisons among urban area, building area and overall intensity

According to the table above, the expansion of the city resulted in reduce of the city overall intensity. Because of the encouragement of land granting, the lowest intensity was came up in 2000, for only 0.9, which only a half of that in 1990. According to the comparison of policy effect and development intensity, they didn't match very well. However, from the figure 4 and figure 5, the growing of development intensity can be clearly showed, with the control of policies in 2000-2010

At the beginning of carrying out the new land transfer system, the amount of new land quantity was less; the expansion ability of Shanghai was relatively weak. The average FAR of the new urban land can maintain in a certain level. During 2000-2003, with the loose of the land policy and pursuit of sustainable tax sources for the local government, Shanghai expanded quickly. Especially the set up of several industrial parks around Shanghai resulted in the lowest FAR of new urban land these years. The reduction of the intensity was not only happened in the whole city, not also in the downtown. The quantity and intensity of the new development in downtown were also slow down. During 2000-2003, only 1387 new high buildings (8 floors and above) built in this time, and the construction area was 2265 million m^2. Comparing the large amount of the new granting land, the increase of the

development intensity in downtown was much less.

Since 2004, the government paid more attention on the intensive of the land use. The change of Shanghai from expansionary city to internal reconstruction brought a great opportunity to ascend the development intensity. The high buildings in the downtown were going up on after one in this period. Especially in 2007-2010, when the whole area of new transferring land was decreasing while the demand for inrush population and industry were still increasing, high density became the only way to deal with this conflict. During these four years, the average FAR of the new transferring land reached 1.55, which was 74.15% higher than that in 2002. That is to say, those control policies, not only control the city expansion and guide the urban development efficiently, but also promote the develop intensity much more economic and rational.

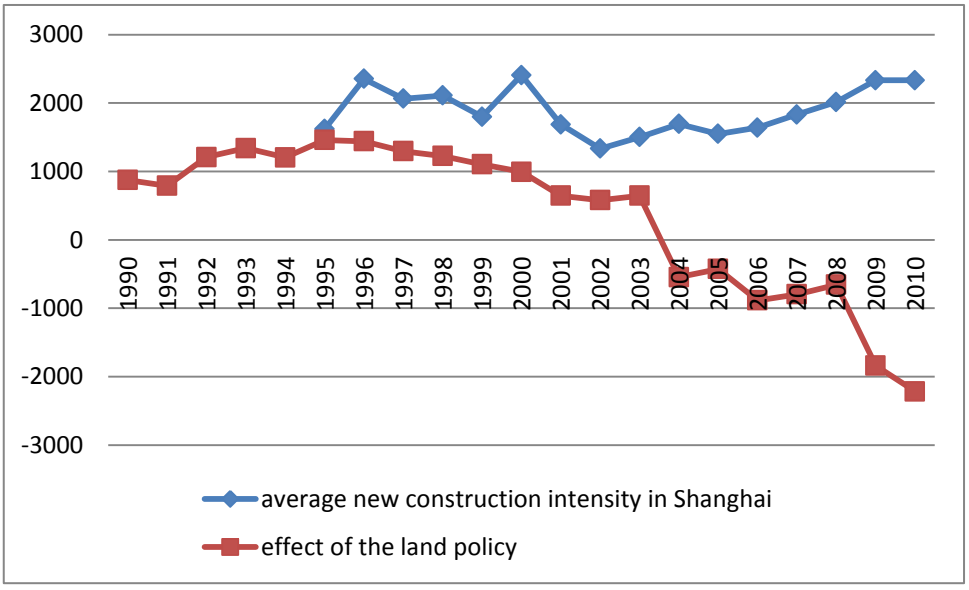

Figure 4. The influences of land policy on new land intensity (1990-2010)

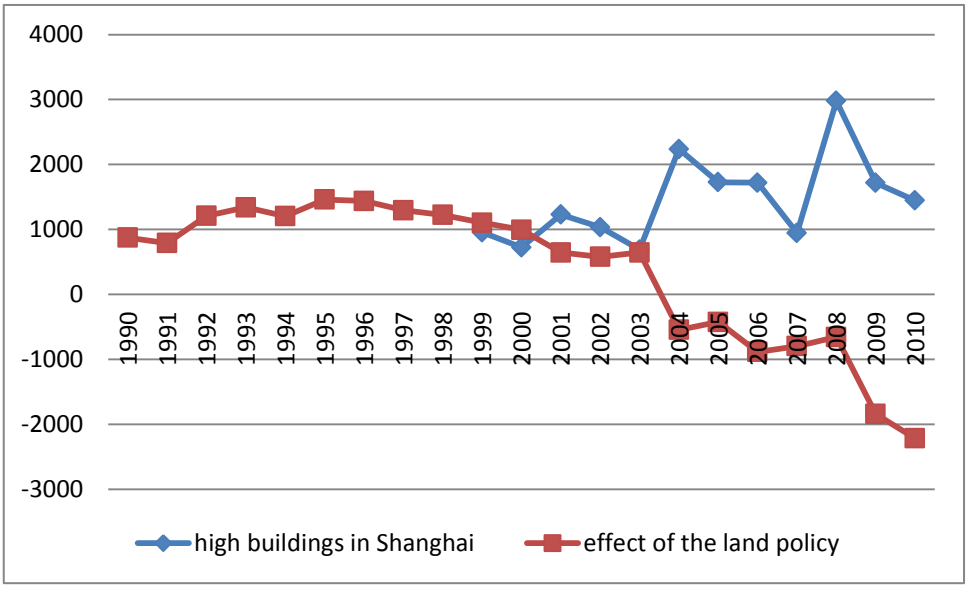

Figure 5. The influences of land policy on the amount of high buildings (1990-2010)

3.3.3 The influences of land policy on urban fragmentation:

Urban fragmentation is the performance for the land size in city, which measures the reasonability of the land size. Along with the development of shanghai and perfection of the property right system, the construction land were attached to certain use and cannot change it for a long time. Therefore the revival of urban land, especially in downtown became more difficult. The size of new developing land was reducing and the city space was tended to be broken. However, when the land reserve system came up in the late 1990s, the situation changed. With the effect of relevant authorities and policies, the land market became marketization and transparent, which provide an opportunities to integration of urban space.

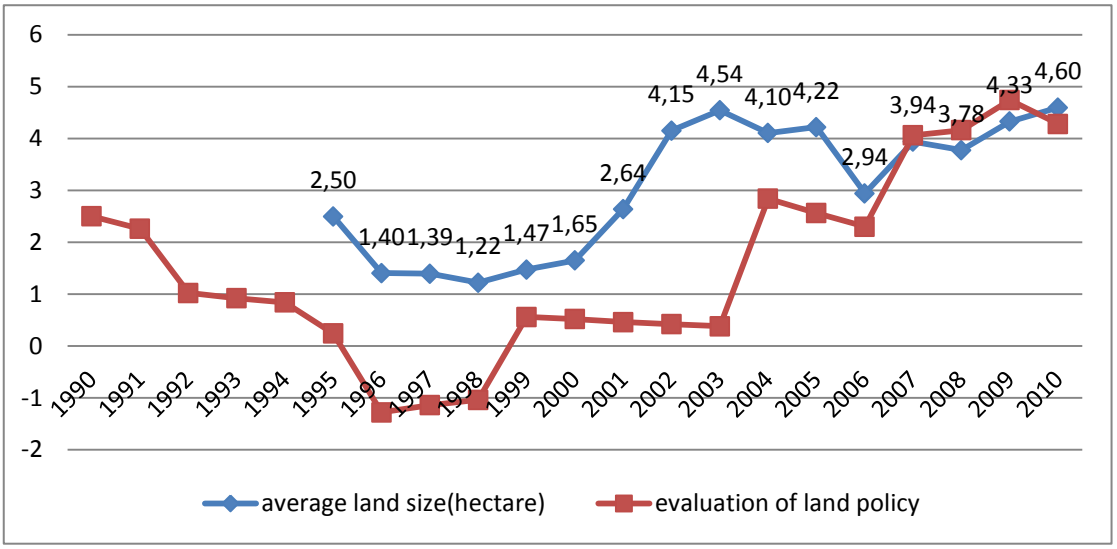

Figure 6. The influences of land policy on urban fragmentation(1995-2010)

According to the figure above, it can be seen clearly that there were two peaks and two troughs in the average land size from 1995 to 2010. From *the administration of ecouraging large-scale development for foriegn inventors* which was published in 1990, China began to step into a era for construction. İn 1992, the national government published severl policies to define the properity right and though land registration and land supervision to strenthen the management of the land use. So the space of shanghai became relatively fixed down and as the formation of land market price, the cost of demolition tended to be higher and higher, which made the city in the further fragment from 1995. The size of the transfer land in 1995 was 2.49 hectare. however, just 5 years later, the average of the land size was just 1.67 hectare in 2000, only 67.06% of that in 1995. Several reasons can be concluded as follows: 1) relative land policies to define the land right clearly resulted in the difficulty of urban demolition. 2) the lacking of policies for demolitionmade the chaos of urban revial. The tense relationship of the government and the residential delayed the step of urban intergaration. 3) the common existance of vacant land and lacking of handling metheod hinder accerating the speed of fragment. 4) lacking of the effective administration. Raw land transfer which was common in China, make the whole land market lacking a plan of the urban space.

The phonommon of space fragment was paid more attention by national government. From 1999, serveral of land consolidation and reservation policies were published, including The vacant land treatment method (1999), land reservation method of shanghai (2004) and the national management methof of land reservation (2007). The land reservation means the government obtain the use right of the land through back, purchase requisition or other legal way, and reserve or consolidate them instead of transfer immidiately. This behaviour was benifit for government to intergate the

urban space and grant them as the plan. The foundation of land reservation system marked the land transfer from the disorder to well-planned way. Unified demolition, unified facility supporting and reserve the idle, vacant and inenfficient utilization state-owned land priority, made more effective of the city internal integration. Althogh the land reservation policy was published in 2004, shanghai set up the reservation center from 1996. Therefore, from the year of 2000, the influence of these policy worked out and the size of land increased to 4.59 hectare in 2010, much more rational than that in 2000.

4. Conclusions and Suggestions:

This research is focus on the influences of the land policy to the urban space. Because of the limited data, only national policy was considered in this paper, which has certain restriction. However considering the national policy is the guide of the local policy, it also has some significant meaning. At the same time, shanghai was experiencing several times of administrative division adjustment. So all the space data cannot correspond to the specific space spot, only macroscopic level can be analysis in this paper.

In this paper, we found that China's land policy was stability and continuity. From market formation, market cultivation and market control, the government basically finished the transformation of the land market from the administrative distribution to market distribution. What is more, it plays an important role in the crazy expansion of urban space in these years.

Secondly, the promotion of land policies to the urban space control was found in this paper. With the help of clear property right, the gradual tax system and appropriate regulatory, the land market in China developed quickly and paid more attention by both government and developers. Through the land use plan, the minimum price control and protection of farmland and national resource, the government try to control the scale of construction land and set intensive land use as the main criteria for the land transfer. At the same time, the land consolidation and reservation also play an important role in the rational and intensive urban space. The interaction of different policies became the key to rule the urban space to a healthier way from different angles.

Last but not least, the study also shows that the influences of land policy sometimes were not so directly to the urban space. It usually operates with a lag. So the stimulate of the outside environment, either economical or political was important to promote the whole policy to implementation, which became the turning point in the transformation.

China now is in a rapid urbanization stage, and the urban space is forming at this time. Whether the land policy guides the land use rational and effective or not, is meaningful to the urban planning in China. Therefore, following suggestion should be followed in the policy implementation in the future.

1) Continuing to strengthen the policy guidance of intensive land utilization. The policy should to be changed from a single suggestion notice to a mandatory policy, strengthening the legal binding of the land policy gradually.
2) Guiding the land use from various angles. Diversified ways should be adopted and the interaction of different policies should be noticed. Using the land planning policies, land use policies, land supply policies, and cultivated land protection policy, the land law enforcement surveillance policies comprehensively to guide the urban space.
3) As a leading policy, the land policy should be forward looking. Considering the policy effects have certain hysteresis, the policy should be cooperate with various aspects of external factors, such as the international economic environment, the orientation of the city, urban land and population capacity and so on. Only in this way can it lead the urban space to rationalize direction.

RECENT ACTIONS OF SOCIAL HOUSING
FOCUS ON NORTHERN ITALY

Nadia Caruso[1]

Abstract

From the 80s a general trend of withdrawal of state support from housing policies and social housing is recognized in the majority of European countries. Social housing provision began to decrease and the sector opened up to economic pressures. Housing has been a focus for neo-liberal reforms, but it is not the only sector influenced by it: also practices and interventions in the cities changed with this broad worldwide trend. In urban arena social exclusion and polarization are sharpening, aggravating socio-economical inequalities. In the last decades recent actions and interventions of social housing are taking place: at the local level tools and measures are created to maintain and continue housing policies. Housing is an important issue for local communities and new actions are developed to deal with lack of funding and creativity, even though, after the financial crisis of 2007 housing and development market collapsed. The availability of state support is even more reduced, together with the willingness to subsidies social housing.
The paper presents the social housing scenario summarizing the European common trends. Then the focus is moved on the Italian context, in particular to the city of Turin, in the North-West of Italy. The author collected social housing norms, plans and initiatives of this city in the recent years (from 2000). In this complex scenario the paper presents the analysis of these recent actions, highlighting their innovative characters. The main criteria for the case study analysis are chosen applying a qualitative approach studying the European context and its references.
Examining these recent social housing actions can provide a better understanding of local practices and of how they contribute to develop new methods and forms of actions at the urban level. On the other hand, considering that social housing sector has been in a critical situation for decades, its developments are showing the effectiveness of different forms of responses. Indeed, the paper allows to recognize the evolution of housing practices and provides innovative ideas to face the complex actual context at the urban scale.

1. Introduction

From the 80s a general trend of withdrawal of state support from housing policies and social housing is recognized in the majority of European countries (Priemus & Dieleman, 1999; Doherty, 2004). Social housing provision began to decrease and the sector opened up to economic pressures. The main features of this trend are: decline in scope and size; privatization and disappearance of institutions and particular forms of funding; transformation from supply-side to demand-side subsidies; promotion of home ownership through mortgage loans. Housing has been also a focus for neo-

[1] Politecnico di Torino, Turin, Italy – nadia.caruso@polito.it

liberal reforms, but it is not the only sector influenced by it: also practices and interventions in the cities changed with this broad worldwide trend. Neo-liberal reforms took place through: shrinking and privatization of social services; dismantling of welfare programs; promotion of supply-side competitiveness.
Furthermore, it is important to remember the actual impact of financial crisis. It is nowadays a real issue to develop new policies and new intervention at the urban level. In particular, different issues can affect social housing sector and housing need:

- decline in taxes for public authorities;
- promotion of education and research reduced;
- public investment in infrastructure and environment postponed;
- fall in price of GDP (also houses' prices, sales of existing and new built dwellings) and rise of unemployment.

Indeed, in urban arena social exclusion and polarization are sharpening, aggravating socio-economical inequalities (Allen et al., 2003; MacLeod, 2002).
At the European level, CECODHAS, Housing Europe's Observatory, recognizes common trends in social housing sector (Pittini & Laino, 2011). Despite the critical scenario, housing need is still an issue and various initiatives are taking place trying to tackle it. The main finding of European social housing studies is a complex and differentiate scenario of actions. Dealing with crisis dynamics forced actions and interventions in social housing sector to be residual. It is important to understand the heyday of social housing is over, housing practices and polices of recent years are no longer a full response to housing need. These trends are specialised and targeted to local issues or to specific populations. Indeed, considering these trends and initiatives permits to improve the knowledge about this sector in recent years, but also it could show various responses in a situation of no resources. Nowadays urban governance has to deal with lack of financial resources, social housing could be useful showing different types of actions and their effectiveness.

2. The European trends in social housing sector

In this section of the paper European trends and initiatives are summarized. They are important references studying the Italian case.
At the national level, in the recent years (from 2000) there are some responses in the form of stabilising factors to help recover the housing and social housing sector. In the aftermath of the crisis some governments invested in social housing as part of recovery programmes. In France and England the number of social housing dwellings increased in 2008-09 (Pittini & Laino, 2011, p.25) If the size of social housing has been shrinking since the 1980s (with some exceptions in Europe like Austria, Belgium, Denmark and Finland), the numbers of applicants has been increased. Homelessness levels are growing, the housing affordability is worsening with the crisis scenario, creating an increase of housing exclusion. The figures are rising counting an increasing numbers of working poor and middle-class families as new category at risk of exclusion.
Focusing on local trends described by CECODHAS, they can be read through main dimensions: intervention on dwellings, actors involved in providing social housing,

financial mechanisms, and tenants' involvement. Regarding the dwellings and their management, use and improvement, the registered European trends are:

- privatisation of the existing stock with the objectives of satisfying tenants' aspirations and generating extra resources for improvement or new constructions;
- reduction of overall availability and sales of better located and better quality stock (result of the privatisation pointed before);
- the demand-side subsidies, (mainly in the form of housing benefits to low income tenants helping them paying the rent), has led to a decline in bricks and mortar subsidies and a substantial increase in demand assistance strategies.

Regarding the actors involved in social housing provision, the main trend is providing social housing through private and not-for-profit initiatives with a wide range of social agencies. Indeed, the actors' dynamics are:

- combination of actors involved with public provision (usually by municipalities, either directly or through dedicated publicly owned-companies) often coexisting with a growing private sector, mainly consisting of specialised non-profit or limited-profit bodies (e.g. housing associations);
- local authorities in most cases retreating from the production of new social housing and concentrating on the management of the existing stock, leaving the private sector as the main responsible for new developments;
- increasing involvement with social housing provision by non-specialised actors (commercial developers and private landlords, as opposed to specialised "approved" not-for-profit providers) who have been included as possible recipients of public subsidies in exchange for the use of dwellings for social purposes (low rents, tenants from social housing lists), usually for a limited period of time.

The third dimension concerns financial mechanisms to overcome the economic issues and manage the built environment. In this case the points are various and different since each contexts is trying to deal with financial troubles:

- financing housing projects means combining different sources: standard bank loans (mortgages), public grants/loans, own funds of housing organisations and sometimes also tenants' contributions. Municipalities may also provide additional funding for the construction of social housing;
- supporting the provision of social housing through the availability of land at discounted prices (in countries like Austria, Italy and Luxemburg) and tax privileges for social housing providers (income and investment deduction, depreciation allowances, reduced sales and property taxes, exemption from capital gain tax, and reduced VAT rate);
- widespread practice to set a minimum percentage of social housing in new developments (for instance in England, Spain, Belgium, France), with the aim of: increasing social mix and avoid social and spatial segregation. This mechanism implies that social housing provision is tied to the provision of market housing and therefore might not be particularly useful to increase the availability of affordable housing in times of crisis and low levels of construction by private developers;

- borrowing in the private market: social housing providers are getting rated by international rating agencies to show the soundness of their economic activities and their governance and management reliability (especially in the United Kingdom and the Netherlands). Providers in different countries are implementing innovative ways of pooling risk (for instance in Austria with the sale of bonds via Housing Banks);
- system of intermediation as key element for the sustainability of any financing model for social housing: structures meant to make the link between the market and the providers, supervised by public authorities and under an obligation to provide funding for social housing. Various forms of this intermediation can be found in Austria, France, Netherlands and United Kingdom;
- housing organisations' resources and surpluses can be used to invest in additional housing, to support weaker organisations or to promote innovation and competition (in Netherlands, Denmark and France);
- undertaking non-landlord activities as a mean to cross-subsidise their social dwellings via the development of profitable activities (e.g. building of commercial properties), examples in United Kingdom and Netherlands. In the global financial crisis opportunities to cross subsidise new development from the sale of low cost home ownership properties has drastically diminished;
- some funding models incorporate a small tenant equity contribution (in some cases tenants equity is higher and implies right to buy the dwelling), in countries like Denmark, Austria and Slovenia. There might be government assistance for low-income households to pay this contribution.

The last points regard tenants participation and involvement:

- involvement of the benefiting households in both the management of the service and the functioning of the company providing the service;
- restricting the provision of social housing defining stricter categories of beneficiaries. Some countries can be identified as exceptions: in Denmark and Sweden the registration on waiting lists is open to anyone and no income ceilings are used.

Considering these four dimensions and their points, it is clear how each of them is related and linked to the others.

Some of these trends or practices can be associated to the conventional practices of last years in urban development projects or urban regeneration practices. For instance, public-private partnerships, involvement of different actors and combination of financial resources are methods well known in the urban planning field of the last decades. The integrated approach, typical of URBAN initiatives, relates to a lot of these points. Indeed, in most Western European countries, the social housing sector forms an important part of regeneration schemes. Social housing is both actor and subject to urban renewal. Housing associations are key actors because they own the housing stock and social rented housing neighbourhoods are the targets of a lot of renewal processes.

Referring to the last two dimensions (financial mechanisms and dwellers), the various forms used to diversificate and to find new sources and the involvement of tenants not only in their dwelling's management but also in the general company

provider of the service constitute the main changes and improvement. It is important to highlight the importance of change the role of the dwellers from beneficiaries to active workers in their housing organisation or company. The financial methods are the most differentiated from the conventional ones, like: the minimum percentage in new developments, the ways of pooling risk and get rated, the systems of intermediation, undertaking non-landlord activities and the small tenant equity contribution.
An other issue is the energy efficiency, a physical feature for new buildings and renovation's processes of the older ones. It strongly linked to the general attention towards the principle of sustainability. Public authorities often promote energy efficient renovation as criteria for regeneration practices (for instance, in France, Bulgaria and Sweden specific measures are in force). The use of the best technologies related to energy efficiency is also a parameter for new developments.

3. Northern Italy case study: the city of Turin

3.1. Italian national context

An official definition of social housing in Italy has been provided in 2008 (*Decreto Ministeriale* 22/04/2008). It consists: "mainly of dwellings rented on a permanent basis; also to be considered as social housing are dwellings built or rehabilitated through public and private contribution or the use of public funding, rented for at least eight years and also sold at affordable price, with the goal of achieving social mix". The definition involves also social cohesion principle and the aim is reducing housing distress, offering housing opportunities to families and people who cannot access to free market housing. Housing is considered as part of primary needs.
Social rental housing currently represents about the 4% of the national housing stock[2]. There are three main types of publicly supported housing: subsidised housing (*edilizia sovvenzionata*), assisted housing (*edilizia agevolata*) and agreed housing (*edilizia convenzionata*). The amount of public funding varies according to the different types of publicly supported housing as explained in the table below (Table 1.).

Table 1. Types of supported housing in Italy.
(Table modified by the author, primary source: Pittini & Laino, 2011, p. 58)

	DEFINITION	FINANCIAL MECHANISMS	PROVIDER
SUBSIDIZED HOUSING	Rental housing owned by the public sector. It is addressed to those with lowest income.	Subsidies cover between 60% and 100% of the cost, and the rents are proportional to the income of the tenant. Rents in the public sector are very low, corresponding on average to 1⁄4 of market rents.	Municipalities and public housing agencies.

[2] The information about the Italian national context are taken from CECODHAS documents, which have Federcasa as main source of evidence.

ASSISTED HOUSING	Housing provided both for rent and for sale and aimed at households on low to middle income.	Subsidies for rental assisted housing are between 20 and 60% of the cost and the rent is limited to the minimum price of the market or the 4.5% of the construction cost. Assisted housing for sale is entitled to between 10 and 30% subsidies and the price of the dwelling may not be higher than that of subsidised housing.	Mainly cooperatives.
AGREED HOUSING	Private housing provided for rent or for sale, whose transfer costs or rents are regulated by a specific agreement drawn up between the Municipality and the housing provider.	Providers benefit from a discount on the local tax for building permission, and a lease on the land for 99 years.	Private and public providers: the most active are building firms and cooperatives.

During the 1990s, public investment in housing fell further than before and the limited public resources that had been allocated in this area went to the so-called "integrated urban programmes", which in Italy fuelled urban renewal and regeneration policy. Tosi (2007) defined this change of attention as a "elusive exchange" between housing needs to regeneration of urban peripheries. The privatisation of part of the state-owned housing stock is another development which has been widespread in Italy over the last decade.

The demand of social housing has changed during the decades, the strong differences in economic and social conditions widened the categories of population demanding social housing. Not only the lower segments of the population are suffering housing hardship, but risk of housing deprivation is diffused also in the traditional middle class. For instance, this phenomenon regards young or older people who cannot afford a rent for economic instability, precarious job, etc. The family has always had a stronger role in Southern Europe supporting and providing housing, since the national states were often neglecting this sector (Allen et al. 2004). Nowadays, the economic crisis is impacting also on the housing need, making it a critical issue.

Furthermore, the concept of social housing is obtaining in Italy new attention; these English words are becoming in the recent years a fashionable slogan promoting housing with a social approach. It has not a clear and defined meaning, also private initiatives with scarce social value are using it to advertise themselves.

3.2. The experience of Turin

Turin is the capital city of Piedmont Region, it has about 900,000 inhabitants and is located in the North-West of Italy. It has always been an industrial city, the car industry FIAT was born here. Nevertheless nowadays it is in search of a new identity and new cultural and economic sectors to surpass its Fordist image.

From the 70s the Fordist industry started to crumble and in the last decades manufacturing jobs were cut and the differentiation in skills and qualifications became important to be competitive in the job market. Social issues began to change from unemployment, ageing population and a growing demand for services. The population also decreased from almost one million in 1991 to 865,263 inhabitants in 2001 (ISTAT). In the urban structure, many industrial buildings became empty shells signs of industrial decline. A process of counter-urbanisation can be identified in those years, the municipalities closed to Turin have attracted population searching for better living conditions and less polluted environment. Furthermore, various waves of migration brought thousands of foreign inhabitants to Turin, especially from North Africa and Eastern Europe (Città di Torino, 2011). Indeed, the metropolitan area reached a population of almost one and half million.

During the last 25 years, the large-scale social, economic and physical change has marked a huge transformation for the city of Turin. In 2006, the city hosted the Winter Olympic Games. And from that moment it tried to attract and put in place different kinds of cultural events. The old industrial spaces were transformed and a new season of real estate's expansion took place. On the other hand, urban development projects transformed the urban structure substituting industrial areas (especially located along the railroad system, now underground) with dwellings[3]. This generated issues about the re-use of cultural and sports buildings and the numerous new residential constructions in the free market.

Since the middle of the 90s, the local government of Turin has begun to implement various innovations in urban policies, above all in the field of urban regeneration (Regione Piemonte, 2004) and strategic planning (Turin was the first city in Italy promoting a strategic plan, it was voluntary and involved numerous city's actors).

Governa and Saccomani (2009) summarize the current housing situation in Turin: *Despite this boom in activity in the building sector, until the beginning of 2008 the Turin real estate market did not seem to be affected by an oversupply of housing and, overall, house prices have remained lower than in other big Italian cities. The situation is, however, rapidly changing, with the emergence of unsold buildings, growing difficulties with loan repayments, and the inability of many residential buildings to respond to the growing and varied demand from the more vulnerable social groups which find themselves, for a variety of reasons, in situations of housing hardship* (p.398). Housing hardship is socially quite widespread, affecting heterogeneous groups, and spatially concentrated in certain areas of the city (Citta` di Torino, 2006). Some key social factors (ageing population, low education, low professional qualifications and unemployment) are increasingly concentrated in public housing neighbourhoods built at the time of maximum industrialisation of the city. The weakness of public intervention in the housing sector should be linked to the inability of the rental housing market to provide satisfactory responses to an increasingly complex and diverse housing demand, particularly with respect to the excessive cost of renting and, consequently, the difficulty of some parties, typically non-EU migrants, to access the market.

[3] The new Master Plan, approved in 1995, supported the revitalisation of the real estate sector. After years of stagnation, building production recently accelerated.

3.2.1. Actors, plans, programs and initiatives of social housing in Turin

The actors interested in social housing in Turin metropolitan areas are basically four: the region, the city council, the bank foundations and the third sector (associations and not-for-profit organizations). An other actor should be remembered: the territorial housing agency managing all the social housing estate in the Turin's Province (ATC, former agency of IACP). It cannot promote policies, but it manages the most part of social housing in Turin.
The initiatives' framework of Turin can be summarized considering two main categories: the institutional public plans/programs/norms and the various initiatives or projects (with public or private origin). This distinction can be seen in the next tables. The plans, programs and initiatives analysed are the ones in force from 2000 and they show a recent interest of public and private actors for social housing sector.

Table 2. Plans, programs and norms of social housing in force in Turin.

PROMOTER ACTOR	PLANS, PROGRAMS AND NORMS	BRIEF DESCRIPTION
National State	Housing Plan (*Piano Casa*, Law 133/2008)	Improving national housing stock through new construction and recovering of old dwellings. 5 types of actions. Specific categories of beneficiaries.
Piedmont Region	Housing Program: 10.000 dwellings for the 2012 (*Programma Casa: 10.000 alloggi entro il 2012*), in force from 2006 to 2012.	3 two-years periods. 8 types of housing initiatives.
	Guidelines for social housing (2007, D.G.R. 27-7346/2007).	Integration to the Housing Program, improving it adding two types of initiatives (temporary residences and dwellings to be rented).
	Call for pilot projects concerning social collective residences (2008, D.G.R. 55-9151/2008).	Implementation of the previous guidelines.
	Regional Law on social housing 3/2010.	Regional regulation about social housing.
Turin Municipality	Change in the Master Plan of the city providing a 10% of agreed housing in new housing development (over 4000 m2), (Variante 37/02, art.6 comma 10bis Norme di Piano).	Increasing social housing, promoting social mix in new urban developments.
	Guidelines promoting social mix in the neighbourhoods where are in force urban regeneration programs (D.G.C. 31/08/2004, n.06990/012).	Promoting social mix in social housing neighbourhoods
	Housing Plan 2009-2010 (*Piano*	The plan describes the actual

	Casa, D.C.C. 205/2008).	situation and it defines the strategies and initiatives for the next years.

The main attribute of the national housing plan is promoting housing as a trigger for economic development and not focusing on social housing and the urgent needs of the population. The national plan is also a slow tool, which is going in force only in the recent years. Indeed, this plan's concrete accomplishments are going to be assessed only in the next years.

Housing program of the Piedmont Region represents the general regional frame where the most part of the regional social housing initiatives finds some sort of funding. It is important to remember that this program is a sectorial policy, it is not integrated with the regional spatial planning strategies or the social services policies. The program has 8 main axes of interventions: from improvement of social housing estate, to promoting private rent market. The intent is also promoting sustainability: re-using existing buildings, not consuming land, using sustainable energies and technologies.

The Housing Program has been "updated" during 2007 with the Guidelines for social housing. In this document, the Region extends social housing promotion to temporary residences and dwellings to be rented. The temporary residences have the aim of responding to insecurity's issues like working precariousness, housing market's difficulties and changes in families' structure. These residences intend promoting social inclusion and social integration. The dwellings to be rented are, instead, an improvement for Piedmont's rented sector. They are meant to be a solution for people who cannot access subsidized housing, the rents' prices are lower than the free market's ones.

The next document is the implementation of those guidelines. It is a call for application for pilot cases as temporary residences and dwellings to be rented. The document defines the criteria choosing the pilot cases like: promoting social mix, building/strengthening social networks, supportive housing forms, part of urban regeneration projects. In the next table (Table 3.) about social housing initiatives in Turin the city's pilot cases are presented and described.

The Regional Law 3/2010 is the main law related to social housing in force in the regional context. It focuses on three attributes: the social housing' allocation and social rent's assessment; the organization of the entities and actors working in the sector; the definition of criteria to remove social housing binds from social rented dwellings.

The region intends to experiment on the regional scale also the "social doorman" meaning the presence of a caretaker, a social cooperative/association/organization in difficult neighbourhoods (social housing and vulnerable people), (L. 3/2010 art. 21). The aim is improving the social relations of the neighbourhoods creating networks, services and social events, strengthening the community.

The city of Turin has three documents (norms and plan) which are relevant describing its housing policy in these years. The first norm is improving the social housing estate and the social mix. According to this norm, the Municipality has the pre-emption right to purchase the flats in 12 months or the flats are going to be

rented out as agreed housing. The Municipality provides also a list of people for this rented agreed housing. The low financial resources are the main trigger for this change. Imposing this norm to the private housing developers constitutes a form of private's contribution for the housing development and new social housing flats are improving the public estate.

The second relevant document is a urban norm related to social mix. These guidelines promote different forms of actions improving social mix in social housing neighbourhoods. These actions are promoted mainly in the urban areas where are in force urban integrated programs. Four axes constitute the guidelines:

1. creation of "special lists" of people to access social housing: the normal lists are defined according to economical, social and health criteria. "Special lists" can contain elders, young couples, migrants workers waiting to go back to their countries, disabled people, workers of police forces. Using "special lists" permits of mixing the traditional most vulnerable people with these categories of population, rebalancing the community.
2. Appointing 10-20% of free social housing dwellings in the future call for applicants to people with different entry requirements. For instance, these requirements could be being a young without parents or a family with little children, with an income not too high than the normal economic requirement. The different entry requirements can be studied in relation to the neighbourhoods' free dwellings. The aim could be inserting young people in elderly neighbourhoods, improving the independence of young people, etc.
3. Better management of dwellings' changes: ATC, the social housing manager, should collaborate with the city of Turin aiming to improve the social mix of the neighbourhoods.
4. Transfer of social housing bind: inserting different categories of people in the social housing neighbourhoods means opening the access to people who could not rent them under normal circumstances. The social housing bind has to be transfer to an other public dwelling, avoiding the loss of dwellings.

Then these guidelines are promoted with a specific project of implementation (Allegato D.G.C. 10/03/2009 n.01113/012). The project was approved by the city council in 2009 and it contains the details about the first experiments of the previous four axes.

The local initiatives are summarized in the next table (Table 3.). The active actors are mainly two: the city and the ethic investor (the bank foundation *Compagnia di San Paolo*). The city promotes various initiatives tackling different kinds of housing issue[4], while the bank foundation constitutes a complementary partner financing and promoting similar initiatives and projects.

Table 3. Initiatives of social housing in force in Turin.

[4] There are also Municipality's ordinary practices which are not in the next table (Table 3.). These are: the families evicted by their dwellings have the right to be hosted in hotel or guesthouse until the city provides a decent dwelling; the city checks the requirements for social housing of current tenants; the city can buy new dwellings.

PROMOTER ACTOR	INTIATIVE	DESCRIPTION
Turin Municipality	Lo.C.A.Re., public housing agency supporting the private rented sector.	Public agency promoting the meeting between demand and supply of private rented housing market. It provides economic incentives and guarantees for the owners and economic contribution for the tenants. A huge number of rental contracts have been concluded (more than 3000 of families, Città di Torino, 2008). MAIN GOAL: supporting rented housing, avoiding risk of eviction and housing hardship. FUNDING: Municipal funds and Regional fund (this type of agency is supported by the Housing Program).
	Granting public spaces to the territorial housing agency (ATC) to build social housing & Building of new social housing	Some of the new buildings are going to be provided for different categories of beneficiaries, (not only the most vulnerable population). MAIN GOAL: improvement of social housing real estate, social mix. FUNDING: regional funds (Housing Program)
	Sale's plan of city's subsidized housing	A national law governs this sale (L. 560/93), defining prices and selling ways. The city of Turin has its own plan. Actually, the city has some dwellings outside its boundary, in the municipalities around Turin. These dwellings are going to be sold. MAIN GOAL: the national goal is promoting home ownership and earning financial resources, the goal of Turin is recovering resources to better managing the other dwellings.
	Temporary Residences (Social hotel "Sharing")	Private managed hotel, which provides accommodation for a limited period of time (from few month to one year). From Sept 2011 it hosts city's temporary residents (for financial, familiar, job related issues, no special requirements) and 20 families (chosen by the municipality's waiting-list) waiting for subsidized housing. In the building there are also private health and social services. MAIN GOAL: promoting new forms of housing, solving the housing issue for temporary residents in the city (without high costs and providing independent housing), avoiding the deterioration of a building in a peripheral neighbourhood. FUNDING: A private partnership (between an ethic investor, a social cooperative, and an agency of social venture capital) invested in the transformation and management of the hotel.
	Social Collective	Temporary housing (18 months maximum) for

	Residences (*Residenze collettive sociali*), pilot cases for Piedmont Region	vulnerable people in housing need, moving towards the independence from social services' care. In these buildings there are common services and spaces. The services are open to the neighbourhood, promoting the integration. There's a social manager of each residence, promoting social and care networks. MAIN GOAL: create new paths towards independence for vulnerable people, integration in the neighbourhood/city FUNDING: public funds, regional Housing Program
	Supportive Condo (*Condominio Solidale*)	This form of housing is in the middle between social housing and independent/autonomous housing. There's no limited time and it is targeted on specific category of people: the elderly (in social housing lists). This demand has different issues: various social needs and health services, accessible spaces. Social housing supply is often not suitable for these needs. In these buildings there are common spaces and services for the tenants and the neighbourhood. MAIN GOAL: giving better housing conditions to the elderly population, mixing them with other categories of people and promoting integration with the neighbourhood. FUNDING: public funds, regional funds from Housing Program. One of this building was financed in partnership with *Compagnia di San Paolo*.
	Supportive Co-housing (*Coabitazioni Solidali*)	From 2007 experimental settling of young people in social housing neighbourhoods. The young offer 10 h/week of voluntary work for the community and the municipality gives a discount of 90% of the rent. MAIN GOAL: supporting integration and cohesion in the multi-problematic social housing settlements, promoting respect and education taking care of common spaces, promoting young people's independence from families. FUNDING: there are no special funds for this initiative, there's the loss of 90% of the young' rents. Their work in the neighbourhoods replaces these costs.
Compagnia di S. Paolo, Housing Program	Stesso Piano, private housing agency supporting private rented sector	Stesso Piano is a similar to the public agency LO.C.A.RE.. It offers an help to young people looking for a house/room to rent and it promotes cohabitations forms. A cooperative and an association are working on this initiative. MAIN GOAL: supporting rented housing, avoiding

		housing hardship, promoting young's housing independence.
	Temporary residences	Two buildings destined hosting vulnerable people and people with housing hardship. The initiative is part of the Housing Programme of the *Compagnia di San Paolo*, but there are going to be managers of the service: social cooperatives and associations. MAIN GOAL: giving better housing conditions to vulnerable categories of population, solving housing issue for temporary residents of the city
	Support to other housing initiatives, funding to third sector projects	The bank foundation supports social cooperatives and associations in their housing projects. These projects aim to particular categories of people with social needs (women, elderly, migrants, etc.) and they are often single experiments. Each association/cooperative asking for funding to this ethical investor manages one or few residences. MAIN GOAL: giving better housing conditions to vulnerable categories of population, helping social cooperatives and association to accomplish their housing projects.

The city intends supporting different housing demands. The initiatives summarized in the table represent this complex framework. It is clear a general attention towards the people in housing hardship or at risk of eviction. Different categories of people are coming in the picture of housing issue: elderly, migrants, temporary city's users, young with precarious jobs, etc. The differentiation of these initiatives proves this situation.

The other feature to highlight is the social housing sale's plan, it is obvious its unusual character in a crisis scenario like this one. The previous government promoted this policy, and the main goal was another boost towards home ownership.

The provision of neighbourhood's services in the majority of these initiatives is an important strategy to increase living conditions. The presence of services in low-income and social housing neighbourhoods has always been a critical aspect. The services are not traditional public services, but private, public-private services developed responding complex needs.

Focusing on the initiatives of *Compagnia di San Paolo*, they result similar to the city's ones. Indeed, they constitute a complementary actor provider of housing solutions and funds to experimentations with social attributes. The funding of the *Compagnia di San Paolo*'s initiatives are obviously private, this bank foundation provides its own funds as ethical investor.

4. Conclusions

The numbers and types of social housing initiatives and plans are clearly not responding to housing needs of a metropolitan city of almost 1 million inhabitants. The plans and initiatives collected and presented in this paper have no ambition to substitute the traditional social housing policies. They can be read as particular

experiences and cases born from the lack of financial resources and the urgent local needs. Like in the European context, they interest particular housing demands and population's categories.
In the local context of Turin social housing's concept has been opened up and various types of interventions are part of housing public policies. The public authorities are taking care not only of the most vulnerable classes of the population, but also of different categories of people with housing needs. Indeed, the city public entities and its private not-for profit actors recognize the growing diversity of housing demand. The intent is adapting housing policies to social groups in housing hardship or at risk of housing deprivation. This feature can be identified also in the European context.
In the Italian context the traditional social housing policies were responding to housing needs of low-income groups of population. Nowadays the city intends promoting a "second generation" of housing policies promoting public-private partnerships, a better involvement of tenants, various forms of support for different housing needs. These are the main trends recognized also by CECODHAS (better definition of beneficiaries' categories). The main criticism to this policy is the attention to new forms of social vulnerability than to persistent situations of acute housing deprivation. The general answer is that the implementation of a plurality of housing policies seeks to respond to increasingly detailed and complex needs. Nevertheless, the attention shifts from the lower classes to the middle ones, with less financial resources but more ways to deal with complex issues.
In Turin a balanced relationship between public and private actors can be recognized: the Region, who promotes and finances policies and initiatives; the ethical investors, who became a complementary actor implementing these strategies together with the Municipality; and the not-for-profit sector, who manages specific projects. The private actors involvement is an important feature in this "generation" of policies, the social policies related to housing sector was dismantled and the market is the first reference for neo-liberalism. This is a common issue within Europe, although the focus on various types of financial mechanisms is not so experimented in the case studied. The reason could be that these financial mechanisms are mainly related to housing organizations (in Northern and Central Europe), their management expertise, and their strong role in each national context.
Other important feature of these practices is social mix as goal of housing initiatives. Set a minimum percentage of social housing in new development is an innovative planning obligation improving dwellings' number and promoting social mix. The same mechanism was set in UK and France. Furthermore, the social dimension of the majority of these initiatives reclaims an important link with integrated urban approach and urban governance issues. In this case, the parallelism with the European frame, which is recognized for the other trends and attributes, is less clear. In Turin there is a strong attention creating social relations and promoting integration in the neighbourhoods.
The differentiation of initiatives involves also their forms, they can be norms, rules, or plans, programs, or also initiatives, projects, measures. The change in the city's housing policies demonstrates the attempt to overcome the quantitative approach, moving towards a less aggregate representation of the demand. A relevant element in

this change of policies is the goal change: the supply of services to increase assistance's quality and its different forms. The environmental quality and sustainability criteria are also considered as relevant parameters defining new housing models and a better quality of life.
Furthermore, implementing the policies related to rent subsidies is a relevant dynamic part of a general diversification's frame. Rented housing is a traditional weak sector in Italy and Turin's initiative subsidies the tenant or the owner, better matching demand and supply. This initiative surpasses the city's dimension, other municipalities are involved in the process of matching demand and supply, dealing with housing issue on metropolitan level.

CONTESTING NEOLIBERAL URBANISATION: CONTEMPORARY URBAN MOVEMENTS IN ISTANBUL

Esin Ozdemir[1], Ayda Eraydin[2]

Abstract

The shift from Keynesian to neo-liberal economic policies, which meant the deterioration of welfare state principles and increasing policies based on competitiveness, marked the changes in the urban agenda and the nature of urban movements in the last three decades. The neo-liberal urban agenda reinforced outstanding transformations on the development, management and planning of urban space, especially in metropolitan areas, including Istanbul. The urban transformation projects, functioning as main tools of neoliberal urban development, result in serious changes in this huge metropolitan area and encounter resistances from different groups of people in the city. Two types of urban movements can be defined; the first type is highly property based and shaped around individual issues and develop as reactions of deprived groups against the effects of the transformation on their own property. The second type of mobilisation, on the other hand, has been shaped as reactions of discontent groups to neoliberal urban policies. However, urban movements of the contemporary city, in particular those of the deprived groups, do not only oppose neoliberal urbanisation, but are increasingly shaped by them. The instruments of neoliberal urban transformation projects such as urban development as a means of wealth generation and redistribution, redefine the movements both in terms of content, based on defence of individual property rights and methods used based on negotiation with the relevant authorities. As a result, a fragmented variety of urban movements occur in the city, which are far from demanding a broader social, economic and cultural transformation.

1. Introduction

Neoliberalisation and market-oriented policies have been affecting the way urban areas develop and function for more than thirty years now. These policies, which prioritised the market mechanism in urban development, resulted in a rapid urban change, particularly in large metropolitan areas through urban transformation projects. In this era, the role of the planning institution has changed substantially, while the commodification of urban land along with land and property development projects has become a means of redistribution of wealth among different groups. The increasing inequalities and differences in the access of different groups to this newly

[1] Middle East Technical University, Ankara, Turkey – esoz1980@gmail.com
[2] Middle East Technical University, Ankara, Turkey – ayda@metu.edu.tr

generated wealth mobilised them under neoliberal rules and new modes of governance practices emerged.

The functioning of neoliberal urbanisation has austere reflections on urban space, its users, functioning and management, as one of the most profound impacts of neoliberalism is on built environment of cities. This manifests itself in an intense and rapid urban change, which reinforces the cities as places of conflict and tension. Neoliberal urbanisation as the consequence of neoliberal forms of urban policy, transforms the built environment and the urban form in its own way by eliminating or keeping the urban public spaces under intensified surveillance and creating new privatized spaces of elite/corporate consumption. It enforces the destruction of the degraded residential neighbourhoods of low-income groups who formerly constituted the traditional working-class, for speculative redevelopment and constructing large-scale mega projects to attract corporate investment reconfiguring the existing land-use patterns, creating gated communities, urban enclaves and other purified spaces (Brenner and Theodore, 2002). These changes in the urban space encounter resistances from groups of people in the city, which are either deprived of or discontent by them. Consequently, two main types of urban movements in contemporary cities develop; urban movements of the deprived and the urban movements of the discontent groups. The former are deprived by and mobilise against the above mentioned destruction in residential or mixed-use neighbourhoods for speculative redevelopment, which are realised generally by urban transformation projects. The latter on the other hand, mobilise generally against all kinds of neoliberal urban polices including urban transformation projects in residential areas as well as special projects as a part of broader investment attraction and place-marketing goals.

The aim of the paper is to discuss the dialectical relationship between neoliberal urbanisation and both types of mobilisations that unfold against it, building upon the literature on neoliberal urbanisation and urban movements and related experiences in Istanbul. The paper defines the characteristics of both, in terms of what they are actually struggling against, what they aim to get by opposition and what kinds of relationships they form within themselves and with the external actors. To this end, the dynamics of neoliberal urbanisation is examined in the second section of the paper, showing that neoliberal urbanisation reconfigures the way the urban built environment in a creatively destructive way, which lays the grounds for a different type of urban movements. The third section analyses how the neoliberal urbanisation shape the urban movements. The fourth section, based on findings from Istanbul, including those of various case studies, introduces urban movements of deprived groups developing in a more interest-based fashion, and of discontents acting against increasing penetration of neoliberal urbanisation into our everyday lives. Finally, the paper is concluded by arguing that urban movements do not react only against neoliberal urban policies, but they are increasingly shaped by them.

2. Dynamics of Neoliberal Urbanisation

Neoliberalism and neoliberal policies, as a response to the crisis of Fordist/Keynesian capitalism in the beginning of 1970s, have so far attempted to impose the market rules upon all aspects of social, political and economic life. Neoliberalism is also a restructuring strategy, having a creative destructive role on regulatory frameworks (Brenner and Theodore, 2002; Brenner and Theodore, 2005), one of which is the urban change and the urbanisation itself. In parallel, cities have become 'increasingly important geographical targets and institutional laboratories for a variety of neoliberal policy experiments...' such as place-marketing, urban development corporations, public-private partnerships, property re-development schemes and etc., the goal of which is to 'mobilize city space as an arena both for market-oriented economic growth and for elite consumption practices' (Brenner and Theodore, 2002). Today's urbanisation and concomitant urban development projects –referred to as 'urban transformation projects' throughout the paper- come to the fore as localised forms of neoliberal policies and perhaps the most evident intervention area of the neo-liberal agenda.

The different facets of neoliberal urbanism can be better understood by tracing the changes in built environment, which are connected to restructuring the urban economy, the changes in urban governance including planning institutions and practice.

Restructuring the urban economy and increasing importance of the services sector accompanied with the driving of the industry out of the city marks the current economy of the cities. Urban revitalisation is presented and promoted as an opportunity to change economic hierarchies and functions in the urban area, creating new jobs and empowering the city in urban division of labour (Swyngedouw, Mouleart, and Rodriguez, 2002). Parallel to this, the driving force of the global urban economy becomes the real-estate and construction sectors at the service of growing and changing demands of high-qualified workforce of the services sector. Thereby, an extensive part of the neoliberal policies are today made of urban policies, which boost the private sector, construction, finance and tourism sectors being the leading ones. These neoliberal policies aim to eliminate all kinds of barriers against the construction firms involved in the urban transformation projects, pass the needed laws and regulations as soon as possible, and change the zoning status of areas where previously no development was allowed to facilitate the operation of the construction sector.

Large-scale urban development schemes are one of the important features of neoliberal urbanisation, with the objective to turn the city into a global competitor in line with the aspirations of the elites. Parallel to globalisation and increasing mobility of capital, large-scale capital investments are oriented into cities usually in the form of large-scale property development projects, as a target for capital investors, instead of small-scale property developers as in the past. The production of urban rent as well as profitable economic activities is the central goal of these projects. They are implemented as a part of place marketing strategies by urban elites in search of economic growth and competitiveness. They usually take the form of meeting the

inner-city land demand for business or tourism centres, housing complexes for high or middle-high income groups or 'gentrification' projects in degraded areas of especially inner city, where rant has considerably decreased. They are legitimized through a neo-liberal discourse as the renewal of cities and revaluing the city by attributing new functions to areas, which have lost their functions. However, they are criticised for laying the ground for privatizing the already valuable public land, rather than revaluing it. Furthermore, urban land and property development through these projects also constitute a new type of income transfer mechanisms when implemented for redevelopment in degraded residential areas of the low income groups and have therefore, increasingly become means of wealth generation (Eraydin, 2012).

With regards to planning and policy procedures, these urban transformation projects, or urban development projects as used in western literature, are implemented as exceptionality measures, such as the freezing of conventional planning tools, bypassing statutory regulations and institutions, creation of project agencies with special powers of intervention and a change in national or regional regulations (Swyngedouw, et al, 2002). In this process, the zoning regulations of historical and archaeological sites, green areas and forest areas are changed and urban transformation projects proposing housing areas, hotels, shopping malls etc. are implemented by large-scale firms, usually as a part of public-private partnerships. In parallel, these areas have evacuated from their residents. Therefore, these projects accentuate socioeconomic polarisation through the working of real-estate markets that results in price rises and displacement of lower-income groups (Swyngedouw, *et al*, 2002). Furthermore, this type of project-based urban policy does not treat the neighbourhoods as a unity, which results in proliferation of self-contained and isolated islands in the city, created through special plans having special construction rights that are completely disconnected from the rest of the city. Consequently, 'urban islands and a patchwork of discrete spaces with increasingly sharp boundaries' in a physically and socially fragmented city are produced (Swyngedouw, *et al*, 2002).

Changing role of the planning institution enforcing the change in statutory planning is another outcome of neoliberal urbanisation. At this point, the planning institution is not totally displaced, since it still is the prerequisite of neoliberal urban development (Taşan-Kok, 2012), yet acquired new goals and tools incorporating more flexible intervention mechanisms. The above mentioned urban transformation projects come to the fore as important new tools of planning. Thus, it can be argued that it is now project-based urban planning, in which projects precede planning and the planner becomes the agent of neoliberal urbanisation. The process therefore of the planning as an institution going through is called 'neoliberalisation of planning', in which the planning process itself becomes not only 'more flexible and negotiable strategic one", but also a mere corrective mechanism, attempting to 'introduce changes without formulating an overall policy to regulate new development' (Taşan-Kok, 2012).

The new urban governance in this era supported neoliberal urbanisation, defined by Harvey (1989) as a change from managerialism to entrepreneurialism. Entrepreneurial forms of governance began to be adopted by local governments, as territorial competitiveness has become priority for them (Eraydin, 2012). Project based urban interventions brought together a more assertive and entrepreneurial style of urban governance, while formal government structures are subordinated to new institutions, which are highly autonomous organisations that compete with and even supersede local authorities as managers of urban renewal (Swyngedouw, *et al*, 2002). Especially after 1990s, neoliberalisation process itself has been subject to restructuring giving way to "emergent combination of neoliberal economic management and authoritarian state forms (Peck and Tickell, 2002). In practice, it has entailed a dramatic intensification of coercive, disciplinary forms of state intervention in order to impose the market rule in all aspects of social life (Brenner and Theodore, 2002). Furthermore, entrepreneurial forms of urban governance have a significant deficit in terms of accountability, transparency and representation. 'A system of representative urban government has been turned into stakeholder urban governance that is centred on newly established institutional arrangements, lacking formalized mechanisms of representation' (Swyngedouw, et al, 2002). Important decisions are made in closed and mostly elite circles including government representatives, excluding the urban citizens. Local authorities gained a more proactive role, playing the role of an enabler, client or partner.

In sum, neoliberalism creates its own city, by causing dramatic changes in the way urban built environment is planned and managed, tough without making the state institutions and its instruments obsolete, but reconfiguring them. This situation nurtures and defines the oppositions against itself, which constitutes the subject of the paper.

3. Urban Movements Shaped by Neoliberal Urbanisation

Urban oppositions and mobilisation processes of different social groups against urban policies in general or their outcomes are defined as urban movements. In more precise words, they are 'processes of purposive social mobilization, organized as in a given territory, oriented towards urban related-goals' (Castells, 1997:60). From 1980s onwards, as the neoliberal paradigm began to dominate, a transformation occurred in the way urban movements develop. As the surrounding context changed and issues like ethnicity, gender and local autonomy came to the fore, urban movements began to develop less as parts of broader class-struggles. Today, they are not necessarily or essentially class-based; class cleavages have long not been the motivation factor behind urban movements. In parallel, non-class factors such as identity defined in cultural autonomy, gender and ethnicity are among the motivational elements. Secondly, and more recently, they moved even more away from its conflictual character to co-operation and consensus seeking with different stakeholders and the government. Thirdly, before 1980, urban social movements were much more homogenous, involving social interests groups, namely social NGOs. However, from late 1980s onwards and in 1990s, 'the social composition and

the political orientation of the urban movement milieu have become increasingly heterogeneous, manifesting more and more polarizations, cleavage and also forms of implosion' (Mayer, 2006a, p.138). They get fragmented and gained heterogeneity in terms of social composition and political orientation parallel to the erosion of Welfare state and rise of neoliberal policies instead. Neoliberalisation has changed people's motivations in such a way that no broad-based or strong grassroots contestation occurs. The project-based urban restructuring policies 'prevent these movements from transcending the localized issues associated with a project's implementation' (Swyngedouw, *et al*, 2002, p.574), since project-based urban development appears 'too divisive for the local populace to provide a basis for widespread collective mobilisation" (Loopmans and Dirckx, 2012, p.112).

The urban restructuring boosted by neoliberalism resulted in further changes in urban movements. Urban transformation projects aiming at and successfully result in the increasing values of urban land and property, induced 'urban movements' as reactions directed towards this transformation and the consequent uneven distribution of the benefits. However, it also gave rise to a dualism in urban movements. Accordingly, building upon Castells' (1977, 1983, 1996) and Mayer's (2000, 2003, 2006b) frameworks and employing Marcuse's (2009) analysis distinguishing the demands of those deprived of certain basic material and legal rights and those who are discontent with life, two main types of urban movements can be defined; movements whose main mobilisation factor is deprivation and movements whose main mobilisation factor is discontent. First type of movements is those who mobilise against the effects of urban transformation projects on their own property or land and the unequal distribution of the newly generated rent increase. They arise out of dissatisfaction and a sense of deprivation out of the functioning of urban property markets. They are therefore built more around individual-property based concerns. The second type of urban movements has more transcendental goals. These are movements whose main motivation is some kind of discontent with the spatial developments in neoliberal urbanization. The characteristics of each type of movements will be elaborated in the next sections based on Istanbul case.

4. Neoliberal Urban Development in Istanbul

As discussed in the preceding section, cities are today perhaps the most evident intervention area of the neo-liberal agenda. The rapid urban change, particularly in large metropolitan areas, which has begun earlier in advanced capitalist countries and sprawled later to the peripheral ones, comes into being through urban transformation projects. Accordingly, what is experienced in the new neo-liberal era is a project-based urban development. A project-based approach in urban development has also begun to dominate the current urban planning practices of Turkey (Eraydin, 2012), Istanbul being the paramount area of its exercise.

In Turkey, urban transformation process has gained momentum in 2000s. It started with the excuse of protecting the old settlements and cultural heritage areas and reached its current state by projects introduced in almost all metropolitan areas of

Turkey. One reason for this rapidly gained momentum is the high demand for urban land bringing pressure on the low amount of publicly owned urban land. In most Turkish metropolitan cities, pressure on land is so dramatic due to very high population and economic growth rates, that urban transformation projects proliferated. The legal amendments for the empowerment of the authority of the public institutions including municipalities and Turkish Housing Development Agency (HDA) as important actors of such projects, has been predominant in the urban transformation process. It gives the relevant public authorities the rights to planning, making expropriation and implementation and leaves the rest to negotiation and bargaining.

The effects of urban development through neoliberal transformation projects are particularly intensive in Istanbul due to its high rates of economic and population growth as well increasing global functions. Since the 1980s, the importance of the global economic functions in the economy of Istanbul increased substantially, supported by the increasing flow of foreign investment. Its large economic hinterland and its proximity to the European market strengthened the role of Istanbul as a city that can host some global functions. Several studies (Beaverstock, et al., 2000; Taylor and Walker, 2001; Taylor, 2001 and 2003; Beaverstock, et. al., 1999) indicated that Istanbul takes place within the second tier 'important centres' in certain global functions and in the third tier of global cities. In the study by Taylor (2003), Istanbul took the 7th place in finance and banking sector and 14th place in services sector among the European cities. This role is accelerated by the increasing inward foreign investment, especially after Turkey became an accession country to the European Union.

Increasing competitive advantages and attraction of Istanbul for global market players prevail, similar to the other metropolitan areas of the Central Eastern European countries. The increasing attractiveness of Istanbul both for foreign and domestic firms as well as migrants both from rest of the country and abroad increased the pressure on the different levels of the metropolitan government, which have rights to plan and approve[3]. This induced further changes in the legislation on planning, housing and urban land market and enabled the different central government institutions to have power to shape metropolitan development[4]. This changes stimulated the increasing interest of central government becoming a main decison maker on certain parts of the Istanbul metropolitan area, via the activities of Privatisation Agency and HDA, which are functioning under Primeministry. Moreover, Turkish Maritime Enterprises, General Directorate of State Railways,

[3] Metropolitan Municipalities (1/25000 and 1/5000) and district municipalities (1/1000) have rights to plan, which approved by Metropolitan Municipal Councils and District Municipal Councils respectively.

[4] New laws were adopted to create new mechanisms to transfer major spending powers to Special Provincial Administrations, Metropolitan Municipalities and other Municipalities and redefined the roles for metropolitan governments in the provision of services. The new legislation that was adopted in 2005 also increased the financial resources of local governments, especially in Istanbul and introduced participatory processes, which should be evaluated as a first step towards the participation of the different social groups.

State Railways, Harbours and Aiports Construction began to act as entrepreneurs to transfer the ownership rights of their existing facilities.

Therefore, beginning from the 2000s onwards Istanbul became a playfield of different actors that have different interests. The new entrepreneurial urban land regime and struggles around property and collective consumption which translate into territorial projects leading to different governance practices. The urban transformation projects in Istanbul can be grouped into two. First group is territorially-based urban transformation projects, which are named as 'urban renewal projects' in planning terminology that are implemented in a certain territory for new housing and additional urban services, which lead to gentrification of these areas. Second is projects developed as a part of broader policies for global competitiveness and place-marketing. They are in the form of 'special projects' which may be territorially-based or urban infrastructure projects. These projects are distributed all over Istanbul metropolitan area and their high quantity, which is not even exactly known by the authorities of Metropolitan Municipality, indicates the dominance of entrepreneurial urban land regime in Istanbul. The most prominent examples that draw media attraction and trigger opposition are described below and mapped in Figure 1.

4.1 Terrorially-based Urban Transformation Projects

There is a long list of territorially-based urban transformation projects in Istanbul that are mostly related to housing, but also to provision of cultural and touristic facilities. As neoliberalism, began to penetrate into the areas where low income groups settled after 1990s, Turkey's and especially Istanbul's urban development got its share from this trend, though at a later stage. The illegally developed areas as well as the low quality deprived historical neighbourhoods began to be new attraction points of such transformation projects, a result of a set of concerns related to crime, welfare dependency and social breakdown; also for rent generation through revaluing the urban land and wealth transfer. Therefore, the primary method for urban transformation in Istanbul became 'urban renewal', which is in essence a complete pulling down of the existing building stock and reconstruction. This is particularly implemented in 'gecekondu'[5] areas. In the course of these urban renewal projects, as in most of the Turkish cities, many of such gecekondu neighbourhoods are being evicted for developing luxury housing, tourism, trade and etc. Units of apartments to be constructed during the course of the transformation projects are assigned to land owners[6], in return of their land/property by HDA (Eraydin, 2012), which is a public agency established for housing supply for low- and medium-income groups. The remaining apartment units are sold in the market, primarily to those who do not own a housing unit in the same city.

[5] The term *gecekondu* derives from the Turkish words "gece", meaning "night" and "kondu" – meaning "placed" or "landed" (infinitive: konmak) and can thus be translated as "placed overnight".

[6] They are generally former squatters of public land, emigrated from rural areas of the country, but later acquired their title deeds after certain of laws in 1984 and 1985 allowed up to four-storey buildings on such land.

The user profile is aimed to be completely changed in these areas through increase in rents. These renewals are legitimized by highlighting two aspects; first, these areas are informally built on public land and existing property rights are unjustly acquired, and second, they have become criminalized. On the other hand, in neighbourhoods of cultural and historical value, which have a more mixed usage rather than only residential, the transformation project meant gentrification in order to create vivid areas for touristic, commercial and cultural activities.

There are said to be more than a hundred such urban transformation areas (neighbourhoods) in Istanbul, some of which are Gülsuyu-Gülensu, Başıbüyük, Tarlabaşı, Sulukule, Bağcılar, Derbent, Aydınlı, Fikirtepe, Tozkoparan, Fener-Balat-Ayvansaray and etc. Some of these projects are implemented in areas of cultural and historical value, such as Sulukule, Tarlabaşı and Fener-Balat-Avansaray. The opposition and collective action that arises as a response to these projects form mainly the 'urban movements of the deprived' in Istanbul. However, 'urban movements of the discontent' also mobilise against these projects at least as external actors in the case of pure residential areas, or as main actors in areas having historical and cultural value.

In most of these urban renewal projects, HDA, the Metropolitan Municipality and the District Municipality as well as the construction firm are engaged in. HDA is a critical actor in these projects for it has the power to execute the projects as well as to revise planning and zoning regulations in 'transformation' zones. Using these powers, HDA can intervene in any area it deems distressed or obsolete, evict the residents to its public housing and regenerate and market the area to economically more powerful customers. Together with the municipality, HDA also negotiates with land/property owners residing in the area, on property rights they will acquire at the end of the project. In this sense, it became a rival against the old small-scale real estate developers that had long established their hegemony in the city (Erder, 2009).

4.2 Projects for Global Competitiveness: Prestige and Urban Infrastructure Projects

One of the new types of entrepreneurial governance relations in Istanbul have been shaped by projects 'towards competitive regionalism' which characterises entrepreneurial mode of governance in urban land and property markets. Special projects such as Haydarpaşa Redevelopment Project, project for the demolishment of a theatre building named "Emek" in Beyoğlu for reconstruction, Beyoğlu Demirören Shopping Mall Construction, the so-called 'crazy project' that envisages a huge canal that would run parallel to the Bosphorus Strait and Taksim Project (Pedestrianisaiton of Taksim Area) show how different sites in the urban areas became the core of interest of different groups. Especially the ones developed under the privatisation schemes stimulated open and formal negotiations between public and private parties, which resulted in both collaboration and conflict among the existing and new actors of the urban land and property markets. However, the collaborative relations denote

only one part of the relations due to the change in how central and local governments perceived urban areas. This also led to conflicts among public institutions, namely central government departments, metropolitan municipalities and district municipalities. Thereby, Istanbul became a playfield of power struggles between central and local governments. Different ministries wanted to use their legal rights and to intervene in a number of policy areas, especially in infrastructure and land use development, sometimes contrary to the interests of Metropolitan Municipality. Haydarpasa Redevelopment Project, where the Ministry of Public Works wanted to regenerate the existing harbour and very large areas at the back of it for a commercial property development project is one of the examples of conflicting interests. Other prominent examples of urban infrastructure projects on the other hand are, a 3rd Bridge over the real Bosphorus, Haliç Metro Bridge Project, and Bosphorus Highway Tube Tunnel Project for enabling vehicle traffic under Bosphorus.

The contestations and collective action against these projects are usually carried out by discontent groups.

5. Opposition, Resistance and Mobilisations against Neoliberal Policies and Practice: Contemporary Urban Movements in Istanbul

There is an increasing number of research made on urban development in Istanbul, ranging from studies gecekondu and the urban poor focusing on the changing meaning of gecekondu after 1980s and changes in the position of and perception about gecekondu population in the city (Erder 1996, 2009; Erman, 2001; Erkan 2009; Senyapili, 2004; Isik and Pinarcioglu, 2001; Altinok and Enlil, 2008; Pinarcioglu and Isik, 2008), to more recently emerging studies of urban restructuring in the city under neoliberal policies with a view to its socioeconomical and spatial outcomes (Genis, 2007; Eraydın, 2008; Ercan, 2010; Gunay, 2010; Dincer, 2011; Enlil, 2011; Eraydin, 2011; Lovering and Turkmen, 2011; Oktem, 2011; Ozus, Turk and Dokmeci, 2011; Turkun, 2011; Aksoy, 2012). There is on the other hand limited research on grassroots resistances against this restructuring. They generally focus on the deprived groups and usually take a supportive stance towards their struggle (Ozdemir, 2005; Bozkulak, 2005; Celik, 2008; Kuyucu and Unsal, 2010).

In the following, urban opposition and mobilisations in Istanbul are tried to be described and analysed as regards to the movements of both the deprived and the discontent, also referring to the findings of certain case studies. The information used to make the analysis is gathered through textual analysis including researches, reports, and media resources; interviewing the activists of each type of movements as well as municipality staff; attending the meetings of urban movement fractions and following their activities through e-mails by being a member of their e-mail group. In this respect, three meetings were attended, which are a two-day meeting of activists, residents and professionals from different movements named 'Urban Movements Forum' held on 26-27 June 2010, two half-day workshops on urban development and urban opposition organised during 6th World Social Forum held in Istanbul on 1-4 July 2010 and a one-day meeting with the participation of deprived groups from

mainly gecekondu areas of Ankara as well as representatives from Istanbul under the title 'Sheltering Rights Congress' held on 11th of December 2011. Interviews were made with one architect/city planner from Chamber of Architects Istanbul Branch on

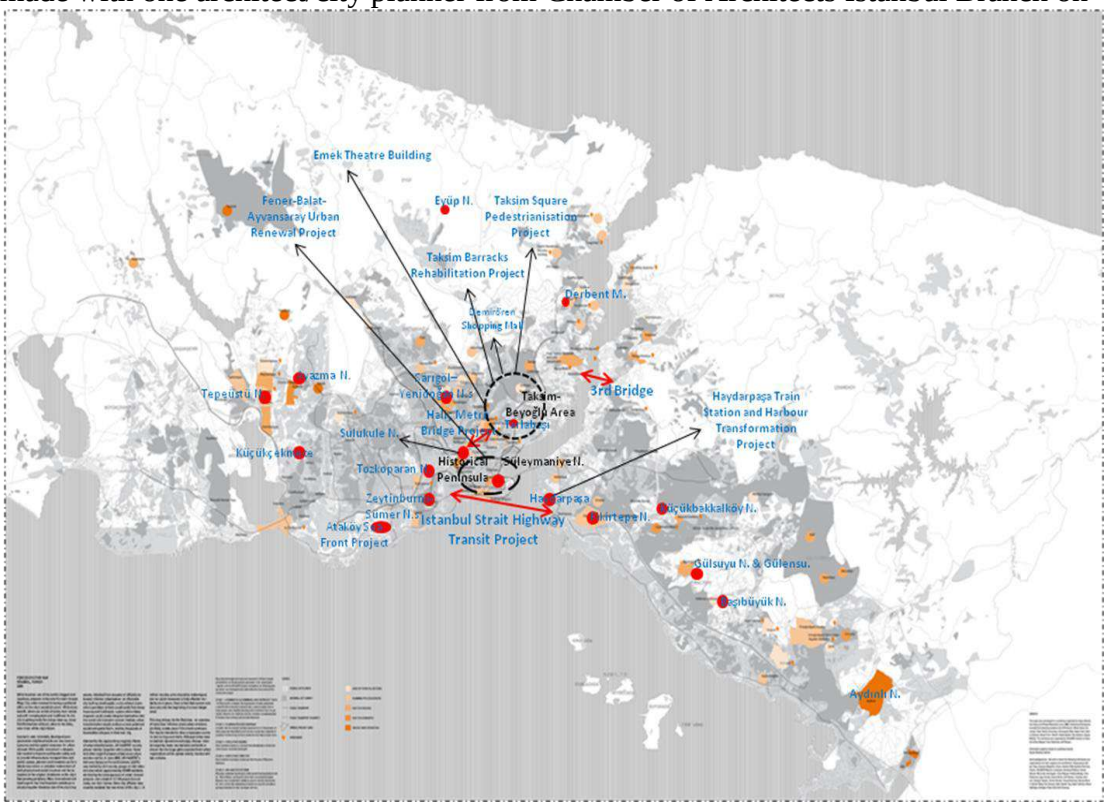

Figure 1. Map of Main Urban Transformation Projects in Istanbul

10th of November 2010, a resident and an activist from Gülsuyu-Gülensu neighbourhoods on 31st of March 2012, a private architect acting as a voluntary supporter of the movements of the deprived and two urban planners from Maltepe District Municipality on 23rd of April 2012. During the course of the Urban Movements Forum, an 'urban movements forum e-mail group' was set up to exchange information and opinions with the members and to carry on more frequent discussions. Soon after its first large meeting mentioned above, this forum began to organise more regular meetings in smaller groups and shared and even continued the discussions made during these meetings via e-mails. As a member of the e-mail group, all these discussions and information shared could be followed.

The two year work following the urban movements summarised above enables us to scrutinize the two main urban movement categories and their subcategories based on Istanbul case.

5.1 Urban Movements of the Deprived

Urban transformation projects in Istanbul generally result in the destruction for speculative redevelopment of the degraded, mainly old working-class

neighbourhoods or neighbourhoods of degradation with cultural and historical assets in basically inner-city areas. Before elaborating on this category, it should be noted that, urban transformation projects do not necessarily give rise to mobilisations. In fact, mobilisations against projects develop as exceptions. Reactions of certain disadvantaged groups have been stabilized through the urban land and property regime, by which low quality or informal hosing is transformed into new housing units, especially through HDA and new property rights in the form of apartment units are assigned to land owners in return of their existing land or property. Many of the residents are satisfied through such wealth transfers by rent generation, functioning as a new means of income redistribution. As a result, many of the residents in gecekondu areas move out, having their share from the urban rent and do not get in any contentious action.

A major type of urban movements in Istanbul are mobilised by social groups who are unsatisfied with the aforementioned wealth transfer and thereby find themselves in a deprived position as a result of the neoliberal urban transformation projects. The movements reacting against these projects generally struggle against the negative effects of the urban transformation on their own property or land, and try to reverse these effects as much as they can. As shown in Table 1, two sub-categories of such movements develop.

First sub-category, movements against projects implemented in degraded residential areas of low-income groups, is the predominant type in Istanbul. Such movements develop when the residents are unsatisfied with the compensation they get out of the rent generated by the transformation project based on their existing property rights, or get no share at all as in the case of tenants and squatters. They spend most of their resources for counteracting this deprivation; claiming 'right to the city' usually remains as a discourse, rather than a motivation factor behind concrete actions. It is even perceived as a romantic slogan within the movements whose target is their own neighbourhood, rather than the whole city (Turkmen, 2011). Accordingly, these movements develop around individual property motives and effects of the projects on the exchange value of the land or property possessed or used by the residents. Moreover, as Kuyucu and Unsal (2010) showed in their study on Başıbüyük and Tarlabaşı in Istanbul, this appetite for personal gain weaken the movements turning them into bargaining processes resulting in more residents agreeing with the offer of the project. In this, these movements do not aim at a broader socio-cultural transformation, although they stem from traditionally working-class areas. As an activist from Gülsuyu-Gülensu neighbourhood stated, they are not against urban transformation – which might have negative effects on the built environment as a whole-, but they just claim their rights. In other words, they oppose their dispossession and demand their share out of the newly generated wealth through rent increase, or at least a 'fair distribution'. In this, satisfaction of material/ economic demands becomes their priority.

Parallel to developing around individual property rights, what movements also resist in is displacement and dispossession as shown by Kuyucu and Unsal (2010).

Residents who do not agree on their property rights given by the transformation project or those who have no rights at all are forced by the municipality, mostly by police force as well, to evict their homes, which is called 'forced evictions'. Moreover, as these projects usually have no social or economic programmes for the residents, they result in some kind of a social exclusion (Kuyucu and Unsal, 2010). Moreover, exclusion from decision making (especially in the processes while the neighbourhood was declared as urban renewal area) as a concern of the residents is another aspect of these movements, as stated by an activist in Gülsuyu-Gülensu neighbourhood and by an urban planner working for a district municipality, since exclusion may result in more dispossession. As claimed by Erder (2009), such exclusion can also hinder the formation of opposition as people are not sufficiently informed about their rights.

The actors of the these movements are mainly residents (property owners and tenants) and supporters as external actors like academics, students, professionals and their organisations, platforms bringing together these different actors. Academics from especially Istanbul Technical University, Mimar Sinan Fine Arts University and Yıldız Technical University, students, professionals such city planners, architects and lawyers, and their organisations like Chamber of City Planners, Chambers of Architects and platforms of different actors are involved in the movements as external actors. They basically provide technical and logistical support to these movements and help them in communicating with different movements of the deprived in the city. Moreover, as discussions in meetings and e-mails among neighbourhood residents and external actors show, the latter encourage the neighbourhoods to unite and act together, claim their sheltering rights as a basic human right and contest their exclusion in decision making regarding the redevelopment in their area. For example, a group of academics together with volunteer professionals work together with the residents of Gülsuyu and Gülensu neighbourhoods and support them in their negotiations with the district municipality which is responsible for and intends to soon start the preparation of 1/1000 implementation plan of the area. In addition, academics and students of Mimar Sinan Fine Arts University City and Regional Planning Department carried out a workshop with the residents, called 'Solidarity Workshop' ('Dayanışmacı Atöyle') to prepare an alternative plan for the neighbourhood as stated by the activist in the area and the private architect. By this way, these external actors aim to somehow bring the 'right to the city' into the agendas of these movements, which is characterised as a more proactive involvement as opposed to the reactive actions of the residents of the neighbourhoods (Turkmen, 2011).

As discussed intensely in meetings and e-mail discussions, there are three types of oppositional ways of action movements under this sub-category apply to; institutional, legal and street struggle. As a part of their institutional struggle, which is the dominant one, they usually adopt negotiational tactics with the municipalities, relevant public agencies and businesses that take part in the project, by sitting around the same table and bargaining on their returns from the redevelopment, with the help of the external actors, particularly at the stage of assignment of new property rights.

They are engaged in this institutional struggle through their neighbourhood associations bargaining with the municipality. These are newly established associations or remobilised existing ones, aiming to defend the residents' rights in front of municipalities, public agencies or businesses involved in the urban transformation. In almost all such project areas, an association is established by volunteer residents, as the driving force of the movement; Başıbüyük, Derbent, Tarlabaşı, Gülsuyu-Gülensu, Tozkoparan being examples. Legal struggle is on the other hand carried out through grating petitions or taking the case to the court. The bargaining process between the association and the municipalities are so determining that Aksoy defines this in her analysis of recent urban trends in Istanbul as the reduction of citizenship into a bargaining process (Aksoy, 2012).

Legal struggle is usually applied to, when the residents are totally unsatisfied with the plan/project in general or what is offered by it. For example in Gülsuyu- Gülensu neighbourhoods, 6500 petitions were given against the master plan including the neighbourhood. Against the 2004 'Urban Renewal Plan', 4.600 signatures were collected and the plan was sued twice. But they did not produce any result. As for the street struggle, demonstrations and building barricades to impede the intervention of police are among the actions. In meetings participated, the residents of most of the project areas as well as external actors claimed that they did not deny the need for legal struggle, but contended that street struggle was inevitable for them to protect their houses. Legal struggle is also sometimes criticized for not being sufficiently representative with regard to the respective neighbourhood as a whole. Moreover, as discussed in such meetings, legal struggle is considered to be possibly difficult, whereas street struggle is always there as an option to be utilized. In general, movements use a mixture of these different struggle methods, including more innovative ones. In Ayazma for example, as a response to demolishment and evictions, 18 families who had no property rights began to keep guard in front of the Municipality and remained there more than 35 weeks. They also established Ayazma Mağdurları Derneği (Associaiton of the Deprived People of Ayazma) and carried on their struggle with the help of different external actors, mainly the The Assocaition named '1 Umut. 1 Umut, together with the association, organised a solidarity day with the families of Ayazma with the participation of different activists who are member of fractions of urban movements, prepared a letter in English for international support and an 'anti-commercial' video as opposed to the famous commercial of Ali Ağaoğlu on the transformation project in the area. They also organised evening meals during Ramadan with the families to show their support.

On the other hand, there may be certain tensions among the adherents of these movements. Since the movements under this sub-category are area-based, there are residents with different priorities, anticipations and at times conflicts among themselves. Accordingly, one type of adherents is property or land/property owners in areas where urban transformation has began or will begin; another is those with no property rights who are actually under most severe risk in similar areas. The former here tend to behave more with individual property based interests and thereby form the core of the movements of the deprived. The latter on the other hand are usually

offered subsidized houses by HDA, which they rarely can afford. This situation results in segregation between the property owners and the tenants during the mobilisation (Turkmen, 2011). Moreover, as argued by Kuyucu and Unsal, the tenure structure may become the most important determinant of the form and the strength of the resistance; as formal property owners, contrary to tenants and occupiers, tend to finally agree with the offer of the municipality pursuing their individual interests. There are even reported cases of serious tensions between those who agree with the offer and agree to evacuate their houses and those who are not satisfied. For example in Derbent, 14 activists were taken under custody for death threat against residents who agree with the municipality (Bianet, 2012). Moreover, the activist from Gülsuyu-Gülensu has stated during the interview, that there have been certain divergences in the neighbourhood due to ideological reasons. Groups with radical leftist ideologies did not want to act with the rest and left the movement accusing them of negotiating with the system.

Second sub-category is movements that mobilise against urban renewal in mixed-use areas having historical and cultural values. These are generally inner-city areas such as Sulukule, Tarlabaşı and Fener-Balat-Ayvansaray, where rents and demand for extra land have risen too high. They are surrounded by more prestigious areas specialised in business, touristic and commercial facilities. These movements are highly similar to the first sub-category as shown in Table 1, and they go through very similar processes. However, as these movements mobilise in areas with cultural diversity and historical buildings, collective interests against the loss of quality of space as well as cultural and historical values gain importance. Thus, the movements under the second sub-category defend also certain collective rights and use value against exchange value, though to a lesser extent. Moreover, the projects contested by these movements attract more attention from the urban 'elites' such as academicians, politicians, NGOS and the media as argued by Erder (2009). In parallel, the above mentioned external actors become the internal actors of these movements making them relatively more effective. For example in Sulukule Platform or Fener-Balat-Ayvansaray Association, many activists act as residents of the area in street struggle and legal struggle, right reports, make interviews with the media as a part of the movement. There are also channels for alternative planning, though in a weak form. 'Illimitable Autonomous Planers' initiative is an example for this, who has prepared an alternative plan for Sulukule, in 'Sulukule worshop' in cooperation the community (Sulukule Blogspot, 2008). This also helps them gain even more media and public attention and support. However, they are still regarded as individual property based, since the determining motivational factor is deprivation based on property rights. Therefore, they are similar to first category in all other aspects.

In sum, the movements under this category are mainly concerned with what they are offered in return for their property or land for redevelopment; in other words with their individual property rights and its exchange value rather than use value. Thus, it can be argued that they mobilise and are engaged in collective action based on more individual interest-based concerns and less on collective ones. As a result, and also

because they are territorially-based stemming from distinct areas of the city, they develop as various weak components of urban movements in the city, without becoming a mass movement. In this, they demonstrate that neoliberal urbanisation today shapes its opposition based on its own rules and accordingly, it redefines the agendas and ways of action used by urban movements in line with its own rules. Thus, urban movements are now reconfigured by what they actually oppose, namely the system itself.

5.2 Urban Movements of the Discontent

Whatever changes are brought by neoliberal urbanisation, political action and oppositions are still significant. Thereby, urban movements with more transcendental goals and ideological backgrounds also develop. These are urban movements whose main motivation is some kind of discontent or dissatisfaction with the spatial developments in neoliberal urbanization. Three widely different sub-categories of this category can be observed in Istanbul.

First sub-category is the movements opposing, based on specific cases, the unjust rent generation on urban land, at the expense of alienation and impoverishment of the urban residents in general. Non-material demands are more prominent in their agenda compared to the movements of the deprived. They feel a need to reclaim and redefine the public space as both a dimension of democratic participation and a field for use. They can be defined as marginal movements against loss of urban values and assets. In these movements; academics, students, lawyers, professionals and their organisations such as professional chambers, community based organisations and platforms bringing together these different actors take part. As mentioned above, these actors may constitute external actors for the movements of the deprived, in terms of providing technical expertise and logistical support or even active participation in their actions. These discontent movements are at times so heavily engaged with the problems of the deprived that they can even be regarded as by-product of the movements of the deprived.

On the other hand, movements under this sub-category may also engage in solely generic issues. For example, against 3rd Bridge project, a platform named ‘Life Platform Instead of the 3rd Bridge’ is organised by a group of volunteers. According to their own blog, the Platform gave out a notice in front of the General Directorate of Highways against the project on the same date as the tendering process began There are also ad-hoc platforms where different neighbourhood associations can come together such as ‘Beyoğlu Platform of Neighbourhood Associations’. IMECE, as an organisation mostly of urban planners, also acts in this sphere by carrying out studies and organizes events to promote ‘a more social approach to urbanism in Turkey that goes beyond marketism and narrow professionalism’ according to the information give at their web site. They produce reports and organize meetings to inform and support the struggle of urban movements.

There are other initiatives like, 'Istanbul S.O.S' and Social Rights Association, who work on different issues, but on similar terms in that they all mobilise against issue-based projects and support neighbourhoods in their struggle against urban transformation projects. However, there is no established cooperation among these different fractions; not even between neighbourhood organisations as stated by two interviewed people -one from Chamber of Architects and the other from Gülsuyu-Gülensu neighbourhood- as well as during meetings organised/participated by movements. There is no unified movement, but movement fractions for both categories of movements. Therefore, the urban movements of the discontent are at the stage of asking questions of what organisational practices they should develop, and what kinds of real relations they should build in between the different fragments. In last couple of years, they have managed to come under an Urban Movements Forum and hold meetings where they discuss urgent matter as regards to neighbourhoods or broader issues like a mass demonstration on 1st of May. However, they are still far from constituting a broad-based urban movement that can bring a change, as they also admit.

The last two sub-categories of movements of the discontent are minor and weak movements in Istanbul. *Second sub-category* is the movement led by elite middle or upper-middle classes who are not content with the redevelopment in their neighbourhoods for it worsens living conditions and they were not involved in decision-making. These movements are in fact built around collective interests, which are confined to the well-being of the community only, but not the whole city. They correspond to the elitist and defensive movements in the West, the so-called NIMBYs in Mayer's terms (Mayer, 2003). They are generally mobilised by loss of quality in their own neighbourhood and consequent worsening of living conditions, an unwanted development in the area that affects their quality of life or lack of decision making regarding the development in the area. The actors of these movements are usually middle or upper-middle class citizens and neighbourhood associations they have established. Mobilisations against the planned redevelopment in Ataköy coastal area is an example in Istanbul for this sub-category. *The third sub-category* is conservative individual property based movements of mainly those who are dissatisfied with the rent generated in the area and struggle for more rent-generating urban development. They support the redevelopment projects that will increase the value of private. In this, they are built around individual interests, seeking to extract the maximum profit from the newly generated urban rent out of redevelopment. The movement in Beyoğlu initiated by The Beyoğlu Beautification Association including the private entrepreneurs in the area is an example of this sub-category in Istanbul (Erman and Coskun-Yildar, 2007).

6. Conclusion

The already week redistribution mechanisms in Turkey coupled with the increasingly depriving functioning of the neo-liberal policies, the uneven distribution of the property rights that have been increased or produced by urban transformation projects constitute the main motivational factor behind the urban movements in

Istanbul. Other possible motivational factors such as identity and claims for democracy and local political autonomy are not neglected, but come out as concerns in the lifespan of the movement. They feed and enrich the movement, but do not trigger it.

Table 1. Categories of Movements

Movement		Fields of conflict	Actors involved	Type of interest	Type of right defended	Action type	Type of Project and Examples
MOVEMENTS OF THE DEPRIVED	a	- insufficient compensation of existing property rights - preservation of individual property motives - displacement - exclusion from decision making	- neighbourhood organisations - residents - external actors: academics, students, professionals and their organisations like chambers of planners / architects - platforms of different actors	- individual (Individual gains are the primary goal.)	- individual property rights (to utilize the exchange value of the property / land) - right to housing / sheltering (in cases where the property is used for use value only)	- negotiation and bargaining - opposition	Urban Renewal in lower income residential areas l(Gülsuyu-Gülensu, Başıbüyük, Derbent, Ayazma, etc.)
	b	- insufficient compensation of existing property rights - preservation of individual property motives - displacement - loss of quality of space - exclusion from decision making	- neighbourhood organisations - residents - academics, students, professionals and their organisations like chambers of planners / architects - platforms of different actors	- individual (Individual gains are the primary goal.) - collective (against loss of quality of space)	- individual property rights and right to housing - right to housing / sheltering (in cases where the property is used for use value only) - collective rights	- negotiation and bargaining - opposition	Urban Renewal in sites or neighbourhoods of degradation in basically inner-city areas (Tarlabaşı, Sulukule, Fener-Balat-Ayvansaray).

Movement		Fields of conflict	Actors involved	Type of interest	Type of right defended	Action type	Type of Project and Examples
MOVEMENTS OF THE DISCONTENT	**a**	- lack of participation in decision making - loss of quality of space	- academics and students - professional organisations like chambers of planners / architects - platforms of different actors - neighbourhood associations and local activists	- collective (and social in broader terms)	- city-wide collective consumption rights, 'right to the city'	- opposition	Special projects (Emek Theatre Building, Beyoğlu Demirören AVM, Haydarpaşa Redevelopment Project, etc.); Urban infrastructure projects (3rd Bridge, Haliç Metro Bridge Project, Istanbul Strait Highway Transit Project, etc.)
	b	- worsening living conditions - unwanted development in the area - lack of participation in decision making	- neighbourhood associations, - planners, architects and lawyers), - their organisations like Chamber of City Planners, and Chambers of Architects	- collective (confined to the community affected)	- collective consumption rights within the community (use value is the primary concern)	-opposition - cooperative (but not as a part of movement activities)	Urban Renewal Projects in middle income residential areas (Ataköy District, etc.)
	c	- maximisation of individual property rights	- neighbourhood associations including private entrepreneurs	- individual (Extraction of maximum profit from urban land rent is the primary goal.)	- individual property rights (to utilize the exchange value of their property is the concern).	-cooperation	Any rent increasing urban redevelopment (Beyoğlu Association, etc.)

As different cases from Istanbul illustrates and the theoretical review in the previous section have informed us, urban movements of the contemporary neoliberal urbanisation do not mobilise based on class-based factors, function less on antagonistic terms and can negotiate with business and public agencies, and do not constitute a homogenous entity, but are highly fragmented. Furthermore, especially in the last decade, they have become increasingly based on individual interests and begin to mobilise as a reaction to neoliberal policies' negative effects on the adherents' own property or land.

The movements of the deprived groups demonstrate this change towards mobilisation out of interest based motivations. As regards to these type of movements, which is the predominant and most vivid type in today's cities, residents do not react against transformation provided that they are satisfied with what is given to them as mentioned earlier. As a consequence, no movement occurs when there is no interest to rest it upon. However, neoliberal urbanisation creates its own kind of movement. Researches made in poor areas of urban transformation projects and interviews made with key actors by the authors themselves demonstrate that, reactions and collective action start when the residents are not satisfied with their share in the rent to be generated, having quite individualistic and interest-based concerns as discussed in the preceding. When they feel they get an unfair share from the rent that is to be generated by the project based on their already acquired property rights, and think that their property rights are seriously violated, they get engaged in collective action.

The movements of discontent groups on the other hand demonstrate that the fragmentation trend in movements still prevails and even in an aggravated fashion under neoliberal urbanisation. Since, neoliberal state is hostile towards any kind of social mobilisation and solidarity that will hinder the capital accumulation; individuals tend to build weak associations rather than broader collective institutions such as the trade-unions of the past. The end result is even more fragmented urban movements without a collective mobilisation of power. A fragmented variety of urban movement fractions that fall under either or each one of these categories appear, who are not tightly coupled and have weak connections with each other. Therefore, one cannot talk, at least for now, about the existence of a broad social movement in Turkey, not even in Istanbul Metropolitan Region. Accordingly, spatial changes brought by these movements are minimal. In other words, they are far from reshaping 'the city in a different image from that put forward by the developers, who are backed by finance, corporate capital and an increasingly entrepreneurially minded local state apparatus' (Harvey, 2008).

In conclusion, neoliberal urbanisation today redefines the opposition against itself via its own instruments like urban development as a means of income distribution. It moreover defines their content based on defence of individual property rights. Even if it retreats at some points as a result of the negotiation and bargaining mechanisms built with the movement actors, in it finally maintains its own sustainability. At this point, it is crucial to complement this analysis made in the general context of Istanbul's urban movements with more focused analysis on certain different localities, particularly in residential areas, in order to see if these urban movements have a potential to overcome their being bound by motivations based on individual interests towards more collective interests, exploring the complex relationships in the form of conflicts and alliances they develop within the movements and with the external actors. This will help us better understand whether, to what extent and under what conditions urban movements can free themselves from the rules of neo-liberal urbanisation.

BARRIERS AND DRIVERS IN COLLABORATIVE PLANNING PROJECTS: A COMPARATIVE STUDY OF TRANSFORMATION PROJECTS WITH CULTURAL HERITAGE IN THE NETHERLANDS

M.Y. (Marlijn) Baarveld MSc[1], dr. M. Smit[2], Prof. dr. G.P.M.R. Dewulf[3]

Abstract

Due to technological, economic and spatial developments, various inner-city industrial areas with cultural-historical valuable elements, have lost their former use and their original economic value. Governments, private parties, citizens and interest groups in urban redevelopments are often convinced of the desirability of preserving this cultural heritage. However, transformation processes are complex and especially financial agreements seem hard to attain when plans have to be made effective. Recent planning approaches argue that urban developments are shaped through the interaction of many different stakeholders. As interests conflict, negotiation is needed to reach decisions regarding long term vision, short term actions and organizational and financial settlements. At some moments in the process the actors will cooperate, while at other moments they will compete.. This paper gives insight in the interaction processes and the encountered difficulties in urban redevelopments with cultural heritage. In particular, an attempt is made to identify barriers and drivers of complex collaborative planning projects. Therefore, we conducted an explorative case study of ten urban redevelopment projects with cultural heritage in the Netherlands. Based on an analytical framework, we identified important differences and similarities between the cases, and analyzed whether and how project and interaction characteristics have implications for project performance. The results can be used for further research or for process improvements

Keywords: planning approaches, interaction, urban redevelopment, cultural heritage, barriers and drivers

1. Introduction

Present day urban development is characterized by complex and interrelated issues. To find solutions for these issues an integrated approach is needed (De Kort, 2009). Recent planning approaches acknowledge a growing interdependence and the need for adequate interaction between various

stakeholders. However, different normative planning approaches have different ideas on how these interaction processes should evolve. A main issue is how to deal with the various conflicting interests and achieve outcomes that are favorable for individual stakeholders and at the same time take into account the common interest. Our paper explores how various urban redevelopment projects with cultural heritage buildings deal with this tension. We aim to increase insight in the barriers and drivers in this transformation process, focusing on the implications of stakeholder interaction on project performance.

1.1 Collaborative planning: learning or deal making?

In planning, mutual dependent actors make decisions about the abilities to act and commit to future actions that will satisfy their interests (Forester, 2006). However, decision-making is difficult in a network setting as actors have various (possibly conflicting) interests and resources are fragmented. This implies that negotiation is needed to reach decisions regarding the content of the plan and settlements regarding costs and benefits (Koppenjan and Klijn, 2004). From this point of view, planning is a matter of deal-making, contracting and negotiation between actors whose resources are needed for successful implementation. Negotiation also requires a certain degree of understanding about underlying values and about how to turn these into action (Albrechts, 2001). Thus, planning is a matter of deal-making on the one hand and a process of more democratic mutual learning on the other hand. Both are intertwined and actors learn from each other and make deals at the same time (Leeuwis, 2000).

Individual actors in planning processes can employ different behavior, focusing more on the deal-making aspect or on learning elements. This difference in behavior is related to the distinction between distributive and integrative negotiation processes (Leeuwis, 2000). In a distributive negotiation process actors hold on to their own perceptions and positions and basically use negotiations to divide the value that will be created by a planned physical-spatial intervention. In contrast, in integrative negotiation actors try to expand the amount of value to be divided (Thompson and Hastie, 1990). Actors are cooperative and try to develop new and often wider problem definitions. They change perceptions on the basis of a creative collective learning process, resulting in the identification of so called ‘win-win solutions’ (Sebenius, 2009).

Lax and Sebenius (1986) reconceptualised the processes of integrative and distributive negotiation as value-creating and value-claiming. They argued that creating and claiming value strategies were inseparable. At a certain point in the process, the created value has to be divided and a claim on the increased value by one party implies there will be less for the others. The actors must choose between two opposing motives: cooperate to create value or compete to claim value. For cooperative action the actor will have to share information to find a possible mutual gain and have a good relationship with other actors. However,

showing his interests and giving information makes him more vulnerable of exploitation. On the other hand, competitive moves to claim value individually often drive out cooperative moves to jointly create value (Sebenius, 2009). This puts the actor in a dilemma of strategy, the so called negotiators dilemma (Lax and Sebenius, 1986). This dilemma is related to the well-known Prisoner's Dilemma. Dealing with the tension between creating and claiming value strategies of stakeholders is a main issue in urban development. In the subsequent lines we will argue that this especially accounts for urban redevelopment projects with cultural heritage.

1.2 Creating and claiming value in cultural heritage projects

Urban redevelopment projects are generally characterized by high contextual and organizational complexity. The presence of built cultural heritage makes redevelopment for a number of reasons even more complex. First, regulations for officially registered monuments limit the possibilities for adapting heritage buildings. Second, investments needed to make re-use of built heritage possible are often high due to the costs of restoration and sanitation (Saris et al., 2008); (Bade and Smid, 2008). Third, finding appropriate new uses for built heritage which do right to the unique character and are also financially feasible appears to be difficult. Fourth, the tangible and intangible returns of investments are uncertain as the value of the heritage can rarely be expressed in financial terms alone (Linssen et al., 2009). Despite these difficulties, government, market parties, citizens and interest groups are often convinced of the desirability to preserve cultural heritage in urban redevelopments. Various studies (Ruijgrok et al., 2004); ABF Research, 2008) show that the presence of cultural heritage adds value to an area. It gives an area a specific identity, historical conscience and generally improves the satisfaction of people living in the neighborhood (Linssen et al., 2009); (Aarsen et al., 2010). Besides, cultural heritage offers opportunities for social-economic development, such as the development of tourism, leisure and cultural activities (Bizzarro and Nijkamp, 1997). Although the added value of cultural heritage for urban redevelopment is nowadays generally acknowledged, in practice settlements regarding costs and benefits seem hard to attain. A number of parties profit from investments to preserve and/or transform cultural heritage without contributing in the costs. If parties do not contribute at all, this is known as the problem of free-riders for collective goods. Parties could also choose a more competitive strategy and only claim value to fulfill their own interest, instead of employing cooperative behavior to create or add value by preserving cultural heritage. This misbalance in costs and benefits causes heritage projects to fail or leave opportunities unused. The characteristics imply that especially in heritage projects stakeholders need to deal with the tension between creating and claiming value.

In literature little is known on how value creation and value claiming processes unfold in practice. Interaction often seems like a black box to planners, while planning requires a fine grained analysis of what actually takes place (Albrechts,

2006). To learn more about how these planning processes work and how 'performance' is achieved, more research should be done on perceptions, performances, strategies and more (Forester, 2011). To obtain insight in the interaction between stakeholders in cultural heritage projects and how this effects agreements on costs and benefits and re-use of built cultural heritage, we conducted an explorative case study of ten urban redevelopment projects in the Netherlands.

The outline of the paper is as follows. Section 2 introduces the analytical framework used in the case study. Section 3 describes the research method. Section 4 shows the empirical data. Section 5 presents the main results and shows the main barriers and drivers in urban redevelopment projects in which cultural heritage plays an important role.

2. Analytical framework

Based on insights from literature on negotiation and planning we developed an analytical framework to explore stakeholder interaction and study whether and how it effects the agreement on costs and benefits and re-use of the heritage. Use of our framework should be seen as a means to focus on specific subjects and to understand and interpret certain actions. In other words, it is a guidance for prioritizing in data-collection and data-analysis (Hutjes and van Buuren, 1992);(Yin, 2003). However, it is not meant to condition the research in any way (Eisenhardt, 1989).

Starting point is that urban redevelopments are shaped through the interaction among actors, who are aiming to get the best deal, a deal which creates added value by preserving the cultural heritage and contributes to the aims of the individual actors. Beside the characteristics of stakeholder interaction, the project characteristics are also taken into account as the setup of the interaction is partly shaped by the issues and actors involved (Lax and Sebenius, 2002).

2.1 Project characteristics

Stakeholder interaction takes place in the specific institutional and situational setting. This setting influences the interaction processes and outcomes as it complicates or simplifies possibilities for development and preservation of the cultural heritage. Therefore we described a number of relevant project characteristics. A first characteristic is *project complexity*. We used the scale of built heritage, the maintenance state of the heritage buildings and ground pollution as indicators for complexity, because these have implications for the costs and uncertainty of the redevelopment. Other characteristics we studied are who takes *initiative* and the *participation of crucial actors in planning*. To increase the likelihood of redevelopment plans to be realized, close interaction is needed with actors whose cooperation is necessary for implementation (Albrechts, 2004). The actor's resources determine whether its cooperation is

needed. There are four crucial resources: authority, finances, land ownership and specific knowledge and skills (De Kort, 2009, De Bruijn and Heuvelof, 2008, Walter and Scholz, 2007). These resources give actors power to influence the decision-making and the outcome of the process. As a main bottleneck in heritage redevelopment is assumed to be the lack of balance between the costs and benefits of stakeholders, we further focused on the *contribution in costs of those who benefit* of the re-use of the heritage. Finally, we determined the *distribution of risks* among actors as the benefits of heritage preservation are uncertain and often hard to express in financial terms.

2.2 Interaction characteristics

During interactions we can distinguish two types of processes: formal and informal processes (Ring and Van de Ven, 1994). To assure commitment of the stakeholders whose resources are needed, relationships are often formalized in cooperation agreement. Therefore, we analyzed the *type of cooperation*. The likelihood an actor will use his power, depends on his interests and objectives on specific topics (Olander and Landin, 2005). Conflicting interests on main topics may hamper the process. Therefore, *conflict topics* were analyzed. Based on their own perceptions, interests and objectives, actors will use different strategies to deal with these topics and influence planning processes (Koppenjan and Klijn, 2004). How processes unfold, depends on the interaction strategies of actors. In literature it is argued that integrative interaction more likely results in outcomes that are beneficial for both common interest as for individual interests (Innes and Booher, 2010, Fisher et al., 1991, Leeuwis, 2000, Lax and Sebenius, 2002). In our analysis we indicated the *type of interaction*. The interaction among actors can be typified as integrative negotiation or as distributive negotiation, depending on actors' behavior (Leeuwis, 2000). The contradicting behavior is summarized in table 1 (based on (Lax and Sebenius, 2002)).

Table 1. Indicators of integrative and distributive interaction

	Integrative Interaction	Distributive Interaction
Joined forces	Working together, have shared aim	Each working for themselves, focus on self interest
Perception	Willing to change perception, flexible, learning	Holding on to own perceptions, non-flexible, not willing to learn or change
Communi-cation	Open communication, share information	Communication is hard, not sharing information
Relation	Trust each other	Distrust each other

2.3 Performance

In general, urban redevelopment projects aim to improve the spatial quality of an area. As we study barriers and drivers in transformation processes, an indicator of performance is the re-use of heritage buildings. However, determining whether the re-use actually has been realized will not always be possible as urban redevelopment projects have a long time frame and some of the urban redevelopments will not be finished within the next 10 years. Therefore, the first criterion we used is *commitment of key stakeholders to the preservation of the cultural heritage buildings*. As preservation and re-use of built cultural heritage requires high investments agreement between key stakeholders on the costs and benefits is needed. The second criterion is *agreement on costs and benefits of heritage preservation between key stakeholders*. Furthermore, literature on network managements explains that evaluation of multi-actor processes should be evaluated in actor-specific or process-oriented terms. Performance measurement should pay attention both to the process and to its outcomes. An often used indicator is actor satisfaction (De Bruijn and Heuvelof, 2008, De Kort, 2009, De Graaf, 2005). Actor satisfaction is important to ensure their commitment to further actions. The problem-owner (land-owner of the area and cultural heritage) is the actor who will be most affected if agreement is not attained. In that case, this key-actor will have to invest a large amount without (total) counterbalance of his expenses or accept the decline of the cultural heritage buildings and the area. Therefore, a third criterion we use is the *satisfaction of the problem-owner on the division of costs and benefits*.

In conclusion, our analytical framework we use is shown in table 2.

Table 2. Analytical framework

Characteristic/criterion	Categories
PROJECT CHARACTERISTICS	
(Financial) complexity	high/medium/low
Initiative	1. mainly public/2. Mainly private/3. Public-private
Participation of key-stakeholders	high/medium/low
Contribution of parties who benefit from heritage preservation	high/medium/low
Financiers and risks bearers	1. mainly public/2. Mainly private/3. Joint public-private
Type of cooperation	1. traditional/2. Concession/3. Joint venture
Conflict topics	1. mainly financial/2. Other/3. No conflicts
Type of interaction	integrative / Distributive

PERFORMANCE	
Commitment to preservation of CH	High/medium/low
Agreement on costs and benefits of heritage preservation	yes/no
Satisfaction problem-owner on division of costs and benefits	high/medium/low

3. Research method

To increase insight in the barriers and drivers in cultural heritage projects, we used table 2 in a comparative evaluation of various empirical cases. To specifically study the relationship between interaction and our performance indicators we chose to vary the context in which planning takes place, as little as possible. We studied large scale urban redevelopment projects with cultural heritage in the Netherlands. The general procedure for the case study was straightforward: selection of potentially interesting cases; assessment of available information relevant for a systematic case study approach; execution of a semi structured interview with the land-/real estate owner(s); collection of relevant data from reports, and; systematic data-analysis.

Case selection

We selected ten projects. Eisenhardt (1989) indicates that linkages between qualitative variables or indicators in a framework model can be achieved using a cross-case analysis of 5-10 cases. Case selection was based on the following criteria: 1) redevelopment of an entire area instead of a single object; 2) development of multiple new functions; 3) one or more buildings in the area are considered to be of cultural-historical value and transformation of these buildings is considered desirable; 4) urban located area, and 5) the project is at the end of the planning stage or in the realization stage.

Data collection

For each case, we conducted a semi structured face-to-face interview. The interviewees were the project managers of the owners of the built heritage. Also, a document analysis was executed. Among others, master plans, official decision documents of the city council, studies of the cultural-historical elements and progress reports were studied. For each case the systematic information was put in a data matrix. This information was qualitative in nature.

Data analysis

The comparative purpose of our study calls for a description of the various attributes of the individual cases. A comparison of the interaction in urban heritage projects leads to the need for systematic insight in the situational and organizational characteristics. We used cross-case analysis to deepen our understanding and explanation of conditions by finding similarities and

differences across cases (Miles and Huberman, 1994). Such analysis can show the specific conditions under which a finding will occur and it also helps to form more general categories of how conditions may be related (Miles and Huberman, 1994). The qualitative information about the cases will be used in the discussion and conclusions to derive barriers and drivers.

4. Project Data

4.1 Project description

Strijp S is part of a former industrial area (27 ha) in the city of Eindhoven (215.000 residents). The area consists of mainly large industrial complexes, formerly used for the manufacturing of radios and televisions. Seven of the buildings (build around 1928) are listed cultural heritage. In 2001 Philips sold the area to a private developer. From that moment plans are made to transform the area to a "new dynamic and creative urban quarter to live, work and play'. Several heritage buildings are already (temporarily) in use for cultural activities and (small) working offices. In two other buildings they recently started the transformation to lofts and working space.

Enka Ede is located between the city center of Ede (110.000 residents) and nature reserve "de Veluwe". The area of 42 ha was formerly used by the artificial silk manufacturer. In 2002 the manufacturer closed down, leaving the heritage buildings disused and the ground heavily polluted. Several buildings (build around 1922) are listed, others are protected by a covenant between the developer and the municipality. Ambition is to realize a residential area of 1400 houses, including public and commercial uses.

De Hallen is located in the western part of the city of Amsterdam (790.000 residents) and consists of the transformation of the former tram depot and maintenance place, and the realization of 400 houses. In total, the area is 16 ha. The tram depot is characterized by large halls of around 100 meter long and sawtooth roofs. In 1996 the area was abandoned and several plans were made by various actors. In 2011 the municipality selected a developer, who has the ambition to re-use the heritage buildings as lively meetings place in which handicraft plays an important role.

Scheldekwartier (KSG) is a former shipbuilding yard of 32 ha between the city center of Vlissingen (35.000 residents) and the harbor. Since 2000 the activities were replaced to the eastern part of Vlissingen and the yard became disused. Several large buildings are demolished, but four buildings, the docks and a crane are appointed as heritage. Plan-making started in 2003, when the municipality bought the area. The ambition is to create a new city quarter with a unique waterfront, mondain character and mixed use, including cultural activities in the heritage buildings.

Dru Industriepark is located in Ulft (10.000 residents), a village surrounded by green, Till 2003 the area of 14 ha was used as an iron foundry for bathtubs, stoves and casseroles. Main aim of the redevelopment is to preserve the seven heritage buildings and realize an area to live, work and play. Two buildings are already transformed; one is used for living, the other for cultural activities and accommodates a library, theatre and a stage. For the four other buildings plans are currently made.

The **Roerdelta (ECI)** project is 54 hectares and located between the city center of Roermond (56.000) and the river Maas. In the center of this area, a large complex of "Electro Chemical Industry (ECI)", including a hydro-electric power station, was used for chemical industry. Since 1970 the building is disused and the area lost its value for industry. The ECI complex is considered to be of cultural-historical value. Just around 2011 transformation of the ECI complex and pre-selling of the houses started. The ambition is to realize a green residential area, with a large park and a cultural and creative meeting point in the ECI Complex.

The **Indiëterrein** in Almelo (73.000 residents) is an area of 23 ha located near the city center. It was formerly used for textile industry of Ten Cate. Some of the buildings are still used by textile related companies, other buildings are temporarily used for artists to create liveliness in the area. The ambition is to transform the area slowly to a new green city quarter with housing and working possibilities. The former industrial buildings of cultural-historical value, like the water tower, arched buildings and sawtooth roof buildings, will be re-used.

The **NDSM** yard (43 ha land and 25 ha water) at the Northern IJ-bank in Amsterdam (790.000 residents) is the location of the former shipbuilding company "Nederlanse Droogdok en Scheepsbouw Maatschappij" (NDSM). In 1984 NDSM went bankrupt and the area lost its use. Only in 2003 a first plan was presented for the redevelopment. The ensemble of large halls (build between 1920 and 1957), cranes, slips and docks are listed as cultural-historical valuable. The aim is to create a creative and cultural hotspot, with mixed uses, giving opportunities to all kind of (private) initiatives. In 2007 MTV Networks was the first company who moved into one of the heritage buildings. Other buildings are (temporarily) used for indoor-skating, bars and small offices for creative entrepreneurs.

Stadhouderspark Vught (38 ha) is located in the northern part of Vught (26.000 residents) on former barracks, sport fields of the barracks and private land in between. As the barracks closed down, the municipality bought the area. The area will be transformed to a residential area of 650 houses, including various facilities as a school, bar and health center. Various buildings of the barracks, build around 1900, are considered to be cultural-historical valuable.

Two barracks formerly used to quarter troops, are already transformed into rental apartments.

Overhoeks is an area of 27 ha located at the Northern IJ-bank in Amsterdam (790.000 residents). Shell uses 7 ha for their Shell Technology Centre Amsterdam (STCA) and the municipality bought 20 ha, which is mainly rented by the bank ING. The aim is to create a mixed use area with (rental) housing, office space, shops, restaurants and bars. The cultural heritage is a large tower. The new use of this tower is yet unknown.

4.2 Differences and similarities in the cases

Based on the analytical framework we analyzed the project characteristics, interaction characteristics and performance. The results are summarized in table 3. The important differences and similarities are highlighted in this paragraph to give insight in the process and performance.

Project performance
Commitment of key stakeholders to preserve the cultural heritage is generally high. Often heritage buildings are listed as a (state) monument, and preservation is a precondition for the redevelopment. In many projects the key stakeholders commit themselves also to the non-listed cultural-historical valuable buildings. These buildings are embedded in plans to contribute to the unique character of the area. Only in two projects (Enka Ede and Stadshouderspark Vught) some buildings are demolished and elaborate discussion took place on whether or not to preserve the cultural heritage buildings. The latter also applies to Scheldekwartier.

In all projects, except one, there is agreement between key actors on costs and benefits. In most cases, the costs and benefits of the redevelopment are not equally shared, but divided among the actors, depending on their responsibilities for a specific redevelopment component (housing, cultural heritage, public spaces). Only in one project (Strijp S) costs and benefits are shared among the key actors and the components of the plan.

The satisfaction on the agreement on costs and benefits of the problem-owner is medium to high. In many projects the problem-owner needs to invest without fully counterbalancing their expenses. However, they are willing to invest as they are convinced of the desirability to preserve and re-use the heritage buildings. Municipalities may be willing as they assume preservation contributes to the public interests, while private parties are motivated as preservation may positively contribute to sales of their real estate. When asked, most interviewees expect that the project will generally succeed in the long term. Almost all of them indicate that it will not be an easy process to achieve the aims. One interviewee indicates: "*Yes, the project will be successful. It will not*

be easy, especially not in these economic times, but we will finally put up a unique performance".

Table 3. Comparison of the urban redevelopment projects

	Project characteristics					Interaction characteristics			Performance		
	Complexity of the project	Initiative	Participation of key-stakeholders	Contribution of parties who benefit from heritage	Financiers and risks bearers	Type of cooperation	Conflict topics	Type of interaction	Commitment to preserving CH	Agreement costs and benefits	Satisfaction problem owner on division of costs and benefits
Strijp S	Low	3	High	High	3	3	1	Distrib.	High	Yes-shared	High
Enka	High	2	Med	Low	2	2	2	Distrib.	Med	Yes	Med
De Hallen	Low	1	Med	High	3	1	1	Distrib.	High	Yes	High
KSG	Med	1	Med	Low	3	1	1	Integr.	Med	Yes	Med
Dru	High	1	High	High	3	3	1	Integr.	High	Yes	Med
ECI	Med	3	Med	Med	2	2	1	Integr.	High	Yes	High
Indie	Med	2	Low	Low	2	2	2	Neither	High	no	High
